
Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqld` normally reads the `[mysqld]` group. If the `--defaults-group-suffix=_other` option is given, `mysqld` also reads the `[mysqld_other]` group.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• `--early-plugin-load=plugin_list`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--early-plugin-load=plugin_list</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
This option tells the server which plugins to load before loading mandatory built-in plugins and before
storage engine initialization. If multiple `--early-plugin-load` options are given, only the last one is
used.

The option value is a semicolon-separated list of `name=plugin_library` and `plugin_library`
values. Each `name` is the name of a plugin to load, and `plugin_library` is the name of the library
file that contains the plugin code. If a plugin library is named without any preceding plugin name, the
server loads all plugins in the library. The server looks for plugin library files in the directory named by
the `plugin_dir` system variable.

For example, if plugins named `myplug1` and `myplug2` have library files `myplug1.so` and
`myplug2.so`, use this option to perform an early plugin load:

```
shell> mysqld --early-plugin-load="myplug1=myplug1.so;myplug2=myplug2.so"
```

Quotes are used around the argument value because otherwise a semicolon (;) is interpreted as a
special character by some command interpreters. (Unix shells treat it as a command terminator, for
example.)

Each named plugin is loaded early for a single invocation of `mysqld` only. After a restart, the plugin is
not loaded early unless `--early-plugin-load` is used again.

If the server is started using `--initialize` or `--initialize-insecure`, plugins specified by `--early-plugin-load` are not loaded.

If the server is run with `--help`, plugins specified by `--early-plugin-load` are loaded but not
initialized. This behavior ensures that plugin options are displayed in the help message.

The default `--early-plugin-load` value is empty. To load the `keyring_file` plugin, you must use
an explicit `--early-plugin-load` option with a nonempty value.

The InnoDB tablespace encryption feature relies on the `keyring_file` plugin for encryption key
management, and the `keyring_file` plugin must be loaded prior to storage engine initialization to
facilitate InnoDB recovery for encrypted tables. Administrators who want the `keyring_file` plugin
loaded at startup should use the appropriate nonempty option value (for example, `keyring_file.so`
on Unix and Unix-like systems and `keyring_file.dll` on Windows).

For information about InnoDB tablespace encryption, see Section 15.13, “InnoDB Data-at-Rest
Encryption”. For general information about plugin loading, see Section 5.6.1, “Installing and Uninstalling
Plugins”.

- `--exit-info[=flags], -T [flags]`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--exit-info[=flags]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

This is a bitmask of different flags that you can use for debugging the `mysqld` server. Do not use this
option unless you know exactly what it does!

- `--external-locking`

| Command-Line Format | --external-locking[=(OFF|ON)] |
|---------------------|-----------------------------|
| Type                | Boolean                     |
Enable external locking (system locking), which is disabled by default. If you use this option on a system on which `lockd` does not fully work (such as Linux), it is easy for MySQL to deadlock.

To disable external locking explicitly, use `--skip-external-locking`.

External locking affects only MyISAM table access. For more information, including conditions under which it can and cannot be used, see Section 8.11.5, “External Locking”.

- **--flush**

  Flush (synchronize) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See Section B.3.3.3, “What to Do If MySQL Keeps Crashing”.

  **Note**

  If `--flush` is specified, the value of `flush_time` does not matter and changes to `flush_time` have no effect on flush behavior.

- **--gdb**

  Install an interrupt handler for SIGINT (needed to stop `mysqld` with `^C` to set breakpoints) and disable stack tracing and core file handling. See Section 5.9.1.4, “Debugging mysqld under gdb”.

  On Windows, this option also suppresses the forking that is used to implement the `RESTART` statement: Forking enables one process to act as a monitor to the other, which acts as the server. However, forking makes determining the server process to attach to for debugging more difficult, so starting the server with `--gdb` suppresses forking. For a server started with this option, `RESTART` simply exits and does not restart.

  In non-debug settings, `--no-monitor` may be used to suppress forking the monitor process.

- **--initialize, -I**

  Install an interrupt handler for SIGINT (needed to stop `mysqld` with `^C` to set breakpoints) and disable stack tracing and core file handling. See Section 5.9.1.4, “Debugging mysqld under gdb”.

  On Windows, this option also suppresses the forking that is used to implement the `RESTART` statement: Forking enables one process to act as a monitor to the other, which acts as the server. However, forking makes determining the server process to attach to for debugging more difficult, so starting the server with `--gdb` suppresses forking. For a server started with this option, `RESTART` simply exits and does not restart.

  In non-debug settings, `--no-monitor` may be used to suppress forking the monitor process.
This option is used to initialize a MySQL installation by creating the data directory and populating the tables in the `mysql` system schema. For more information, see Section 2.10.1, “Initializing the Data Directory”.

When the server is started with `--initialize`, some functionality is unavailable that limits the statements permitted in any file named by the `init_file` system variable. For more information, see the description of that variable. In addition, the `disabled_storage_engines` system variable has no effect.

The `--ndbcluster` option is ignored when used together with `--initialize`.

`--initialize` is mutually exclusive with `--daemonize`.

`-I` is a synonym for `--initialize`.

• `--initialize-insecure`

| Command-Line Format     | `--initialize-insecure[={OFF|ON}]` |
|-------------------------|----------------------------------|
| Type                    | Boolean                          |
| Default Value           | OFF                              |

This option is used to initialize a MySQL installation by creating the data directory and populating the tables in the `mysql` system schema. This option implies `--initialize`. For more information, see the description of that option, and Section 2.10.1, “Initializing the Data Directory”.

`--initialize-insecure` is mutually exclusive with `--daemonize`.

• `--innodb-xxx`

Set an option for the InnoDB storage engine. The InnoDB options are listed in Section 15.14, “InnoDB Startup Options and System Variables”.

• `--install [service_name]`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--install [service_name]</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
</tbody>
</table>

(Windows only) Install the server as a Windows service that starts automatically during Windows startup. The default service name is MySQL if no `service_name` value is given. For more information, see Section 2.3.4.8, “Starting MySQL as a Windows Service”.

Note

If the server is started with the `--defaults-file` and `--install` options, `--install` must be first.

• `--install-manual [service_name]`

| Command-Line Format | `--install-manual [service_name]` |
Server Command Options

<table>
<thead>
<tr>
<th>Platform Specific</th>
<th>Windows</th>
</tr>
</thead>
</table>

(Windows only) Install the server as a Windows service that must be started manually. It does not start automatically during Windows startup. The default service name is MySQL if no service_name value is given. For more information, see Section 2.3.4.8, “Starting MySQL as a Windows Service”.

**Note**

If the server is started with the --defaults-file and --install-manual options, --install-manual must be first.

- **--language=lang_name, -L lang_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--language=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes; use lc-messages-dir instead</td>
</tr>
<tr>
<td>System Variable</td>
<td>language</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td>/usr/local/mysql/share/mysql/english/</td>
</tr>
</tbody>
</table>

The language to use for error messages. lang_name can be given as the language name or as the full path name to the directory where the language files are installed. See Section 10.12, “Setting the Error Message Language”.

--lc-messages-dir and --lc-messages should be used rather than --language, which is deprecated (and handled as a synonym for --lc-messages-dir). You should expect the --language option to be removed in a future MySQL release.

- **--large-pages**

| Command-Line Format | --large-pages[=(OFF|ON)] |
|---------------------|-------------------------|
| System Variable     | large_pages |
| Scope               | Global |
| Dynamic             | No |
| SET_VAR Hint Applies| No |
| Platform Specific   | Linux |
| Type                | Boolean |
| Default Value       | OFF |

Some hardware/operating system architectures support memory pages greater than the default (usually 4KB). The actual implementation of this support depends on the underlying hardware and operating
Applications that perform a lot of memory accesses may obtain performance improvements by using large pages due to reduced Translation Lookaside Buffer (TLB) misses.

MySQL supports the Linux implementation of large page support (which is called HugeTLB in Linux). See Section 8.12.3.2, “Enabling Large Page Support”. For Solaris support of large pages, see the description of the `--super-large-pages` option.

`--large-pages` is disabled by default.

- `--lc-messages=locale_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--lc-messages=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>lc_messages</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>en_US</td>
</tr>
</tbody>
</table>

The locale to use for error messages. The default is `en_US`. The server converts the argument to a language name and combines it with the value of `--lc-messages-dir` to produce the location for the error message file. See Section 10.12, “Setting the Error Message Language”.

- `--lc-messages-dir=dir_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--lc-messages-dir=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>lc_messages_dir</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

The directory where error messages are located. The server uses the value together with the value of `--lc-messages` to produce the location for the error message file. See Section 10.12, “Setting the Error Message Language”.

- `--local-service`

  (Windows only) A `--local-service` option following the service name causes the server to run using the LocalService Windows account that has limited system privileges. If both `--defaults-file` and `--local-service` are given following the service name, they can be in any order. See Section 2.3.4.8, “Starting MySQL as a Windows Service”.

- `--log-error[=file_name]`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--log-error[=file_name]</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>log_error</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>
Server Command Options

<table>
<thead>
<tr>
<th>Dynamic</th>
<th>No</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET_VAR</td>
<td>Hint Applies No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

Set the default error log destination to the named file. This affects log sinks that base their own output destination on the default destination. See Section 5.4.2, “The Error Log”.

If the option names no file, the default error log destination on Unix and Unix-like systems is a file named `host_name.err` in the data directory. The default destination on Windows is the same, unless the `--pid-file` option is specified. In that case, the file name is the PID file base name with a suffix of `.err` in the data directory.

If the option names a file, the default destination is that file (with an `.err` suffix added if the name has no suffix), located under the data directory unless an absolute path name is given to specify a different location.

If error log output cannot be redirected to the error log file, an error occurs and startup fails.

On Windows, `--console` takes precedence over `--log-error` if both are given. In this case, the default error log destination is the console rather than a file.

- `--log-isam[=file_name]`

  Command-Line Format  `--log-isam[=file_name]`
  Type                File name

  Log all MyISAM changes to this file (used only when debugging MyISAM).

- `--log-raw`

  Command-Line Format  `--log-raw[={OFF|ON}]`
  System Variable  `log_raw`
  Scope  `Global`
  Dynamic  `Yes`
  SET_VAR| Hint Applies No |
  Type    | Boolean |
  Default Value | OFF |

Passwords in certain statements written to the general query log, slow query log, and binary log are rewritten by the server not to occur literally in plain text. Password rewriting can be suppressed for the general query log by starting the server with the `--log-raw` option. This option may be useful for diagnostic purposes, to see the exact text of statements as received by the server, but for security reasons is not recommended for production use.

If a query rewrite plugin is installed, the `--log-raw` option affects statement logging as follows:

- Without `--log-raw`, the server logs the statement returned by the query rewrite plugin. This may differ from the statement as received.
Server Command Options

• With `--log-raw`, the server logs the original statement as received.

For more information, see Section 6.1.2.3, “Passwords and Logging”.

• `--log-short-format`

| Command-Line Format       | `--log-short-format=[{OFF|ON}]` |
|---------------------------|---------------------------------|
| Type                      | Boolean                         |
| Default Value             | OFF                             |

Log less information to the slow query log, if it has been activated.

• `--log-tc=file_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--log-tc=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>tc.log</code></td>
</tr>
</tbody>
</table>

The name of the memory-mapped transaction coordinator log file (for XA transactions that affect multiple storage engines when the binary log is disabled). The default name is `tc.log`. The file is created under the data directory if not given as a full path name. This option is unused.

• `--log-tc-size=size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--log-tc-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>6 * page size</code></td>
</tr>
<tr>
<td>Minimum Value</td>
<td><code>6 * page size</code></td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td><code>18446744073709551615</code></td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td><code>4294967295</code></td>
</tr>
</tbody>
</table>

The size in bytes of the memory-mapped transaction coordinator log. The default and minimum values are 6 times the page size, and the value must be a multiple of the page size.

• `--memlock`

| Command-Line Format       | `--memlock=[{OFF|ON}]`          |
|---------------------------|---------------------------------|
| Type                      | Boolean                         |
| Default Value             | OFF                             |

Lock the `mysqld` process in memory. This option might help if you have a problem where the operating system is causing `mysqld` to swap to disk.

`--memlock` works on systems that support the `mlockall()` system call; this includes Solaris, most Linux distributions that use a 2.4 or higher kernel, and perhaps other Unix systems. On Linux systems,
you can tell whether or not `mlockall()` (and thus this option) is supported by checking to see whether or not it is defined in the system `mman.h` file, like this:

```shell
shell> grep mlockall /usr/include/sys/mman.h
```

If `mlockall()` is supported, you should see in the output of the previous command something like the following:

```c
extern int mlockall (int __flags) __THROW;
```

**Important**

Use of this option may require you to run the server as `root`, which, for reasons of security, is normally not a good idea. See Section 6.1.5, “How to Run MySQL as a Normal User”.

On Linux and perhaps other systems, you can avoid the need to run the server as `root` by changing the `limits.conf` file. See the notes regarding the memlock limit in Section 8.12.3.2, “Enabling Large Page Support”.

You must not use this option on a system that does not support the `mlockall()` system call; if you do so, `mysqld` is very likely to exit as soon as you try to start it.

• **--myisam-block-size=N**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--myisam-block-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1024</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1024</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>16384</td>
</tr>
</tbody>
</table>

The block size to be used for `MyISAM` index pages.

• **--no-defaults**

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read. This must be the first option on the command line if it is used.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• **--no-dd-upgrade**

| Command-Line Format       | --no-dd-upgrade=[{OFF|ON}] |
|---------------------------|-----------------------------|
| Deprecated                | 8.0.16                      |
| Type                      | Boolean                     |
| Default Value             | OFF                         |

**Note**

This option is deprecated as of MySQL 8.0.16. It is superseded by the `--upgrade` option, which provides finer control over data dictionary and server upgrade behavior.
Prevent automatic upgrade of the data dictionary tables during the MySQL server startup process. This option is typically used when starting the MySQL server following an in-place upgrade of an existing installation to a newer MySQL version, which may include changes to data dictionary table definitions.

When `--no-dd-upgrade` is specified, and the server finds that its expected version of the data dictionary differs from the version stored in the data dictionary itself, startup fails with an error stating that data dictionary upgrade is prohibited:

```
[ERROR] [MY-011091] [Server] Data dictionary upgrade prohibited by the command line option '--no_dd_upgrade'.
[ERROR] [MY-010020] [Server] Data Dictionary initialization failed.
```

During a normal startup, the data dictionary version of the server is compared to the version stored in the data dictionary to determine whether data dictionary table definitions should be upgraded. If an upgrade is necessary and supported, the server creates data dictionary tables with updated definitions, copies persisted metadata to the new tables, atomically replaces the old tables with the new ones, and reinitializes the data dictionary. If an upgrade is not necessary, startup continues without updating data dictionary tables.

- `--no-monitor`

| Command-Line Format       | `--no-monitor=[{OFF|ON}]` |
|---------------------------|--------------------------|
| Introduced                | 8.0.12                   |
| Platform Specific         | Windows                  |
| Type                      | Boolean                  |
| Default Value             | OFF                      |

(Windows only). This option suppresses the forking that is used to implement the `RESTART` statement: Forking enables one process to act as a monitor to the other, which acts as the server. For a server started with this option, `RESTART` simply exits and does not restart.

`--no-monitor` is not available prior to MySQL 8.0.12. The `--gdb` option can be used as a workaround.

- `--old-style-user-limits`

| Command-Line Format       | `--old-style-user-limits=[{OFF|ON}]` |
|---------------------------|-------------------------------------|
| Type                      | Boolean                             |
| Default Value             | OFF                                 |

Enable old-style user limits. (Before MySQL 5.0.3, account resource limits were counted separately for each host from which a user connected rather than per account row in the `user` table.) See Section 6.2.20, “Setting Account Resource Limits”.

- `--performance-schema-xxx`

Configure a Performance Schema option. For details, see Section 26.14, “Performance Schema Command Options”.

- `--plugin-load=plugin_list`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--plugin-load=plugin_list</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>plugin_load</code></td>
</tr>
</tbody>
</table>
This option tells the server to load the named plugins at startup. If multiple `--plugin-load` options are given, only the last one is used. Additional plugins to load may be specified using `--plugin-load-add` options.

The option value is a semicolon-separated list of `name=plugin_library` and `plugin_library` values. Each `name` is the name of a plugin to load, and `plugin_library` is the name of the library file that contains the plugin code. If a plugin library is named without any preceding plugin name, the server loads all plugins in the library. The server looks for plugin library files in the directory named by the `plugin_dir` system variable.

For example, if plugins named `myplug1` and `myplug2` have library files `myplug1.so` and `myplug2.so`, use this option to perform an early plugin load:

```
shell> mysqld --plugin-load="myplug1=myplug1.so;myplug2=myplug2.so"
```

Quotes are used around the argument value here because otherwise semicolon (`;`) is interpreted as a special character by some command interpreters. (Unix shells treat it as a command terminator, for example.)

Each named plugin is loaded for a single invocation of `mysqld` only. After a restart, the plugin is not loaded unless `--plugin-load` is used again. This is in contrast to `INSTALL PLUGIN`, which adds an entry to the `mysql.plugins` table to cause the plugin to be loaded for every normal server startup.

During the normal startup sequence, the server determines which plugins to load by reading the `mysql.plugins` system table. If the server is started with the `--skip-grant-tables` option, plugins registered in the `mysql.plugins` table are not loaded and are unavailable. `--plugin-load` enables plugins to be loaded even when `--skip-grant-tables` is given. `--plugin-load` also enables plugins to be loaded at startup that cannot be loaded at runtime.

For additional information about plugin loading, see Section 5.6.1, "Installing and Uninstalling Plugins".

- `--plugin-load-add=plugin_list`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--plugin-load-add=plugin_list</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>plugin_load_add</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
Server Command Options

--plugin-load-add can be used to avoid specifying a large set of plugins as a single long unwieldy --plugin-load argument.

--plugin-load-add can be given in the absence of --plugin-load, but any instance of --plugin-load-add that appears before --plugin-load has no effect because --plugin-load resets the set of plugins to load. In other words, these options:

--plugin-load=x --plugin-load-add=y

are equivalent to this option:

--plugin-load="x;y"

But these options:

--plugin-load-add=y --plugin-load=x

are equivalent to this option:

--plugin-load=x

For additional information about plugin loading, see Section 5.6.1, “Installing and Uninstalling Plugins”.

• --plugin-xxx

Specifies an option that pertains to a server plugin. For example, many storage engines can be built as plugins, and for such engines, options for them can be specified with a --plugin prefix. Thus, the --innodb-file-per-table option for InnoDB can be specified as --plugin-innodb-file-per-table.

For boolean options that can be enabled or disabled, the --skip prefix and other alternative formats are supported as well (see Section 4.2.2.4, “Program Option Modifiers”). For example, --skip-plugin-innodb-file-per-table disables innodb-file-per-table.

The rationale for the --plugin prefix is that it enables plugin options to be specified unambiguously if there is a name conflict with a built-in server option. For example, were a plugin writer to name a plugin “sql” and implement a “mode” option, the option name might be --sql-mode, which would conflict with the built-in option of the same name. In such cases, references to the conflicting name are resolved in favor of the built-in option. To avoid the ambiguity, users can specify the plugin option as --plugin-sql-mode. Use of the --plugin prefix for plugin options is recommended to avoid any question of ambiguity.

• --port=port_num, -P port_num

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--port=port_num</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>port</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>3306</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>
The port number to use when listening for TCP/IP connections. On Unix and Unix-like systems, the port number must be 1024 or higher unless the server is started by the root operating system user. Setting this option to 0 causes the default value to be used.

- **--port-open-timeout=num**

  Command-Line Format: `--port-open-timeout=#`
  
  Type: Integer
  
  Default Value: 0

  On some systems, when the server is stopped, the TCP/IP port might not become available immediately. If the server is restarted quickly afterward, its attempt to reopen the port can fail. This option indicates how many seconds the server should wait for the TCP/IP port to become free if it cannot be opened. The default is not to wait.

- **--print-defaults**

  Print the program name and all options that it gets from option files. Password values are masked. This must be the first option on the command line if it is used, except that it may be used immediately after `--defaults-file` or `--defaults-extra-file`.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--remove [service_name]**

  Command-Line Format: `--remove [service_name]`
  
  Platform Specific: Windows

  (Windows only) Remove a MySQL Windows service. The default service name is MySQL if no `service_name` value is given. For more information, see Section 2.3.4.8, “Starting MySQL as a Windows Service”.

- **--safe-user-create**

  Command-Line Format: `--safe-user-create[{OFF|ON}]`
  
  Type: Boolean
  
  Default Value: OFF

  If this option is enabled, a user cannot create new MySQL users by using the GRANT statement unless the user has the INSERT privilege for the `mysql.user` system table or any column in the table. If you want a user to have the ability to create new users that have those privileges that the user has the right to grant, you should grant the user the following privilege:

  ```
  GRANT INSERT(user) ON mysql.user TO 'user_name'@'host_name';
  ```

  This ensures that the user cannot change any privilege columns directly, but has to use the GRANT statement to give privileges to other users.

- **--skip-grant-tables**

  Command-Line Format: `--skip-grant-tables[{OFF|ON}]`
This option affects the server startup sequence:

- `--skip-grant-tables` causes the server not to read the grant tables in the `mysql` system schema, and thus to start without using the privilege system at all. This gives anyone with access to the server unrestricted access to all databases.

Because starting the server with `--skip-grant-tables` disables authentication checks, the server also disables remote connections in that case by enabling `skip_networking`.

To cause a server started with `--skip-grant-tables` to load the grant tables at runtime, perform a privilege-flushing operation, which can be done in these ways:

- Issue a MySQL `FLUSH PRIVILEGES` statement after connecting to the server.
- Execute a `mysqladmin flush-privileges` or `mysqladmin reload` command from the command line.

Privilege flushing might also occur implicitly as a result of other actions performed after startup, thus causing the server to start using the grant tables. For example, the server flushes the privileges if it performs an upgrade during the startup sequence.

- `--skip-grant-tables` disables failed-login tracking and temporary account locking because those capabilities depend on the grant tables. See Section 6.2.15, “Password Management”.

- `--skip-grant-tables` causes the server not to load certain other objects registered in the data dictionary or the `mysql` system schema:
  
  - Scheduled events installed using `CREATE EVENT` and registered in the `events` data dictionary table.
  - Plugins installed using `INSTALL PLUGIN` and registered in the `mysql.plugin` system table.

  To cause plugins to be loaded even when using `--skip-grant-tables`, use the `--plugin-load` or `--plugin-load-add` option.

- User-defined functions (UDFs) installed using `CREATE FUNCTION` and registered in the `mysql.func` system table.

  `--skip-grant-tables` does not suppress loading during startup of server components.

- `--skip-grant-tables` causes the `disabled_storage_engines` system variable to have no effect.
• **--skip-host-cache**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--skip-host-cache</th>
</tr>
</thead>
</table>

Disable use of the internal host cache for faster name-to-IP resolution. With the cache disabled, the server performs a DNS lookup every time a client connects.

Use of **--skip-host-cache** is similar to setting the `host_cache_size` system variable to 0, but `host_cache_size` is more flexible because it can also be used to resize, enable, or disable the host cache at runtime, not just at server startup.

Starting the server with **--skip-host-cache** does not prevent runtime changes to the value of `host_cache_size`, but such changes have no effect and the cache is not re-enabled even if `host_cache_size` is set larger than 0.

For more information about how the host cache works, see Section 5.1.12.3, “DNS Lookups and the Host Cache”.

• **--skip-innodb**

Disable the InnoDB storage engine. In this case, because the default storage engine is InnoDB, the server does not start unless you also use **--default-storage-engine** and **--default-tmp-storage-engine** to set the default to some other engine for both permanent and TEMPORARY tables.

The InnoDB storage engine cannot be disabled, and the **--skip-innodb** option is deprecated and has no effect. Its use results in a warning. Expect this option to be removed in a future MySQL release.

• **--skip-new**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--skip-new</th>
</tr>
</thead>
</table>

This option disables (what used to be considered) new, possibly unsafe behaviors. It results in these settings: `delay_key_write=OFF`, `concurrent_insert=NEVER`, `automatic_sp_privileges=OFF`. It also causes `OPTIMIZE TABLE` to be mapped to `ALTER TABLE` for storage engines for which `OPTIMIZE TABLE` is not supported.

• **--skip-show-database**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--skip-show-database</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>skip_show_database</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>

This option sets the `skip_show_database` system variable that controls who is permitted to use the `SHOW DATABASES` statement. See Section 5.1.8, “Server System Variables”.

• **--skip-stack-trace**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--skip-stack-trace</th>
</tr>
</thead>
</table>

Do not write stack traces. This option is useful when you are running `mysql` under a debugger. On some systems, you also must use this option to get a core file. See Section 5.9, “Debugging MySQL”.

- **--slow-start-timeout=timeout**

  **Command-Line Format**
  
  ```
  --slow-start-timeout=#
  ```

  **Type**
  
  Integer

  **Default Value**
  
  15000

  This option controls the Windows service control manager’s service start timeout. The value is the maximum number of milliseconds that the service control manager waits before trying to kill the windows service during startup. The default value is 15000 (15 seconds). If the MySQL service takes too long to start, you may need to increase this value. A value of 0 means there is no timeout.

- **--socket=path**

  **Command-Line Format**
  
  ```
  --socket={file_name|pipe_name}
  ```

  **System Variable**
  
  socket

  **Scope**
  
  Global

  **Dynamic**
  
  No

  **SET_VAR**
  
  Hint Applies
  
  No

  **Type**
  
  String

  **Default Value (Other)**
  
  /tmp/mysql.sock

  **Default Value (Windows)**
  
  MySQL

  On Unix, this option specifies the Unix socket file to use when listening for local connections. The default value is /tmp/mysql.sock. If this option is given, the server creates the file in the data directory unless an absolute path name is given to specify a different directory. On Windows, the option specifies the pipe name to use when listening for local connections that use a named pipe. The default value is MySQL (not case sensitive).

- **--sql-mode=value[,value[,value...]]**

  **Command-Line Format**
  
  ```
  --sql-mode=name
  ```

  **System Variable**
  
  sql_mode

  **Scope**
  
  Global, Session

  **Dynamic**
  
  Yes

  **SET_VAR**
  
  Hint Applies
  
  Yes

  **Type**
  
  Set

  **Default Value**
  
  ONLY_FULL_GROUP_BY STRICT_TRANS_TABLES NO_ZERO_IN_DATE NO_ZERO_DATE ERROR_FOR_DIVISION_BY_ZERO NO_ENGINE_SUBSTITUTION

  **Valid Values**
  
  ALLOW_INVALID_DATES

  ANSI_QUOTES

  ERROR_FOR_DIVISION_BY_ZERO

  HIGH_NOT_PRECEDENCE

  IGNORE_SPACE
Server Command Options

<table>
<thead>
<tr>
<th>NO_AUTO_VALUE_ON_ZERO</th>
</tr>
</thead>
<tbody>
<tr>
<td>NO_BACKSLASH_ESCAPES</td>
</tr>
<tr>
<td>NO_DIR_IN_CREATE</td>
</tr>
<tr>
<td>NO_ENGINE_SUBSTITUTION</td>
</tr>
<tr>
<td>NO_UNSIGNED_SUBTRACTION</td>
</tr>
<tr>
<td>NO_ZERO_DATE</td>
</tr>
<tr>
<td>NO_ZERO_IN_DATE</td>
</tr>
<tr>
<td>ONLY_FULL_GROUP_BY</td>
</tr>
<tr>
<td>PAD_CHAR_TO_FULL_LENGTH</td>
</tr>
<tr>
<td>PIPES_AS_CONCAT</td>
</tr>
<tr>
<td>REAL_AS_FLOAT</td>
</tr>
<tr>
<td>STRICT_ALL_TABLES</td>
</tr>
<tr>
<td>STRICT_TRANS_TABLES</td>
</tr>
<tr>
<td>TIME_TRUNCATE_FRACTIONAL</td>
</tr>
</tbody>
</table>

Set the SQL mode. See Section 5.1.11, “Server SQL Modes”.

Note

MySQL installation programs may configure the SQL mode during the installation process. If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

- **--ssl, --skip-ssl**

| Command-Line Format | --ssl[={OFF|ON}] |
|---------------------|------------------|
| Disabled by         | skip-ssl         |
| Type                | Boolean          |
| Default Value       | ON               |

The **--ssl** option specifies that the server permits but does not require encrypted connections. This option is enabled by default.

**--ssl** can be specified in negated form as **--skip-ssl** or a synonym (**--ssl=OFF, --disable-ssl**). In this case, the option specifies that the server does not permit encrypted connections, regardless of the settings of the **tls_*** and **ssl_*** system variables.

The **--ssl** option has an effect only at server startup on whether the server supports encrypted connections. It is ignored and has no effect on the operation of **ALTER INSTANCE RELOAD TLS** at runtime. For example, you can use **--ssl=OFF** to start the server with encrypted connections disabled.
then reconfigure TLS and execute `ALTER INSTANCE RELOAD TLS` to enable encrypted connections at runtime.

For more information about configuring whether the server permits clients to connect using SSL and indicating where to find SSL keys and certificates, see Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”, which also describes server capabilities for certificate and key file autogeneration and autodiscovery. Consider setting at least the `ssl_cert` and `ssl_key` system variables on the server side and the `--ssl-ca` (or `--ssl-capath`) option on the client side.

- **--standalone**
  
<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--standalone</th>
</tr>
</thead>
<tbody>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
</tbody>
</table>

  Available on Windows only; instructs the MySQL server not to run as a service.

- **--super-large-pages**
  
  | Command-Line Format | --super-large-pages={OFF|ON} |
  |----------------------|-----------------------------|
  | Platform Specific    | Solaris                     |
  | Type                 | Boolean                     |
  | Default Value        | OFF                         |

  Standard use of large pages in MySQL attempts to use the largest size supported, up to 4MB. Under Solaris, a “super large pages” feature enables uses of pages up to 256MB. This feature is available for recent SPARC platforms. It can be enabled or disabled by using the `--super-large-pages` or `--skip-super-large-pages` option.

- **--symbolic-links, --skip-symbolic-links**
  
  | Command-Line Format | --symbolic-links={OFF|ON} |
  |----------------------|---------------------------|
  | Deprecated           | Yes                       |
  | Type                 | Boolean                   |
  | Default Value        | OFF                       |

  Enable or disable symbolic link support. On Unix, enabling symbolic links means that you can link a MyISAM index file or data file to another directory with the `INDEX DIRECTORY` or `DATA DIRECTORY` option of the `CREATE TABLE` statement. If you delete or rename the table, the files that its symbolic links point to also are deleted or renamed. See Section 8.12.2.2, “Using Symbolic Links for MyISAM Tables on Unix”.

  **Note**
  
  Symbolic link support, along with the `--symbolic-links` option that controls it, is deprecated; you should expect it to be removed in a future version of MySQL. In addition, the option is disabled by default. The related `have_symlink` system variable also is deprecated; expect it be removed in a future version of MySQL.

  This option has no meaning on Windows.

- **--sysdate-is-now**
  
  | Command-Line Format | --sysdate-is-now={OFF|ON} |
  |----------------------|---------------------------|
Server Command Options

<table>
<thead>
<tr>
<th>Type</th>
<th>Boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

SYSDATE() by default returns the time at which it executes, not the time at which the statement in which it occurs begins executing. This differs from the behavior of NOW(). This option causes SYSDATE() to be a synonym for NOW(). For information about the implications for binary logging and replication, see the description for SYSDATE() in Section 12.7, “Date and Time Functions” and for SET TIMESTAMP in Section 5.1.8, “Server System Variables”.

• --tc-heuristic-recover={COMMIT|ROLLBACK}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--tc-heuristic-recover=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
<tr>
<td>Valid Values</td>
<td>OFF, COMMIT, ROLLBACK</td>
</tr>
</tbody>
</table>

The decision to use in a manual heuristic recovery.

If a --tc-heuristic-recover option is specified, the server exits regardless of whether manual heuristic recovery is successful.

On systems with more than one storage engine capable of two-phase commit, the ROLLBACK option is not safe and causes recovery to halt with the following error:

```
[ERROR] --tc-heuristic-recover rollback
strategy is not safe on systems with more than one 2-phase-commit-capable
storage engine. Aborting crash recovery.
```

• --transaction-isolation=level

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--transaction-isolation=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>transaction_isolation</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>REPEATABLE-READ</td>
</tr>
</tbody>
</table>
| Valid Values        | READ-UNCOMMITTED, READ-
                       | COMMITTED, REPEATABLE-READ, |
                       | SERIALIZABLE               |

Sets the default transaction isolation level. The level value can be READ-UNCOMMITTED, READ-
COMMITTED, REPEATABLE-READ, or SERIALIZABLE. See Section 13.3.7, “SET TRANSACTION
Statement”.

719
The default transaction isolation level can also be set at runtime using the `SET TRANSACTION` statement or by setting the `transaction_isolation` system variable.

- **--transaction-read-only**

  | Command-Line Format | `--transaction-read-only[={OFF|ON}]` |
  |---------------------|-------------------------------------|
  | System Variable     | `transaction_read_only`             |
  | Scope               | Global, Session                     |
  | Dynamic             | Yes                                 |
  | `SET_VAR` Hint Applies | No                               |
  | Type                | Boolean                            |
  | Default Value       | OFF                                 |

  Sets the default transaction access mode. By default, read-only mode is disabled, so the mode is read/write.

  To set the default transaction access mode at runtime, use the `SET TRANSACTION` statement or set the `transaction_read_only` system variable. See Section 13.3.7, “SET TRANSACTION Statement”.

- **--tmpdir=dir_name, -t dir_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--tmpdir=dir_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>tmpdir</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

  The path of the directory to use for creating temporary files. It might be useful if your default `/tmp` directory resides on a partition that is too small to hold temporary tables. This option accepts several paths that are used in round-robin fashion. Paths should be separated by colon characters (:) on Unix and semicolon characters (;) on Windows.

  `--tmpdir` can be a non-permanent location, such as a directory on a memory-based file system or a directory that is cleared when the server host restarts. If the MySQL server is acting as a replica, and you are using a non-permanent location for `--tmpdir`, consider setting a different temporary directory for the replica using the `slave_load_tmpdir` system variable. For a replica, the temporary files used to replicate `LOAD DATA` statements are stored in this directory, so with a permanent location they can survive machine restarts, although replication can now continue after a restart if the temporary files have been removed.

  For more information about the storage location of temporary files, see Section B.3.3.5, “Where MySQL Stores Temporary Files”.

- **--upgrade=value**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--upgrade=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.16</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
</tbody>
</table>
This option controls whether and how the server performs an automatic upgrade at startup. Automatic upgrade involves two steps:

- **Step 1: Data dictionary upgrade.**
  
  This step upgrades:
  
  - The data dictionary tables in the `mysql` schema. If the actual data dictionary version is lower than the current expected version, the server upgrades the data dictionary. If it cannot, or is prevented from doing so, the server cannot run.
  
  - The Performance Schema and `INFORMATION_SCHEMA`.

- **Step 2: Server upgrade.**
  
  This step comprises all other upgrade tasks. If the existing installation data has a lower MySQL version than the server expects, it must be upgraded:
  
  - The system tables in the `mysql` schema (the remaining non-data dictionary tables).
  
  - The `sys` schema.
  
  - User schemas.

For details about upgrade steps 1 and 2, see Section 2.11.3, “What the MySQL Upgrade Process Upgrades”.

These `--upgrade` option values are permitted:

- **AUTO**
  
  The server performs an automatic upgrade of anything it finds to be out of date (steps 1 and 2). This is the default action if `--upgrade` is not specified explicitly.

- **NONE**
  
  The server performs no automatic upgrade steps during the startup process (skips steps 1 and 2). Because this option value prevents a data dictionary upgrade, the server exits with an error if the data dictionary is found to be out of date:

  ```
  [ERROR] [MY-013381] [Server] Server shutting down because upgrade is required, yet prohibited by the command line option 'upgrade=NONE'.
  [ERROR] [MY-010334] [Server] Failed to initialize DD Storage Engine
  ```
MINIMAL

The server upgrades the data dictionary, the Performance Schema, and the INFORMATION_SCHEMA, if necessary (step 1). Note that following an upgrade with this option, Group Replication cannot be started, because system tables on which the replication internals depend are not updated, and reduced functionality might also be apparent in other areas.

FORCE

The server upgrades the data dictionary, the Performance Schema, and the INFORMATION_SCHEMA, if necessary (step 1). In addition, the server forces an upgrade of everything else (step 2). Expect server startup to take longer with this option because the server checks all objects in all schemas.

FORCE is useful to force step 2 actions to be performed if the server thinks they are not necessary. For example, you may believe that a system table is missing or has become damaged and want to force a repair.

The following table summarizes the actions taken by the server for each option value.

<table>
<thead>
<tr>
<th>Option Value</th>
<th>Server Performs Step 1?</th>
<th>Server Performs Step 2?</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTO</td>
<td>If necessary</td>
<td>If necessary</td>
</tr>
<tr>
<td>NONE</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>MINIMAL</td>
<td>If necessary</td>
<td>No</td>
</tr>
<tr>
<td>FORCE</td>
<td>If necessary</td>
<td>Yes</td>
</tr>
</tbody>
</table>

--user={user_name|user_id}, -u {user_name|user_id}

Command-Line Format | --user=name
Type               | String

Run the mysqld server as the user having the name user_name or the numeric user ID user_id. (“User” in this context refers to a system login account, not a MySQL user listed in the grant tables.)

This option is mandatory when starting mysqld as root. The server changes its user ID during its startup sequence, causing it to run as that particular user rather than as root. See Section 6.1.1, “Security Guidelines”.

To avoid a possible security hole where a user adds a --user=root option to a my.cnf file (thus causing the server to run as root), mysqld uses only the first --user option specified and produces a warning if there are multiple --user options. Options in /etc/my.cnf and $MYSQL_HOME/my.cnf are processed before command-line options, so it is recommended that you put a --user option in /etc/my.cnf and specify a value other than root. The option in /etc/my.cnf is found before any other --user options, which ensures that the server runs as a user other than root, and that a warning results if any other --user option is found.

--validate-config

Command-Line Format | --validate-config=[OFF|ON]
Introduced           | 8.0.16
Type                 | Boolean
Server System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>OFF</th>
</tr>
</thead>
</table>

Validate the server startup configuration. If no errors are found, the server terminates with an exit code of 0. If an error is found, the server displays a diagnostic message and terminates with an exit code of 1. Warning and information messages may also be displayed, depending on the `log_error_verbosity` value, but do not produce immediate validation termination or an exit code of 1. For more information, see Section 5.1.3, “Server Configuration Validation”.

- **--verbose, -v**
  Use this option with the `--help` option for detailed help.

- **--version, -V**
  Display version information and exit.

### 5.1.8 Server System Variables

The MySQL server maintains many system variables that configure its operation. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically at runtime using the `SET` statement, which enables you to modify operation of the server without having to stop and restart it. You can also use system variable values in expressions.

Setting a global system variable runtime value normally requires the `SYSTEM_VARIABLES_ADMIN` privilege (or the deprecated `SUPER` privilege). Setting a session system runtime variable value normally requires no special privileges and can be done by any user, although there are exceptions. For more information, see Section 5.1.9.1, “System Variable Privileges”.

There are several ways to see the names and values of system variables:

- To see the values that a server uses based on its compiled-in defaults and any option files that it reads, use this command:

  ```
  mysql --verbose --help
  ```

- To see the values that a server uses based only on its compiled-in defaults, ignoring the settings in any option files, use this command:

  ```
  mysql --no-defaults --verbose --help
  ```

- To see the current values used by a running server, use the `SHOW VARIABLES` statement or the Performance Schema system variable tables. See Section 26.12.14, “Performance Schema System Variable Tables”.

This section provides a description of each system variable. For a system variable summary table, see Section 5.1.5, “Server System Variable Reference”. For more information about manipulation of system variables, see Section 5.1.9, “Using System Variables”.

For additional system variable information, see these sections:

- Section 5.1.9, “Using System Variables”, discusses the syntax for setting and displaying system variable values.

- Section 5.1.9.2, “Dynamic System Variables”, lists the variables that can be set at runtime.

- Information on tuning system variables can be found in Section 5.1.1, “Configuring the Server”.

- Section 15.14, “InnoDB Startup Options and System Variables”, lists InnoDB system variables.
Server System Variables

- **NDB Cluster System Variables**, lists system variables which are specific to NDB Cluster.

- For information on server system variables specific to replication, see Section 17.1.6, “Replication and Binary Logging Options and Variables”.

**Note**

Some of the following variable descriptions refer to “enabling” or “disabling” a variable. These variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. Boolean variables can be set at startup to the values `ON`, `TRUE`, `OFF`, and `FALSE` (not case sensitive), as well as `1` and `0`. See Section 4.2.2.4, “Program Option Modifiers”.

Some system variables control the size of buffers or caches. For a given buffer, the server might need to allocate internal data structures. These structures typically are allocated from the total memory allocated to the buffer, and the amount of space required might be platform dependent. This means that when you assign a value to a system variable that controls a buffer size, the amount of space actually available might differ from the value assigned. In some cases, the amount might be less than the value assigned. It is also possible that the server adjusts a value upward. For example, if you assign a value of 0 to a variable for which the minimal value is 1024, the server sets the value to 1024.

Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

Some system variables take file name values. Unless otherwise specified, the default file location is the data directory if the value is a relative path name. To specify the location explicitly, use an absolute path name. Suppose that the data directory is `/var/mysql/data`. If a file-valued variable is given as a relative path name, it is located under `/var/mysql/data`. If the value is an absolute path name, its location is as given by the path name.

- **activate_all_roles_on_login**

  | Command-Line Format | `--activate-all-roles-on-login=[{OFF|ON}]` |
  |---------------------|------------------------------------------|
  | System Variable     | `activate_all_roles_on_login`            |
  | Scope               | Global                                   |
  | Dynamic             | Yes                                      |
  | `SET_VAR` Hint Applies | No                                      |
  | Type                | Boolean                                  |
  | Default Value       | `OFF`                                    |

Whether to enable automatic activation of all granted roles when users log in to the server:

- If `activate_all_roles_on_login` is enabled, the server activates all roles granted to each account at login time. This takes precedence over default roles specified with `SET DEFAULT ROLE`.

- If `activate_all_roles_on_login` is disabled, the server activates the default roles specified with `SET DEFAULT ROLE`, if any, at login time.

Granted roles include those granted explicitly to the user and those named in the `mandatory_roles` system variable value.

`activate_all_roles_on_login` applies only at login time, and at the beginning of execution for stored programs and views that execute in definer context. To change the active roles within a session, use `SET ROLE`. To change the active roles for a stored program, the program body should execute `SET ROLE`.
- **admin_address**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--admin-address=addr</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.14</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>admin_address</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The IP address on which to listen for TCP/IP connections on the administrative network interface (see Section 5.1.12.1, “Connection Interfaces”). There is no default `admin_address` value. If this variable is not specified at startup, the server maintains no administrative interface. The server also has a `bind_address` system variable for configuring regular (nonadministrative) client TCP/IP connections. See Section 5.1.12.1, “Connection Interfaces”.

If `admin_address` is specified, its value must satisfy these requirements:

- The value must be a single IPv4 address, IPv6 address, or host name.
- The value cannot specify a wildcard address format (`*`, `0.0.0.0`, or `::`).
- As of MySQL 8.0.22, the value may include a network namespace specifier.

An IP address can be specified as an IPv4 or IPv6 address. If the value is a host name, the server resolves the name to an IP address and binds to that address. If a host name resolves to multiple IP addresses, the server uses the first IPv4 address if there are any, or the first IPv6 address otherwise.

The server treats different types of addresses as follows:

- If the address is an IPv4-mapped address, the server accepts TCP/IP connections for that address, in either IPv4 or IPv6 format. For example, if the server is bound to `::ffff:127.0.0.1`, clients can connect using `--host=127.0.0.1` or `--host=::ffff:127.0.0.1`.
- If the address is a “regular” IPv4 or IPv6 address (such as `127.0.0.1` or `::1`), the server accepts TCP/IP connections only for that IPv4 or IPv6 address.

These rules apply to specifying a network namespace for an address:

- A network namespace can be specified for an IP address or a host name.
- A network namespace cannot be specified for a wildcard IP address.
- For a given address, the network namespace is optional. If given, it must be specified as a `/ns` suffix immediately following the address.
- An address with no `/ns` suffix uses the host system global namespace. The global namespace is therefore the default.
- An address with a `/ns` suffix uses the namespace named `ns`.
The host system must support network namespaces and each named namespace must previously have been set up. Naming a nonexistent namespace produces an error.

For additional information about network namespaces, see Section 5.1.14, "Network Namespace Support".

If binding to the address fails, the server produces an error and does not start.

The `admin_address` system variable is similar to the `bind_address` system variable that binds the server to an address for ordinary client connections, but with these differences:

- `bind_address` permits multiple addresses. `admin_address` permits a single address.
- `bind_address` permits wildcard addresses. `admin_address` does not.

**Command-Line Format**

```
--admin-port=port_num
```

| Introduced | 8.0.14 |
| System Variable | `admin_port` |
| Scope | Global |
| Dynamic | No |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 33062 |
| Minimum Value | 0 |
| Maximum Value | 65535 |

The TCP/IP port number to use for connections on the administrative network interface (see Section 5.1.12.1, "Connection Interfaces"). Setting this variable to 0 causes the default value to be used.

Setting `admin_port` has no effect if `admin_address` is not specified because in that case the server maintains no administrative network interface.

**Command-Line Format**

```
--admin-ssl-ca=file_name
```

| Introduced | 8.0.21 |
| System Variable | `admin_ssl_ca` |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | File name |
| Default Value | NULL |

The `admin_ssl_ca` system variable is like `ssl_ca`, except that it applies to the administrative connection interface rather than the main connection interface. For information about configuring
encryption support for the administrative interface, see Administrative Interface Support for Encrypted Connections.

• **admin_ssl_capath**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--admin-ssl-capath=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.21</td>
</tr>
<tr>
<td>System Variable</td>
<td>admin_ssl_capath</td>
</tr>
<tr>
<td>Scope</td>

<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The `admin_ssl_capath` system variable is like `ssl_capath`, except that it applies to the administrative connection interface rather than the main connection interface. For information about configuring encryption support for the administrative interface, see Administrative Interface Support for Encrypted Connections.

• **admin_ssl_cert**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--admin-ssl-cert=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.21</td>
</tr>
<tr>
<td>System Variable</td>
<td>admin_ssl_cert</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The `admin_ssl_cert` system variable is like `ssl_cert`, except that it applies to the administrative connection interface rather than the main connection interface. For information about configuring encryption support for the administrative interface, see Administrative Interface Support for Encrypted Connections.

• **admin_ssl_cipher**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--admin-ssl-cipher=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.21</td>
</tr>
<tr>
<td>System Variable</td>
<td>admin_ssl_cipher</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>NULL</th>
</tr>
</thead>
</table>

The `admin_ssl_cipher` system variable is like `ssl_cipher`, except that it applies to the administrative connection interface rather than the main connection interface. For information about configuring encryption support for the administrative interface, see [Administrative Interface Support for Encrypted Connections](#).

- **`admin_ssl_crl`**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--admin-ssl-crl=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.21</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>admin_ssl_crl</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The `admin_ssl_crl` system variable is like `ssl_crl`, except that it applies to the administrative connection interface rather than the main connection interface. For information about configuring encryption support for the administrative interface, see [Administrative Interface Support for Encrypted Connections](#).

- **`admin_ssl_crlpath`**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--admin-ssl-crlpath=dir_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.21</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>admin_ssl_crlpath</code></td>
</tr>
<tr>
<td>Scope</td>

</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The `admin_ssl_crlpath` system variable is like `ssl_crlpath`, except that it applies to the administrative connection interface rather than the main connection interface. For information about configuring encryption support for the administrative interface, see [Administrative Interface Support for Encrypted Connections](#).

- **`admin_ssl_key`**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--admin-ssl-key=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.21</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>admin_ssl_key</code></td>

<td>No</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>File name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The `admin_ssl_key` system variable is like `ssl_key`, except that it applies to the administrative connection interface rather than the main connection interface. For information about configuring encryption support for the administrative interface, see Administrative Interface Support for Encrypted Connections.

- `admin_tls_ciphersuites`

Command-Line Format: `--admin-tls-ciphersuites=ciphersuite_list`

Introduced: 8.0.21

System Variable: `admin_tls_ciphersuites`

Scope: Global

Dynamic: Yes

`SET_VAR` Hint Applies: No

Type: String

Default Value: NULL

The `admin_tls_ciphersuites` system variable is like `tls_ciphersuites`, except that it applies to the administrative connection interface rather than the main connection interface. For information about configuring encryption support for the administrative interface, see Administrative Interface Support for Encrypted Connections.

- `admin_tls_version`

Command-Line Format: `--admin-tls-version=protocol_list`

Introduced: 8.0.21

System Variable: `admin_tls_version`

Scope: Global

Dynamic: Yes

`SET_VAR` Hint Applies: No

Type: String

Default Value: TLSv1,TLSv1.1,TLSv1.2,TLSv1.3 (OpenSSL 1.1.1 and higher)

TLSv1,TLSv1.1,TLSv1.2 (otherwise)

The `admin_tls_version` system variable is like `tls_version`, except that it applies to the administrative connection interface rather than the main connection interface. For information about configuring encryption support for the administrative interface, see Administrative Interface Support for Encrypted Connections.

- `authentication_windows_log_level`

Command-Line Format: `--authentication-windows-log-level=#`

System Variable: `authentication_windows_log_level`

Scope: Global
Server System Variables

<table>
<thead>
<tr>
<th>Dynamic</th>
<th>No</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4</td>
</tr>
</tbody>
</table>

This variable is available only if the `authentication_windows` Windows authentication plugin is enabled and debugging code is enabled. See Section 6.4.1.6, “Windows Pluggable Authentication”.

This variable sets the logging level for the Windows authentication plugin. The following table shows the permitted values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No logging</td>
</tr>
<tr>
<td>1</td>
<td>Log only error messages</td>
</tr>
<tr>
<td>2</td>
<td>Log level 1 messages and warning messages</td>
</tr>
<tr>
<td>3</td>
<td>Log level 2 messages and information notes</td>
</tr>
<tr>
<td>4</td>
<td>Log level 3 messages and debug messages</td>
</tr>
</tbody>
</table>

- `authentication_windows_use_principal_name`

  | Command-Line Format | `--authentication-windows-use-principal-name[={OFF|ON}]` |
|---------------------|----------------------------------------------------|
| System Variable     | `authentication_windows_use_principal_name` |
| Scope               | Global |
| Dynamic             | No |
| **SET_VAR** Hint Applies | No |
| Type                | Boolean |
| Default Value       | ON |

This variable is available only if the `authentication_windows` Windows authentication plugin is enabled. See Section 6.4.1.6, “Windows Pluggable Authentication”.

A client that authenticates using the `InitSecurityContext()` function should provide a string identifying the service to which it connects (`targetName`). MySQL uses the principal name (UPN) of the account under which the server is running. The UPN has the form `user_id@computer_name` and need not be registered anywhere to be used. This UPN is sent by the server at the beginning of authentication handshake.

This variable controls whether the server sends the UPN in the initial challenge. By default, the variable is enabled. For security reasons, it can be disabled to avoid sending the server's account name to a client as cleartext. If the variable is disabled, the server always sends a 0x00 byte in the first challenge, the client does not specify `targetName`, and as a result, NTLM authentication is used.

If the server fails to obtain its UPN (which happens primarily in environments that do not support Kerberos authentication), the UPN is not sent by the server and NTLM authentication is used.
Server System Variables

- **autocommit**

| Command-Line Format | --autocommit[={OFF|ON}] |
|---------------------|---------------------------|
| System Variable     | autocommit                |
| Scope               | Global, Session           |
| Dynamic             | Yes                       |
| SET_VAR Hint Applies| No                        |
| Type                | Boolean                   |
| Default Value       | ON                        |

The autocommit mode. If set to 1, all changes to a table take effect immediately. If set to 0, you must use `COMMIT` to accept a transaction or `ROLLBACK` to cancel it. If `autocommit` is 0 and you change it to 1, MySQL performs an automatic `COMMIT` of any open transaction. Another way to begin a transaction is to use a `START TRANSACTION` or `BEGIN` statement. See Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Statements”.

By default, client connections begin with `autocommit` set to 1. To cause clients to begin with a default of 0, set the global `autocommit` value by starting the server with the `--autocommit=0` option. To set the variable using an option file, include these lines:

```
[mysqld]
autocommit=0
```

- **automatic_sp_privileges**

| Command-Line Format | --automatic-sp-privileges[={OFF|ON}] |
|---------------------|-------------------------------------|
| System Variable     | automatic_sp_privileges             |
| Scope               | Global                              |
| Dynamic             | Yes                                 |
| SET_VAR Hint Applies| No                                  |
| Type                | Boolean                             |
| Default Value       | ON                                  |

When this variable has a value of 1 (the default), the server automatically grants the `EXECUTE` and `ALTER ROUTINE` privileges to the creator of a stored routine, if the user cannot already execute and alter or drop the routine. (The `ALTER ROUTINE` privilege is required to drop the routine.) The server also automatically drops those privileges from the creator when the routine is dropped. If `automatic_sp_privileges` is 0, the server does not automatically add or drop these privileges.

The creator of a routine is the account used to execute the `CREATE` statement for it. This might not be the same as the account named as the `DEFINER` in the routine definition.

If you start `mysql` with `--skip-new`, `automatic_sp_privileges` is set to `OFF`.

See also Section 24.2.2, “Stored Routines and MySQL Privileges”.

- **auto_generate_certs**

| Command-Line Format | --auto-generate-certs[={OFF|ON}] |
|---------------------|----------------------------------|
| System Variable     | auto_generate_certs              |

731
Server System Variables

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

This variable controls whether the server autogenerates SSL key and certificate files in the data directory, if they do not already exist.

At startup, the server automatically generates server-side and client-side SSL certificate and key files in the data directory if the `auto_generate_certs` system variable is enabled, no SSL options other than `--ssl` are specified, and the server-side SSL files are missing from the data directory. These files enable secure client connections using SSL; see Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

For more information about SSL file autogeneration, including file names and characteristics, see Section 6.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”.

The `sha256_password_auto_generate_rsa_keys` and `caching_sha2_password_auto_generate_rsa_keys` system variables are related but control autogeneration of RSA key-pair files needed for secure password exchange using RSA over unencrypted connections.

- `avoid_temporal_upgrade`

| Command-Line Format         | `--avoid-temporal-upgrade[={OFF|ON}]` |
|----------------------------|--------------------------------------|
| Deprecated                 | Yes                                  |
| System Variable            | `avoid_temporal_upgrade`              |
| Scope                      | Global                               |
| Dynamic                    | Yes                                  |
| SET_VAR Hint Applies       | No                                   |
| Type                       | Boolean                              |
| Default Value              | OFF                                  |

This variable controls whether `ALTER TABLE` implicitly upgrades temporal columns found to be in pre-5.6.4 format (`TIME`, `DATETIME`, and `TIMESTAMP` columns without support for fractional seconds precision). Upgrading such columns requires a table rebuild, which prevents any use of fast alterations that might otherwise apply to the operation to be performed.

This variable is disabled by default. Enabling it causes `ALTER TABLE` not to rebuild temporal columns and thereby be able to take advantage of possible fast alterations.

This variable is deprecated; expect it to be removed in a future MySQL release.

- `back_log`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--back-log=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>back_log</code></td>
</tr>
<tr>

</thead>
<tbody>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>(-1) (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

The number of outstanding connection requests MySQL can have. This comes into play when the main MySQL thread gets very many connection requests in a very short time. It then takes some time (although very little) for the main thread to check the connection and start a new thread. The `back_log` value indicates how many requests can be stacked during this short time before MySQL momentarily stops answering new requests. You need to increase this only if you expect a large number of connections in a short period of time.

In other words, this value is the size of the listen queue for incoming TCP/IP connections. Your operating system has its own limit on the size of this queue. The manual page for the Unix `listen()` system call should have more details. Check your OS documentation for the maximum value for this variable. `back_log` cannot be set higher than your operating system limit.

The default value is the value of `max_connections`, which enables the permitted backlog to adjust to the maximum permitted number of connections.

- **basedir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--basedir=dir_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>basedir</code></td>
</tr>
<tr>

<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td>parent of mysqld installation directory</td>
</tr>
</tbody>
</table>

The path to the MySQL installation base directory.

- **big_tables**

  | Command-Line Format | `--big-tables[={OFF|ON}]` |
  | --- | --- |
  | System Variable | `big_tables` |
  | Scope | Global, Session |
  | Dynamic | Yes |
  | **SET_VAR** Hint Applies | No |
  | Type | Boolean |
If enabled, the server stores all temporary tables on disk rather than in memory. This prevents most `The table tbl_name is full` errors for `SELECT` operations that require a large temporary table, but also slows down queries for which in-memory tables would suffice.

The default value for new connections is `OFF` (use in-memory temporary tables). Normally, it should never be necessary to enable this variable. When in-memory internal temporary tables are managed by the `TempTable` storage engine (the default), and the maximum amount of memory that can be occupied by the `TempTable` storage engine is exceeded, the `TempTable` storage engine starts storing data to temporary files on disk. When in-memory temporary tables are managed by the `MEMORY` storage engine, in-memory tables are automatically converted to disk-based tables as required. For more information, see Section 8.4.4, “Internal Temporary Table Use in MySQL”.

**bind_address**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--bind-address=addr</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>bind_address</code></td>
</tr>
<tr>

</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>*</code></td>
</tr>
</tbody>
</table>

The MySQL server listens on one or more network sockets for TCP/IP connections. Each socket is bound to one address, but it is possible for an address to map onto multiple network interfaces. To specify how the server should listen for TCP/IP connections, set the `bind_address` system variable at server startup. The server also has an `admin_address` system variable that enables administrative connections on a dedicated interface. See Section 5.1.12.1, “Connection Interfaces”.

If `bind_address` is specified, its value must satisfy these requirements:

- Prior to MySQL 8.0.13, `bind_address` accepts a single address value, which may specify a single non-wildcard IP address or host name, or one of the wildcard address formats that permit listening on multiple network interfaces (`*`, `0.0.0.0`, or `:`).

- As of MySQL 8.0.13, `bind_address` accepts either a single value as just described, or a list of comma-separated values. When the variable names a list of multiple values, each value must specify a single non-wildcard IP address (either IPv4 or IPv6) or a host name. Wildcard address formats (`*`, `0.0.0.0`, or `:`) are not allowed in a list of values.

- As of MySQL 8.0.22, addresses may include a network namespace specifier.

IP addresses can be specified as IPv4 or IPv6 addresses. For any value that is a host name, the server resolves the name to an IP address and binds to that address. If a host name resolves to multiple IP addresses, the server uses the first IPv4 address if there are any, or the first IPv6 address otherwise.

The server treats different types of addresses as follows:

- If the address is `*`, the server accepts TCP/IP connections on all server host IPv4 interfaces, and, if the server host supports IPv6, on all IPv6 interfaces. Use this address to permit both IPv4 and IPv6
connections on all server interfaces. This value is the default. If the variable specifies a list of multiple values, this value is not permitted.

- If the address is 0.0.0.0, the server accepts TCP/IP connections on all server host IPv4 interfaces. If the variable specifies a list of multiple values, this value is not permitted.

- If the address is ::, the server accepts TCP/IP connections on all server host IPv4 and IPv6 interfaces. If the variable specifies a list of multiple values, this value is not permitted.

- If the address is an IPv4-mapped address, the server accepts TCP/IP connections for that address, in either IPv4 or IPv6 format. For example, if the server is bound to ::ffff:127.0.0.1, clients can connect using --host=127.0.0.1 or --host=::ffff:127.0.0.1.

- If the address is a “regular” IPv4 or IPv6 address (such as 127.0.0.1 or ::1), the server accepts TCP/IP connections only for that IPv4 or IPv6 address.

These rules apply to specifying a network namespace for an address:

- A network namespace can be specified for an IP address or a host name.

- A network namespace cannot be specified for a wildcard IP address.

- For a given address, the network namespace is optional. If given, it must be specified as a /ns suffix immediately following the address.

- An address with no /ns suffix uses the host system global namespace. The global namespace is therefore the default.

- An address with a /ns suffix uses the namespace named ns.

- The host system must support network namespaces and each named namespace must previously have been set up. Naming a nonexistent namespace produces an error.

- If the variable value specifies multiple addresses, it can include addresses in the global namespace, in named namespaces, or a mix.

For additional information about network namespaces, see Section 5.1.14, “Network Namespace Support”.

If binding to any address fails, the server produces an error and does not start.

Examples:

- **bind_address=***

  The server listens on all IPv4 or IPv6 addresses, as specified by the * wildcard.

- **bind_address=198.51.100.20**

  The server listens only on the 198.51.100.20 IPv4 address.

- **bind_address=198.51.100.20,2001:db8:0:f101::1**

  The server listens on the 198.51.100.20 IPv4 address and the 2001:db8:0:f101::1 IPv6 address.
Server System Variables

- `bind_address=198.51.100.20,*`

  This produces an error because wildcard addresses are not permitted when `bind_address` names a list of multiple values.

- `bind_address=198.51.100.20/red,2001:db8:0:f101::1/blue,192.0.2.50`

  The server listens on the `198.51.100.20` IPv4 address in the `red` namespace, the `2001:db8:0:f101::1` IPv6 address in the `blue` namespace, and the `192.0.2.50` IPv4 address in the global namespace.

  When `bind_address` names a single value (wildcard or non-wildcard), the server listens on a single socket, which for a wildcard address may be bound to multiple network interfaces. When `bind_address` names a list of multiple values, the server listens on one socket per value, with each socket bound to a single network interface. The number of sockets is linear with the number of values specified. Depending on operating system connection-acceptance efficiency, long value lists might incur a performance penalty for accepting TCP/IP connections.

  Because file descriptors are allocated for listening sockets and network namespace files, it may be necessary to increase the `open_files_limit` system variable.

  If you intend to bind the server to a specific address, be sure that the `mysql.user` system table contains an account with administrative privileges that you can use to connect to that address. Otherwise, you cannot shut down the server. For example, if you bind the server to `*`, you can connect to it using all existing accounts. But if you bind the server to `::1`, it accepts connections only on that address. In that case, first make sure that the `root'@'::1'` account is present in the `mysql.user` table so you can still connect to the server to shut it down.

- `block_encryption_mode`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--block-encryption-mode=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>block_encryption_mode</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>aes-128-ecb</code></td>
</tr>
</tbody>
</table>

  This variable controls the block encryption mode for block-based algorithms such as AES. It affects encryption for `AES_ENCRYPT()` and `AES_DECRYPT()`.

  `block_encryption_mode` takes a value in `aes-keylen-mode` format, where `keylen` is the key length in bits and `mode` is the encryption mode. The value is not case-sensitive. Permitted `keylen` values are 128, 192, and 256. Permitted `mode` values are `ECB`, `CBC`, `CFB1`, `CFB8`, `CFB128`, and `OFB`.

  For example, this statement causes the AES encryption functions to use a key length of 256 bits and the CBC mode:

  ```sql
  SET block_encryption_mode = 'aes-256-cbc';
  ```

  An error occurs for attempts to set `block_encryption_mode` to a value containing an unsupported key length or a mode that the SSL library does not support.
Server System Variables

- **bulk_insert_buffer_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--bulk-insert-buffer-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>bulk_insert_buffer_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8388608</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

  *MyISAM* uses a special tree-like cache to make bulk inserts faster for `INSERT ... SELECT`, `INSERT ... VALUES (...)`, `(...), ...`, and `LOAD DATA` when adding data to nonempty tables. This variable limits the size of the cache tree in bytes per thread. Setting it to 0 disables this optimization. The default value is 8MB.

  As of MySQL 8.0.14, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

- **caching_sha2_password_auto_generate_rsa_keys**

  | Command-Line Format          | --caching-sha2-password-auto-generate-rsa-keys[={OFF|ON}] |
  |-------------------------------|----------------------------------------------------------|
  | System Variable               | caching_sha2_password_auto_generate_rsa_keys             |
  | Scope                         | Global                                                   |
  | Dynamic                       | No                                                       |
  | SET_VAR Hint Applies          | No                                                       |
  | Type                          | Boolean                                                  |
  | Default Value                 | ON                                                       |

  The server uses this variable to determine whether to autogenerate RSA private/public key-pair files in the data directory if they do not already exist.

  At startup, the server automatically generates RSA private/public key-pair files in the data directory if all of these conditions are true: The `sha256_password_auto_generate_rsa_keys` or `caching_sha2_password_auto_generate_rsa_keys` system variable is enabled; no RSA options are specified; the RSA files are missing from the data directory. These key-pair files enable secure password exchange using RSA over unencrypted connections for accounts authenticated by the
sha256_password or caching_sha2_password plugin; see Section 6.4.1.3, “SHA-256 Pluggable Authentication”, and Section 6.4.1.2, “Caching SHA-2 Pluggable Authentication”.

For more information about RSA file autogeneration, including file names and characteristics, see Section 6.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”.

The auto_generate_certs system variable is related but controls autogeneration of SSL certificate and key files needed for secure connections using SSL.

- **caching_sha2_password_private_key_path**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--caching-sha2-password-private-key-path=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>caching_sha2_password_private_key_path</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>private_key.pem</td>
</tr>
</tbody>
</table>

This variable specifies the path name of the RSA private key file for the caching_sha2_password authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format.

**Important**

Because this file stores a private key, its access mode should be restricted so that only the MySQL server can read it.

For information about caching_sha2_password, see Section 6.4.1.2, “Caching SHA-2 Pluggable Authentication”.

- **caching_sha2_password_public_key_path**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--caching-sha2-password-public-key-path=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>caching_sha2_password_public_key_path</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>public_key.pem</td>
</tr>
</tbody>
</table>

This variable specifies the path name of the RSA public key file for the caching_sha2_password authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format.

For information about caching_sha2_password, including information about how clients request the RSA public key, see Section 6.4.1.2, “Caching SHA-2 Pluggable Authentication”.

- **character_set_client**

| System Variable | character_set_client |
Server System Variables

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global, Session</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>utf8mb4</td>
</tr>
</tbody>
</table>

The character set for statements that arrive from the client. The session value of this variable is set using the character set requested by the client when the client connects to the server. (Many clients support a `--default-character-set` option to enable this character set to be specified explicitly. See also Section 10.4, “Connection Character Sets and Collations”.) The global value of the variable is used to set the session value in cases when the client-requested value is unknown or not available, or the server is configured to ignore client requests:

- The client requests a character set not known to the server. For example, a Japanese-enabled client requests `sjis` when connecting to a server not configured with `sjis` support.
- The client is from a version of MySQL older than MySQL 4.1, and thus does not request a character set.
- `mysqld` was started with the `--skip-character-set-client-handshake` option, which causes it to ignore client character set configuration. This reproduces MySQL 4.0 behavior and is useful should you wish to upgrade the server without upgrading all the clients.

Some character sets cannot be used as the client character set. Attempting to use them as the `character_set_client` value produces an error. See Impermissible Client Character Sets.

- `character_set_connection`

<table>
<thead>
<tr>
<th>System Variable</th>
<th>character_set_connection</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>utf8mb4</td>
</tr>
</tbody>
</table>

The character set used for literals specified without a character set introducer and for number-to-string conversion. For information about introducers, see Section 10.3.8, “Character Set Introducers”.

- `character_set_database`

<table>
<thead>
<tr>
<th>System Variable</th>
<th>character_set_database</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>utf8mb4</td>
</tr>
</tbody>
</table>
Server System Variables

| Footnote | This option is dynamic, but only the server should set this information. You should not set the value of this variable manually. |

The character set used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `character_set_server`.

As of MySQL 8.0.14, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

The global `character_set_database` and `collation_database` system variables are deprecated; expect them to be removed in a future version of MySQL.

Assigning a value to the session `character_set_database` and `collation_database` system variables is deprecated and assignments produce a warning. Expect the session variables to become read-only (and assignments to them to produce an error) in a future version of MySQL in which it remains possible to access the session variables to determine the database character set and collation for the default database.

- `character_set_filesystem`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--character-set-filesystem=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>character_set_filesystem</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>binary</code></td>
</tr>
</tbody>
</table>

The file system character set. This variable is used to interpret string literals that refer to file names, such as in the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. Such file names are converted from `character_set_client` to `character_set_filesystem` before the file opening attempt occurs. The default value is `binary`, which means that no conversion occurs. For systems on which multibyte file names are permitted, a different value may be more appropriate. For example, if the system represents file names using UTF-8, set `character_set_filesystem` to `'utf8mb4'`.

As of MySQL 8.0.14, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

- `character_set_results`

<table>
<thead>
<tr>
<th>System Variable</th>
<th><code>character_set_results</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>utf8mb4</th>
</tr>
</thead>
</table>

The character set used for returning query results to the client. This includes result data such as column values, result metadata such as column names, and error messages.

- **character_set_server**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--character-set-server=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>character_set_server</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>utf8mb4</td>
</tr>
</tbody>
</table>

The server’s default character set. See Section 10.15, “Character Set Configuration”. If you set this variable, you should also set `collation_server` to specify the collation for the character set.

- **character_set_system**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>character_set_system</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>utf8</td>
</tr>
</tbody>
</table>

The character set used by the server for storing identifiers. The value is always utf8.

- **character_sets_dir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--character-sets-dir=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>character_sets_dir</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

The directory where character sets are installed. See Section 10.15, “Character Set Configuration”.

- **check_proxy_users**

  | Command-Line Format | --check-proxy-users={OFF|ON} |
  |--------------------|-----------------------------|
  | System Variable    | check_proxy_users           |
  | Scope              | Global                      |
  | Dynamic            | Yes                         |
  | SET_VAR Hint Applies | No                        |
Some authentication plugins implement proxy user mapping for themselves (for example, the PAM and Windows authentication plugins). Other authentication plugins do not support proxy users by default. Of these, some can request that the MySQL server itself map proxy users according to granted proxy privileges: `mysql_native_password`, `sha256_password`.

If the `check_proxy_users` system variable is enabled, the server performs proxy user mapping for any authentication plugins that make such a request. However, it may also be necessary to enable plugin-specific system variables to take advantage of server proxy user mapping support:

- For the `mysql_native_password` plugin, enable `mysql_native_password_proxy_users`.
- For the `sha256_password` plugin, enable `sha256_password_proxy_users`.

For information about user proxying, see Section 6.2.18, “Proxy Users”.

**collation_connection**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>collation_connection</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The collation of the connection character set. `collation_connection` is important for comparisons of literal strings. For comparisons of strings with column values, `collation_connection` does not matter because columns have their own collation, which has a higher collation precedence (see Section 10.8.4, “Collation Coercibility in Expressions”).

**collation_database**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>collation_database</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>utf8mb4_0900_ai_ci</td>
</tr>
</tbody>
</table>
The collation used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `collation_server`.

As of MySQL 8.0.18, setting the session value of this system variable is no longer a restricted operation.

The global `character_set_database` and `collation_database` system variables are deprecated; expect them to be removed in a future version of MySQL.

Assigning a value to the session `character_set_database` and `collation_database` system variables is deprecated and assignments produce a warning. Expect the session variables to become read-only (and assignments to produce an error) in a future version of MySQL in which it remains possible to access the session variables to determine the database character set and collation for the default database.

- **collation_server**

  The server's default collation. See Section 10.15, "Character Set Configuration".

- **completion_type**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--completion-type=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>completion_type</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>NO_CHAIN</td>
</tr>
<tr>
<td>Valid Values</td>
<td>NO_CHAIN, CHAIN,</td>
</tr>
<tr>
<td></td>
<td>RELEASE, 0, 1</td>
</tr>
</tbody>
</table>
The transaction completion type. This variable can take the values shown in the following table. The variable can be assigned using either the name values or corresponding integer values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NO_CHAIN</td>
<td>COMMIT and ROLLBACK are unaffected. This is the default value.</td>
</tr>
<tr>
<td>(or 0)</td>
<td></td>
</tr>
<tr>
<td>CHAIN</td>
<td>COMMIT and ROLLBACK are equivalent to COMMIT AND CHAIN and</td>
</tr>
<tr>
<td>(or 1)</td>
<td>ROLLBACK AND CHAIN, respectively. (A new transaction starts immediately</td>
</tr>
<tr>
<td></td>
<td>with the same isolation level as the just-terminated transaction.)</td>
</tr>
<tr>
<td>RELEASE</td>
<td>COMMIT and ROLLBACK are equivalent to COMMIT RELEASE and ROLLBACK</td>
</tr>
<tr>
<td>(or 2)</td>
<td>RELEASE, respectively. (The server disconnects after terminating the</td>
</tr>
<tr>
<td></td>
<td>transaction.)</td>
</tr>
</tbody>
</table>

completion_type affects transactions that begin with START TRANSACTION or BEGIN and end with COMMIT or ROLLBACK. It does not apply to implicit commits resulting from execution of the statements listed in Section 13.3.3, “Statements That Cause an Implicit Commit”. It also does not apply for XA COMMIT, XA ROLLBACK, or when autocommit=1.

- concurrent_insert

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--concurrent-insert[=value]</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>concurrent_insert</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>AUTO</td>
</tr>
<tr>
<td>Valid Values</td>
<td>NEVER, AUTO, ALWAYS, 0, 1, 2</td>
</tr>
</tbody>
</table>

If AUTO (the default), MySQL permits INSERT and SELECT statements to run concurrently for MyISAM tables that have no free blocks in the middle of the data file.

This variable can take the values shown in the following table. The variable can be assigned using either the name values or corresponding integer values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NEVER</td>
<td>Disables concurrent inserts</td>
</tr>
<tr>
<td>(or 0)</td>
<td></td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTO (or 1)</td>
<td>(Default) Enables concurrent insert for MyISAM tables that do not have holes</td>
</tr>
<tr>
<td>ALWAYS (or 2)</td>
<td>Enables concurrent inserts for all MyISAM tables, even those that have holes. For a table with a hole, new rows are inserted at the end of the table if it is in use by another thread. Otherwise, MySQL acquires a normal write lock and inserts the row into the hole.</td>
</tr>
</tbody>
</table>

If you start `mysql` with `--skip-new`, `concurrent_insert` is set to NEVER.

See also Section 8.11.3, “Concurrent Inserts”.

- **connect_timeout**
  - Command-Line Format: `--connect-timeout=#`
  - System Variable: `connect_timeout`
  - Scope: Global
  - Dynamic: Yes
  - SET_VAR Hint Applies: No
  - Type: Integer
  - Default Value: 10
  - Minimum Value: 2
  - Maximum Value: 31536000

The number of seconds that the `mysql` server waits for a connect packet before responding with Bad handshake. The default value is 10 seconds.

Increasing the `connect_timeout` value might help if clients frequently encounter errors of the form Lost connection to MySQL server at 'XXX', system error: errno.

- **core_file**
  - System Variable: `core_file`
  - Scope: Global
  - Dynamic: No
  - SET_VAR Hint Applies: No
  - Type: Boolean
  - Default Value: OFF

Whether to write a core file if the server unexpectedly exits. This variable is set by the `--core-file` option.

- **create_admin_listener_thread**
  - Command-Line Format: `--create-admin-listener-thread=[{OFF|ON}]`
  - Introduced: 8.0.14
  - System Variable: `create_admin_listener_thread`
  - Scope: Global
Whether to use a dedicated listening thread for client connections on the administrative network interface (see Section 5.1.12.1, "Connection Interfaces"). The default is \textit{OFF}; that is, the manager thread for ordinary connections on the main interface also handles connections for the administrative interface.

Depending on factors such as platform type and workload, you may find one setting for this variable yields better performance than the other setting.

**Setting:** create\_admin\_listener\_thread has no effect if admin\_address is not specified because in that case the server maintains no administrative network interface.

**cte\_max\_recursion\_depth**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--cte-max-recursion-depth=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>cte_max_recursion_depth</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>\textit{SET_VAR} Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The common table expression (CTE) maximum recursion depth. The server terminates execution of any CTE that recurses more levels than the value of this variable. For more information, see Limiting Common Table Expression Recursion.

**datadir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--datadir=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>datadir</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>\textit{SET_VAR} Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

The path to the MySQL server data directory. Relative paths are resolved with respect to the current directory. If you expect the server to be started automatically (that is, in contexts for which you cannot know the current directory in advance), it is best to specify the datadir value as an absolute path.

**debug**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--debug[=debug_options]</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>debug</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global, Session</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value (Windows)</td>
<td><code>d:t:i:0,\mysqld.trace</code></td>
</tr>
<tr>
<td>Default Value (Unix)</td>
<td><code>d:t:i:o,/tmp/mysqld.trace</code></td>
</tr>
</tbody>
</table>

This variable indicates the current debugging settings. It is available only for servers built with debugging support. The initial value comes from the value of instances of the `--debug` option given at server startup. The global and session values may be set at runtime.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

Assigning a value that begins with `+` or `−` cause the value to added to or subtracted from the current value:

```
mysql> SET debug = 'T';
mysql> SELECT @@debug;
+--------+
| @@debug |
+--------+
| T       |
mysql> SET debug = '+P';
mysql> SELECT @@debug;
+--------+
| @@debug |
+--------+
| P:T     |
mysql> SET debug = '-P';
mysql> SELECT @@debug;
+--------+
| @@debug |
+--------+
| T       |
```

For more information, see Section 5.9.4, “The DBUG Package”.

• **debug_sync**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>debug_sync</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>
**Server System Variables**

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
</table>

This variable is the user interface to the Debug Sync facility. Use of Debug Sync requires that MySQL be configured with the `-DENABLE_DEBUG_SYNC=1` CMake option (see Section 2.9.7, “MySQL Source-Configuration Options”). If Debug Sync is not compiled in, this system variable is not available.

The global variable value is read only and indicates whether the facility is enabled. By default, Debug Sync is disabled and the value of `debug_sync` is OFF. If the server is started with `--debug-sync-timeout=N`, where \(N\) is a timeout value greater than 0, Debug Sync is enabled and the value of `debug_sync` is ON - current signal followed by the signal name. Also, \(N\) becomes the default timeout for individual synchronization points.

The session value can be read by any user and has the same value as the global variable. The session value can be set to control synchronization points.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

For a description of the Debug Sync facility and how to use synchronization points, see *MySQL Internals: Test Synchronization*.

- **default_authentication_plugin**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--default-authentication-plugin=plugin_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>default_authentication_plugin</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>caching_sha2_password</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>mysql_native_password</code></td>
</tr>
<tr>
<td></td>
<td><code>sha256_password</code></td>
</tr>
<tr>
<td></td>
<td><code>caching_sha2_password</code></td>
</tr>
</tbody>
</table>

The default authentication plugin. These values are permitted:

- **mysql_native_password**: Use MySQL native passwords; see Section 6.4.1.1, “Native Pluggable Authentication”.

- **sha256_password**: Use SHA-256 passwords; see Section 6.4.1.3, “SHA-256 Pluggable Authentication”.

- **caching_sha2_password**: Use SHA-256 passwords; see Section 6.4.1.2, “Caching SHA-2 Pluggable Authentication”.

**Note**

In MySQL 8.0, `caching_sha2_password` is the default authentication plugin rather than `mysql_native_password`. For information about the implications...
The `default_authentication_plugin` value affects these aspects of server operation:

- It determines which authentication plugin the server assigns to new accounts created by `CREATE USER` and `GRANT` statements that do not explicitly specify an authentication plugin.

- For an account created with the following statement, the server associates the account with the default authentication plugin and assigns the account the given password, hashed as required by that plugin:

  ```sql
  CREATE USER ... IDENTIFIED BY 'cleartext password';
  ```

- `default_collation_for_utf8mb4`

<table>
<thead>
<tr>
<th>System Variable</th>
<th>default_collation_for_utf8mb4</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Valid Values</td>
<td>utf8mb4_0900_ai_ci</td>
</tr>
<tr>
<td></td>
<td>utf8mb4_general_ci</td>
</tr>
</tbody>
</table>

For internal use by replication. This system variable is set to the default collation for the `utf8mb4` character set. The value of the variable is replicated from a source to a replica so that the replica can correctly process data originating from a source with a different default collation for `utf8mb4`. This variable is primarily intended to support replication from a MySQL 5.7 or older replication source server to a MySQL 8.0 replica server, or group replication with a MySQL 5.7 primary node and one or more MySQL 8.0 secondaries. The default collation for `utf8mb4` in MySQL 5.7 is `utf8mb4_general_ci`, but `utf8mb4_0900_ai_ci` in MySQL 8.0. The variable is not present in releases earlier than MySQL 8.0, so if the replica does not receive a value for the variable, it assumes the source is from an earlier release and sets the value to the previous default collation `utf8mb4_general_ci`.

As of MySQL 8.0.18, setting the session value of this system variable is no longer a restricted operation.

The default `utf8mb4` collation is used in the following statements:

- `SHOW COLLATION` and `SHOW CHARACTER SET`.

- `CREATE TABLE` and `ALTER TABLE` having a `CHARACTER SET utf8mb4` clause without a `COLLATION` clause, either for the table character set or for a column character set.

- `CREATE DATABASE` and `ALTER DATABASE` having a `CHARACTER SET utf8mb4` clause without a `COLLATION` clause.

- Any statement containing a string literal of the form `_utf8mb4'some text'` without a `COLLATE` clause.

- `default_password_lifetime`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--default-password-lifetime=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>default_password_lifetime</td>
</tr>
</tbody>
</table>
This variable defines the global automatic password expiration policy. The default `default_password_lifetime` value is 0, which disables automatic password expiration. If the value of `default_password_lifetime` is a positive integer \( N \), it indicates the permitted password lifetime; passwords must be changed every \( N \) days.

The global password expiration policy can be overridden as desired for individual accounts using the password expiration option of the `CREATE USER` and `ALTER USER` statements. See Section 6.2.15, "Password Management".

- `default_storage_engine`

The default storage engine for tables. See Chapter 16, Alternative Storage Engines. This variable sets the storage engine for permanent tables only. To set the storage engine for `TEMPORARY` tables, set the `default_tmp_storage_engine` system variable.

To see which storage engines are available and enabled, use the `SHOW ENGINES` statement or query the `INFORMATION_SCHEMA.ENGINES` table.

If you disable the default storage engine at server startup, you must set the default engine for both permanent and `TEMPORARY` tables to a different engine, or else the server does not start.

- `default_table_encryption`

The default table encryption for tables. See Chapter 16, Alternative Storage Engines. This variable sets the storage engine for permanent tables only. To set the storage engine for `TEMPORARY` tables, set the `default_tmp_storage_engine` system variable.

To see which storage engines are available and enabled, use the `SHOW ENGINES` statement or query the `INFORMATION_SCHEMA.ENGINES` table.

If you disable the default storage engine at server startup, you must set the default engine for both permanent and `TEMPORARY` tables to a different engine, or else the server does not start.
Server System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>OFF</th>
</tr>
</thead>
</table>

Defines the default encryption setting applied to schemas and general tablespaces when they are created without specifying an ENCRYPTION clause.

The `default_table_encryption` variable is only applicable to user-created schemas and general tablespaces. It does not govern encryption of the mysql system tablespace.

Setting the runtime value of `default_table_encryption` requires the `SYSTEM_VARIABLES_ADMIN` and `TABLE_ENCRYPTION_ADMIN` privileges, or the deprecated `SUPER` privilege.

`default_table_encryption` supports SET PERSIST and SET PERSIST_ONLY syntax. See Section 5.1.9.3, “Persisted System Variables”.

For more information, see Defining an Encryption Default for Schemas and General Tablespaces.

- **default_tmp_storage_engine**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--default-tmp-storage-engine=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>default_tmp_storage_engine</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>InnoDB</td>
</tr>
</tbody>
</table>

The default storage engine for TEMPORARY tables (created with `CREATE TEMPORARY TABLE`). To set the storage engine for permanent tables, set the `default_storage_engine` system variable. Also see the discussion of that variable regarding possible values.

If you disable the default storage engine at server startup, you must set the default engine for both permanent and TEMPORARY tables to a different engine, or else the server does not start.

- **default_week_format**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--default-week-format=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>default_week_format</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>7</td>
</tr>
</tbody>
</table>

The default mode value to use for the `WEEK()` function. See Section 12.7, “Date and Time Functions”.

- **delay_key_write**

  | Command-Line Format | `--delay-key-write=[OFF|ON|ALL]` |
  |---------------------|---------------------------------|

---

751
This variable specifies how to use delayed key writes. It applies only to MyISAM tables. Delayed key writing causes key buffers not to be flushed between writes. See also Section 16.2.1, “MyISAM Startup Options”.

This variable can have one of the following values to affect handling of the `DELAY_KEY_WRITE` table option that can be used in `CREATE TABLE` statements.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFF</td>
<td><code>DELAY_KEY_WRITE</code> is ignored.</td>
</tr>
<tr>
<td>ON</td>
<td>MySQL honors any <code>DELAY_KEY_WRITE</code> option specified in <code>CREATE TABLE</code> statements. This is the default value.</td>
</tr>
<tr>
<td>ALL</td>
<td>All new opened tables are treated as if they were created with the <code>DELAY_KEY_WRITE</code> option enabled.</td>
</tr>
</tbody>
</table>

Note

If you set this variable to `ALL`, you should not use MyISAM tables from within another program (such as another MySQL server or `myisamchk`) when the tables are in use. Doing so leads to index corruption.

If `DELAY_KEY_WRITE` is enabled for a table, the key buffer is not flushed for the table on every index update, but only when the table is closed. This speeds up writes on keys a lot, but if you use this feature, you should add automatic checking of all MyISAM tables by starting the server with the `myisam_recover_options` system variable set (for example, `myisam_recover_options='BACKUP,FORCE'`). See Section 5.1.8, “Server System Variables”, and Section 16.2.1, “MyISAM Startup Options”.

If you start `mysqld` with `--skip-new`, `delay_key_write` is set to `OFF`.

Warning

If you enable external locking with `--external-locking`, there is no protection against index corruption for tables that use delayed key writes.

- `delayed_insert_limit`
### Server System Variables

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR</td>
<td>Hint Applies</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>100</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This system variable is deprecated (because **DELAYED** inserts are not supported), and you should expect it to be removed in a future release.

- **delayed_insert_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--delayed-insert-timeout=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>delayed_insert_timeout</td>

<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR</td>
<td>Hint Applies</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>300</td>
</tr>
</tbody>
</table>

This system variable is deprecated (because **DELAYED** inserts are not supported), and you should expect it to be removed in a future release.

- **delayed_queue_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--delayed-queue-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>delayed_queue_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR</td>
<td>Hint Applies</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Maximum Value (32-bit platforms)</th>
<th>4294967295</th>
</tr>
</thead>
</table>

This system variable is deprecated (because `DELAYED` inserts are not supported), and you should expect it to be removed in a future release.

- **disabled_storage_engines**

  **Command-Line Format**
  ```
  --disabled-storage-engines=engine[,engine]...
  ```

  **System Variable**
  ```
  disabled_storage_engines
  ```

  **Scope**
  ```
  Global
  ```

  **Dynamic**
  ```
  No
  ```

  **SET_VAR Hint Applies**
  ```
  No
  ```

  **Type**
  ```
  String
  ```

  **Default Value**
  ```
  empty string
  ```

  This variable indicates which storage engines cannot be used to create tables or tablespaces. For example, to prevent new `MyISAM` or `FEDERATED` tables from being created, start the server with these lines in the server option file:

  ```
  [mysqld]
  disabled_storage_engines="MyISAM,FEDERATED"
  ```

  By default, `disabled_storage_engines` is empty (no engines disabled), but it can be set to a comma-separated list of one or more engines (not case sensitive). Any engine named in the value cannot be used to create tables or tablespaces with `CREATE TABLE` or `CREATE TABLESPACE`, and cannot be used with `ALTER TABLE ... ENGINE` or `ALTER TABLESPACE ... ENGINE` to change the storage engine of existing tables or tablespaces. Attempts to do so result in an `ER_DISABLED_STORAGE_ENGINE` error.

  `disabled_storage_engines` does not restrict other DDL statements for existing tables, such as `CREATE INDEX`, `TRUNCATE TABLE`, `ANALYZE TABLE`, `DROP TABLE`, or `DROP TABLESPACE`. This permits a smooth transition so that existing tables or tablespaces that use a disabled engine can be migrated to a permitted engine by means such as `ALTER TABLE ... ENGINE permitted_engine`.

  It is permitted to set the `default_storage_engine` or `default_tmp_storage_engine` system variable to a storage engine that is disabled. This could cause applications to behave erratically or fail, although that might be a useful technique in a development environment for identifying applications that use disabled engines, so that they can be modified.

  `disabled_storage_engines` is disabled and has no effect if the server is started with any of these options: `--initialize`, `--initialize-insecure`, `--skip-grant-tables`.

  **Note**
  Setting `disabled_storage_engines` might cause an issue with `mysql_upgrade`. For details, see Section 4.4.5, "mysql_upgrade — Check and Upgrade MySQL Tables".

- **disconnect_on_expired_password**

  **Command-Line Format**
  ```
  --disconnect-on-expired-password[={OFF|ON}]
  ```

  **System Variable**
  ```
  disconnect_on_expired_password
  ```
Server System Variables

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

This variable controls how the server handles clients with expired passwords:

- If the client indicates that it can handle expired passwords, the value of `disconnect_on_expired_password` is irrelevant. The server permits the client to connect but puts it in sandbox mode.

- If the client does not indicate that it can handle expired passwords, the server handles the client according to the value of `disconnect_on_expired_password`:
  - If `disconnect_on_expired_password` is enabled, the server disconnects the client.
  - If `disconnect_on_expired_password` is disabled, the server permits the client to connect but puts it in sandbox mode.

For more information about the interaction of client and server settings relating to expired-password handling, see Section 6.2.16, “Server Handling of Expired Passwords”.

- `div_precision_increment`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--div-precision-increment=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>div_precision_increment</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>30</td>
</tr>
</tbody>
</table>

This variable indicates the number of digits by which to increase the scale of the result of division operations performed with the `/` operator. The default value is 4. The minimum and maximum values are 0 and 30, respectively. The following example illustrates the effect of increasing the default value.

```
mysql> SELECT 1/7;
+--------+
| 1/7    |
+--------+
| 0.1429 |
+--------+
mysql> SET div_precision_increment = 12;
mysql> SELECT 1/7;
+----------------+
| 1/7            |
+----------------+
| 0.142857142857 |
+----------------+
```
• **dragnet.log_error_filter_rules**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--dragnet.log-error-filter-rules=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>dragnet.log_error_filter_rules</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>IF prio&gt;=INFORMATION THEN drop. IF EXISTS source_line THEN unset source_line.</td>
</tr>
</tbody>
</table>

The filter rules that control operation of the `log_filter_dragnet` error log filter component. If `log_filter_dragnet` is not installed, `dragnet.log_error_filter_rules` is unavailable. If `log_filter_dragnet` is installed but not enabled, changes to `dragnet.log_error_filter_rules` have no effect.

The effect of the default value is similar to the filtering performed by the `log_sink_internal` filter with a setting of `log_error_verbosity=2`.

As of MySQL 8.0.12, the `dragnet.Status` status variable can be consulted to determine the result of the most recent assignment to `dragnet.log_error_filter_rules`.

Prior to MySQL 8.0.12, successful assignments to `dragnet.log_error_filter_rules` at runtime produce a note confirming the new value:

```sql
mysql> SET GLOBAL dragnet.log_error_filter_rules = 'IF prio <> 0 THEN unset prio.';
Query OK, 0 rows affected, 1 warning (0.00 sec)
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Note
Code: 4569
Message: filter configuration accepted: SET @@GLOBAL.dragnet.log_error_filter_rules= 'IF prio!=ERROR THEN unset prio.';
```

The value displayed by `SHOW WARNINGS` indicates the “decompiled” canonical representation after the rule set has been successfully parsed and compiled into internal form. Semantically, this canonical form is identical to the value assigned to `dragnet.log_error_filter_rules`, but there may be some differences between the assigned and canonical values, as illustrated by the preceding example:

- The `<>` operator is changed to `!=`.
- The numeric priority of 0 is changed to the corresponding priority symbol `ERROR`.
- Optional spaces are removed.

For additional information, see Section 5.4.2.4, “Types of Error Log Filtering”, and Section 5.5.3, “Error Log Components”.

• **end_markers_in_json**

| Command-Line Format | --end-markers-in-json[=(OFF|ON)] |
|---------------------|----------------------------------|
| System Variable     | end_markers_in_json              |
Whether optimizer JSON output should add end markers. See MySQL Internals: The `end_markers_in_json` System Variable.

- `eq_range_index_dive_limit`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--eq-range-index-dive-limit=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>eq_range_index_dive_limit</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>200</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This variable indicates the number of equality ranges in an equality comparison condition when the optimizer should switch from using index dives to index statistics in estimating the number of qualifying rows. It applies to evaluation of expressions that have either of these equivalent forms, where the optimizer uses a nonunique index to look up `col_name` values:

\[
\text{col}_n \text{ame } \text{IN}(\text{val}_1, \ldots, \text{val}_N) \\
\text{col}_n \text{ame } = \text{val}_1 \text{ OR } \ldots \text{ OR } \text{col}_n \text{ame } = \text{val}_N
\]

In both cases, the expression contains \( N \) equality ranges. The optimizer can make row estimates using index dives or index statistics. If `eq_range_index_dive_limit` is greater than 0, the optimizer uses existing index statistics instead of index dives if there are `eq_range_index_dive_limit` or more equality ranges. Thus, to permit use of index dives for up to \( N \) equality ranges, set `eq_range_index_dive_limit` to \( N + 1 \). To disable use of index statistics and always use index dives regardless of \( N \), set `eq_range_index_dive_limit` to 0.

For more information, see Equality Range Optimization of Many-Valued Comparisons.

To update table index statistics for best estimates, use `ANALYZE TABLE`.

- `error_count`

The number of errors that resulted from the last statement that generated messages. This variable is read only. See Section 13.7.7.17, “SHOW ERRORS Statement”.

- `event_scheduler`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--event-scheduler[=value]</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>event_scheduler</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Dynamic</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ON, OFF, DISABLED</td>
</tr>
</tbody>
</table>

This variable enables or disables, and starts or stops, the Event Scheduler. The possible status values are ON, OFF, and DISABLED, with the default being OFF. Turning the Event Scheduler OFF is not the same as disabling the Event Scheduler, which requires setting the status to DISABLED. This variable and its effects on the Event Scheduler's operation are discussed in greater detail in Section 24.4.2, “Event Scheduler Configuration”

- `explicit_defaults_for_timestamp`

| Command-Line Format | --explicit-defaults-for-timestamp=\{OFF|ON\} |
|---------------------|-------------------------------------|
| Deprecated          | Yes                                  |
| System Variable     | `explicit_defaults_for_timestamp`    |
| Scope               | Global, Session                      |
| Dynamic             | Yes                                  |
| **SET_VAR** Hint Applies | No |
| Type                | Boolean                              |
| Default Value       | ON                                   |

This system variable determines whether the server enables certain nonstandard behaviors for default values and NULL-value handling in TIMESTAMP columns. By default, `explicit_defaults_for_timestamp` is enabled, which disables the nonstandard behaviors. Disabling `explicit_defaults_for_timestamp` results in a warning.

As of MySQL 8.0.18, setting the session value of this system variable is no longer a restricted operation.

If `explicit_defaults_for_timestamp` is disabled, the server enables the nonstandard behaviors and handles TIMESTAMP columns as follows:

- **TIMESTAMP** columns not explicitly declared with the NULL attribute are automatically declared with the NOT NULL attribute. Assigning such a column a value of NULL is permitted and sets the column to the current timestamp. **Exception:** As of MySQL 8.0.22, attempting to insert NULL into a generated column declared as TIMESTAMP NOT NULL is rejected with an error.

- The first **TIMESTAMP** column in a table, if not explicitly declared with the NULL attribute or an explicit DEFAULT or ON UPDATE attribute, is automatically declared with the DEFAULT CURRENT_TIMESTAMP and ON UPDATE CURRENT_TIMESTAMP attributes.

- **TIMESTAMP** columns following the first one, if not explicitly declared with the NULL attribute or an explicit DEFAULT attribute, are automatically declared as DEFAULT '0000-00-00 00:00:00' (the
“zero” timestamp). For inserted rows that specify no explicit value for such a column, the column is assigned '0000-00-00 00:00:00' and no warning occurs.

Depending on whether strict SQL mode or the NO_ZERO_DATE SQL mode is enabled, a default value of '0000-00-00 00:00:00' may be invalid. Be aware that the TRADITIONAL SQL mode includes strict mode and NO_ZERO_DATE. See Section 5.1.11, “Server SQL Modes”.

The nonstandard behaviors just described are deprecated; expect them to be removed in a future MySQL release.

If explicit_defaults_for_timestamp is enabled, the server disables the nonstandard behaviors and handles TIMESTAMP columns as follows:

- It is not possible to assign a TIMESTAMP column a value of NULL to set it to the current timestamp. To assign the current timestamp, set the column to CURRENT_TIMESTAMP or a synonym such as NOW().

- TIMESTAMP columns not explicitly declared with the NOT NULL attribute are automatically declared with the NULL attribute and permit NULL values. Assigning such a column a value of NULL sets it to NULL, not the current timestamp.

- TIMESTAMP columns declared with the NOT NULL attribute do not permit NULL values. For inserts that specify NULL for such a column, the result is either an error for a single-row insert or if strict SQL mode is enabled, or '0000-00-00 00:00:00' is inserted for multiple-row inserts with strict SQL mode disabled. In no case does assigning the column a value of NULL set it to the current timestamp.

- TIMESTAMP columns explicitly declared with the NOT NULL attribute and without an explicit DEFAULT attribute are treated as having no default value. For inserted rows that specify no explicit value for such a column, the result depends on the SQL mode. If strict SQL mode is enabled, an error occurs. If strict SQL mode is not enabled, the column is declared with the implicit default of '0000-00-00 00:00:00' and a warning occurs. This is similar to how MySQL treats other temporal types such as DATETIME.

- No TIMESTAMP column is automatically declared with the DEFAULT CURRENT_TIMESTAMP or ON UPDATE CURRENT_TIMESTAMP attributes. Those attributes must be explicitly specified.

- The first TIMESTAMP column in a table is not handled differently from TIMESTAMP columns following the first one.

If explicit_defaults_for_timestamp is disabled at server startup, this warning appears in the error log:

[Warning] TIMESTAMP with implicit DEFAULT value is deprecated.
Please use --explicit_defaults_for_timestamp server option (see documentation for more details).

As indicated by the warning, to disable the deprecated nonstandard behaviors, enable the explicit_defaults_for_timestamp system variable at server startup.

Note

explicit_defaults_for_timestamp is itself deprecated because its only purpose is to permit control over deprecated TIMESTAMP behaviors that are to be removed in a future MySQL release. When removal of those behaviors occurs, expect explicit_defaults_for_timestamp to be removed as well.

For additional information, see Section 11.2.5, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”.
• **external_user**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>external_user</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this variable is NULL. See Section 6.2.18, “Proxy Users”.

• **flush**

| Command-Line Format | --flush=[{OFF|ON}] |
|---------------------|--------------------|
| System Variable     | flush              |
| Scope               | Global             |
| Dynamic             | Yes                |
| SET_VAR Hint Applies| No                 |
| Type                | Boolean            |
| Default Value       | OFF                |

If ON, the server flushes (synchronizes) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See Section B.3.3.3, “What to Do If MySQL Keeps Crashing”. This variable is set to ON if you start mysqld with the --flush option.

**Note**

If flush is enabled, the value of flush_time does not matter and changes to flush_time have no effect on flush behavior.

• **flush_time**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--flush-time=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>flush_time</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>
Server System Variables

| Minimum Value | 0 |

If this is set to a nonzero value, all tables are closed every `flush_time` seconds to free up resources and synchronize unflushed data to disk. This option is best used only on systems with minimal resources.

**Note**

If `flush` is enabled, the value of `flush_time` does not matter and changes to `flush_time` have no effect on flush behavior.

- **foreign_key_checks**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>foreign_key_checks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

If set to 1 (the default), foreign key constraints are checked. If set to 0, foreign key constraints are ignored, with a couple of exceptions. When re-creating a table that was dropped, an error is returned if the table definition does not conform to the foreign key constraints referencing the table. Likewise, an `ALTER TABLE` operation returns an error if a foreign key definition is incorrectly formed. For more information, see Section 13.1.20.5, “FOREIGN KEY Constraints”.

Setting this variable has the same effect on NDB tables as it does for InnoDB tables. Typically you leave this setting enabled during normal operation, to enforce referential integrity. Disabling foreign key checking can be useful for reloading InnoDB tables in an order different from that required by their parent/child relationships. See Section 13.1.20.5, “FOREIGN KEY Constraints”.

Setting `foreign_key_checks` to 0 also affects data definition statements: `DROP SCHEMA` drops a schema even if it contains tables that have foreign keys that are referred to by tables outside the schema, and `DROP TABLE` drops tables that have foreign keys that are referred to by other tables.

**Note**

Setting `foreign_key_checks` to 1 does not trigger a scan of the existing table data. Therefore, rows added to the table while `foreign_key_checks = 0` are not verified for consistency.

Dropping an index required by a foreign key constraint is not permitted, even with `foreign_key_checks=0`. The foreign key constraint must be removed before dropping the index.

- **ft_boolean_syntax**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--ft-boolean-syntax</code>=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>ft_boolean_syntax</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>
The list of operators supported by boolean full-text searches performed using `IN BOOLEAN MODE`. See Section 12.10.2, “Boolean Full-Text Searches”.

The default variable value is `'+ -><( )~*: "&|'`. The rules for changing the value are as follows:

- Operator function is determined by position within the string.
- The replacement value must be 14 characters.
- Each character must be an ASCII nonalphanumeric character.
- Either the first or second character must be a space.
- No duplicates are permitted except the phrase quoting operators in positions 11 and 12. These two characters are not required to be the same, but they are the only two that may be.
- Positions 10, 13, and 14 (which by default are set to `:`, `&`, and `|`) are reserved for future extensions.

### ft_max_word_len

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ft-max-word-len=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ft_max_word_len</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>10</td>
</tr>
</tbody>
</table>

The maximum length of the word to be included in a `MyISAM FULLTEXT` index.

---

**Note**

FULLTEXT indexes on `MyISAM` tables must be rebuilt after changing this variable. Use `REPAIR TABLE tbl_name QUICK`.

### ft_min_word_len

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ft-min-word-len=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ft_min_word_len</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Minimum Value</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>The minimum length of the word to be included in a <strong>MyISAM FULLTEXT</strong> index.</td>
<td></td>
</tr>
</tbody>
</table>

**Note**

**FULLTEXT** indexes on **MyISAM** tables must be rebuilt after changing this variable. Use **REPAIR TABLE tbl_name QUICK**.

- **ft_query_expansion_limit**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><strong>--ft-query-expansion-limit=#</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><strong>ft_query_expansion_limit</strong></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>20</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1000</td>
</tr>
</tbody>
</table>

The number of top matches to use for full-text searches performed using **WITH QUERY EXPANSION**.

- **ft_stopword_file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><strong>--ft-stopword-file=file_name</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><strong>ft_stopword_file</strong></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

The file from which to read the list of stopwords for full-text searches on **MyISAM** tables. The server looks for the file in the data directory unless an absolute path name is given to specify a different directory. All the words from the file are used; comments are not honored. By default, a built-in list of stopwords is used (as defined in the **storage/myisam/ft_static.c** file). Setting this variable to the empty string ('') disables stopword filtering. See also Section 12.10.4, “Full-Text Stopwords”.

**Note**

**FULLTEXT** indexes on **MyISAM** tables must be rebuilt after changing this variable or the contents of the stopword file. Use **REPAIR TABLE tbl_name QUICK**.

- **general_log**

  | Command-Line Format | **--general-log=[OFF|ON]** |
  |---------------------|--------------------------|
  | System Variable     | **general_log**          |
  | Scope               | Global                   |
  | Dynamic             | Yes                      |
### Server System Variables

<table>
<thead>
<tr>
<th><strong>SET_VAR</strong></th>
<th>Hint Applies</th>
<th>Type</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>No</td>
<td>Boolean</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Whether the general query log is enabled. The value can be 0 (or **OFF**) to disable the log or 1 (or **ON**) to enable the log. The destination for log output is controlled by the `log_output` system variable; if that value is **NONE**, no log entries are written even if the log is enabled.

- **general_log_file**

  | Command-Line Format       | `--general-log-file=file_name` |
  | System Variable           | `general_log_file`             |
  | Scope                     | Global                        |
  | Dynamic                   | Yes                           |
  | **SET_VAR** Hint Applies  | No                            |
  | Type                      | File name                     |
  | Default Value             | `host_name.log`               |

The name of the general query log file. The default value is `host_name.log`, but the initial value can be changed with the `--general-log-file` option.

- **generated_random_password_length**

  | Command-Line Format       | `--generated-random-password-length=#` |
  | Introduced                | 8.0.18                                  |
  | System Variable           | `generated_random_password_length`      |
  | Scope                     | Global, Session                        |
  | Dynamic                   | Yes                                     |
  | **SET_VAR** Hint Applies  | No                                      |
  | Type                      | Integer                                 |
  | Default Value             | 20                                      |
  | Minimum Value             | 5                                       |
  | Maximum Value             | 255                                     |

The maximum number of characters permitted in random passwords generated for `CREATE USER`, `ALTER USER`, and `SET PASSWORD` statements. For more information, see Random Password Generation.

- **group_concat_max_len**

  | Command-Line Format       | `--group-concat-max-len=#` |
  | System Variable           | `group_concat_max_len`      |
  | Scope                     | Global, Session            |
  | Dynamic                   | Yes                        |
  | **SET_VAR** Hint Applies  | Yes                        |
  | Type                      | Integer                    |
Server System Variables

<table>
<thead>
<tr>
<th>System Variable</th>
<th>have_ssl</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Valid Values</td>
<td>YES (SSL support available)</td>
</tr>
</tbody>
</table>

The maximum permitted result length in bytes for the `GROUP_CONCAT()` function. The default is 1024.

- **have_compress**
  
  YES if the `zlib` compression library is available to the server, NO if not. If not, the `COMPRESS()` and `UNCOMPRESS()` functions cannot be used.

- **have_dynamic_loading**
  
  YES if `mysqld` supports dynamic loading of plugins, NO if not. If the value is NO, you cannot use options such as `--plugin-load` to load plugins at server startup, or the `INSTALL PLUGIN` statement to load plugins at runtime.

- **have_geometry**
  
  YES if the server supports spatial data types, NO if not.

- **have_openssl**
  
  This variable is a synonym for `have_ssl`.

- **have_profiling**
  
  YES if statement profiling capability is present, NO if not. If present, the `profiling` system variable controls whether this capability is enabled or disabled. See Section 13.7.7.31, “SHOW PROFILES Statement”.

  This variable is deprecated and you should expect it to be removed in a future MySQL release.

- **have_query_cache**
  
  The query cache was removed in MySQL 8.0.3. `have_query_cache` is deprecated, always has a value of NO, and you should expect it to be removed in a future MySQL release.

- **have_rtree_keys**
  
  YES if RTREE indexes are available, NO if not. (These are used for spatial indexes in MyISAM tables.)

- **have_ssl**

<table>
<thead>
<tr>
<th>Default Value</th>
<th>1024</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td>4</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>
**Server System Variables**

**DISABLED** (SSL support was compiled into the server, but the server was not started with the necessary options to enable it)

**YES** if mysqld supports SSL connections, **DISABLED** if the server was compiled with SSL support, but was not started with the appropriate connection-encryption options. For more information, see Section 2.9.6, “Configuring SSL Library Support”.

- **have_statement_timeout**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>have_statement_timeout</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>

Whether the statement execution timeout feature is available (see Statement Execution Time Optimizer Hints). The value can be **NO** if the background thread used by this feature could not be initialized.

- **have_symlink**

**YES** if symbolic link support is enabled, **NO** if not. This is required on Unix for support of the DATA DIRECTORY and INDEX DIRECTORY table options. If the server is started with the **--skip-symbolic-links** option, the value is **DISABLED**.

This variable has no meaning on Windows.

**Note**

Symbolic link support, along with the **--symbolic-links** option that controls it, is deprecated; expect these to be removed in a future version of MySQL. In addition, the option is disabled by default. The related have_symlink system variable also is deprecated and you should expect it to be removed in a future version of MySQL.

- **histogram_generation_max_mem_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--histogram-generation-max-mem-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>histogram_generation_max_mem_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>20000000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1000000</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
</tbody>
</table>
Server System Variables

| Maximum Value (32-bit platforms) | 4294967295 |

The maximum amount of memory available for generating histogram statistics. See Section 8.9.6, “Optimizer Statistics”, and Section 13.7.3.1, “ANALYZE TABLE Statement”.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

- **host_cache_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--host-cache-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>host_cache_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65536</td>
</tr>
</tbody>
</table>

The MySQL server maintains an in-memory host cache that contains client host name and IP address information and is used to avoid Domain Name System (DNS) lookups; see Section 5.1.12.3, “DNS Lookups and the Host Cache”.

The `host_cache_size` variable controls the size of the host cache, as well as the size of the Performance Schema `host_cache` table that exposes the cache contents. Setting `host_cache_size` has these effects:

- Setting the size to 0 disables the host cache. With the cache disabled, the server performs a DNS lookup every time a client connects.
- Changing the size at runtime causes an implicit host cache flushing operation that clears the host cache, truncates the `host_cache` table, and unblocks any blocked hosts.

The default value is autosized to 128, plus 1 for a value of `max_connections` up to 500, plus 1 for every increment of 20 over 500 in the `max_connections` value, capped to a limit of 2000.

Using the `--skip-host-cache` option is similar to setting the `host_cache_size` system variable to 0, but `host_cache_size` is more flexible because it can also be used to resize, enable, and disable the host cache at runtime, not just at server startup. Starting the server with `--skip-host-cache` does not prevent runtime changes to the value of `host_cache_size`, but such changes have no effect and the cache is not re-enabled even if `host_cache_size` is set larger than 0.

- **hostname**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>hostname</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
</table>

The server sets this variable to the server host name at startup. The maximum length is 255 characters as of MySQL 8.0.17, per RFC 1034, and 60 characters before that.

- **identity**

  This variable is a synonym for the `last_insert_id` variable. It exists for compatibility with other database systems. You can read its value with `SELECT @@identity`, and set it using `SET identity`.

- **init_connect**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--init-connect=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>init_connect</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

A string to be executed by the server for each client that connects. The string consists of one or more SQL statements, separated by semicolon characters.

For users that have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege), the content of `init_connect` is not executed. This is done so that an erroneous value for `init_connect` does not prevent all clients from connecting. For example, the value might contain a statement that has a syntax error, thus causing client connections to fail. Not executing `init_connect` for users that have the `CONNECTION_ADMIN` or `SUPER` privilege enables them to open a connection and fix the `init_connect` value.

`init_connect` execution is skipped for any client user with an expired password. This is done because such a user cannot execute arbitrary statements, and thus `init_connect` execution fails, leaving the client unable to connect. Skipping `init_connect` execution enables the user to connect and change password.

The server discards any result sets produced by statements in the value of `init_connect`.

- **information_schema_stats_expiry**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--information-schema-stats-expiry=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>information_schema_stats_expiry</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>86400</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>
Server System Variables

| Maximum Value | 31536000 |

Some INFORMATION_SCHEMA tables contain columns that provide table statistics:

- STATISTICS.CARDINALITY
- TABLES.AUTO_INCREMENT
- TABLES.AVG_ROW_LENGTH
- TABLES.CHECKSUM
- TABLES.CHECK_TIME
- TABLES.CREATE_TIME
- TABLES.DATA_FREE
- TABLES.DATA_LENGTH
- TABLES.INDEX_LENGTH
- TABLES.MAX_DATA_LENGTH
- TABLES.TABLE_ROWS
- TABLES.UPDATE_TIME

Those columns represent dynamic table metadata; that is, information that changes as table contents change.

By default, MySQL retrieves cached values for those columns from the mysql.index_stats and mysql.table_stats dictionary tables when the columns are queried, which is more efficient than retrieving statistics directly from the storage engine. If cached statistics are not available or have expired, MySQL retrieves the latest statistics from the storage engine and caches them in the mysql.index_stats and mysql.table_stats dictionary tables. Subsequent queries retrieve the cached statistics until the cached statistics expire.

The information_schema_stats_expiry session variable defines the period of time before cached statistics expire. The default is 86400 seconds (24 hours), but the time period can be extended to as much as one year.

To update cached values at any time for a given table, use ANALYZE TABLE.

To always retrieve the latest statistics directly from the storage engine and bypass cached values, set information_schema_stats_expiry to 0.

Querying statistics columns does not store or update statistics in the mysql.index_stats and mysql.table_stats dictionary tables under these circumstances:

- When cached statistics have not expired.
- When information_schema_stats_expiry is set to 0.
- When the server is started in read_only, super_read_only, transaction_read_only, or innodb_read_only mode.
- When the query also fetches Performance Schema data.

information_schema_stats_expiry is a session variable, and each client session can define its own expiration value. Statistics that are retrieved from the storage engine and cached by one session are available to other sessions.

For related information, see Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”.

- init_file
Server System Variables

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

If specified, this variable names a file containing SQL statements to be read and executed during the startup process. Prior to MySQL 8.0.18, each statement must be on a single line and should not include comments. As of MySQL 8.0.18, the acceptable format for statements in the file is expanded to support these constructs:

- `delimiter ;`, to set the statement delimiter to the `;` character.
- `delimiter $$`, to set the statement delimiter to the `$$` character sequence.
- Multiple statements on the same line, delimited by the current delimiter.
- Multiple-line statements.
- Comments from a `#` character to the end of the line.
- Comments from a `--` sequence to the end of the line.
- C-style comments from a `/*` sequence to the following `*/` sequence, including over multiple lines.
- Multiple-line string literals enclosed within either single quote (`'`) or double quote (`"`) characters.

If the server is started with the `--initialize` or `--initialize-insecure` option, it operates in bootstrap mode and some functionality is unavailable that limits the statements permitted in the file. These include statements that relate to account management (such as `CREATE USER` or `GRANT`), replication, and global transaction identifiers. See Section 17.1.3, “Replication with Global Transaction Identifiers”.

As of MySQL 8.0.17, threads created during server startup are used for tasks such as creating the data dictionary, running upgrade procedures, and creating system tables. To ensure a stable and predictable environment, these threads are executed with the server built-in defaults for some system variables, such as `sql_mode`, `character_set_server`, `collation_server`, `completion_type`, `explicit_defaults_for_timestamp`, and `default_table_encryption`.

These threads are also used to execute the statements in any file specified with `init_file` when starting the server, so such statements execute with the server's built-in default values for those system variables.

- `innodb_xxx`

InnoDB system variables are listed in Section 15.14, “InnoDB Startup Options and System Variables”. These variables control many aspects of storage, memory use, and I/O patterns for InnoDB tables, and are especially important now that InnoDB is the default storage engine.

- `insert_id`

The value to be used by the following `INSERT` or `ALTER TABLE` statement when inserting an `AUTO_INCREMENT` value. This is mainly used with the binary log.
### interactive_timeout

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--interactive-timeout=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>interactive_timeout</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>28800</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

The number of seconds the server waits for activity on an interactive connection before closing it. An interactive client is defined as a client that uses the CLIENT_INTERACTIVE option to `mysql_real_connect()`. See also `wait_timeout`.

### internal_tmp_disk_storage_engine

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--internal-tmp-disk-storage-engine=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Removed</td>
<td>8.0.16</td>
</tr>
<tr>
<td>System Variable</td>
<td>internal_tmp_disk_storage_engine</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>INNODB</td>
</tr>
<tr>
<td>Valid Values</td>
<td>MYISAM, INNODB</td>
</tr>
</tbody>
</table>

⚠️ Important

In MySQL 8.0.16 and later, on-disk internal temporary tables always use the InnoDB storage engine; as of MySQL 8.0.16, this variable has been removed and is thus no longer supported.

Prior to MySQL 8.0.16, this variable determines the storage engine used for on-disk internal temporary tables (see Storage Engine for On-Disk Internal Temporary Tables). Permitted values are MYISAM and INNODB (the default).

### internal_tmp_mem_storage_engine

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--internal-tmp-mem-storage-engine=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>internal_tmp_mem_storage_engine</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
</tbody>
</table>

771
Server System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>TempTable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Valid Values</td>
<td>TempTable</td>
</tr>
<tr>
<td></td>
<td>MEMORY</td>
</tr>
</tbody>
</table>

The storage engine for in-memory internal temporary tables (see Section 8.4.4, “Internal Temporary Table Use in MySQL”). Permitted values are TempTable (the default) and MEMORY.

The optimizer uses the storage engine defined by internal_tmp_mem_storage_engine for in-memory internal temporary tables.

- **join_buffer_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--join-buffer-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>join_buffer_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>262144</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>128</td>
</tr>
<tr>
<td>Maximum Value (Other, 64-bit platforms)</td>
<td>18446744073709547520</td>
</tr>
<tr>
<td>Maximum Value (Other, 32-bit platforms)</td>
<td>4294967295</td>
</tr>
<tr>
<td>Maximum Value (Windows)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The minimum size of the buffer that is used for plain index scans, range index scans, and joins that do not use indexes and thus perform full table scans. Normally, the best way to get fast joins is to add indexes. Increase the value of join_buffer_size to get a faster full join when adding indexes is not possible. One join buffer is allocated for each full join between two tables. For a complex join between several tables for which indexes are not used, multiple join buffers might be necessary.

Unless a Block Nested-Loop or Batched Key Access algorithm is used, there is no gain from setting the buffer larger than required to hold each matching row, and all joins allocate at least the minimum size, so use caution in setting this variable to a large value globally. It is better to keep the global setting small and change the session setting to a larger value only in sessions that are doing large joins, or change the setting on a per-query basis by using a SET_VAR optimizer hint (see Section 8.9.3, “Optimizer
Hints”). Memory allocation time can cause substantial performance drops if the global size is larger than needed by most queries that use it.

When Block Nested-Loop is used, a larger join buffer can be beneficial up to the point where all required columns from all rows in the first table are stored in the join buffer. This depends on the query; the optimal size may be smaller than holding all rows from the first tables.

When Batched Key Access is used, the value of `join_buffer_size` defines how large the batch of keys is in each request to the storage engine. The larger the buffer, the more sequential access is made to the right hand table of a join operation, which can significantly improve performance.

The default is 256KB. The maximum permissible setting for `join_buffer_size` is 4GB–1. Larger values are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB–1 with a warning).

For additional information about join buffering, see Section 8.2.1.7, “Nested-Loop Join Algorithms”. For information about Batched Key Access, see Section 8.2.1.12, “Block Nested-Loop and Batched Key Access Joins”.

- `keep_files_on_create`

| Command-Line Format | `--keep-files-on-create[={OFF|ON}]` |
|---------------------|-----------------------------------|
| System Variable     | `keep_files_on_create`            |
| Scope               | Global, Session                   |
| Dynamic             | Yes                               |
| `SET_VAR` Hint Applies | No                               |
| Type                | Boolean                           |
| Default Value       | `OFF`                             |

If a MyISAM table is created with no `DATA DIRECTORY` option, the `.MYD` file is created in the database directory. By default, if MyISAM finds an existing `.MYD` file in this case, it overwrites it. The same applies to `.MYI` files for tables created with no `INDEX DIRECTORY` option. To suppress this behavior, set the `keep_files_on_create` variable to `ON` (1), in which case MyISAM does not overwrite existing files and returns an error instead. The default value is `OFF` (0).

If a MyISAM table is created with a `DATA DIRECTORY` or `INDEX DIRECTORY` option and an existing `.MYD` or `.MYI` file is found, MyISAM always returns an error. It does not overwrite a file in the specified directory.

- `key_buffer_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--key-buffer-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>key_buffer_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>8388608</code></td>
</tr>
<tr>
<td>Minimum Value</td>
<td><code>8</code></td>
</tr>
</tbody>
</table>
Index blocks for `MyISAM` tables are buffered and are shared by all threads. `key_buffer_size` is the size of the buffer used for index blocks. The key buffer is also known as the key cache.

The maximum permissible setting for `key_buffer_size` is 4GB−1 on 32-bit platforms. Larger values are permitted for 64-bit platforms. The effective maximum size might be less, depending on your available physical RAM and per-process RAM limits imposed by your operating system or hardware platform. The value of this variable indicates the amount of memory requested. Internally, the server allocates as much memory as possible up to this amount, but the actual allocation might be less.

You can increase the value to get better index handling for all reads and multiple writes; on a system whose primary function is to run MySQL using the `MyISAM` storage engine, 25% of the machine's total memory is an acceptable value for this variable. However, you should be aware that, if you make the value too large (for example, more than 50% of the machine's total memory), your system might start to page and become extremely slow. This is because MySQL relies on the operating system to perform file system caching for data reads, so you must leave some room for the file system cache. You should also consider the memory requirements of any other storage engines that you may be using in addition to `MyISAM`.

For even more speed when writing many rows at the same time, use `LOCK TABLES`. See Section 8.2.5.1, "Optimizing INSERT Statements".

You can check the performance of the key buffer by issuing a `SHOW STATUS` statement and examining the `Key_read_requests`, `Key_reads`, `Key_write_requests`, and `Key_writes` status variables. (See Section 13.7.7, "SHOW Statements"). The `Key_reads/Key_read_requests` ratio should normally be less than 0.01. The `Key_writes/Key_write_requests` ratio is usually near 1 if you are using mostly updates and deletes, but might be much smaller if you tend to do updates that affect many rows at the same time or if you are using the `DELAY_KEY_WRITE` table option.

The fraction of the key buffer in use can be determined using `key_buffer_size` in conjunction with the `Key_blocks_unused` status variable and the buffer block size, which is available from the `key_cache_block_size` system variable:

\[
1 - \frac{(Key\_blocks\_unused \times key\_cache\_block\_size)}{key\_buffer\_size}
\]

This value is an approximation because some space in the key buffer is allocated internally for administrative structures. Factors that influence the amount of overhead for these structures include block size and pointer size. As block size increases, the percentage of the key buffer lost to overhead tends to decrease. Larger blocks results in a smaller number of read operations (because more keys are obtained per read), but conversely an increase in reads of keys that are not examined (if not all keys in a block are relevant to a query).

It is possible to create multiple `MyISAM` key caches. The size limit of 4GB applies to each cache individually, not as a group. See Section 8.10.2, "The MyISAM Key Cache".

- `key_cache_age_threshold`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--key-cache-age-threshold=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>key_cache_age_threshold</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Dynamic</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>300</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>100</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This value controls the demotion of buffers from the hot sublist of a key cache to the warm sublist. Lower values cause demotion to happen more quickly. The minimum value is 100. The default value is 300. See Section 8.10.2, “The MyISAM Key Cache”.

- **key_cache_block_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--key-cache-block-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>key_cache_block_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1024</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>512</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>16384</td>
</tr>
</tbody>
</table>

The size in bytes of blocks in the key cache. The default value is 1024. See Section 8.10.2, “The MyISAM Key Cache”.

- **key_cache_division_limit**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--key-cache-division-limit=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>key_cache_division_limit</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>100</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>100</td>
</tr>
</tbody>
</table>

The division point between the hot and warm sublists of the key cache buffer list. The value is the percentage of the buffer list to use for the warm sublist. Permissible values range from 1 to 100. The default value is 100. See Section 8.10.2, “The MyISAM Key Cache”.

- **large_files_support**
Server System Variables

<table>
<thead>
<tr>
<th>System Variable</th>
<th>large_files_support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>

Whether `mysqld` was compiled with options for large file support.

- **large_pages**

  | Command-Line Format | --large-pages[={OFF|ON}] |
  |--------------------|--------------------------|
  | System Variable    | large_pages              |
  | Scope              | Global                   |
  | Dynamic            | No                       |
  | SET_VAR Hint Applies | No                     |
  | Platform Specific  | Linux                    |
  | Type               | Boolean                  |
  | Default Value      | OFF                      |

Whether large page support is enabled (via the `--large-pages` option). See Section 8.12.3.2, "Enabling Large Page Support".

- **large_page_size**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>large_page_size</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

If large page support is enabled, this shows the size of memory pages. Large memory pages are supported only on Linux; on other platforms, the value of this variable is always 0. See Section 8.12.3.2, "Enabling Large Page Support".

- **last_insert_id**

  The value to be returned from `LAST_INSERT_ID()`. This is stored in the binary log when you use `LAST_INSERT_ID()` in a statement that updates a table. Setting this variable does not update the value returned by the `mysql_insert_id()` C API function.

- **lc_messages**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--lc-messages=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>lc_messages</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th><strong>SET_VAR</strong></th>
<th>Hint Applies</th>
<th>No</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>Default Value</td>
<td>en_US</td>
<td></td>
</tr>
</tbody>
</table>

The locale to use for error messages. The default is `en_US`. The server converts the argument to a language name and combines it with the value of `lc_messages_dir` to produce the location for the error message file. See Section 10.12, “Setting the Error Message Language”.

- **lc_messages_dir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--lc-messages-dir=dir_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>lc_messages_dir</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong></td>
<td>Hint Applies</td>
</tr>
<tr>
<td></td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

The directory where error messages are located. The server uses the value together with the value of `lc_messages` to produce the location for the error message file. See Section 10.12, “Setting the Error Message Language”.

- **lc_time_names**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--lc-time-names=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>lc_time_names</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong></td>
<td>Hint Applies</td>
</tr>
<tr>
<td></td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

This variable specifies the locale that controls the language used to display day and month names and abbreviations. This variable affects the output from the `DATE_FORMAT()`, `DAYNAME()` and `MONTHNAME()` functions. Locale names are POSIX-style values such as `ja_JP` or `pt_BR`. The default value is `en_US` regardless of your system's locale setting. For further information, see Section 10.16, “MySQL Server Locale Support”.

- **license**

<table>
<thead>
<tr>
<th>System Variable</th>
<th><code>license</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong></td>
<td>Hint Applies</td>
</tr>
<tr>
<td></td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>GPL</td>
</tr>
</tbody>
</table>

The type of license the server has.

- **local_infile**
Server System Variables

| Command-Line Format | --local-infile[={OFF|ON}] |
|---------------------|---------------------------|
| System Variable     | local_infile              |
| Scope               | Global                    |
| Dynamic             | Yes                       |
| SET_VAR Hint Applies| No                        |
| Type                | Boolean                   |
| Default Value       | OFF                       |

This variable controls server-side LOCAL capability for LOAD DATA statements. Depending on the local_infile setting, the server refuses or permits local data loading by clients that have LOCAL enabled on the client side.

To explicitly cause the server to refuse or permit LOAD DATA LOCAL statements (regardless of how client programs and libraries are configured at build time or runtime), start mysqld with local_infile disabled or enabled, respectively. local_infile can also be set at runtime. For more information, see Section 6.1.6, “Security Considerations for LOAD DATA LOCAL”.

• lock_wait_timeout

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--lock-wait-timeout=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>lock_wait_timeout</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>31536000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>31536000</td>
</tr>
</tbody>
</table>

This variable specifies the timeout in seconds for attempts to acquire metadata locks. The permissible values range from 1 to 31536000 (1 year). The default is 31536000.

This timeout applies to all statements that use metadata locks. These include DML and DDL operations on tables, views, stored procedures, and stored functions, as well as LOCK TABLES, FLUSH TABLES WITH READ LOCK, and HANDLER statements.

This timeout does not apply to implicit accesses to system tables in the mysql database, such as grant tables modified by GRANT or REVOKE statements or table logging statements. The timeout does apply to system tables accessed directly, such as with SELECT or UPDATE.

The timeout value applies separately for each metadata lock attempt. A given statement can require more than one lock, so it is possible for the statement to block for longer than the lock_wait_timeout value before reporting a timeout error. When lock timeout occurs, ER_LOCK_WAIT_TIMEOUT is reported.

lock_wait_timeout also defines the amount of time that a LOCK INSTANCE FOR BACKUP statement waits for a lock before giving up.
### Server System Variables

<table>
<thead>
<tr>
<th>System Variable</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>locked_in_memory</strong></td>
<td></td>
</tr>
</tbody>
</table>

**Scope**: Global  
**Dynamic**: No  
**SET_VAR Hint Applies**: No  

Whether `mysqld` was locked in memory with `--memlock`.

### log_error

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--log-error[=file_name]</code></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Variable</strong></td>
<td><code>log_error</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>File name</td>
</tr>
</tbody>
</table>

The default error log destination. If the destination is the console, the value is `stderr`. Otherwise, the destination is a file and the `log_error` value is the file name. See Section 5.4.2, “The Error Log”.

### log_error_services

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--log-error-services=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Variable</strong></td>
<td><code>log_error_services</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>String</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td><code>log_filter_internal; log_sink_internal</code></td>
</tr>
</tbody>
</table>

The components to enable for error logging. The variable may contain a list with 0, 1, or many elements. In the latter case, elements may be delimited by semicolon or (as of MySQL 8.0.12) comma, optionally followed by space. A given setting cannot use both semicolon and comma separators. Component order is significant because the server executes components in the order listed. Any loadable (not built in) component named in the `log_error_services` value must first be installed with `INSTALL COMPONENT`. For more information, see Section 5.4.2.1, “Error Log Configuration”.

### log_error_suppression_list

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--log-error-suppression-list=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Introduced</strong></td>
<td>8.0.13</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>log_error_suppression_list</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>String</td>
</tr>
</tbody>
</table>
The `log_error_suppression_list` system variable applies to events intended for the error log and specifies which events to suppress when they occur with a priority of `WARNING` or `INFORMATION`. For example, if a particular type of warning is considered undesirable “noise” in the error log because it occurs frequently but is not of interest, it can be suppressed. This variable affects filtering performed by the `log_filter_internal` error log filter component, which is enabled by default (see Section 5.5.3, “Error Log Components”). If `log_filter_internal` is disabled, `log_error_suppression_list` has no effect.

The `log_error_suppression_list` value may be the empty string for no suppression, or a list of one or more comma-separated values indicating the error codes to suppress. Error codes may be specified in symbolic or numeric form. A numeric code may be specified with or without the `MY-` prefix. Leading zeros in the numeric part are not significant. Examples of permitted code formats:

```
ER_SERVER_SHUTDOWN_COMPLETE
MY-000031
000031
MY-31
31
```

Symbolic values are preferable to numeric values for readability and portability. For information about the permitted error symbols and numbers, see MySQL 8.0 Error Message Reference.

The effect of `log_error_suppression_list` combines with that of `log_error_verbosity`. For additional information, see Section 5.4.2.5, “Priority-Based Error Log Filtering (log_filter_internal)”.

- `log_error_verbosity`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--log-error-verbosity=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>log_error_verbosity</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>3</td>
</tr>
</tbody>
</table>

The `log_error_verbosity` system variable specifies the verbosity for handling events intended for the error log. This variable affects filtering performed by the `log_filter_internal` error log filter component, which is enabled by default (see Section 5.5.3, “Error Log Components”). If `log_filter_internal` is disabled, `log_error_verbosity` has no effect.

Events intended for the error log have a priority of `ERROR`, `WARNING`, or `INFORMATION`. `log_error_verbosity` controls verbosity based on which priorities to permit for messages written to the log, as shown in the following table.

<table>
<thead>
<tr>
<th><code>log_error_verbosity</code> Value</th>
<th>Permitted Message Priorities</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>ERROR</code></td>
</tr>
<tr>
<td>2</td>
<td><code>ERROR, WARNING</code></td>
</tr>
</tbody>
</table>
Server System Variables

### log_error_verbosity Value

<table>
<thead>
<tr>
<th>log_error_verbosity Value</th>
<th>Permitted Message Priorities</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>ERROR, WARNING, INFORMATION</td>
</tr>
</tbody>
</table>

There is also a priority of **SYSTEM**. System messages about non-error situations are printed to the error log regardless of the `log_error_verbosity` value. These messages include startup and shutdown messages, and some significant changes to settings.

The effect of `log_error_verbosity` combines with that of `log_error_suppression_list`. For additional information, see Section 5.4.2.5, “Priority-Based Error Log Filtering (log_filter_internal)”.

- **log_output**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--log-output=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>log_output</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Set</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>FILE</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>TABLE</code> <code>FILE</code> <code>NONE</code></td>
</tr>
</tbody>
</table>

The destination or destinations for general query log and slow query log output. The value is a list one or more comma-separated words chosen from `TABLE`, `FILE`, and `NONE`. `TABLE` selects logging to the `general_log` and `slow_log` tables in the `mysql` system schema. `FILE` selects logging to log files. `NONE` disables logging. If `NONE` is present in the value, it takes precedence over any other words that are present. `TABLE` and `FILE` can both be given to select both log output destinations.

This variable selects log output destinations, but does not enable log output. To do that, enable the `general_log` and `slow_query_log` system variables. For `FILE` logging, the `general_log_file` and `slow_query_log_file` system variables determine the log file locations. For more information, see Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”.

- **log_queries_not_using_indexes**

| Command-Line Format | `--log-queries-not-using-indexes[={OFF|ON}]` |
|---------------------|---------------------------------------------|
| System Variable     | `log_queries_not_using_indexes`             |
| Scope               | Global                                      |
| Dynamic             | Yes                                         |
| `SET_VAR` Hint Applies | No                               |
| Type                | Boolean                                     |
| Default Value       | `OFF`                                        |

If you enable this variable with the slow query log enabled, queries that are expected to retrieve all rows are logged. See Section 5.4.5, “The Slow Query Log”. This option does not necessarily mean that
no index is used. For example, a query that uses a full index scan uses an index but would be logged because the index would not limit the number of rows.

- **log_raw**

| Command-Line Format | `--log-raw[={OFF|ON}]` |
|---------------------|-------------------------|
| System Variable     | `log_raw`               |
| Scope               | Global                  |
| Dynamic             | Yes                     |
| SET_VAR Hint Applies| No                      |
| Type                | Boolean                 |
| Default Value       | OFF                     |

The `log_raw` system variable is initially set to the value of the `--log-raw` option. See the description of that option for more information. The system variable may also be set at runtime to change password masking behavior.

- **log_slow_admin_statements**

| Command-Line Format | `--log-slow-admin-statements[={OFF|ON}]` |
|---------------------|-----------------------------------------|
| System Variable     | `log_slow_admin_statements`             |
| Scope               | Global                                  |
| Dynamic             | Yes                                     |
| SET_VAR Hint Applies| No                                      |
| Type                | Boolean                                 |
| Default Value       | OFF                                     |

Include slow administrative statements in the statements written to the slow query log. Administrative statements include `ALTER TABLE`, `ANALYZE TABLE`, `CHECK TABLE`, `CREATE INDEX`, `DROP INDEX`, `OPTIMIZE TABLE`, and `REPAIR TABLE`.

- **log_slow_extra**

| Command-Line Format | `--log-slow-extra[={OFF|ON}]` |
|---------------------|-------------------------------|
| Introduced          | 8.0.14                        |
| System Variable     | `log_slow_extra`              |
| Scope               | Global                        |
| Dynamic             | Yes                           |
| SET_VAR Hint Applies| No                            |
| Type                | Boolean                       |
| Default Value       | OFF                           |

If the slow query log is enabled and the output destination includes `FILE`, the server writes additional fields to log file lines that provide information about slow statements. See Section 5.4.5, “The Slow Query Log”. `TABLE` output is unaffected.

- **log_syslog**
### log_syslog

| Command-Line Format          | --log-syslog={OFF|ON} |
|------------------------------|-----------------------|
| Deprecated                   | Yes (removed in 8.0.13) |
| System Variable              | log_syslog            |
| Scope                        | Global                |
| Dynamic                      | Yes                   |
| SET_VAR Hint Applies         | No                    |
| Type                         | Boolean               |
| Default Value                | ON (when error logging to system log is enabled) |

Prior to MySQL 8.0, this variable controlled whether to perform error logging to the system log (the Event Log on Windows, and `syslog` on Unix and Unix-like systems).

In MySQL 8.0, the `log_sink_syseventlog` log component implements error logging to the system log (see Section 5.4.2.8, "Error Logging to the System Log"), so this type of logging can be enabled by adding that component to the `log_error_services` system variable. `log_syslog` is removed. (Prior to MySQL 8.0.13, `log_syslog` exists but is deprecated and has no effect.)

#### log_syslog_facility

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--log-syslog-facility=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Removed</td>
<td>8.0.13</td>
</tr>
<tr>
<td>System Variable</td>
<td>log_syslog_facility</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>daemon</td>
</tr>
</tbody>
</table>

This variable was removed in MySQL 8.0.13 and replaced by `syseventlog.facility`.

#### log_syslog_include_pid

| Command-Line Format          | --log-syslog-include-pid={OFF|ON} |
|------------------------------|----------------------------------|
| Removed                      | 8.0.13                           |
| System Variable              | log_syslog_include_pid           |
| Scope                        | Global                           |
| Dynamic                      | Yes                              |
| SET_VAR Hint Applies         | No                               |
| Type                         | Boolean                          |
| Default Value                | ON                               |

This variable was removed in MySQL 8.0.13 and replaced by `syseventlog.include_pid`.
### log_syslog_tag

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--log-syslog-tag=tag</th>
</tr>
</thead>
<tbody>
<tr>
<td>Removed</td>
<td>8.0.13</td>
</tr>
<tr>
<td>System Variable</td>
<td>log_syslog_tag</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>empty string</td>
</tr>
</tbody>
</table>

This variable was removed in MySQL 8.0.13 and replaced by `syseventlog.tag`.

### log_timestamps

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--log-timestamps=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>log_timestamps</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>UTC</td>
</tr>
</tbody>
</table>
| Valid Values        | UTC
|                     | SYSTEM             |

This variable controls the time zone of timestamps in messages written to the error log, and in general query log and slow query log messages written to files. It does not affect the time zone of general query log and slow query log messages written to tables (`mysql.general_log`, `mysql.slow_log`). Rows retrieved from those tables can be converted from the local system time zone to any desired time zone with `CONVERT_TZ()` or by setting the session `time_zone` system variable.

Permitted `log_timestamps` values are UTC (the default) and SYSTEM (the local system time zone).

Timestamps are written using ISO 8601 / RFC 3339 format: `YYYY-MM-DDThh:mm:ss.ffffff` plus a tail value of `Z` signifying Zulu time (UTC) or `±hh:mm` (an offset from UTC).

### log_throttle_queries_not_using_indexes

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--log-throttle-queries-not-using-indexes=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>log_throttle_queries_not_using_indexes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>
If `log_queries_not_using_indexes` is enabled, the `log_throttle_queries_not_using_indexes` variable limits the number of such queries per minute that can be written to the slow query log. A value of 0 (the default) means "no limit". For more information, see Section 5.4.5, "The Slow Query Log".

- **long_query_time**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--long-query-time=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>long_query_time</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

If a query takes longer than this many seconds, the server increments the `Slow_queries` status variable. If the slow query log is enabled, the query is logged to the slow query log file. This value is measured in real time, not CPU time, so a query that is under the threshold on a lightly loaded system might be above the threshold on a heavily loaded one. The minimum and default values of `long_query_time` are 0 and 10, respectively. The value can be specified to a resolution of microseconds. See Section 5.4.5, "The Slow Query Log".

Smaller values of this variable result in more statements being considered long-running, with the result that more space is required for the slow query log. For very small values (less than one second), the log may grow quite large in a small time. Increasing the number of statements considered long-running may also result in false positives for the “excessive Number of Long Running Processes” alert in MySQL Enterprise Monitor, especially if Group Replication is enabled. For these reasons, very small values should be used in test environments only, or, in production environments, only for a short period.

- **low_priority_updates**

| Command-Line Format | --low-priority-updates[={OFF|ON}] |
|---------------------|-----------------------------------|
| System Variable     | low_priority_updates              |
| Scope               | Global, Session                   |
| Dynamic             | Yes                               |
| SET_VAR Hint Applies| No                                |
| Type                | Boolean                           |
| Default Value       | OFF                               |

If set to 1, all `INSERT`, `UPDATE`, `DELETE`, and `LOCK TABLE WRITE` statements wait until there is no pending `SELECT` or `LOCK TABLE READ` on the affected table. The same effect can be obtained using `(INSERT | REPLACE | DELETE | UPDATE) LOW_PRIORITY ...` to lower the priority of only one query. This variable affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`). See Section 8.11.2, “Table Locking Issues”.

785
• **lower_case_file_system**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>lower_case_file_system</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>

This variable describes the case sensitivity of file names on the file system where the data directory is located. **OFF** means file names are case-sensitive, **ON** means they are not case-sensitive. This variable is read only because it reflects a file system attribute and setting it would have no effect on the file system.

• **lower_case_table_names**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--lower-case-table-names[=#]</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>lower_case_table_names</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2</td>
</tr>
</tbody>
</table>

If set to 0, table names are stored as specified and comparisons are case-sensitive. If set to 1, table names are stored in lowercase on disk and comparisons are not case sensitive. If set to 2, table names are stored as given but compared in lowercase. This option also applies to database names and table aliases. For additional details, see *Section 9.2.3, “Identifier Case Sensitivity”*.

On Windows the default value is 1. On macOS, the default value is 2. On Linux, a value of 2 is not supported; the server forces the value to 0 instead.

You should *not* set **lower_case_table_names** to 0 if you are running MySQL on a system where the data directory resides on a case-insensitive file system (such as on Windows or macOS). It is an unsupported combination that could result in a hang condition when running an `INSERT INTO ... SELECT ... FROM tbl_name` operation with the wrong `tbl_name` lettercase. With MyISAM, accessing table names using different lettercases could cause index corruption.

An error message is printed and the server exits if you attempt to start the server with `--lower_case_table_names=0` on a case-insensitive file system.

If you are using InnoDB tables, you should set this variable to 1 on all platforms to force names to be converted to lowercase.

The setting of this variable affects the behavior of replication filtering options with regard to case sensitivity. For more information, see *Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”*.

It is prohibited to start the server with a **lower_case_table_names** setting that is different from the setting used when the server was initialized. The restriction is necessary because collations used by
various data dictionary table fields are determined by the setting defined when the server is initialized, and restarting the server with a different setting would introduce inconsistencies with respect to how identifiers are ordered and compared.

It is therefore necessary to configure `lower_case_table_names` to the desired setting before initializing the server. In most cases, this requires configuring `lower_case_table_names` in a MySQL option file before starting the MySQL server for the first time. For APT installations on Debian and Ubuntu, however, the server is initialized for you, and there is no opportunity to configure the setting in an option file beforehand. You must therefore use the `debconf-set-selection` utility prior to installing MySQL using APT to enable `lower_case_table_names`. To do so, run this command before installing MySQL using APT:

```
shell> sudo debconf-set-selections <<< "mysql-server mysql-server/lowercase-table-names select Enabled"
```

**Note**

The ability to enable `lower_case_table_names` using `debconf-set-selection` was added in MySQL 8.0.17. Enabling `lower_case_table_names` sets the value to 1.

- `mandatory_roles`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mandatory-roles=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>mandatory_roles</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
Roles the server should treat as mandatory. In effect, these roles are automatically granted to every user, although setting `mandatory_roles` does not actually change any user accounts, and the granted roles are not visible in the `mysql.role_edges` system table.

The variable value is a comma-separated list of role names. Example:

```sql
SET PERSIST mandatory_roles = '"role1'@'%'','role2','role3',role4@localhost';
```

Setting the runtime value of `mandatory_roles` requires the `ROLE_ADMIN` privilege, in addition to the `SYSTEM_VARIABLES_ADMIN` privilege (or the deprecated `SUPER` privilege) normally required to set a global system variable runtime value.

Role names consist of a user part and host part in `user_name@host_name` format. The host part, if omitted, defaults to `%`. For additional information, see Section 6.2.5, “Specifying Role Names”.

The `mandatory_roles` value is a string, so user names and host names, if quoted, must be written in a fashion permitted for quoting within quoted strings.

Roles named in the value of `mandatory_roles` cannot be revoked with `REVOKE` or dropped with `DROP ROLE` or `DROP USER`.

To prevent sessions from being made system sessions by default, a role that has the `SYSTEM_USER` privilege cannot be listed in the value of the `mandatory_roles` system variable:

- If `mandatory_roles` is assigned a role at startup that has the `SYSTEM_USER` privilege, the server writes a message to the error log and exits.
- If `mandatory_roles` is assigned a role at runtime that has the `SYSTEM_USER` privilege, an error occurs and the `mandatory_roles` value remains unchanged.

Mandatory roles, like explicitly granted roles, do not take effect until activated (see Activating Roles). At login time, role activation occurs for all granted roles if the `activate_all_roles_on_login` system variable is enabled; otherwise, or for roles that are set as default roles otherwise. At runtime, `SET ROLE` activates roles.

Roles that do not exist when assigned to `mandatory_roles` but are created later may require special treatment to be considered mandatory. For details, see Defining Mandatory Roles.

`SHOW GRANTS` displays mandatory roles according to the rules described in Section 13.7.7.21, “SHOW GRANTS Statement”.

- **max_allowed_packet**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-allowed-packet=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>max_allowed_packet</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>67108864</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1024</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Maximum Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1073741824</td>
</tr>
</tbody>
</table>

The maximum size of one packet or any generated/intermediate string, or any parameter sent by the `mysql_stmt_send_long_data()` C API function. The default is 64MB.

The packet message buffer is initialized to `net_buffer_length` bytes, but can grow up to `max_allowed_packet` bytes when needed. This value by default is small, to catch large (possibly incorrect) packets.

You must increase this value if you are using large BLOB columns or long strings. It should be as big as the largest BLOB you want to use. The protocol limit for `max_allowed_packet` is 1GB. The value should be a multiple of 1024; nonmultiples are rounded down to the nearest multiple.

When you change the message buffer size by changing the value of the `max_allowed_packet` variable, you should also change the buffer size on the client side if your client program permits it. The default `max_allowed_packet` value built in to the client library is 1GB, but individual client programs might override this. For example, `mysql` and `mysqldump` have defaults of 16MB and 24MB, respectively. They also enable you to change the client-side value by setting `max_allowed_packet` on the command line or in an option file.

The session value of this variable is read only. The client can receive up to as many bytes as the session value. However, the server does not send to the client more bytes than the current global `max_allowed_packet` value. (The global value could be less than the session value if the global value is changed after the client connects.)

• **max_connect_errors**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-connect-errors=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>max_connect_errors</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>

<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>100</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

After `max_connect_errors` successive connection requests from a host are interrupted without a successful connection, the server blocks that host from further connections. If a connection from a host is established successfully within fewer than `max_connect_errors` attempts after a previous connection was interrupted, the error count for the host is cleared to zero. To unblock blocked hosts, flush the host cache; see Flushing the Host Cache.

• **max_connections**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-connections=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>max_connections</td>
</tr>
</tbody>
</table>
The maximum permitted number of simultaneous client connections. For more information, see Section 5.1.12.1, “Connection Interfaces”.

• **max_delayed_threads**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-delayed-threads=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>max_delayed_threads</code></td>
</tr>
<tr>

</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

The maximum number of bytes of memory reserved per session for computation of normalized statement digests. Once that amount of space is used during digest computation, truncation occurs: no further tokens from a parsed statement are collected or figure into its digest value. Statements that
Server System Variables

differ only after that many bytes of parsed tokens produce the same normalized statement digest and are considered identical if compared or if aggregated for digest statistics.

Decreasing the `max_digest_length` value reduces memory use but causes the digest value of more statements to become indistinguishable if they differ only at the end. Increasing the value permits longer statements to be distinguished but increases memory use, particularly for workloads that involve large numbers of simultaneous sessions (the server allocates `max_digest_length` bytes per session).

The parser uses this system variable as a limit on the maximum length of normalized statement digests that it computes. The Performance Schema, if it tracks statement digests, makes a copy of the digest value, using the `performance_schema_max_digest_length` system variable as a limit on the maximum length of digests that it stores. Consequently, if `performance_schema_max_digest_length` is less than `max_digest_length`, digest values stored in the Performance Schema are truncated relative to the original digest values.

For more information about statement digesting, see Section 26.10, “Performance Schema Statement Digests and Sampling”.

• `max_error_count`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-error-count=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>max_error_count</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>

<td>Yes</td>
</tr>
<tr>
<td>SET_VAR</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1024</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

The maximum number of error, warning, and information messages to be stored for display by the `SHOW ERRORS` and `SHOW WARNINGS` statements. This is the same as the number of condition areas in the diagnostics area, and thus the number of conditions that can be inspected by `GET DIAGNOSTICS`.

• `max_execution_time`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-execution-time=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>max_execution_time</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>
**Server System Variables**

| Default Value | 0 |

The execution timeout for `SELECT` statements, in milliseconds. If the value is 0, timeouts are not enabled.

`max_execution_time` applies as follows:

- The global `max_execution_time` value provides the default for the session value for new connections. The session value applies to `SELECT` executions executed within the session that include no `MAX_EXECUTION_TIME(N)` optimizer hint or for which `N` is 0.

- `max_execution_time` applies to read-only `SELECT` statements. Statements that are not read only are those that invoke a stored function that modifies data as a side effect.

- `max_execution_time` is ignored for `SELECT` statements in stored programs.

**max_heap_table_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--max-heap-table-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>max_heap_table_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>

</tr>
<tr>
<td>Minimum Value</td>
<td>16384</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>1844674407370954752</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This variable sets the maximum size to which user-created `MEMORY` tables are permitted to grow. The value of the variable is used to calculate `MEMORY` table `MAX_ROWS` values. Setting this variable has no effect on any existing `MEMORY` table, unless the table is re-created with a statement such as `CREATE TABLE` or altered with `ALTER TABLE` or `TRUNCATE TABLE`. A server restart also sets the maximum size of existing `MEMORY` tables to the global `max_heap_table_size` value.

This variable is also used in conjunction with `tmp_table_size` to limit the size of internal in-memory tables. See Section 8.4.4, "Internal Temporary Table Use in MySQL".

`max_heap_table_size` is not replicated. See Section 17.5.1.21, "Replication and MEMORY Tables", and Section 17.5.1.38, "Replication and Variables", for more information.

**max_insert_delayed_threads**

<table>
<thead>
<tr>
<th>Deprecated</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>max_insert_delayed_threads</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
</table>

This variable is a synonym for `max_delayed_threads`.

This system variable is deprecated (because `DELAYED` inserts are not supported); expect it to be removed in a future release.

- `max_join_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--max-join-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>max_join_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>18446744073709551615</td>
</tr>
</tbody>
</table>

Do not permit statements that probably need to examine more than `max_join_size` rows (for single-table statements) or row combinations (for multiple-table statements) or that are likely to do more than `max_join_size` disk seeks. By setting this value, you can catch statements where keys are not used properly and that would probably take a long time. Set it if your users tend to perform joins that lack a `WHERE` clause, that take a long time, or that return millions of rows. For more information, see Using Safe-Updates Mode (`--safe-updates`).

Setting this variable to a value other than `DEFAULT` resets the value of `sql_big_selects` to 0. If you set the `sql_big_selects` value again, the `max_join_size` variable is ignored.

- `max_length_for_sort_data`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--max-length-for-sort-data=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>8.0.20</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>max_length_for_sort_data</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4096</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>8388608</td>
</tr>
</tbody>
</table>

This variable is deprecated as of MySQL 8.0.20 due to optimizer changes that make it obsolete and of no effect. Previously, it acted as the cutoff on the size of index values that determines which `filesort` algorithm to use. See Section 8.2.1.16, “ORDER BY Optimization”. 

Server System Variables

• **max_points_in_geometry**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-points-in-geometry=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>max_points_in_geometry</td>

<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>65536</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>3</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

The maximum value of the *points_per_circle* argument to the `ST_Buffer_Strategy()` function.

• **max_prepared_stmt_count**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-prepared-stmt-count=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>max_prepared_stmt_count</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>16382</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value (≥ 8.0.18)</td>
<td>4194304</td>
</tr>
<tr>
<td>Maximum Value (≤ 8.0.17)</td>
<td>1048576</td>
</tr>
</tbody>
</table>

This variable limits the total number of prepared statements in the server. It can be used in environments where there is the potential for denial-of-service attacks based on running the server out of memory by preparing huge numbers of statements. If the value is set lower than the current number of prepared statements, existing statements are not affected and can be used, but no new statements can be prepared until the current number drops below the limit. Setting the value to 0 disables prepared statements.

• **max_seeks_for_key**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-seeks-for-key=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>max_seeks_for_key</td>
</tr>
<tr>

<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>18446744073709551615</td>
</tr>
</tbody>
</table>

794
Limit the assumed maximum number of seeks when looking up rows based on a key. The MySQL optimizer assumes that no more than this number of key seeks are required when searching for matching rows in a table by scanning an index, regardless of the actual cardinality of the index (see Section 13.7.7.22, “SHOW INDEX Statement”). By setting this to a low value (say, 100), you can force MySQL to prefer indexes instead of table scans.

- **max_sort_length**

The number of bytes to use when sorting data values. The server uses only the first `max_sort_length` bytes of each value and ignores the rest. Consequently, values that differ only after the first `max_sort_length` bytes compare as equal for `GROUP BY`, `ORDER BY`, and `DISTINCT` operations.

Increasing the value of `max_sort_length` may require increasing the value of `sort_buffer_size` as well. For details, see Section 8.2.1.16, “ORDER BY Optimization”

- **max_sp_recursion_depth**

---

<table>
<thead>
<tr>
<th>Default Value (32-bit platforms)</th>
<th>4294967295</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

---

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-sort-length=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>max_sort_length</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1024</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>8388608</td>
</tr>
</tbody>
</table>
Server System Variables

| Maximum Value | 255 |

The number of times that any given stored procedure may be called recursively. The default value for this option is 0, which completely disables recursion in stored procedures. The maximum value is 255.

Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup.

- **max_user_connections**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-user-connections=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>max_user_connections</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The maximum number of simultaneous connections permitted to any given MySQL user account. A value of 0 (the default) means “no limit.”

This variable has a global value that can be set at server startup or runtime. It also has a read-only session value that indicates the effective simultaneous-connection limit that applies to the account associated with the current session. The session value is initialized as follows:

- If the user account has a nonzero `MAX_USER_CONNECTIONS` resource limit, the session `max_user_connections` value is set to that limit.

- Otherwise, the session `max_user_connections` value is set to the global value.

Account resource limits are specified using the `CREATE USER` or `ALTER USER` statement. See Section 6.2.20, “Setting Account Resource Limits”.

- **max_write_lock_count**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-write-lock-count=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>max_write_lock_count</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Default Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
</tbody>
</table>
Server System Variables

| Maximum Value (64-bit platforms) | 18446744073709551615 |
| Maximum Value (32-bit platforms) | 4294967295 |

After this many write locks, permit some pending read lock requests to be processed in between. Write lock requests have higher priority than read lock requests. However, if `max_write_lock_count` is set to some low value (say, 10), read lock requests may be preferred over pending write lock requests if the read lock requests have already been passed over in favor of 10 write lock requests. Normally this behavior does not occur because `max_write_lock_count` by default has a very large value.

- **mecab_rc_file**

  | Command-Line Format | `--mecab-rc-file=file_name` |
  | System Variable     | `mecab_rc_file` |
  | Scope               | Global |
  | Dynamic             | No |
  | SET_VAR Hint Applies| No |
  | Type                | File name |

  The `mecab_rc_file` option is used when setting up the MeCab full-text parser.

  The `mecab_rc_file` option defines the path to the `mecabrc` configuration file, which is the configuration file for MeCab. The option is read-only and can only be set at startup. The `mecabrc` configuration file is required to initialize MeCab.

  For information about the MeCab full-text parser, see Section 12.10.9, “MeCab Full-Text Parser Plugin”.

  For information about options that can be specified in the MeCab `mecabrc` configuration file, refer to the MeCab Documentation on the Google Developers site.

- **metadata_locks_cache_size**

  | Command-Line Format | `--metadata-locks-cache-size=#` |
  | Deprecated          | Yes (removed in 8.0.13) |
  | System Variable     | `metadata_locks_cache_size` |
  | Scope               | Global |
  | Dynamic             | No |
  | SET_VAR Hint Applies| No |
  | Type                | Integer |
  | Default Value       | 1024 |
  | Minimum Value       | 1 |
  | Maximum Value       | 1048576 |

  This system variable was removed in MySQL 8.0.13.

- **metadata_locks_hash_instances**

  | Command-Line Format | `--metadata-locks-hash-instances=#` |
### Server System Variables

<table>
<thead>
<tr>
<th>Deprecated</th>
<th>Yes (removed in 8.0.13)</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>metadata_locks_hash_instances</td>
</tr>
<tr>
<td>Scope</td>

</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Queries that examine fewer than this number of rows are not logged to the slow query log.

- **myisam_data_pointer_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--myisam-data-pointer-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>myisam_data_pointer_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>6</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>2</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>7</td>
</tr>
</tbody>
</table>

The default pointer size in bytes, to be used by `CREATE TABLE` for MyISAM tables when no `MAX_ROWS` option is specified. This variable cannot be less than 2 or larger than 7. The default value is 6. See Section B.3.2.10, “The table is full”.
Server System Variables

• myisam_max_sort_file_size

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--myisam-max-sort-file-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>myisam_max_sort_file_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value (64-bit platforms)</td>
<td>9223372036854775807</td>
</tr>
<tr>
<td>Default Value (32-bit platforms)</td>
<td>2147483648</td>
</tr>
</tbody>
</table>

The maximum size of the temporary file that MySQL is permitted to use while re-creating a MyISAM index (during REPAIR TABLE, ALTER TABLE, or LOAD DATA). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

If MyISAM index files exceed this size and disk space is available, increasing the value may help performance. The space must be available in the file system containing the directory where the original index file is located.

• myisam_mmap_size

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--myisam-mmap-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>myisam_mmap_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Default Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The maximum amount of memory to use for memory mapping compressed MyISAM files. If many compressed MyISAM tables are used, the value can be decreased to reduce the likelihood of memory-swapping problems.

• myisam_recover_options

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--myisam-recover-options[=list]</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>myisam_recover_options</td>
</tr>
</tbody>
</table>
Set the MyISAM storage engine recovery mode. The variable value is any combination of the values of OFF, DEFAULT, BACKUP, FORCE, or QUICK. If you specify multiple values, separate them by commas. Specifying the variable with no value at server startup is the same as specifying DEFAULT, and specifying with an explicit value of "" disables recovery (same as a value of OFF). If recovery is enabled, each time mysqld opens a MyISAM table, it checks whether the table is marked as crashed or was not closed properly. (The last option works only if you are running with external locking disabled.) If this is the case, mysqld runs a check on the table. If the table was corrupted, mysqld attempts to repair it.

The following options affect how the repair works.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFF</td>
<td>No recovery.</td>
</tr>
<tr>
<td>DEFAULT</td>
<td>Recovery without backup, forcing, or quick checking.</td>
</tr>
<tr>
<td>BACKUP</td>
<td>If the data file was changed during recovery, save a backup of the \texttt{tbl_name.MYD} file as \texttt{tbl_name-datetime.BAK}.</td>
</tr>
<tr>
<td>FORCE</td>
<td>Run recovery even if we would lose more than one row from the .MYD file.</td>
</tr>
<tr>
<td>QUICK</td>
<td>Do not check the rows in the table if there are not any delete blocks.</td>
</tr>
</tbody>
</table>

Before the server automatically repairs a table, it writes a note about the repair to the error log. If you want to be able to recover from most problems without user intervention, you should use the options \texttt{BACKUP, FORCE}. This forces a repair of a table even if some rows would be deleted, but it keeps the old data file as a backup so that you can later examine what happened.

See Section 16.2.1, “MyISAM Startup Options”.

- \texttt{myisam_repair_threads}

**Command-Line Format**

\texttt{--myisam-repair-threads=\#}

**System Variable**

\texttt{myisam_repair_threads}

**Scope**

Global, Session

**Dynamic**

Yes

**SET_VAR Hint Applies**

No

**Type**

Integer
### Server System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

If this value is greater than 1, MyISAM table indexes are created in parallel (each index in its own thread) during the Repair by sorting process. The default value is 1.

**Note**

Multithreaded repair is still beta-quality code.

- **myisam_sort_buffer_size**

<table>
<thead>
<tr>

</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Variables</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>nulls_unequal</td>
<td></td>
</tr>
<tr>
<td>nulls_ignored</td>
<td></td>
</tr>
</tbody>
</table>

How the server treats NULL values when collecting statistics about the distribution of index values for MyISAM tables. This variable has three possible values, nulls_equal, nulls_unequal, and nulls_ignored. For nulls_equal, all NULL index values are considered equal and form a single value group that has a size equal to the number of NULL values. For nulls_unequal, NULL values are considered unequal, and each NULL forms a distinct value group of size 1. For nulls_ignored, NULL values are ignored.

The method that is used for generating table statistics influences how the optimizer chooses indexes for query execution, as described in Section 8.3.8, “InnoDB and MyISAM Index Statistics Collection”.

- **myisam_use_mmap**

  Command-Line Format: `--myisam-use-mmap=[OFF|ON]`
  
  System Variable: `myisam_use_mmap`
  
  Scope: Global
  
  Dynamic: Yes
  
  SET_VAR Hint Applies: No
  
  Type: Boolean
  
  Default Value: OFF

  Use memory mapping for reading and writing MyISAM tables.

- **mysql_native_password_proxy_users**

  Command-Line Format: `--mysql-native-password-proxy-users=[OFF|ON]`
  
  System Variable: `mysql_native_password_proxy_users`
  
  Scope: Global
  
  Dynamic: Yes
  
  SET_VAR Hint Applies: No
  
  Type: Boolean
  
  Default Value: OFF

  This variable controls whether the mysql_native_password built-in authentication plugin supports proxy users. It has no effect unless the check_proxy_users system variable is enabled. For information about user proxying, see Section 6.2.18, “Proxy Users”.

- **named_pipe**

  Command-Line Format: `--named-pipe=[OFF|ON]`
  
  System Variable: `named_pipe`
  
  Scope: Global
  
  Dynamic: No
  
  SET_VAR Hint Applies: No
Server System Variables

<table>
<thead>
<tr>
<th>Platform Specific</th>
<th>Windows</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

(Windows only.) Indicates whether the server supports connections over named pipes.

• **named_pipe_full_access_group**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--named-pipe-full-access-group=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.14</td>
</tr>
<tr>
<td>System Variable</td>
<td>named_pipe_full_access_group</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><em>everyone</em></td>
</tr>
<tr>
<td>Valid Values</td>
<td><em>everyone</em></td>
</tr>
<tr>
<td></td>
<td>empty string</td>
</tr>
</tbody>
</table>

(Windows only.) The access control granted to clients on the named pipe created by the MySQL server is set to the minimum necessary for successful communication when the `named_pipe` system variable is enabled to support named-pipe connections. Newer MySQL client software can open named pipe connections without any additional configuration, however, older client software may still require full access to open a named pipe connection.

This variable sets the name of a Windows local group whose members are granted sufficient access by the MySQL server to use older named-pipe clients. Initially, the value is set to '*everyone*' by default, which permits users of the Everyone group on Windows to continue using older clients until the older clients are upgraded. In contrast, setting the value to an empty string means that no Windows user is granted full access to the named pipe. The default value '*everyone*' provides a language-independent way of referring to the Everyone group on Windows.

Ideally, a new Windows local group name (for example, mysql_old_client_users) should be created in Windows and then used to replace the default value for this variable when access to older client software is absolutely necessary. In this case, limit the membership of the group to as few users as possible, removing users from the group when their client software is upgraded. A non-member of the group who attempts to open a connection to MySQL with the older named-pipe client is denied access until the user is added to the group by a Windows administrator, and then the user logs out and logs in (required by Windows).

• **net_buffer_length**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--net-buffer-length=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>net_buffer_length</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>
Each client thread is associated with a connection buffer and result buffer. Both begin with a size given by `net_buffer_length` but are dynamically enlarged up to `max_allowed_packet` bytes as needed. The result buffer shrinks to `net_buffer_length` after each SQL statement.

This variable should not normally be changed, but if you have very little memory, you can set it to the expected length of statements sent by clients. If statements exceed this length, the connection buffer is automatically enlarged. The maximum value to which `net_buffer_length` can be set is 1MB.

The session value of this variable is read only.

- **net_read_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--net-read-timeout=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>net_read_timeout</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>30</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

The number of seconds to wait for more data from a connection before aborting the read. When the server is reading from the client, `net_read_timeout` is the timeout value controlling when to abort. When the server is writing to the client, `net_write_timeout` is the timeout value controlling when to abort. See also `slave_net_timeout`.

- **net_retry_count**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--net-retry-count=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>net_retry_count</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
</tbody>
</table>
Server System Variables

| Maximum Value (32-bit platforms) | 4294967295 |

If a read or write on a communication port is interrupted, retry this many times before giving up. This value should be set quite high on FreeBSD because internal interrupts are sent to all threads.

- **net_write_timeout**

  | Command-Line Format | --net-write-timeout=# |
  | System Variable     | net_write_timeout     |
  | Scope               | Global, Session      |
  | Dynamic             | Yes                  |
  | SET_VAR Hint Applies| No                   |
  | Type                | Integer              |
  | Default Value       | 60                   |
  | Minimum Value       | 1                    |

The number of seconds to wait for a block to be written to a connection before aborting the write. See also **net_read_timeout**.

- **new**

  | Command-Line Format | --new=[OFF|ON] |
  | System Variable     | new            |
  | Scope               | Global, Session|
  | Dynamic             | Yes            |
  | SET_VAR Hint Applies| No              |
  | Disabled by         | skip-new       |
  | Type                | Boolean        |
  | Default Value       | OFF             |

This variable was used in MySQL 4.0 to turn on some 4.1 behaviors, and is retained for backward compatibility. Its value is always OFF.

In NDB Cluster, setting this variable to ON makes it possible to employ partitioning types other than KEY or LINEAR KEY with NDB tables. This feature is experimental only, and not supported in production. For additional information, see User-defined partitioning and the NDB storage engine (NDB Cluster).

- **ngram_token_size**

  | Command-Line Format | --ngram-token-size=# |
  | System Variable     | ngram_token_size     |
  | Scope               | Global               |
  | Dynamic             | No                   |
  | SET_VAR Hint Applies| No                   |
  | Type                | Integer              |
  | Default Value       | 2                    |
### Server System Variables

<table>
<thead>
<tr>
<th>Minimum Value</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum Value</td>
<td>10</td>
</tr>
</tbody>
</table>

Defines the n-gram token size for the n-gram full-text parser. The `ngram_token_size` option is read-only and can only be modified at startup. The default value is 2 (bigram). The maximum value is 10.

For more information about how to configure this variable, see Section 12.10.8, “ngram Full-Text Parser”.

- **offline_mode**

  | Command-Line Format   | `--offline-mode=[{OFF|ON}]` |
  |-----------------------|----------------------------|
  | System Variable       | `offline_mode`             |
  | Scope                 | Global                     |
  | Dynamic               | Yes                        |
  | `SET_VAR Hint Applies`| No                         |
  | Type                  | Boolean                    |
  | `Default Value`       | OFF                        |

Whether the server is in “offline mode”, which has these characteristics:

- Connected client users who do not have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege) are disconnected on the next request, with an appropriate error. Disconnection includes terminating running statements and releasing locks. Such clients also cannot initiate new connections, and receive an appropriate error.

- Connected client users who have the `CONNECTION_ADMIN` or `SUPER` privilege are not disconnected, and can initiate new connections to manage the server.

- Replication threads are permitted to keep applying data to the server.

Only users who have the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege can control offline mode. To put a server in offline mode, change the value of the `offline_mode` system variable from `OFF` to `ON`. To resume normal operations, change `offline_mode` from `ON` to `OFF`. In offline mode, clients that are refused access receive an `ER_SERVER_OFFLINE_MODE` error.

- **old**

  | Command-Line Format   | `--old=[{OFF|ON}]` |
  |-----------------------|-------------------|
  | System Variable       | `old`             |
  | Scope                 | Global            |
  | Dynamic               | No                |
  | `SET_VAR Hint Applies`| No                |
  | Type                  | Boolean           |
old is a compatibility variable. It is disabled by default, but can be enabled at startup to revert the server to behaviors present in older versions.

When old is enabled, it changes the default scope of index hints to that used prior to MySQL 5.1.17. That is, index hints with no FOR clause apply only to how indexes are used for row retrieval and not to resolution of ORDER BY or GROUP BY clauses. (See Section 8.9.4, “Index Hints”.) Take care about enabling this in a replication setup. With statement-based binary logging, having different modes for the source and replicas might lead to replication errors.

- old_alter_table

| Command-Line Format | --old-alter-table[=(OFF|ON)] |
|---------------------|------------------------------|
| System Variable     | old_alter_table              |
| Scope               | Global, Session              |
| Dynamic             | Yes                          |
| SET_VAR Hint Applies| No                           |
| Type                | Boolean                      |
| Default Value       | OFF                          |

When this variable is enabled, the server does not use the optimized method of processing an ALTER TABLE operation. It reverts to using a temporary table, copying over the data, and then renaming the temporary table to the original, as used by MySQL 5.0 and earlier. For more information on the operation of ALTER TABLE, see Section 13.1.9, “ALTER TABLE Statement”.

ALTER TABLE ... DROP PARTITION with old_alter_table=ON rebuilds the partitioned table and attempts to move data from the dropped partition to another partition with a compatible PARTITION ... VALUES definition. Data that cannot be moved to another partition is deleted. In earlier releases, ALTER TABLE ... DROP PARTITION with old_alter_table=ON deletes data stored in the partition and drops the partition.

- open_files_limit

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--open-files-limit=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>open_files_limit</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>5000, with possible adjustment</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>platform dependent</td>
</tr>
</tbody>
</table>

The number of file descriptors available to mysqld from the operating system:

- At startup, mysqld reserves descriptors with setrlimit(), using the value requested at by setting this variable directly or by using the --open-files-limit option to mysqld_safe. If mysqld produces the error Too many open files, try increasing the open_files_limit value.
Internally, the maximum value for this variable is the maximum unsigned integer value, but the actual maximum is platform dependent.

- At runtime, the value of `open_files_limit` indicates the number of file descriptors actually permitted to `mysqld` by the operating system, which might differ from the value requested at startup. If the number of file descriptors requested during startup cannot be allocated, `mysqld` writes a warning to the error log.

The effective `open_files_limit` value is based on the value specified at system startup (if any) and the values of `max_connections` and `table_open_cache`, using these formulas:

- $10 + \text{max_connections} + (\text{table_open_cache} \times 2)$
- $\text{max_connections} \times 5$
- MySQL 8.0.19 and higher: The operating system limit.
- Prior to MySQL 8.0.19:
  - The operating system limit if that limit is positive but not Infinity.
  - If the operating system limit is Infinity: `open_files_limit` value if specified at startup, 5000 if not.

The server attempts to obtain the number of file descriptors using the maximum of those values, capped to the maximum unsigned integer value. If that many descriptors cannot be obtained, the server attempts to obtain as many as the system permits.

The effective value is 0 on systems where MySQL cannot change the number of open files.

On Unix, the value cannot be set greater than the value displayed by the `ulimit -n` command.

- **optimizer_prune_level**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--optimizer-prune-level=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>optimizer_prune_level</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

Controls the heuristics applied during query optimization to prune less-promising partial plans from the optimizer search space. A value of 0 disables heuristics so that the optimizer performs an exhaustive search. A value of 1 causes the optimizer to prune plans based on the number of rows retrieved by intermediate plans.

- **optimizer_search_depth**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--optimizer-search-depth=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>optimizer_search_depth</code></td>
</tr>
</tbody>
</table>
The maximum depth of search performed by the query optimizer. Values larger than the number of relations in a query result in better query plans, but take longer to generate an execution plan for a query. Values smaller than the number of relations in a query return an execution plan quicker, but the resulting plan may be far from being optimal. If set to 0, the system automatically picks a reasonable value.

- **optimizer_switch**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--optimizer-switch=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>optimizer_switch</td>
</tr>

The `optimizer_switch` system variable enables control over optimizer behavior. The value of this variable is a set of flags, each of which has a value of `on` or `off` to indicate whether the corresponding optimizer behavior is enabled or disabled. This variable has global and session values and can be changed at runtime. The global default can be set at server startup.

To see the current set of optimizer flags, select the variable value:

```sql
mysql> SELECT @@optimizer_switch
```

```
*************************** 1. row ***************************
@optimizer_switch: index_merge=on,index_merge_union=on,

<td>4294967295</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>10000000</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The maximum amount of memory available to the parser. The default value places no limit on memory available. The value can be reduced to protect against out-of-memory situations caused by parsing long or complex SQL statements.

• **partial_revokes**

| Command-Line Format | --partial-revokes[={OFF|ON}] |
|---------------------|-------------------------------|
| Introduced          | 8.0.16                        |
| System Variable     | partial_revokes               |
| Scope               | Global                        |
| Dynamic             | Yes                           |
| SET_VAR Hint Applies| No                            |
| Type                | Boolean                       |
| Default Value       | OFF (if partial revokes do not exist) |
|                     | ON (if partial revokes exist)  |

Enabling this variable makes it possible to revoke privileges partially. Specifically, for users who have privileges at the global level, **partial_revokes** enables privileges for specific schemas to be revoked while leaving the privileges in place for other schemas. For example, a user who has the global **UPDATE** privilege can be restricted from exercising this privilege on the **mysql** system schema. (Or, stated
another way, the user is enabled to exercise the `UPDATE` privilege on all schemas except the `mysql` schema.) In this sense, the user’s global `UPDATE` privilege is partially revoked.

Once enabled, `partial_revokes` cannot be disabled if any account has privilege restrictions. If any such account exists, disabling `partial_revokes` fails:

- For attempts to disable `partial_revokes` at startup, the server logs an error message and enables `partial_revokes`.
- For attempts to disable `partial_revokes` at runtime, an error occurs and the `partial_revokes` value remains unchanged.

To disable `partial_revokes` in this case, first modify each account that has partially revoked privileges, either by re-granting the privileges or by removing the account.

For more information, including instructions for removing partial revokes, see Section 6.2.12, “Privilege Restriction Using Partial Revokes”.

- `password_history`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--password-history=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>password_history</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This variable defines the global policy for controlling reuse of previous passwords based on required minimum number of password changes. For an account password used previously, this variable indicates the number of subsequent account password changes that must occur before the password can be reused. If the value is 0 (the default), there is no reuse restriction based on number of password changes.

Changes to this variable apply immediately to all accounts defined with the `PASSWORD HISTORY DEFAULT` option.

The global number-of-changes password reuse policy can be overridden as desired for individual accounts using the `PASSWORD HISTORY` option of the `CREATE USER` and `ALTER USER` statements. See Section 6.2.15, “Password Management”.

- `password_require_current`

| Command-Line Format | `--password-require-current[={OFF|ON}]` |
|---------------------|----------------------------------------|
| Introduced          | 8.0.13                                 |
| System Variable     | `password_require_current`             |
| Scope               | Global                                |
| Dynamic             | Yes                                    |
**Server System Variables**

<table>
<thead>
<tr>
<th><strong>SET_VAR</strong></th>
<th>Hint Applies</th>
<th>No</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
<td></td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
<td></td>
</tr>
</tbody>
</table>

This variable defines the global policy for controlling whether attempts to change an account password must specify the current password to be replaced.

Changes to this variable apply immediately to all accounts defined with the `PASSWORD REQUIRE CURRENT DEFAULT` option.

The global verification-required policy can be overridden as desired for individual accounts using the `PASSWORD REQUIRE` option of the `CREATE USER` and `ALTER USER` statements. See Section 6.2.15, "Password Management".

- **password_reuse_interval**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--password-reuse-interval=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>password_reuse_interval</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This variable defines the global policy for controlling reuse of previous passwords based on time elapsed. For an account password used previously, this variable indicates the number of days that must pass before the password can be reused. If the value is 0 (the default), there is no reuse restriction based on time elapsed.

Changes to this variable apply immediately to all accounts defined with the `PASSWORD REUSE INTERVAL DEFAULT` option.

The global time-elapsed password reuse policy can be overridden as desired for individual accounts using the `PASSWORD REUSE INTERVAL` option of the `CREATE USER` and `ALTER USER` statements. See Section 6.2.15, "Password Management".

- **persisted_globals_load**

| Command-Line Format | `--persisted-globals-load[={OFF|ON}]` |
|---------------------|--------------------------------------|
| System Variable     | `persisted_globals_load`             |
| Scope               | Global                               |
| Dynamic             | No                                   |
| **SET_VAR** Hint Applies | No                         |
| Type                | Boolean                              |

817
Server System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>ON</th>
</tr>
</thead>
</table>

Whether to load persisted configuration settings from the `mysqld-auto.cnf` file in the data directory. The server normally processes this file at startup after all other option files (see Section 4.2.2.2, “Using Option Files”). Disabling `persisted_globals_load` causes the server startup sequence to skip `mysqld-auto.cnf`.

To modify the contents of `mysqld-auto.cnf`, use the `SET PERSIST`, `SET PERSIST_ONLY`, and `RESET PERSIST` statements. See Section 5.1.9.3, “Persisted System Variables”.

- **persist_only_admin_x509_subject**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--persist-only-admin-x509-subject=string</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.14</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>persist_only_admin_x509_subject</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>empty string</code></td>
</tr>
</tbody>
</table>

`SET PERSIST` and `SET PERSIST_ONLY` enable system variables to be persisted to the `mysqld-auto.cnf` option file in the data directory (see Section 13.7.6.1, “SET Syntax for Variable Assignment”). Persisting system variables enables runtime configuration changes that affect subsequent server restarts, which is convenient for remote administration not requiring direct access to MySQL server host option files. However, some system variables are nonpersistent or can be persisted only under certain restrictive conditions.

The `persist_only_admin_x509_subject` system variable specifies the SSL certificate X.509 Subject value that users must have to be able to persist system variables that are persist-restricted. The default value is the empty string, which disables the Subject check so that persist-restricted system variables cannot be persisted by any user.

If `persist_only_admin_x509_subject` is nonempty, users who connect to the server using an encrypted connection and supply an SSL certificate with the designated Subject value then can use `SET PERSIST_ONLY` to persist persist-restricted system variables. For information about persist-restricted system variables and instructions for configuring MySQL to enable `persist_only_admin_x509_subject`, see Section 5.1.9.4, “Nonpersistent and Persist-Restricted System Variables”.

- **pid_file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--pid-file=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>pid_file</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>File name</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The path name of the file in which the server writes its process ID. The server creates the file in the data directory unless an absolute path name is given to specify a different directory. If you specify this variable, you must specify a value. If you do not specify this variable, MySQL uses a default value of <code>host_name.pid</code>, where <code>host_name</code> is the name of the host machine. The process ID file is used by other programs such as <code>mysqld_safe</code> to determine the server's process ID. On Windows, this variable also affects the default error log file name. See Section 5.4.2, “The Error Log”.</td>
</tr>
</tbody>
</table>

- **plugin_dir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--plugin-dir=dir_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>plugin_dir</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>BASEDIR/lib/plugin</code></td>
</tr>
</tbody>
</table>

The path name of the plugin directory.

If the plugin directory is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making `plugin_dir` read only to the server or by setting `secure_file_priv` to a directory where `SELECT` writes can be made safely.

- **port**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--port=port_num</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>port</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>3306</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

The number of the port on which the server listens for TCP/IP connections. This variable can be set with the `--port` option.

- **preload_buffer_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--preload-buffer-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>preload_buffer_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Dynamic</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>32768</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1024</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1073741824</td>
</tr>
</tbody>
</table>

The size of the buffer that is allocated when preloading indexes.

- **print_identified_with_as_hex**

  | Command-Line Format | --print-identified-with-as-hex=[{OFF|ON}] |
  |---------------------|------------------------------------------|
  | Introduced          | 8.0.17                                    |
  | System Variable     | print_identified_with_as_hex              |
  | Scope               | Global, Session                          |
  | Dynamic             | Yes                                       |
  | SET_VAR Hint Applies| No                                        |
  | Type                | Boolean                                   |
  | Default Value       | OFF                                       |

Password hash values displayed in the IDENTIFIED WITH clause of output from SHOW CREATE USER may contain unprintable characters that have adverse effects on terminal displays and in other environments. Enabling print_identified_with_as_hex causes SHOW CREATE USER to display such hash values as hexadecimal strings rather than as regular string literals. Hash values that do not contain unprintable characters still display as regular string literals, even with this variable enabled.

- **profiling**

  If set to 0 or OFF (the default), statement profiling is disabled. If set to 1 or ON, statement profiling is enabled and the SHOW PROFILE and SHOW PROFILES statements provide access to profiling information. See Section 13.7.7.31, “SHOW PROFILES Statement”.

  This variable is deprecated; expect it to be removed in a future MySQL release.

- **profiling_history_size**

  The number of statements for which to maintain profiling information if profiling is enabled. The default value is 15. The maximum value is 100. Setting the value to 0 effectively disables profiling. See Section 13.7.7.31, “SHOW PROFILES Statement”.

  This variable is deprecated; expect it to be removed in a future MySQL release.

- **protocol_compression_algorithms**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--protocol-compression-algorithms=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.18</td>
</tr>
<tr>
<td>System Variable</td>
<td>protocol_compression_algorithms</td>
</tr>
<tr>

<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>SET_VAR</th>
<th>Hint Applies</th>
<th>No</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Set</td>
<td></td>
</tr>
<tr>
<td>Default Value</td>
<td>zlib, zstd, uncompressed</td>
<td></td>
</tr>
<tr>
<td>Valid Values</td>
<td>zlib</td>
<td></td>
</tr>
<tr>
<td></td>
<td>zstd</td>
<td></td>
</tr>
<tr>
<td></td>
<td>uncompressed</td>
<td></td>
</tr>
</tbody>
</table>

The compression algorithms that the server permits for incoming connections. These include connections by client programs and by servers participating in source/replica replication or Group Replication. Compression does not apply to connections for FEDERATED tables.

`protocol_compression_algorithms` does not control connection compression for X Protocol. See Section 20.5.5, “Connection Compression with X Plugin” for information on how this operates.

The variable value is a list of one or more comma-separated compression algorithm names, in any order, chosen from the following items (not case-sensitive):

- `zlib`: Permit connections that use the `zlib` compression algorithm.
- `zstd`: Permit connections that use the `zstd` compression algorithm (zstd 1.3).
- `uncompressed`: Permit uncompressed connections. If this algorithm name is not included in the `protocol_compression_algorithms` value, the server does not permit uncompressed connections. It permits only compressed connections that use whichever other algorithms are specified in the value, and there is no fallback to uncompressed connections.

The default value of `zlib, zstd, uncompressed` indicates that the server permits all compression algorithms.

For more information, see Section 4.2.8, “Connection Compression Control”.

- `protocol_version`

<table>
<thead>
<tr>
<th>System Variable</th>
<th>protocol_version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

The version of the client/server protocol used by the MySQL server.

- `proxy_user`

<table>
<thead>
<tr>
<th>System Variable</th>
<th>proxy_user</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
</table>

If the current client is a proxy for another user, this variable is the proxy user account name. Otherwise, this variable is NULL. See Section 6.2.18, “Proxy Users”.

- **pseudo_slave_mode**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>pseudo_slave_mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

This system variable is for internal server use. `pseudo_slave_mode` assists with the correct handling of transactions that originated on older or newer servers than the server currently processing them. `mysqlbinlog` sets the value of `pseudo_slave_mode` to true before executing any SQL statements.

Setting the session value of this system variable is a restricted operation. The session user must have either the `REPLICATION_APPLIER` privilege (see Section 17.3.3, “Replication Privilege Checks”), or privileges sufficient to set restricted session variables (see Section 5.1.9.1, “System Variable Privileges”). However, note that the variable is not intended for users to set; it is set automatically by the replication infrastructure.

`pseudo_slave_mode` has the following effects on the handling of prepared XA transactions, which can be attached to or detached from the handling session (by default, the session that issues `XA START`):

- If true, and the handling session has executed an internal-use `BINLOG` statement, XA transactions are automatically detached from the session as soon as the first part of the transaction up to `XA PREPARE` finishes, so they can be committed or rolled back by any session that has the `XA_RECOVER_ADMIN` privilege.

- If false, XA transactions remain attached to the handling session as long as that session is alive, during which time no other session can commit the transaction. The prepared transaction is only detached if the session disconnects or the server restarts.

`pseudo_slave_mode` has the following effects on the `original_commit_timestamp` replication delay timestamp and the `original_server_version` system variable:

- If true, transactions that do not explicitly set `original_commit_timestamp` or `original_server_version` are assumed to originate on another, unknown server, so the value 0, meaning unknown, is assigned to both the timestamp and the system variable.

- If false, transactions that do not explicitly set `original_commit_timestamp` or `original_server_version` are assumed to originate on the current server, so the current timestamp and the current server’s version are assigned to the timestamp and the system variable.

In MySQL 8.0.14 and later, `pseudo_slave_mode` has the following effects on the handling of a statement that sets one or more unsupported (removed or unknown) SQL modes:

- If true, the server ignores the unsupported mode and raises a warning.

- If false, the server rejects the statement with `ER_UNSUPPORTED_SQL_MODE`.
### Server System Variables

- **pseudo_thread_id**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>pseudo_thread_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

This variable is for internal server use.

**Warning**

Changing the session value of the `pseudo_thread_id` system variable changes the value returned by the `CONNECTION_ID()` function.

As of MySQL 8.0.14, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

- **query_alloc_block_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--query-alloc-block-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>query_alloc_block_size</code></td>

</tbody>
</table>

The allocation size in bytes of memory blocks that are allocated for objects created during statement parsing and execution. If you have problems with memory fragmentation, it might help to increase this parameter.

- **query_prealloc_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--query-prealloc-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>query_prealloc_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8192</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>8192</td>
</tr>
</tbody>
</table>
The size in bytes of the persistent buffer used for statement parsing and execution. This buffer is not freed between statements. If you are running complex queries, a larger `query_prealloc_size` value might be helpful in improving performance, because it can reduce the need for the server to perform memory allocation during query execution operations.

- **rand_seed1**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>rand_seed1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

The `rand_seed1` and `rand_seed2` variables exist as session variables only, and can be set but not read. The variables—but not their values—are shown in the output of `SHOW VARIABLES`.

The purpose of these variables is to support replication of the `RAND()` function. For statements that invoke `RAND()`, the source passes two values to the replica, where they are used to seed the random number generator. The replica uses these values to set the session variables `rand_seed1` and `rand_seed2` so that `RAND()` on the replica generates the same value as on the source.

- **rand_seed2**

See the description for `rand_seed1`.

- **range_alloc_block_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--range.alloc-block-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>range_alloc_block_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4096</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4096</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
<tr>
<td>Block Size</td>
<td>1024</td>
</tr>
</tbody>
</table>

The size in bytes of blocks that are allocated when doing range optimization.

- **range_optimizer_max_mem_size**
### Server System Variables

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--range-optimizer-max-mem-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>range_optimizer_max_mem_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8388608</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>18446744073709551615</td>
</tr>
</tbody>
</table>

The limit on memory consumption for the range optimizer. A value of 0 means “no limit.” If an execution plan considered by the optimizer uses the range access method but the optimizer estimates that the amount of memory needed for this method would exceed the limit, it abandons the plan and considers other plans. For more information, see Limiting Memory Use for Range Optimization.

- **rbr_exec_mode**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>rbr_exec_mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>STRICT</td>
</tr>
<tr>
<td>Valid Values</td>
<td>IDEMPOTENT, STRICT</td>
</tr>
</tbody>
</table>

For internal use by mysqlbinlog. This variable switches the server between IDEMPOTENT mode and STRICT mode. IDEMPOTENT mode causes suppression of duplicate-key and no-key-found errors in BINLOG statements generated by mysqlbinlog. This mode is useful when replaying a row-based binary log on a server that causes conflicts with existing data. mysqlbinlog sets this mode when you specify the --idempotent option by writing the following to the output:

```
SET SESSION RBR_EXEC_MODE=IDEMPOTENT;
```

As of MySQL 8.0.18, setting the session value of this system variable is no longer a restricted operation.

- **read_buffer_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--read-buffer-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>read_buffer_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>131072</td>
</tr>
</tbody>
</table>
Each thread that does a sequential scan for a MyISAM table allocates a buffer of this size (in bytes) for each table it scans. If you do many sequential scans, you might want to increase this value, which defaults to 131072. The value of this variable should be a multiple of 4KB. If it is set to a value that is not a multiple of 4KB, its value is rounded down to the nearest multiple of 4KB.

This option is also used in the following context for all storage engines:

- For caching the indexes in a temporary file (not a temporary table), when sorting rows for `ORDER BY`.
- For bulk insert into partitions.
- For caching results of nested queries.

`read_buffer_size` is also used in one other storage engine-specific way: to determine the memory block size for `MEMORY` tables.

Beginning with MySQL 8.0.22, the value of `select_into_buffer_size` is used in place of the value of `read_buffer_size` for the buffer used when executing `SELECT INTO DUMPFILE` and `SELECT INTO OUTFILE` statements.

For more information about memory use during different operations, see Section 8.12.3.1, “How MySQL Uses Memory”.

- `read_only`

| Command-Line Format | --read-only[={OFF|ON}] |
|---------------------|------------------------|
| System Variable     | read_only              |
| Scope               | Global                 |
| Dynamic             | Yes                    |
| SET_VAR Hint Applies| No                     |
| Type                | Boolean                |
| Default Value       | OFF                    |

If the `read_only` system variable is enabled, the server permits no client updates except from users who have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege). This variable is disabled by default.

The server also supports a `super_read_only` system variable (disabled by default), which has these effects:

- If `super_read_only` is enabled, the server prohibits client updates, even from users who have the `CONNECTION_ADMIN` or `SUPER` privilege.
- Setting `super_read_only` to `ON` implicitly forces `read_only` to `ON`. 
Setting `read_only` to `OFF` implicitly forces `super_read_only` to `OFF`.

Even with `read_only` enabled, the server permits these operations:

- Updates performed by replication threads, if the server is a replica. In replication setups, it can be useful to enable `read_only` on replica servers to ensure that replicas accept updates only from the replication source server and not from clients.

- Writes to the system table `mysql.gtid_executed`, which stores GTIDs for executed transactions that are not present in the current binary log file.

- Use of `ANALYZE TABLE` or `OPTIMIZE TABLE` statements. The purpose of read-only mode is to prevent changes to table structure or contents. Analysis and optimization do not qualify as such changes. This means, for example, that consistency checks on read-only replicas can be performed with `mysqlcheck --all-databases --analyze`.

- Operations on `TEMPORARY` tables.

- Inserts into the log tables (`mysql.general_log` and `mysql.slow_log`); see Section 5.4.1, "Selecting General Query Log and Slow Query Log Output Destinations".

- Updates to Performance Schema tables, such as `UPDATE` or `TRUNCATE TABLE` operations.

Changes to `read_only` on a replication source server are not replicated to replica servers. The value can be set on a replica server independent of the setting on the source.

The following conditions apply to attempts to enable `read_only` (including implicit attempts resulting from enabling `super_read_only`):

- The attempt fails and an error occurs if you have any explicit locks (acquired with `LOCK TABLES`) or have a pending transaction.

- The attempt blocks while other clients have any ongoing statement, active `LOCK TABLES WRITE`, or ongoing commit, until the locks are released and the statements and transactions end. While the attempt to enable `read_only` is pending, requests by other clients for table locks or to begin transactions also block until `read_only` has been set.

- The attempt blocks if there are active transactions that hold metadata locks, until those transactions end.

- `read_only` can be enabled while you hold a global read lock (acquired with `FLUSH TABLES WITH READ LOCK`) because that does not involve table locks.

**read_rnd_buffer_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--read-rnd-buffer-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>read_rnd_buffer_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>262144</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Minimum Value</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

This variable is used for reads from MyISAM tables, and, for any storage engine, for Multi-Range Read optimization.

When reading rows from a MyISAM table in sorted order following a key-sorting operation, the rows are read through this buffer to avoid disk seeks. See Section 8.2.1.16, “ORDER BY Optimization”. Setting the variable to a large value can improve ORDER BY performance by a lot. However, this is a buffer allocated for each client, so you should not set the global variable to a large value. Instead, change the session variable only from within those clients that need to run large queries.

For more information about memory use during different operations, see Section 8.12.3.1, “How MySQL Uses Memory”. For information about Multi-Range Read optimization, see Section 8.2.1.11, “Multi-Range Read Optimization”.

• regexp_stack_limit

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--regexp-stack-limit=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>regexp_stack_limit</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8000000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

The maximum available memory in bytes for the internal stack used for regular expression matching operations performed by REGEXP_LIKE() and similar functions (see Section 12.8.2, “Regular Expressions”).

• regexp_time_limit

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--regexp-time-limit=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>regexp_time_limit</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>32</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

The time limit for regular expression matching operations performed by REGEXP_LIKE() and similar functions (see Section 12.8.2, “Regular Expressions”). This limit is expressed as the maximum permitted number of steps performed by the match engine, and thus affects execution time only indirectly. Typically, it is on the order of milliseconds.
**Server System Variables**

- **require_row_format**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>8.0.19</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>require_row_format</td>
</tr>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

This variable is for internal server use by replication and `mysqlbinlog`. It restricts DML events executed in the session to events encoded in row-based binary logging format only, and temporary tables cannot be created. Queries that do not respect the restrictions fail.

Setting the session value of this system variable to **ON** requires no privileges. Setting the session value of this system variable to **OFF** is a restricted operation, and the session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, "System Variable Privileges".

- **require_secure_transport**

| Command-Line Format |  --require-secure-transport=[{OFF|ON}] |
|---------------------|-------------------------------------|
| System Variable | require_secure_transport |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value | OFF |

Whether client connections to the server are required to use some form of secure transport. When this variable is enabled, the server permits only TCP/IP connections encrypted using TLS/SSL, or connections that use a socket file (on Unix) or shared memory (on Windows). The server rejects nonsecure connection attempts, which fail with an **ER_SECURE_TRANSPORT_REQUIRED** error.

This capability supplements per-account SSL requirements, which take precedence. For example, if an account is defined with **REQUIRE SSL**, enabling **require_secure_transport** does not make it possible to use the account to connect using a Unix socket file.

It is possible for a server to have no secure transports available. For example, a server on Windows supports no secure transports if started without specifying any SSL certificate or key files and with the `shared_memory` system variable disabled. Under these conditions, attempts to enable **require_secure_transport** at startup cause the server to write a message to the error log and exit. Attempts to enable the variable at runtime fail with an **ER_NO_SECURE_TRANSPORTS_CONFIGURED** error.

See also Configuring Encrypted Connections as Mandatory.

- **resultset_metadata**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>resultset_metadata</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
</tbody>
</table>
Server System Variables

### Server System Variables

<table>
<thead>
<tr>
<th>Dynamic</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>FULL</td>
</tr>
<tr>
<td>Valid Values</td>
<td>FULL, NONE</td>
</tr>
</tbody>
</table>

For connections for which metadata transfer is optional, the client sets the `resultset_metadata` system variable to control whether the server returns result set metadata. Permitted values are FULL (return all metadata; this is the default) and NONE (return no metadata).

For connections that are not metadata-optional, setting `resultset_metadata` to NONE produces an error.

For details about managing result set metadata transfer, see [C API Optional Result Set Metadata](https://dev.mysql.com/doc/refman/8.0/en/c-api-result-set-metadata.html).

- **secondary_engine_cost_threshold**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>8.0.16</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>secondary_engine_cost_threshold</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>100000.000000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>DBL_MAX (maximum double value)</td>
</tr>
</tbody>
</table>

For future use.

- **schema_definition_cache**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--schema-definition-cache=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>schema_definition_cache</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>256</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>256</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Maximum Value</th>
<th>524288</th>
</tr>
</thead>
</table>

Defines a limit for the number of schema definition objects, both used and unused, that can be kept in the dictionary object cache.

Unused schema definition objects are only kept in the dictionary object cache when the number in use is less than the capacity defined by `schema_definition_cache`.

A setting of 0 means that schema definition objects are only kept in the dictionary object cache while they are in use.

For more information, see Section 14.4, “Dictionary Object Cache”.

- `secure_file_priv`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--secure-file-priv=dir_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>secure_file_priv</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>platform specific</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>empty string</code></td>
</tr>
<tr>
<td></td>
<td><code>dirname</code></td>
</tr>
<tr>
<td></td>
<td><code>NULL</code></td>
</tr>
</tbody>
</table>

This variable is used to limit the effect of data import and export operations, such as those performed by the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. These operations are permitted only to users who have the `FILE` privilege.

`secure_file_priv` may be set as follows:

- If empty, the variable has no effect. This is not a secure setting.

- If set to the name of a directory, the server limits import and export operations to work only with files in that directory. The directory must exist; the server does not create it.

- If set to `NULL`, the server disables import and export operations.

The default value is platform specific and depends on the value of the `INSTALL_LAYOUT` `CMake` option, as shown in the following table. To specify the default `secure_file_priv` value explicitly if you are building from source, use the `INSTALL_SECURE_FILE_PRIVDIR` `CMake` option.

<table>
<thead>
<tr>
<th><code>INSTALL_LAYOUT</code> Value</th>
<th>Default <code>secure_file_priv</code> Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>STANDALONE</code></td>
<td><code>empty</code></td>
</tr>
<tr>
<td><code>DEB, RPM, SVR4</code></td>
<td><code>/var/lib/mysql-files</code></td>
</tr>
</tbody>
</table>
The server checks the value of `secure_file_priv` at startup and writes a warning to the error log if the value is insecure. A non-NULL value is considered insecure if it is empty, or the value is the data directory or a subdirectory of it, or a directory that is accessible by all users. If `secure_file_priv` is set to a nonexistent path, the server writes an error message to the error log and exits.

- **select_into_buffer_size**

  Command-Line Format: `--select-into-buffer-size=#`
  Introduced: 8.0.22
  System Variable: `select_into_buffer_size`
  Scope: Global, Session
  Dynamic: Yes
  SET_VAR Hint Applies: Yes
  Type: Integer
  Default Value: 131072
  Minimum Value: 8192
  Maximum Value: 2147479552
  Unit: bytes

  When using `SELECT INTO OUTFILE` or `SELECT INTO DUMPFILE` to dump data into one or more files for backup creation, data migration, or other purposes, writes can often be buffered and then trigger a large burst of write I/O activity to the disk or other storage device and stall other queries that are more sensitive to latency. You can use this variable to control the size of the buffer used to write data to the storage device to determine when buffer synchronization should occur, and thus to prevent write stalls of the kind just described from occurring.

  `select_into_buffer_size` overrides any value set for `read_buffer_size`. (`select_into_buffer_size` and `read_buffer_size` have the same default, maximum, and minimum values.) You can also use `select_into_disk_sync_delay` to set a timeout to be observed afterwards, each time synchronization takes place.

- **select_into_disk_sync**

  Command-Line Format: `--select-into-disk-sync={ON|OFF}`
  Introduced: 8.0.22
  System Variable: `select_into_disk_sync`
  Scope: Global, Session
  Dynamic: Yes
  SET_VAR Hint Applies: Yes
  Type: Boolean
  Default Value: OFF
  Valid Values: OFF
Server System Variables

| ON |

When set on ON, enables buffer synchronization of writes to an output file by a long-running SELECT INTO OUTFILE or SELECT INTO DUMPFILE statement using select_into_buffer_size.

- **select_into_disk_sync_delay**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--select-into-disk-sync-delay=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.22</td>
</tr>
<tr>
<td>System Variable</td>
<td>select_into_disk_sync_delay</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>31536000</td>
</tr>
<tr>
<td>Unit</td>
<td>milliseconds</td>
</tr>
</tbody>
</table>

When buffer synchronization of writes to an output file by a long-running SELECT INTO OUTFILE or SELECT INTO DUMPFILE statement is enabled by select_into_disk_sync, this variable sets an optional delay (in milliseconds) following synchronization. 0 (the default) means no delay.

- **session_track_gtids**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--session-track-gtids=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>session_track_gtids</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
<tr>
<td>Valid Values</td>
<td>OFF</td>
</tr>
<tr>
<td></td>
<td>OWN_GTID</td>
</tr>
<tr>
<td></td>
<td>ALL_GTIDS</td>
</tr>
</tbody>
</table>

Controls whether the server returns GTIDs to the client, enabling the client to use them to track the server state. Depending on the variable value, at the end of executing each transaction, the server’s GTIDs are captured and returned to the client as part of the acknowledgement. The possible values for session_track_gtids are as follows:

- **OFF**: The server does not return GTIDs to the client. This is the default.
- **OWN_GTID**: The server returns the GTIDs for all transactions that were successfully committed by this client in its current session since the last acknowledgement. Typically, this is the single GTID for the
last transaction committed, but if a single client request resulted in multiple transactions, the server returns a GTID set containing all the relevant GTIDs.

- **ALL_GTIDS**: The server returns the global value of its `gtid_executed` system variable, which it reads at a point after the transaction is successfully committed. As well as the GTID for the transaction just committed, this GTID set includes all transactions committed on the server by any client, and can include transactions committed after the point when the transaction currently being acknowledged was committed.

  `session_track_gtids` cannot be set within transactional context.

  For more information about session state tracking, see Section 5.1.18, “Server Tracking of Client Session State Changes”.

- **session_track_schema**

  | Command-Line Format | `--session-track-schema[={OFF|ON}]` |
  |---------------------|-----------------------------------|
  | System Variable     | `session_track_schema`            |
  | Scope               | Global, Session                   |
  | Dynamic             | Yes                               |
  | SET_VAR Hint Applies| No                                |
  | Type                | Boolean                           |
  | Default Value       | `ON`                              |

  Controls whether the server tracks when the default schema (database) is set within the current session and notifies the client to make the schema name available.

  If the schema name tracker is enabled, name notification occurs each time the default schema is set, even if the new schema name is the same as the old.

  For more information about session state tracking, see Section 5.1.18, “Server Tracking of Client Session State Changes”.

- **session_track_state_change**

  | Command-Line Format | `--session-track-state-change[={OFF|ON}]` |
  |---------------------|-----------------------------------------|
  | System Variable     | `session_track_state_change`            |
  | Scope               | Global, Session                         |
  | Dynamic             | Yes                                      |
  | SET_VAR Hint Applies| No                                       |
  | Type                | Boolean                                 |
  | Default Value       | `OFF`                                    |

  Controls whether the server tracks changes to the state of the current session and notifies the client when state changes occur. Changes can be reported for these attributes of client session state:

  - The default schema (database).
  - Session-specific values for system variables.
  - User-defined variables.
• Temporary tables.
• Prepared statements.

If the session state tracker is enabled, notification occurs for each change that involves tracked session attributes, even if the new attribute values are the same as the old. For example, setting a user-defined variable to its current value results in a notification.

The `session_track_state_change` variable controls only notification of when changes occur, not what the changes are. For example, state-change notifications occur when the default schema is set or tracked session system variables are assigned, but the notification does not include the schema name or variable values. To receive notification of the schema name or session system variable values, use the `session_track_schema` or `session_track_system_variables` system variable, respectively.

Note

Assigning a value to `session_track_state_change` itself is not considered a state change and is not reported as such. However, if its name listed in the value of `session_track_system_variables`, any assignments to it do result in notification of the new value.

For more information about session state tracking, see Section 5.1.18, “Server Tracking of Client Session State Changes”.

• `session_track_system_variables`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--session-track-system-variables=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>session_track_system_variables</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>time_zone, autocommit, character_set_client, character_set_results, character_set_connection</code></td>
</tr>
</tbody>
</table>

Controls whether the server tracks assignments to session system variables and notifies the client of the name and value of each assigned variable. The variable value is a comma-separated list of variables for which to track assignments. By default, notification is enabled for `time_zone, autocommit, character_set_client, character_set_results, character_set_connection`. (The latter three variables are those affected by `SET NAMES`.)

The special value `*` causes the server to track assignments to all session variables. If given, this value must be specified by itself without specific system variable names.

To disable notification of session variable assignments, set `session_track_system_variables` to the empty string.

If session system variable tracking is enabled, notification occurs for all assignments to tracked session variables, even if the new values are the same as the old.

For more information about session state tracking, see Section 5.1.18, “Server Tracking of Client Session State Changes”.

• **session_track_transaction_info**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--session-track-transaction-info=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>session_track_transaction_info</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
<tr>
<td>Valid Values</td>
<td>OFF, STATE, CHARACTERISTICS</td>
</tr>
</tbody>
</table>

Controls whether the server tracks the state and characteristics of transactions within the current session and notifies the client to make this information available. These `session_track_transaction_info` values are permitted:

- **OFF**: Disable transaction state tracking. This is the default.
- **STATE**: Enable transaction state tracking without characteristics tracking. State tracking enables the client to determine whether a transaction is in progress and whether it could be moved to a different session without being rolled back.
- **CHARACTERISTICS**: Enable transaction state tracking, including characteristics tracking. Characteristics tracking enables the client to determine how to restart a transaction in another session so that it has the same characteristics as in the original session. The following characteristics are relevant for this purpose:

<table>
<thead>
<tr>
<th>ISOLATION LEVEL</th>
</tr>
</thead>
<tbody>
<tr>
<td>READ ONLY</td>
</tr>
<tr>
<td>READ WRITE</td>
</tr>
<tr>
<td>WITH CONSISTENT SNAPSHOT</td>
</tr>
</tbody>
</table>

For a client to safely relocate a transaction to another session, it must track not only transaction state but also transaction characteristics. In addition, the client must track the `transaction_isolation` and `transaction_read_only` system variables to correctly determine the session defaults. (To track these variables, list them in the value of the `session_track_system_variables` system variable.)

For more information about session state tracking, see Section 5.1.18, “Server Tracking of Client Session State Changes”.

• **sha256_password_auto_generate_rsa_keys**

| Command-Line Format | --sha256-password-auto-generate-rsa-keys[={OFF|ON}] |
|---------------------|---------------------------------------------------|
| System Variable     | sha256_password_auto_generate_rsa_keys             |
| Scope               | Global                                            |
| Dynamic             | No                                                |
| SET_VAR Hint Applies| No                                                |
| Type                | Boolean                                           |
The server uses this variable to determine whether to autogenerate RSA private/public key-pair files in the data directory if they do not already exist.

At startup, the server automatically generates RSA private/public key-pair files in the data directory if all of these conditions are true: The `sha256_password_auto_generate_rsa_keys` or `caching_sha2_password_auto_generate_rsa_keys` system variable is enabled; no RSA options are specified; the RSA files are missing from the data directory. These key-pair files enable secure password exchange using RSA over unencrypted connections for accounts authenticated by the `sha256_password` or `caching_sha2_password` plugin; see Section 6.4.1.3, “SHA-256 Pluggable Authentication”, and Section 6.4.1.2, “Caching SHA-2 Pluggable Authentication”.

For more information about RSA file autogeneration, including file names and characteristics, see Section 6.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”.

The `auto_generate_certs` system variable is related but controls autogeneration of SSL certificate and key files needed for secure connections using SSL.

### sha256_password_private_key_path

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--sha256-password-private-key-path=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>sha256_password_private_key_path</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>private_key.pem</td>
</tr>
</tbody>
</table>

The value of this variable is the path name of the RSA private key file for the `sha256_password` authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format.

**Important**

Because this file stores a private key, its access mode should be restricted so that only the MySQL server can read it.

For information about `sha256_password`, see Section 6.4.1.3, “SHA-256 Pluggable Authentication”.

### sha256_password_proxy_users

| Command-Line Format | --sha256-password-proxy-users=[OFF|ON] |
|---------------------|---------------------------------------|
| System Variable     | sha256_password_proxy_users            |
| Scope               | Global                                |
| Dynamic             | Yes                                   |
| SET_VAR Hint Applies| No                                    |
| Type                | Boolean                               |
This variable controls whether the `sha256_password` built-in authentication plugin supports proxy users. It has no effect unless the `check_proxy_users` system variable is enabled. For information about user proxying, see Section 6.2.18, "Proxy Users".

- **sha256_password_public_key_path**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--sha256-password-public-key-path=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>sha256_password_public_key_path</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>public_key.pem</code></td>
</tr>
</tbody>
</table>

The value of this variable is the path name of the RSA public key file for the `sha256_password` authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format. Because this file stores a public key, copies can be freely distributed to client users. (Clients that explicitly specify a public key when connecting to the server using RSA password encryption must use the same public key as that used by the server.)

For information about `sha256_password`, including information about how clients specify the RSA public key, see Section 6.4.1.3, “SHA-256 Pluggable Authentication”.

- **shared_memory**

  | Command-Line Format          | `--shared-memory[]={OFF|ON}]` |
  |-------------------------------|--------------------------------|
  | System Variable               | `shared_memory`                |
  | Scope                         | Global                         |
  | Dynamic                       | No                             |
  | `SET_VAR` Hint Applies        | No                             |
  | Platform Specific             | Windows                        |
  | Type                          | Boolean                        |
  | Default Value                 | `OFF`                          |

(Windows only.) Whether the server permits shared-memory connections.

- **shared_memory_base_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--shared-memory-base-name=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>shared_memory_base_name</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>MYSQL</th>
</tr>
</thead>
</table>

(Windows only.) The name of shared memory to use for shared-memory connections. This is useful when running multiple MySQL instances on a single physical machine. The default name is MYSQL. The name is case-sensitive.

This variable applies only if the server is started with the `shared_memory` system variable enabled to support shared-memory connections.

- **show_create_table_skip_secondary_engine**

  | Command-Line Format | `--show-create-table-skip-secondary-engine[={OFF|ON}]` |
  |---------------------|-----------------------------------------------------|
  | Introduced          | 8.0.18                                               |
  | System Variable     | `show_create_table_skip_secondary_engine`          |
  | Scope               | Session                                             |
  | Dynamic             | Yes                                                 |
  | `SET_VAR` Hint Applies | Yes                                             |
  | Type                | Boolean                                             |
  | Default Value       | OFF                                                 |

Enabling `show_create_table_skip_secondary_engine` causes the `SECONDARY ENGINE` clause to be excluded from `SHOW CREATE TABLE` output, and from `CREATE TABLE` statements dumped by the `mysqldump` utility.

`mysqldump` provides the `--show-create-skip-secondary-engine` option. When specified, it enables the `show_create_table_skip_secondary_engine` system variable for the duration of the dump operation.

Attempting a `mysqldump` operation with the `--show-create-skip-secondary-engine` option on a release prior to MySQL 8.0.18 that does not support the `show_create_table_skip_secondary_engine` variable causes an error.

- **show_create_table_verbosity**

  | Command-Line Format | `--show-create-table-verbosity[={OFF|ON}]` |
  |---------------------|------------------------------------------------|
  | System Variable     | `show_create_table_verbosity` |
  | Scope               | Global, Session |
  | Dynamic             | Yes |
  | `SET_VAR` Hint Applies | No |
  | Type                | Boolean |
  | Default Value       | OFF |

`SHOW CREATE TABLE` normally does not show the `ROW_FORMAT` table option if the row format is the default format. Enabling this variable causes `SHOW CREATE TABLE` to display `ROW_FORMAT` regardless of whether it is the default format.

- **show_old_temporals**

  | Command-Line Format | `--show-old-temporals[={OFF|ON}]` |
  |---------------------|------------------------------------------------|
  |                     | 839 |

Whether `SHOW CREATE TABLE` output includes comments to flag temporal columns found to be in pre-5.6.4 format (`TIME`, `DATETIME`, and `TIMESTAMP` columns without support for fractional seconds precision). This variable is disabled by default. If enabled, `SHOW CREATE TABLE` output looks like this:

```
CREATE TABLE `mytbl` (  
    `ts` timestamp /* 5.5 binary format */ NOT NULL DEFAULT CURRENT_TIMESTAMP,  
    `dt` datetime /* 5.5 binary format */ DEFAULT NULL,  
    `t` time /* 5.5 binary format */ DEFAULT NULL  
) DEFAULT CHARSET=utf8mb4
```

Output for the `COLUMN_TYPE` column of the `INFORMATION_SCHEMA.COLUMNS` table is affected similarly.

This variable is deprecated; expect it to be removed in a future MySQL release.

- `skip_external_locking`

```
Command-Line Format     --skip-external-locking[={OFF|ON}]
System Variable         skip_external_locking
Scope                   Global
Dynamic                 No
SET_VAR Hint Applies    No
Type                    Boolean
Default Value           ON
```

This is `OFF` if `mysqld` uses external locking (system locking), `ON` if external locking is disabled. This affects only `MyISAM` table access.

This variable is set by the `--external-locking` or `--skip-external-locking` option. External locking is disabled by default.

External locking affects only `MyISAM` table access. For more information, including conditions under which it can and cannot be used, see `Section 8.11.5, “External Locking”`.

- `skip_name_resolve`

```
Command-Line Format     --skip-name-resolve[={OFF|ON}]
System Variable         skip_name_resolve
Scope                   Global
Dynamic                 No
SET_VAR Hint Applies    No
Type                    Boolean
Default Value           ON
```

840
Whether to resolve host names when checking client connections. If this variable is OFF, mysqld resolves host names when checking client connections. If it is ON, mysqld uses only IP numbers; in this case, all Host column values in the grant tables must be IP addresses. See Section 5.1.12.3, “DNS Lookups and the Host Cache”.

Depending on the network configuration of your system and the Host values for your accounts, clients may need to connect using an explicit --host option, such as --host=127.0.0.1 or --host=:1.

An attempt to connect to the host 127.0.0.1 normally resolves to the localhost account. However, this fails if the server is run with skip_name_resolve enabled. If you plan to do that, make sure an account exists that can accept a connection. For example, to be able to connect as root using --host=127.0.0.1 or --host=:1, create these accounts:

```
CREATE USER 'root'@'127.0.0.1' IDENTIFIED BY 'root-password';
CREATE USER 'root'@'::1' IDENTIFIED BY 'root-password';
```

* skip_networking

This variable controls whether the server permits TCP/IP connections. By default, it is disabled (permit TCP connections). If enabled, the server permits only local (non-TCP/IP) connections and all interaction with mysqld must be made using named pipes or shared memory (on Windows) or Unix socket files (on Unix). This option is highly recommended for systems where only local clients are permitted. See Section 5.1.12.3, “DNS Lookups and the Host Cache”.

Because starting the server with --skip-grant-tables disables authentication checks, the server also disables remote connections in that case by enabling skip_networking.

* skip_show_database

This prevents people from using the SHOW DATABASES statement if they do not have the SHOW DATABASES privilege. This can improve security if you have concerns about users being able to see databases belonging to other users. Its effect depends on the SHOW DATABASES privilege: If the variable value is ON, the SHOW DATABASES statement is permitted only to users who have the SHOW DATABASES privilege, and the statement displays all database names. If the value is OFF, SHOW DATABASES is permitted to all users.
**DATABASES** is permitted to all users, but displays the names of only those databases for which the user has the **SHOW DATABASES** or other privilege.

**Caution**

Because any static global privilege is considered a privilege for all databases, any static global privilege enables a user to see all database names with **SHOW DATABASES** or by examining the **SCHEMATA** table of **INFORMATION_SCHEMA**, except databases that have been restricted at the database level by partial revokes.

- **slow_launch_time**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--slow-launch-time=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><strong>slow_launch_time</strong></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2</td>
</tr>
</tbody>
</table>

If creating a thread takes longer than this many seconds, the server increments the **Slow_launch_threads** status variable.

- **slow_query_log**

  | Command-Line Format | --slow-query-log=[{OFF|ON}] |
  |---------------------|-----------------------------|
  | System Variable     | **slow_query_log**          |
  | Scope               | Global                      |
  | Dynamic             | Yes                         |
  | SET_VAR Hint Applies| No                          |
  | Type                | Boolean                     |
  | Default Value       | OFF                         |

Whether the slow query log is enabled. The value can be 0 (or **OFF**) to disable the log or 1 (or **ON**) to enable the log. The destination for log output is controlled by the **log_output** system variable; if that value is **NONE**, no log entries are written even if the log is enabled.

“Slow” is determined by the value of the **long_query_time** variable. See Section 5.4.5, “The Slow Query Log”.

- **slow_query_log_file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--slow-query-log-file=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><strong>slow_query_log_file</strong></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>File name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>host_name-slow.log</td>
</tr>
</tbody>
</table>

The name of the slow query log file. The default value is `host_name-slow.log`, but the initial value can be changed with the `--slow_query_log_file` option.

- **socket**

  | Command-Line Format | --socket={file_name|pipe_name} |
  |---------------------|---------------------------------|
  | System Variable     | socket                          |
  | Scope               | Global                          |
  | Dynamic             | No                              |
  | SET_VAR Hint Applies| No                              |
  | Type                | String                          |
  | Default Value (Other)| /tmp/mysql.sock               |
  | Default Value (Windows)| MySQL                      |

On Unix platforms, this variable is the name of the socket file that is used for local client connections. The default is `/tmp/mysql.sock`. (For some distribution formats, the directory might be different, such as `/var/lib/mysql` for RPMs.)

On Windows, this variable is the name of the named pipe that is used for local client connections. The default value is `MySQL` (not case-sensitive).

- **sort_buffer_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--sort-buffer-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>sort_buffer_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>262144</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>32768</td>
</tr>
<tr>
<td>Maximum Value (Other, 64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (Other, 32-bit platforms)</td>
<td>4294967295</td>
</tr>
<tr>
<td>Maximum Value (Windows)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Each session that must perform a sort allocates a buffer of this size. `sort_buffer_size` is not specific to any storage engine and applies in a general manner for optimization. At minimum the `sort_buffer_size` value must be large enough to accommodate fifteen tuples in the sort buffer. Also,
increasing the value of `max_sort_length` may require increasing the value of `sort_buffer_size`. For more information, see Section 8.2.1.16, “ORDER BY Optimization”

If you see many `Sort_merge_passes` per second in `SHOW GLOBAL STATUS` output, you can consider increasing the `sort_buffer_size` value to speed up `ORDER BY` or `GROUP BY` operations that cannot be improved with query optimization or improved indexing.

The optimizer tries to work out how much space is needed but can allocate more, up to the limit. Setting it larger than required globally slows down most queries that perform sorts. It is best to increase it as a session setting, and only for the sessions that need a larger size. On Linux, there are thresholds of 256KB and 2MB where larger values may significantly slow down memory allocation, so you should consider staying below one of those values. Experiment to find the best value for your workload. See Section B.3.3.5, “Where MySQL Stores Temporary Files”.

The maximum permissible setting for `sort_buffer_size` is 4GB−1. Larger values are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB−1 with a warning).

• `sql_auto_is_null`

<table>
<thead>
<tr>
<th>System Variable</th>
<th>sql_auto_is_null</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

If this variable is enabled, then after a statement that successfully inserts an automatically generated `AUTO_INCREMENT` value, you can find that value by issuing a statement of the following form:

```sql
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

If the statement returns a row, the value returned is the same as if you invoked the `LAST_INSERT_ID()` function. For details, including the return value after a multiple-row insert, see Section 12.16, “Information Functions”. If no `AUTO_INCREMENT` value was successfully inserted, the `SELECT` statement returns no row.

The behavior of retrieving an `AUTO_INCREMENT` value by using an `IS NULL` comparison is used by some ODBC programs, such as Access. See Obtaining Auto-Increment Values. This behavior can be disabled by setting `sql_auto_is_null` to `OFF`.

Prior to MySQL 8.0.16, the transformation of `WHERE auto_col IS NULL` to `WHERE auto_col = LAST_INSERT_ID()` was performed only when the statement was executed, so that the value of `sql_auto_is_null` during execution determined whether the query was transformed. In MySQL 8.0.16 and later, the transformation is performed during statement preparation.

The default value of `sql_auto_is_null` is `OFF`.

• `sql_big_selects`

<table>
<thead>
<tr>
<th>System Variable</th>
<th>sql_big_selects</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>
If set to OFF, MySQL aborts SELECT statements that are likely to take a very long time to execute (that is, statements for which the optimizer estimates that the number of examined rows exceeds the value of max_join_size). This is useful when an inadvisable WHERE statement has been issued. The default value for a new connection is ON, which permits all SELECT statements.

If you set the max_join_size system variable to a value other than DEFAULT, sql_big_selects is set to OFF.

• sql_buffer_result

This variable controls whether logging to the general query log is disabled for the current session (assuming that the general query log itself is enabled). The default value is OFF (that is, enable logging). To disable or enable general query logging for the current session, set the session sql_log_off variable to ON or OFF.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

• sql_mode
<table>
<thead>
<tr>
<th>Scope</th>
<th>Global, Session</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Set</td>
</tr>
<tr>
<td>Default Value</td>
<td>ONLY_FULL_GROUP_BY STRICT_TRANS_TABLES NO_ZERO_IN_DATE NO_ZERO_DATE ERROR_FOR_DIVISION_BY_ZERO NO_ENGINE_SUBSTITUTION</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ALLOW_INVALID_DATES ANSI_QUOTES ERROR_FOR_DIVISION_BY_ZERO HIGH_NOT_PRECEDENCE IGNORE_SPACE NO_AUTO_VALUE_ON_ZERO NO_BACKSLASH_ESCAPES NO_DIR_IN_CREATE NO_ENGINE_SUBSTITUTION NO_UNSIGNED_SUBTRACTION NO_ZERO_DATE NO_ZERO_IN_DATE ONLY_FULL_IN_DATE PAD_CHAR_TO_FULL_LENGTH PIPES_AS_CONCAT REAL_AS_FLOAT STRICT_ALL_TABLES STRICT_TRANS_TABLES TIME_TRUNCATE_FRACTIONAL</td>
</tr>
</tbody>
</table>

The current server SQL mode, which can be set dynamically. For details, see Section 5.1.11, “Server SQL Modes”.

**Note**

MySQL installation programs may configure the SQL mode during the installation process.

If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.
### Server System Variables

- **sql_notes**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>sql_notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

If enabled (the default), diagnostics of `Note` level increment `warning_count` and the server records them. If disabled, `Note` diagnostics do not increment `warning_count` and the server does not record them. `mysqldump` includes output to disable this variable so that reloading the dump file does not produce warnings for events that do not affect the integrity of the reload operation.

- **sql_quote_show_create**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>sql_quote_show_create</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

If enabled (the default), the server quotes identifiers for `SHOW CREATE TABLE` and `SHOW CREATE DATABASE` statements. If disabled, quoting is disabled. This option is enabled by default so that replication works for identifiers that require quoting. See Section 13.7.7.10, “SHOW CREATE TABLE Statement”, and Section 13.7.7.6, “SHOW CREATE DATABASE Statement”.

- **sql_require_primary_key**

| Command-Line Format         | --sql-require-primary-key=[{OFF|ON}] |
|----------------------------|-------------------------------------|
| Introduced                 | 8.0.13                              |
| System Variable            | sql_require_primary_key             |
| Scope                      | Global, Session                     |
| Dynamic                    | Yes                                 |
| **SET_VAR** Hint Applies   | Yes                                 |
| Type                       | Boolean                             |
| Default Value              | OFF                                 |

Whether statements that create new tables or alter the structure of existing tables enforce the requirement that tables have a primary key.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

Enabling this variable helps avoid performance problems in row-based replication that can occur when tables have no primary key. Suppose that a table has no primary key and an update or delete modifies multiple rows. On the replication source server, this operation can be performed using a single table
scan but, when replicated using row-based replication, results in a table scan for each row to be modified on the replica. With a primary key, these table scans do not occur.

`sql_require_primary_key` applies to both base tables and `TEMPORARY` tables, and changes to its value are replicated to replica servers. As of MySQL 8.0.18, it applies only to storage engines that can participate in replication.

When enabled, `sql_require_primary_key` has these effects:

- Attempts to create a new table with no primary key fail with an error. This includes `CREATE TABLE ... LIKE`. It also includes `CREATE TABLE ... SELECT`, unless the `CREATE TABLE` part includes a primary key definition.

- Attempts to drop the primary key from an existing table fail with an error, with the exception that dropping the primary key and adding a primary key in the same `ALTER TABLE` statement is permitted.

  Dropping the primary key fails even if the table also contains a `UNIQUE NOT NULL` index.

- Attempts to import a table with no primary key fail with an error.

The `REQUIRE_TABLE_PRIMARY_KEY_CHECK` option of the `CHANGE MASTER TO` statement enables a replica to select its own policy for primary key checks. When the option is set to `ON` for a replication channel, the replica always uses the value `ON` for the `sql_require_primary_key` system variable in replication operations, requiring a primary key. When the option is set to `OFF`, the replica always uses the value `OFF` for the `sql_require_primary_key` system variable in replication operations, so that a primary key is never required, even if the source required one. When the `REQUIRE_TABLE_PRIMARY_KEY_CHECK` option is set to `STREAM`, which is the default, the replica uses whatever value is replicated from the source for each transaction. With the `STREAM` setting for the `REQUIRE_TABLE_PRIMARY_KEY_CHECK` option, if privilege checks are in use for the replication channel, the `PRIVILEGE_CHECKS_USER` account needs privileges sufficient to set restricted session variables, so that it can set the session value for the `sql_require_primary_key` system variable. With the `ON` or `OFF` settings, the account does not need these privileges. For more information, see Section 17.3.3, “Replication Privilege Checks”.

- `sql_safe_updates`

<table>
<thead>
<tr>
<th>System Variable</th>
<th>sql_safe_updates</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

If this variable is enabled, `UPDATE` and `DELETE` statements that do not use a key in the `WHERE` clause or a `LIMIT` clause produce an error. This makes it possible to catch `UPDATE` and `DELETE` statements where keys are not used properly and that would probably change or delete a large number of rows. The default value is `OFF`.

For the `mysql` client, `sql_safe_updates` can be enabled by using the `--safe-updates` option. For more information, see Using Safe-Updates Mode (`--safe-updates`).
### Server System Variables

- **sql_select_limit**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>sql_select_limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

The maximum number of rows to return from `SELECT` statements. For more information, see Using Safe-Updates Mode (`--safe-updates`).

The default value for a new connection is the maximum number of rows that the server permits per table. Typical default values are \((2^{32})-1\) or \((2^{64})-1\). If you have changed the limit, the default value can be restored by assigning a value of **DEFAULT**.

If a `SELECT` has a `LIMIT` clause, the `LIMIT` takes precedence over the value of `sql_select_limit`.

- **sql_warnings**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>sql_warnings</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

This variable controls whether single-row `INSERT` statements produce an information string if warnings occur. The default is **OFF**. Set the value to **ON** to produce an information string.

- **ssl_ca**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ssl-ca=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ssl_ca</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic (≥ 8.0.16)</td>
<td>Yes</td>
</tr>
<tr>
<td>Dynamic (≤ 8.0.15)</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The path name of the Certificate Authority (CA) certificate file in PEM format. The file contains a list of trusted SSL Certificate Authorities.

As of MySQL 8.0.16, this variable is dynamic and can be modified at runtime to affect the TSL context the server uses for new connections. See Server-Side Runtime Configuration and Monitoring for Encrypted Connections. Prior to MySQL 8.0.16, this variable can be set only at server startup.
### Server System Variables

- **ssl_capath**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--ssl-capath=dir_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>ssl_capath</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic (≥ 8.0.16)</td>
<td>Yes</td>
</tr>
<tr>
<td>Dynamic (≤ 8.0.15)</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The path name of the directory that contains trusted SSL Certificate Authority (CA) certificate files in PEM format.

As of MySQL 8.0.16, this variable is dynamic and can be modified at runtime to affect the TSL context the server uses for new connections. See Server-Side Runtime Configuration and Monitoring for Encrypted Connections. Prior to MySQL 8.0.16, this variable can be set only at server startup.

- **ssl_cert**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--ssl-cert=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>ssl_cert</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic (≥ 8.0.16)</td>
<td>Yes</td>
</tr>
<tr>
<td>Dynamic (≤ 8.0.15)</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The path name of the server SSL public key certificate file in PEM format.

If the server is started with `ssl_cert` set to a certificate that uses any restricted cipher or cipher category, the server starts with support for encrypted connections disabled. For information about cipher restrictions, see Connection Cipher Configuration.

As of MySQL 8.0.16, this variable is dynamic and can be modified at runtime to affect the TSL context the server uses for new connections. See Server-Side Runtime Configuration and Monitoring for Encrypted Connections. Prior to MySQL 8.0.16, this variable can be set only at server startup.

- **ssl_cipher**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--ssl-cipher=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>ssl_cipher</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic (≥ 8.0.16)</td>
<td>Yes</td>
</tr>
<tr>
<td>Dynamic (≤ 8.0.15)</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>String</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The list of permissible encryption ciphers for connections that use TLS protocols up through TLSv1.2. If no cipher in the list is supported, encrypted connections that use these TLS protocols do not work.

For greatest portability, the cipher list should be a list of one or more cipher names, separated by colons. Examples:

```
[mysqld]
ssl_cipher="AES128-SHA"
ssl_cipher="DHE-RSA-AES128-GCM-SHA256:AES128-SHA"
```

OpenSSL supports the syntax for specifying ciphers described in the OpenSSL documentation at https://www.openssl.org/docs/manmaster/man1/ciphers.html.

For information about which encryption ciphers MySQL supports, see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

As of MySQL 8.0.16, this variable is dynamic and can be modified at runtime to affect the TSL context the server uses for new connections. See Server-Side Runtime Configuration and Monitoring for Encrypted Connections. Prior to MySQL 8.0.16, this variable can be set only at server startup.

- **ssl_crl**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ssl-crl=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ssl_crl</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic (≥ 8.0.16)</td>
<td>Yes</td>
</tr>
<tr>
<td>Dynamic (≤ 8.0.15)</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The path name of the file containing certificate revocation lists in PEM format.

As of MySQL 8.0.16, this variable is dynamic and can be modified at runtime to affect the TSL context the server uses for new connections. See Server-Side Runtime Configuration and Monitoring for Encrypted Connections. Prior to MySQL 8.0.16, this variable can be set only at server startup.

- **ssl_crlpath**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ssl-crlpath=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ssl_crlpath</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic (≥ 8.0.16)</td>
<td>Yes</td>
</tr>
<tr>
<td>Dynamic (≤ 8.0.15)</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>
Server System Variables

The path of the directory that contains certificate revocation-list files in PEM format.

As of MySQL 8.0.16, this variable is dynamic and can be modified at runtime to affect the TSL context the server uses for new connections. See Server-Side Runtime Configuration and Monitoring for Encrypted Connections. Prior to MySQL 8.0.16, this variable can be set only at server startup.

- **ssl_fips_mode**

  Command-Line Format  
  ```
  --ssl-fips-mode={OFF|ON|STRICT}
  ```

  System Variable  
  `ssl_fips_mode`

  Scope  
  Global

  Dynamic  
  Yes

  `SET_VAR` Hint Applies  
  No

  Type  
  Enumeration

  Default Value  
  OFF

  Valid Values  
  OFF (or 0)  
  ON (or 1)  
  STRICT (or 2)

Controls whether to enable FIPS mode on the server side. The `ssl_fips_mode` system variable differs from other `ssl_xxx` system variables in that it is not used to control whether the server permits encrypted connections, but rather to affect which cryptographic operations are permitted. See Section 6.8, “FIPS Support”.

These `ssl_fips_mode` values are permitted:

- **OFF** (or 0): Disable FIPS mode.
- **ON** (or 1): Enable FIPS mode.
- **STRICT** (or 2): Enable “strict” FIPS mode.

**Note**

If the OpenSSL FIPS Object Module is not available, the only permitted value for `ssl_fips_mode` is **OFF**. In this case, setting `ssl_fips_mode` to **ON** or **STRICT** at startup causes the server to produce an error message and exit.

- **ssl_key**

  Command-Line Format  
  ```
  --ssl-key=file_name
  ```

  System Variable  
  `ssl_key`

  Scope  
  Global

  Dynamic (≥ 8.0.16)  
  Yes

  Dynamic (≤ 8.0.15)  
  No

  `SET_VAR` Hint Applies  
  No

  Type  
  File name
Server System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>NULL</th>
</tr>
</thead>
</table>

The path name of the server SSL private key file in PEM format. For better security, use a certificate with an RSA key size of at least 2048 bits.

If the key file is protected by a passphrase, the server prompts the user for the passphrase. The password must be given interactively; it cannot be stored in a file. If the passphrase is incorrect, the program continues as if it could not read the key.

As of MySQL 8.0.16, this variable is dynamic and can be modified at runtime to affect the TSL context the server uses for new connections. See Server-Side Runtime Configuration and Monitoring for Encrypted Connections. Prior to MySQL 8.0.16, this variable can be set only at server startup.

- **stored_program_cache**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--stored-program-cache=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>stored_program_cache</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>256</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>16</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>524288</td>
</tr>
</tbody>
</table>

Sets a soft upper limit for the number of cached stored routines per connection. The value of this variable is specified in terms of the number of stored routines held in each of the two caches maintained by the MySQL Server for, respectively, stored procedures and stored functions.

Whenever a stored routine is executed this cache size is checked before the first or top-level statement in the routine is parsed; if the number of routines of the same type (stored procedures or stored functions according to which is being executed) exceeds the limit specified by this variable, the corresponding cache is flushed and memory previously allocated for cached objects is freed. This allows the cache to be flushed safely, even when there are dependencies between stored routines.

The stored procedure and stored function caches exists in parallel with the stored program definition cache partition of the dictionary object cache. The stored procedure and stored function caches are per connection, while the stored program definition cache is shared. The existence of objects in the stored procedure and stored function caches have no dependence on the existence of objects in the stored program definition cache, and vice versa. For more information, see Section 14.4, “Dictionary Object Cache”.

- **stored_program_definition_cache**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--stored-program-definition-cache=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>stored_program_definition_cache</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

853
Server System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>256</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td>256</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>524288</td>
</tr>
</tbody>
</table>

Defines a limit for the number of stored program definition objects, both used and unused, that can be kept in the dictionary object cache.

Unused stored program definition objects are only kept in the dictionary object cache when the number in use is less than the capacity defined by `stored_program_definition_cache`.

A setting of 0 means that stored program definition objects are only kept in the dictionary object cache while they are in use.

The stored program definition cache partition exists in parallel with the stored procedure and stored function caches that are configured using the `stored_program_cache` option.

The `stored_program_cache` option sets a soft upper limit for the number of cached stored procedures or functions per connection, and the limit is checked each time a connection executes a stored procedure or function. The stored program definition cache partition, on the other hand, is a shared cache that stores stored program definition objects for other purposes. The existence of objects in the stored program definition cache partition has no dependence on the existence of objects in the stored procedure cache or stored function cache, and vice versa.

For related information, see Section 14.4, “Dictionary Object Cache”.

- `super_read_only`

| Command-Line Format | --super-read-only=[OFF|ON] |
|---------------------|---------------------------|
| System Variable     | `super_read_only`         |
| Scope               | Global                    |
| Dynamic             | Yes                       |
| `SET_VAR` Hint Applies | No                        |
| Type                | Boolean                   |
| Default Value       | OFF                       |

If the `read_only` system variable is enabled, the server permits no client updates except from users who have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege). If the `super_read_only` system variable is also enabled, the server prohibits client updates even from users who have `CONNECTION_ADMIN` or `SUPER`. See the description of the `read_only` system variable for a description of read-only mode and information about how `read_only` and `super_read_only` interact.

Client updates prevented when `super_read_only` is enabled include operations that do not necessarily appear to be updates, such as `CREATE FUNCTION` (to install a UDF), `INSTALL PLUGIN`, and `INSTALL COMPONENT`. These operations are prohibited because they involve changes to tables in the `mysql` system schema.

Changes to `super_read_only` on a replication source server are not replicated to replica servers. The value can be set on a replica independent of the setting on the source.

- `syseventlog.facility`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--syseventlog.facility=value</th>
</tr>
</thead>
</table>
### syseventlog.facility

<table>
<thead>
<tr>
<th>Introduced</th>
<th>8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>syseventlog.facility</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>daemon</td>
</tr>
</tbody>
</table>

The facility for error log output written to `syslog` (what type of program is sending the message). This variable is unavailable unless the `log_sink_syseventlog` error log component is installed. See Section 5.4.2.8, “Error Logging to the System Log”.

The permitted values can vary per operating system; consult your system `syslog` documentation.

This variable does not exist on Windows.

- **syseventlog.include_pid**

| Command-Line Format | --syseventlog.include-pid={OFF|ON} |
|---------------------|-----------------------------------|
| Introduced          | 8.0.13 |
| System Variable     | syseventlog.include_pid |
| Scope               | Global |
| Dynamic             | Yes    |
| SET_VAR Hint Applies| No     |
| Type                | Boolean |
| Default Value       | ON     |

Whether to include the server process ID in each line of error log output written to `syslog`. This variable is unavailable unless the `log_sink_syseventlog` error log component is installed. See Section 5.4.2.8, “Error Logging to the System Log”.

This variable does not exist on Windows.

- **syseventlog.tag**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--syseventlog.tag=tag</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.13</td>
</tr>
<tr>
<td>System Variable</td>
<td>syseventlog.tag</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>empty string</th>
</tr>
</thead>
</table>

The tag to be added to the server identifier in error log output written to syslog or the Windows Event Log. This variable is unavailable unless the log_sink_syseventlog error log component is installed. See Section 5.4.2.8, “Error Logging to the System Log”.

By default, no tag is set, so the server identifier is simply MySQL on Windows, and mysqld on other platforms. If a tag value of tag is specified, it is appended to the server identifier with a leading hyphen, resulting in a syslog identifier of mysqld-tag (or MySQL-tag on Windows).

On Windows, to use a tag that does not already exist, the server must be run from an account with Administrator privileges, to permit creation of a registry entry for the tag. Elevated privileges are not required if the tag already exists.

- system_time_zone

<table>
<thead>
<tr>
<th>System Variable</th>
<th>system_time_zone</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The server system time zone. When the server begins executing, it inherits a time zone setting from the machine defaults, possibly modified by the environment of the account used for running the server or the startup script. The value is used to set system_time_zone. Typically the time zone is specified by the TZ environment variable. It also can be specified using the --timezone option of the mysqld_safe script.

The system_time_zone variable differs from time_zone. Although they might have the same value, the latter variable is used to initialize the time zone for each client that connects. See Section 5.1.15, “MySQL Server Time Zone Support”.

- table_definition_cache

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--table-definition-cache=#</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

The number of table definitions that can be stored in the definition cache. If you use a large number of tables, you can create a large table definition cache to speed up opening of tables. The table definition
Server System Variables

cache takes less space and does not use file descriptors, unlike the normal table cache. The minimum value is 400. The default value is based on the following formula, capped to a limit of 2000:

\[
\text{MIN}(400 + \text{table_open_cache} / 2, 2000)
\]

For InnoDB, **table_definition_cache** acts as a soft limit for the number of open table instances in the InnoDB data dictionary cache. If the number of open table instances exceeds the **table_definition_cache** setting, the LRU mechanism begins to mark table instances for eviction and eventually removes them from the data dictionary cache. The limit helps address situations in which significant amounts of memory would be used to cache rarely used table instances until the next server restart. The number of table instances with cached metadata could be higher than the limit defined by **table_definition_cache**, because parent and child table instances with foreign key relationships are not placed on the LRU list and are not subject to eviction from memory.

Additionally, **table_definition_cache** defines a soft limit for the number of InnoDB file-per-table tablespaces that can be open at one time, which is also controlled by **innodb_open_files**. If both **table_definition_cache** and **innodb_open_files** are set, the highest setting is used. If neither variable is set, **table_definition_cache**, which has a higher default value, is used. If the number of open tablespace file handles exceeds the limit defined by **table_definition_cache** or **innodb_open_files**, the LRU mechanism searches the tablespace file LRU list for files that are fully flushed and are not currently being extended. This process is performed each time a new tablespace is opened. If there are no “inactive” tablespaces, no tablespace files are closed.

The table definition cache exists in parallel with the table definition cache partition of the dictionary object cache. Both caches store table definitions but serve different parts of the MySQL server. Objects in one cache have no dependence on the existence objects in the other. For more information, see Section 14.4, “Dictionary Object Cache”.

- **table_encryption_privilege_check**

| Command-Line Format | --table-encryption-privilege-check={OFF|ON} |
|---------------------|---------------------------------------|
| Introduced          | 8.0.16                                 |
| System Variable     | table_encryption_privilege_check       |
| Scope               | Global                                |
| Dynamic             | Yes                                   |
| SET_VAR Hint Applies| No                                    |
| Type                | Boolean                               |
| Default Value       | OFF                                   |

Controls the **TABLE_ENCRYPTION_ADMIN** privilege check that occurs when creating or altering a schema or general tablespace with encryption that differs from the **default_table_encryption** setting, or when creating or altering a table with an encryption setting that differs from the default schema encryption. The check is disabled by default.

Setting **table_encryption_privilege_check** at runtime requires the **SUPER** privilege.

**table_encryption_privilege_check** supports **SET** **PERSIST** and **SET** **PERSIST_ONLY** syntax. See Section 5.1.9.3, “Persisted System Variables”.

For more information, see Defining an Encryption Default for Schemas and General Tablespaces.
• **table_open_cache**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--table-open-cache=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>table_open_cache</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>524288</td>
</tr>
</tbody>
</table>

The number of open tables for all threads. Increasing this value increases the number of file descriptors that `mysqld` requires. You can check whether you need to increase the table cache by checking the `Opened_tables` status variable. See Section 5.1.10, “Server Status Variables”. If the value of `Opened_tables` is large and you do not use `FLUSH TABLES` often (which just forces all tables to be closed and reopened), then you should increase the value of the `table_open_cache` variable. For more information about the table cache, see Section 8.4.3.1, “How MySQL Opens and Closes Tables”.

• **table_open_cache_instances**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--table-open-cache-instances=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>table_open_cache_instances</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>16</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>64</td>
</tr>
</tbody>
</table>

The number of open tables cache instances. To improve scalability by reducing contention among sessions, the open tables cache can be partitioned into several smaller cache instances of size `table_open_cache/table_open_cache_instances`. A session needs to lock only one instance to access it for DML statements. This segments cache access among instances, permitting higher performance for operations that use the cache when there are many sessions accessing tables. (DDL statements still require a lock on the entire cache, but such statements are much less frequent than DML statements.)

A value of 8 or 16 is recommended on systems that routinely use 16 or more cores.

• **tablespace_definition_cache**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--tablespace-definition-cache=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>tablespace_definition_cache</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Server System Variables

<table>
<thead>
<tr>
<th>SET_VAR</th>
<th>Hint Applies</th>
<th>No</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
<td></td>
</tr>
<tr>
<td>Default Value</td>
<td>256</td>
<td></td>
</tr>
<tr>
<td>Minimum Value</td>
<td>256</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td>524288</td>
<td></td>
</tr>
</tbody>
</table>

Defines a limit for the number of tablespace definition objects, both used and unused, that can be kept in the dictionary object cache.

Unused tablespace definition objects are only kept in the dictionary object cache when the number in use is less than the capacity defined by `tablespace_definition_cache`.

A setting of 0 means that tablespace definition objects are only kept in the dictionary object cache while they are in use.

For more information, see Section 14.4, “Dictionary Object Cache”.

• **temptable_max_ram**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--temptable-max-ram=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>temptable_max_ram</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1073741824</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>2097152</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>$2^{64}-1$</td>
</tr>
</tbody>
</table>

Defines the maximum amount of memory that can be occupied by the TempTable storage engine before it starts storing data on disk. The default value is 1073741824 bytes (1GiB). For more information, see Section 8.4.4, “Internal Temporary Table Use in MySQL”.

• **temptable_use_mmap**

  | Command-Line Format | `--temptable-use-mmap[{OFF|ON}]` |
  |---------------------|---------------------------------|
  | Introduced          | 8.0.16                          |
  | System Variable     | `temptable_use_mmap`            |
  | Scope               | Global                          |
  | Dynamic             | Yes                             |
  | SET_VAR Hint Applies| No                              |
  | Type                | Boolean                         |
  | Default Value       | ON                              |

Defines whether the TempTable storage engine allocates space for internal in-memory temporary tables as memory-mapped temporary files when the amount of memory occupied by the TempTable storage engine exceeds the limit defined by the `temptable_max_ram` variable. When `temptable_use_mmap`
is disabled, the TempTable storage engine uses InnoDB on-disk internal temporary tables instead. For more information, see Section 8.4.4, “Internal Temporary Table Use in MySQL”.

- **thread_cache_size**

  ```
  Command-Line Format  --thread-cache-size=#
  System Variable      thread_cache_size
  Scope                Global
  Dynamic              Yes
  SET_VAR Hint Applies No
  Type                 Integer
  Default Value        -1 (signifies autosizing; do not assign this literal value)
  Minimum Value        0
  Maximum Value        16384
  ```

  How many threads the server should cache for reuse. When a client disconnects, the client’s threads are put in the cache if there are fewer than `thread_cache_size` threads there. Requests for threads are satisfied by reusing threads taken from the cache if possible, and only when the cache is empty is a new thread created. This variable can be increased to improve performance if you have a lot of new connections. Normally, this does not provide a notable performance improvement if you have a good thread implementation. However, if your server sees hundreds of connections per second you should normally set `thread_cache_size` high enough so that most new connections use cached threads. By examining the difference between the Connections and Threads_created status variables, you can see how efficient the thread cache is. For details, see Section 5.1.10, “Server Status Variables”.

  The default value is based on the following formula, capped to a limit of 100:

  $\text{8 + (max_connections / 100)}$

- **thread_handling**

  ```
  Command-Line Format  --thread-handling=name
  System Variable      thread_handling
  Scope                Global
  Dynamic              No
  SET_VAR Hint Applies No
  Type                 Enumeration
  Default Value        one-thread-per-connection
  Valid Values         no-threads
                       one-thread-per-connection
                       loaded-dynamically
  ```

  The thread-handling model used by the server for connection threads. The permissible values are no-threads (the server uses a single thread to handle one connection), one-thread-per-connection (the server uses one thread to handle each client connection), and loaded-dynamically (set by the thread pool plugin when it initializes). no-threads is useful for debugging under Linux; see Section 5.9, “Debugging MySQL”.

860
### thread_pool_algorithm

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--thread-pool-algorithm=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>thread_pool_algorithm</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

This variable controls which algorithm the thread pool plugin uses:

- A value of 0 (the default) uses a conservative low-concurrency algorithm which is most well tested and is known to produce very good results.

- A value of 1 increases the concurrency and uses a more aggressive algorithm which at times has been known to perform 5–10% better on optimal thread counts, but has degrading performance as the number of connections increases. Its use should be considered as experimental and not supported.

This variable is available only if the thread pool plugin is enabled. See Section 5.6.3, “MySQL Enterprise Thread Pool”

### thread_pool_high_priority_connection

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--thread-pool-high-priority-connection=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>thread_pool_high_priority_connection</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

This variable affects queuing of new statements prior to execution. If the value is 0 (false, the default), statement queuing uses both the low-priority and high-priority queues. If the value is 1 (true), queued statements always go to the high-priority queue.

This variable is available only if the thread pool plugin is enabled. See Section 5.6.3, “MySQL Enterprise Thread Pool”

### thread_pool_max_active_query_threads

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--thread-pool-max-active-query-threads</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.19</td>
</tr>
<tr>
<td>System Variable</td>
<td>thread_pool_max_active_query_threads</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>512</td>
</tr>
</tbody>
</table>

The maximum permissible number of active (running) query threads per group. If the value is 0, the thread pool plugin uses up to as many threads as are available.

This variable is available only if the thread pool plugin is enabled. See Section 5.6.3, “MySQL Enterprise Thread Pool”

- **thread_pool_max_unused_threads**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--thread-pool-max-unused-threads=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>thread_pool_max_unused_threads</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4096</td>
</tr>
</tbody>
</table>

The maximum permitted number of unused threads in the thread pool. This variable makes it possible to limit the amount of memory used by sleeping threads.

A value of 0 (the default) means no limit on the number of sleeping threads. A value of $N$ where $N$ is greater than 0 means 1 consumer thread and $N-1$ reserve threads. In this case, if a thread is ready to sleep but the number of sleeping threads is already at the maximum, the thread exits rather than going to sleep.

A sleeping thread is either sleeping as a consumer thread or a reserve thread. The thread pool permits one thread to be the consumer thread when sleeping. If a thread goes to sleep and there is no existing consumer thread, it sleeps as a consumer thread. When a thread must be woken up, a consumer thread is selected if there is one. A reserve thread is selected only when there is no consumer thread to wake up.

This variable is available only if the thread pool plugin is enabled. See Section 5.6.3, “MySQL Enterprise Thread Pool”

- **thread_pool_prio_kickup_timer**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--thread-pool-prio-kickup-timer=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>thread_pool_prio_kickup_timer</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Dynamic</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967294</td>
</tr>
</tbody>
</table>

This variable affects statements waiting for execution in the low-priority queue. The value is the number of milliseconds before a waiting statement is moved to the high-priority queue. The default is 1000 (1 second).

This variable is available only if the thread pool plugin is enabled. See Section 5.6.3, "MySQL Enterprise Thread Pool"

- **thread_pool_size**

  Command-Line Format  
  
  ```
  --thread-pool-size=#
  ```

  System Variable  
  
  `thread_pool_size`

  Scope  
  
  Global

  Dynamic  
  
  No

  **SET_VAR** Hint Applies  
  
  No

  Type  
  
  Integer

  Default Value  
  
  16

  Minimum Value  
  
  1

  Maximum Value (≥ 8.0.19)  
  
  512

  Maximum Value (≤ 8.0.18)  
  
  64

  The number of thread groups in the thread pool. This is the most important parameter controlling thread pool performance. It affects how many statements can execute simultaneously. If a value outside the range of permissible values is specified, the thread pool plugin does not load and the server writes a message to the error log.

  This variable is available only if the thread pool plugin is enabled. See Section 5.6.3, "MySQL Enterprise Thread Pool"

- **thread_pool_stall_limit**

  Command-Line Format  
  
  ```
  --thread-pool-stall-limit=#
  ```

  System Variable  
  
  `thread_pool_stall_limit`

  Scope  
  
  Global

  Dynamic  
  
  Yes

  **SET_VAR** Hint Applies  
  
  No

  Type  
  
  Integer

  Default Value  
  
  6

  Minimum Value  
  
  4

  Maximum Value  
  
  600
This variable affects executing statements. The value is the amount of time a statement has to finish after starting to execute before it becomes defined as stalled, at which point the thread pool permits the thread group to begin executing another statement. The value is measured in 10 millisecond units, so the default of 6 means 60ms. Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

This variable is available only if the thread pool plugin is enabled. See Section 5.6.3, “MySQL Enterprise Thread Pool”

- **thread_stack**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--thread-stack=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>thread_stack</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value (64-bit platforms)</td>
<td>286720</td>
</tr>
<tr>
<td>Default Value (32-bit platforms)</td>
<td>221184</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>131072</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
<tr>
<td>Block Size</td>
<td>1024</td>
</tr>
</tbody>
</table>

The stack size for each thread. The default is large enough for normal operation. If the thread stack size is too small, it limits the complexity of the SQL statements that the server can handle, the recursion depth of stored procedures, and other memory-consuming actions.

- **time_zone**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>time_zone</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies (≥ 8.0.17)</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies (≤ 8.0.16)</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>SYSTEM</td>
</tr>
<tr>
<td>Minimum Value (≥ 8.0.19)</td>
<td>-14:00</td>
</tr>
<tr>
<td>Minimum Value (≤ 8.0.18)</td>
<td>-12:59</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Maximum Value (≥ 8.0.19)</th>
<th>+14:00</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum Value (≤ 8.0.18)</td>
<td>+13:00</td>
</tr>
</tbody>
</table>

The current time zone. This variable is used to initialize the time zone for each client that connects. By default, the initial value of this is 'SYSTEM' (which means, "use the value of system_time_zone"). The value can be specified explicitly at server startup with the --default-time-zone option. See Section 5.1.15, "MySQL Server Time Zone Support".

Note

If set to SYSTEM, every MySQL function call that requires a time zone calculation makes a system library call to determine the current system time zone. This call may be protected by a global mutex, resulting in contention.

- timestamp

<table>
<thead>
<tr>
<th>System Variable</th>
<th>timestamp</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>UNIX_TIMESTAMP()</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

Set the time for this client. This is used to get the original timestamp if you use the binary log to restore rows. timestamp_value should be a Unix epoch timestamp (a value like that returned by UNIX_TIMESTAMP(), not a value in 'YYYY-MM-DD hh:mm:ss' format) or DEFAULT.

Setting timestamp to a constant value causes it to retain that value until it is changed again. Setting timestamp to DEFAULT causes its value to be the current date and time as of the time it is accessed.

timestamp is a DOUBLE rather than BIGINT because its value includes a microseconds part. The maximum value corresponds to '2038-01-19 03:14:07' UTC, the same as for the TIMESTAMP data type.

SET timestamp affects the value returned by NOW() but not by SYSDATE(). This means that timestamp settings in the binary log have no effect on invocations of SYSDATE(). The server can be started with the --sysdate-is-now option to cause SYSDATE() to be a synonym for NOW(), in which case SET timestamp affects both functions.

- tls_ciphersuites

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--tls-ciphersuites=ciphersuite_list</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.16</td>
</tr>
<tr>
<td>System Variable</td>
<td>tls_ciphersuites</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

Which ciphersuites the server permits for encrypted connections that use TLSv1.3. The value is a list of zero or more colon-separated ciphersuite names.

The ciphersuites that can be named for this variable depend on the SSL library used to compile MySQL. If this variable is not set, its default value is NULL, which means that the server permits the default set of ciphersuites. If the variable is set to the empty string, no ciphersuites are enabled and encrypted connections cannot be established. For more information, see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

- **tls_version**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--tls-version=protocol_list</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>tls_version</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic (≥ 8.0.16)</td>
<td>Yes</td>
</tr>
<tr>
<td>Dynamic (≤ 8.0.15)</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value (≥ 8.0.16)</td>
<td>TLSv1,TLSv1.1,TLSv1.2,TLSv1.3 (OpenSSL 1.1.1 and higher)</td>
</tr>
<tr>
<td></td>
<td>TLSv1,TLSv1.1,TLSv1.2 (otherwise)</td>
</tr>
<tr>
<td>Default Value (≤ 8.0.15)</td>
<td>TLSv1,TLSv1.1,TLSv1.2</td>
</tr>
</tbody>
</table>

Which protocols the server permits for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this variable depend on the SSL library used to compile MySQL. Permitted protocols should be chosen such as not to leave “holes” in the list. For details, see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

As of MySQL 8.0.16, this variable is dynamic and can be modified at runtime to affect the TSL context the server uses for new connections. See Server-Side Runtime Configuration and Monitoring for Encrypted Connections. Prior to MySQL 8.0.16, this variable can be set only at server startup.

- **tmp_table_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>

<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>16777216</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1024</td>
</tr>
</tbody>
</table>
Server System Variables

Maximum Value | 18446744073709551615
--- | ---
The maximum size of internal in-memory temporary tables. This variable does not apply to user-created MEMORY tables.

The actual limit is the smaller of `tmp_table_size` and `max_heap_table_size`. When an in-memory temporary table exceeds the limit, MySQL automatically converts it to an on-disk temporary table.

Increase the value of `tmp_table_size` (and `max_heap_table_size` if necessary) if you do many advanced GROUP BY queries and you have lots of memory.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing `Created_tmp_disk_tables` and `Created_tmp_tables` values.

See also Section 8.4.4, "Internal Temporary Table Use in MySQL".

- `tmpdir`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--tmpdir=dir_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>tmpdir</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

The path of the directory to use for creating temporary files. It might be useful if your default /tmp directory resides on a partition that is too small to hold temporary tables. This variable can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (:) on Unix and semicolon characters (;) on Windows.

`tmpdir` can be a non-permanent location, such as a directory on a memory-based file system or a directory that is cleared when the server host restarts. If the MySQL server is acting as a replica, and you are using a non-permanent location for `tmpdir`, consider setting a different temporary directory for the replica using the `slave_load_tmpdir` variable. For a replica, the temporary files used to replicate LOAD DATA statements are stored in this directory, so with a permanent location they can survive machine restarts, although replication can now continue after a restart if the temporary files have been removed.

For more information about the storage location of temporary files, see Section B.3.3.5, "Where MySQL Stores Temporary Files".

- `transaction_alloc_block_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--transaction-alloc-block-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>transaction_alloc_block_size</code></td>
</tr>
<tr>

</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8192</td>
</tr>
</tbody>
</table>
The amount in bytes by which to increase a per-transaction memory pool which needs memory. See the description of `transaction_prealloc_size`.

- `transaction_isolation`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--transaction-isolation=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>transaction_isolation</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>REPEATABLE-READ</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>READ-UNCOMMITTED</code></td>
</tr>
<tr>
<td></td>
<td><code>READ-COMMITTED</code></td>
</tr>
<tr>
<td></td>
<td><code>REPEATABLE-READ</code></td>
</tr>
<tr>
<td></td>
<td><code>SERIALIZABLE</code></td>
</tr>
</tbody>
</table>

The transaction isolation level. The default is `REPEATABLE-READ`.

The transaction isolation level has three scopes: global, session, and next transaction. This three-scope implementation leads to some nonstandard isolation-level assignment semantics, as described later.

To set the global transaction isolation level at startup, use the `--transaction-isolation` server option.

At runtime, the isolation level can be set directly using the `SET` statement to assign a value to the `transaction_isolation` system variable, or indirectly using the `SET TRANSACTION` statement. If you set `transaction_isolation` directly to an isolation level name that contains a space, the name should be enclosed within quotation marks, with the space replaced by a dash. For example, use this `SET` statement to set the global value:

```sql
SET GLOBAL transaction_isolation = 'READ-COMMITTED';
```

Setting the global `transaction_isolation` value sets the isolation level for all subsequent sessions. Existing sessions are unaffected.

To set the session or next-level `transaction_isolation` value, use the `SET` statement. For most session system variables, these statements are equivalent ways to set the value:

```sql
SET @@SESSION.var_name = value;
SET SESSION var_name = value;
SET var_name = value;
```
As mentioned previously, the transaction isolation level has a next-transaction scope, in addition to the
global and session scopes. To enable the next-transaction scope to be set, SET syntax for assigning
session system variable values has nonstandard semantics for transaction_isolation:

- To set the session isolation level, use any of these syntaxes:

  ```sql
  SET @@SESSION.transaction_isolation = value;
  SET SESSION transaction_isolation = value;
  SET transaction_isolation = value;
  ```

  For each of those syntaxes, these semantics apply:
  
  - Sets the isolation level for all subsequent transactions performed within the session.
  - Permitted within transactions, but does not affect the current ongoing transaction.
  - If executed between transactions, overrides any preceding statement that sets the next-transaction
    isolation level.
  - Corresponds to SET SESSION TRANSACTION ISOLATION LEVEL (with the SESSION keyword).

- To set the next-transaction isolation level, use this syntax:

  ```sql
  SET @@transaction_isolation = value;
  ```

  For that syntax, these semantics apply:
  
  - Sets the isolation level only for the next single transaction performed within the session.
  - Subsequent transactions revert to the session isolation level.
  - Not permitted within transactions.
  - Corresponds to SET TRANSACTION ISOLATION LEVEL (without the SESSION keyword).

For more information about SET TRANSACTION and its relationship to the transaction_isolation
system variable, see Section 13.3.7, “SET TRANSACTION Statement”.

- `transaction_prealloc_size`
There is a per-transaction memory pool from which various transaction-related allocations take memory. The initial size of the pool in bytes is `transaction_prealloc_size`. For every allocation that cannot be satisfied from the pool because it has insufficient memory available, the pool is increased by `transaction_alloc_block_size` bytes. When the transaction ends, the pool is truncated to `transaction_prealloc_size` bytes.

By making `transaction_prealloc_size` sufficiently large to contain all statements within a single transaction, you can avoid many `malloc()` calls.

### Command-Line Format

| Command-Line Format | `--transaction-read-only[={OFF|ON}]` |
|---------------------|--------------------------------------|
| System Variable     | `transaction_read_only` |
| Scope               | Global, Session |
| Dynamic             | Yes |
| `SET_VAR` Hint Applies | No |
| Type                | Boolean |
| Default Value       | OFF |

The transaction access mode. The value can be OFF (read/write; the default) or ON (read only).

The transaction access mode has three scopes: global, session, and next transaction. This three-scope implementation leads to some nonstandard access-mode assignment semantics, as described later.

To set the global transaction access mode at startup, use the `--transaction-read-only` server option.

At runtime, the access mode can be set directly using the `SET` statement to assign a value to the `transaction_read_only` system variable, or indirectly using the `SET TRANSACTION` statement. For example, use this `SET` statement to set the global value:

```
SET GLOBAL transaction_read_only = ON;
```

Setting the global `transaction_read_only` value sets the access mode for all subsequent sessions. Existing sessions are unaffected.

To set the session or next-level `transaction_read_only` value, use the `SET` statement. For most session system variables, these statements are equivalent ways to set the value:

```
SET @SESSION.var_name = value;
SET SESSION var_name = value;
SET var_name = value;
SET @@var_name = value;
```

As mentioned previously, the transaction access mode has a next-transaction scope, in addition to the global and session scopes. To enable the next-transaction scope to be set, `SET` syntax for assigning session system variable values has nonstandard semantics for `transaction_read_only`,

### To set the session access mode, use any of these syntaxes:

```
SET @SESSION.transaction_read_only = value;
SET SESSION transaction_read_only = value;
```
Server System Variables

**Server System Variables**

```sql
SET transaction_read_only = value;
```

For each of those syntaxes, these semantics apply:

- Sets the access mode for all subsequent transactions performed within the session.
- Permitted within transactions, but does not affect the current ongoing transaction.
- If executed between transactions, overrides any preceding statement that sets the next-transaction access mode.
- Corresponds to `SET SESSION TRANSACTION {READ WRITE | READ ONLY}` (with the `SESSION` keyword).

To set the next-transaction access mode, use this syntax:

```sql
SET @@transaction_read_only = value;
```

For that syntax, these semantics apply:

- Sets the access mode only for the next single transaction performed within the session.
- Subsequent transactions revert to the session access mode.
- Not permitted within transactions.
- Corresponds to `SET TRANSACTION {READ WRITE | READ ONLY}` (without the `SESSION` keyword).

For more information about `SET TRANSACTION` and its relationship to the `transaction_read_only` system variable, see Section 13.3.7, “SET TRANSACTION Statement”.

### unique_checks

<table>
<thead>
<tr>
<th>System Variable</th>
<th>unique_checks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

If set to 1 (the default), uniqueness checks for secondary indexes in `InnoDB` tables are performed. If set to 0, storage engines are permitted to assume that duplicate keys are not present in input data. If you know for certain that your data does not contain uniqueness violations, you can set this to 0 to speed up large table imports to `InnoDB`.

Setting this variable to 0 does not require storage engines to ignore duplicate keys. An engine is still permitted to check for them and issue duplicate-key errors if it detects them.

### updatable_views_with_limit

| Command-Line Format             | --updatable-views-with-limit=[{OFF|ON}] |
|--------------------------------|----------------------------------------|
| System Variable                | `updatable_views_with_limit`           |
| Scope                          | Global, Session                        |

871
This variable controls whether updates to a view can be made when the view does not contain all columns of the primary key defined in the underlying table, if the update statement contains a \texttt{LIMIT} clause. (Such updates often are generated by GUI tools.) An update is an \texttt{UPDATE} or \texttt{DELETE} statement. Primary key here means a \texttt{PRIMARY KEY}, or a \texttt{UNIQUE} index in which no column can contain \texttt{NULL}.

The variable can have two values:

- \texttt{1} or \texttt{YES}: Issue a warning only (not an error message). This is the default value.
- \texttt{0} or \texttt{NO}: Prohibit the update.

\texttt{use_secondary_engine}

For future use.

- \texttt{validate_password.xxx}

The \texttt{validate_password} component implements a set of system variables having names of the form \texttt{validate_password.xxx}. These variables affect password testing by that component; see Section 6.4.3.2, “Password Validation Options and Variables”.

- \texttt{validate_user_plugins}
Server System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>ON</th>
</tr>
</thead>
</table>

If this variable is enabled (the default), the server checks each user account and produces a warning if conditions are found that would make the account unusable:

- The account requires an authentication plugin that is not loaded.
- The account requires the `sha256_password` or `caching_sha2_password` authentication plugin but the server was started with neither SSL nor RSA enabled as required by the plugin.

Enabling `validate_user_plugins` slows down server initialization and `FLUSH PRIVILEGES`. If you do not require the additional checking, you can disable this variable at startup to avoid the performance decrement.

- **version**

  The version number for the server. The value might also include a suffix indicating server build or configuration information. `-debug` indicates that the server was built with debugging support enabled.

- **version_comment**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>version_comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

  The **CMake** configuration program has a `COMPILATION_COMMENT_SERVER` option that permits a comment to be specified when building MySQL. This variable contains the value of that comment. (Prior to MySQL 8.0.14, `version_comment` is set by the `COMPILATION_COMMENT` option.) See Section 2.9.7, “MySQL Source-Configuration Options”.

- **version_compile_machine**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>version_compile_machine</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

  The type of the server binary.

- **version_compile_os**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>version_compile_os</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

  The type of operating system on which MySQL was built.
Server System Variables

- **version_compile_zlib**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>version_compile_zlib</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The version of the compiled-in `zlib` library.

- **wait_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--wait-timeout=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>wait_timeout</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>28800</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value (Other)</td>
<td>31536000</td>
</tr>
<tr>
<td>Maximum Value (Windows)</td>
<td>2147483</td>
</tr>
</tbody>
</table>

The number of seconds the server waits for activity on a noninteractive connection before closing it.

On thread startup, the session `wait_timeout` value is initialized from the global `wait_timeout` value or from the global `interactive_timeout` value, depending on the type of client (as defined by the `CLIENT_INTERACTIVE` connect option to `mysql_real_connect()`). See also `interactive_timeout`.

- **warning_count**

The number of errors, warnings, and notes that resulted from the last statement that generated messages. This variable is read only. See Section 13.7.7.42, “SHOW WARNINGS Statement”.

- **windowing_use_high_precision**

| Command-Line Format     | --windowing-use-high-precision=[{OFF|ON}] |
|-------------------------|------------------------------------------|
| System Variable         | windowing_use_high_precision             |
| Scope                   | Global, Session                          |
| Dynamic                 | Yes                                       |
| SET_VAR Hint Applies    | Yes                                       |
| Type                    | Boolean                                  |
| Default Value           | ON                                        |

Whether to compute window operations without loss of precision. See Section 8.2.1.21, “Window Function Optimization”.
5.1.9 Using System Variables

The MySQL server maintains many system variables that configure its operation. Section 5.1.8, “Server System Variables”, describes the meaning of these variables. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically while the server is running by means of the set statement, which enables you to modify operation of the server without having to stop and restart it. You can also use system variable values in expressions.

Many system variables are built in. System variables may also be installed by server plugins or components:

- System variables implemented by a server plugin are exposed when the plugin is installed and have names that begin with the plugin name. For example, the audit_log plugin implements a system variable named audit_log_policy.

- System variables implemented by a server component are exposed when the component is installed and have names that begin with a component-specific prefix. For example, the log_filter_dragnet error log filter component implements a system variable named log_error_filter_rules, the full name of which is dragnet.log_error_filter_rules. To refer to this variable, use the full name.

There are two scopes in which system variables exist. Global variables affect the overall operation of the server. Session variables affect its operation for individual client connections. A given system variable can have both a global and a session value. Global and session system variables are related as follows:

- When the server starts, it initializes each global variable to its default value. These defaults can be changed by options specified on the command line or in an option file. (See Section 4.2.2, “Specifying Program Options”.)

- The server also maintains a set of session variables for each client that connects. The client's session variables are initialized at connect time using the current values of the corresponding global variables. For example, a client's SQL mode is controlled by the session sql_mode value, which is initialized when the client connects to the value of the global sql_mode value.

For some system variables, the session value is not initialized from the corresponding global value; if so, that is indicated in the variable description.

System variable values can be set globally at server startup by using options on the command line or in an option file. At startup, the syntax for system variables is the same as for command options, so within variable names, dashes and underscores may be used interchangeably. For example, --general_log=ON and --general-log=ON are equivalent.

When you use a startup option to set a variable that takes a numeric value, the value can be given with a suffix of K, M, or G (either uppercase or lowercase) to indicate a multiplier of 1024, 1024² or 1024³; that is, units of kilobytes, megabytes, or gigabytes, respectively. As of MySQL 8.0.14, a suffix can also be T, P, and E to indicate a multiplier of 1024⁴, 1024⁵ or 1024⁶. Thus, the following command starts the server with an InnoDB log file size of 16 megabytes and a maximum packet size of one gigabyte:

```
mysqld --innodb-log-file-size=16M --max-allowed-packet=1G
```

Within an option file, those variables are set like this:

```
[mysqld]
inno
db_log_file_size=16M
max_allowed_packet=1G
```

The lettercase of suffix letters does not matter; 16M and 16m are equivalent, as are 1G and 1g.
To restrict the maximum value to which a system variable can be set at runtime with the `SET` statement, specify this maximum by using an option of the form `--maximum-var_name=value` at server startup. For example, to prevent the value of `innodb_log_file_size` from being increased to more than 32MB at runtime, use the option `--maximum-innodb-log-file-size=32M`.

Many system variables are dynamic and can be changed at runtime by using the `SET` statement. For a list, see Section 5.1.9.2, “Dynamic System Variables”. To change a system variable with `SET`, refer to it by name, optionally preceded by a modifier. At runtime, system variable names must be written using underscores, not dashes. The following examples briefly illustrate this syntax:

- Set a global system variable:
  ```
  SET GLOBAL max_connections = 1000;
  SET @@GLOBAL.max_connections = 1000;
  ```

- Persist a global system variable to the `mysqld-auto.cnf` file (and set the runtime value):
  ```
  SET PERSIST max_connections = 1000;
  SET @@PERSIST.max_connections = 1000;
  ```

- Persist a global system variable to the `mysqld-auto.cnf` file (without setting the runtime value):
  ```
  SET PERSIST_ONLY back_log = 1000;
  SET @@PERSIST_ONLY.back_log = 1000;
  ```

- Set a session system variable:
  ```
  SET SESSION sql_mode = 'TRADITIONAL';
  SET @@SESSION.sql_mode = 'TRADITIONAL';
  SET @sql_mode = 'TRADITIONAL';
  ```

For complete details about `SET` syntax, see Section 13.7.6.1, “SET Syntax for Variable Assignment”. For a description of the privilege requirements for setting and persisting system variables, see Section 5.1.9.1, “System Variable Privileges”.

Suffixes for specifying a value multiplier can be used when setting a variable at server startup, but not to set the value with `SET` at runtime. On the other hand, with `SET` you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at server startup, but the second is not:

```shell
shell> mysql --max_allowed_packet=16M
shell> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```shell
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

Note

Some system variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. However, to set such a variable on the command line or in an option file, you must set it to `1` or `0`; setting it to `ON` or `OFF` does not work. For example, on the command line, `--delay_key_write=1` works but `--delay_key_write=ON` does not.

To display system variable names and values, use the `SHOW VARIABLES` statement:

```shell
mysql> SHOW VARIABLES;
```

</tbody>
</table>

With a LIKE clause, the statement displays only those variables that match the pattern. To obtain a specific variable name, use a LIKE clause as shown:

SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';

To get a list of variables whose name match a pattern, use the % wildcard character in a LIKE clause:

SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because _ is a wildcard that matches any single character, you should escape it as \_ to match it literally. In practice, this is rarely necessary.

For SHOW VARIABLES, if you specify neither GLOBAL nor SESSION, MySQL returns SESSION values.

The reason for requiring the GLOBAL keyword when setting GLOBAL-only variables but not when retrieving them is to prevent problems in the future:

- Were a SESSION variable to be removed that has the same name as a GLOBAL variable, a client with privileges sufficient to modify global variables might accidentally change the GLOBAL variable rather than just the SESSION variable for its own session.
- Were a SESSION variable to be added with the same name as a GLOBAL variable, a client that intends to change the GLOBAL variable might find only its own SESSION variable changed.

5.1.9.1 System Variable Privileges
Using System Variables

A system variable can have a global value that affects server operation as a whole, a session value that affects only the current session, or both:

- For dynamic system variables, the `SET` statement can be used to change their global or session runtime value (or both), to affect operation of the current server instance. (For information about dynamic variables, see Section 5.1.9.2, “Dynamic System Variables”.)

- For certain global system variables, `SET` can be used to persist their value to the `mysqld-auto.cnf` file in the data directory, to affect server operation for subsequent startups. (For information about persisting system variables and the `mysqld-auto.cnf` file, see Section 5.1.9.3, “Persisted System Variables”.)

- For persisted global system variables, `RESET PERSIST` can be used to remove their value from `mysqld-auto.cnf`, to affect server operation for subsequent startups.

This section describes the privileges required for operations that assign values to system variables at runtime. This includes operations that affect runtime values, and operations that persist values.

To set a global system variable, use a `SET` statement with the appropriate keyword. These privileges apply:

- To set a global system variable runtime value, use the `SET GLOBAL` statement, which requires the `SYSTEM_VARIABLES_ADMIN` privilege (or the deprecated `SUPER` privilege).

- To persist a global system variable to the `mysqld-auto.cnf` file (and set the runtime value), use the `SET PERSIST` statement, which requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege.

- To persist a global system variable to the `mysqld-auto.cnf` file (without setting the runtime value), use the `SET PERSISTONLY` statement, which requires the `SYSTEM_VARIABLES_ADMIN` and `PERSIST_RO_VARIABLES_ADMIN` privileges. `SET PERSISTONLY` can be used for both dynamic and read-only system variables, but is particularly useful for persisting read-only variables, for which `SET PERSIST` cannot be used.

- Some global system variables are persist-restricted (see Section 5.1.9.4, “Nonpersistible and Persist-Restricted System Variables”). To persist these variables, use the `SET PERSISTONLY` statement, which requires the privileges described previously. In addition, you must connect to the server using an encrypted connection and supply an SSL certificate with the Subject value specified by the `persist_only_admin_x509_subject` system variable.

To remove a persisted global system variable from the `mysqld-auto.cnf` file, use the `RESET PERSIST` statement. These privileges apply:

- For dynamic system variables, `RESET PERSIST` requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege.

- For read-only system variables, `RESET PERSIST` requires the `SYSTEM_VARIABLES_ADMIN` and `PERSIST_RO_VARIABLES_ADMIN` privileges.

- For persist-restricted variables, `RESET PERSIST` does not require an encrypted connection to the server made using a particular SSL certificate.

If a global system variable has any exceptions to the preceding privilege requirements, the variable description indicates those exceptions. Examples include `default_table_encryption` and `mandatory_roles`, which require additional privileges. These additional privileges apply to operations that set the global runtime value, but not operations that persist the value.

To set a session system variable runtime value, use the `SET SESSION` statement. In contrast to setting global runtime values, setting session runtime values normally requires no special privileges and can be done by any user to affect the current session. For some system variables, setting the session value may
have effects outside the current session and thus is a restricted operation that can be done only by users who have a special privilege:

- As of MySQL 8.0.14, the privilege required is `SESSION_VARIABLES_ADMIN`.

**Note**

Any user who has `SYSTEM_VARIABLES_ADMIN` or `SUPER` effectively has `SESSION_VARIABLES_ADMIN` by implication and need not be granted `SESSION_VARIABLES_ADMIN` explicitly.

- Prior to MySQL 8.0.14, the privilege required is `SYSTEM_VARIABLES_ADMIN` or `SUPER`.

If a session system variable is restricted, the variable description indicates that restriction. Examples include `binlog_format` and `sql_log_bin`. Setting the session value of these variables affects binary logging for the current session, but may also have wider implications for the integrity of server replication and backups.

`SESSION_VARIABLES_ADMIN` enables administrators to minimize the privilege footprint of users who may previously have been granted `SYSTEM_VARIABLES_ADMIN` or `SUPER` for the purpose of enabling them to modify restricted session system variables. Suppose that an administrator has created the following role to confer the ability to set restricted session system variables:

```sql
CREATE ROLE set_session_sysvars;
GRANT SYSTEM_VARIABLES_ADMIN ON *.* TO set_session_sysvars;
```

Any user granted the `set_session_sysvars` role (and who has that role active) is able to set restricted session system variables. However, that user is also able to set global system variables, which may be undesirable.

By modifying the role to have `SESSION_VARIABLES_ADMIN` instead of `SYSTEM_VARIABLES_ADMIN`, the role privileges can be reduced to the ability to set restricted session system variables and nothing else. To modify the role, use these statements:

```sql
GRANT SESSION_VARIABLES_ADMIN ON *.* TO set_session_sysvars;
REVOKE SYSTEM_VARIABLES_ADMIN ON *.* FROM set_session_sysvars;
```

Modifying the role has an immediate effect: Any account granted the `set_session_sysvars` role no longer has `SYSTEM_VARIABLES_ADMIN` and is not able to set global system variables without being granted that ability explicitly. A similar `GRANT/REVOKE` sequence can be applied to any account that was granted `SYSTEM_VARIABLES_ADMIN` directly rather than by means of a role.

### 5.1.9.2 Dynamic System Variables

Many server system variables are dynamic and can be set at runtime. See Section 13.7.6.1, "SET Syntax for Variable Assignment". For a description of the privilege requirements for setting system variables, see Section 5.1.9.1, "System Variable Privileges"

The following table lists all dynamic system variables applicable within `mysqld`.

The table lists each variable's data type and scope. The last column indicates whether the scope for each variable is Global, Session, or both. Please see the corresponding item descriptions for details on setting and using the variables. Where appropriate, direct links to further information about the items are provided.

Variables that have a type of "string" take a string value. Variables that have a type of "numeric" take a numeric value. Variables that have a type of "boolean" can be set to 0, 1, `ON` or `OFF`. Variables that are marked as "enumeration" normally should be set to one of the available values for the variable, but can also be set to the number that corresponds to the desired enumeration value. For enumerated system...
variables, the first enumeration value corresponds to 0. This differs from the **ENUM** data type used for table columns, for which the first enumeration value corresponds to 1.

### Table 5.4 Dynamic System Variable Summary

#### 5.1.9.3 Persisted System Variables

The MySQL server maintains system variables that configure its operation. A system variable can have a global value that affects server operation as a whole, a session value that affects the current session, or both. Many system variables are dynamic and can be changed at runtime using the `SET` statement to affect operation of the current server instance. `SET` can also be used to persist certain global system variables to the `mysqld-auto.cnf` file in the data directory, to affect server operation for subsequent startups. `RESET PERSIST` removes persisted settings from `mysqld-auto.cnf`. 
Using System Variables

The following discussion describes aspects of persisting system variables:

- **Overview of Persisted System Variables**
- **Syntax for Persisting System Variables**
- **Obtaining Information About Persisted System Variables**
- **Format and Server Handling of the mysqld-auto.cnf File**

**Overview of Persisted System Variables**

The capability of persisting global system variables at runtime enables server configuration that persists across server startups. Although many system variables can be set at startup from a `my.cnf` option file, or at runtime using the `SET` statement, those methods of configuring the server either require login access to the server host, or do not provide the capability of persistently configuring the server at runtime or remotely:

- Modifying an option file requires direct access to that file, which requires login access to the MySQL server host. This is not always convenient.

- Modifying system variables with `SET GLOBAL` is a runtime capability that can be done from clients run locally or from remote hosts, but the changes affect only the currently running server instance. The settings are not persistent and do not carry over to subsequent server startups.

To augment administrative capabilities for server configuration beyond what is achievable by editing option files or using `SET GLOBAL`, MySQL provides variants of `SET` syntax that persist system variable settings to a file named `mysqld-auto.cnf` file in the data directory. Examples:

```
SET PERSIST max_connections = 1000;
SET @@PERSIST.max_connections = 1000;
SET PERSIST ONLY back_log = 100;
SET @@PERSIST_ONLY.back_log = 100;
```

MySQL also provides a `RESET PERSIST` statement for removing persisted system variables from `mysqld-auto.cnf`.

Server configuration performed by persisting system variables has these characteristics:

- Persisted settings are made at runtime.
- Persisted settings are permanent. They apply across server restarts.
- Persisted settings can be made from local clients or clients who connect from a remote host. This provides the convenience of remotely configuring multiple MySQL servers from a central client host.

- To persist system variables, you need not have login access to the MySQL server host or file system access to option files. Ability to persist settings is controlled using the MySQL privilege system. See [Section 5.1.9.1, “System Variable Privileges”](#).

- An administrator with sufficient privileges can reconfigure a server by persisting system variables, then cause the server to use the changed settings immediately by executing a `RESTART` statement.

- Persisted settings provide immediate feedback about errors. An error in a manually entered setting might not be discovered until much later. `SET` statements that persist system variables avoid the possibility of malformed settings because settings with syntax errors do not succeed and do not change server configuration.
Syntax for Persisting System Variables

These `SET` syntax options are available for persisting system variables:

- To persist a global system variable to the `mysqld-auto.cnf` option file in the data directory, precede the variable name by the `PERSIST` keyword or the `@@PERSIST.` qualifier:

  ```
  SET PERSIST max_connections = 1000;
  SET @@PERSIST.max_connections = 1000;
  ```

  Like `SET GLOBAL, SET PERSIST` sets the global variable runtime value, but also writes the variable setting to the `mysqld-auto.cnf` file (replacing any existing variable setting if there is one).

- To persist a global system variable to the `mysqld-auto.cnf` file without setting the global variable runtime value, precede the variable name by the `PERSIST_ONLY` keyword or the `@@PERSIST_ONLY.` qualifier:

  ```
  SET PERSIST_ONLY back_log = 1000;
  SET @@PERSIST_ONLY.back_log = 1000;
  ```

  Like `PERSIST, PERSIST_ONLY` writes the variable setting to `mysqld-auto.cnf`. However, unlike `PERSIST, PERSIST_ONLY` does not modify the global variable runtime value. This makes `PERSIST_ONLY` suitable for configuring read-only system variables that can be set only at server startup.

For more information about `SET`, see [Section 13.7.6.1, “SET Syntax for Variable Assignment”](#).

These `RESET PERSIST` syntax options are available for removing persisted system variables:

- To remove all persisted variables from `mysqld-auto.cnf`, use `RESET PERSIST` without naming any system variable:

  ```
  RESET PERSIST;
  ```

- To remove a specific persisted variable from `mysqld-auto.cnf`, name it in the statement:

  ```
  RESET PERSIST system_var_name;
  ```

  This includes plugin system variables, even if the plugin is not currently installed. If the variable is not present in the file, an error occurs.

- To remove a specific persisted variable from `mysqld-auto.cnf`, but produce a warning rather than an error if the variable is not present in the file, add an `IF EXISTS` clause to the previous syntax:

  ```
  RESET PERSIST IF EXISTS system_var_name;
  ```

For more information about `RESET PERSIST`, see [Section 13.7.8.7, “RESET PERSIST Statement”](#).

Using `SET` to persist a global system variable to a value of `DEFAULT` or to its literal default value assigns the variable its default value and adds a setting for the variable to `mysqld-auto.cnf`. To remove the variable from the file, use `RESET PERSIST`.

Some system variables cannot be persisted. See [Section 5.1.9.4, “Nonpersistible and Persist-Restricted System Variables”](#).

A system variable implemented by a plugin can be persisted if the plugin is installed when the `SET` statement is executed. Assignment of the persisted plugin variable takes effect for subsequent server restarts if the plugin is still installed. If the plugin is no longer installed, the plugin variable does not exist
Using System Variables

when the server reads the `mysqld-auto.cnf` file. In this case, the server writes a warning to the error log and continues:

```
currently unknown variable 'var_name'
was read from the persisted config file
```

Obtaining Information About Persisted System Variables

The Performance Schema `persisted_variables` table provides an SQL interface to the `mysqld-auto.cnf` file, enabling its contents to be inspected at runtime using `SELECT` statements. See Section 26.12.14.1, “Performance Schema persisted_variables Table”.

The Performance Schema `variables_info` table contains information showing when and by which user each system variable was most recently set. See Section 26.12.14.2, “Performance Schema variables_info Table”.

`RESET PERSIST` affects the contents of the `persisted_variables` table because the table contents correspond to the contents of the `mysqld-auto.cnf` file. On the other hand, because `RESET PERSIST` does not change variable values, it has no effect on the contents of the `variables_info` table until the server is restarted.

Format and Server Handling of the mysqld-auto.cnf File

The `mysqld-auto.cnf` file uses a JSON format like this (reformatted slightly for readability):

```
{
   "Version": 1,
   "mysql_server": {
      "max_connections": {
         "Value": "152",
         "Metadata": {
            "Timestamp": 1519921341372531,
            "User": "root",
            "Host": "localhost"
         }
      },
      "transaction_isolation": {
         "Value": "READ-COMMITTED",
         "Metadata": {
            "Timestamp": 1519921553880520,
            "User": "root",
            "Host": "localhost"
         }
      },
      "mysql_server_static_options": {
         "innodb_api_enable_mdl": {
            "Value": "0",
            "Metadata": {
               "Timestamp": 1519922873467872,
               "User": "root",
               "Host": "localhost"
            }
         },
         "log_slave_updates": {
            "Value": "1",
            "Metadata": {
               "Timestamp": 1519925628441588,
               "User": "root",
               "Host": "localhost"
            }
         }
      }
   }
}
```
At startup, the server processes the `mysqld-auto.cnf` file after all other option files (see Section 4.2.2.2, “Using Option Files”). The server handles the file contents as follows:

- If the `persisted_globals_load` system variable is disabled, the server ignores the `mysqld-auto.cnf` file.

- Only read-only variables persisted using `SET PERSIST_ONLY` appear in the "mysql_server_static_options" section. All variables present inside this section are appended to the command line and processed with other command-line options.

- All remaining persisted variables are set by executing the equivalent of a `SET GLOBAL` statement later, just before the server starts listening for client connections. These settings therefore do not take effect until late in the startup process, which might be unsuitable for certain system variables. It may be preferable to set such variables in `my.cnf` rather than in `mysqld-auto.cnf`.

Management of the `mysqld-auto.cnf` file should be left to the server. Manipulation of the file should be performed only using `SET` and `RESET PERSIST` statements, not manually:

- Removal of the file results in a loss of all persisted settings at the next server startup. (This is permissible if your intent is to reconfigure the server without these settings.) To remove all settings in the file without removing the file itself, use this statement:
  ```
  RESET PERSIST;
  ```

- Manual changes to the file may result in a parse error at server startup. In this case, the server reports an error and exits. If this issue occurs, start the server with the `persisted_globals_load` system variable disabled or with the `--no-defaults` option. Alternatively, remove the `mysqld-auto.cnf` file. However, as noted previously, removing this file results in a loss of all persisted settings.

### 5.1.9.4 Nonpersistible and Persist-Restricted System Variables

`SET PERSIST` and `SET PERSIST_ONLY` enable global system variables to be persisted to the `mysqld-auto.cnf` option file in the data directory (see Section 13.7.6.1, “SET Syntax for Variable Assignment”). However, not all system variables can be persisted, or can be persisted only under certain restrictive conditions. Here are some reasons why a system variable might be nonpersistible or persist-restricted:

- Session system variables cannot be persisted. Session variables cannot be set at server startup, so there is no reason to persist them.

- A global system variable might involve sensitive data such that it should be settable only by a user with direct access to the server host.

- A global system variable might be read only (that is, set only by the server). In this case, it cannot be set by users at all, whether at server startup or at runtime.

- A global system variable might be intended only for internal use.

Nonpersistible system variables cannot be persisted under any circumstances. As of MySQL 8.0.14, persist-restricted system variables can be persisted with `SET PERSIST_ONLY`, but only by users for which the following conditions are satisfied:

- The `persist_only_admin_x509_subject` system variable is set to an SSL certificate X.509 Subject value.

- The user connects to the server using an encrypted connection and supplies an SSL certificate with the designated Subject value.

- The user has sufficient privileges to use `SET PERSIST_ONLY` (see Section 5.1.9.1, “System Variable Privileges”).
Using System Variables

For example, `protocol_version` is read only and set only by the server, so it cannot be persisted under any circumstances. On the other hand, `bind_address` is persist-restricted, so it can be set by users who satisfy the preceding conditions.

The following system variables are nonpersistible. This list may change with ongoing development.

```plaintext

To configure the server to enable persisting persist-restricted system variables, use this procedure:

1. Ensure that MySQL is configured to support encrypted connections. See Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

2. Designate an SSL certificate X.509 Subject value that signifies the ability to persist persist-restricted system variables, and generate a certificate that has that Subject. See Section 6.3.3, “Creating SSL and RSA Certificates and Keys”.

3. Start the server with persist_only_admin_x509_subject set to the designated Subject value. For example, put these lines in your server my.cnf file:

```
[mysqld]
persist_only_admin_x509_subject="subject-value"
```

The format of the Subject value is the same as used for CREATE USER ... REQUIRE SUBJECT. See Section 13.7.1.3, “CREATE USER Statement”. 
You must perform this step directly on the MySQL server host because `persist_only_admin_x509_subject` itself cannot be persisted at runtime.

4. Restart the server.

5. Distribute the SSL certificate that has the designated Subject value to users who are to be permitted to persist persist-restricted system variables.

Suppose that `myclient-cert.pem` is the SSL certificate to be used by clients who can persist persist-restricted system variables. Display the certificate contents using the `openssl` command:

```shell
openssl x509 -text -in myclient-cert.pem
```

Certificate:

```
Data:
  Version: 3 (0x2)
  Serial Number: 2 (0x2)
  Signature Algorithm: md5WithRSAEncryption
  Issuer: C=US, ST=IL, L=Chicago, O=MyOrg, OU=CA, CN=MyCN
  Validity
    Not Before: Oct 18 17:03:03 2018 GMT
    Not After : Oct 15 17:03:03 2028 GMT
  Subject: C=US, ST=IL, L=Chicago, O=MyOrg, OU=client, CN=MyCN
```

The `openssl` output shows that the certificate Subject value is:

```
C=US, ST=IL, L=Chicago, O=MyOrg, OU=client, CN=MyCN
```

To specify the Subject for MySQL, use this format:

```
/C=US/ST=IL/L=Chicago/O=MyOrg/OU=client/CN=MyCN
```

Configure the server `my.cnf` file with the Subject value:

```
[mysqld]
persist_only_admin_x509_subject="/C=US/ST=IL/L=Chicago/O=MyOrg/OU=client/CN=MyCN"
```

Restart the server so that the new configuration takes effect.

Distribute the SSL certificate (and any other associated SSL files) to the appropriate users. Such a user then connects to the server with the certificate and any other SSL options required to establish an encrypted connection.

To use X.509, clients must specify the `--ssl-key` and `--ssl-cert` options to connect. It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified. For example:

```shell
mysql --ssl-key=myclient-key.pem --ssl-cert=myclient-cert.pem --ssl-ca=mycacert.pem
```

Assuming that the user has sufficient privileges to use `SET PERSIST_ONLY`, persist-restricted system variables can be persisted like this:

```sql
mysql> SET PERSIST_ONLY socket = '/tmp/mysql.sock';
Query OK, 0 rows affected (0.00 sec)
```

If the server is not configured to enable persisting persist-restricted system variables, or the user does not satisfy the required conditions for that capability, an error occurs:

```sql
mysql> SET PERSIST_ONLY socket = '/tmp/mysql.sock';
ERROR 1238 (HY000): Variable 'socket' is a non persistent read only variable
```
5.1.9.5 Structured System Variables

A structured variable differs from a regular system variable in two respects:

- Its value is a structure with components that specify server parameters considered to be closely related.
- There might be several instances of a given type of structured variable. Each one has a different name and refers to a different resource maintained by the server.

MySQL supports one structured variable type, which specifies parameters governing the operation of key caches. A key cache structured variable has these components:

- `key_buffer_size`
- `key_cache_block_size`
- `key_cache_division_limit`
- `key_cache_age_threshold`

This section describes the syntax for referring to structured variables. Key cache variables are used for syntax examples, but specific details about how key caches operate are found elsewhere, in Section 8.10.2, “The MyISAM Key Cache”.

To refer to a component of a structured variable instance, you can use a compound name in `instance_name.component_name` format. Examples:

```
hot_cache.key_buffer_size
hot_cache.key_cache_block_size
cold_cache.key_cache_block_size
```

For each structured system variable, an instance with the name of `default` is always predefined. If you refer to a component of a structured variable without any instance name, the `default` instance is used. Thus, `default.key_buffer_size` and `key_buffer_size` both refer to the same system variable.

Structured variable instances and components follow these naming rules:

- For a given type of structured variable, each instance must have a name that is unique within variables of that type. However, instance names need not be unique across structured variable types. For example, each structured variable has an instance named `default`, so `default` is not unique across variable types.

- The names of the components of each structured variable type must be unique across all system variable names. If this were not true (that is, if two different types of structured variables could share component member names), it would not be clear which default structured variable to use for references to member names that are not qualified by an instance name.

- If a structured variable instance name is not legal as an unquoted identifier, refer to it as a quoted identifier using backticks. For example, `hot-cache` is not legal, but ``hot-cache`` is.

- `global`, `session`, and `local` are not legal instance names. This avoids a conflict with notation such as `@@GLOBAL.var_name` for referring to nonstructured system variables.

Currently, the first two rules have no possibility of being violated because the only structured variable type is the one for key caches. These rules may assume greater significance if some other type of structured variable is created in the future.

With one exception, you can refer to structured variable components using compound names in any context where simple variable names can occur. For example, you can assign a value to a structured variable using a command-line option:
Server Status Variables

Shell> mysqld --hot_cache.key_buffer_size=64K

In an option file, use this syntax:

[mysqld]
hot_cache.key_buffer_size=64K

If you start the server with this option, it creates a key cache named `hot_cache` with a size of 64KB in addition to the default key cache that has a default size of 8MB.

Suppose that you start the server as follows:

Shell> mysqld --key_buffer_size=256K \
    --extra_cache.key_buffer_size=128K \
    --extra_cache.key_cache_block_size=2048

In this case, the server sets the size of the default key cache to 256KB. (You could also have written `--default.key_buffer_size=256K`.) In addition, the server creates a second key cache named `extra_cache` that has a size of 128KB, with the size of block buffers for caching table index blocks set to 2048 bytes.

The following example starts the server with three different key caches having sizes in a 3:1:1 ratio:

Shell> mysqld --key_buffer_size=6M \
    --hot_cache.key_buffer_size=2M \
    --cold_cache.key_buffer_size=2M

Structured variable values may be set and retrieved at runtime as well. For example, to set a key cache named `hot_cache` to a size of 10MB, use either of these statements:

MySQL> SET GLOBAL hot_cache.key_buffer_size = 10*1024*1024;
MySQL> SET @@GLOBAL.hot_cache.key_buffer_size = 10*1024*1024;

To retrieve the cache size, do this:

MySQL> SELECT @@GLOBAL.hot_cache.key_buffer_size;

However, the following statement does not work. The variable is not interpreted as a compound name, but as a simple string for a `LIKE` pattern-matching operation:

MySQL> SHOW GLOBAL VARIABLES LIKE 'hot_cache.key_buffer_size';

This is the exception to being able to use structured variable names anywhere a simple variable name may occur.

### 5.1.10 Server Status Variables

The MySQL server maintains many status variables that provide information about its operation. You can view these variables and their values by using the `SHOW [GLOBAL | SESSION] STATUS` statement (see Section 13.7.7.37, “SHOW STATUS Statement”). The optional `GLOBAL` keyword aggregates the values over all connections, and `SESSION` shows the values for the current connection.

MySQL> SHOW GLOBAL STATUS;

+----------------+----------------+|
| Variable_name  | Value          |
|----------------+----------------+|
| Aborted_clients| 0              |
| Aborted_connects| 0             |
| Bytes_received | 155372598      |
| Bytes_sent     | 1176560426     |
| ...            |                |
| Connections    | 30023          |
| Created_tmp_disk_tables | 0   |
|----------------+----------------+|

905
Many status variables are reset to 0 by the `FLUSH STATUS` statement.

This section provides a description of each status variable. For a status variable summary, see Section 5.1.6, "Server Status Variable Reference".

The status variables have the following meanings.

- **Aborted_clients**
  
  The number of connections that were aborted because the client died without closing the connection properly. See Section B.3.2.9, “Communication Errors and Aborted Connections”.

- **Aborted_connects**
  
  The number of failed attempts to connect to the MySQL server. See Section B.3.2.9, “Communication Errors and Aborted Connections”.

  For additional connection-related information, check the `Connection_errors_xxx` status variables and the `host_cache` table.

- **Authentication_ldap_sasl_supported_methods**
  
  The `authentication_ldap_sasl` plugin that implements SASL LDAP authentication supports multiple authentication methods, but depending on host system configuration, they might not all be available. The `Authentication_ldap_sasl_supported_methods` variable provides discoverability for the supported methods. Its value is a string consisting of supported method names separated by spaces. Example: "SCRAM-SHA 1 SCRAM-SHA-256 GSSAPI"

  This variable was added in MySQL 8.0.21.

- **Binlog_cache_disk_use**
  
  The number of transactions that used the temporary binary log cache but that exceeded the value of `binlog_cache_size` and used a temporary file to store statements from the transaction.

  The number of nontransactional statements that caused the binary log transaction cache to be written to disk is tracked separately in the `Binlog_stmt_cache_disk_use` status variable.

- **Acl_cache_items_count**
  
  The number of cached privilege objects. Each object is the privilege combination of a user and its active roles.

- **Binlog_cache_use**
  
  The number of transactions that used the binary log cache.

- **Binlog_stmt_cache_disk_use**
  
  The number of nontransactional statements that used the binary log statement cache but that exceeded the value of `binlog_stmt_cache_size` and used a temporary file to store those statements.
Server Status Variables

• **Binlog_stmt_cache_use**
  The number of nontransactional statements that used the binary log statement cache.

• **Bytes_received**
  The number of bytes received from all clients.

• **Bytes_sent**
  The number of bytes sent to all clients.

• **Caching_sha2_password_rsa_public_key**
  The public key used by the `caching_sha2_password` authentication plugin for RSA key pair-based password exchange. The value is nonempty only if the server successfully initializes the private and public keys in the files named by the `caching_sha2_password_private_key_path` and `caching_sha2_password_public_key_path` system variables. The value of `Caching_sha2_password_rsa_public_key` comes from the latter file.

• **Com_***
  The `Com_***` statement counter variables indicate the number of times each `***` statement has been executed. There is one status variable for each type of statement. For example, `Com_delete` and `Com_update` count `DELETE` and `UPDATE` statements, respectively. `Com_delete_multi` and `Com_update_multi` are similar but apply to `DELETE` and `UPDATE` statements that use multiple-table syntax.

  All `Com_stmt_***` variables are increased even if a prepared statement argument is unknown or an error occurred during execution. In other words, their values correspond to the number of requests issued, not to the number of requests successfully completed. For example, because status variables are initialized for each server startup and do not persist across restarts, the `Com_restart` and `Com_shutdown` variables that track `RESTART` and `SHUTDOWN` statements normally have a value of zero, but can be nonzero if `RESTART` or `SHUTDOWN` statements were executed but failed.

  The `Com_stmt_***` status variables are as follows:

  • **Com_stmt_prepare**
  • **Com_stmt_execute**
  • **Com_stmt_fetch**
  • **Com_stmt_send_long_data**
  • **Com_stmt_reset**
  • **Com_stmt_close**

  Those variables stand for prepared statement commands. Their names refer to the `COM_***` command set used in the network layer. In other words, their values increase whenever prepared statement API calls such as `mysql_stmt_prepare()`, `mysql_stmt_execute()`, and so forth are executed. However, `Com_stmt_prepare`, `Com_stmt_execute` and `Com_stmt_close` also increase for `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE`, respectively. Additionally, the values of the older statement counter variables `Com_prepare_sql`, `Com_execute_sql`, and `Com_dealloc_sql` increase for the `PREPARE`, `EXECUTE`, and `DEALLOCATE PREPARE` statements. `Com_stmt_fetch` stands for the total number of network round-trips issued when fetching from cursors.
Server Status Variables

Com_stmt_reprepare indicates the number of times statements were automatically reprepared by the server, for example, after metadata changes to tables or views referred to by the statement. A reprepare operation increments Com_stmt_reprepare, and also Com_stmt_prepare.

Com_explain_other indicates the number of EXPLAIN FOR CONNECTION statements executed. See Section 8.8.4, “Obtaining Execution Plan Information for a Named Connection”.

Com_change_repl_filter indicates the number of CHANGE REPLICATION FILTER statements executed.

• Compression

Whether the client connection uses compression in the client/server protocol.

As of MySQL 8.0.18, this status variable is deprecated; expect it to be removed in a future version of MySQL. See Configuring Legacy Connection Compression.

• Compression_algorithm

The name of the compression algorithm in use for the current connection to the server. The value can be any algorithm permitted in the value of the protocol_compression_algorithms system variable. For example, the value is uncompressed if the connection does not use compression, or zlib if the connection uses the zlib algorithm.

For more information, see Section 4.2.8, “Connection Compression Control”.

This variable was added in MySQL 8.0.18.

• Compression_level

The compression level in use for the current connection to the server. The value is 6 for zlib connections (the default zlib algorithm compression level), 1 to 22 for zstd connections, and 0 for uncompressed connections.

For more information, see Section 4.2.8, “Connection Compression Control”.

This variable was added in MySQL 8.0.18.

• Connection_errors_xxx

These variables provide information about errors that occur during the client connection process. They are global only and represent error counts aggregated across connections from all hosts. These variables track errors not accounted for by the host cache (see Section 5.1.12.3, “DNS Lookups and the Host Cache”), such as errors that are not associated with TCP connections, occur very early in the connection process (even before an IP address is known), or are not specific to any particular IP address (such as out-of-memory conditions).

• Connection_errors_accept

The number of errors that occurred during calls to accept() on the listening port.

• Connection_errors_internal

The number of connections refused due to internal errors in the server, such as failure to start a new thread or an out-of-memory condition.

• Connection_errors_max_connections
Server Status Variables

The number of connections refused because the server `max_connections` limit was reached.

- **Connection_errors_peer_address**
  
  The number of errors that occurred while searching for connecting client IP addresses.

- **Connection_errors_select**
  
  The number of errors that occurred during calls to `select()` or `poll()` on the listening port. (Failure of this operation does not necessarily mean a client connection was rejected.)

- **Connection_errors/tcpwrap**
  
  The number of connections refused by the `libwrap` library.

- **Connections**
  
  The number of connection attempts (successful or not) to the MySQL server.

- **Created_tmp_disk_tables**
  
  The number of internal on-disk temporary tables created by the server while executing statements.

  You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing `Created_tmp_disk_tables` and `Created_tmp_tables` values.

  
  **Note**
  
  Due to a known limitation, `Created_tmp_disk_tables` does not count on-disk temporary tables created in memory-mapped files. By default, the TempTable storage engine overflow mechanism creates internal temporary tables in memory-mapped files. This behavior is controlled by the `temptable_use_mmap` variable, which is enabled by default.

  See also Section 8.4.4, “Internal Temporary Table Use in MySQL”.

- **Created_tmp_files**
  
  How many temporary files `mysqld` has created.

- **Created_tmp_tables**
  
  The number of internal temporary tables created by the server while executing statements.

  You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing `Created_tmp_disk_tables` and `Created_tmp_tables` values.

  See also Section 8.4.4, “Internal Temporary Table Use in MySQL”.

  Each invocation of the `SHOW STATUS` statement uses an internal temporary table and increments the global `Created_tmp_tables` value.
Server Status Variables

- **Current_tls_ca**
  
The active `ssl_ca` value in the SSL context that the server uses for new connections. This context value may differ from the current `ssl_ca` system variable value if the system variable has been changed but `ALTER INSTANCE RELOAD TLS` has not subsequently been executed to reconfigure the SSL context from the context-related system variable values and update the corresponding status variables. (This potential difference in values applies to each corresponding pair of context-related system and status variables. See Server-Side Runtime Configuration and Monitoring for Encrypted Connections.)

  This variable was added in MySQL 8.0.16.

- **Current_tls_capath**
  
The active `ssl_capath` value in the TSL context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of **Current_tls_ca**.

  This variable was added in MySQL 8.0.16.

- **Current_tls_cert**
  
The active `ssl_cert` value in the TSL context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of **Current_tls_ca**.

  This variable was added in MySQL 8.0.16.

- **Current_tls_cipher**
  
The active `ssl_cipher` value in the TSL context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of **Current_tls_ca**.

  This variable was added in MySQL 8.0.16.

- **Current_tls_ciphersuites**
  
The active `tls_ciphersuites` value in the TSL context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of **Current_tls_ca**.

  This variable was added in MySQL 8.0.16.

- **Current_tls_crl**
  
The active `ssl_crl` value in the TSL context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of **Current_tls_ca**.

  This variable was added in MySQL 8.0.16.
• **Current_tls_crlpath**

The active `ssl_crlpath` value in the TSL context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of `Current_tls_ca`.

This variable was added in MySQL 8.0.16.

• **Current_tls_key**

The active `ssl_key` value in the TSL context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of `Current_tls_ca`.

This variable was added in MySQL 8.0.16.

• **Current_tls_version**

The active `tls_version` value in the TSL context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of `Current_tls_ca`.

This variable was added in MySQL 8.0.16.

• **Delayed_errors**

This status variable is deprecated (because `DELAYED` inserts are not supported); expect it to be removed in a future release.

• **Delayed_insert_threads**

This status variable is deprecated (because `DELAYED` inserts are not supported); expect it to be removed in a future release.

• **Delayed_writes**

This status variable is deprecated (because `DELAYED` inserts are not supported); expect it to be removed in a future release.

• **dragnet.Status**

The result of the most recent assignment to the `dragnet.log_error_filter_rules` system variable, empty if no such assignment has occurred.

This variable was added in MySQL 8.0.12.

• **Error_log_buffered_bytes**

The number of bytes currently used in the Performance Schema `error_log` table. It is possible for the value to decrease, for example, if a new event cannot fit until discarding an old event, but the new event is smaller than the old one.

This variable was added in MySQL 8.0.22.

• **Error_log_buffered_events**

The number of events currently present in the Performance Schema `error_log` table. As with `Error_log_buffered_bytes`, it is possible for the value to decrease.
This variable was added in MySQL 8.0.22.

- **Error_log_expired_events**
  
The number of events discarded from the Performance Schema `error_log` table to make room for new events.
  
This variable was added in MySQL 8.0.22.

- **Error_log_latest_write**
  
The time of the last write to the Performance Schema `error_log` table.
  
This variable was added in MySQL 8.0.22.

- **Flush_commands**
  
The number of times the server flushes tables, whether because a user executed a `FLUSH TABLES` statement or due to internal server operation. It is also incremented by receipt of a `COM_REFRESH` packet. This is in contrast to `Com_flush`, which indicates how many `FLUSH` statements have been executed, whether `FLUSH TABLES`, `FLUSH LOGS`, and so forth.

- **group_replication_primary_member**
  
Shows the primary member's UUID when the group is operating in single-primary mode. If the group is operating in multi-primary mode, shows an empty string.

The `group_replication_primary_member` status variable is deprecated and is scheduled to be removed in a future version.

- **Handler_commit**
  
The number of internal `COMMIT` statements.

- **Handler_delete**
  
The number of times that rows have been deleted from tables.

- **Handler_external_lock**
  
The server increments this variable for each call to its `external_lock()` function, which generally occurs at the beginning and end of access to a table instance. There might be differences among storage engines. This variable can be used, for example, to discover for a statement that accesses a partitioned table how many partitions were pruned before locking occurred: Check how much the counter increased for the statement, subtract 2 (2 calls for the table itself), then divide by 2 to get the number of partitions locked.

- **Handler_mrr_init**
  
The number of times the server uses a storage engine's own Multi-Range Read implementation for table access.

- **Handler_prepare**
  
A counter for the prepare phase of two-phase commit operations.

- **Handler_read_first**
The number of times the first entry in an index was read. If this value is high, it suggests that the server is doing a lot of full index scans (for example, SELECT col1 FROM foo, assuming that col1 is indexed).

- **Handler_read_key**
  The number of requests to read a row based on a key. If this value is high, it is a good indication that your tables are properly indexed for your queries.

- **Handler_read_last**
  The number of requests to read the last key in an index. With ORDER BY, the server issues a first-key request followed by several next-key requests, whereas with ORDER BY DESC, the server issues a last-key request followed by several previous-key requests.

- **Handler_read_next**
  The number of requests to read the next row in key order. This value is incremented if you are querying an index column with a range constraint or if you are doing an index scan.

- **Handler_read_prev**
  The number of requests to read the previous row in key order. This read method is mainly used to optimize ORDER BY ... DESC.

- **Handler_read_rnd**
  The number of requests to read a row based on a fixed position. This value is high if you are doing a lot of queries that require sorting of the result. You probably have a lot of queries that require MySQL to scan entire tables or you have joins that do not use keys properly.

- **Handler_read_rnd_next**
  The number of requests to read the next row in the data file. This value is high if you are doing a lot of table scans. Generally this suggests that your tables are not properly indexed or that your queries are not written to take advantage of the indexes you have.

- **Handler_rollback**
  The number of requests for a storage engine to perform a rollback operation.

- **Handler_savepoint**
  The number of requests for a storage engine to place a savepoint.

- **Handler_savepoint_rollback**
  The number of requests for a storage engine to roll back to a savepoint.

- **Handler_update**
  The number of requests to update a row in a table.

- **Handler_write**
  The number of requests to insert a row in a table.

- **Innodb_buffer_pool_dump_status**
Server Status Variables

The progress of an operation to record the pages held in the InnoDB buffer pool, triggered by the setting of `innodb_buffer_pool_dump_at_shutdown` or `innodb_buffer_pool_dump_now`.

For related information and examples, see Section 15.8.3.6, “Saving and Restoring the Buffer Pool State”.

- `Innodb_buffer_pool_load_status`

The progress of an operation to warm up the InnoDB buffer pool by reading in a set of pages corresponding to an earlier point in time, triggered by the setting of `innodb_buffer_pool_load_at_startup` or `innodb_buffer_pool_load_now`. If the operation introduces too much overhead, you can cancel it by setting `innodb_buffer_pool_load_abort`.

For related information and examples, see Section 15.8.3.6, “Saving and Restoring the Buffer Pool State”.

- `Innodb_buffer_pool_bytes_data`

The total number of bytes in the InnoDB buffer pool containing data. The number includes both dirty and clean pages. For more accurate memory usage calculations than with `Innodb_buffer_pool_pages_data`, when compressed tables cause the buffer pool to hold pages of different sizes.

- `Innodb_buffer_pool_pages_data`

The number of pages in the InnoDB buffer pool containing data. The number includes both dirty and clean pages. When using compressed tables, the reported `Innodb_buffer_pool_pages_data` value may be larger than `Innodb_buffer_pool_pages_total` (Bug #59550).

- `Innodb_buffer_pool_bytes_dirty`

The total current number of bytes held in dirty pages in the InnoDB buffer pool. For more accurate memory usage calculations than with `Innodb_buffer_pool_pages_dirty`, when compressed tables cause the buffer pool to hold pages of different sizes.

- `Innodb_buffer_pool_pages_dirty`

The current number of dirty pages in the InnoDB buffer pool.

- `Innodb_buffer_pool_pages_flushed`

The number of requests to flush pages from the InnoDB buffer pool.

- `Innodb_buffer_pool_pages_free`

The number of free pages in the InnoDB buffer pool.

- `Innodb_buffer_pool_pages_latched`

The number of latched pages in the InnoDB buffer pool. These are pages currently being read or written, or that cannot be flushed or removed for some other reason. Calculation of this variable is expensive, so it is available only when the `UNIV_DEBUG` system is defined at server build time.

- `Innodb_buffer_pool_pages_misc`

The number of pages in the InnoDB buffer pool that are busy because they have been allocated for administrative overhead, such as row locks or the adaptive hash
Server Status Variables

index. This value can also be calculated as \texttt{Innodb\_buffer\_pool\_pages\_total} - \texttt{Innodb\_buffer\_pool\_pages\_free} - \texttt{Innodb\_buffer\_pool\_pages\_data}. When using \textit{compressed tables}, \texttt{Innodb\_buffer\_pool\_pages\_misc} may report an out-of-bounds value (Bug \#59550).

- **Innodb\_buffer\_pool\_pages\_total**

The total size of the InnoDB buffer pool, in pages. When using \textit{compressed tables}, the reported \texttt{Innodb\_buffer\_pool\_pages\_data} value may be larger than \texttt{Innodb\_buffer\_pool\_pages\_total} (Bug \#59550).

- **Innodb\_buffer\_pool\_read\_ahead**

The number of pages read into the InnoDB buffer pool by the \textit{read-ahead} background thread.

- **Innodb\_buffer\_pool\_read\_ahead\_evicted**

The number of pages read into the InnoDB buffer pool by the \textit{read-ahead} background thread that were subsequently evicted without having been accessed by queries.

- **Innodb\_buffer\_pool\_read\_ahead\_rnd**

The number of “random” read-aheads initiated by InnoDB. This happens when a query scans a large portion of a table but in random order.

- **Innodb\_buffer\_pool\_read\_requests**

The number of logical read requests.

- **Innodb\_buffer\_pool\_reads**

The number of logical reads that InnoDB could not satisfy from the buffer pool, and had to read directly from disk.

- **Innodb\_buffer\_pool\_resize\_status**

The status of an operation to resize the InnoDB buffer pool dynamically, triggered by setting the \texttt{innodb\_buffer\_pool\_size} parameter dynamically. The \texttt{innodb\_buffer\_pool\_size} parameter is dynamic, which allows you to resize the buffer pool without restarting the server. See Configuring InnoDB Buffer Pool Size Online for related information.

- **Innodb\_buffer\_pool\_wait\_free**

Normally, writes to the InnoDB buffer pool happen in the background. When InnoDB needs to read or create a page and no clean pages are available, InnoDB flushes some \textit{dirty pages} first and waits for that operation to finish. This counter counts instances of these waits. If \texttt{innodb\_buffer\_pool\_size} has been set properly, this value should be small.

- **Innodb\_buffer\_pool\_write\_requests**

The number of writes done to the InnoDB buffer pool.

- **Innodb\_data\_fsyncs**

The number of \texttt{fsync()} operations so far. The frequency of \texttt{fsync()} calls is influenced by the setting of the \texttt{innodb\_flush\_method} configuration option.

- **Innodb\_data\_pending\_fsyncs**
Server Status Variables

The current number of pending `fsync()` operations. The frequency of `fsync()` calls is influenced by the setting of the `innodb_flush_method` configuration option.

- **Innodb_data_pending_reads**
  The current number of pending reads.

- **Innodb_data_pending_writes**
  The current number of pending writes.

- **Innodb_data_read**
  The amount of data read since the server was started (in bytes).

- **Innodb_data_reads**
  The total number of data reads (OS file reads).

- **Innodb_data_writes**
  The total number of data writes.

- **Innodb_data_written**
  The amount of data written so far, in bytes.

- **Innodb_dblwr_pages_written**
  The number of pages that have been written to the doublewrite buffer. See Section 15.11.1, “InnoDB Disk I/O”.

- **Innodb_dblwr_writes**
  The number of doublewrite operations that have been performed. See Section 15.11.1, “InnoDB Disk I/O”.

- **Innodb_have_atomic_builtins**
  Indicates whether the server was built with atomic instructions.

- **Innodb_log_waits**
  The number of times that the log buffer was too small and a wait was required for it to be flushed before continuing.

- **Innodb_log_write_requests**
  The number of write requests for the InnoDB redo log.

- **Innodb_log_writes**
  The number of physical writes to the InnoDB redo log file.

- **Innodb_num_open_files**
  The number of files InnoDB currently holds open.

- **Innodb_os_log_fsyncs**
Server Status Variables

The number of `fsync()` writes done to the InnoDB redo log files.

- **Innodb_os_log_pending_fsyncs**
  The number of pending `fsync()` operations for the InnoDB redo log files.

- **Innodb_os_log_pending_writes**
  The number of pending writes to the InnoDB redo log files.

- **Innodb_os_log_written**
  The number of bytes written to the InnoDB redo log files.

- **Innodb_page_size**
  InnoDB page size (default 16KB). Many values are counted in pages; the page size enables them to be easily converted to bytes.

- **Innodb_pages_created**
  The number of pages created by operations on InnoDB tables.

- **Innodb_pages_read**
  The number of pages read from the InnoDB buffer pool by operations on InnoDB tables.

- **Innodb_pages_written**
  The number of pages written by operations on InnoDB tables.

- **Innodb_redo_log_enabled**
  Whether redo logging is enabled or disabled. Introduced in MySQL 8.0.21.
  See [Disabling Redo Logging](#).

- **Innodb_row_lock_current_waits**
  The number of row locks currently being waited for by operations on InnoDB tables.

- **Innodb_row_lock_time**
  The total time spent in acquiring row locks for InnoDB tables, in milliseconds.

- **Innodb_row_lock_time_avg**
  The average time to acquire a row lock for InnoDB tables, in milliseconds.

- **Innodb_row_lock_time_max**
  The maximum time to acquire a row lock for InnoDB tables, in milliseconds.

- **Innodb_row_lock_waits**
  The number of times operations on InnoDB tables had to wait for a row lock.

- **Innodb_rows_deleted**
  917
Server Status Variables

The number of rows deleted from InnoDB tables.

- **Innodb_rows_inserted**
  The number of rows inserted into InnoDB tables.

- **Innodb_rows_read**
  The number of rows read from InnoDB tables.

- **Innodb_rows_updated**
  The number of rows updated in InnoDB tables.

- **Innodb_system_rows_deleted**
  The number of rows deleted from InnoDB tables belonging to system-created schemas.

- **Innodb_system_rows_inserted**
  The number of rows inserted into InnoDB tables belonging to system-created schemas.

- **Innodb_system_rows_read**
  The number of rows read from InnoDB tables belonging to system-created schemas.

- **Innodb_truncated_status_writes**
  The number of times output from the `SHOW ENGINE INNODB STATUS` statement has been truncated.

- **Innodb_undo_tablespaces_active**
  The number of active undo tablespaces. Includes both implicit (InnoDB-created) and explicit (user-created) undo tablespaces. For information about undo tablespaces, see Section 15.6.3.4, “Undo Tablespaces”.

- **Innodb_undo_tablespaces_explicit**
  The number of user-created undo tablespaces. For information about undo tablespaces, see Section 15.6.3.4, “Undo Tablespaces”.

- **Innodb_undo_tablespaces_implicit**
  The number of undo tablespaces created by InnoDB. Two default undo tablespaces are created by InnoDB when the MySQL instance is initialized. For information about undo tablespaces, see Section 15.6.3.4, “Undo Tablespaces”.

- **Innodb_undo_tablespaces_total**
  The total number of undo tablespaces. Includes both implicit (InnoDB-created) and explicit (user-created) undo tablespaces, active and inactive. For information about undo tablespaces, see Section 15.6.3.4, “Undo Tablespaces”.

- **Key_blocks_not_flushed**
  The number of key blocks in the MyISAM key cache that have changed but have not yet been flushed to disk.

- **Key_blocks_unused**
Server Status Variables

The number of unused blocks in the MyISAM key cache. You can use this value to determine how much of the key cache is in use; see the discussion of key_buffer_size in Section 5.1.8, “Server System Variables”.

- **Key_blocks_used**
  The number of used blocks in the MyISAM key cache. This value is a high-water mark that indicates the maximum number of blocks that have ever been in use at one time.

- **Key_read_requests**
  The number of requests to read a key block from the MyISAM key cache.

- **Key_reads**
  The number of physical reads of a key block from disk into the MyISAM key cache. If Key_reads is large, then your key_buffer_size value is probably too small. The cache miss rate can be calculated as Key_reads/Key_read_requests.

- **Key_write_requests**
  The number of requests to write a key block to the MyISAM key cache.

- **Key_writes**
  The number of physical writes of a key block from the MyISAM key cache to disk.

- **Last_query_cost**
  The total cost of the last compiled query as computed by the query optimizer. This is useful for comparing the cost of different query plans for the same query. The default value of 0 means that no query has been compiled yet. The default value is 0. Last_query_cost has session scope.

  In MySQL 8.0.16 and later, this variable shows the cost of queries that have multiple query blocks, summing the cost estimates of each query block, estimating how many times non-cacheable subqueries are executed, and multiplying the cost of those query blocks by the number of subquery executions. (Bug #92766, Bug #28786951) Prior to MySQL 8.0.16, Last_query_cost was computed accurately only for simple, “flat” queries, but not for complex queries such as those containing subqueries or UNION. (For the latter, the value was set to 0.)

- **Last_query_partial_plans**
  The number of iterations the query optimizer made in execution plan construction for the previous query. Last_query_cost has session scope.

- **Locked_connects**
  The number of attempts to connect to locked user accounts. For information about account locking and unlocking, see Section 6.2.19, “Account Locking”.

- **Max_execution_time_exceeded**
  The number of SELECT statements for which the execution timeout was exceeded.

- **Max_execution_time_set**
  The number of SELECT statements for which a nonzero execution timeout was set. This includes statements that include a nonzero MAX_EXECUTION_TIME optimizer hint, and statements that include...
Server Status Variables

no such hint but execute while the timeout indicated by the `max_execution_time` system variable is nonzero.

- **Max_execution_time_set_failed**
  The number of `SELECT` statements for which the attempt to set an execution timeout failed.

- **Max_used_connections**
  The maximum number of connections that have been in use simultaneously since the server started.

- **Max_used_connections_time**
  The time at which `Max_used_connections` reached its current value.

- **Not_flushed_delayed_rows**
  This status variable is deprecated (because `DELAYED` inserts are not supported); expect it to be removed in a future release.

- **mecab_charset**
  The character set currently used by the MeCab full-text parser plugin. For related information, see Section 12.10.9, “MeCab Full-Text Parser Plugin”.

- **Ongoing_anonymous_transaction_count**
  Shows the number of ongoing transactions which have been marked as anonymous. This can be used to ensure that no further transactions are waiting to be processed.

- **Ongoing_anonymous_gtid_violating_transaction_count**
  This status variable is only available in debug builds. Shows the number of ongoing transactions which use `gtid_next=ANONYMOUS` and that violate GTID consistency.

- **Ongoing_automatic_gtid_violating_transaction_count**
  This status variable is only available in debug builds. Shows the number of ongoing transactions which use `gtid_next=AUTOMATIC` and that violate GTID consistency.

- **Open_files**
  The number of files that are open. This count includes regular files opened by the server. It does not include other types of files such as sockets or pipes. Also, the count does not include files that storage engines open using their own internal functions rather than asking the server level to do so.

- **Open_streams**
  The number of streams that are open (used mainly for logging).

- **Open_table_definitions**
  The number of cached table definitions.

- **Open_tables**
  The number of tables that are open.

- **Opened_files**
Server Status Variables

The number of files that have been opened with `my_open()` (a `mysys` library function). Parts of the server that open files without using this function do not increment the count.

- **Opened_table_definitions**
  The number of table definitions that have been cached.

- **Opened_tables**
  The number of tables that have been opened. If `Opened_tables` is big, your `table_open_cache` value is probably too small.

- **Performance_schema_***
  Performance Schema status variables are listed in Section 26.16, “Performance Schema Status Variables”. These variables provide information about instrumentation that could not be loaded or created due to memory constraints.

- **Prepared_stmt_count**
  The current number of prepared statements. (The maximum number of statements is given by the `max_prepared_stmt_count` system variable.)

- **Queries**
  The number of statements executed by the server. This variable includes statements executed within stored programs, unlike the `Questions` variable. It does not count `COM_PING` or `COM_STATISTICS` commands.

  The discussion at the beginning of this section indicates how to relate this statement-counting status variable to other such variables.

- **Questions**
  The number of statements executed by the server. This includes only statements sent to the server by clients and not statements executed within stored programs, unlike the `Queries` variable. This variable does not count `COM_PING`, `COM_STATISTICS`, `COM_STMT_PREPARE`, `COM_STMT_CLOSE`, or `COM_STMT_RESET` commands.

  The discussion at the beginning of this section indicates how to relate this statement-counting status variable to other such variables.

- **Rpl_semi_sync_master_clients**
  The number of semisynchronous replicas.

  This variable is available only if the source-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_net_avg_wait_time**
  The average time in microseconds the source waited for a replica reply. This variable is always 0, and is deprecated; expect it to be removed in a future version.

  This variable is available only if the source-side semisynchronous replication plugin is installed.
**Server Status Variables**

- **Rpl_semi_sync_master_net_wait_time**
  The total time in microseconds the source waited for replica replies. This variable is always 0, and is deprecated; expect it to be removed in a future version.
  This variable is available only if the source-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_net_waits**
  The total number of times the source waited for replica replies.
  This variable is available only if the source-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_no_times**
  The number of times the source turned off semisynchronous replication.
  This variable is available only if the source-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_no_tx**
  The number of commits that were not acknowledged successfully by a replica.
  This variable is available only if the source-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_status**
  Whether semisynchronous replication currently is operational on the source. The value is ON if the plugin has been enabled and a commit acknowledgment has occurred. It is OFF if the plugin is not enabled or the source has fallen back to asynchronous replication due to commit acknowledgment timeout.
  This variable is available only if the source-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_timefunc_failures**
  The number of times the source failed when calling time functions such as gettimeofday().
  This variable is available only if the source-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_tx_avg_wait_time**
  The average time in microseconds the source waited for each transaction.
  This variable is available only if the source-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_tx_wait_time**
  The total time in microseconds the source waited for transactions.
  This variable is available only if the source-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_tx_waits**
  The total number of times the source waited for transactions.
  This variable is available only if the source-side semisynchronous replication plugin is installed.
Server Status Variables

- **Rpl_semi_sync_master_wait_pos_backtraverse**
  
The total number of times the source waited for an event with binary coordinates lower than events waited for previously. This can occur when the order in which transactions start waiting for a reply is different from the order in which their binary log events are written.

  This variable is available only if the source-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_wait_sessions**
  
The number of sessions currently waiting for replica replies.

  This variable is available only if the source-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_yes_tx**
  
The number of commits that were acknowledged successfully by a replica.

  This variable is available only if the source-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_slave_status**
  
  Whether semisynchronous replication currently is operational on the replica. This is **ON** if the plugin has been enabled and the replication I/O thread is running, **OFF** otherwise.

  This variable is available only if the replica-side semisynchronous replication plugin is installed.

- **Rsa_public_key**
  
The value of this variable is the public key used by the `sha256_password` authentication plugin for RSA key pair-based password exchange. The value is nonempty only if the server successfully initializes the private and public keys in the files named by the `sha256_password_private_key_path` and `sha256_password_public_key_path` system variables. The value of `Rsa_public_key` comes from the latter file.

  For information about `sha256_password`, see Section 6.4.1.3, “SHA-256 Pluggable Authentication”.

- **Secondary_engine_execution_count**
  
  For future use. This variable was added in MySQL 8.0.13.

- **Select_full_join**
  
The number of joins that perform table scans because they do not use indexes. If this value is not 0, you should carefully check the indexes of your tables.

- **Select_full_range_join**
  
The number of joins that used a range search on a reference table.

- **Select_range**
  
The number of joins that used ranges on the first table. This is normally not a critical issue even if the value is quite large.

- **Select_range_check**
  
The number of joins without keys that check for key usage after each row. If this is not 0, you should carefully check the indexes of your tables.
• **Select_scan**
  The number of joins that did a full scan of the first table.

• **Slave_open_temp_tables**
  The number of temporary tables that the replication SQL thread currently has open. If the value is greater than zero, it is not safe to shut down the replica; see Section 17.5.1.30, “Replication and Temporary Tables”. This variable reports the total count of open temporary tables for all replication channels.

• **Slave_rows_last_search_algorithm_used**
  The search algorithm that was most recently used by this replica to locate rows for row-based replication. The result shows whether the replica used indexes, a table scan, or hashing as the search algorithm for the last transaction executed on any channel.

  The method used depends on the setting for the `slave_rows_search_algorithms` system variable, and the keys that are available on the relevant table.

  This variable is available only for debug builds of MySQL.

• **Slow_launch_threads**
  The number of threads that have taken more than `slow_launch_time` seconds to create.

• **Slow_queries**
  The number of queries that have taken more than `long_query_time` seconds. This counter increments regardless of whether the slow query log is enabled. For information about that log, see Section 5.4.5, “The Slow Query Log”.

• **Sort_merge_passes**
  The number of merge passes that the sort algorithm has had to do. If this value is large, you should consider increasing the value of the `sort_buffer_size` system variable.

• **Sort_range**
  The number of sorts that were done using ranges.

• **Sort_rows**
  The number of sorted rows.

• **Sort_scan**
  The number of sorts that were done by scanning the table.

• **Ssl_accept_renegotiates**
  The number of negotiates needed to establish the connection.

• **Ssl_accepts**
  The number of accepted SSL connections.

• **Ssl_callback_cache_hits**
  The number of callback cache hits.
Server Status Variables

- **Ssl_cipher**
  The current encryption cipher (empty for unencrypted connections).

- **Ssl_cipher_list**
  The list of possible SSL ciphers (empty for non-SSL connections). If MySQL supports TLSv1.3, the value includes the possible TLSv1.3 ciphersuites. See Section 6.3.2, "Encrypted Connection TLS Protocols and Ciphers".

- **Ssl_client_connects**
  The number of SSL connection attempts to an SSL-enabled replication source server.

- **Ssl_connect_renegotiates**
  The number of negotiations needed to establish the connection to an SSL-enabled replication source server.

- **Ssl_ctx_verify_depth**
  The SSL context verification depth (how many certificates in the chain are tested).

- **Ssl_ctx_verify_mode**
  The SSL context verification mode.

- **Ssl_default_timeout**
  The default SSL timeout.

- **Ssl_finished_accepts**
  The number of successful SSL connections to the server.

- **Ssl_finished_connects**
  The number of successful replica connections to an SSL-enabled replication source server.

- **Ssl_server_not_after**
  The last date for which the SSL certificate is valid. To check SSL certificate expiration information, use this statement:

  ```
  mysql> SHOW STATUS LIKE 'Ssl_server_not%';
  +-----------------------+--------------------------+
  | Variable_name         | Value                    |
  +-----------------------+--------------------------+
  | Ssl_server_not_after  | Apr 28 14:16:39 2025 GMT |
  | Ssl_server_not_before | May  1 14:16:39 2015 GMT |
  +-----------------------+--------------------------+
  ```

- **Ssl_server_not_before**
  The first date for which the SSL certificate is valid.

- **Ssl_session_cache_hits**
  The number of SSL session cache hits.

- **Ssl_session_cache_misses**
The number of SSL session cache misses.

- **Ssl_session_cache_mode**
  The SSL session cache mode.

- **Ssl_session_cache_overflows**
  The number of SSL session cache overflows.

- **Ssl_session_cache_size**
  The SSL session cache size.

- **Ssl_session_cache_timeouts**
  The number of SSL session cache timeouts.

- **Ssl_sessions_reused**
  How many SSL connections were reused from the cache.

- **Ssl_used_session_cache_entries**
  How many SSL session cache entries were used.

- **Ssl_verify_depth**
  The verification depth for replication SSL connections.

- **Ssl_verify_mode**
  The verification mode used by the server for a connection that uses SSL. The value is a bitmask; bits are defined in the `openssl/ssl.h` header file:

  ```
  # define SSL_VERIFY_NONE                 0x00
  # define SSL_VERIFY_PEER                 0x01
  # define SSL_VERIFY_FAIL_IF_NO_PEER_CERT 0x02
  # define SSL_VERIFY_CLIENT_ONCE          0x04
  ```

  *SSL_VERIFY_PEER* indicates that the server asks for a client certificate. If the client supplies one, the server performs verification and proceeds only if verification is successful. *SSL_VERIFY_CLIENT_ONCE* indicates that a request for the client certificate is performed only in the initial handshake.

- **Ssl_version**
  The SSL protocol version of the connection (for example, TLSv1). If the connection is not encrypted, the value is empty.

- **Table_locks_immediate**
  The number of times that a request for a table lock could be granted immediately.

- **Table_locks_waited**
  The number of times that a request for a table lock could not be granted immediately and a wait was needed. If this is high and you have performance problems, you should first optimize your queries, and then either split your table or tables or use replication.
Server Status Variables

- **Table_open_cache_hits**
  The number of hits for open tables cache lookups.

- **Table_open_cache_misses**
  The number of misses for open tables cache lookups.

- **Table_open_cache_overflows**
  The number of overflows for the open tables cache. This is the number of times, after a table is opened or closed, a cache instance has an unused entry and the size of the instance is larger than `table_open_cache / table_open_cache_instances`.

- **Tc_log_max_pages_used**
  For the memory-mapped implementation of the log that is used by `mysqld` when it acts as the transaction coordinator for recovery of internal XA transactions, this variable indicates the largest number of pages used for the log since the server started. If the product of `Tc_log_max_pages_used` and `Tc_log_page_size` is always significantly less than the log size, the size is larger than necessary and can be reduced. (The size is set by the `--log-tc-size` option. This variable is unused: It is unneeded for binary log-based recovery, and the memory-mapped recovery log method is not used unless the number of storage engines that are capable of two-phase commit and that support XA transactions is greater than one. (`InnoDB` is the only applicable engine.)

- **Tc_log_page_size**
  The page size used for the memory-mapped implementation of the XA recovery log. The default value is determined using `getpagesize()`. This variable is unused for the same reasons as described for `Tc_log_max_pages_used`.

- **Tc_log_page_waits**
  For the memory-mapped implementation of the recovery log, this variable increments each time the server was not able to commit a transaction and had to wait for a free page in the log. If this value is large, you might want to increase the log size (with the `--log-tc-size` option). For binary log-based recovery, this variable increments each time the binary log cannot be closed because there are two-phase commits in progress. (The close operation waits until all such transactions are finished.)

- **Threads_cached**
  The number of threads in the thread cache.

- **Threads_connected**
  The number of currently open connections.

- **Threads_created**
  The number of threads created to handle connections. If `Threads_created` is big, you may want to increase the `thread_cache_size` value. The cache miss rate can be calculated as `Threads_created/Connections`.

- **Threads_running**
  The number of threads that are not sleeping.

- **Uptime**
The number of seconds that the server has been up.

- **Uptime_since_flush_status**

The number of seconds since the most recent `FLUSH STATUS` statement.

### 5.1.11 Server SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients, depending on the value of the `sql_mode` system variable. DBAs can set the global SQL mode to match site server operating requirements, and each application can set its session SQL mode to its own requirements.

Modes affect the SQL syntax MySQL supports and the data validation checks it performs. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

- Setting the SQL Mode
- The Most Important SQL Modes
- Full List of SQL Modes
- Combination SQL Modes
- Strict SQL Mode
- Comparison of the IGNORE Keyword and Strict SQL Mode

For answers to questions often asked about server SQL modes in MySQL, see Section A.3, “MySQL 8.0 FAQ: Server SQL Mode”.

When working with InnoDB tables, consider also the `innodb_strict_mode` system variable. It enables additional error checks for InnoDB tables.

#### Setting the SQL Mode

The default SQL mode in MySQL 8.0 includes these modes: `ONLY_FULL_GROUP_BY`, `STRICT_TRANS_TABLES`, `NO_ZERO_IN_DATE`, `NO_ZERO_DATE`, `ERROR_FOR_DIVISION_BY_ZERO`, and `NO_ENGINE_SUBSTITUTION`.

To set the SQL mode at server startup, use the `--sql-mode="modes"` option on the command line, or `sql-mode="modes"` in an option file such as `my.cnf` (Unix operating systems) or `my.ini` (Windows). `modes` is a list of different modes separated by commas. To clear the SQL mode explicitly, set it to an empty string using `--sql-mode=""` on the command line, or `sql-mode=""` in an option file.

Note

MySQL installation programs may configure the SQL mode during the installation process.

If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

To change the SQL mode at runtime, set the global or session `sql_mode` system variable using a `SET` statement:

```sql
SET GLOBAL sql_mode = 'modes';
SET SESSION sql_mode = 'modes';
```
Setting the `GLOBAL` variable requires the `SYSTEM_VARIABLES_ADMIN` privilege (or the deprecated `SUPER` privilege) and affects the operation of all clients that connect from that time on. Setting the `SESSION` variable affects only the current client. Each client can change its session `sql_mode` value at any time.

To determine the current global or session `sql_mode` setting, select its value:

```
SELECT @@GLOBAL.sql_mode;
SELECT @@SESSION.sql_mode;
```

---

**Important**

**SQL mode and user-defined partitioning.** Changing the server SQL mode after creating and inserting data into partitioned tables can cause major changes in the behavior of such tables, and could lead to loss or corruption of data. It is strongly recommended that you never change the SQL mode once you have created tables employing user-defined partitioning.

When replicating partitioned tables, differing SQL modes on the source and replica can also lead to problems. For best results, you should always use the same server SQL mode on the source and replica.

For more information, see Section 23.6, “Restrictions and Limitations on Partitioning”.

---

**The Most Important SQL Modes**

The most important `sql_mode` values are probably these:

- **ANSI**

  This mode changes syntax and behavior to conform more closely to standard SQL. It is one of the special combination modes listed at the end of this section.

- **STRICT_TRANS_TABLES**

  If a value could not be inserted as given into a transactional table, abort the statement. For a nontransactional table, abort the statement if the value occurs in a single-row statement or the first row of a multiple-row statement. More details are given later in this section.

- **TRADITIONAL**

  Make MySQL behave like a “traditional” SQL database system. A simple description of this mode is “give an error instead of a warning” when inserting an incorrect value into a column. It is one of the special combination modes listed at the end of this section.

**Note**

With `TRADITIONAL` mode enabled, an `INSERT` or `UPDATE` aborts as soon as an error occurs. If you are using a nontransactional storage engine, this may not be what you want because data changes made prior to the error may not be rolled back, resulting in a “partially done” update.

When this manual refers to “strict mode,” it means a mode with either or both `STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES` enabled.

---

**Full List of SQL Modes**

The following list describes all supported SQL modes:
• **ALLOW_INVALID_DATES**

Do not perform full checking of dates. Check only that the month is in the range from 1 to 12 and the day is in the range from 1 to 31. This may be useful for Web applications that obtain year, month, and day in three different fields and store exactly what the user inserted, without date validation. This mode applies to `DATE` and `DATETIME` columns. It does not apply to `TIMESTAMP` columns, which always require a valid date.

With `ALLOW_INVALID_DATES` disabled, the server requires that month and day values be legal, and not merely in the range 1 to 12 and 1 to 31, respectively. With strict mode disabled, invalid dates such as '2004-04-31' are converted to '0000-00-00' and a warning is generated. With strict mode enabled, invalid dates generate an error. To permit such dates, enable `ALLOW_INVALID_DATES`.

• **ANSI_QUOTES**

Treat " as an identifier quote character (like the ` quote character) and not as a string quote character. You can still use ` to quote identifiers with this mode enabled. With `ANSI_QUOTES` enabled, you cannot use double quotation marks to quote literal strings because they are interpreted as identifiers.

• **ERROR_FOR_DIVISION_BY_ZERO**

The `ERROR_FOR_DIVISION_BY_ZERO` mode affects handling of division by zero, which includes \( \text{MOD}(N, 0) \). For data-change operations (`INSERT`, `UPDATE`), its effect also depends on whether strict SQL mode is enabled.

- If this mode is not enabled, division by zero inserts `NULL` and produces no warning.
- If this mode is enabled, division by zero inserts `NULL` and produces a warning.
- If this mode and strict mode are enabled, division by zero produces an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, division by zero inserts `NULL` and produces a warning.

For `SELECT`, division by zero returns `NULL`. Enabling `ERROR_FOR_DIVISION_BY_ZERO` causes a warning to be produced as well, regardless of whether strict mode is enabled.

`ERROR_FOR_DIVISION_BY_ZERO` is deprecated. `ERROR_FOR_DIVISION_BY_ZERO` is not part of strict mode, but should be used in conjunction with strict mode and is enabled by default. A warning occurs if `ERROR_FOR_DIVISION_BY_ZERO` is enabled without also enabling strict mode or vice versa.

Because `ERROR_FOR_DIVISION_BY_ZERO` is deprecated, you should expect it to be removed in a future MySQL release as a separate mode name and its effect included in the effects of strict SQL mode.

• **HIGH_NOT_PRECEDENCE**

The precedence of the `NOT` operator is such that expressions such as `NOT a BETWEEN b AND c` are parsed as `NOT (a BETWEEN b AND c)`. In some older versions of MySQL, the expression was parsed as `(NOT a) BETWEEN b AND c`. The old higher-precedence behavior can be obtained by enabling the `HIGH_NOT_PRECEDENCE` SQL mode.

```
mysql> SET sql_mode = '';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
-> 0
mysql> SET sql_mode = 'HIGH_NOT_PRECEDENCE';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
-> 1
```

• **IGNORE_SPACE**
Permit spaces between a function name and the ( character. This causes built-in function names to be treated as reserved words. As a result, identifiers that are the same as function names must be quoted as described in Section 9.2, “Schema Object Names”. For example, because there is a COUNT() function, the use of count as a table name in the following statement causes an error:

```sql
comyql> CREATE TABLE count (i INT);
ERROR 1064 (42000): You have an error in your SQL syntax
```

The table name should be quoted:

```sql
comyql> CREATE TABLE `count` (i INT);
Query OK, 0 rows affected (0.00 sec)
```

The IGNORE_SPACE SQL mode applies to built-in functions, not to user-defined functions or stored functions. It is always permissible to have spaces after a UDF or stored function name, regardless of whether IGNORE_SPACE is enabled.

For further discussion of IGNORE_SPACE, see Section 9.2.5, “Function Name Parsing and Resolution”.

- **NO_AUTO_VALUE_ON_ZERO**

  NO_AUTO_VALUE_ON_ZERO affects handling of AUTO_INCREMENT columns. Normally, you generate the next sequence number for the column by inserting either NULL or 0 into it. NO_AUTO_VALUE_ON_ZERO suppresses this behavior for 0 so that only NULL generates the next sequence number.

  This mode can be useful if 0 has been stored in a table's AUTO_INCREMENT column. (Storing 0 is not a recommended practice, by the way.) For example, if you dump the table with mysqldump and then reload it, MySQL normally generates new sequence numbers when it encounters the 0 values, resulting in a table with contents different from the one that was dumped. Enabling NO_AUTO_VALUE_ONZERO before reloading the dump file solves this problem. For this reason, mysqldump automatically includes in its output a statement that enables NO_AUTO_VALUE_ON_ZERO.

- **NO_BACKSLASH_ESCAPES**

  Disable the use of the backslash character (\) as an escape character within strings and identifiers. With this mode enabled, backslash becomes an ordinary character like any other.

- **NO_DIR_IN_CREATE**

  When creating a table, ignore all INDEX DIRECTORY and DATA DIRECTORY directives. This option is useful on replica servers.

- **NO_ENGINE_SUBSTITUTION**

  Control automatic substitution of the default storage engine when a statement such as CREATE TABLE or ALTER TABLE specifies a storage engine that is disabled or not compiled in.

  By default, NO_ENGINE_SUBSTITUTION is enabled.

  Because storage engines can be pluggable at runtime, unavailable engines are treated the same way:

  With NO_ENGINE_SUBSTITUTION disabled, for CREATE TABLE the default engine is used and a warning occurs if the desired engine is unavailable. For ALTER TABLE, a warning occurs and the table is not altered.

  With NO_ENGINE_SUBSTITUTION enabled, an error occurs and the table is not created or altered if the desired engine is unavailable.
• **NO UNSIGNED_SUBTRACTION**

Subtraction between integer values, where one is of type `UNSIGNED`, produces an unsigned result by default. If the result would otherwise have been negative, an error results:

```
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
ERROR 1690 (22003): BIGINT UNSIGNED value is out of range in '(cast(0 as unsigned) - 1)'
```

If the **NO UNSIGNED_SUBTRACTION** SQL mode is enabled, the result is negative:

```
mysql> SET sql_mode = 'NO_UNSIGNED_SUBTRACTION';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-------------------------+
<table>
<thead>
<tr>
<th>CAST(0 AS UNSIGNED) - 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
</tr>
</tbody>
</table>
```

If the result of such an operation is used to update an `UNSIGNED` integer column, the result is clipped to the maximum value for the column type, or clipped to 0 if **NO_UNSIGNED_SUBTRACTION** is enabled. With strict SQL mode enabled, an error occurs and the column remains unchanged.

When **NO_UNSIGNED_SUBTRACTION** is enabled, the subtraction result is signed, even if any operand is unsigned. For example, compare the type of column `c2` in table `t1` with that of column `c2` in table `t2`:

```
mysql> SET sql_mode='';
mysql> CREATE TABLE test (c1 BIGINT UNSIGNED NOT NULL);
mysql> CREATE TABLE t1 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t1;
+-------+---------------------+------+-----+---------+-------+
| Field | Type                | Null | Key | Default | Extra |
+-------+---------------------+------+-----+---------+-------+
| c2    | bigint(21) unsigned | NO   |     | 0       |       |
+-------+---------------------+------+-----+---------+-------+
mysql> SET sql_mode='NO_UNSIGNED_SUBTRACTION';
mysql> CREATE TABLE t2 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t2;
+-------+------------+------+-----+---------+-------+
| Field | Type       | Null | Key | Default | Extra |
+-------+------------+------+-----+---------+-------+
| c2    | bigint(21) | NO   |     | 0       |       |
+-------+------------+------+-----+---------+-------+
```

This means that **BIGINT UNSIGNED** is not 100% usable in all contexts. See Section 12.11, “Cast Functions and Operators”.

---

932
Server SQL Modes

- **NO_ZERO_DATE**

  The *NO_ZERO_DATE* mode affects whether the server permits '0000-00-00' as a valid date. Its effect also depends on whether strict SQL mode is enabled.

  - If this mode is not enabled, '0000-00-00' is permitted and inserts produce no warning.
  
  - If this mode is enabled, '0000-00-00' is permitted and inserts produce a warning.
  
  - If this mode and strict mode are enabled, '0000-00-00' is not permitted and inserts produce an error, unless *IGNORE* is given as well. For *INSERT IGNORE* and *UPDATE IGNORE*, '0000-00-00' is permitted and inserts produce a warning.

  *NO_ZERO_DATE* is deprecated. *NO_ZERO_DATE* is not part of strict mode, but should be used in conjunction with strict mode and is enabled by default. A warning occurs if *NO_ZERO_DATE* is enabled without also enabling strict mode or vice versa.

  Because *NO_ZERO_DATE* is deprecated, you should expect it to be removed in a future MySQL release as a separate mode name and its effect included in the effects of strict SQL mode.

- **NO_ZERO_IN_DATE**

  The *NO_ZERO_IN_DATE* mode affects whether the server permits dates in which the year part is nonzero but the month or day part is 0. (This mode affects dates such as '2010-00-01' or '2010-01-00', but not '0000-00-00'. To control whether the server permits '0000-00-00', use the *NO_ZERO_DATE* mode.) The effect of *NO_ZERO_IN_DATE* also depends on whether strict SQL mode is enabled.

  - If this mode is not enabled, dates with zero parts are permitted and inserts produce no warning.
  
  - If this mode is enabled, dates with zero parts are inserted as '0000-00-00' and produce a warning.
  
  - If this mode and strict mode are enabled, dates with zero parts are not permitted and inserts produce an error, unless *IGNORE* is given as well. For *INSERT IGNORE* and *UPDATE IGNORE*, dates with zero parts are inserted as '0000-00-00' and produce a warning.

  *NO_ZERO_IN_DATE* is deprecated. *NO_ZERO_IN_DATE* is not part of strict mode, but should be used in conjunction with strict mode and is enabled by default. A warning occurs if *NO_ZERO_IN_DATE* is enabled without also enabling strict mode or vice versa.

  Because *NO_ZERO_IN_DATE* is deprecated, you should expect it to be removed in a future MySQL release as a separate mode name and its effect included in the effects of strict SQL mode.

- **ONLY_FULL_GROUP_BY**

  Reject queries for which the select list, *HAVING* condition, or *ORDER BY* list refer to nonaggregated columns that are neither named in the *GROUP BY* clause nor are functionally dependent on (uniquely determined by) *GROUP BY* columns.

  A MySQL extension to standard SQL permits references in the *HAVING* clause to aliased expressions in the select list. The *HAVING* clause can refer to aliases regardless of whether *ONLY_FULL_GROUP_BY* is enabled.

  For additional discussion and examples, see Section 12.20.3, “MySQL Handling of GROUP BY”.
• **PAD_CHAR_TO_FULL_LENGTH**

By default, trailing spaces are trimmed from `CHAR` column values on retrieval. If `PAD_CHAR_TO_FULL_LENGTH` is enabled, trimming does not occur and retrieved `CHAR` values are padded to their full length. This mode does not apply to `VARCHAR` columns, for which trailing spaces are retained on retrieval.

---

**Note**

As of MySQL 8.0.13, `PAD_CHAR_TO_FULL_LENGTH` is deprecated. Expect it to be removed in a future version of MySQL.

---

mysql> CREATE TABLE t1 (c1 CHAR(10));
Query OK, 0 rows affected (0.37 sec)

mysql> INSERT INTO t1 (c1) VALUES('xy');
Query OK, 1 row affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+------+-----------------+
| c1   | CHAR_LENGTH(c1) |
| xy   | 2               |
+------+-----------------+
1 row in set (0.00 sec)

mysql> SET sql_mode = 'PAD_CHAR_TO_FULL_LENGTH';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+------------+-----------------+
| c1         | CHAR_LENGTH(c1) |
| xy         | 10              |
+------------+-----------------+
1 row in set (0.00 sec)

• **PIPES_AS_CONCAT**

Treat `||` as a string concatenation operator (same as `CONCAT()`) rather than as a synonym for `OR`.

• **REAL_AS_FLOAT**

Treat `REAL` as a synonym for `FLOAT`. By default, MySQL treats `REAL` as a synonym for `DOUBLE`.

• **STRICT_ALL_TABLES**

Enable strict SQL mode for all storage engines. Invalid data values are rejected. For details, see Strict SQL Mode.

• **STRICT_TRANS_TABLES**

Enable strict SQL mode for transactional storage engines, and when possible for nontransactional storage engines. For details, see Strict SQL Mode.
• **TIME_TRUNCATE FRACTIONAL**

Control whether rounding or truncation occurs when inserting a `TIME`, `DATE`, or `TIMESTAMP` value with a fractional seconds part into a column having the same type but fewer fractional digits. The default behavior is to use rounding. If this mode is enabled, truncation occurs instead. The following sequence of statements illustrates the difference:

```sql
CREATE TABLE t (id INT, tval TIME(1));
SET sql_mode='';
INSERT INTO t (id, tval) VALUES(1, 1.55);
SET sql_mode='TIME_TRUNCATE_FRACTIONAL';
INSERT INTO t (id, tval) VALUES(2, 1.55);
```

The resulting table contents look like this, where the first value has been subject to rounding and the second to truncation:

```sql
mysql> SELECT id, tval FROM t ORDER BY id;
+------+------------+
<table>
<thead>
<tr>
<th>id</th>
<th>tval</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>00:00:01.6</td>
</tr>
<tr>
<td>2</td>
<td>00:00:01.5</td>
</tr>
</tbody>
</table>
```

See also Section 11.2.6, “Fractional Seconds in Time Values”.

**Combination SQL Modes**

The following special modes are provided as shorthand for combinations of mode values from the preceding list.

• **ANSI**

   Equivalent to `REAL_AS_FLOAT`, `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, and `ONLY_FULL_GROUP_BY`.

   **ANSI** mode also causes the server to return an error for queries where a set function $S$ with an outer reference $S(\text{outer-ref})$ cannot be aggregated in the outer query against which the outer reference has been resolved. This is such a query:

   ```sql
   SELECT * FROM t1 WHERE t1.a IN (SELECT MAX(t1.b) FROM t2 WHERE ...);
   ```

   Here, `MAX(t1.b)` cannot aggregated in the outer query because it appears in the `WHERE` clause of that query. Standard SQL requires an error in this situation. If **ANSI** mode is not enabled, the server treats $S(\text{outer-ref})$ in such queries the same way that it would interpret $S(\text{const})$.

   See Section 1.7, “MySQL Standards Compliance”.

• **TRADITIONAL**

   **TRADITIONAL** is equivalent to `STRICT_TRANS_TABLES`, `STRICT_ALL_TABLES`, `NO_ZERO_IN_DATE`, `NO_ZERO_DATE`, `ERROR_FOR_DIVISION_BY_ZERO`, and `NO_ENGINE_SUBSTITUTION`.

**Strict SQL Mode**

Strict mode controls how MySQL handles invalid or missing values in data-change statements such as `INSERT` or `UPDATE`. A value can be invalid for several reasons. For example, it might have the wrong data type for the column, or it might be out of range. A value is missing when a new row to be inserted does not contain a value for a non-`NULL` column that has no explicit `DEFAULT` clause in its definition. (For a `NULL`
column, **NULL** is inserted if the value is missing.) Strict mode also affects DDL statements such as **CREATE TABLE**.

If strict mode is not in effect, MySQL inserts adjusted values for invalid or missing values and produces warnings (see Section 13.7.7.42, "SHOW WARNINGS Statement"). In strict mode, you can produce this behavior by using **INSERT IGNORE** or **UPDATE IGNORE**.

For statements such as **SELECT** that do not change data, invalid values generate a warning in strict mode, not an error.

Strict mode produces an error for attempts to create a key that exceeds the maximum key length. When strict mode is not enabled, this results in a warning and truncation of the key to the maximum key length.

Strict mode does not affect whether foreign key constraints are checked. **foreign_key_checks** can be used for that. (See Section 5.1.8, "Server System Variables").

Strict SQL mode is in effect if either **STRICT_ALL_TABLES** or **STRICT_TRANS_TABLES** is enabled, although the effects of these modes differ somewhat:

- For transactional tables, an error occurs for invalid or missing values in a data-change statement when either **STRICT_ALL_TABLES** or **STRICT_TRANS_TABLES** is enabled. The statement is aborted and rolled back.

- For nontransactional tables, the behavior is the same for either mode if the bad value occurs in the first row to be inserted or updated: The statement is aborted and the table remains unchanged. If the statement inserts or modifies multiple rows and the bad value occurs in the second or later row, the result depends on which strict mode is enabled:
  - For **STRICT_ALL_TABLES**, MySQL returns an error and ignores the rest of the rows. However, because the earlier rows have been inserted or updated, the result is a partial update. To avoid this, use single-row statements, which can be aborted without changing the table.
  - For **STRICT_TRANS_TABLES**, MySQL converts an invalid value to the closest valid value for the column and inserts the adjusted value. If a value is missing, MySQL inserts the implicit default value for the column data type. In either case, MySQL generates a warning rather than an error and continues processing the statement. Implicit defaults are described in Section 11.6, "Data Type Default Values".

Strict mode affects handling of division by zero, zero dates, and zeros in dates as follows:

- **Strict mode affects handling of division by zero, which includes** \( \text{MOD}(N, 0) \):
  - For data-change operations (**INSERT, UPDATE**):
    - If strict mode is not enabled, division by zero inserts **NULL** and produces no warning.
    - If strict mode is enabled, division by zero produces an error, unless **IGNORE** is given as well. For **INSERT IGNORE** and **UPDATE IGNORE**, division by zero inserts **NULL** and produces a warning.
  - For **SELECT**, division by zero returns **NULL**. Enabling strict mode causes a warning to be produced as well.

- **Strict mode affects whether the server permits '0000-00-00' as a valid date**:
  - If strict mode is not enabled, '0000-00-00' is permitted and inserts produce no warning.
• If strict mode is enabled, '0000-00-00' is not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, '0000-00-00' is permitted and inserts produce a warning.

• Strict mode affects whether the server permits dates in which the year part is nonzero but the month or day part is 0 (dates such as '2010-00-01' or '2010-01-00'):
  • If strict mode is not enabled, dates with zero parts are permitted and inserts produce no warning.
  • If strict mode is enabled, dates with zero parts are not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, dates with zero parts are inserted as '0000-00-00' (which is considered valid with `IGNORE`) and produce a warning.

For more information about strict mode with respect to `IGNORE`, see Comparison of the IGNORE Keyword and Strict SQL Mode.

Strict mode affects handling of division by zero, zero dates, and zeros in dates in conjunction with the `ERROR_FOR_DIVISION_BY_ZERO`, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE` modes.

Comparison of the IGNORE Keyword and Strict SQL Mode

This section compares the effect on statement execution of the `IGNORE` keyword (which downgrades errors to warnings) and strict SQL mode (which upgrades warnings to errors). It describes which statements they affect, and which errors they apply to.

The following table presents a summary comparison of statement behavior when the default is to produce an error versus a warning. An example of when the default is to produce an error is inserting a `NULL` into a `NOT NULL` column. An example of when the default is to produce a warning is inserting a value of the wrong data type into a column (such as inserting the string 'abc' into an integer column).

<table>
<thead>
<tr>
<th>Operational Mode</th>
<th>When Statement Default is</th>
<th>When Statement Default is</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Error</td>
<td>Warning</td>
</tr>
<tr>
<td>Without <code>IGNORE</code> or strict SQL</td>
<td>Error</td>
<td>Warning</td>
</tr>
<tr>
<td>mode</td>
<td></td>
<td></td>
</tr>
<tr>
<td>With <code>IGNORE</code></td>
<td>Warning</td>
<td>Warning (same as without <code>IGNORE</code> or strict SQL mode)</td>
</tr>
<tr>
<td>With strict SQL mode</td>
<td>Error (same as without <code>IGNORE</code> or strict SQL mode)</td>
<td>Error</td>
</tr>
<tr>
<td>With <code>IGNORE</code> and strict SQL mode</td>
<td>Warning</td>
<td>Warning</td>
</tr>
</tbody>
</table>

One conclusion to draw from the table is that when the `IGNORE` keyword and strict SQL mode are both in effect, `IGNORE` takes precedence. This means that, although `IGNORE` and strict SQL mode can be considered to have opposite effects on error handling, they do not cancel when used together.

• The Effect of `IGNORE` on Statement Execution

• The Effect of Strict SQL Mode on Statement Execution

The Effect of `IGNORE` on Statement Execution

Several statements in MySQL support an optional `IGNORE` keyword. This keyword causes the server to downgrade certain types of errors and generate warnings instead. For a multiple-row statement, `IGNORE` causes the statement to skip to the next row instead of aborting. (For nonignorable errors, an error occurs regardless of the `IGNORE` keyword.)
Example: If the table `t` has a primary key column `i`, attempting to insert the same value of `i` into multiple rows normally produces a duplicate-key error:

```sql
mysql> INSERT INTO t (i) VALUES(1),(1);
ERROR 1062 (23000): Duplicate entry '1' for key 't.PRIMARY'
```

With `IGNORE`, the row containing the duplicate key still is not inserted, but a warning occurs instead of an error:

```sql
mysql> INSERT IGNORE INTO t (i) VALUES(1),(1);
Query OK, 1 row affected, 1 warning (0.01 sec)
Records: 2  Duplicates: 1  Warnings: 1
```

```sql
mysql> SHOW WARNINGS;
+---------+------+-----------------------------------------+
| Level   | Code | Message                                 |
+---------+------+-----------------------------------------+
| Warning | 1062 | Duplicate entry '1' for key 't.PRIMARY' |
+---------+------+-----------------------------------------+
1 row in set (0.00 sec)
```

These statements support the `IGNORE` keyword:

- **CREATE TABLE ... SELECT: IGNORE** does not apply to the `CREATE TABLE` or `SELECT` parts of the statement but to inserts into the table of rows produced by the `SELECT`. Rows that duplicate an existing row on a unique key value are discarded.

- **DELETE: IGNORE** causes MySQL to ignore errors during the process of deleting rows.

- **INSERT: With IGNORE**, rows that duplicate an existing row on a unique key value are discarded. Rows set to values that would cause data conversion errors are set to the closest valid values instead.

  For partitioned tables where no partition matching a given value is found, `IGNORE` causes the insert operation to fail silently for rows containing the unmatched value.

- **LOAD DATA, LOAD XML: With IGNORE**, rows that duplicate an existing row on a unique key value are discarded.

- **UPDATE: With IGNORE**, rows for which duplicate-key conflicts occur on a unique key value are not updated. Rows updated to values that would cause data conversion errors are updated to the closest valid values instead.

The `IGNORE` keyword applies to the following ignorable errors:

- `ER_BAD_NULL_ERROR`
- `ER_DUP_ENTRY`
- `ER_DUP_ENTRY_WITH_KEY_NAME`
- `ER_DUP_KEY`
- `ER_NO_PARTITION_FOR_GIVEN_VALUE`
- `ER_NO_PARTITION_FOR_GIVEN_VALUE_SILENT`
- `ER_NO_REFERENCED_ROW_2`
- `ER_ROW_DOES_NOT_MATCH_GIVEN_PARTITION_SET`
- `ER_ROW_IS_REFERENCED_2`
- `ER_SUBQUERY_NO_1_ROW`
- `ER_VIEW_CHECK_FAILED`

**The Effect of Strict SQL Mode on Statement Execution**

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients, depending on the value of the `sql_mode` system variable. In “strict” SQL mode, the server upgrades certain warnings to errors.
For example, in non-strict SQL mode, inserting the string ‘abc’ into an integer column results in conversion of the value to 0 and a warning:

```sql
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t (i) VALUES('abc');
Query OK, 1 row affected, 1 warning (0.01 sec)

mysql> SHOW WARNINGS;
+---------+------+--------------------------------------------------------+
| Level   | Code | Message                                                |
+---------+------+--------------------------------------------------------+
| Warning | 1366 | Incorrect integer value: 'abc' for column 'i' at row 1 |
+---------+------+--------------------------------------------------------+
1 row in set (0.00 sec)
```

In strict SQL mode, the invalid value is rejected with an error:

```sql
mysql> SET sql_mode = 'STRICT_ALL_TABLES';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t (i) VALUES('abc');
ERROR 1366 (HY000): Incorrect integer value: 'abc' for column 'i' at row 1
```

For more information about possible settings of the `sql_mode` system variable, see Section 5.1.11, “Server SQL Modes”.

Strict SQL mode applies to the following statements under conditions for which some value might be out of range or an invalid row is inserted into or deleted from a table:

- `ALTER TABLE`
- `CREATE TABLE`
- `CREATE TABLE ... SELECT`
- `DELETE` (both single table and multiple table)
- `INSERT`
- `LOAD DATA`
- `LOAD XML`
- `SELECT SLEEP()`
- `UPDATE` (both single table and multiple table)

Within stored programs, individual statements of the types just listed execute in strict SQL mode if the program was defined while strict mode was in effect.

Strict SQL mode applies to the following errors, which represent a class of errors in which an input value is either invalid or missing. A value is invalid if it has the wrong data type for the column or might be out of range. A value is missing if a new row to be inserted does not contain a value for a `NOT NULL` column that has no explicit `DEFAULT` clause in its definition.

- `ER_BAD_NULL_ERROR`
- `ER_CUT_VALUE_GROUP_CONCAT`
- `ER_DATA_TOO_LONG`
- `ER_DATETIME_FUNCTION_OVERFLOW`
- `ER_DIVISION_BY_ZERO`
- `ER_INVALID_ARGUMENT_FOR_LOGARITHM`
- `ER_NO_DEFAULT_FOR_FIELD`
5.1.12 Connection Management

This section describes how MySQL Server manages connections. This includes a description of the available connection interfaces, how the server uses connection handler threads, details about the administrative connection interface, and management of DNS lookups.

5.1.12.1 Connection Interfaces

This section describes aspects of how the MySQL server manages client connections.

- **Network Interfaces and Connection Manager Threads**
- **Client Connection Thread Management**
- **Connection Volume Management**

### Network Interfaces and Connection Manager Threads

The server is capable of listening for client connections on multiple network interfaces. Connection manager threads handle client connection requests on the network interfaces that the server listens to:

- On all platforms, one manager thread handles TCP/IP connection requests.
- On Unix, the same manager thread also handles Unix socket file connection requests.
- On Windows, one manager thread handles shared-memory connection requests, and another handles named-pipe connection requests.
- On all platforms, an additional network interface may be enabled to accept administrative TCP/IP connection requests. This interface can use the manager thread that handles “ordinary” TCP/IP requests, or a separate thread.

The server does not create threads to handle interfaces that it does not listen to. For example, a Windows server that does not have support for named-pipe connections enabled does not create a thread to handle them.

Individual server plugins or components may implement their own connection interface:

- **X Plugin** enables MySQL Server to communicate with clients using X Protocol. See Section 20.5, “X Plugin”.

### Client Connection Thread Management

Connection manager threads associate each client connection with a thread dedicated to it that handles authentication and request processing for that connection. Manager threads create a new thread when...
necessary but try to avoid doing so by consulting the thread cache first to see whether it contains a thread that can be used for the connection. When a connection ends, its thread is returned to the thread cache if the cache is not full.

In this connection thread model, there are as many threads as there are clients currently connected, which has some disadvantages when server workload must scale to handle large numbers of connections. For example, thread creation and disposal becomes expensive. Also, each thread requires server and kernel resources, such as stack space. To accommodate a large number of simultaneous connections, the stack size per thread must be kept small, leading to a situation where it is either too small or the server consumes large amounts of memory. Exhaustion of other resources can occur as well, and scheduling overhead can become significant.

MySQL Enterprise Edition includes a thread pool plugin that provides an alternative thread-handling model designed to reduce overhead and improve performance. It implements a thread pool that increases server performance by efficiently managing statement execution threads for large numbers of client connections. See Section 5.6.3, “MySQL Enterprise Thread Pool”.

To control and monitor how the server manages threads that handle client connections, several system and status variables are relevant. (See Section 5.1.8, “Server System Variables”, and Section 5.1.10, “Server Status Variables”.)

- The **thread_cache_size** system variable determines the thread cache size. By default, the server autosizes the value at startup, but it can be set explicitly to override this default. A value of 0 disables caching, which causes a thread to be set up for each new connection and disposed of when the connection terminates. To enable \(N\) inactive connection threads to be cached, set **thread_cache_size** to \(N\) at server startup or at runtime. A connection thread becomes inactive when the client connection with which it was associated terminates.

- To monitor the number of threads in the cache and how many threads have been created because a thread could not be taken from the cache, check the **Threads_cached** and **Threads_created** status variables.

- When the thread stack is too small, this limits the complexity of the SQL statements the server can handle, the recursion depth of stored procedures, and other memory-consuming actions. To set a stack size of \(N\) bytes for each thread, start the server with **thread_stack** set to \(N\).

### Connection Volume Management

To control the maximum number of clients the server permits to connect simultaneously, set the **max_connections** system variable at server startup or at runtime. It may be necessary to increase **max_connections** if more clients attempt to connect simultaneously than the server is configured to handle (see Section B.3.2.5, “Too many connections”). If the server refuses a connection because the **max_connections** limit is reached, it increments the **Connection_errors_max_connections** status variable.

**mysql** actually permits **max_connections** + 1 client connections. The extra connection is reserved for use by accounts that have the **CONNECTION_ADMIN** privilege (or the deprecated **SUPER** privilege). By granting the privilege to administrators and not to normal users (who should not need it), an administrator can connect to the server and use **SHOW PROCESSLIST** to diagnose problems even if the maximum number of unprivileged clients are connected. See Section 13.7.7.29, “SHOW PROCESSLIST Statement”.

As of MySQL 8.0.14, the server also permits administrative connections on an administrative network interface, which you can set up using a dedicated IP address and port. See Section 5.1.12.2, “Administrative Connection Management”.

The Group Replication plugin interacts with MySQL Server using internal sessions to perform SQL API operations. In releases to MySQL 8.0.18, these sessions count towards the client connections limit.
specified by the `max_connections` server system variable. In those releases, if the server has reached the `max_connections` limit when Group Replication is started or attempts to perform an operation, the operation is unsuccessful and Group Replication or the server itself might stop. From MySQL 8.0.19, Group Replication’s internal sessions are handled separately from client connections, so they do not count towards the `max_connections` limit and are not refused if the server has reached this limit.

The maximum number of client connections MySQL supports (that is, the maximum value to which `max_connections` can be set) depends on several factors:

- The quality of the thread library on a given platform.
- The amount of RAM available.
- The amount of RAM is used for each connection.
- The workload from each connection.
- The desired response time.
- The number of file descriptors available.

Linux or Solaris should be able to support at least 500 to 1000 simultaneous connections routinely and as many as 10,000 connections if you have many gigabytes of RAM available and the workload from each is low or the response time target undemanding.

Increasing the `max_connections` value increases the number of file descriptors that `mysql` requires. If the required number of descriptors are not available, the server reduces the value of `max_connections`. For comments on file descriptor limits, see Section 8.4.3.1, “How MySQL Opens and Closes Tables”.

Increasing the `open_files_limit` system variable may be necessary, which may also require raising the operating system limit on how many file descriptors can be used by MySQL. Consult your operating system documentation to determine whether it is possible to increase the limit and how to do so. See also Section B.3.2.16, “File Not Found and Similar Errors”.

### 5.1.12.2 Administrative Connection Management

As mentioned in Connection Volume Management, to allow for the need to perform administrative operations even when `max_connections` connections are already established on the interfaces used for ordinary connections, the MySQL server permits a single administrative connection to users who have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege).

Additionally, as of MySQL 8.0.14, the server permits dedicating a TCP/IP port for administrative connections, as described in the following sections.

- Administrative Interface Characteristics
- Administrative Interface Support for Encrypted Connections

#### Administrative Interface Characteristics

The administrative connection interface has these characteristics:

- The server enables the interface only if the `admin_address` system variable is set at startup to indicate the IP address for it. If `admin_address` is not set, the server maintains no administrative interface.
- The `admin_port` system variable specifies the interface TCP/IP port number (default 33062).
Connection Management

- There is no limit on the number of administrative connections.
- Connections are permitted only for users who have the `SERVICE_CONNECTION_ADMIN` privilege.
- The `create_admin_listener_thread` system variable enables DBAs to choose at startup whether the administrative interface has its own separate thread. The default is `OFF`; that is, the manager thread for ordinary connections on the main interface also handles connections for the administrative interface.

These lines in the server `my.cnf` file enable the administrative interface on the loopback interface and configure it to use port number 33064 (that is, a port different from the default):

```
[mysqld]
admin_address=127.0.0.1
admin_port=33064
```

MySQL client programs connect to either the main or administrative interface by specifying appropriate connection parameters. If the server running on the local host is using the default TCP/IP port numbers of 3306 and 33062 for the main and administrative interfaces, these commands connect to those interfaces:

```
mysql --protocol=TCP --port=3306
mysql --protocol=TCP --port=33062
```

Administrative Interface Support for Encrypted Connections

Prior to MySQL 8.0.21, the administrative interface supports encrypted connections using the connection-encryption configuration that applies to the main interface. As of MySQL 8.0.21, the administrative interface has its own configuration parameters for encrypted connections. These correspond to the main interface parameters but enable independent configuration of encrypted connections for the administrative interface:

- The `--admin-ssl` option is like the `--ssl` option, but it enables or disables encrypted connections for the administrative interface rather than the main interface.
- The `admin_tls_xxx` and `admin_ssl_xxx` system variables are like the `tls_xxx` and `ssl_xxx` system variables, but they configure the TLS context for the administrative interface rather than the main interface.

For general information about configuring connection-encryption support, see Section 6.3.1, "Configuring MySQL to Use Encrypted Connections". That discussion is written for the main connection interface, but the parameter names are similar for the administrative connection interface. The following remarks provide information specific to the administrative interface.

TLS configuration for the administrative interface follows these rules:

- If `--admin-ssl` is enabled (the default), the administrative interface supports encrypted connections. For connections on the interface, the applicable TLS context depends on whether any nondefault administrative TLS parameter is configured:
  - If all administrative TLS parameters have their default values, the administrative interface uses the same TLS context as the main interface.
  - If any administrative TLS parameter has a nondefault value, the administrative interface uses the TLS context defined by its own parameters. (This is the case if any `admin_tls_xxx` or `admin_ssl_xxx` system variable is set to a value different from its default.) If a valid TLS context cannot be created from those parameters, the administrative interface falls back to the main interface TLS context.
  - If `--admin-ssl` is disabled, encrypted connections to the administrative interface are disabled. (This is true even if administrative TLS parameters have nondefault values because disabling `--admin-ssl` takes precedence.)
Examples:

- This configuration in the server `my.cnf` file enables the administrative interface, but does not set any of the TLS parameters specific to that interface:

  ```
  [mysqld]
  admin_address=127.0.0.1
  ```

  As a result, the administrative interface supports encrypted connections (because encryption is supported by default when the administrative interface is enabled), but uses the main interface TLS context. When clients connect to the administrative interface, they should use the same certificate and key files as for ordinary connections on the main interface. For example (enter the command on a single line):

  ```
  mysql --protocol=TCP --port=33062
  --ssl-ca=ca.pem
  --ssl-cert=client-cert.pem
  --ssl-key=client-key.pem
  ```

- This server configuration enables the administrative interface and sets the TLS certificate and key file parameters specific to that interface:

  ```
  [mysqld]
  admin_address=127.0.0.1
  admin_ssl_ca=admin-ca.pem
  admin_ssl_cert=admin-server-cert.pem
  admin_ssl_key=admin-server-key.pem
  ```

  As a result, the administrative interface supports encrypted connections using its own TLS context. When clients connect to the administrative interface, they should use certificate and key files specific to that interface. For example (enter the command on a single line):

  ```
  mysql --protocol=TCP --port=33062
  --ssl-ca=admin-ca.pem
  --ssl-cert=admin-client-cert.pem
  --ssl-key=admin-client-key.pem
  ```

- This server configuration enables the administrative interface but disables encrypted connections for it:

  ```
  [mysqld]
  admin-ssl=OFF
  admin_address=127.0.0.1
  ```

  In this case, if the configuration were to also set administrative TLS parameters such as `admin_ssl_ca`, those parameter settings would have no effect because `admin-ssl=OFF` takes precedence.

### 5.1.12.3 DNS Lookups and the Host Cache

The MySQL server maintains an in-memory host cache that contains information about clients: IP address, host name, and error information. The Performance Schema `host_cache` table exposes the contents of the host cache so that it can be examined using `SELECT` statements. This may help you diagnose the causes of connection problems. See Section 26.12.19.2, “The `host_cache` Table”.

The following sections discuss how the host cache works, as well as other topics such as how to configure and monitor the cache.

- Host Cache Operation
- Configuring the Host Cache
Connection Management

• Monitoring the Host Cache
• Flushing the Host Cache
• Dealing with Blocked Hosts

Host Cache Operation

The server uses the host cache only for non-localhost TCP connections. It does not use the cache for TCP connections established using a loopback interface address (for example, 127.0.0.1 or ::1), or for connections established using a Unix socket file, named pipe, or shared memory.

The server uses the host cache for several purposes:

• By caching the results of IP-to-host name lookups, the server avoids doing a Domain Name System (DNS) lookup for each client connection. Instead, for a given host, it needs to perform a lookup only for the first connection from that host.

• The cache contains information about errors that occur during the client connection process. Some errors are considered “blocking.” If too many of these occur successively from a given host without a successful connection, the server blocks further connections from that host. The `max_connect_errors` system variable determines the permitted number of successive errors before blocking occurs.

For each applicable new client connection, the server uses the client IP address to check whether the client host name is in the host cache. If so, the server refuses or continues to process the connection request depending on whether or not the host is blocked. If the host is not in the cache, the server attempts to resolve the host name. First, it resolves the IP address to a host name and resolves that host name back to an IP address. Then it compares the result to the original IP address to ensure that they are the same. The server stores information about the result of this operation in the host cache. If the cache is full, the least recently used entry is discarded.

The server performs host name resolution using the `gethostbyaddr()` and `gethostbyname()` system calls.

The server handles entries in the host cache like this:

1. When the first TCP client connection reaches the server from a given IP address, a new cache entry is created to record the client IP, host name, and client lookup validation flag. Initially, the host name is set to `NULL` and the flag is false. This entry is also used for subsequent client TCP connections from the same originating IP.

2. If the validation flag for the client IP entry is false, the server attempts an IP-to-host name-to-IP DNS resolution. If that is successful, the host name is updated with the resolved host name and the validation flag is set to true. If resolution is unsuccessful, the action taken depends on whether the error is permanent or transient. For permanent failures, the host name remains `NULL` and the validation flag is set to true. For transient failures, the host name and validation flag remain unchanged. (In this case, another DNS resolution attempt occurs the next time a client connects from this IP.)

3. If an error occurs while processing an incoming client connection from a given IP address, the server updates the corresponding error counters in the entry for that IP. For a description of the errors recorded, see Section 26.12.19.2, “The host_cache Table”.

To unblock blocked hosts, flush the host cache; see Dealing with Blocked Hosts.

It is possible for a blocked host to become unblocked even without flushing the host cache if activity from other hosts occurs:
Connection Management

• If the cache is full when a connection arrives from a client IP not in the cache, the server discards the least recently used cache entry to make room for the new entry.

• If the discarded entry is for a blocked host, that host becomes unblocked.

Some connection errors are not associated with TCP connections, occur very early in the connection process (even before an IP address is known), or are not specific to any particular IP address (such as out-of-memory conditions). For information about these errors, check the Connection_errors_xxx status variables (see Section 5.1.10, “Server Status Variables”).

Configuring the Host Cache

The host cache is enabled by default. The host_cache_size system variable controls its size, as well as the size of the Performance Schema host_cache table that exposes the cache contents. The cache size can be set at server startup and changed at runtime. For example, to set the size to 100 at startup, put these lines in the server my.cnf file:

```
[mysqld]
host_cache_size=200
```

To change the size to 300 at runtime, do this:

```
SET GLOBAL host_cache_size=300;
```

Setting host_cache_size to 0, either at server startup or at runtime, disables the host cache. With the cache disabled, the server performs a DNS lookup every time a client connects.

Changing the cache size at runtime causes an implicit host cache flushing operation that clears the host cache, truncates the host_cache table, and unblocks any blocked hosts; see Flushing the Host Cache.

Using the --skip-host-cache option is similar to setting the host_cache_size system variable to 0, but host_cache_size is more flexible because it can also be used to resize, enable, and disable the host cache at runtime, not just at server startup. Starting the server with --skip-host-cache does not prevent runtime changes to the value of host_cache_size, but such changes have no effect and the cache is not re-enabled even if host_cache_size is set larger than 0.

To disable DNS host name lookups, start the server with the skip_name_resolve system variable enabled. In this case, the server uses only IP addresses and not host names to match connecting hosts to rows in the MySQL grant tables. Only accounts specified in those tables using IP addresses can be used. (A client may not be able to connect if no account exists that specifies the client IP address.)

If you have a very slow DNS and many hosts, you might be able to improve performance either by enabling skip_name_resolve to disable DNS lookups, or by increasing the value of host_cache_size to make the host cache larger.

To disallow TCP/IP connections entirely, start the server with the skip_networking system variable enabled.

To adjust the permitted number of successive connection errors before host blocking occurs, set the max_connect_errors system variable. For example, to set the value at startup put these lines in the server my.cnf file:

```
[mysqld]
max_connect_errors=10000
```

To change the value at runtime, do this:
Monitoring the Host Cache

The Performance Schema `host_cache` table exposes the contents of the host cache. This table can be examined using `SELECT` statements, which may help you diagnose the causes of connection problems. For information about this table, see Section 26.12.19.2, “The `host_cache` Table”.

Flushing the Host Cache

Flushing the host cache might be advisable or desirable under these conditions:

- Some of your client hosts change IP address.
- The error message `Host 'host_name' is blocked` occurs for connections from legitimate hosts. (See Dealing with Blocked Hosts.)

Flushing the host cache has these effects:

- It clears the in-memory host cache.
- It removes all rows from the Performance Schema `host_cache` table that exposes the cache contents.
- It unblocks any blocked hosts. This enables further connection attempts from those hosts.

To flush the host cache, use any of these methods:

- Change the value of the `host_cache_size` system variable. This requires the `SYSTEM_VARIABLES_ADMIN` privilege (or the deprecated `SUPER` privilege).
- Execute a `TRUNCATE TABLE` statement that truncates the Performance Schema `host_cache` table. This requires the `DROP` privilege for the table.
- Execute a `FLUSH HOSTS` statement. This requires the `RELOAD` privilege.
- Execute a `mysqladmin flush-hosts` command. This requires the `DROP` privilege for the Performance Schema `host_cache` table or the `RELOAD` privilege.

Dealing with Blocked Hosts

The server uses the host cache to track errors that occur during the client connection process. If the following error occurs, it means that `mysqld` has received many connection requests from the given host that were interrupted in the middle:

```
Host 'host_name' is blocked because of many connection errors.
Unblock with 'mysqladmin flush-hosts'
```

The value of the `max_connect_errors` system variable determines how many successive interrupted connection requests the server permits before blocking a host. After `max_connect_errors` failed requests without a successful connection, the server assumes that something is wrong (for example, that someone is trying to break in), and blocks the host from further connection requests.

To unblock blocked hosts, flush the host cache; see Flushing the Host Cache.

Alternatively, to avoid having the error message occur, set `max_connect_errors` as described in Configuring the Host Cache. The default value of `max_connect_errors` is 100. Increasing `max_connect_errors` to a large value makes it less likely that a host will reach the threshold and
become blocked. However, if the Host 'host_name' is blocked error message occurs, first verify that there is nothing wrong with TCP/IP connections from the blocked hosts. It does no good to increase the value of max_connect_errors if there are network problems.

### 5.1.13 IPv6 Support

Support for IPv6 in MySQL includes these capabilities:

- MySQL Server can accept TCP/IP connections from clients connecting over IPv6. For example, this command connects over IPv6 to the MySQL server on the local host:

  ```
  shell> mysql -h ::1
  ```

  To use this capability, two things must be true:

  - Your system must be configured to support IPv6. See Section 5.1.13.1, “Verifying System Support for IPv6”.

  - The default MySQL server configuration permits IPv6 connections in addition to IPv4 connections. To change the default configuration, start the server with the `bind_address` system variable set to an appropriate value. See Section 5.1.8, “Server System Variables”.

- MySQL account names permit IPv6 addresses to enable DBAs to specify privileges for clients that connect to the server over IPv6. See Section 6.2.4, “Specifying Account Names”. IPv6 addresses can be specified in account names in statements such as `CREATE USER`, `GRANT`, and `REVOKE`. For example:

  ```
  mysql> CREATE USER 'bill'@'::1' IDENTIFIED BY 'secret';
  mysql> GRANT SELECT ON mydb.* TO 'bill'@'::1';
  ```

- IPv6 functions enable conversion between string and internal format IPv6 address formats, and checking whether values represent valid IPv6 addresses. For example, `INET6_ATON()` and `INET6_NTOA()` are similar to `INET_ATON()` and `INET_NTOA()`, but handle IPv6 addresses in addition to IPv4 addresses. See Section 12.24, “Miscellaneous Functions”.

- From MySQL 8.0.14, Group Replication group members can use IPv6 addresses for communications within the group. A group can contain a mix of members using IPv6 and members using IPv4. See Section 18.4.5, “Support For IPv6 And For Mixed IPv6 And IPv4 Groups”.

The following sections describe how to set up MySQL so that clients can connect to the server over IPv6.

### 5.1.13.1 Verifying System Support for IPv6

Before MySQL Server can accept IPv6 connections, the operating system on your server host must support IPv6. As a simple test to determine whether that is true, try this command:

```
shell> ping6 ::1
16 bytes from ::1, icmp_seq=0 hlim=64 time=0.171 ms
16 bytes from ::1, icmp_seq=1 hlim=64 time=0.077 ms
... 
```

To produce a description of your system’s network interfaces, invoke `ifconfig -a` and look for IPv6 addresses in the output.

If your host does not support IPv6, consult your system documentation for instructions on enabling it. It might be that you need only reconfigure an existing network interface to add an IPv6 address. Or a more extensive change might be needed, such as rebuilding the kernel with IPv6 options enabled.

These links may be helpful in setting up IPv6 on various platforms:
IPv6 Support

- Windows
- Gentoo Linux
- Ubuntu Linux
- Linux (Generic)
- macOS

5.1.13.2 Configuring the MySQL Server to Permit IPv6 Connections

The MySQL server listens on one or more network sockets for TCP/IP connections. Each socket is bound to one address, but it is possible for an address to map onto multiple network interfaces.

Set the `bind_address` system variable at server startup to specify the TCP/IP connections that a server instance accepts. As of MySQL 8.0.13, you can specify multiple values for this option, including any combination of IPv6 addresses, IPv4 addresses, and host names that resolve to IPv6 or IPv4 addresses. Alternatively, you can specify one of the wildcard address formats that permit listening on multiple network interfaces. A value of `*`, which is the default, or a value of `::`, permit both IPv4 and IPv6 connections on all server host IPv4 and IPv6 interfaces. For more information, see the `bind_address` description in Section 5.1.8, “Server System Variables”.

5.1.13.3 Connecting Using the IPv6 Local Host Address

The following procedure shows how to configure MySQL to permit IPv6 connections by clients that connect to the local server using the `::1` local host address. The instructions given here assume that your system supports IPv6.

1. Start the MySQL server with an appropriate `bind_address` setting to permit it to accept IPv6 connections. For example, put the following lines in the server option file and restart the server:

   ```
   [mysqld]
   bind_address = *
   ```

   Specifying `*` (or `::`) as the value for `bind_address` permits both IPv4 and IPv6 connections on all server host IPv4 and IPv6 interfaces. If you want to bind the server to a specific list of addresses, you can do this as of MySQL 8.0.13 by specifying a comma-separated list of values for `bind_address`. This example specifies the local host addresses for both IPv4 and IPv6:

   ```
   [mysqld]
   bind_address = 127.0.0.1,::1
   ```

   For more information, see the `bind_address` description in Section 5.1.8, “Server System Variables”.

2. As an administrator, connect to the server and create an account for a local user who can connect from the `::1` local IPv6 host address:

   ```
   mysql> CREATE USER 'ipv6user'@'::1' IDENTIFIED BY 'ipv6pass';
   ```

   For the permitted syntax of IPv6 addresses in account names, see Section 6.2.4, “Specifying Account Names”. In addition to the `CREATE USER` statement, you can issue `GRANT` statements that give specific privileges to the account, although that is not necessary for the remaining steps in this procedure.

3. Invoke the `mysql` client to connect to the server using the new account:

   ```
   shell> mysql -h ::1 -u ipv6user -pipv6pass
   ```

4. Try some simple statements that show connection information:
5.1.13.4 Connecting Using IPv6 Nonlocal Host Addresses

The following procedure shows how to configure MySQL to permit IPv6 connections by remote clients. It is similar to the preceding procedure for local clients, but the server and client hosts are distinct and each has its own nonlocal IPv6 address. The example uses these addresses:

| Server host: 2001:db8:0:f101::1
| Client host: 2001:db8:0:f101::2

These addresses are chosen from the nonroutable address range recommended by IANA for documentation purposes and suffice for testing on your local network. To accept IPv6 connections from clients outside the local network, the server host must have a public address. If your network provider assigns you an IPv6 address, you can use that. Otherwise, another way to obtain an address is to use an IPv6 broker; see Section 5.1.13.5, "Obtaining an IPv6 Address from a Broker".

1. Start the MySQL server with an appropriate `bind_address` setting to permit it to accept IPv6 connections. For example, put the following lines in the server option file and restart the server:

   ```
   [mysqld]
   bind_address = *
   ```

   Specifying * (or `::`) as the value for `bind_address` permits both IPv4 and IPv6 connections on all server host IPv4 and IPv6 interfaces. If you want to bind the server to a specific list of addresses, you can do this as of MySQL 8.0.13 by specifying a comma-separated list of values for `bind_address`. This example specifies an IPv4 address as well as the required server host IPv6 address:

   ```
   [mysqld]
   bind_address = 198.51.100.20,2001:db8:0:f101::1
   ```

   For more information, see the `bind_address` description in Section 5.1.8, “Server System Variables”.

2. On the server host (2001:db8:0:f101::1), create an account for a user who can connect from the client host (2001:db8:0:f101::2):

   ```
   mysql> CREATE USER 'remoteipv6user'@'2001:db8:0:f101::2' IDENTIFIED BY 'remoteipv6pass';
   ```

3. On the client host (2001:db8:0:f101::2), invoke the `mysql` client to connect to the server using the new account:

   ```
   shell> mysql -h 2001:db8:0:f101::1 -u remoteipv6user -premoteipv6pass
   ```

4. Try some simple statements that show connection information:

   ```
   mysql> STATUS
   ... Connection: 2001:db8:0:f101::1 via TCP/IP
   ...
5.1.13.5 Obtaining an IPv6 Address from a Broker

If you do not have a public IPv6 address that enables your system to communicate over IPv6 outside your local network, you can obtain one from an IPv6 broker. The Wikipedia IPv6 Tunnel Broker page lists several brokers and their features, such as whether they provide static addresses and the supported routing protocols.

After configuring your server host to use a broker-supplied IPv6 address, start the MySQL server with an appropriate `bind_address` setting to permit the server to accept IPv6 connections. You can specify * (or `::`) as the `bind_address` value, or bind the server to the specific IPv6 address provided by the broker. For more information, see the `bind_address` description in Section 5.1.8, “Server System Variables”.

Note that if the broker allocates dynamic addresses, the address provided for your system might change the next time you connect to the broker. If so, any accounts you create that name the original address become invalid. To bind to a specific address but avoid this change-of-address problem, you might be able to arrange with the broker for a static IPv6 address.

The following example shows how to use Freenet6 as the broker and the gogoc IPv6 client package on Gentoo Linux.

1. Create an account at Freenet6 by visiting this URL and signing up:
   ```
   http://gogonet.gogo6.com
   ```

2. After creating the account, go to this URL, sign in, and create a user ID and password for the IPv6 broker:
   ```
   http://gogonet.gogo6.com/page/freenet6-registration
   ```

3. As root, install gogoc:
   ```
   shell> emerge gogoc
   ```

4. Edit `/etc/gogoc/gogoc.conf` to set the `userid` and `password` values. For example:
   ```
   userid=gogouser
   passwd=gogopass
   ```

5. Start gogoc:
   ```
   shell> /etc/init.d/gogoc start
   ```

   To start gogoc each time your system boots, execute this command:
   ```
   shell> rc-update add gogoc default
   ```

6. Use ping6 to try to ping a host:
   ```
   shell> ping6 ipv6.google.com
   ```

7. To see your IPv6 address:
   ```
   shell> ifconfig tun
   ```
Network Namespace Support

5.1.14 Network Namespace Support

A network namespace is a logical copy of the network stack from the host system. Network namespaces are useful for setting up containers or virtual environments. Each namespace has its own IP addresses, network interfaces, routing tables, and so forth. The default or global namespace is the one in which the host system physical interfaces exist.

Namespace-specific address spaces can lead to problems when MySQL connections cross namespaces. For example, the network address space for a MySQL instance running in a container or virtual network may differ from the address space of the host machine. This can produce phenomena such as a client connection from an address in one namespace appearing to the MySQL server to be coming from a different address, even for client and server running on the same machine. Suppose that both processes run on a host with IP address 203.0.113.10 but use different namespaces. A connection may produce a result like this:

```
shell> mysql --user=admin --host=203.0.113.10 --protocol=tcp
mysql> SELECT USER();
+--------------------+
| USER()             |
+--------------------+
| admin@198.51.100.2 |
+--------------------+
```

In this case, the expected USER() value is admin@203.0.113.10. Such behavior can make it difficult to assign account permissions properly if the address from which an connection originates is not what it appears.

To address this issue, MySQL enables specifying the network namespace to use for TCP/IP connections, so that both endpoints of connections use an agreed-upon common address space.

MySQL 8.0.22 and higher supports network namespaces on platforms that implement them. Support within MySQL applies to:

- The MySQL server, mysqld.
- X Plugin.
- The mysql client and the mysqlxtest test suite client. (Other clients are not supported. They must be invoked from within the network namespace of the server to which they are to connect.)
- Regular replication. (Group Replication is not supported.)

The following sections describe how to use network namespaces in MySQL:

- **Host System Prerequisites**
- **MySQL Configuration**
- **Network Namespace Monitoring**

**Host System Prerequisites**

Prior to using network namespace support in MySQL, these host system prerequisites must be satisfied:

- The host operating system must support network namespaces. (For example, Linux.)
- Any network namespace to be used by MySQL must first be created on the host system.
Network Namespace Support

• Host name resolution must be configured by the system administrator to support network namespaces.

Note

A known limitation is that, within MySQL, host name resolution does not work for names specified in network namespace-specific host files. For example, if the address for a host name in the red namespace is specified in the /etc/netns/red/hosts file, binding to the name fails on both the server and client sides. The workaround is to use the IP address rather than the host name.

• The system administrator must enable the CAP_SYS_ADMIN operating system privilege for the MySQL binaries that support network namespaces (mysqld, mysql, mysqlxtest).

Important

Enabling CAP_SYS_ADMIN is a security sensitive operation because it enables a process to perform other privileged actions in addition to setting namespaces. For a description of its effects, see https://man7.org/linux/man-pages/man7/capabilities.7.html.

Because CAP_SYS_ADMIN must be enabled explicitly by the system administrator, MySQL binaries by default do not have network namespace support enabled. The system administrator should evaluate the security implications of running MySQL processes with CAP_SYS_ADMIN before enabling it.

The instructions in the following example set up network namespaces named red and blue. The names you choose may differ, as may the network addresses and interfaces on your host system.

Invoke the commands shown here either as the root operating system user or by prefixing each command with sudo. For example, to invoke the ip or setcap command if you are not root, use sudo ip or sudo setcap.

To configure network namespaces, use the ip command. For some operations, the ip command must execute within a particular namespace (which must already exist). In such cases, begin the command like this:

```
ip netns exec namespace_name
```

For example, this command executes within the red namespace to bring up the loopback interface:

```
ip netns exec red ip link set lo up
```

To add namespaces named red and blue, each with its own virtual Ethernet device used as a link between namespaces and its own loopback interface:

```
ip netns add red
ip link add veth-red type veth peer name vpeer-red
ip link set vpeer-red netns red
ip addr add 192.0.2.1/24 dev veth-red
ip link set veth-red up
ip netns exec red ip addr add 192.0.2.2/24 dev vpeer-red
ip netns exec red ip link set vpeer-red up
ip netns exec red ip link set lo up
ip netns add blue
ip link add veth-blue type veth peer name vpeer-blue
ip link set vpeer-blue netns blue
ip addr add 198.51.100.1/24 dev veth-blue
```
Network Namespace Support

ip link set veth-blue up
ip netns exec blue ip addr add 198.51.100.2/24 dev vpeer-blue
ip netns exec blue ip link set vpeer-blue up
ip netns exec blue ip link set lo up

# if you want to enable inter-subnet routing...
sysctl net.ipv4.ip_forward=1
ip netns exec red ip route add default via 192.0.2.1
ip netns exec blue ip route add default via 198.51.100.1

A diagram of the links between namespaces looks like this:

<table>
<thead>
<tr>
<th>red</th>
<th>global</th>
<th>blue</th>
</tr>
</thead>
<tbody>
<tr>
<td>192.0.2.2 &lt;--&gt; 192.0.2.1</td>
<td>198.51.100.1 &lt;--&gt; 198.51.100.2</td>
<td></td>
</tr>
<tr>
<td>(vpeer-red) (veth-red)</td>
<td>(veth-blue) (vpeer-blue)</td>
<td></td>
</tr>
</tbody>
</table>

To check which namespaces and links exist:

ip netns list
ip link list

To see the routing tables for the global and named namespaces:

ip route show
ip netns exec red ip route show
ip netns exec blue ip route show

To remove the red and blue links and namespaces:

ip link del veth-red
ip link del veth-blue
ip netns del red
ip netns del blue
sysctl net.ipv4.ip_forward=0

So that the MySQL binaries that include network namespace support can actually use namespaces, you must grant them the CAP_SYS_ADMIN capability. The following setcap commands assume that you have changed location to the directory containing your MySQL binaries (adjust the pathname for your system as necessary):

cd /usr/local/mysql/bin

To grant CAP_SYS_ADMIN capability to the appropriate binaries:

setcap cap_sys_admin+ep ./mysqld
setcap cap_sys_admin+ep ./mysql
setcap cap_sys_admin+ep ./mysqlxtest

To check CAP_SYS_ADMIN capability:

shell> getcap ./mysqld ./mysql ./mysqlxtest
./mysqld = cap_sys_admin+ep
./mysql = cap_sys_admin+ep
./mysqlxtest = cap_sys_admin+ep

To remove CAP_SYS_ADMIN capability:
setcap -r ./mysqld
setcap -r ./mysql
setcap -r ./mysqlxtest

Important

If you reinstall binaries to which you have previously applied `setcap`, you must use `setcap` again. For example, if you perform an in-place MySQL upgrade, failure to grant the `CAP_SYS_ADMIN` capability again results in namespace-related failures. The server fails with this error for attempts to bind to an address with a named namespace:

```
[ERROR] [MY-013408] [Server] setns() failed with error 'Operation not permitted'
```

A client invoked with the `--network-namespace` option fails like this:

```
ERROR: Network namespace error: Operation not permitted
```

MySQL Configuration

Assuming that the preceding host system prerequisites have been satisfied, MySQL enables configuring the server-side namespace for the listening (inbound) side of connections and the client-side namespace for the outbound side of connections.

On the server side, the `bind_address`, `admin_address`, and `mysqlx_bind_address` system variables have extended syntax for specifying the network namespace to use for a given IP address or host name on which to listen for incoming connections. To specify a namespace for an address, add a slash and the namespace name. For example, a server `my.cnf` file might contain these lines:

```
[mysqld]
bind_address = 127.0.1.1,192.0.2.2/red,198.51.100.2/blue
admin_address = 102.0.2.2/red
mysqlx_bind_address = 102.0.2.2/red
```

These rules apply:

- A network namespace can be specified for an IP address or a host name.
- A network namespace cannot be specified for a wildcard IP address.
- For a given address, the network namespace is optional. If given, it must be specified as a `/ns` suffix immediately following the address.
- An address with no `/ns` suffix uses the host system global namespace. The global namespace is therefore the default.
- An address with a `/ns` suffix uses the namespace named `ns`.
- The host system must support network namespaces and each named namespace must previously have been set up. Naming a nonexistent namespace produces an error.
- `bind_address` and (as of MySQL 8.0.21) `mysqlx_bind_address` accept a list of multiple comma-separated addresses, the variable value can specify addresses in the global namespace, in named namespaces, or a mix.

If an error occurs during server startup for attempts to use a namespace, the server does not start. If errors occur for X Plugin during plugin initialization such that it is unable to bind to any address, the plugin fails its initialization sequence and the server does not load it.
On the client side, a network namespace can be specified in these contexts:

- For the `mysql` client and the `mysqlxtest` test suite client, use the `--network-namespace` option. For example:

  ```
  mysql --host=192.0.2.2 --network-namespace=red
  ```

  If the `--network-namespace` option is omitted, the connection uses the default (global) namespace.

- For replication connections from replica servers to source servers, use the `CHANGE MASTER TO` statement and specify the `NETWORK_NAMESPACE` option. For example:

  ```
  CHANGE MASTER TO
  MASTER_HOST = '192.0.2.2',
  NETWORK_NAMESPACE = 'red';
  ```

  If the `NETWORK_NAMESPACE` option is omitted, replication connections use the default (global) namespace.

The following example sets up a MySQL server that listens for connections in the global, red, and blue namespaces, and shows how to configure accounts that connect from the red and blue namespaces. It is assumed that the red and blue namespaces have already been created as shown in Host System Prerequisites.

1. Configure the server to listen on addresses in multiple namespaces. Put these lines in the server `my.cnf` file and start the server:

   ```
   [mysqld]
   bind_address = 127.0.1.1,192.0.2.2/red,198.51.100.2/blue
   ```

   The value tells the server to listen on the loopback address `127.0.0.1` in the global namespace, the address `192.0.2.2` in the red namespace, and the address `198.51.100.2` in the blue namespace.

2. Connect to the server in the global namespace and create accounts that have permission to connect from an address in the address space of each named namespace:

   ```
   shell> mysql -u root -h 127.0.0.1 -p
   Enter password: root_password

   mysql> CREATE USER 'red_user'@'192.0.2.2'
      IDENTIFIED BY 'red_user_password';

   mysql> CREATE USER 'blue_user'@'198.51.100.2'
      IDENTIFIED BY 'blue_user_password';
   ```

3. Verify that you can connect to the server in each named namespace:

   ```
   shell> mysql -u red_user -h 192.0.2.2 --network-namespace=red -p
   Enter password: red_user_password

   mysql> SELECT USER();
   :+:------------------------+
   | USER()                  |
   :+:------------------------+
   | red_user@192.0.2.2      |
   :+:------------------------+

   shell> mysql -u blue_user -h 198.51.100.2 --network-namespace=blue -p
   Enter password: blue_user_password

   mysql> SELECT USER();
   :+:------------------------+
MySQL Server Time Zone Support

<table>
<thead>
<tr>
<th>USER()</th>
</tr>
</thead>
<tbody>
<tr>
<td>blue_user@198.51.100.2</td>
</tr>
</tbody>
</table>

**Note**

You might see different results from `USER()`, which can return a value that includes a host name rather than an IP address if your DNS is configured to be able to resolve the address to the corresponding host name and the server is not run with the `skip_name_resolve` system variable enabled. You might also try invoking `mysql` without the `--network-namespace` option to see whether the connection attempt succeeds, and, if so, how the `USER()` value is affected.

**Network Namespace Monitoring**

For replication monitoring purposes, these information sources have a column that displays the applicable network namespace for connections:

- The Performance Schema `replication_connection_configuration` table. See Section 26.12.11.1, “The replication_connection_configuration Table”.
- The replica server connection metadata repository. See Section 17.2.4.2, “Replication Metadata Repositories”.
- The `SHOW REPLICA | SLAVE STATUS` statement. See Section 13.7.7.35, “SHOW REPLICA | SLAVE STATUS Statement”.

**5.1.15 MySQL Server Time Zone Support**

This section describes the time zone settings maintained by MySQL, how to load the system tables required for named time support, how to stay current with time zone changes, and how to enable leap-second support.

Beginning with MySQL 8.0.19, time zone offsets are also supported for inserted datetime values; see Section 11.2.2, “The DATE, DATETIME, and TIMESTAMP Types”, for more information.

- Time Zone Variables
- Populating the Time Zone Tables
- Staying Current with Time Zone Changes
- Time Zone Leap Second Support

For information about time zone settings in replication setups, see Section 17.5.1.14, “Replication and System Functions” and Section 17.5.1.32, “Replication and Time Zones”.

**Time Zone Variables**

MySQL Server maintains several time zone settings:

- The system time zone. When the server starts, it attempts to determine the time zone of the host machine automatically and uses it to set the `system_time_zone` system variable. The value does not change thereafter.
To explicitly specify the system time zone for MySQL Server at startup, set the `TZ` environment variable before you start `mysqld`. If you start the server using `mysqld_safe`, its `--timezonename` option provides another way to set the system time zone. The permissible values for `TZ` and `--timezonename` are system dependent. Consult your operating system documentation to see what values are acceptable.

- The server current time zone. The global `time_zone` system variable indicates the time zone the server currently is operating in. The initial `time_zone` value is 'SYSTEM', which indicates that the server time zone is the same as the system time zone.

  **Note**

  If set to 'SYSTEM', every MySQL function call that requires a time zone calculation makes a system library call to determine the current system time zone. This call may be protected by a global mutex, resulting in contention.

The initial global server time zone value can be specified explicitly at startup with the `--default-time-zone` option on the command line, or you can use the following line in an option file:

```ini
[mysqld]
default-time-zone='timezone'
```

If you have the `SYSTEM_VARIABLES_ADMIN` privilege (or the deprecated `SUPER` privilege), you can set the global server time zone value at runtime with this statement:

```sql
SET GLOBAL time_zone = timezone;
```

- Per-session time zones. Each client that connects has its own session time zone setting, given by the session `time_zone` variable. Initially, the session variable takes its value from the global `time_zone` variable, but the client can change its own time zone with this statement:

```sql
SET time_zone = timezone;
```

The session time zone setting affects display and storage of time values that are zone-sensitive. This includes the values displayed by functions such as `NOW()` or `CURTIME()`, and values stored in and retrieved from `TIMESTAMP` columns. Values for `TIMESTAMP` columns are converted from the session time zone to UTC for storage, and from UTC to the session time zone for retrieval.

The session time zone setting does not affect values displayed by functions such as `UTC_TIMESTAMP()` or values in `DATE`, `TIME`, or `DATETIME` columns. Nor are values in those data types stored in UTC; the time zone applies for them only when converting from `TIMESTAMP` values. If you want locale-specific arithmetic for `DATE`, `TIME`, or `DATETIME` values, convert them to UTC, perform the arithmetic, and then convert back.

The current global and session time zone values can be retrieved like this:

```sql
SELECT @@GLOBAL.time_zone, @@SESSION.time_zone;
```

timezone values can be given in several formats, none of which are case-sensitive:

- As the value 'SYSTEM', indicating that the server time zone is the same as the system time zone.

- As a string indicating an offset from UTC of the form `[HH]:MM`, prefixed with a + or −, such as '+10:00', '-6:00', or '+05:30'. A leading zero can optionally be used for hours values less than 10; MySQL prepends a leading zero when storing and retrieving the value in such cases. MySQL converts '-00:00' or '-0:00' to '+00:00'.

Prior to MySQL 8.0.19, this value had to be in the range '-12:59' to '+13:00', inclusive; beginning with MySQL 8.0.19, the permitted range is '-14:00' to '+14:00', inclusive.
MySQL Server Time Zone Support

- As a named time zone, such as 'Europe/Helsinki', 'US/Eastern', 'MET', or 'UTC'.

Note

Named time zones can be used only if the time zone information tables in the mysql database have been created and populated. Otherwise, use of a named time zone results in an error:

```
mysql> SET time_zone = 'UTC';
ERROR 1298 (HY000): Unknown or incorrect time zone: 'UTC'
```

Populating the Time Zone Tables

Several tables in the mysql system schema exist to store time zone information (see Section 5.3, “The mysql System Schema”). The MySQL installation procedure creates the time zone tables, but does not load them. To do so manually, use the following instructions.

Note

Loading the time zone information is not necessarily a one-time operation because the information changes occasionally. When such changes occur, applications that use the old rules become out of date and you may find it necessary to reload the time zone tables to keep the information used by your MySQL server current. See Staying Current with Time Zone Changes.

If your system has its own zoneinfo database (the set of files describing time zones), use the mysql_tzinfo_to_sql program to load the time zone tables. Examples of such systems are Linux, macOS, FreeBSD, and Solaris. One likely location for these files is the /usr/share/zoneinfo directory. If your system has no zoneinfo database, you can use a downloadable package, as described later in this section.

To load the time zone tables from the command line, pass the zoneinfo directory path name to mysql_tzinfo_to_sql and send the output into the mysql program. For example:

```
mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root -p mysql
```

The mysql command shown here assumes that you connect to the server using an account such as root that has privileges for modifying tables in the mysql system schema. Adjust the connection parameters as required.

mysql_tzinfo_to_sql reads your system’s time zone files and generates SQL statements from them. mysql processes those statements to load the time zone tables.

mysql_tzinfo_to_sql also can be used to load a single time zone file or generate leap second information:

- To load a single time zone file tz_file that corresponds to a time zone name tz_name, invoke mysql_tzinfo_to_sql like this:

  ```
  mysql_tzinfo_to_sql tz_file tz_name | mysql -u root -p mysql
  ```

  With this approach, you must execute a separate command to load the time zone file for each named zone that the server needs to know about.

- If your time zone must account for leap seconds, initialize leap second information like this, where tz_file is the name of your time zone file:

  ```
  mysql_tzinfo_to_sql --leap tz_file | mysql -u root -p mysql
  ```
MySQL Server Time Zone Support

After running `mysql_tzinfo_to_sql`, restart the server so that it does not continue to use any previously cached time zone data.

If your system has no zoneinfo database (for example, Windows), you can use a package containing SQL statements that is available for download at the MySQL Developer Zone:

[https://dev.mysql.com/downloads/timezones.html](https://dev.mysql.com/downloads/timezones.html)

**Warning**

Do not use a downloadable time zone package if your system has a zoneinfo database. Use the `mysql_tzinfo_to_sql` utility instead. Otherwise, you may cause a difference in datetime handling between MySQL and other applications on your system.

To use an SQL-statement time zone package that you have downloaded, unpack it, then load the unpacked file contents into the time zone tables:

```
mysql -u root -p mysql < file_name
```

Then restart the server.

**Warning**

Do not use a downloadable time zone package that contains MyISAM tables. That is intended for older MySQL versions. MySQL now uses InnoDB for the time zone tables. Trying to replace them with MyISAM tables causes problems.

### Staying Current with Time Zone Changes

When time zone rules change, applications that use the old rules become out of date. To stay current, it is necessary to make sure that your system uses current time zone information is used. For MySQL, there are multiple factors to consider in staying current:

- The operating system time affects the value that the MySQL server uses for times if its time zone is set to `SYSTEM`. Make sure that your operating system is using the latest time zone information. For most operating systems, the latest update or service pack prepares your system for the time changes. Check the website for your operating system vendor for an update that addresses the time changes.

- If you replace the system's `/etc/localtime` time zone file with a version that uses rules differing from those in effect at `mysqld` startup, restart `mysqld` so that it uses the updated rules. Otherwise, `mysqld` might not notice when the system changes its time.

- If you use named time zones with MySQL, make sure that the time zone tables in the `mysql` database are up to date:
  - If your system has its own zoneinfo database, reload the MySQL time zone tables whenever the zoneinfo database is updated.
  - For systems that do not have their own zoneinfo database, check the MySQL Developer Zone for updates. When a new update is available, download it and use it to replace the content of your current time zone tables.

For instructions for both methods, see Populating the Time Zone Tables. `mysqld` caches time zone information that it looks up, so after updating the time zone tables, restart `mysqld` to make sure that it does not continue to serve outdated time zone data.
MySQL Server Time Zone Support

If you are uncertain whether named time zones are available, for use either as the server’s time zone setting or by clients that set their own time zone, check whether your time zone tables are empty. The following query determines whether the table that contains time zone names has any rows:

```
mysql> SELECT COUNT(*) FROM mysql.time_zone_name;
+----------+
<table>
<thead>
<tr>
<th>COUNT(*)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
```

A count of zero indicates that the table is empty. In this case, no applications currently are using named time zones, and you need not update the tables (unless you want to enable named time zone support). A count greater than zero indicates that the table is not empty and that its contents are available to be used for named time zone support. In this case, be sure to reload your time zone tables so that applications that use named time zones can obtain correct query results.

To check whether your MySQL installation is updated properly for a change in Daylight Saving Time rules, use a test like the one following. The example uses values that are appropriate for the 2007 DST 1-hour change that occurs in the United States on March 11 at 2 a.m.

The test uses this query:

```
SELECT
  CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central') AS time1,
  CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central') AS time2;
```

The two time values indicate the times at which the DST change occurs, and the use of named time zones requires that the time zone tables be used. The desired result is that both queries return the same result (the input time, converted to the equivalent value in the 'US/Central' time zone).

Before updating the time zone tables, you see an incorrect result like this:

```
+---------------------+---------------------+
| time1               | time2               |
| 2007-03-11 01:00:00 | 2007-03-11 02:00:00 |
+---------------------+---------------------+
```

After updating the tables, you should see the correct result:

```
+---------------------+---------------------+
| time1               | time2               |
| 2007-03-11 01:00:00 | 2007-03-11 01:00:00 |
+---------------------+---------------------+
```

Time Zone Leap Second Support

Leap second values are returned with a time part that ends with 0:59:59. This means that a function such as NOW() can return the same value for two or three consecutive seconds during the leap second. It remains true that literal temporal values having a time part that ends with 0:59:60 or 0:59:61 are considered invalid.

If it is necessary to search for TIMESTAMP values one second before the leap second, anomalous results may be obtained if you use a comparison with 'YYYY-MM-DD hh:mm:ss' values. The following example demonstrates this. It changes the session time zone to UTC so there is no difference between internal TIMESTAMP values (which are in UTC) and displayed values (which have time zone correction applied).

```
mysql> CREATE TABLE t1 (}
```
To work around this, you can use a comparison based on the UTC value actually stored in the column, which has the leap second correction applied:

```
  SELECT * FROM t1 WHERE UNIX_TIMESTAMP(ts) = 1230768000;
```

1 row in set (0.00 sec)

### 5.1.16 Resource Groups

MySQL supports creation and management of resource groups, and permits assigning threads running within the server to particular groups so that threads execute according to the resources available to the group. Group attributes enable control over its resources, to enable or restrict resource consumption by threads in the group. DBAs can modify these attributes as appropriate for different workloads.
Currently, CPU time is a manageable resource, represented by the concept of “virtual CPU” as a term that includes CPU cores, hyperthreads, hardware threads, and so forth. The server determines at startup how many virtual CPUs are available, and database administrators with appropriate privileges can associate these CPUs with resource groups and assign threads to groups.

For example, to manage execution of batch jobs that need not execute with high priority, a DBA can create a Batch resource group, and adjust its priority up or down depending on how busy the server is. (Perhaps batch jobs assigned to the group should run at lower priority during the day and at higher priority during the night.) The DBA can also adjust the set of CPUs available to the group. Groups can be enabled or disabled to control whether threads are assignable to them.

The following sections describe aspects of resource group use in MySQL:

• Resource Group Elements
• Resource Group Attributes
• Resource Group Management
• Resource Group Replication
• Resource Group Restrictions

Important
On some platforms or MySQL server configurations, resource groups are unavailable or have limitations. In particular, Linux systems might require a manual step for some installation methods. For details, see Resource Group Restrictions.

Resource Group Elements

These capabilities provide the SQL interface for resource group management in MySQL:

• SQL statements enable creating, altering, and dropping resource groups, and enable assigning threads to resource groups. An optimizer hint enables assigning individual statements to resource groups.

• Resource group privileges provide control over which users can perform resource group operations.

• The INFORMATION_SCHEMA.RESOURCE_GROUPS table exposes information about resource group definitions and the Performance Schema threads table shows the resource group assignment for each thread.

• Status variables provide execution counts for each management SQL statement.

Resource Group Attributes

Resource groups have attributes that define the group. All attributes can be set at group creation time. Some attributes are fixed at creation time; others can be modified any time thereafter.

These attributes are defined at resource group creation time and cannot be modified:

• Each group has a name. Resource group names are identifiers like table and column names, and need not be quoted in SQL statements unless they contain special characters or are reserved words. Group names are not case-sensitive and may be up to 64 characters long.

• Each group has a type, which is either SYSTEM or USER. The resource group type affects the range of priority values assignable to the group, as described later. This attribute together with the differences
Resource Groups

in permitted priorities enables system threads to be identified so as to protect them from contention for CPU resources against user threads.

System and user threads correspond to background and foreground threads as listed in the Performance Schema `threads` table.

These attributes are defined at resource group creation time and can be modified any time thereafter:

- The CPU affinity is the set of virtual CPUs the resource group can use. An affinity can be any nonempty subset of the available CPUs. If a group has no affinity, it can use all available CPUs.

- The thread priority is the execution priority for threads assigned to the resource group. Priority values range from -20 (highest priority) to 19 (lowest priority). The default priority is 0, for both system and user groups.

System groups are permitted a higher priority than user groups, ensuring that user threads never have a higher priority than system threads:

- For system resource groups, the permitted priority range is -20 to 0.
- For user resource groups, the permitted priority range is 0 to 19.

- Each group can be enabled or disabled, affording administrators control over thread assignment. Threads can be assigned only to enabled groups.

Resource Group Management

By default, there is one system group and one user group, named `SYS_default` and `USR_default`, respectively. These default groups cannot be dropped and their attributes cannot be modified. Each default group has no CPU affinity and priority 0.

Newly created system and user threads are assigned to the `SYS_default` and `USR_default` groups, respectively.

For user-defined resource groups, all attributes are assigned at group creation time. After a group has been created, its attributes can be modified, with the exception of the name and type attributes.

To create and manage user-defined resource groups, use these SQL statements:

- `CREATE RESOURCE GROUP` creates a new group. See Section 13.7.2.2, “CREATE RESOURCE GROUP Statement”.

- `ALTER RESOURCE GROUP` modifies an existing group. See Section 13.7.2.1, “ALTER RESOURCE GROUP Statement”.

- `DROP RESOURCE GROUP` drops an existing group. See Section 13.7.2.3, “DROP RESOURCE GROUP Statement”.

Those statements require the `RESOURCE_GROUP_ADMIN` privilege.

To manage resource group assignments, use these capabilities:

- `SET RESOURCE GROUP` assigns threads to a group. See Section 13.7.2.4, “SET RESOURCE GROUP Statement”.

- The `RESOURCE_GROUP` optimizer hint assigns individual statements to a group. See Section 8.9.3, “OptimizerHints”.

964
Those operations require the `RESOURCE_GROUP_ADMIN` or `RESOURCE_GROUP_USER` privilege.

Resource group definitions are stored in the `resource_groups` data dictionary table so that groups persist across server restarts. Because `resource_groups` is part of the data dictionary, it is not directly accessible by users. Resource group information is available using the `INFORMATION_SCHEMA.RESOURCE_GROUPS` table, which is implemented as a view on the data dictionary table. See Section 25.26, "The INFORMATION_SCHEMA RESOURCE_GROUPS Table".

Initially, the `RESOURCE_GROUPS` table has these rows describing the default groups:

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.RESOURCE_GROUPS\G
*************************** 1. row ***************************
 RESOURCE_GROUP_NAME: USR_default
 RESOURCE_GROUP_TYPE: USER
 RESOURCE_GROUP_ENABLED: 1
 VCPU_IDS: 0-3
 THREAD_PRIORITY: 0
*************************** 2. row ***************************
 RESOURCE_GROUP_NAME: SYS_default
 RESOURCE_GROUP_TYPE: SYSTEM
 RESOURCE_GROUP_ENABLED: 1
 VCPU_IDS: 0-3
 THREAD_PRIORITY: 0
```

The `THREAD_PRIORITY` values are 0, indicating the default priority. The `VCPU_IDS` values show a range comprising all available CPUs. For the default groups, the displayed value varies depending on the system on which the MySQL server runs.

Earlier discussion mentioned a scenario involving a resource group named `Batch` to manage execution of batch jobs that need not execute with high priority. To create such a group, use a statement similar to this:

```sql
CREATE RESOURCE GROUP Batch
  TYPE = USER
  VCPU = 2-3            -- assumes a system with at least 4 CPUs
  THREAD_PRIORITY = 10;
```

To verify that the resource group was created as expected, check the `RESOURCE_GROUPS` table:

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.RESOURCE_GROUPS
       WHERE RESOURCE_GROUP_NAME = 'Batch'\G
*************************** 1. row ***************************
 RESOURCE_GROUP_NAME: Batch
 RESOURCE_GROUP_TYPE: USER
 RESOURCE_GROUP_ENABLED: 1
 VCPU_IDS: 2-3
 THREAD_PRIORITY: 10
```

If the `THREAD_PRIORITY` value is 0 rather than 10, check whether your platform or system configuration limits the resource group capability; see Resource Group Restrictions.

To assign a thread to the `Batch` group, do this:

```sql
SET RESOURCE GROUP Batch FOR thread_id;
```

Thereafter, statements in the named thread execute with `Batch` group resources.

If a session’s own current thread should be in the `Batch` group, execute this statement within the session:

```sql
SET RESOURCE GROUP Batch;
```

Thereafter, statements in the session execute with `Batch` group resources.

To execute a single statement using the `Batch` group, use the `RESOURCE_GROUP` optimizer hint:
Threads assigned to the **Batch** group execute with its resources, which can be modified as desired:

- For times when the system is highly loaded, decrease the number of CPUs assigned to the group, lower its priority, or (as shown) both:

  ```sql
  ALTER RESOURCE GROUP Batch
  VCPU = 3
  THREAD_PRIORITY = 19;
  ```

- For times when the system is lightly loaded, increase the number of CPUs assigned to the group, raise its priority, or (as shown) both:

  ```sql
  ALTER RESOURCE GROUP Batch
  VCPU = 0-3
  THREAD_PRIORITY = 0;
  ```

**Resource Group Replication**

Resource group management is local to the server on which it occurs. Resource group SQL statements and modifications to the `resource_groups` data dictionary table are not written to the binary log and are not replicated.

**Resource Group Restrictions**

On some platforms or MySQL server configurations, resource groups are unavailable or have limitations:

- Resource groups are unavailable if the thread pool plugin is installed.
- Resource groups are unavailable on macOS, which provides no API for binding CPUs to a thread.
- On FreeBSD and Solaris, resource group thread priorities are ignored. (Effectively, all threads run at priority 0.) Attempts to change priorities result in a warning:

  ```sql
  mysql> ALTER RESOURCE GROUP abc THREAD_PRIORITY = 10;
  Query OK, 0 rows affected, 1 warning (0.18 sec)
  mysql> SHOW WARNINGS;
  +---------+------+-------------------------------------------------------------+
  | Level   | Code | Message                                                     |
  +---------+------+-------------------------------------------------------------+
  | Warning | 4560 | Attribute thread_priority is ignored (using default value). |
  +---------+------+-------------------------------------------------------------+
  ```

- On Linux, resource groups thread priorities are ignored unless the `CAP_SYS_NICE` capability is set. Granting `CAP_SYS_NICE` capability to a process enables a range of privileges; consult [http://man7.org/linux/man-pages/man7/capabilities.7.html](http://man7.org/linux/man-pages/man7/capabilities.7.html) for the full list. Please be careful when enabling this capability.

  ```none
  On Linux platforms using systemd and kernel support for Ambient Capabilities (Linux 4.3 or newer), the recommended way to enable `CAP_SYS_NICE` capability is to modify the MySQL service file and leave the `mysqld` binary unmodified. To adjust the service file for MySQL, use this procedure:
  ```
  1. Run the appropriate command for your platform:
     - Oracle Linux, Red Hat, and Fedora systems:
       ```bash
       shell> sudo systemctl edit mysqld
       ```
     - SUSE, Ubuntu, and Debian systems:
  ```
2. Using an editor, add the following text to the service file:

```
[Service]
AmbientCapabilities=CAP_SYS_NICE
```

3. Restart the MySQL service.

If you cannot enable the `CAP_SYS_NICE` capability as just described, it can be set manually using the `setcap` command, specifying the path name to the `mysqld` executable (this requires `sudo` access).

You can check the capabilities using `getcap`. For example:

```
shell> sudo setcap cap_sys_nice+ep /path/to/mysqld
shell> getcap /path/to/mysqld
/path/to/mysqld = cap_sys_nice+ep
```

As a safety measure, restrict execution of the `mysqld` binary to the `root` user and users with `mysql` group membership:

```
shell> sudo chown root:mysql /path/to/mysqld
shell> sudo chmod 0750 /path/to/mysqld
```

**Important**

If manual use of `setcap` is required, it must be performed after each reinstall.

- On Windows, threads run at one of five thread priority levels. The resource group thread priority range of -20 to 19 maps onto those levels as indicated in the following table.

**Table 5.5 Resource Group Thread Priority on Windows**

<table>
<thead>
<tr>
<th>Priority Range</th>
<th>Windows Priority Level</th>
</tr>
</thead>
<tbody>
<tr>
<td>-20 to -10</td>
<td>THREAD_PRIORITY_HIGHEST</td>
</tr>
<tr>
<td>-9 to -1</td>
<td>THREAD_PRIORITY_ABOVE_NORMAL</td>
</tr>
<tr>
<td>0</td>
<td>THREAD_PRIORITY_NORMAL</td>
</tr>
<tr>
<td>1 to 10</td>
<td>THREAD_PRIORITY_BELOW_NORMAL</td>
</tr>
<tr>
<td>11 to 19</td>
<td>THREAD_PRIORITY_LOWEST</td>
</tr>
</tbody>
</table>

### 5.1.17 Server-Side Help Support

MySQL Server supports a `HELP` statement that returns information from the MySQL Reference Manual (see Section 13.8.3, “HELP Statement”). This information is stored in several tables in the `mysql` schema (see Section 5.3, “The mysql System Schema”). Proper operation of the `HELP` statement requires that these help tables be initialized.

For a new installation of MySQL using a binary or source distribution on Unix, help-table content initialization occurs when you initialize the data directory (see Section 2.10.1, “Initializing the Data Directory”). For an RPM distribution on Linux or binary distribution on Windows, content initialization occurs as part of the MySQL installation process.

For a MySQL upgrade using a binary distribution, help-table content is upgraded automatically by the server as of MySQL 8.0.16. Prior to MySQL 8.0.16, the content is not upgraded automatically, but you can upgrade it manually. Locate the `fill_help_tables.sql` file in the `share` or `share/mysql` directory. Change location into that directory and process the file with the `mysql` client as follows:
mysql -u root -p mysql < fill_help_tables.sql

The command shown here assumes that you connect to the server using an account such as `root` that has privileges for modifying tables in the `mysql` schema. Adjust the connection parameters as required.

Prior to MySQL 8.0.16, if you are working with Git and a MySQL development source tree, the source tree contains only a “stub” version of `fill_help_tables.sql`. To obtain a non-stub copy, use one from a source or binary distribution.

**Note**
Each MySQL series has its own series-specific reference manual, so help-table content is series specific as well. This has implications for replication because help-table content should match the MySQL series. If you load MySQL 8.0 help content into a MySQL 8.0 replication server, it does not make sense to replicate that content to a replica server from a different MySQL series and for which that content is not appropriate. For this reason, as you upgrade individual servers in a replication scenario, you should upgrade each server’s help tables, using the instructions given earlier. (Manual help-content upgrade is necessary only for replication servers from versions lower than 8.0.16. As mentioned in the preceding instructions, content upgrades occur automatically as of MySQL 8.0.16.)

### 5.1.18 Server Tracking of Client Session State Changes

The MySQL server implements several session state trackers. A client can enable these trackers to receive notification of changes to its session state.

One use for the tracker mechanism is to provide a means for MySQL connectors and client applications to determine whether any session context is available to permit session migration from one server to another. (To change sessions in a load-balanced environment, it is necessary to detect whether there is session state to take into consideration when deciding whether a switch can be made.)

Another use for the tracker mechanism is to permit applications to know when transactions can be moved from one session to another. Transaction state tracking enables this, which is useful for applications that may wish to move transactions from a busy server to one that is less loaded. For example, a load-balancing connector managing a client connection pool could move transactions between available sessions in the pool.

However, session switching cannot be done at arbitrary times. If a session is in the middle of a transaction for which reads or writes have been done, switching to a different session implies a transaction rollback on the original session. A session switch must be done only when a transaction does not yet have any reads or writes performed within it.

Examples of when transactions might reasonably be switched:

- Immediately after `START TRANSACTION`
- After `COMMIT AND CHAIN`

In addition to knowing transaction state, it is useful to know transaction characteristics, so as to use the same characteristics if the transaction is moved to a different session. The following characteristics are relevant for this purpose:

- `READ ONLY`
- `READ WRITE`
- `ISOLATION LEVEL`
- `WITH CONSISTENT_SNAPSHOT`
To support the preceding session-switching activities, notification is available for these types of client session state information:

- Changes to these attributes of client session state:
  - The default schema (database).
  - Session-specific values for system variables.
  - User-defined variables.
  - Temporary tables.
  - Prepared statements.

  The `session_track_state_change` system variable controls this tracker.

- Changes to the default schema name. The `session_track_schema` system variable controls this tracker.

- Changes to the session values of system variables. The `session_track_system_variables` system variable controls this tracker.

- Available GTIDs. The `session_track_gtid` system variable controls this tracker.

- Information about transaction state and characteristics. The `session_track_transaction_info` system variable controls this tracker.

For descriptions of the tracker-related system variables, see Section 5.1.8, "Server System Variables". Those system variables permit control over which change notifications occur, but do not provide a way to access notification information. Notification occurs in the MySQL client/server protocol, which includes tracker information in OK packets so that session state changes can be detected. To enable client applications to extract state-change information from OK packets returned by the server, the MySQL C API provides a pair of functions:

- `mysql_session_track_get_first()` fetches the first part of the state-change information received from the server. See `mysql_session_track_get_first()`.

- `mysql_session_track_get_next()` fetches any remaining state-change information received from the server. Following a successful call to `mysql_session_track_get_first()`, call this function repeatedly as long as it returns success. See `mysql_session_track_get_next()`.

The `mysqltest` program has `disable_session_track_info` and `enable_session_track_info` commands that control whether session tracker notifications occur. You can use these commands to see from the command line what notifications SQL statements produce. Suppose that a file `testscript` contains the following `mysqltest` script:

```sql
DROP TABLE IF EXISTS test.t1;
CREATE TABLE test.t1 (i INT, f FLOAT);
--enable_session_track_info
SET @@SESSION.session_track_schema=ON;
SET @@SESSION.session_track_system_variables='*';
SET @@SESSION.session_track_state_change=ON;
USE information_schema;
SET NAMES 'utf8mb4';
SET @@SESSION.session_track_transaction_info='CHARACTERISTICS';
SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
SET TRANSACTION READ WRITE;
START TRANSACTION;
```
SELECT 1;
INSERT INTO test.t1 () VALUES();
INSERT INTO test.t1 () VALUES(i, RAND());
COMMIT;

Run the script as follows to see the information provided by the enabled trackers. For a description of the Tracker: information displayed by mysqltest for the various trackers, see mysql_session_track_get_first().

```
shell> mysqltest < testscript
DROP TABLE IF EXISTS test.t1;
CREATE TABLE test.t1 (i INT, f FLOAT);
SET @@SESSION.session_track_schema=ON;
SET @@SESSION.session_track_system_variables='*';
-- Tracker : SESSION_TRACK_SYSTEM_VARIABLES
-- session_track_system_variables
-- *
SET @@SESSION.session_track_state_change=ON;
-- Tracker : SESSION_TRACK_SYSTEM_VARIABLES
-- session_track_state_change
-- ON
USE information_schema;
-- Tracker : SESSION_TRACK_SCHEMA
-- information_schema
-- Tracker : SESSION_TRACK_STATE_CHANGE
-- 1
SET NAMES 'utf8mb4';
-- Tracker : SESSION_TRACK_SYSTEM_VARIABLES
-- character_set_client
-- utf8mb4
-- character_set_connection
-- utf8mb4
-- character_set_results
-- utf8mb4
-- Tracker : SESSION_TRACK_STATE_CHANGE
-- 1
SET @@SESSION.session_track_transaction_info='CHARACTERISTICS';
-- Tracker : SESSION_TRACK_SYSTEM_VARIABLES
-- session_track_transaction_info
-- CHARACTERISTICS
-- Tracker : SESSION_TRACK_STATE_CHANGE
-- 1
-- Tracker : SESSION_TRACK_TRANSACTION_CHARACTERISTICS
--
-- Tracker : SESSION_TRACK_TRANSACTION_STATE
-- ________
SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
-- Tracker : SESSION_TRACK_TRANSACTION_CHARACTERISTICS
-- SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
SET TRANSACTION READ WRITE;
-- Tracker : SESSION_TRACK_TRANSACTION_CHARACTERISTICS
-- SET TRANSACTION ISOLATION LEVEL SERIALIZABLE; SET TRANSACTION READ WRITE;
START TRANSACTION;
-- Tracker : SESSION_TRACK_TRANSACTION_CHARACTERISTICS
-- SET TRANSACTION ISOLATION LEVEL SERIALIZABLE; START TRANSACTION READ WRITE;
```
The Server Shutdown Process

Preceding the `START TRANSACTION` statement, two `SET TRANSACTION` statements execute that set the isolation level and access mode characteristics for the next transaction. The `SESSION_TRACK_TRANSACTION_CHARACTERISTICS` value indicates those next-transaction values that have been set.

Following the `COMMIT` statement that ends the transaction, the `SESSION_TRACK_TRANSACTION_CHARACTERISTICS` value is reported as empty. This indicates that the next-transaction characteristics that were set preceding the start of the transaction have been reset, and that the session defaults apply. To track changes to those session defaults, track the session values of the `transaction_isolation` and `transaction_read_only` system variables.

5.1.19 The Server Shutdown Process

The server shutdown process takes place as follows:

1. The shutdown process is initiated.

   This can occur initiated several ways. For example, a user with the `SHUTDOWN` privilege can execute a `mysqladmin shutdown` command. `mysqladmin` can be used on any platform supported by MySQL. Other operating system-specific shutdown initiation methods are possible as well: The server shuts down on Unix when it receives a `SIGTERM` signal. A server running as a service on Windows shuts down when the services manager tells it to.

2. The server creates a shutdown thread if necessary.

   Depending on how shutdown was initiated, the server might create a thread to handle the shutdown process. If shutdown was requested by a client, a shutdown thread is created. If shutdown is the result of receiving a `SIGTERM` signal, the signal thread might handle shutdown itself, or it might create a separate thread to do so. If the server tries to create a shutdown thread and cannot (for example, if memory is exhausted), it issues a diagnostic message that appears in the error log:

   ```
   Error: Can't create thread to kill server
   ```

3. The server stops accepting new connections.
To prevent new activity from being initiated during shutdown, the server stops accepting new client connections by closing the handlers for the network interfaces to which it normally listens for connections: the TCP/IP port, the Unix socket file, the Windows named pipe, and shared memory on Windows.

4. The server terminates current activity.

For each thread associated with a client connection, the server breaks the connection to the client and marks the thread as killed. Threads die when they notice that they are so marked. Threads for idle connections die quickly. Threads that currently are processing statements check their state periodically and take longer to die. For additional information about thread termination, see Section 13.7.8.4, "KILL Statement", in particular for the instructions about killed REPAIR TABLE or OPTIMIZE TABLE operations on MyISAM tables.

For threads that have an open transaction, the transaction is rolled back. If a thread is updating a nontransactional table, an operation such as a multiple-row UPDATE or INSERT may leave the table partially updated because the operation can terminate before completion.

If the server is a replication source server, it treats threads associated with currently connected replicas like other client threads. That is, each one is marked as killed and exits when it next checks its state.

If the server is a replica server, it stops the replication I/O and SQL threads, if they are active, before marking client threads as killed. The SQL thread is permitted to finish its current statement (to avoid causing replication problems), and then stops. If the SQL thread is in the middle of a transaction at this point, the server waits until the current replication event group (if any) has finished executing, or until the user issues a KILL_QUERY or KILL_CONNECTION statement. See also Section 13.4.2.9, "STOP_SLAVE | REPLICA Statement". Since nontransactional statements cannot be rolled back, in order to guarantee crash-safe replication, only transactional tables should be used.

Note
To guarantee crash safety on the replica, you must run the replica with --relay-log-recovery enabled.

See also Section 17.2.4, "Relay Log and Replication Metadata Repositories".

5. The server shuts down or closes storage engines.

At this stage, the server flushes the table cache and closes all open tables.

Each storage engine performs any actions necessary for tables that it manages. InnoDB flushes its buffer pool to disk (unless innodb_fast_shutdown is 2), writes the current LSN to the tablespace, and terminates its own internal threads. MyISAM flushes any pending index writes for a table.

6. The server exits.

To provide information to management processes, the server returns one of the exit codes described in the following list. The phrase in parentheses indicates the action taken by systemd in response to the code, for platforms on which systemd is used to manage the server.

- 0 = successful termination (no restart done)
- 1 = unsuccessful termination (no restart done)
- 2 = unsuccessful termination (restart done)
5.2 The MySQL Data Directory

Information managed by the MySQL server is stored under a directory known as the data directory. The following list briefly describes the items typically found in the data directory, with cross references for additional information:

- Data directory subdirectories. Each subdirectory of the data directory is a database directory and corresponds to a database managed by the server. All MySQL installations have certain standard databases:
  - The `mysql` directory corresponds to the `mysql` system schema, which contains information required by the MySQL server as it runs. This database contains data dictionary tables and system tables. See Section 5.3, “The mysql System Schema”.
  - The `performance_schema` directory corresponds to the Performance Schema, which provides information used to inspect the internal execution of the server at runtime. See Chapter 26, MySQL Performance Schema.
  - The `sys` directory corresponds to the `sys` schema, which provides a set of objects to help interpret Performance Schema information more easily. See Chapter 27, MySQL sys Schema.
  - The `ndbinfo` directory corresponds to the `ndbinfo` database that stores information specific to NDB Cluster (present only for installations built to include NDB Cluster). See Section 22.5.14, “ndbinfo: The NDB Cluster Information Database”.

Other subdirectories correspond to databases created by users or applications.

**Note**

**INFORMATION_SCHEMA** is a standard database, but its implementation uses no corresponding database directory.

- Log files written by the server. See Section 5.4, “MySQL Server Logs”.
- InnoDB tablespace and log files. See Chapter 15, The InnoDB Storage Engine.
- Default/autogenerated SSL and RSA certificate and key files. See Section 6.3.3, “Creating SSL and RSA Certificates and Keys”.
- The server process ID file (while the server is running).
- The `mysqld-auto.cnf` file that stores persisted global system variable settings. See Section 13.7.6.1, “SET Syntax for Variable Assignment”.

Some items in the preceding list can be relocated elsewhere by reconfiguring the server. In addition, the `--datadir` option enables the location of the data directory itself to be changed. For a given MySQL installation, check the server configuration to determine whether items have been moved.

5.3 The mysql System Schema

The `mysql` schema is the system schema. It contains tables that store information required by the MySQL server as it runs. A broad categorization is that the `mysql` schema contains data dictionary tables that store database object metadata, and system tables used for other operational purposes. The following discussion further subdivides the set of system tables into smaller categories.

- Data Dictionary Tables
Data Dictionary Tables

- Grant System Tables
- Object Information System Tables
- Log System Tables
- Server-Side Help System Tables
- Time Zone System Tables
- Replication System Tables
- Optimizer System Tables
- Miscellaneous System Tables

The remainder of this section enumerates the tables in each category, with cross references for additional information. Data dictionary tables and system tables use the InnoDB storage engine unless otherwise indicated.

mysql system tables and data dictionary tables reside in a single InnoDB tablespace file named mysql.ibd in the MySQL data directory. Previously, these tables were created in individual tablespace files in the mysql database directory.

Data-at-rest encryption can be enabled for the mysql system schema tablespace. For more information, see Section 15.13, “InnoDB Data-at-Rest Encryption”.

Data Dictionary Tables

These tables comprise the data dictionary, which contains metadata about database objects. For additional information, see Chapter 14, MySQL Data Dictionary.

Important

The data dictionary is new in MySQL 8.0. A data dictionary-enabled server entails some general operational differences compared to previous MySQL releases. For details, see Section 14.7, “Data Dictionary Usage Differences”. Also, for upgrades to MySQL 8.0 from MySQL 5.7, the upgrade procedure differs somewhat from previous MySQL releases and requires that you verify the upgrade readiness of your installation by checking specific prerequisites. For more information, see Section 2.11, “Upgrading MySQL”, particularly Section 2.11.5, “Preparing Your Installation for Upgrade”.

- catalogs: Catalog information.
- character_sets: Information about available character sets.
- check_constraints: Information about CHECK constraints defined on tables. See Section 13.1.20.6, “CHECK Constraints”.
- collations: Information about collations for each character set.
- column_statistics: Histogram statistics for column values. See Section 8.9.6, “Optimizer Statistics”.
- column_type_elements: Information about types used by columns.
- columns: Information about columns in tables.
Data Dictionary Tables

- **dd_properties**: A table that identifies data dictionary properties, such as its version. The server uses this to determine whether the data dictionary must be upgraded to a newer version.

- **events**: Information about Event Scheduler events. See Section 24.4, “Using the Event Scheduler”. If the server is started with the `--skip-grant-tables` option, the event scheduler is disabled and events registered in the table do not run. See Section 24.4.2, “Event Scheduler Configuration”.

- **foreign_keys, foreign_key_column_usage**: Information about foreign keys.

- **index_column_usage**: Information about columns used by indexes.

- **index_partitions**: Information about partitions used by indexes.

- **index_stats**: Used to store dynamic index statistics generated when `ANALYZE TABLE` is executed.

- **indexes**: Information about table indexes.

- **innodb_ddl_log**: Stores DDL logs for crash-safe DDL operations.

- **parameter_type_elements**: Information about stored procedure and function parameters, and about return values for stored functions.

- **parameters**: Information about stored procedures and functions. See Section 24.2, “Using Stored Routines”.

- **resource_groups**: Information about resource groups. See Section 5.1.16, “Resource Groups”.

- **routines**: Information about stored procedures and functions. See Section 24.2, “Using Stored Routines”.

- **schemata**: Information about schemata. In MySQL, a schema is a database, so this table provides information about databases.

- **st_spatial_reference_systems**: Information about available spatial reference systems for spatial data.

- **table_partition_values**: Information about values used by table partitions.

- **table_partitions**: Information about partitions used by tables.

- **table_stats**: Information about dynamic table statistics generated when `ANALYZE TABLE` is executed.

- **tables**: Information about tables in databases.

- **tablespace_files**: Information about files used by tablespaces.

- **tablespaces**: Information about active tablespaces.

- **triggers**: Information about triggers.

- **view_routine_usage**: Information about dependencies between views and stored functions used by them.

- **view_table_usage**: Used to track dependencies between views and their underlying tables.

Data dictionary tables are invisible. They cannot be read with `SELECT`, do not appear in the output of `SHOW TABLES`, are not listed in the `INFORMATION_SCHEMA.TABLES` table, and so forth. However, in most cases there are corresponding `INFORMATION_SCHEMA` tables that can be queried. Conceptually, the `INFORMATION_SCHEMA` provides a view through which MySQL exposes data dictionary metadata. For example, you cannot select from the `mysql.schemata` table directly:
Instead, select that information from the corresponding \texttt{INFORMATION\_SCHEMA} table:

```sql
mysql> SELECT * FROM INFORMATION\_SCHEMA\_SCHEMATA;
```

```
+-------------------+--------------+-----------------+-----------------+----------+
| CATALOG\_NAME     | SCHEMA\_NAME | DEFAULT\_CHARACTER\_SET\_NAME | DEFAULT\_COLLATION\_NAME | SQL\_PATH |
| def               | mysql        | utf8mb4          | utf8mb4\_0900\_ai\_ci  | NULL      |
|                   |              |                  |                       |          |
|                   |              |                  |                       |          |
+-------------------+--------------+-----------------+-----------------+----------+
```

There is no \texttt{INFORMATION\_SCHEMA} table that corresponds exactly to \texttt{mysql.indexes}, but \texttt{INFORMATION\_SCHEMA\_STATISTICS} contains much of the same information.

As of yet, there are no \texttt{INFORMATION\_SCHEMA} tables that correspond exactly to \texttt{mysql.foreign\_keys}, \texttt{mysql.foreign\_key\_column\_usage}. The standard SQL way to obtain foreign key information is by using the \texttt{INFORMATION\_SCHEMA\_REFERENTIAL\_CONSTRAINTS} and \texttt{KEY\_COLUMN\_USAGE} tables; these tables are now implemented as views on the \texttt{foreign\_keys}, \texttt{foreign\_key\_column\_usage}, and other data dictionary tables.

Some system tables from before MySQL 8.0 have been replaced by data dictionary tables and are no longer present in the \texttt{mysql} system schema:

- The \texttt{events} data dictionary table supersedes the \texttt{event} table from before MySQL 8.0.
- The \texttt{parameters} and \texttt{routines} data dictionary tables together supersede the \texttt{proc} table from before MySQL 8.0.

### Grant System Tables

These system tables contain grant information about user accounts and the privileges held by them. For additional information about the structure, contents, and purpose of these tables, see Section 6.2.3, “Grant Tables”.

As of MySQL 8.0, the grant tables are InnoDB (transactional) tables. Previously, these were MyISAM (nontransactional) tables. The change of grant-table storage engine underlies an accompanying change in MySQL 8.0 to the behavior of account-management statements such as \texttt{CREATE USER} and \texttt{GRANT}. Previously, an account-management statement that named multiple users could succeed for some users and fail for others. The statements are now transactional and either succeed for all named users or roll back and have no effect if any error occurs.

#### Note

If MySQL is upgraded from an older version but the grant tables have not been upgraded from MyISAM to InnoDB, the server considers them read only and account-management statements produce an error. For upgrade instructions, see Section 2.11, “Upgrading MySQL”.

- \texttt{user}: User accounts, global privileges, and other nonprivilege columns.
Object Information System Tables

- **global_grants**: Assignments of dynamic global privileges to users; see Static Versus Dynamic Privileges.
- **db**: Database-level privileges.
- **tables_priv**: Table-level privileges.
- **columns_priv**: Column-level privileges.
- **procs_priv**: Stored procedure and function privileges.
- **proxies_priv**: Proxy-user privileges.
- **default_roles**: This table lists default roles to be activated after a user connects and authenticates, or executes `SET ROLE DEFAULT`.
- **role_edges**: This table lists edges for role subgraphs.

A given user table row might refer to a user account or a role. The server can distinguish whether a row represents a user account, a role, or both by consulting the `role_edges` table for information about relations between authentication IDs.

- **password_history**: Information about password changes.

Object Information System Tables

These system tables contain information about components, user-defined functions, and server-side plugins:

- **component**: The registry for server components installed using `INSTALL COMPONENT`. Any components listed in this table are installed by a loader service during the server startup sequence. See Section 5.5.1, “Installing and Uninstalling Components”.

- **func**: The registry for user-defined functions (UDFs) installed using `CREATE FUNCTION`. During the normal startup sequence, the server loads UDFs registered in this table. If the server is started with the `--skip-grant-tables` option, UDFs registered in the table are not loaded and are unavailable. See Section 5.7.1, “Installing and Uninstalling User-Defined Functions”.

  **Note**

  Like the `mysql.func` system table, the Performance Schema `user_defined_functions` table lists UDFs installed using `CREATE FUNCTION`. Unlike the `mysql.func` table, the `user_defined_functions` table also lists UDFs installed automatically by server components or plugins. This difference makes `user_defined_functions` preferable to `mysql.func` for checking which UDFs are installed. See Section 26.12.19.9, “The user_defined_functions Table”.

- **plugin**: The registry for server-side plugins installed using `INSTALL PLUGIN`. During the normal startup sequence, the server loads plugins registered in this table. If the server is started with the `--skip-grant-tables` option, plugins registered in the table are not loaded and are unavailable. See Section 5.6.1, “Installing and Uninstalling Plugins”.

Log System Tables

The server uses these system tables for logging:

- **general_log**: The general query log table.
• **slow_log**: The slow query log table.

Log tables use the **CSV** storage engine.

For more information, see Section 5.4, “MySQL Server Logs”.

**Server-Side Help System Tables**

These system tables contain server-side help information:

• **help_category**: Information about help categories.
• **help_keyword**: Keywords associated with help topics.
• **help_relation**: Mappings between help keywords and topics.
• **help_topic**: Help topic contents.

For more information, see Section 5.1.17, “Server-Side Help Support”.

**Time Zone System Tables**

These system tables contain time zone information:

• **time_zone**: Time zone IDs and whether they use leap seconds.
• **time_zone_leap_second**: When leap seconds occur.
• **time_zone_name**: Mappings between time zone IDs and names.
• **time_zone_transition, time_zone_transition_type**: Time zone descriptions.

For more information, see Section 5.1.15, “MySQL Server Time Zone Support”.

**Replication System Tables**

The server uses these system tables to support replication:

• **gtid_executed**: Table for storing GTID values. See *mysql.gtid_executed Table*.
• **ndb_binlog_index**: Binary log information for NDB Cluster replication. This table is created only if the server is built with **NDBCLUSTER** support. See Section 22.6.4, “NDB Cluster Replication Schema and Tables”.
• **slave_master_info, slave_relay_log_info, slave_worker_info**: Used to store replication information on replica servers. See Section 17.2.4, “Relay Log and Replication Metadata Repositories”.

All of the tables just listed use the **InnoDB** storage engine.

**Optimizer System Tables**

These system tables are for use by the optimizer:

• **innodb_index_stats, innodb_table_stats**: Used for InnoDB persistent optimizer statistics. See Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”.
• **server_cost, engine_cost**: The optimizer cost model uses tables that contain cost estimate information about operations that occur during query execution. **server_cost** contains optimizer cost estimates for general server operations. **engine_cost** contains estimates for operations specific to particular storage engines. See Section 8.9.5, “The Optimizer Cost Model”.
Miscellaneous System Tables

Other system tables do not fit the preceding categories:

- **audit_log_filter, audit_log_user**: If MySQL Enterprise Audit is installed, these tables provide persistent storage of audit log filter definitions and user accounts. See Audit Log Tables.

- **firewall_users, firewall_whitelist**: If MySQL Enterprise Firewall is installed, these tables provide persistent storage for information used by the firewall. See Section 6.4.7, “MySQL Enterprise Firewall”.

- **servers**: Used by the FEDERATED storage engine. See Section 16.8.2.2, “Creating a FEDERATED Table Using CREATE SERVER”.

- **innodb_dynamic_metadata**: Used by the InnoDB storage engine to store fast-changing table metadata such as auto-increment counter values and index tree corruption flags. Replaces the data dictionary buffer table that resided in the InnoDB system tablespace.

5.4 MySQL Server Logs

MySQL Server has several logs that can help you find out what activity is taking place.

<table>
<thead>
<tr>
<th>Log Type</th>
<th>Information Written to Log</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error log</td>
<td>Problems encountered starting, running, or stopping mysqld</td>
</tr>
<tr>
<td>General query log</td>
<td>Established client connections and statements received from clients</td>
</tr>
<tr>
<td>Binary log</td>
<td>Statements that change data (also used for replication)</td>
</tr>
<tr>
<td>Relay log</td>
<td>Data changes received from a replication source server</td>
</tr>
<tr>
<td>Slow query log</td>
<td>Queries that took more than long_query_time seconds to execute</td>
</tr>
<tr>
<td>DDL log (metadata log)</td>
<td>Metadata operations performed by DDL statements</td>
</tr>
</tbody>
</table>

By default, no logs are enabled, except the error log on Windows. (The DDL log is always created when required, and has no user-configurable options; see The DDL Log.) The following log-specific sections provide information about the server options that enable logging.

By default, the server writes files for all enabled logs in the data directory. You can force the server to close and reopen the log files (or in some cases switch to a new log file) by flushing the logs. Log flushing occurs when you issue a `FLUSH LOGS` statement; execute `mysqladmin` with a `flush-logs` or `refresh` argument; or execute `mysqldump` with a `--flush-logs` or `--master-data` option. See Section 13.7.8.3, “FLUSH Statement”, Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”, and Section 4.5.4, “mysqldump — A Database Backup Program”. In addition, the binary log is flushed when its size reaches the value of the `max_binlog_size` system variable.

You can control the general query and slow query logs during runtime. You can enable or disable logging, or change the log file name. You can tell the server to write general query and slow query entries to log tables, log files, or both. For details, see Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”, Section 5.4.3, “The General Query Log”, and Section 5.4.5, “The Slow Query Log”.

The relay log is used only on replicas, to hold data changes from the replication source server that must also be made on the replica. For discussion of relay log contents and configuration, see Section 17.2.4.1, “The Relay Log”.

For information about log maintenance operations such as expiration of old log files, see Section 5.4.6, “Server Log Maintenance”.

For information about keeping logs secure, see Section 6.1.2.3, “Passwords and Logging”.

979
5.4.1 Selecting General Query Log and Slow Query Log Output Destinations

MySQL Server provides flexible control over the destination of output written to the general query log and the slow query log, if those logs are enabled. Possible destinations for log entries are log files or the `general_log` and `slow_log` tables in the `mysql` system database. File output, table output, or both can be selected.

- **Log Control at Server Startup**
- **Log Control at Runtime**
- **Log Table Benefits and Characteristics**

**Log Control at Server Startup**

The `log_output` system variable specifies the destination for log output. Setting this variable does not in itself enable the logs; they must be enabled separately.

- If `log_output` is not specified at startup, the default logging destination is `FILE`.
- If `log_output` is specified at startup, its value is a list one or more comma-separated words chosen from `TABLE` (log to tables), `FILE` (log to files), or `NONE` (do not log to tables or files). `NONE`, if present, takes precedence over any other specifiers.

The `general_log` system variable controls logging to the general query log for the selected log destinations. If specified at server startup, `general_log` takes an optional argument of 1 or 0 to enable or disable the log. To specify a file name other than the default for file logging, set the `general_log_file` variable. Similarly, the `slow_query_log` variable controls logging to the slow query log for the selected destinations and setting `slow_query_log_file` specifies a file name for file logging. If either log is enabled, the server opens the corresponding log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected.

Examples:

- To write general query log entries to the log table and the log file, use `--log_output=TABLE,FILE` to select both log destinations and `--general_log` to enable the general query log.
- To write general and slow query log entries only to the log tables, use `--log_output=TABLE` to select tables as the log destination and `--general_log` and `--slow_query_log` to enable both logs.
- To write slow query log entries only to the log file, use `--log_output=FILE` to select files as the log destination and `--slow_query_log` to enable the slow query log. In this case, because the default log destination is `FILE`, you could omit the `log_output` setting.

**Log Control at Runtime**

The system variables associated with log tables and files enable runtime control over logging:

- The `log_output` variable indicates the current logging destination. It can be modified at runtime to change the destination.
- The `general_log` and `slow_query_log` variables indicate whether the general query log and slow query log are enabled (`ON`) or disabled (`OFF`). You can set these variables at runtime to control whether the logs are enabled.
- The `general_log_file` and `slow_query_log_file` variables indicate the names of the general query log and slow query log files. You can set these variables at server startup or at runtime to change the names of the log files.
Selecting General Query Log and Slow Query Log Output Destinations

• To disable or enable general query logging for the current session, set the session `sql_log_off` variable to `ON` or `OFF`. (This assumes that the general query log itself is enabled.)

Log Table Benefits and Characteristics

The use of tables for log output offers the following benefits:

• Log entries have a standard format. To display the current structure of the log tables, use these statements:

```sql
SHOW CREATE TABLE mysql.general_log;
SHOW CREATE TABLE mysql.slow_log;
```

• Log contents are accessible through SQL statements. This enables the use of queries that select only those log entries that satisfy specific criteria. For example, to select log contents associated with a particular client (which can be useful for identifying problematic queries from that client), it is easier to do this using a log table than a log file.

• Logs are accessible remotely through any client that can connect to the server and issue queries (if the client has the appropriate log table privileges). It is not necessary to log in to the server host and directly access the file system.

The log table implementation has the following characteristics:

• In general, the primary purpose of log tables is to provide an interface for users to observe the runtime execution of the server, not to interfere with its runtime execution.

• `CREATE TABLE`, `ALTER TABLE`, and `DROP TABLE` are valid operations on a log table. For `ALTER TABLE` and `DROP TABLE`, the log table cannot be in use and must be disabled, as described later.

• By default, the log tables use the `CSV` storage engine that writes data in comma-separated values format. For users who have access to the `.CSV` files that contain log table data, the files are easy to import into other programs such as spreadsheets that can process CSV input.

The log tables can be altered to use the `MyISAM` storage engine. You cannot use `ALTER TABLE` to alter a log table that is in use. The log must be disabled first. No engines other than `CSV` or `MyISAM` are legal for the log tables.

Log Tables and “Too many open files” Errors. If you select `TABLE` as a log destination and the log tables use the `CSV` storage engine, you may find that disabling and enabling the general query log or slow query log repeatedly at runtime results in a number of open file descriptors for the `.CSV` file, possibly resulting in a “Too many open files” error. To work around this issue, execute `FLUSH TABLES` or ensure that the value of `open_files_limit` is greater than the value of `table_open_cache_instances`.

• To disable logging so that you can alter (or drop) a log table, you can use the following strategy. The example uses the general query log; the procedure for the slow query log is similar but uses the `slow_log` table and `slow_query_log` system variable.

```sql
SET @old_log_state = @@GLOBAL.general_log;
SET GLOBAL general_log = 'OFF';
ALTER TABLE mysql.general_log ENGINE = MyISAM;
SET GLOBAL general_log = @old_log_state;
```

• `TRUNCATE TABLE` is a valid operation on a log table. It can be used to expire log entries.

• `RENAME TABLE` is a valid operation on a log table. You can atomically rename a log table (to perform log rotation, for example) using the following strategy:

```sql
USE mysql;
```
The Error Log

```sql
DROP TABLE IF EXISTS general_log2;
CREATE TABLE general_log2 LIKE general_log;
RENAME TABLE general_log TO general_log_backup, general_log2 TO general_log;
```

- **CHECK TABLE** is a valid operation on a log table.
- **LOCK TABLES** cannot be used on a log table.
- **INSERT, DELETE, and UPDATE** cannot be used on a log table. These operations are permitted only internally to the server itself.
- **FLUSH TABLES WITH READ LOCK** and the state of the **read_only** system variable have no effect on log tables. The server can always write to the log tables.
- Entries written to the log tables are not written to the binary log and thus are not replicated to replicas.
- To flush the log tables or log files, use **FLUSH TABLES** or **FLUSH LOGS**, respectively.
- Partitioning of log tables is not permitted.
- A **mysqldump** dump includes statements to recreate those tables so that they are not missing after reloading the dump file. Log table contents are not dumped.

### 5.4.2 The Error Log

This section discusses how to configure the MySQL server for logging of diagnostic messages to the error log. For information about selecting the error message character set and language, see Section 10.6, “Error Message Character Set”, and Section 10.12, “Setting the Error Message Language”.

The error log contains a record of `mysqld` startup and shutdown times. It also contains diagnostic messages such as errors, warnings, and notes that occur during server startup and shutdown, and while the server is running. For example, if `mysqld` notices that a table needs to be automatically checked or repaired, it writes a message to the error log.

Depending on error log configuration, error messages may also populate the Performance Schema `error_log` table, to provide an SQL interface to the log and enable its contents to be queried. See Section 26.12.19.1, “The error_log Table”.

On some operating systems, the error log contains a stack trace if `mysqld` exits abnormally. The trace can be used to determine where `mysqld` exited. See Section 5.9, “Debugging MySQL”.

If used to start `mysqld`, `mysqld_safe` may write messages to the error log. For example, when `mysqld_safe` notices abnormal `mysqld` exits, it restarts `mysqld` and writes a `mysqld restarted` message to the error log.

The following sections discuss aspects of configuring error logging.

#### 5.4.2.1 Error Log Configuration

In MySQL 8.0, error logging uses the MySQL component architecture described at Section 5.5, “MySQL Server Components”. The error log subsystem consists of components that perform log event filtering and writing, as well as a system variable that configures which components to enable to achieve the desired logging result.

This section discusses how to select components for error logging. For instructions specific to log filters, see Section 5.4.2.4, “Types of Error Log Filtering”. For instructions specific to the JSON and system log sinks, see Section 5.4.2.7, “Error Logging in JSON Format”, and Section 5.4.2.8, “Error Logging to the System Log”. For additional details about all available log components, see Section 5.5.3, “Error Log Components”.

982
Component-based error logging offers these features:

- Log events can be filtered by filter components to affect the information available for writing.
- Log events are output by sink (writer) components. Multiple sink components can be enabled, to write error log output to multiple destinations.
- Built-in filter and sink components combine to implement the default error log format.
- A loadable sink enables logging in JSON format.
- A loadable sink enables logging to the system log.
- System variables control which log components to enable and how each component operates.

The `log_error_services` system variable controls which log components to enable for error logging. The variable may contain a list with 0, 1, or many elements. In the latter case, elements may be delimited by semicolon or (as of MySQL 8.0.12) comma, optionally followed by space. A given setting cannot use both semicolon and comma separators. Component order is significant because the server executes components in the order listed.

By default, `log_error_services` has this value:

```
mysql> SELECT @@GLOBAL.log_error_services;
+----------------------------------------+
| @@GLOBAL.log_error_services            |
+----------------------------------------+
| log_filter_internal; log_sink_internal |
+----------------------------------------+
```

That value indicates that log events first pass through the `log_filter_internal` filter component, then through the `log_sink_internal` sink component, both of which are built in. A filter modifies log events seen by components named later in the `log_error_services` value. A sink is a destination for log events. Typically, a sink processes log events into log messages that have a particular format and writes these messages to its associated output, such as a file or the system log.

**Note**

The final component in the `log_error_services` value cannot be a filter. This is an error because any changes it has on events would have no effect on output:

```
mysql> SET GLOBAL log_error_services = 'log_filter_internal';
ERROR 1231 (42000): Variable 'log_error_services' can't be set to the value of 'log_filter_internal'
```

To correct the problem, include a sink at the end of the value:

```
mysql> SET GLOBAL log_error_services = 'log_filter_internal; log_sink_internal';
Query OK, 0 rows affected (0.00 sec)
```

The combination of `log_filter_internal` and `log_sink_internal` implements the default error log filtering and output behavior. The action of these components is affected by other server options and system variables:

- The output destination is determined by the `--log-error` option (and, on Windows, `--pid-file` and `--console`). These determine whether to write error messages to the console or a file and, if to a file, the error log file name. See Section 5.4.2.2, “Default Error Log Destination Configuration”.
- The `log_error_verbosity` and `log_error_suppression_list` system variables affect which types of log events `log_filter_internal` permits or suppresses. See Section 5.4.2.5, “Priority-Based Error Log Filtering (log_filter_internal)”.

---

983
To change the set of log components used for error logging, load components as necessary, perform any component-specific configuration, and modify the `log_error_services` value. Adding or removing log components is subject to these constraints:

- **To add a log component to the list of enabled components:**
  - Load the component using `INSTALL COMPONENT` (unless it is built in or already loaded).
  - If the component exposes any system variables that must be set for component initialization to succeed, assign those variables appropriate values.
  - Enable the component by listing it in the `log_error_services` value.
- **For a component to be permitted in the `log_error_services` value, it must be known.** A component is known if it is built in, or if it is loadable and has been loaded using `INSTALL COMPONENT`. Attempts to name an unknown component at server startup cause `log_error_services` to be set to its default value. Attempts to name an unknown component at runtime produce an error and the `log_error_services` value remains unchanged.

- **To disable a log component, remove it from the `log_error_services` value.** Then, if the component is loadable and you also want to unload it, use `UNINSTALL COMPONENT`.

  Attempts to use `UNINSTALL COMPONENT` to unload a loadable component that is still named in the `log_error_services` value produce an error.

For example, to use the system log sink (`log_sink_syseventlog`) instead of the default sink (`log_sink_internal`), first load the sink component, then modify the `log_error_services` value:

```sql
INSTALL COMPONENT 'file://component_log_sink_syseventlog';
SET GLOBAL log_error_services = 'log_filter_internal; log_sink_syseventlog';
```

**Note**
The URN to use for loading a log component with `INSTALL COMPONENT` is the component name prefixed with `file://component_`. For example, for the `log_sink_syseventlog` component, the corresponding URN is `file://component_log_sink_syseventlog`.

It is possible to configure multiple log sinks, which enables sending output to multiple destinations. To enable the system log sink in addition to (rather than instead of) the default sink, set the `log_error_services` value like this:

```sql
SET GLOBAL log_error_services = 'log_filter_internal; log_sink_internal; log_sink_syseventlog';
```

To revert to using only the default sink and unload the system log sink, execute these statements:

```sql
SET GLOBAL log_error_services = 'log_filter_internal; log_sink_internal';
UNINSTALL COMPONENT 'file://component_log_sink_syseventlog';
```

To configure a log component to be enabled at each server startup, use this procedure:

1. If the component is loadable, load it at runtime using `INSTALL COMPONENT`. Loading the component registers it in the `mysql.component` system table so that the server loads it automatically for subsequent startups.

2. Set the `log_error_services` value at startup to include the component name. Set the value either in the server `my.cnf` file, or use `SET PERSIST`, which sets the value for the running MySQL instance and also saves the value to be used for subsequent server restarts; see Section 13.7.6.1, “`SET Syntax for Variable Assignment`”. A value set in `my.cnf` takes effect at the next restart. A value set using `SET PERSIST` takes effect immediately, and for subsequent restarts.
Suppose that you want to configure, for every server startup, use of the JSON log sink (log_sink_json) in addition to the built-in log filter and sink (log_filter_internal, log_sink_internal). First load the JSON sink if it is not loaded:

```
INSTALL COMPONENT 'file://component_log_sink_json';
```

Then set `log_error_services` to take effect at server startup. You can set it in `my.cnf`:

```
[mysqld]
log_error_services='log_filter_internal; log_sink_internal; log_sink_json'
```

Or you can set it using `SET PERSIST`:

```
SET PERSIST log_error_services = 'log_filter_internal; log_sink_internal; log_sink_json';
```

The order of components named in `log_error_services` is significant, particularly with respect to the relative order of filters and sinks. Consider this `log_error_services` value:

```
log_filter_internal; log_sink_1; log_sink_2
```

In this case, log events pass to the built-in filter, then to the first sink, then to the second sink. Both sinks receive the filtered log events.

Compare that to this `log_error_services` value:

```
log_sink_1; log_filter_internal; log_sink_2
```

In this case, log events pass to the first sink, then to the built-in filter, then to the second sink. The first sink receives unfiltered events. The second sink receives filtered events. You might configure error logging this way if you want one log that contains messages for all log events, and another log that contains messages only for a subset of log events.

**Note**

If the enabled log components include a sink that provides Performance Schema support, events written to the error log are also written to the Performance Schema `error_log` table. This enables examining error log contents using SQL queries. Currently, the traditional-format log_sink_internal and JSON-format log_sink_json sinks support this capability. See Section 26.12.19.1, “The error_log Table”.

### 5.4.2.2 Default Error Log Destination Configuration

This section describes which server options configure the default error log destination, which can be the console or a named file. It also indicates which log sink components base their own output destination on the default destination.

In this discussion, "console" means `stderr`, the standard error output. This is your terminal or console window unless the standard error output has been redirected to a different destination.

The server interprets options that determine the default error log destination somewhat differently for Windows and Unix systems. Be sure to configure the destination using the information appropriate to your platform. After the server interprets the default error log destination options, it sets the `log_error` system variable to indicate the default destination, which affects where several log sink components write error messages. The following sections address these topics.

- Default Error Log Destination on Windows
- Default Error Log Destination on Unix and Unix-Like Systems
- How the Default Error Log Destination Affects Log Sinks
The Error Log

Default Error Log Destination on Windows

On Windows, \texttt{mysqld} uses the \texttt{--log-error}, \texttt{--pid-file}, and \texttt{--console} options to determine whether the default error log destination is the console or a file, and, if a file, the file name:

- If \texttt{--console} is given, the default destination is the console. (\texttt{--console} takes precedence over \texttt{--log-error} if both are given, and the following items regarding \texttt{--log-error} do not apply.)

- If \texttt{--log-error} is not given, or is given without naming a file, the default destination is a file named \texttt{host_name.err} in the data directory, unless the \texttt{--pid-file} option is specified. In that case, the file name is the PID file base name with a suffix of .\texttt{err} in the data directory.

- If \texttt{--log-error} is given to name a file, the default destination is that file (with an \texttt{.err} suffix added if the name has no suffix). The file location is under the data directory unless an absolute path name is given to specify a different location.

If the default error log destination is the console, the server sets the \texttt{log_error} system variable to \texttt{stderr}. Otherwise, the default destination is a file and the server sets \texttt{log_error} to the file name.

Default Error Log Destination on Unix and Unix-Like Systems

On Unix and Unix-like systems, \texttt{mysqld} uses the \texttt{--log-error} option to determine whether the default error log destination is the console or a file, and, if a file, the file name:

- If \texttt{--log-error} is not given, the default destination is the console.

- If \texttt{--log-error} is given without naming a file, the default destination is a file named \texttt{host_name.err} in the data directory.

- If \texttt{--log-error} is given to name a file, the default destination is that file (with an \texttt{.err} suffix added if the name has no suffix). The file location is under the data directory unless an absolute path name is given to specify a different location.

- If \texttt{--log-error} is given in an option file in a \texttt{[mysqld]}, \texttt{[server]}, or \texttt{[mysqld_safe]} section, on systems that use \texttt{mysqld_safe} to start the server, \texttt{mysqld_safe} finds and uses the option, and passes it to \texttt{mysqld}.

\begin{itemize}
  \item \textbf{Note}\n  \begin{itemize}
    \item It is common for Yum or APT package installations to configure an error log file location under /\texttt{var/log} with an option like \texttt{log-error=/var/log/mysqld.log} in a server configuration file. Removing the path name from the option causes the \texttt{host_name.err} file in the data directory to be used.
  \end{itemize}
\end{itemize}

If the default error log destination is the console, the server sets the \texttt{log_error} system variable to \texttt{stderr}. Otherwise, the default destination is a file and the server sets \texttt{log_error} to the file name.

How the Default Error Log Destination Affects Log Sinks

After the server interprets the error log destination configuration options, it sets the \texttt{log_error} system variable to indicate the default error log destination. Log sink components may base their own output destination on the \texttt{log_error} value, or determine their destination independently of \texttt{log_error}.

If \texttt{log_error} is \texttt{stderr}, the default error log destination is the console, and log sinks that base their output destination on the default destination also write to the console:

- \texttt{log_sink_internal}, \texttt{log_sink_json}, \texttt{log_sink_test}: These sinks write to the console. This is true even for sinks such as \texttt{log_sink_json} that can be enabled multiple times; all instances write to the console.
• **log_sink_syseventlog**: This sink writes to the system log, regardless of the `log_error` value. If `log_error` is not `stderr`, the default error log destination is a file and `log_error` indicates the file name. Log sinks that base their output destination on the default destination base output file naming use that file name. (A sink might use exactly that name, or it might use some variant thereof.) Suppose that the `log_error` value is `file_name`. Then log sinks use the name like this:

• **log_sink_internal, log_sink_test**: These sinks write to `file_name`.

• **log_sink_json**: Successive instances of this sink named in the `log_error_services` value write to files named `file_name` plus a numbered `.NN.json` suffix: `file_name.00.json`, `file_name.01.json`, and so forth.

• **log_sink_syseventlog**: This sink writes to the system log, regardless of the `log_error` value.

### 5.4.2.3 Error Event Fields

Error events intended for the error log contain a set of fields, each of which consists of a key/value pair. An event field may be classified as core, optional, or user-defined:

• A core field is set up automatically for error events. However, its presence in the event during event processing is not guaranteed because a core field, like any type of field, may be unset by a log filter. If this happens, the field cannot be found by subsequent processing within that filter and by components that execute after the filter (such as log sinks).

• An optional field is normally absent but may be present for certain event types. When present, an optional field provides additional event information as appropriate and available.

• A user-defined field is any field with a name that is not already defined as a core or optional field. A user-defined field does not exist until created by a log filter.

As implied by the preceding description, any given field may be absent during event processing, either because it was not present in the first place, or was discarded by a filter. For log sinks, the effect of field absence is sink specific. For example, a sink might omit the field from the log message, indicate that the field is missing, or substitute a default. When in doubt, test: use a filter that unsets the field, then check what the log sink does with it.

The following sections describe the core and optional error event fields. For individual log filter components, there may be additional filter-specific considerations for these fields, or filters may add user-defined fields not listed here. For details, see the documentation for specific filters.

• **Core Error Event Fields**

• **Optional Error Event Fields**

#### Core Error Event Fields

These error event fields are core fields:

• **time**
  
The event timestamp, with microsecond precision.

• **msg**
  
The event message string.

• **prio**
The event priority, to indicate a system, error, warning, or note/information event. This field corresponds to severity in syslog. The following table shows the possible priority levels.

<table>
<thead>
<tr>
<th>Event Type</th>
<th>Numeric Priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>System event</td>
<td>0</td>
</tr>
<tr>
<td>Error event</td>
<td>1</td>
</tr>
<tr>
<td>Warning event</td>
<td>2</td>
</tr>
<tr>
<td>Note/information event</td>
<td>3</td>
</tr>
</tbody>
</table>

The `prio` value is numeric. Related to it, an error event may also include an optional `label` field representing the priority as a string. For example, an event with a `prio` value of 2 may have a `label` value of 'Warning'.

Filter components may include or drop error events based on priority, except that system events are mandatory and cannot be dropped.

In general, message priorities are determined as follows:

Is the situation or event actionable?
- Yes: Is the situation or event ignorable?
  - Yes: Priority is warning.
  - No: Priority is error.
- No: Is the situation or event mandatory?
  - Yes: Priority is system.
  - No: Priority is note/information.

- `err_code`
  The event error code, as a number (for example, `1022`).

- `err_symbol`
  The event error symbol, as a string (for example, 'ER_DUP_KEY').

- `SQL_state`
  The event SQLSTATE value, as a string (for example, '23000').

- `subsystem`
  The subsystem in which the event occurred. Possible values are InnoDB (the InnoDB storage engine), Repl (the replication subsystem), Server (otherwise).

**Optional Error Event Fields**

Optional error event fields fall into the following categories:

- Additional information about the error, such as the error signaled by the operating system or the error label:
The Error Log

- **OS_errno**
  The operating system error number.

- **OS_errmsg**
  The operating system error message.

- **label**
  The label corresponding to the `prio` value, as a string.

- Identification of the client for which the event occurred:
  - **user**
    The client user.
  - **host**
    The client host.
  - **thread**
    The ID of the thread within `mysqld` responsible for producing the error event. This ID indicates which part of the server produced the event, and is consistent with general query log and slow query log messages, which include the connection thread ID.

- **query_id**
  The query ID.

- Debugging information:
  - **source_file**
    The source file in which the event occurred, without any leading path.
  - **source_line**
    The line within the source file at which the event occurred.
  - **function**
    The function in which the event occurred.
  - **component**
    The component or plugin in which the event occurred.

### 5.4.2.4 Types of Error Log Filtering

Error log configuration normally includes one log filter component and one or more log sink components. For error log filtering, MySQL offers a choice of components:

- **log_filter_internal**: This filter component provides error log filtering based on log event priority and error code, in combination with the `log_error_verbosity` and
log_error_suppression_list system variables. log_filter_internal is built in and enabled by default. See Section 5.4.2.5, “Priority-Based Error Log Filtering (log_filter_internal)".

- log_filter_dragnet: This filter component provides error log filtering based on user-supplied rules, in combination with the dragnet.log_error_filter_rules system variable. See Section 5.4.2.6, “Rule-Based Error Log Filtering (log_filter_dragnet)".

5.4.2.5 Priority-Based Error Log Filtering (log_filter_internal)

The log_filter_internal log filter component implements a simple form of log filtering based on error event priority and error code. To affect how log_filter_internal permits or suppresses error, warning, and information events intended for the error log, set the log_error_verbosity and log_error_suppression_list system variables.

log_filter_internal is built in and enabled by default. If this filter is disabled, log_filter_internal and log_error_suppression_list have no effect, so filtering must be performed using another filter service instead where desired (for example, with individual filter rules when using log_filter_dragnet). For information about filter configuration, see Section 5.4.2.1, “Error Log Configuration”.

- Verbosity Filtering
- Suppression-List Filtering
- Verbosity and Suppression-List Interaction

Verbosity Filtering

Events intended for the error log have a priority of ERROR, WARNING, or INFORMATION. The log_error_verbosity system variable controls verbosity based on which priorities to permit for messages written to the log, as shown in the following table.

<table>
<thead>
<tr>
<th>log_error_verbosity Value</th>
<th>Permitted Message Priorities</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ERROR</td>
</tr>
<tr>
<td>2</td>
<td>ERROR, WARNING</td>
</tr>
<tr>
<td>3</td>
<td>ERROR, WARNING, INFORMATION</td>
</tr>
</tbody>
</table>

If log_error_verbosity is 2 or greater, the server logs messages about statements that are unsafe for statement-based logging. If the value is 3, the server logs aborted connections and access-denied errors for new connection attempts. See Section B.3.2.9, “Communication Errors and Aborted Connections”.

If you use replication, a log_error_verbosity value of 2 or greater is recommended, to obtain more information about what is happening, such as messages about network failures and reconnections.

If log_error_verbosity is 2 or greater on a replica, the replica prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, and so forth.

There is also a message priority of SYSTEM that is not subject to verbosity filtering. System messages about non-error situations are printed to the error log regardless of the log_error_verbosity value. These messages include startup and shutdown messages, and some significant changes to settings.

In the MySQL error log, system messages are labeled as “System”. Other log sinks might or might not follow the same convention, and in the resulting logs, system messages might be assigned the label used for the information priority level, such as “Note” or “Information”. If you apply any additional filtering or
redirection for logging based on the labeling of messages, system messages do not override your filter, but are handled by it in the same way as other messages.

**Suppression-List Filtering**

The `log_error_suppression_list` system variable applies to events intended for the error log and specifies which events to suppress when they occur with a priority of `WARNING` or `INFORMATION`. For example, if a particular type of warning is considered undesirable “noise” in the error log because it occurs frequently but is not of interest, it can be suppressed. `log_error_suppression_list` does not suppress messages with a priority of `ERROR` or `SYSTEM`.

The `log_error_suppression_list` value may be the empty string for no suppression, or a list of one or more comma-separated values indicating the error codes to suppress. Error codes may be specified in symbolic or numeric form. A numeric code may be specified with or without the `MY-` prefix. Leading zeros in the numeric part are not significant. Examples of permitted code formats:

<table>
<thead>
<tr>
<th>Symbolic Code</th>
<th>Numeric Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>ER_SERVER_SHUTDOWN_COMPLETE</td>
<td>MY-000031</td>
</tr>
<tr>
<td>000031</td>
<td>MY-31</td>
</tr>
<tr>
<td>31</td>
<td></td>
</tr>
</tbody>
</table>

For readability and portability, symbolic values are preferable to numeric values.

Although codes to be suppressed can be expressed in symbolic or numeric form, the numeric value of each code must be in a permitted range:

- 1 to 999: Global error codes that are used by the server as well as by clients.
- 10000 and higher: Server error codes intended to be written to the error log (not sent to clients).

In addition, each error code specified must actually be used by MySQL. Attempts to specify a code not within a permitted range or within a permitted range but not used by MySQL produce an error and the `log_error_suppression_list` value remains unchanged.

For information about error code ranges and the error symbols and numbers defined within each range, see Section B.1, “Error Message Sources and Elements”, and MySQL 8.0 Error Message Reference.

The server can generate messages for a given error code at differing priorities, so suppression of a message associated with an error code listed in `log_error_suppression_list` depends on its priority. Suppose that the variable has a value of `'ER_PARSER_TRACE,MY-010001,10002'`. Then `log_error_suppression_list` has these effects on messages for those codes:

- Messages generated with a priority of `WARNING` or `INFORMATION` are suppressed.
- Messages generated with a priority of `ERROR` or `SYSTEM` are not suppressed.

**Verbosity and Suppression-List Interaction**

The effect of `log_error_verbosity` combines with that of `log_error_suppression_list`. Consider a server started with these settings:

```
[mysqld]
log_error_verbosity=2     # error and warning messages only
log_error_suppression_list='ER_PARSER_TRACE,MY-010001,10002'
```

In this case, `log_error_verbosity` permits messages with `ERROR` or `WARNING` priority and discards messages with `INFORMATION` priority. Of the nondiscarded messages, `log_error_suppression_list` discards messages with `WARNING` priority and any of the named error codes.
The Error Log

Note

The `log_error_verbosity` value of 2 shown in the example is also its default value, so the effect of this variable on INFORMATION messages is as just described by default, without an explicit setting. You must set `log_error_verbosity` to 3 if you want `log_error_suppression_list` to affect messages with INFORMATION priority.

Consider a server started with this setting:

```
[mysqld]
log_error_verbosity=1  # error messages only
```

In this case, `log_error_verbosity` permits messages with ERROR priority and discards messages with WARNING or INFORMATION priority. Setting `log_error_suppression_list` has no effect because all error codes it might suppress are already discarded due to the `log_error_verbosity` setting.

5.4.2.6 Rule-Based Error Log Filtering (log_filter_dragnet)

The `log_filter_dragnet` log filter component enables log filtering based on user-defined rules.

To enable the `log_filter_dragnet` filter, first load the filter component, then modify the `log_error_services` value. The following example enables `log_filter_dragnet` in combination with the built-in log sink:

```
INSTALL COMPONENT 'file://component_log_filter_dragnet';
SET GLOBAL log_error_services = 'log_filter_dragnet; log_sink_internal';
```

To set `log_error_services` to take effect at server startup, use the instructions at Section 5.4.2.1, “Error Log Configuration”. Those instructions apply to other error-logging system variables as well.

With `log_filter_dragnet` enabled, define its filter rules by setting the `dragnet.log_error_filter_rules` system variable. A rule set consists of zero or more rules, where each rule is an IF statement terminated by a period (.) character. If the variable value is empty (zero rules), no filtering occurs.

Example 1. This rule set drops information events, and, for other events, removes the `source_line` field:

```
SET GLOBAL dragnet.log_error_filter_rules =
'IF prio>=INFORMATION THEN drop. IF EXISTS source_line THEN unset source_line.';
```

The effect is similar to the filtering performed by the `log_sink_internal` filter with a setting of `log_error_verbosity=2`.

For readability, you might find it preferable to list the rules on separate lines. For example:

```
SET GLOBAL dragnet.log_error_filter_rules =
  'IF prio>=INFORMATION THEN drop.
   IF EXISTS source_line THEN unset source_line.';
```

Example 2: This rule limits information events to no more than one per 60 seconds:

```
SET GLOBAL dragnet.log_error_filter_rules =
  'IF prio>=INFORMATION THEN throttle 1/60.';
```

Once you have the filtering configuration set up as you desire, consider assigning `dragnet.log_error_filter_rules` using `SET PERSIST` rather than `SET GLOBAL` to make the setting persist across server restarts. Alternatively, add the setting to the server option file.

To stop using the filtering language, first remove it from the set of error logging components. Usually this means using a different filter component rather than no filter component. For example:
The Error Log

SET GLOBAL log_error_services = 'log_filter_internal; log_sink_internal';

Again, consider using using SET PERSIST rather than SET GLOBAL to make the setting persist across server restarts.

Then uninstall the filter log_filter_dragnet component:

UNINSTALL COMPONENT 'file://component_log_filter_dragnet';

The following sections describe aspects of log_filter_dragnet operation in more detail:

• Grammar for log_filter_dragnet Rule Language
• Actions for log_filter_dragnet Rules
• Field References in log_filter_dragnet Rules

Grammar for log_filter_dragnet Rule Language

The following grammar defines the language for log_filter_dragnet filter rules. Each rule is an IF statement terminated by a period (.) character. The language is not case-sensitive.

rule:
  IF condition THEN action
  [ELSEIF condition THEN action] ...
  [ELSE action]
.
condition: {
  field comparator value
  | [NOT] EXISTS field
  | condition {AND | OR} condition
}

action: {
  drop
  | throttle {count | count / window_size}
  | set field [:= | =] value
  | unset [field]
}

field: {
  core_field
  | optional_field
  | user_defined_field
}

core_field: {
  time
  | msg
  | prio
  | err_code
  | err_symbol
  | SQL_state
  | subsystem
}

optional_field: {
  OS_errno
  OS_errmsg
  label
  user
  host
  thread
  query_id
}
Simple conditions compare a field to a value or test field existence. To construct more complex conditions, use the **AND** and **OR** operators. Both operators have the same precedence and evaluate left to right.

To escape a character within a string, precede it by a backslash (\). A backslash is required to include backslash itself or the string-quoting character, optional for other characters.

For convenience, `log_filter_dragonet` supports symbolic names for comparisons to certain fields. For readability and portability, symbolic values are preferable (where applicable) to numeric values.

- Event priority values 1, 2, and 3 can be specified as **ERROR**, **WARNING**, and **INFORMATION**. Priority symbols are recognized only in comparisons with the `prio` field. These comparisons are equivalent:

  ```plaintext
  IF prio == INFORMATION THEN ...
  IF prio == 3 THEN ...
  ```

- Error codes can be specified in numeric form or as the corresponding error symbol. For example, **ER_STARTUP** is the symbolic name for error **1408**, so these comparisons are equivalent:

  ```plaintext
  IF err_code == ER_STARTUP THEN ...
  IF err_code == 1408 THEN ...
  ```

Error symbols are recognized only in comparisons with the `err_code` field and user-defined fields.

To find the error symbol corresponding to a given error code number, use one of these methods:
The Error Log

• Check the list of server errors at Server Error Message Reference.

• Use the perror command. Given an error number argument, perror displays information about the error, including its symbol.

Suppose that a rule set with error numbers looks like this:

```plaintext
IF err_code == 10927 OR err_code == 10914 THEN drop.
IF err_code == 1131 THEN drop.
```

Using perror, determine the error symbols:

```shell
shell> perror 10927 10914 1131
MySQL error code MY-010927 (ER_ACCESS_DENIED_FOR_USER_ACCOUNT_LOCKED):
Access denied for user '%-.48s'@'%-.64s'. Account is locked.
MySQL error code MY-010914 (ER_ABORTING_USER_CONNECTION):
Aborted connection %u to db: '%-.192s' user: '%-.48s' host: '%-.64s' (%-.64s).
MySQL error code MY-001131 (ER_PASSWORD_ANONYMOUS_USER):
You are using MySQL as an anonymous user and anonymous users are not allowed to change passwords
```

Substituting error symbols for numbers, the rule set becomes:

```plaintext
IF err_code == ER_ACCESS_DENIED_FOR_USER_ACCOUNT_LOCKED
 OR err_code == ER_ABORTING_USER_CONNECTION THEN drop.
IF err_code == ER_PASSWORD_ANONYMOUS_USER THEN drop.
```

Symbolic names can be specified as quoted strings for comparison with string fields, but in such cases the names are strings that have no special meaning and log_filter_dragnet does not resolve them to the corresponding numeric value. Also, typos may go undetected, whereas an error occurs immediately on SET for attempts to use an unquoted symbol unknown to the server.

**Actions for log_filter_dragnet Rules**

log_filter_dragnet supports these actions in filter rules:

• **drop**: Drop the current log event (do not log it).

• **throttle**: Apply rate limiting to reduce log verbosity for events matching particular conditions. The argument indicates a rate, in the form `count` or `count/window_size`. The `count` value indicates the permitted number of event occurrences to log per time window. The `window_size` value is the time window in seconds; if omitted, the default window is 60 seconds. Both values must be integer literals.

This rule throttles plugin-shutdown messages to 5 occurrences per 60 seconds:

```plaintext
IF err_code == ER_PLUGIN_SHUTTING_DOWN_PLUGIN THEN throttle 5.
```

This rule throttles errors and warnings to 1000 occurrences per hour and information messages to 100 occurrences per hour:

```plaintext
IF prio <= INFORMATION THEN throttle 1000/3600 ELSE throttle 100/3600.
```

• **set**: Assign a value to a field (and cause the field to exist if it did not already). In subsequent rules, EXISTS tests against the field name are true, and the new value can be tested by comparison conditions.

• **unset**: Discard a field. In subsequent rules, EXISTS tests against the field name are false, and comparisons of the field against any value are false.
In the special case that the condition refers to exactly one field name, the field name following `unset` is optional and `unset` discards the named field. These rules are equivalent:

```
IF myfield == 2 THEN unset myfield.
IF myfield == 2 THEN unset.
```

### Field References in `log_filter_dragonet` Rules

`log_filter_dragonet` rules support references to core, optional, and user-defined fields in error events.

- Core Field References
- Optional Field References
- User-Defined Field References

#### Core Field References

The `log_filter_dragonet` grammar at Grammar for `log_filter_dragonet` Rule Language names the core fields that filter rules recognize. For general descriptions of these fields, see Section 5.4.2.3, “Error Event Fields”, with which you are assumed to be familiar. The following remarks provide additional information only as it pertains specifically to core field references as used within `log_filter_dragonet` rules.

- **prio**

  The event priority, to indicate an error, warning, or note/information event. In comparisons, each priority can be specified as a symbolic priority name or an integer literal. Priority symbols are recognized only in comparisons with the `prio` field. These comparisons are equivalent:

  ```
  IF prio == INFORMATION THEN ...
  IF prio == 3 THEN ...
  ```

  The following table shows the permitted priority levels.

<table>
<thead>
<tr>
<th>Event Type</th>
<th>Priority Symbol</th>
<th>Numeric Priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error event</td>
<td>ERROR</td>
<td>1</td>
</tr>
<tr>
<td>Warning event</td>
<td>WARNING</td>
<td>2</td>
</tr>
<tr>
<td>Note/information event</td>
<td>INFORMATION</td>
<td>3</td>
</tr>
</tbody>
</table>

  There is also a message priority of `SYSTEM`, but system messages cannot be filtered and are always written to the error log.

  Priority values follow the principle that higher priorities have lower values, and vice versa. Priority values begin at 1 for the most severe events (errors) and increase for events with decreasing priority. For example, to discard events with priority lower than warnings, test for priority values higher than `WARNING`:

  ```
  IF prio > WARNING THEN drop.
  ```

  The following examples show the `log_filter_dragonet` rules to achieve an effect similar to each `log_errorverbosity` value permitted by the `log_filter_internal` filter:

  - Errors only (`log_errorverbosity=1`):
    ```
    IF prio > ERROR THEN drop.
    ```

  - Errors and warnings (`log_errorverbosity=2`):
The Error Log

IF prio > WARNING THEN drop.

- Errors, warnings, and notes (log_error_verbosity=3):
  IF prio > INFORMATION THEN drop.

This rule can actually be omitted because there are no prio values greater than INFORMATION, so effectively it drops nothing.

- err_code
  The numeric event error code. In comparisons, the value to test can be specified as a symbolic error name or an integer literal. Error symbols are recognized only in comparisons with the err_code field and user-defined fields. These comparisons are equivalent:

  IF err_code == ER_ACCESS_DENIED_ERROR THEN ...
  IF err_code == 1045 THEN ...

- err_symbol
  The event error symbol, as a string (for example, 'ER_DUP_KEY'). err_symbol values are intended more for identifying particular lines in log output than for use in filter rule comparisons because log_filter_dragnet does not resolve comparison values specified as strings to the equivalent numeric error code. (For that to occur, an error must be specified using its unquoted symbol.)

Optional Field References

The log_filter_dragnet grammar at Grammar for log_filter_dragnet Rule Language names the optional fields that filter rules recognize. For general descriptions of these fields, see Section 5.4.2.3, “Error Event Fields”, with which you are assumed to be familiar. The following remarks provide additional information only as it pertains specifically to optional field references as used within log_filter_dragnet rules.

- label
  The label corresponding to the prio value, as a string. Filter rules can change the label for log sinks that support custom labels. label values are intended more for identifying particular lines in log output than for use in filter rule comparisons because log_filter_dragnet does not resolve comparison values specified as strings to the equivalent numeric priority.

- source_file
  The source file in which the event occurred, without any leading path. For example, to test for the sql/gis/distance.cc file, write the comparison like this:

  IF source_file == "distance.cc" THEN ...

User-Defined Field References

Any field name in a log_filter_dragnet filter rule not recognized as a core or optional field name is taken to refer to a user-defined field.

5.4.2.7 Error Logging in JSON Format

This section describes how to configure error logging using the built-in filter, log_filter_internal, and the JSON sink, log_sink_json, to take effect immediately and for subsequent server startups. For general information about configuring error logging, see Section 5.4.2.1, “Error Log Configuration”.
To enable the JSON sink, first load the sink component, then modify the `log_error_services` value:

```
INSTALL COMPONENT 'file://component_log_sink_json';
SET PERSIST log_error_services = 'log_filter_internal; log_sink_json';
```

To set `log_error_services` to take effect at server startup, use the instructions at Section 5.4.2.1, “Error Log Configuration”. Those instructions apply to other error-logging system variables as well.

It is permitted to name `log_sink_json` multiple times in the `log_error_services` value. For example, to write unfiltered events with one instance and filtered events with another instance, you could set `log_error_services` like this:

```
SET PERSIST log_error_services = 'log_sink_json; log_filter_internal; log_sink_json';
```

The JSON sink determines its output destination based on the default error log destination, which is given by the `log_error` system variable. If `log_error` names a file, the JSON sink bases output file naming on that file name, plus a numbered `.NN.json` suffix, with `NN` starting at 00. For example, if `log_error` is `file_name`, successive instances of `log_sink_json` named in the `log_error_services` value write to `file_name.00.json`, `file_name.01.json`, and so forth.

If `log_error` is `stderr`, the JSON sink writes to the console. If `log_sink_json` is named multiple times in the `log_error_services` value, they all write to the console, which is likely not useful.

### 5.4.2.8 Error Logging to the System Log

It is possible to have `mysql` write the error log to the system log (the Event Log on Windows, and `syslog` on Unix and Unix-like systems).

This section describes how to configure error logging using the built-in filter, `log_filter_internal`, and the system log sink, `log_sink_syseventlog`, to take effect immediately and for subsequent server startups. For general information about configuring error logging, see Section 5.4.2.1, “Error Log Configuration”.

To enable the system log sink, first load the sink component, then modify the `log_error_services` value:

```
INSTALL COMPONENT 'file://component_log_sink_syseventlog';
SET PERSIST log_error_services = 'log_filter_internal; log_sink_syseventlog';
```

To set `log_error_services` to take effect at server startup, use the instructions at Section 5.4.2.1, “Error Log Configuration”. Those instructions apply to other error-logging system variables as well.

---

**Note**

For MySQL 8.0 configuration, you must enable error logging to the system log explicitly. This differs from MySQL 5.7 and earlier, for which error logging to the system log is enabled by default on Windows, and on all platforms requires no component loading.

Error logging to the system log may require additional system configuration. Consult the system log documentation for your platform.

On Windows, error messages written to the Event Log within the Application log have these characteristics:

- Entries marked as **Error**, **Warning**, and **Note** are written to the Event Log, but not messages such as information statements from individual storage engines.

- Event Log entries have a source of **MySQL** (or **MySQL-<tag>** if `syseventlog.tag` is defined as `<tag>`).
On Unix and Unix-like systems, logging to the system log uses `syslog`. The following system variables affect `syslog` messages:

- `syseventlog.facility`: The default facility for `syslog` messages is `daemon`. Set this variable to specify a different facility.
- `syseventlog.include_pid`: Whether to include the server process ID in each line of `syslog` output.
- `syseventlog.tag`: This variable defines a tag to add to the server identifier (`mysqld`) in `syslog` messages. If defined, the tag is appended to the identifier with a leading hyphen.

**Note**

Prior to MySQL 8.0.13, use the `log_syslog_facility`, `log_syslog_include_pid`, and `log_syslog_tag` system variables rather than the `syseventlog.xxx` variables.

MySQL uses the custom label “System” for important system messages about non-error situations, such as startup, shutdown, and some significant changes to settings. In logs that do not support custom labels, including the Event Log on Windows, and `syslog` on Unix and Unix-like systems, system messages are assigned the label used for the information priority level. However, these messages are printed to the log even if the MySQL `log_error_verbosity` setting normally excludes messages at the information level.

When a log sink must fall back to a label of “Information” instead of “System” in this way, and the log event is further processed outside of the MySQL server (for example, filtered or forwarded by a `syslog` configuration), these events may by default be processed by the secondary application as being of “Information” priority rather than “System” priority.

### 5.4.2.9 Error Log Output Format

Each error log sink (writer) component has a characteristic output format it uses to write messages to its destination, but other factors may influence the content of the messages:

- The information available to the log sink. If a log filter component executed prior to execution of the sink component removes a log event field, that field is not available for writing. For information about log filtering, see Section 5.4.2.4, “Types of Error Log Filtering”.

- The information relevant to the log sink. Not every sink writes all fields available in error events.

- System variables may affect log sinks. See System Variables That Affect Error Log Format.

For names and descriptions of the fields in error events, see Section 5.4.2.3, “Error Event Fields”. For all log sinks, the thread ID included in error log messages is that of the thread within `mysqld` responsible for writing the message. This ID indicates which part of the server produced the message, and is consistent with general query log and slow query log messages, which include the connection thread ID.

- `log_sink_internal Output Format`
- `log_sink_json Output Format`
- `log_sink_syseventlog Output Format`
- `Early-Startup Logging Output Format`
- System Variables That Affect Error Log Format

**log_sink_internal Output Format**

The internal log sink produces traditional error log output. For example:
Traditional-format messages have these fields:

```
time thread [label] [err_code] [subsystem] msg
```

The square bracket characters are literal characters in the message format. They do not indicate that fields are optional.

The `label` value corresponds to the string form of the `prio` error event priority field.

The `[err_code]` and `[subsystem]` fields were added in MySQL 8.0. They are missing from logs generated by older servers. Log parsers can treat these fields as parts of the message text that is present only for logs written by servers recent enough to include them. Parsers must treat the `err_code` part of `[err_code]` indicators as a string value, not a number, because values such as `MY-012487` and `MY-010051` contain nonnumeric characters.

### log_sink_json Output Format

The JSON-format log sink produces messages as JSON objects that contain key-value pairs. For example:

```json
{
  "prio": 3,
  "err_code": 10051,
  "source_line": 561,
  "source_file": "event_scheduler.cc",
  "function": "run",
  "msg": "Event Scheduler: scheduler thread started with id 5",
  "time": "2020-08-06T14:25:03.109022Z",
  "ts": 1596724012005,
  "thread": 5,
  "err_symbol": "ER_SCHEDULER_STARTED",
  "SQL_state": "HY000",
  "subsystem": "Server",
  "buffered": 1596723903109022,
  "label": "Note"
}
```

The message shown is reformatted for readability. Events written to the error log appear one message per line.

The `ts` (timestamp) key was added in MySQL 8.0.20 and is unique to the JSON-format log sink. The value is an integer indicating milliseconds since the epoch (`'1970-01-01 00:00:00' UTC`).

The `ts` and `buffered` values are Unix timestamp values and can be converted using `FROM_UNIXTIME()` and an appropriate divisor:

```sql
mysql> SET time_zone = '+00:00';
mysql> SELECT FROM_UNIXTIME(1596724012005/1000.0); +---------------------------------------------------+ | FROM_UNIXTIME(1596724012005/1000.0) | +---------------------------------------------------+ | 2020-08-06 14:26:52.0050 | +---------------------------------------------------+
mysql> SELECT FROM_UNIXTIME(1596723903109022/1000000.0); +---------------------------------------------------+ | FROM_UNIXTIME(1596723903109022/1000000.0) | +---------------------------------------------------+ | 2020-08-06 14:25:03.1090 | +---------------------------------------------------+
```
The Error Log

log_sink_sysyseventlog Output Format

The system log sink produces output that conforms to the system log format used on the local platform.

Early-Startup Logging Output Format

The server generates some error log messages before startup options have been processed, and thus before it knows error log settings such as the `log_error_verbosity` and `log_timestamps` system variable values, and before it knows which log components are to be used. The server handles error log messages that are generated early in the startup process as follows:

- Prior to MySQL 8.0.14, the server generates messages with the default timestamp, format, and verbosity level, and buffers them. After the startup options are processed and the error log configuration is known, the server flushes the buffered messages. Because these early messages use the default log configuration, they may differ from what is specified by the startup options. Also, the early messages are not flushed to log sinks other than the default. For example, logging to the JSON sink does not include these early messages because they are not in JSON format.

- As of MySQL 8.0.14, the server buffers log events rather than formatted log messages. This enables it to retroactively apply configuration settings to those events after the settings are known, with the result that flushed messages use the configured settings, not the defaults. Also, messages are flushed to all configured sinks, not just the default sink.

If a fatal error occurs before log configuration is known and the server must exit, the server formats buffered messages using the logging defaults so they are not lost. If no fatal error occurs but startup is excessively slow prior to processing startup options, the server periodically formats and flushes buffered messages using the logging defaults so as not to appear unresponsive. Although this behavior is similar to pre-8.0.14 behavior in that the defaults are used, it is preferable to losing messages when exceptional conditions occur.

System Variables That Affect Error Log Format

The `log_timestamps` system variable controls the time zone of timestamps in messages written to the error log (as well as to general query log and slow query log files). The server applies `log_timestamps` to error events before they reach any log sink; it thus affects error message output from all sinks.

Permitted `log_timestamps` values are UTC (the default) and SYSTEM (the local system time zone). Timestamps are written using ISO 8601 / RFC 3339 format: `YYYY-MM-DDThh:mm:ss.uuuuuu` plus a tail value of `Z` signifying Zulu time (UTC) or `±hh:mm` (an offset that indicates the local system time zone adjustment relative to UTC). For example:

<table>
<thead>
<tr>
<th>Timestamp</th>
<th>Time Zone</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-08-07T15:02:00.832521Z</td>
<td>(UTC)</td>
</tr>
<tr>
<td>2020-08-07T10:02:00.832521-05:00</td>
<td>(SYSTEM)</td>
</tr>
</tbody>
</table>

5.4.2.10 Error Log File Flushing and Renaming

If you flush the error log using a `FLUSH ERROR LOGS` or `FLUSH LOGS` statement, or a `mysqladmin flush-logs` command, the server closes and reopens any error log file to which it is writing. To rename an error log file, do so manually before flushing. Flushing the logs then opens a new file with the original file name. For example, assuming a log file name of `host_name.err`, use the following commands to rename the file and create a new one:

```bash
mv host_name.err host_name.err-old
mysqladmin flush-logs
mv host_name.err-old backup-directory
```
On Windows, use `rename` rather than `mv`.

If the location of the error log file is not writable by the server, the log-flushing operation fails to create a new log file. For example, on Linux, the server might write the error log to the `/var/log/mysqld.log` file, where the `/var/log` directory is owned by `root` and is not writable by `mysqld`. For information about handling this case, see Section 5.4.6, “Server Log Maintenance”.

If the server is not writing to a named error log file, no error log file renaming occurs when the error log is flushed.

### 5.4.3 The General Query Log

The general query log is a general record of what `mysqld` is doing. The server writes information to this log when clients connect or disconnect, and it logs each SQL statement received from clients. The general query log can be very useful when you suspect an error in a client and want to know exactly what the client sent to `mysqld`.

Each line that shows when a client connects also includes `using connection_type` to indicate the protocol used to establish the connection. `connection_type` is one of TCP/IP (TCP/IP connection established without SSL), SSL/TLS (TCP/IP connection established with SSL), Socket (Unix socket file connection), Named Pipe (Windows named pipe connection), or Shared Memory (Windows shared memory connection).

`mysqld` writes statements to the query log in the order that it receives them, which might differ from the order in which they are executed. This logging order is in contrast with that of the binary log, for which statements are written after they are executed but before any locks are released. In addition, the query log may contain statements that only select data while such statements are never written to the binary log.

When using statement-based binary logging on a replication source server, statements received by its replicas are written to the query log of each replica. Statements are written to the query log of the source if a client reads events with the `mysqlbinlog` utility and passes them to the server.

However, when using row-based binary logging, updates are sent as row changes rather than SQL statements, and thus these statements are never written to the query log when `binlog_format` is `ROW`. A given update also might not be written to the query log when this variable is set to `MIXED`, depending on the statement used. See Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”, for more information.

By default, the general query log is disabled. To specify the initial general query log state explicitly, use `--general_log=[{0|1}]`. With no argument or an argument of 1, `--general_log` enables the log. With an argument of 0, this option disables the log. To specify a log file name, use `--general_log_file=file_name`. To specify the log destination, use the `log_output` system variable (as described in Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”).

**Note**

If you specify the `TABLE` log destination, see Log Tables and “Too many open files” Errors.

If you specify no name for the general query log file, the default name is `host_name.log`. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

To disable or enable the general query log or change the log file name at runtime, use the global `general_log` and `general_log_file` system variables. Set `general_log` to 0 (or OFF) to disable the log or to 1 (or ON) to enable it. Set `general_log_file` to specify the name of the log file. If a log file already is open, it is closed and the new file is opened.
When the general query log is enabled, the server writes output to any destinations specified by the `log_output` system variable. If you enable the log, the server opens the log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected. If the destination is `NONE`, the server writes no queries even if the general log is enabled. Setting the log file name has no effect on logging if the log destination value does not contain `FILE`.

Server restarts and log flushing do not cause a new general query log file to be generated (although flushing closes and reopens it). To rename the file and create a new one, use the following commands:

```
shell> mv host_name.log host_name-old.log
shell> mysqladmin flush-logs
shell> mv host_name-old.log backup-directory
```

On Windows, use `rename` rather than `mv`.

You can also rename the general query log file at runtime by disabling the log:

```sql
SET GLOBAL general_log = 'OFF';
```

With the log disabled, rename the log file externally (for example, from the command line). Then enable the log again:

```sql
SET GLOBAL general_log = 'ON';
```

This method works on any platform and does not require a server restart.

To disable or enable general query logging for the current session, set the session `sql_log_off` variable to `ON` or `OFF`. (This assumes that the general query log itself is enabled.)

Passwords in statements written to the general query log are rewritten by the server not to occur literally in plain text. Password rewriting can be suppressed for the general query log by starting the server with the `--log-raw` option. This option may be useful for diagnostic purposes, to see the exact text of statements as received by the server, but for security reasons is not recommended for production use. See also Section 6.1.2.3, “Passwords and Logging”.

An implication of password rewriting is that statements that cannot be parsed (due, for example, to syntax errors) are not written to the general query log because they cannot be known to be password free. Use cases that require logging of all statements including those with errors should use the `--log-raw` option, bearing in mind that this also bypasses password rewriting.

Password rewriting occurs only when plain text passwords are expected. For statements with syntax that expect a password hash value, no rewriting occurs. If a plain text password is supplied erroneously for such syntax, the password is logged as given, without rewriting.

The `log_timestamps` system variable controls the time zone of timestamps in messages written to the general query log file (as well as to the slow query log file and the error log). It does not affect the time zone of general query log and slow query log messages written to log tables, but rows retrieved from those tables can be converted from the local system time zone to any desired time zone with `CONVERT_TZ()` or by setting the session `time_zone` system variable.

### 5.4.4 The Binary Log

The binary log contains “events” that describe database changes such as table creation operations or changes to table data. It also contains events for statements that potentially could have made changes (for example, a `DELETE` which matched no rows), unless row-based logging is used. The binary log also
The Binary Log

contains information about how long each statement took that updated data. The binary log has two important purposes:

- For replication, the binary log on a replication source server provides a record of the data changes to be sent to replicas. The source sends the information contained in its binary log to its replicas, which reproduce those transactions to make the same data changes that were made on the source. See Section 17.2, “Replication Implementation”.

- Certain data recovery operations require use of the binary log. After a backup has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See Section 7.5, “Point-in-Time (Incremental) Recovery”.

The binary log is not used for statements such as SELECT or SHOW that do not modify data. To log all statements (for example, to identify a problem query), use the general query log. See Section 5.4.3, “The General Query Log”.

Running a server with binary logging enabled makes performance slightly slower. However, the benefits of the binary log in enabling you to set up replication and for restore operations generally outweigh this minor performance decrement.

The binary log is resilient to unexpected halts. Only complete events or transactions are logged or read back.

Passwords in statements written to the binary log are rewritten by the server not to occur literally in plain text. See also Section 6.1.2.3, “Passwords and Logging”.

From MySQL 8.0.14, binary log files and relay log files can be encrypted, helping to protect these files and the potentially sensitive data contained in them from being misused by outside attackers, and also from unauthorized viewing by users of the operating system where they are stored. You enable encryption on a MySQL server by setting the binlog_encryption system variable to ON. For more information, see Section 17.3.2, “Encrypting Binary Log Files and Relay Log Files”.

The following discussion describes some of the server options and variables that affect the operation of binary logging. For a complete list, see Section 17.1.6.4, “Binary Logging Options and Variables”.

Binary logging is enabled by default (the log_bin system variable is set to ON). The exception is if you use mysqld to initialize the data directory manually by invoking it with the --initialize or --initialize-insecure option, when binary logging is disabled by default, but can be enabled by specifying the --log-bin option.

To disable binary logging, you can specify the --skip-log-bin or --disable-log-bin option at startup. If either of these options is specified and --log-bin is also specified, the option specified later takes precedence.

The --log-slave-updates and --slave-preserve-commit-order options require binary logging. If you disable binary logging, either omit these options, or specify --log-slave-updates=OFF and --skip-slave-preserve-commit-order. MySQL disables these options by default when --skip-log-bin or --disable-log-bin is specified. If you specify --log-slave-updates or --slave-preserve-commit-order together with --skip-log-bin or --disable-log-bin, a warning or error message is issued.

The --log-bin[=base_name] option is used to specify the base name for binary log files. If you do not supply the --log-bin option, MySQL uses binlog as the default base name for the binary log files. For compatibility with earlier releases, if you supply the --log-bin option with no string or with an empty string, the base name defaults to host_name-bin, using the name of the host machine. It is
The Binary Log

MySQL recommends that you specify a base name, so that if the host name changes, you can easily continue to use the same binary log file names (see Section B.3.7, “Known Issues in MySQL”). If you supply an extension in the log name (for example, `--log-bin=base_name.extension`), the extension is silently removed and ignored.

MySQL appends a numeric extension to the binary log base name to generate binary log file names. The number increases each time the server creates a new log file, thus creating an ordered series of files. The server creates a new file in the series each time any of the following events occurs:

- The server is started or restarted
- The server flushes the logs.
- The size of the current log file reaches `max_binlog_size`.

A binary log file may become larger than `max_binlog_size` if you are using large transactions because a transaction is written to the file in one piece, never split between files.

To keep track of which binary log files have been used, MySQL also creates a binary log index file that contains the names of the binary log files. By default, this has the same base name as the binary log file, with the extension `.index`. You can change the name of the binary log index file with the `--log-bin-index=file_name` option. You should not manually edit this file while MySQL is running; doing so would confuse MySQL.

A binary log file generally denotes an individual numbered file containing database events. The term “binary log” collectively denotes the set of numbered binary log files plus the index file.

The default location for binary log files and the binary log index file is the data directory. You can use the `--log-bin` option to specify an alternative location, by adding a leading absolute path name to the base name to specify a different directory. When the server reads an entry from the binary log index file, which tracks the binary log files that have been used, it checks whether the entry contains a relative path. If it does, the relative part of the path is replaced with the absolute path set using the `--log-bin` option. An absolute path recorded in the binary log index file remains unchanged; in such a case, the index file must be edited manually to enable a new path or paths to be used. The binary log file base name and any specified path are available as the `log_bin_basename` system variable.

In MySQL 5.7, a server ID had to be specified when binary logging was enabled, or the server would not start. In MySQL 8.0, the `server_id` system variable is set to 1 by default. The server can be started with this default ID when binary logging is enabled, but an informational message is issued if you do not specify a server ID explicitly using the `server_id` system variable. For servers that are used in a replication topology, you must specify a unique nonzero server ID for each server.

A client that has privileges sufficient to set restricted session system variables (see Section 5.1.9.1, “System Variable Privileges”) can disable binary logging of its own statements by using a `SET sql_log_bin=OFF` statement.

By default, the server logs the length of the event as well as the event itself and uses this to verify that the event was written correctly. You can also cause the server to write checksums for the events by setting the `binlog_checksum` system variable. When reading back from the binary log, the source uses the event length by default, but can be made to use checksums if available by enabling the `master_verify_checksum` system variable. The replication I/O thread on the replica also verifies events received from the source. You can cause the replication SQL thread to use checksums if available when reading from the relay log by enabling the `slave_sql_verify_checksum` system variable.

The format of the events recorded in the binary log is dependent on the binary logging format. Three format types are supported: row-based logging, statement-based logging and mixed-base logging. The binary logging format used depends on the MySQL version. For general descriptions of the logging formats, see
Section 5.4.4.1, “Binary Logging Formats”. For detailed information about the format of the binary log, see MySQL Internals: The Binary Log.

The server evaluates the `--binlog-do-db` and `--binlog-ignore-db` options in the same way as it does the `--replicate-do-db` and `--replicate-ignore-db` options. For information about how this is done, see Section 17.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”.

A replica is started with the `log_slave_updates` system variable enabled by default, meaning that the replica writes to its own binary log any data modifications that are received from the source. The binary log must be enabled for this setting to work (see Section 17.1.6.3, “Replica Server Options and Variables”). This setting enables the replica to act as a source to other replicas.

You can delete all binary log files with the `RESET MASTER` statement, or a subset of them with `PURGE BINARY LOGS`. See Section 13.7.8.6, “RESET Statement”, and Section 13.4.1.1, “PURGE BINARY LOGS Statement”.

If you are using replication, you should not delete old binary log files on the source until you are sure that no replica still needs to use them. For example, if your replicas never run more than three days behind, once a day you can execute `mysqladmin flush-logs` on the source and then remove any logs that are more than three days old. You can remove the files manually, but it is preferable to use `PURGE BINARY LOGS`, which also safely updates the binary log index file for you (and which can take a date argument). See Section 13.4.1.1, “PURGE BINARY LOGS Statement”.

You can display the contents of binary log files with the `mysqlbinlog` utility. This can be useful when you want to reprocess statements in the log for a recovery operation. For example, you can update a MySQL server from the binary log as follows:

```
shell> mysqlbinlog log_file | mysql -h server_name
```

`mysqlbinlog` also can be used to display the contents of the relay log file on a replica, because they are written using the same format as binary log files. For more information on the `mysqlbinlog` utility and how to use it, see Section 4.6.8, “mysqlbinlog — Utility for Processing Binary Log Files”. For more information about the binary log and recovery operations, see Section 7.5, “Point-in-Time (Incremental) Recovery”.

Binary logging is done immediately after a statement or transaction completes but before any locks are released or any commit is done. This ensures that the log is logged in commit order.

Updates to nontransactional tables are stored in the binary log immediately after execution.

Within an uncommitted transaction, all updates (UPDATE, DELETE, or INSERT) that change transactional tables such as InnoDB tables are cached until a COMMIT statement is received by the server. At that point, `mysqld` writes the entire transaction to the binary log before the COMMIT is executed.

Modifications to nontransactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to nontransactional tables, the entire transaction is logged with a ROLLBACK statement at the end to ensure that the modifications to those tables are replicated.

When a thread that handles the transaction starts, it allocates a buffer of `binlog_cache_size` to buffer statements. If a statement is bigger than this, the thread opens a temporary file to store the transaction. The temporary file is deleted when the thread ends. From MySQL 8.0.17, if binary log encryption is active on the server, the temporary file is encrypted.

The `Binlog_cache_use` status variable shows the number of transactions that used this buffer (and possibly a temporary file) for storing statements. The `Binlog_cache_disk_use` status variable shows how many of those transactions actually had to use a temporary file. These two variables can be used for tuning `binlog_cache_size` to a large enough value that avoids the use of temporary files.
The `max_binlog_cache_size` system variable (default 4GB, which is also the maximum) can be used to restrict the total size used to cache a multiple-statement transaction. If a transaction is larger than this many bytes, it fails and rolls back. The minimum value is 4096.

If you are using the binary log and row based logging, concurrent inserts are converted to normal inserts for `CREATE ... SELECT` or `INSERT ... SELECT` statements. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation. If you are using statement-based logging, the original statement is written to the log.

The binary log format has some known limitations that can affect recovery from backups. See Section 17.5.1, “Replication Features and Issues”.

Binary logging for stored programs is done as described in Section 24.7, “Stored Program Binary Logging”. Note that the binary log format differs in MySQL 8.0 from previous versions of MySQL, due to enhancements in replication. See Section 17.5.2, “Replication Compatibility Between MySQL Versions”.

If the server is unable to write to the binary log, flush binary log files, or synchronize the binary log to disk, the binary log on the replication source server can become inconsistent and replicas can lose synchronization with the source. The `binlog_error_action` system variable controls the action taken if an error of this type is encountered with the binary log.

- The default setting, `ABORT_SERVER`, makes the server halt binary logging and shut down. At this point, you can identify and correct the cause of the error. On restart, recovery proceeds as in the case of an unexpected server halt (see Section 17.4.2, “Handling an Unexpected Halt of a Replica”).

- The setting `IGNORE_ERROR` provides backward compatibility with older versions of MySQL. With this setting, the server continues the ongoing transaction and logs the error, then halts binary logging, but continues to perform updates. At this point, you can identify and correct the cause of the error. To resume binary logging, `log_bin` must be enabled again, which requires a server restart. Only use this option if you require backward compatibility, and the binary log is non-essential on this MySQL server instance. For example, you might use the binary log only for intermittent auditing or debugging of the server, and not use it for replication from the server or rely on it for point-in-time restore operations.

By default, the binary log is synchronized to disk at each write (`sync_binlog=1`). If `sync_binlog` was not enabled, and the operating system or machine (not only the MySQL server) crashed, there is a chance that the last statements of the binary log could be lost. To prevent this, enable the `sync_binlog` system variable to synchronize the binary log to disk after every `N` commit groups. See Section 5.1.8, “Server System Variables”. The safest value for `sync_binlog` is 1 (the default), but this is also the slowest.

In earlier MySQL releases, there was a chance of inconsistency between the table content and binary log content if a crash occurred, even with `sync_binlog` set to 1. For example, if you are using InnoDB tables and the MySQL server processes a `COMMIT` statement, it writes many prepared transactions to the binary log in sequence, synchronizes the binary log, and then commits the transaction into InnoDB. If the server unexpectedly exited between those two operations, the transaction would be rolled back by InnoDB at restart but still exist in the binary log. Such an issue was resolved in previous releases by enabling InnoDB support for two-phase commit in XA transactions. In 8.0.0 and higher, the InnoDB support for two-phase commit in XA transactions is always enabled.

InnoDB support for two-phase commit in XA transactions ensures that the binary log and InnoDB data files are synchronized. However, the MySQL server should also be configured to synchronize the binary log and the InnoDB logs to disk before committing the transaction. The InnoDB logs are synchronized by default, and `sync_binlog=1` ensures the binary log is synchronized. The effect of implicit InnoDB support for two-phase commit in XA transactions and `sync_binlog=1` is that at restart after a crash, after doing a rollback of transactions, the MySQL server scans the latest binary log file to collect transaction `xid` values and calculate the last valid position in the binary log file. The MySQL server then tells InnoDB to
complete any prepared transactions that were successfully written to the binary log, and truncates the binary log to the last valid position. This ensures that the binary log reflects the exact data of InnoDB tables, and therefore the replica remains in synchrony with the source because it does not receive a statement which has been rolled back.

If the MySQL server discovers at crash recovery that the binary log is shorter than it should have been, it lacks at least one successfully committed InnoDB transaction. This should not happen if sync_binlog=1 and the disk/file system do an actual sync when they are requested to (some do not), so the server prints an error message The binary log file_name is shorter than its expected size. In this case, this binary log is not correct and replication should be restarted from a fresh snapshot of the source's data.

The session values of the following system variables are written to the binary log and honored by the replica when parsing the binary log:

- sql_mode (except that the NO_DIR_IN_CREATE mode is not replicated; see Section 17.5.1.38, “Replication and Variables”)
- foreign_key_checks
- unique_checks
- character_set_client
- collation_connection
- collation_database
- collation_server
- sql_auto_is_null

### 5.4.4.1 Binary Logging Formats

The server uses several logging formats to record information in the binary log:

- Replication capabilities in MySQL originally were based on propagation of SQL statements from source to replica. This is called statement-based logging. You can cause this format to be used by starting the server with --binlog-format=STATEMENT.

- In row-based logging (the default), the source writes events to the binary log that indicate how individual table rows are affected. You can cause the server to use row-based logging by starting it with --binlog-format=ROW.

- A third option is also available: mixed logging. With mixed logging, statement-based logging is used by default, but the logging mode switches automatically to row-based in certain cases as described below. You can cause MySQL to use mixed logging explicitly by starting mysqld with the option --binlog-format=MIXED.

The logging format can also be set or limited by the storage engine being used. This helps to eliminate issues when replicating certain statements between a source and replica which are using different storage engines.

With statement-based replication, there may be issues with replicating nondeterministic statements. In deciding whether or not a given statement is safe for statement-based replication, MySQL determines whether it can guarantee that the statement can be replicated using statement-based logging. If MySQL cannot make this guarantee, it marks the statement as potentially unreliable and issues the warning, Statement may not be safe to log in statement format.
You can avoid these issues by using MySQL's row-based replication instead.

### 5.4.4.2 Setting The Binary Log Format

You can select the binary logging format explicitly by starting the MySQL server with `--binlog-format=type`. The supported values for `type` are:

- **STATEMENT** causes logging to be statement based.
- **ROW** causes logging to be row based. This is the default.
- **MIXED** causes logging to use mixed format.

The logging format also can be switched at runtime, although note that there are a number of situations in which you cannot do this, as discussed later in this section. Set the global value of the `binlog_format` system variable to specify the format for clients that connect subsequent to the change:

```
mysql> SET GLOBAL binlog_format = 'STATEMENT';
myisam> SET GLOBAL binlog_format = 'ROW';
mysql> SET GLOBAL binlog_format = 'MIXED';
```

An individual client can control the logging format for its own statements by setting the session value of `binlog_format`:

```
mysql> SET SESSION binlog_format = 'STATEMENT';
mysql> SET SESSION binlog_format = 'ROW';
mysql> SET SESSION binlog_format = 'MIXED';
```

Changing the global `binlog_format` value requires privileges sufficient to set global system variables. Changing the session `binlog_format` value requires privileges sufficient to set restricted session system variables. See Section 5.1.9.1, “System Variable Privileges”.

There are several reasons why a client might want to set binary logging on a per-session basis:

- A session that makes many small changes to the database might want to use row-based logging.
- A session that performs updates that match many rows in the `WHERE` clause might want to use statement-based logging because it is more efficient to log a few statements than many rows.
- Some statements require a lot of execution time on the source, but result in just a few rows being modified. It might therefore be beneficial to replicate them using row-based logging.

There are exceptions when you cannot switch the replication format at runtime:

- The replication format cannot be changed from within a stored function or a trigger.
- If the NDB storage engine is enabled.
- If a session has open temporary tables, the replication format cannot be changed for the session (`SET @@SESSION.binlog_format`).
- If any replication channel has open temporary tables, the replication format cannot be changed globally (`SET @@GLOBAL.binlog_format` or `SET @@PERSIST.binlog_format`).
- If any replication channel applier thread is currently running, the replication format cannot be changed globally (`SET @@GLOBAL.binlog_format` or `SET @@PERSIST.binlog_format`).

Trying to switch the replication format in any of these cases (or attempting to set the current replication format) results in an error. You can, however, use `PERSIST_ONLY` (SET
@PERSIST_ONLY.binlog_format) to change the replication format at any time, because this action does not modify the runtime global system variable value, and takes effect only after a server restart.

Switching the replication format at runtime is not recommended when any temporary tables exist, because temporary tables are logged only when using statement-based replication, whereas with row-based replication and mixed replication, they are not logged.

Switching the replication format while replication is ongoing can also cause issues. Each MySQL Server can set its own and only its own binary logging format (true whether binlog_format is set with global or session scope). This means that changing the logging format on a replication source server does not cause a replica to change its logging format to match. When using STATEMENT mode, the binlog_format system variable is not replicated. When using MIXED or ROW logging mode, it is replicated but is ignored by the replica.

A replica is not able to convert binary log entries received in ROW logging format to STATEMENT format for use in its own binary log. The replica must therefore use ROW or MIXED format if the source does. Changing the binary logging format on the source from STATEMENT to ROW or MIXED while replication is ongoing to a replica with STATEMENT format can cause replication to fail with errors such as Error executing row event: 'Cannot execute statement: impossible to write to binary log since statement is in row format and BINLOG_FORMAT = STATEMENT.' Changing the binary logging format on the replica to STATEMENT format when the source is still using MIXED or ROW format also causes the same type of replication failure. To change the format safely, you must stop replication and ensure that the same change is made on both the source and the replica.

If you are using InnoDB tables and the transaction isolation level is READ COMMITTED or READ UNCOMMITTED, only row-based logging can be used. It is possible to change the logging format to STATEMENT, but doing so at runtime leads very rapidly to errors because InnoDB can no longer perform inserts.

With the binary log format set to ROW, many changes are written to the binary log using the row-based format. Some changes, however, still use the statement-based format. Examples include all DDL (data definition language) statements such as CREATE TABLE, ALTER TABLE, or DROP TABLE.

When row-based binary logging is used, the binlog_row_event_max_size system variable and its corresponding startup option --binlog-row-event-max-size set a soft limit on the maximum size of row events. The default value is 8192 bytes, and the value can only be changed at server startup. Where possible, rows stored in the binary log are grouped into events with a size not exceeding the value of this setting. If an event cannot be split, the maximum size can be exceeded.

The --binlog-row-event-max-size option is available for servers that are capable of row-based replication. Rows are stored into the binary log in chunks having a size in bytes not exceeding the value of this option. The value must be a multiple of 256. The default value is 8192.

**Warning**

When using statement-based logging for replication, it is possible for the data on the source and replica to become different if a statement is designed in such a way that the data modification is nondeterministic; that is, it is left up to the query optimizer. In general, this is not a good practice even outside of replication. For a detailed explanation of this issue, see Section B.3.7, “Known Issues in MySQL”.

### 5.4.4.3 Mixed Binary Logging Format

When running in MIXED logging format, the server automatically switches from statement-based to row-based logging under the following conditions:

- When a function contains UUID().
The Binary Log

- When one or more tables with AUTO_INCREMENT columns are updated and a trigger or stored function is invoked. Like all other unsafe statements, this generates a warning if `binlog_format = STATEMENT`.

  For more information, see Section 17.5.1.1, “Replication and AUTO_INCREMENT”.

- When the body of a view requires row-based replication, the statement creating the view also uses it. For example, this occurs when the statement creating a view uses the `UUID()` function.

- When a call to a UDF is involved.

- When `FOUND_ROWS()` or `ROW_COUNT()` is used. (Bug #12092, Bug #30244)

- When `USER()`, `CURRENT_USER()`, or `CURRENT_USER` is used. (Bug #28086)

- When one of the tables involved is a log table in the `mysql` database.

- When the `LOAD_FILE()` function is used. (Bug #39701)

- When a statement refers to one or more system variables. (Bug #31168)

**Exception.** The following system variables, when used with session scope (only), do not cause the logging format to switch:

- `auto_increment_increment`
- `auto_increment_offset`
- `character_set_client`
- `character_set_connection`
- `character_set_database`
- `character_set_server`
- `collation_connection`
- `collation_database`
- `collation_server`
- `foreign_key_checks`
- `identity`
- `last_insert_id`
- `lc_time_names`
- `pseudo_thread_id`
- `sql_auto_is_null`
- `time_zone`
- `timestamp`
- `unique_checks`
The Binary Log

For information about determining system variable scope, see Section 5.1.9, “Using System Variables”.

For information about how replication treats `sql_mode`, see Section 17.5.1.38, “Replication and Variables”.

In earlier releases, when mixed binary logging format was in use, if a statement was logged by row and the session that executed the statement had any temporary tables, all subsequent statements were treated as unsafe and logged in row-based format until all temporary tables in use by that session were dropped. As of MySQL 8.0, operations on temporary tables are not logged in mixed binary logging format, and the presence of temporary tables in the session has no impact on the logging mode used for each statement.

**Note**

A warning is generated if you try to execute a statement using statement-based logging that should be written using row-based logging. The warning is shown both in the client (in the output of `SHOW WARNINGS`) and through the `mysqld` error log. A warning is added to the `SHOW WARNINGS` table each time such a statement is executed. However, only the first statement that generated the warning for each client session is written to the error log to prevent flooding the log.

In addition to the decisions above, individual engines can also determine the logging format used when information in a table is updated. The logging capabilities of an individual engine can be defined as follows:

- If an engine supports row-based logging, the engine is said to be **row-logging capable**.
- If an engine supports statement-based logging, the engine is said to be **statement-logging capable**.

A given storage engine can support either or both logging formats. The following table lists the formats supported by each engine.

<table>
<thead>
<tr>
<th>Storage Engine</th>
<th>Row Logging Supported</th>
<th>Statement Logging Supported</th>

Whether a statement is to be logged and the logging mode to be used is determined according to the type of statement (safe, unsafe, or binary injected), the binary logging format (`STATEMENT`, `ROW`, or `MIXED`), and the logging capabilities of the storage engine (statement capable, row capable, both, or neither). (Binary injection refers to logging a change that must be logged using `ROW` format.)
Statements may be logged with or without a warning; failed statements are not logged, but generate errors in the log. This is shown in the following decision table. `Type`, `binlog_format`, `SLC`, and `RLC` columns outline the conditions, and `Error / Warning` and `Logged as` columns represent the corresponding actions. `SLC` stands for “statement-logging capable”, and `RLC` stands for “row-logging capable”.

</table>
When a warning is produced by the determination, a standard MySQL warning is produced (and is available using `SHOW WARNINGS`). The information is also written to the `mysqld` error log. Only one error for each error instance per client connection is logged to prevent flooding the log. The log message includes the SQL statement that was attempted.

If a replica has `log_error_verbosity` set to display warnings, the replica prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, statements that are unsafe for statement-based logging, and so forth.

### 5.4.4.4 Logging Format for Changes to mysql Database Tables

The contents of the grant tables in the `mysql` database can be modified directly (for example, with `INSERT` or `DELETE`) or indirectly (for example, with `GRANT` or `CREATE USER`). Statements that affect `mysql` database tables are written to the binary log using the following rules:

- Data manipulation statements that change data in `mysql` database tables directly are logged according to the setting of the `binlog_format` system variable. This pertains to statements such as `INSERT`, `UPDATE`, `DELETE`, `REPLACE`, `DO`, `LOAD DATA`, `SELECT`, and `TRUNCATE TABLE`.

- Statements that change the `mysql` database indirectly are logged as statements regardless of the value of `binlog_format`. This pertains to statements such as `GRANT`, `REVOKE`, `SET PASSWORD`, `RENAME USER`, `CREATE (all forms except CREATE TABLE ... SELECT)`, `ALTER (all forms)`, and `DROP (all forms)`.

`CREATE TABLE ... SELECT` is a combination of data definition and data manipulation. The `CREATE TABLE` part is logged using statement format and the `SELECT` part is logged according to the value of `binlog_format`.

### 5.4.4.5 Binary Log Transaction Compression

From MySQL 8.0.20, you can enable binary log transaction compression on a MySQL server instance. When binary log transaction compression is enabled, transaction payloads are compressed using the zstd algorithm, and then written to the server’s binary log file as a single event (a `Transaction_payload_event`). Compressed transaction payloads remain in a compressed state while they are sent in the replication stream to replicas, other Group Replication group members, or clients such as `mysqlbinlog`. They are not decompressed by receiver threads, and are written to the relay log still in their compressed state. Binary log transaction compression therefore saves storage space both on the originator of the transaction and on the recipient (and for their backups), and saves network bandwidth when the transactions are sent between server instances.

Compressed transaction payloads are decompressed when the individual events contained in them need to be inspected. For example, the `Transaction_payload_event` is decompressed by an applier thread in order to apply the events it contains on the recipient. Decompression is also carried out during recovery, by `mysqlbinlog` when replaying transactions, and by the `SHOW BINLOG EVENTS` and `SHOW RELAYLOG EVENTS` statements.

You can enable binary log transaction compression on a MySQL server instance using the `binlog_transaction_compression` system variable, which defaults to `OFF`. You can also use the
The Binary Log

\texttt{binlog_transaction_compression_level_zstd} system variable to set the level for the zstd algorithm that is used for compression. This value determines the compression effort, from 1 (the lowest effort) to 22 (the highest effort). As the compression level increases, the compression ratio increases, which reduces the storage space and network bandwidth required for the transaction payload. However, the effort required for data compression also increases, taking time and CPU and memory resources on the originating server. Increases in the compression effort do not have a linear relationship to increases in the compression ratio.

The following types of event are excluded from binary log transaction compression, so are always written uncompressed to the binary log:

- Events relating to the GTID for the transaction (including anonymous GTID events).
- Other types of control event, such as view change events and heartbeat events.
- Incident events and the whole of any transactions that contain them.
- Non-transactional events and the whole of any transactions that contain them. A transaction involving a mix of non-transactional and transactional storage engines does not have its payload compressed.
- Events that are logged using statement-based binary logging. Binary log transaction compression is only applied for the row-based binary logging format.

Binary log encryption can be used on binary log files that contain compressed transactions.

**Behaviors When Binary Log Transaction Compression is Enabled**

Transactions with payloads that are compressed can be rolled back like any other transaction, and they can also be filtered out on a replica by the usual filtering options. Binary log transaction compression can be applied to XA transactions.

When binary log transaction compression is enabled, the \texttt{max_allowed_packet} and \texttt{slave_max_allowed_packet} limits for the server still apply, and are measured on the compressed size of the \texttt{Transaction_payload_event}, plus the bytes used for the event header. Note that compressed transaction payloads are sent as a single packet, rather than each event of the transaction being sent in an individual packet, as is the case when binary log transaction compression is not in use.

For multithreaded workers, each transaction (including its GTID event and \texttt{Transaction_payload_event}) is assigned to a worker thread. The worker thread decompresses the transaction payload and applies the individual events in it one by one. If an error is found applying any event within the \texttt{Transaction_payload_event}, the complete transaction is reported to the co-ordinator as having failed. When \texttt{slave_parallel_type} is set to \texttt{DATABASE}, all the databases affected by the transaction are mapped before the transaction is scheduled. The use of binary log transaction compression with the \texttt{DATABASE} policy can reduce parallelism compared to uncompressed transactions, which are mapped and scheduled for each event.

For semisynchronous replication (see Section 17.4.10, “Semisynchronous Replication”), the replica acknowledges the transaction when the complete \texttt{Transaction_payload_event} has been received.

When binary log checksums are enabled (which is the default), the replication source server does not write checksums for individual events in a compressed transaction payload. Instead, a checksum is written for the complete \texttt{Transaction_payload_event}, and individual checksums are written for any events that were not compressed, such as events relating to GTIDs.

For the \texttt{SHOW BINLOG EVENTS} and \texttt{SHOW RELAYLOG EVENTS} statements, the \texttt{Transaction_payload_event} is first printed as a single unit, then it is unpacked and each event inside it is printed.
For operations that reference the end position of an event, such as `START REPLICA | SLAVE` with the `UNTIL` clause, `MASTER_POS_WAIT()`, and `sql_slave_skip_counter`, you must specify the end position of the compressed transaction payload (the `Transaction_payload_event`). When skipping events using `sql_slave_skip_counter`, a compressed transaction payload is counted as a single counter value, so all the events inside it are skipped as a unit.

**Combining Compressed and Uncompressed Transaction Payloads**

MySQL Server releases that support binary log transaction compression can handle a mix of compressed and uncompressed transaction payloads.

- The system variables relating to binary log transaction compression do not need to be set the same on all Group Replication group members, and are not replicated from sources to replicas in a replication topology. You can decide whether or not binary log transaction compression is appropriate for each MySQL Server instance that has a binary log.

- If transaction compression is enabled then disabled on a server, compression is not applied to future transactions originated on that server, but transaction payloads that have been compressed can still be handled and displayed.

- If transaction compression is specified for individual sessions by setting the session value of `binlog_transaction_compression`, the binary log can contain a mix of compressed and uncompressed transaction payloads.

When a source in a replication topology and its replica both have binary log transaction compression enabled, the replica receives compressed transaction payloads and writes them compressed to its relay log. It decompresses the transaction payloads to apply the transactions, and then compresses them again after applying for writing to its binary log. Any downstream replicas receive the compressed transaction payloads.

When a source in a replication topology has binary log transaction compression enabled but its replica does not, the replica receives compressed transaction payloads and writes them compressed to its relay log. It decompresses the transaction payloads to apply the transactions, and then writes them uncompressed to its own binary log, if it has one. Any downstream replicas receive the uncompressed transaction payloads.

When a source in a replication topology does not have binary log transaction compression enabled but its replica does, if the replica has a binary log, it compresses the transaction payloads after applying them, and writes the compressed transaction payloads to its binary log. Any downstream replicas receive the compressed transaction payloads.

When a MySQL server instance has no binary log, if it is at a release from MySQL 8.0.20, it can receive, handle, and display compressed transaction payloads regardless of its value for `binlog_transaction_compression`. Compressed transaction payloads received by such server instances are written in their compressed state to the relay log, so they benefit indirectly from compression that was carried out by other servers in the replication topology.

A replica at a release before MySQL 8.0.20 cannot replicate from a source with binary log transaction compression enabled. A replica at or above MySQL 8.0.20 can replicate from a source at an earlier release that does not support binary log transaction compression, and can carry out its own compression on transactions received from that source when writing them to its own binary log.

**Monitoring Binary Log Transaction Compression**

You can monitor the effects of binary log transaction compression using the Performance Schema table `binary_log_transaction_compression_stats`. The statistics include the data compression ratio for the monitored period, and you can also view the effect of compression on the last transaction on the
The slow query log consists of SQL statements that take more than \texttt{long_query_time} seconds to execute and require at least \texttt{min_examined_row_limit} rows to be examined. The slow query log can be used to find queries that take a long time to execute and are therefore candidates for optimization. However, examining a long slow query log can be a time-consuming task. To make this easier, you can use the \texttt{mysqldumpslow} command to process a slow query log file and summarize its contents. See Section 4.6.9, "mysqldumpslow — Summarize Slow Query Log Files".

The time to acquire the initial locks is not counted as execution time. \texttt{mysqld} writes a statement to the slow query log after it has been executed and after all locks have been released, so log order might differ from execution order.

- Slow Query Log Parameters
- Slow Query Log Contents

**Slow Query Log Parameters**

The minimum and default values of \texttt{long_query_time} are 0 and 10, respectively. The value can be specified to a resolution of microseconds.
By default, administrative statements are not logged, nor are queries that do not use indexes for lookups. This behavior can be changed using `log_slow_admin_statements` and `log_queries_not_using_indexes`, as described later.

By default, the slow query log is disabled. To specify the initial slow query log state explicitly, use `--slow_query_log={0|1}`. With no argument or an argument of 1, `--slow_query_log` enables the log. With an argument of 0, this option disables the log. To specify a log file name, use `--slow_query_log_file=file_name`. To specify the log destination, use the `log_output` system variable (as described in Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”).

Note

If you specify the `TABLE` log destination, see Log Tables and “Too many open files” Errors.

If you specify no name for the slow query log file, the default name is `host_name-slow.log`. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

To disable or enable the slow query log or change the log file name at runtime, use the global `slow_query_log` and `slow_query_log_file` system variables. Set `slow_query_log` to 0 to disable the log or to 1 to enable it. Set `slow_query_log_file` to specify the name of the log file. If a log file already is open, it is closed and the new file is opened.

The server writes less information to the slow query log if you use the `--log-short-format` option.

To include slow administrative statements in the slow query log, enable the `log_slow_admin_statements` system variable. Administrative statements include `ALTER TABLE`, `ANALYZE TABLE`, `CHECK TABLE`, `CREATE INDEX`, `DROP INDEX`, `OPTIMIZE TABLE`, and `REPAIR TABLE`.

To include queries that do not use indexes for row lookups in the statements written to the slow query log, enable the `log_queries_not_using_indexes` system variable. (Even with that variable enabled, the server does not log queries that would not benefit from the presence of an index due to the table having fewer than two rows.)

When queries that do not use an index are logged, the slow query log may grow quickly. It is possible to put a rate limit on these queries by setting the `log_throttle_queries_not_using_indexes` system variable. By default, this variable is 0, which means there is no limit. Positive values impose a per-minute limit on logging of queries that do not use indexes. The first such query opens a 60-second window within which the server logs queries up to the given limit, then suppresses additional queries. If there are suppressed queries when the window ends, the server logs a summary that indicates how many there were and the aggregate time spent in them. The next 60-second window begins when the server logs the next query that does not use indexes.

The server uses the controlling parameters in the following order to determine whether to write a query to the slow query log:

1. The query must either not be an administrative statement, or `log_slow_admin_statements` must be enabled.
2. The query must have taken at least `long_query_time` seconds, or `log_queries_not_using_indexes` must be enabled and the query used no indexes for row lookups.
3. The query must have examined at least `min_examined_row_limit` rows.
4. The query must not be suppressed according to the `log_throttle_queries_not_using_indexes` setting.

The `log_timestamps` system variable controls the time zone of timestamps in messages written to the slow query log file (as well as to the general query log file and the error log). It does not affect the time zone of general query log and slow query log messages written to log tables, but rows retrieved from those tables can be converted from the local system time zone to any desired time zone with `CONVERT_TZ()` or by setting the session `time_zone` system variable.

By default, a replica does not write replicated queries to the slow query log. To change this, enable the `log_slow_slave_statements` system variable. Note that if row-based replication is in use (`binlog_format=ROW`), `log_slow_slave_statements` has no effect. Queries are only added to the replica's slow query log when they are logged in statement format in the binary log, that is, when `binlog_format=STATEMENT` is set, or when `binlog_format=MIXED` is set and the statement is logged in statement format. Slow queries that are logged in row format when `binlog_format=MIXED` is set, or that are logged when `binlog_format=ROW` is set, are not added to the replica's slow query log, even if `log_slow_slave_statements` is enabled.

**Slow Query Log Contents**

When the slow query log is enabled, the server writes output to any destinations specified by the `log_output` system variable. If you enable the log, the server opens the log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected. If the destination is `NONE`, the server writes no queries even if the slow query log is enabled. Setting the log file name has no effect on logging if `FILE` is not selected as an output destination.

If the slow query log is enabled and `FILE` is selected as an output destination, each statement written to the log is preceded by a line that begins with a `#` character and has these fields (with all fields on a single line):

- **Query_time:** duration
  - The statement execution time in seconds.

- **Lock_time:** duration
  - The time to acquire locks in seconds.

- **Rows_sent:** N
  - The number of rows sent to the client.

- **Rows_examined:**
  - The number of rows examined by the server layer (not counting any processing internal to storage engines).

Enabling the `log_slow_extra` system variable (available as of MySQL 8.0.14) causes the server to write the following extra fields to `FILE` output in addition to those just listed (`TABLE` output is unaffected). Some field descriptions refer to status variable names. Consult the status variable descriptions for more information. However, in the slow query log, the counters are per-statement values, not cumulative session values.

- **Thread_id:** ID
  - The statement thread identifier.
• **Errno**: `error_number`
  The statement error number, or 0 if no error occurred.

• **Killed**: `N`
  If the statement was terminated, the error number indicating why, or 0 if the statement terminated normally.

• **Bytes_received**: `N`
  The `Bytes_received` value for the statement.

• **Bytes_sent**: `N`
  The `Bytes_sent` value for the statement.

• **Read_first**: `N`
  The `Handler_read_first` value for the statement.

• **Read_last**: `N`
  The `Handler_read_last` value for the statement.

• **Read_key**: `N`
  The `Handler_read_key` value for the statement.

• **Read_next**: `N`
  The `Handler_read_next` value for the statement.

• **Read_prev**: `N`
  The `Handler_read_prev` value for the statement.

• **Read_rnd**: `N`
  The `Handler_read_rnd` value for the statement.

• **Read_rnd_next**: `N`
  The `Handler_read_rnd_next` value for the statement.

• **Sort_merge_passes**: `N`
  The `Sort_merge_passes` value for the statement.

• **Sort_range_count**: `N`
  The `Sort_range` value for the statement.

• **Sort_rows**: `N`
  The `Sort_rows` value for the statement.

• **Sort_scan_count**: `N`
  The `Sort_scan` value for the statement.
• Created_tmp_disk_tables: N

The Created_tmp_disk_tables value for the statement.

• Created_tmp_tables: N

The Created_tmp_tables value for the statement.

• Start: timestamp

The statement execution start time.

• End: timestamp

The statement execution end time.

A given slow query log file may contain a mix of lines with and without the extra fields added by enabling log_slow_extra. Log file analyzers can determine whether a line contains the additional fields by the field count.

Each statement written to the slow query log file is preceded by a SET statement that includes a timestamp. As of MySQL 8.0.14, the timestamp indicates when the slow statement began executing. Prior to 8.0.14, the timestamp indicates when the slow statement was logged (which occurs after the statement finishes executing).

Passwords in statements written to the slow query log are rewritten by the server not to occur literally in plain text. See Section 6.1.2.3, “Passwords and Logging”.

5.4.6 Server Log Maintenance

As described in Section 5.4, “MySQL Server Logs”, MySQL Server can create several different log files to help you see what activity is taking place. However, you must clean up these files regularly to ensure that the logs do not take up too much disk space.

When using MySQL with logging enabled, you may want to back up and remove old log files from time to time and tell MySQL to start logging to new files. See Section 7.2, “Database Backup Methods”.

On a Linux (Red Hat) installation, you can use the mysql-log-rotate script for log maintenance. If you installed MySQL from an RPM distribution, this script should have been installed automatically. Be careful with this script if you are using the binary log for replication. You should not remove binary logs until you are certain that their contents have been processed by all replicas.

On other systems, you must install a short script yourself that you start from cron (or its equivalent) for handling log files.

Binary log files are automatically removed after the server’s binary log expiration period. Removal of the files can take place at startup and when the binary log is flushed. The default binary log expiration period is 30 days. To specify an alternative expiration period, use the binlog_expire_logs_seconds system variable. If you are using replication, you should specify an expiration period that is no lower than the maximum amount of time your replicas might lag behind the source. To remove binary logs on demand, use the PURGE BINARY LOGS statement (see Section 13.4.1.1, “PURGE BINARY LOGS Statement”).

To force MySQL to start using new log files, flush the logs. Log flushing occurs when you execute a FLUSH LOGS statement or a mysqladmin flush-logs, mysqladmin refresh, mysqldump --flush-logs, or mysqldump --master-data command. See Section 13.7.8.3, “FLUSH Statement”, Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”, and Section 4.5.4, “mysqldump — A
Server Log Maintenance

Database Backup Program. In addition, the server flushes the binary log automatically when current binary log file size reaches the value of the `max_binlog_size` system variable.

`FLUSH LOGS` supports optional modifiers to enable selective flushing of individual logs (for example, `FLUSH BINARY LOGS`). See Section 13.7.8.3, "FLUSH Statement".

A log-flushing operation has the following effects:

- If binary logging is enabled, the server closes the current binary log file and opens a new log file with the next sequence number.
- If general query logging or slow query logging to a log file is enabled, the server closes and reopens the log file.
- If the server was started with the `--log-error` option to cause the error log to be written to a file, the server closes and reopens the log file.

Execution of log-flushing statements or commands requires connecting to the server using an account that has the `RELOAD` privilege. On Unix and Unix-like systems, another way to flush the logs is to send a signal to the server, which can be done by `root` or the account that owns the server process. (See Section 4.10, "Unix Signal Handling in MySQL"). Signals enable log flushing to be performed without having to connect to the server:

- A `SIGHUP` signal flushes all the logs. However, `SIGHUP` has additional effects other than log flushing that might be undesirable.
- As of MySQL 8.0.19, `SIGUSR1` causes the server to flush the error log, general query log, and slow query log. If you are interested in flushing only those logs, `SIGUSR1` can be used as a more “lightweight” signal that does not have the `SIGHUP` effects that are unrelated to logs.

As mentioned previously, flushing the binary log creates a new binary log file, whereas flushing the general query log, slow query log, or error log just closes and reopens the log file. For the latter logs, to cause a new log file to be created on Unix, rename the current log file first before flushing it. At flush time, the server opens the new log file with the original name. For example, if the general query log, slow query log, and error log files are named `mysql.log`, `mysql-slow.log`, and `err.log`, you can use a series of commands like this from the command line:

```
cd mysql-data-directory
mv mysql.log mysql.log.old
mv mysql-slow.log mysql-slow.log.old
mv err.log err.log.old
mysqladmin flush-logs
```

On Windows, use `rename` rather than `mv`.

At this point, you can make a backup of `mysql.log.old`, `mysql-slow.log.old`, and `err.log.old`, then remove them from disk.

To rename the general query log or slow query log at runtime, first connect to the server and disable the log:

```
SET GLOBAL general_log = 'OFF';
SET GLOBAL slow_query_log = 'OFF';
```

With the logs disabled, rename the log files externally (for example, from the command line). Then enable the logs again:

```
SET GLOBAL general_log = 'ON';
```
This method works on any platform and does not require a server restart.

**Note**

For the server to recreate a given log file after you have renamed the file externally, the file location must be writable by the server. This may not always be the case. For example, on Linux, the server might write the error log as `/var/log/mysqld.log`, where `/var/log` is owned by `root` and not writable by `mysqld`. In this case, log-flushing operations fail to create a new log file.

To handle this situation, you must manually create the new log file with the proper ownership after renaming the original log file. For example, execute these commands as `root`:

```
mv /var/log/mysqld.log /var/log/mysqld.log.old
install -omysql -gmysql -m0644 /dev/null /var/log/mysqld.log
```

### 5.5 MySQL Server Components

MySQL Server includes a component-based infrastructure for extending server capabilities. A component provides services that are available to the server and other components. (With respect to service use, the server is a component, equal to other components.) Components interact with each other only through the services they provide.

MySQL distributions include several components that implement server extensions:

- Components for configuring error logging. See Section 5.4.2, “The Error Log”, and Section 5.5.3, “Error Log Components”.

- A component for checking passwords. See Section 6.4.3, “The Password Validation Component”.

- A component that enables applications to add their own message events to the audit log. See Section 6.4.6, “The Audit Message Component”.

System and status variables implemented by a server component are exposed when the component is installed and have names that begin with a component-specific prefix. For example, the `log_filter_dragnet` error log filter component implements a system variable named `log_error_filter_rules`, the full name of which is `dragnet.log_error_filter_rules`. To refer to this variable, use the full name.

The following sections describe how to install and uninstall components, and how to determine at runtime which components are installed and obtain information about them.

For information about the internal implementation of components, see the MySQL Server Doxygen documentation, available at [https://dev.mysql.com/doc/index-other.html](https://dev.mysql.com/doc/index-other.html). For example, if you intend to write your own components, this information is important for understanding how components work.

#### 5.5.1 Installing and Uninstalling Components

Server components must be loaded into the server before they can be used. MySQL supports manual component loading at runtime and automatic loading during server startup.

While a component is loaded, information about it is available as described in Section 5.5.2, “Obtaining Server Component Information”.
Obtaining Server Component Information

The **INSTALL COMPONENT** and **UNINSTALL COMPONENT** SQL statements enable component loading and unloading. For example:

```sql
INSTALL COMPONENT 'file://component_validate_password';
UNINSTALL COMPONENT 'file://component_validate_password';
```

A loader service handles component loading and unloading, and also registers loaded components in the **mysql.component** system table.

The SQL statements for component manipulation affect server operation and the **mysql.component** system table as follows:

- **INSTALL COMPONENT** loads components into the server. The components become active immediately. The loader service also registers loaded components in the **mysql.component** system table. For subsequent server restarts, the loader service loads any components listed in **mysql.component** during the startup sequence. This occurs even if the server is started with the **--skip-grant-tables** option.

- **UNINSTALL COMPONENT** deactivates components and unloads them from the server. The loader service also unregisters the components from the **mysql.component** system table so that the server no longer loads them during its startup sequence for subsequent restarts.

Compared to the corresponding **INSTALL PLUGIN** statement for server plugins, the **INSTALL COMPONENT** statement for components offers the significant advantage that it is not necessary to know any platform-specific file name suffix for naming the component. This means that a given **INSTALL COMPONENT** statement can be executed uniformly across platforms.

A component when installed may also automatically install related user-defined functions (UDFs). If so, the component when uninstalled also automatically uninstalls those UDFs.

### 5.5.2 Obtaining Server Component Information

The **mysql.component** system table contains information about currently loaded components and shows which components have been registered using **INSTALL COMPONENT**. To see which components are installed, use this statement:

```sql
SELECT * FROM mysql.component;
```

### 5.5.3 Error Log Components

This section describes the characteristics of individual error log components. For general information about configuring error logging, see Section 5.4.2, “The Error Log”.

A log component can be a filter or a sink:

- A filter processes log events, to add, remove, or modify event fields, or to delete events entirely. The resulting events pass to the next log component in the list of enabled components.

- A sink is a destination (writer) for log events. Typically, a sink processes log events into log messages that have a particular format and writes these messages to its associated output, such as a file or the system log. A sink may also write to the Performance Schema **error_log** table; see Section 26.12.19.1, “The error_log Table”. Events pass unmodified to the next log component in the list of enabled components (that is, although a sink formats events to produce output messages, it does not modify events as they pass internally to the next component).

The **log_error_services** system variable value lists the enabled log components. Components not named in the list are disabled.
The following sections describe individual log components, grouped by component type:

- **Filter Error Log Components**
- **Sink Error Log Components**

Component descriptions include these types of information:

- The component name and intended purpose.
- Whether the component is built in or must be loaded. For a loadable component, the description specifies the URN to use to load and unload the component with the `INSTALL COMPONENT` and `UNINSTALL COMPONENT` statements.
- Whether the component can be listed multiple times in the `log_error_services` value.
- For a sink component, the destination to which the component writes output.
- For a sink component, whether it supports an interface to the Performance Schema `error_log` table.

### Filter Error Log Components

Error log filter components implement filtering of error log events. If no filter component is enabled, no filtering occurs.

Any enabled filter component affects log events only for components listed later in the `log_error_services` value. In particular, for any log sink component listed in `log_error_services` earlier than any filter component, no log event filtering occurs.

#### The `log_filter_internal` Component

- **Purpose:** Implements filtering based on log event priority and error code, in combination with the `log_error_verbosity` and `log_error_suppression_list` system variables. See Section 5.4.2.5, “Priority-Based Error Log Filtering (log_filter_internal)”.
- **URN:** This component is built in and need not be loaded with `INSTALL COMPONENT` before use.
- **Multiple uses permitted:** No.

If `log_filter_internal` is disabled, `log_error_verbosity` and `log_error_suppression_list` have no effect.

#### The `log_filter_dragnet` Component

- **Purpose:** Implements filtering based on the rules defined by the `dragnet.log_error_filter_rules` system variable setting. See Section 5.4.2.6, “Rule-Based Error Log Filtering (log_filter_dragnet)”.
- **URN:** `file://component_log_filter_dragnet`
- **Multiple uses permitted:** No.

### Sink Error Log Components

Error log sink components are writers that implement error log output. If no sink component is enabled, no log output occurs.

Some sink component descriptions refer to the default error log destination. This is the console or a file and is indicated by the value of the `log_error` system variable, determined as described in Section 5.4.2.2, “Default Error Log Destination Configuration”. 
The `log_sink_internal` Component

- **Purpose:** Implements traditional error log message output format.
- **URN:** This component is built in and need not be loaded with `INSTALL COMPONENT` before use.
- **Multiple uses permitted:** No.
- **Output destination:** Writes to the default error log destination.
- **Performance Schema support:** Writes to the `error_log` table. Provides a parser for reading error log files created by previous server instances.

The `log_sink_json` Component

- **Purpose:** Implements JSON-format error logging. See Section 5.4.2.7, “Error Logging in JSON Format”.
- **URN:** `file://component_log_sink_json`
- **Multiple uses permitted:** Yes.
- **Output destination:** This sink determines its output destination based on the default error log destination, which is given by the `log_error` system variable:
  - If `log_error` names a file, the sink bases output file naming on that file name, plus a numbered `.NN.json` suffix, with `NN` starting at 00. For example, if `log_error` is `file_name`, successive instances of `log_sink_json` named in the `log_error_services` value write to `file_name.00.json`, `file_name.01.json`, and so forth.
  - If `log_error` is `stderr`, the sink writes to the console. If `log_sink_json` is named multiple times in the `log_error_services` value, they all write to the console, which is likely not useful.
- **Performance Schema support:** Writes to the `error_log` table. Provides a parser for reading error log files created by previous server instances.

The `log_sink_syseventlog` Component

- **Purpose:** Implements error logging to the system log. This is the Event Log on Windows, and `syslog` on Unix and Unix-like systems. See Section 5.4.2.8, “Error Logging to the System Log”.
- **URN:** `file://component_log_sink_syseventlog`
- **Multiple uses permitted:** No.
- **Output destination:** Writes to the system log. Does not use the default error log destination.
- **Performance Schema support:** Does not write to the `error_log` table. Does not provide a parser for reading error log files created by previous server instances.

The `log_sink_test` Component

- **Purpose:** Intended for internal use in writing test cases, not for production use.
- **URN:** `file://component_log_sink_test`

Sink properties such as whether multiple uses are permitted and the output destination are not specified for `log_sink_test` because, as mentioned, it is for internal use. As such, its behavior is subject to change at any time.
5.6 MySQL Server Plugins

MySQL supports an plugin API that enables creation of server plugins. Plugins can be loaded at server startup, or loaded and unloaded at runtime without restarting the server. The plugins supported by this interface include, but are not limited to, storage engines, INFORMATION_SCHEMA tables, full-text parser plugins, and server extensions.

MySQL distributions include several plugins that implement server extensions:

- Plugins for authenticating attempts by clients to connect to MySQL Server. Plugins are available for several authentication protocols. See Section 6.2.17, “Pluggable Authentication”.

- A connection-control plugin that enables administrators to introduce an increasing delay after a certain number of consecutive failed client connection attempts. See Section 6.4.2, “The Connection-Control Plugins”.

- A password-validation plugin implements password strength policies and assesses the strength of potential passwords. See Section 6.4.3, “The Password Validation Component”.

- Semisynchronous replication plugins implement an interface to replication capabilities that permit the source to proceed as long as at least one replica has responded to each transaction. See Section 17.4.10, “Semisynchronous Replication”.

- Group Replication enables you to create a highly available distributed MySQL service across a group of MySQL server instances, with data consistency, conflict detection and resolution, and group membership services all built-in. See Chapter 18, Group Replication.

- MySQL Enterprise Edition includes a thread pool plugin that manages connection threads to increase server performance by efficiently managing statement execution threads for large numbers of client connections. See Section 5.6.3, “MySQL Enterprise Thread Pool”.

- MySQL Enterprise Edition includes an audit plugin for monitoring and logging of connection and query activity. See Section 6.4.5, “MySQL Enterprise Audit”.

- MySQL Enterprise Edition includes a firewall plugin that implements an application-level firewall to enable database administrators to permit or deny SQL statement execution based on matching against allowlists of accepted statement patterns. See Section 6.4.7, “MySQL Enterprise Firewall”.

- Query rewrite plugins examine statements received by MySQL Server and possibly rewrite them before the server executes them. See Section 5.6.4, “The Rewriter Query Rewrite Plugin”, and Section 5.6.5, “The ddl_rewriter Plugin”.

- Version Tokens enables creation of and synchronization around server tokens that applications can use to prevent accessing incorrect or out-of-date data. Version Tokens is based on a plugin library that implements a version_tokens plugin and a set of user-defined functions. See Section 5.6.6, “Version Tokens”.

- Keyring plugins provide secure storage for sensitive information. See Section 6.4.4, “The MySQL Keyring”.

- X Plugin extends MySQL Server to be able to function as a document store. Running X Plugin enables MySQL Server to communicate with clients using the X Protocol, which is designed to expose the ACID compliant storage abilities of MySQL as a document store. See Section 20.5, “X Plugin”.

- Clone permits cloning InnoDB data from a local or remote MySQL server instance. See Section 5.6.7, “The Clone Plugin”.

1029
Installing and Uninstalling Plugins

Test framework plugins test server services. For information about these plugins, see the Plugins for Testing Plugin Services section of the MySQL Server Doxygen documentation, available at https://dev.mysql.com/doc/index-other.html.

The following sections describe how to install and uninstall plugins, and how to determine at runtime which plugins are installed and obtain information about them. For information about writing plugins, see The MySQL Plugin API.

5.6.1 Installing and Uninstalling Plugins

Server plugins must be loaded into the server before they can be used. MySQL supports plugin loading at server startup and runtime. It is also possible to control the activation state of loaded plugins at startup, and to unload them at runtime.

While a plugin is loaded, information about it is available as described in Section 5.6.2, “Obtaining Server Plugin Information”.

- Installing Plugins
- Controlling Plugin Activation State
- Uninstalling Plugins
- Plugins and User-Defined Functions

Installing Plugins

Before a server plugin can be used, it must be installed using one of the following methods. In the descriptions, plugin_name stands for a plugin name such as innodb, csv, or validate_password.

- Built-in Plugins
- Plugins Registered in the mysql.plugin System Table
- Plugins Named with Command-Line Options
- Plugins Installed with the INSTALL PLUGIN Statement

Built-in Plugins

A built-in plugin is known by the server automatically. By default, the server enables the plugin at startup. Some built-in plugins permit this to be changed with the --plugin_name[=activation_state] option.

Plugins Registered in the mysql.plugin System Table

The mysql.plugin system table serves as a registry of plugins (other than built-in plugins, which need not be registered). During the normal startup sequence, the server loads plugins registered in the table. By default, for a plugin loaded from the mysql.plugin table, the server also enables the plugin. This can be changed with the --plugin_name[=activation_state] option.

If the server is started with the --skip-grant-tables option, plugins registered in the mysql.plugin table are not loaded and are unavailable.

Plugins Named with Command-Line Options

A plugin located in a plugin library file can be loaded at server startup with the --plugin-load, --plugin-load-add, or --early-plugin-load option. Normally, for a plugin loaded at startup, the
server also enables the plugin. This can be changed with the `--plugin_name[=activation_state]` option.

The `--plugin-load` and `--plugin-load-add` options load plugins after built-in plugins and storage engines have initialized during the server startup sequence. The `--early-plugin-load` option is used to load plugins that must be available prior to initialization of built-in plugins and storage engines.

The value of each plugin-loading option is a semicolon-separated list of `name=plugin_library` and `plugin_library` values. Each `name` is the name of a plugin to load, and `plugin_library` is the name of the library file that contains the plugin code. If a plugin library is named without any preceding plugin name, the server loads all plugins in the library. The server looks for plugin library files in the directory named by the `plugin_dir` system variable.

Plugin-loading options do not register any plugin in the `mysql.plugin` table. For subsequent restarts, the server loads the plugin again only if `--plugin-load`, `--plugin-load-add`, or `--early-plugin-load` is given again. That is, the option produces a one-time plugin-installation operation that persists for a single server invocation.

`--plugin-load`, `--plugin-load-add`, and `--early-plugin-load` enable plugins to be loaded even when `--skip-grant-tables` is given (which causes the server to ignore the `mysql.plugin` table). `--plugin-load`, `--plugin-load-add`, and `--early-plugin-load` also enable plugins to be loaded at startup that cannot be loaded at runtime.

The `--plugin-load-add` option complements the `--plugin-load` option:

- Each instance of `--plugin-load` resets the set of plugins to load at startup, whereas `--plugin-load-add` adds a plugin or plugins to the set of plugins to be loaded without resetting the current set. Consequently, if multiple instances of `--plugin-load` are specified, only the last one takes effect. With multiple instances of `--plugin-load-add`, all of them take effect.
- The argument format is the same as for `--plugin-load`, but multiple instances of `--plugin-load-add` can be used to avoid specifying a large set of plugins as a single long unwieldy `--plugin-load` argument.
- `--plugin-load-add` can be given in the absence of `--plugin-load`, but any instance of `--plugin-load-add` that appears before `--plugin-load` has no effect because `--plugin-load` resets the set of plugins to load.

For example, these options:

```
--plugin-load=x --plugin-load-add=y
```

are equivalent to these options:

```
--plugin-load-add=x --plugin-load-add=y
```

and are also equivalent to this option:

```
--plugin-load="x;y"
```

But these options:

```
--plugin-load-add=y --plugin-load=x
```

are equivalent to this option:

```
--plugin-load=x
```
Installing and Uninstalling Plugins

Plugins Installed with the INSTALL PLUGIN Statement

A plugin located in a plugin library file can be loaded at runtime with the INSTALL PLUGIN statement. The statement also registers the plugin in the mysql.plugin table to cause the server to load it on subsequent restarts. For this reason, INSTALL PLUGIN requires the INSERT privilege for the mysql.plugin table.

The plugin library file base name depends on your platform. Common suffixes are .so for Unix and Unix-like systems, .dll for Windows.

Example: The --plugin-load-add option installs a plugin at server startup. To install a plugin named myplugin from a plugin library file named somepluglib.so, use these lines in a my.cnf file:

```
[mysqld]
plugin-load-add=myplugin=somepluglib.so
```

In this case, the plugin is not registered in mysql.plugin. Restarting the server without the --plugin-load-add option causes the plugin not to be loaded at startup.

Alternatively, the INSTALL PLUGIN statement causes the server to load the plugin code from the library file at runtime:

```
INSTALL PLUGIN myplugin SONAME 'somepluglib.so';
```

INSTALL PLUGIN also causes "permanent" plugin registration: The plugin is listed in the mysql.plugin table to ensure that the server loads it on subsequent restarts.

Many plugins can be loaded either at server startup or at runtime. However, if a plugin is designed such that it must be loaded and initialized during server startup, attempts to load it at runtime using INSTALL PLUGIN produce an error:

```
mysql> INSTALL PLUGIN myplugin SONAME 'somepluglib.so';
ERROR 1721 (HY000): Plugin 'myplugin' is marked as not dynamically installable. You have to stop the server to install it.
```

In this case, you must use --plugin-load, --plugin-load-add, or --early-plugin-load.

If a plugin is named both using a --plugin-load, --plugin-load-add, or --early-plugin-load option and (as a result of an earlier INSTALL PLUGIN statement) in the mysql.plugin table, the server starts but writes these messages to the error log:

```
[ERROR] Function 'plugin_name' already exists
[Warning] Couldn't load plugin named 'plugin_name'
with soname 'plugin_object_file'.
```

Controlling Plugin Activation State

If the server knows about a plugin when it starts (for example, because the plugin is named using a --plugin-load-add option or is registered in the mysql.plugin table), the server loads and enables the plugin by default. It is possible to control activation state for such a plugin using a --plugin-name=[activation_state] startup option, where plugin_name is the name of the plugin to affect, such as innodb, csv, or validate_password. As with other options, dashes and underscores are interchangeable in option names. Also, activation state values are not case-sensitive. For example, --my_plugin=ON and --my-plugin=on are equivalent.

- --plugin_name=OFF
Installing and Uninstalling Plugins

Tells the server to disable the plugin. This may not be possible for certain built-in plugins, such as `mysql_native_password`.

- `--plugin_name[=ON]`
  Tells the server to enable the plugin. (Specifying the option as `--plugin_name` without a value has the same effect.) If the plugin fails to initialize, the server runs with the plugin disabled.

- `--plugin_name=FORCE`
  Tells the server to enable the plugin, but if plugin initialization fails, the server does not start. In other words, this option forces the server to run with the plugin enabled or not at all.

- `--plugin_name=FORCE_PLUS_PERMANENT`
  Like `FORCE`, but in addition prevents the plugin from being unloaded at runtime. If a user attempts to do so with `UNINSTALL PLUGIN`, an error occurs.

Plugin activation states are visible in the `LOAD_OPTION` column of the `INFORMATION_SCHEMA.PLUGINS` table.

Suppose that `CSV`, `BLACKHOLE`, and `ARCHIVE` are built-in pluggable storage engines and that you want the server to load them at startup, subject to these conditions: The server is permitted to run if `CSV` initialization fails, must require that `BLACKHOLE` initialization succeeds, and should disable `ARCHIVE`. To accomplish that, use these lines in an option file:

```sql
[mysqld]
csv=ON
blackhole=FORCE
archive=OFF
```

The `--enable-plugin_name` option format is a synonym for `--plugin_name=ON`. The `--disable-plugin_name` and `--skip-plugin_name` option formats are synonyms for `--plugin_name=OFF`.

If a plugin is disabled, either explicitly with `OFF` or implicitly because it was enabled with `ON` but fails to initialize, aspects of server operation requiring the plugin change. For example, if the plugin implements a storage engine, existing tables for the storage engine become inaccessible, and attempts to create new tables for the storage engine result in tables that use the default storage engine unless the `NO_ENGINE_SUBSTITUTION` SQL mode is enabled to cause an error to occur instead.

Disabling a plugin may require adjustment to other options. For example, if you start the server using `--skip-innodb` to disable InnoDB, other `innodb_xxx` options likely also need to be omitted at startup. In addition, because InnoDB is the default storage engine, it cannot start unless you specify another available storage engine with `--default_storage_engine`. You must also set `--default_tmp_storage_engine`.

Uninstalling Plugins

At runtime, the `UNINSTALL PLUGIN` statement disables and uninstalls a plugin known to the server. The statement unloads the plugin and removes it from the `mysql.plugin` system table, if it is registered there. For this reason, `UNINSTALL PLUGIN` statement requires the `DELETE` privilege for the `mysql.plugin` table. With the plugin no longer registered in the table, the server does not load the plugin during subsequent restarts.

`UNINSTALL PLUGIN` can unload a plugin regardless of whether it was loaded at runtime with `INSTALL PLUGIN` or at startup with a plugin-loading option, subject to these conditions:
Obtaining Server Plugin Information

- It cannot unload plugins that are built in to the server. These can be identified as those that have a library name of `NULL` in the output from `INFORMATION_SCHEMA.PLUGINS` or `SHOW PLUGINS`.

- It cannot unload plugins for which the server was started with `--plugin_name=FORCE_PLUS_PERMANENT`, which prevents plugin unloading at runtime. These can be identified from the `LOAD_OPTION` column of the `INFORMATION_SCHEMA.PLUGINS` table.

To uninstall a plugin that currently is loaded at server startup with a plugin-loading option, use this procedure.

1. Remove from the `my.cnf` file any options and system variables related to the plugin. If any plugin system variables were persisted to the `mysqld-auto.cnf` file, remove them using `RESET PERSIST var_name` for each one to remove it.

2. Restart the server.

3. Plugins normally are installed using either a plugin-loading option at startup or with `INSTALL PLUGIN` at runtime, but not both. However, removing options for a plugin from the `my.cnf` file may not be sufficient to uninstall it if at some point `INSTALL PLUGIN` has also been used. If the plugin still appears in the output from `INFORMATION_SCHEMA.PLUGINS` or `SHOW PLUGINS`, use `UNINSTALL PLUGIN` to remove it from the `mysql.plugin` table. Then restart the server again.

Plugins and User-Defined Functions

A plugin when installed may also automatically install related user-defined functions (UDFs). If so, the plugin when uninstalled also automatically uninstalls those UDFs.

5.6.2 Obtaining Server Plugin Information

There are several ways to determine which plugins are installed in the server:

- The `INFORMATION_SCHEMA.PLUGINS` table contains a row for each loaded plugin. Any that have a `PLUGIN_LIBRARY` value of `NULL` are built in and cannot be unloaded.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.PLUGINS
************** 1. row ********************
<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>binlog</th>
</tr>
</thead>
<tbody>
<tr>
<td>PLUGIN_VERSION</td>
<td>1.0</td>
</tr>
<tr>
<td>PLUGIN_STATUS</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>PLUGIN_TYPE</td>
<td>STORAGE ENGINE</td>
</tr>
<tr>
<td>PLUGIN_TYPE_VERSION</td>
<td>50158.0</td>
</tr>
<tr>
<td>PLUGIN_LIBRARY</td>
<td>NULL</td>
</tr>
<tr>
<td>PLUGIN_LIBRARY_VERSION</td>
<td>NULL</td>
</tr>
<tr>
<td>PLUGIN_AUTHOR</td>
<td>Oracle Corporation</td>
</tr>
<tr>
<td>PLUGIN_DESCRIPTION</td>
<td>This is a pseudo storage engine to represent the binlog in a transaction</td>
</tr>
<tr>
<td>PLUGIN_LICENSE</td>
<td>GPL</td>
</tr>
<tr>
<td>LOAD_OPTION</td>
<td>FORCE</td>
</tr>
</tbody>
</table>

************** 10. row ********************
| PLUGIN_NAME | InnoDB |
| PLUGIN_VERSION | 1.0 |
| PLUGIN_STATUS | ACTIVE |
| PLUGIN_TYPE | STORAGE ENGINE |
| PLUGIN_TYPE_VERSION | 50158.0 |
| PLUGIN_LIBRARY | ha_innodb_plugin.so |
| PLUGIN_LIBRARY_VERSION | 1.0 |
| PLUGIN_AUTHOR | Oracle Corporation |
| PLUGIN_DESCRIPTION | Supports transactions, row-level locking, and foreign keys |
| PLUGIN_LICENSE | GPL |
| LOAD_OPTION | ON |
```
• The `SHOW PLUGINS` statement displays a row for each loaded plugin. Any that have a `Library` value of `NULL` are built in and cannot be unloaded.

```sql
mysql> SHOW PLUGINS\G
*************************** 1. row ***************************
Name: binlog
Status: ACTIVE
Type: STORAGE ENGINE
Library: NULL
License: GPL
...
*************************** 10. row ***************************
Name: InnoDB
Status: ACTIVE
Type: STORAGE ENGINE
Library: ha_innodb_plugin.so
License: GPL
...
```

• The `mysql.plugin` table shows which plugins have been registered with `INSTALL PLUGIN`. The table contains only plugin names and library file names, so it does not provide as much information as the `PLUGINS` table or the `SHOW PLUGINS` statement.

### 5.6.3 MySQL Enterprise Thread Pool

**Note**

MySQL Enterprise Thread Pool is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, [https://www.mysql.com/products/](https://www.mysql.com/products/).

MySQL Enterprise Edition includes MySQL Enterprise Thread Pool, implemented using a server plugin. The default thread-handling model in MySQL Server executes statements using one thread per client connection. As more clients connect to the server and execute statements, overall performance degrades. The thread pool plugin provides an alternative thread-handling model designed to reduce overhead and improve performance. The plugin implements a thread pool that increases server performance by efficiently managing statement execution threads for large numbers of client connections.

The thread pool addresses several problems of the model that uses one thread per connection:

• Too many thread stacks make CPU caches almost useless in highly parallel execution workloads. The thread pool promotes thread stack reuse to minimize the CPU cache footprint.

• With too many threads executing in parallel, context switching overhead is high. This also presents a challenge to the operating system scheduler. The thread pool controls the number of active threads to keep the parallelism within the MySQL server at a level that it can handle and that is appropriate for the server host on which MySQL is executing.

• Too many transactions executing in parallel increases resource contention. In InnoDB, this increases the time spent holding central mutexes. The thread pool controls when transactions start to ensure that not too many execute in parallel.

Section A.15, “MySQL 8.0 FAQ: MySQL Enterprise Thread Pool”

### 5.6.3.1 Thread Pool Elements
MySQL Enterprise Thread Pool comprises these elements:

- A plugin library file implements a plugin for the thread pool code as well as several associated monitoring tables that provide information about thread pool operation:
  - As of MySQL 8.0.14, the monitoring tables are Performance Schema tables; see Section 26.12.16, “Performance Schema Thread Pool Tables”.
  - Prior to MySQL 8.0.14, the monitoring tables are INFORMATION_SCHEMA tables; see Section 25.52, “INFORMATION_SCHEMA Thread Pool Tables”.

The INFORMATION_SCHEMA tables now are deprecated; expect them to be removed in a future version of MySQL. Applications should transition away from the old tables to the new tables. For example, if an application uses this query:

```sql
SELECT * FROM INFORMATION_SCHEMA.TP_THREAD_STATE;
```

The application should use this query instead:

```sql
SELECT * FROM performance_schema.tp_thread_state;
```

**Note**

If you do not load all the monitoring tables, some or all MySQL Enterprise Monitor thread pool graphs may be empty.

For a detailed description of how the thread pool works, see Section 5.6.3.3, “Thread Pool Operation”.

- Several system variables are related to the thread pool. The `thread_handling` system variable has a value of `loaded-dynamically` when the server successfully loads the thread pool plugin.

The other related variables are implemented by the thread pool plugin and are not available unless it is enabled:

- `thread_pool_algorithm`: The concurrency algorithm to use for scheduling.
- `thread_pool_high_priority_connection`: How to schedule statement execution for a session.
- `thread_pool_max_active_query_threads`: How many active threads per group to permit.
- `thread_pool_max_unused_threads`: How many sleeping threads to permit.
- `thread_pool_prio_kickup_timer`: How long before the thread pool moves a statement awaiting execution from the low-priority queue to the high-priority queue.
- `thread_pool_size`: The number of thread groups in the thread pool. This is the most important parameter controlling thread pool performance.
- `thread_pool_stall_limit`: The time before an executing statement is considered to be stalled.

If any variable implemented by the plugin is set to an illegal value at startup, plugin initialization fails and the plugin does not load.

For information about setting thread pool parameters, see Section 5.6.3.4, “Thread Pool Tuning”.

- The Performance Schema has instruments that expose information about the thread pool and may be used to investigate operational performance. To identify them, use this query:

```sql
SELECT * FROM performance_schema.setup_instruments
```
5.6.3.2 Thread Pool Installation

This section describes how to install MySQL Enterprise Thread Pool. For general information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `thread_pool`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

- Thread Pool Installation as of MySQL 8.0.14
- Thread Pool Installation Prior to MySQL 8.0.14

### Thread Pool Installation as of MySQL 8.0.14

In MySQL 8.0.14 and higher, the thread pool monitoring tables are Performance Schema tables that are loaded and unloaded along with the thread pool plugin. The `INFORMATION_SCHEMA` versions of the tables are deprecated but still available; they are installed per the instructions in Thread Pool Installation Prior to MySQL 8.0.14.

To enable thread pool capability, load the plugin by starting the server with the `--plugin-load-add` option. To do this, put these lines in the server `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```
[mysqld]
plugin-load-add=thread_pool.so
```

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
      FROM INFORMATION_SCHEMA.PLUGINS
      WHERE PLUGIN_NAME LIKE 'thread%';
```

<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>PLUGIN_STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>thread_pool</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>

To verify that the Performance Schema monitoring tables are available, examine the `INFORMATION_SCHEMA.TABLES` table or use the `SHOW TABLES` statement. For example:

```
mysql> SELECT TABLE_NAME
      FROM INFORMATION_SCHEMA.TABLES
      WHERE TABLE_SCHEMA = 'performance_schema'
      AND TABLE_NAME LIKE 'tp%';
```

<table>
<thead>
<tr>
<th>TABLE_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>tp_thread_group_state</td>
</tr>
<tr>
<td>tp_thread_group_stats</td>
</tr>
<tr>
<td>tp_thread_state</td>
</tr>
</tbody>
</table>
If the server loads the thread pool plugin successfully, it sets the `thread_handling` system variable to `loaded-dynamically`.

If the plugin fails to initialize, check the server error log for diagnostic messages.

### Thread Pool Installation Prior to MySQL 8.0.14

Prior to MySQL 8.0.14, the thread pool monitoring tables are plugins separate from the thread pool plugin and can be installed separately.

To enable thread pool capability, load the plugins to be used by starting the server with the `--plugin-load-add` option. For example, if you name only the plugin library file, the server loads all plugins that it contains (that is, the thread pool plugin and all the `INFORMATION_SCHEMA` tables). To do this, put these lines in the server `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```
[mysqld]
plugin-load-add=thread_pool.so
```

That is equivalent to loading all thread pool plugins by naming them individually:

```
[mysqld]
plugin-load-add=thread_pool=thread_pool.so
plugin-load-add=tp_thread_state=thread_pool.so
plugin-load-add=tp_thread_group_state=thread_pool.so
plugin-load-add=tp_thread_group_stats=thread_pool.so
```

If desired, you can load individual plugins from the library file. To load the thread pool plugin but not the `INFORMATION_SCHEMA` tables, use an option like this:

```
[mysqld]
plugin-load-add=thread_pool=thread_pool.so
```

To load the thread pool plugin and only the `TP_THREAD_STATE INFORMATION_SCHEMA` table, use options like this:

```
[mysqld]
plugin-load-add=thread_pool=thread_pool.so
plugin-load-add=tp_thread_state=thread_pool.so
```

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```sql
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE 'thread%' OR PLUGIN_NAME LIKE 'tp%';
```

<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>PLUGIN_STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>thread_pool</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>TP_THREAD_STATE</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>TP_THREAD_GROUP_STATE</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>TP_THREAD_GROUP_STATS</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>

If the server loads the thread pool plugin successfully, it sets the `thread_handling` system variable to `loaded-dynamically`.

If a plugin fails to initialize, check the server error log for diagnostic messages.
5.6.3.3 Thread Pool Operation

The thread pool consists of a number of thread groups, each of which manages a set of client connections. As connections are established, the thread pool assigns them to thread groups in round-robin fashion.

To configure the number of thread groups, use the `thread_pool_size` system variable. The default number of groups is 16. For guidelines on setting this variable, see Section 5.6.3.4, “Thread Pool Tuning”.

The maximum number of threads per group is 4096 (or 4095 on some systems where one thread is used internally).

The thread pool separates connections and threads, so there is no fixed relationship between connections and the threads that execute statements received from those connections. This differs from the default thread-handling model that associates one thread with one connection such that a given thread executes all statements from its connection.

By default, the thread pool tries to ensure a maximum of one thread executing in each group at any time, but sometimes permits more threads to execute temporarily for best performance:

- Each thread group has a listener thread that listens for incoming statements from the connections assigned to the group. When a statement arrives, the thread group either begins executing it immediately or queues it for later execution:
  - Immediate execution occurs if the statement is the only one received and no statements are queued or currently executing.
  - Queuing occurs if the statement cannot begin executing immediately.
  - If immediate execution occurs, the listener thread performs it. (This means that temporarily no thread in the group is listening.) If the statement finishes quickly, the executing thread returns to listening for statements. Otherwise, the thread pool considers the statement stalled and starts another thread as a listener thread (creating it if necessary). To ensure that no thread group becomes blocked by stalled statements, the thread pool has a background thread that regularly monitors thread group states.

  By using the listening thread to execute a statement that can begin immediately, there is no need to create an additional thread if the statement finishes quickly. This ensures the most efficient execution possible in the case of a low number of concurrent threads.

When the thread pool plugin starts, it creates one thread per group (the listener thread), plus the background thread. Additional threads are created as necessary to execute statements.

- The value of the `thread_pool_stall_limit` system variable determines the meaning of “finishes quickly” in the previous item. The default time before threads are considered stalled is 60ms but can be set to a maximum of 6s. This parameter is configurable to enable you to strike a balance appropriate for the server work load. Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

- If `thread_pool_max_active_query_threads` is 0, the default algorithm applies as just described for determining the maximum number of active threads per group. The default algorithm takes stalled threads into account and may temporarily permit more active threads. If `thread_pool_max_active_query_threads` is greater than 0, it places a limit on the number of active threads per group.

- The thread pool focuses on limiting the number of concurrent short-running statements. Before an executing statement reaches the stall time, it prevents other statements from beginning to execute.
If the statement executes past the stall time, it is permitted to continue but no longer prevents other statements from starting. In this way, the thread pool tries to ensure that in each thread group there is never more than one short-running statement, although there might be multiple long-running statements. It is undesirable to let long-running statements prevent other statements from executing because there is no limit on the amount of waiting that might be necessary. For example, on a replication source server, a thread that is sending binary log events to a replica effectively runs forever.

- A statement becomes blocked if it encounters a disk I/O operation or a user level lock (row lock or table lock). The block would cause the thread group to become unused, so there are callbacks to the thread pool to ensure that the thread pool can immediately start a new thread in this group to execute another statement. When a blocked thread returns, the thread pool permits it to restart immediately.

- There are two queues, a high-priority queue and a low-priority queue. The first statement in a transaction goes to the low-priority queue. Any following statements for the transaction go to the high-priority queue if the transaction is ongoing (statements for it have begun executing), or to the low-priority queue otherwise. Queue assignment can be affected by enabling the `thread_pool_high_priority_connection` system variable, which causes all queued statements for a session to go into the high-priority queue.

Statements for a nontransactional storage engine, or a transactional engine if `autocommit` is enabled, are treated as low-priority statements because in this case each statement is a transaction. Thus, given a mix of statements for InnoDB and MyISAM tables, the thread pool prioritizes those for InnoDB over those for MyISAM unless `autocommit` is enabled. With `autocommit` enabled, all statements have low priority.

- When the thread group selects a queued statement for execution, it first looks in the high-priority queue, then in the low-priority queue. If a statement is found, it is removed from its queue and begins to execute.

- If a statement stays in the low-priority queue too long, the thread pool moves to the high-priority queue. The value of the `thread_pool_prio_kickup_timer` system variable controls the time before movement. For each thread group, a maximum of one statement per 10ms (100 per second) is moved from the low-priority queue to the high-priority queue.

- The thread pool reuses the most active threads to obtain a much better use of CPU caches. This is a small adjustment that has a great impact on performance.

- While a thread executes a statement from a user connection, Performance Schema instrumentation accounts thread activity to the user connection. Otherwise, Performance Schema accounts activity to the thread pool.

Here are examples of conditions under which a thread group might have multiple threads started to execute statements:

- One thread begins executing a statement, but runs long enough to be considered stalled. The thread group permits another thread to begin executing another statement even through the first thread is still executing.

- One thread begins executing a statement, then becomes blocked and reports this back to the thread pool. The thread group permits another thread to begin executing another statement.

- One thread begins executing a statement, becomes blocked, but does not report back that it is blocked because the block does not occur in code that has been instrumented with thread pool callbacks. In this case, the thread appears to the thread group to be still running. If the block lasts long enough for the statement to be considered stalled, the group permits another thread to begin executing another statement.
The thread pool is designed to be scalable across an increasing number of connections. It is also designed to avoid deadlocks that can arise from limiting the number of actively executing statements. It is important that threads that do not report back to the thread pool do not prevent other statements from executing and thus cause the thread pool to become deadlocked. Examples of such statements follow:

- Long-running statements. These would lead to all resources used by only a few statements and they could prevent all others from accessing the server.

- Binary log dump threads that read the binary log and send it to replicas. This is a kind of long-running “statement” that runs for a very long time, and that should not prevent other statements from executing.

- Statements blocked on a row lock, table lock, sleep, or any other blocking activity that has not been reported back to the thread pool by MySQL Server or a storage engine.

In each case, to prevent deadlock, the statement is moved to the stalled category when it does not complete quickly, so that the thread group can permit another statement to begin executing. With this design, when a thread executes or becomes blocked for an extended time, the thread pool moves the thread to the stalled category and for the rest of the statement's execution, it does not prevent other statements from executing.

The maximum number of threads that can occur is the sum of `max_connections` and `thread_pool_size`. This can happen in a situation where all connections are in execution mode and an extra thread is created per group to listen for more statements. This is not necessarily a state that happens often, but it is theoretically possible.

### 5.6.3.4 Thread Pool Tuning

This section provides guidelines on setting thread pool system variables for best performance, measured using a metric such as transactions per second.

`thread_pool_size` is the most important parameter controlling thread pool performance. It can be set only at server startup. Our experience in testing the thread pool indicates the following:

- If the primary storage engine is InnoDB, the optimal `thread_pool_size` setting is likely to be between 16 and 36, with the most common optimal values tending to be from 24 to 36. We have not seen any situation where the setting has been optimal beyond 36. There may be special cases where a value smaller than 16 is optimal.

  For workloads such as DBT2 and Sysbench, the optimum for InnoDB seems to be usually around 36. For very write-intensive workloads, the optimal setting can sometimes be lower.

- If the primary storage engine is MyISAM, the `thread_pool_size` setting should be fairly low. Optimal performance is often seen with values from 4 to 8. Higher values tend to have a slightly negative but not dramatic impact on performance.

Another system variable, `thread_pool_stall_limit`, is important for handling of blocked and long-running statements. If all calls that block the MySQL Server are reported to the thread pool, it would always know when execution threads are blocked. However, this may not always be true. For example, blocks could occur in code that has not been instrumented with thread pool callbacks. For such cases, the thread pool must be able to identify threads that appear to be blocked. This is done by means of a timeout that can be tuned using the `thread_pool_stall_limit` system variable, the value of which is measured in 10ms units. This parameter ensures that the server does not become completely blocked. The value of `thread_pool_stall_limit` has an upper limit of 6 seconds to prevent the risk of a deadlocked server.

`thread_pool_stall_limit` also enables the thread pool to handle long-running statements. If a long-running statement was permitted to block a thread group, all other connections assigned to the group...
would be blocked and unable to start execution until the long-running statement completed. In the worst case, this could take hours or even days.

The value of `thread_pool_stall_limit` should be chosen such that statements that execute longer than its value are considered stalled. Stalled statements generate a lot of extra overhead since they involve extra context switches and in some cases even extra thread creations. On the other hand, setting the `thread_pool_stall_limit` parameter too high means that long-running statements block a number of short-running statements for longer than necessary. Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

Suppose a server executes a workload where 99.9% of the statements complete within 100ms even when the server is loaded, and the remaining statements take between 100ms and 2 hours fairly evenly spread. In this case, it would make sense to set `thread_pool_stall_limit` to 10 (10 × 10ms = 100ms). The default value of 6 (60ms) is suitable for servers that primarily execute very simple statements. The `thread_pool_stall_limit` parameter can be changed at runtime to enable you to strike a balance appropriate for the server work load. Assuming that the `tp_thread_group_stats` table is enabled, you can use the following query to determine the fraction of executed statements that stalled:

```
SELECT SUM(STALLED_QUERIES_EXECUTED) / SUM(QUERIES_EXECUTED)
FROM performance_schema.tp_thread_group_stats;
```

This number should be as low as possible. To decrease the likelihood of statements stalling, increase the value of `thread_pool_stall_limit`.

When a statement arrives, what is the maximum time it can be delayed before it actually starts executing? Suppose that the following conditions apply:

- There are 200 statements queued in the low-priority queue.
- There are 10 statements queued in the high-priority queue.
- `thread_pool_prio_kickup_timer` is set to 10000 (10 seconds).
- `thread_pool_stall_limit` is set to 100 (1 second).

In the worst case, the 10 high-priority statements represent 10 transactions that continue executing for a long time. Thus, in the worst case, no statements can be moved to the high-priority queue because it always already contains statements awaiting execution. After 10 seconds, the new statement is eligible to be moved to the high-priority queue. However, before it can be moved, all the statements before it must be moved as well. This could take another 2 seconds because a maximum of 100 statements per second are moved to the high-priority queue. Now when the statement reaches the high-priority queue, there could potentially be many long-running statements ahead of it. In the worst case, every one of those becomes stalled and 1 second is required for each statement before the next statement is retrieved from the high-priority queue. Thus, in this scenario, it takes 222 seconds before the new statement starts executing.

This example shows a worst case for an application. How to handle it depends on the application. If the application has high requirements for the response time, it should most likely throttle users at a higher level itself. Otherwise, it can use the thread pool configuration parameters to set some kind of a maximum waiting time.

### 5.6.4 The Rewriter Query Rewrite Plugin

MySQL supports query rewrite plugins that can examine and possibly modify SQL statements received by the server before the server executes them. See [Query Rewrite Plugins](#).
MySQL distributions include a postparse query rewrite plugin named **Rewriter** and scripts for installing the plugin and its associated elements. These elements work together to provide statement-rewriting capability:

- A server-side plugin named **Rewriter** examines statements and may rewrite them, based on its in-memory cache of rewrite rules.

- These statements are subject to rewriting:
  - As of MySQL 8.0.12: `SELECT`, `INSERT`, `REPLACE`, `UPDATE`, and `DELETE`.
  - Prior to MySQL 8.0.12: `SELECT` only.

Standalone statements and prepared statements are subject to rewriting. Statements occurring within view definitions or stored programs are not subject to rewriting.

- The **Rewriter** plugin uses a database named `query_rewrite` containing a table named `rewrite_rules`. The table provides persistent storage for the rules that the plugin uses to decide whether to rewrite statements. Users communicate with the plugin by modifying the set of rules stored in this table. The plugin communicates with users by setting the `message` column of table rows.

- The `query_rewrite` database contains a stored procedure named `flush_rewrite_rules()` that loads the contents of the rules table into the plugin.

- A user-defined function named `load_rewrite_rules()` is used by the `flush_rewrite_rules()` stored procedure.

- The **Rewriter** plugin exposes system variables that enable plugin configuration and status variables that provide runtime operational information.

The following sections describe how to install and use the **Rewriter** plugin, and provide reference information for its associated elements.

### 5.6.4.1 Installing or Uninstalling the Rewriter Query Rewrite Plugin

**Note**

If installed, the **Rewriter** plugin involves some overhead even when disabled. To avoid this overhead, do not install the plugin unless you plan to use it.

To install or uninstall the **Rewriter** query rewrite plugin, choose the appropriate script located in the `share` directory of your MySQL installation:

- **install_rewriter.sql**: Choose this script to install the **Rewriter** plugin and its associated elements.

- **uninstall_rewriter.sql**: Choose this script to uninstall the **Rewriter** plugin and its associated elements.

Run the chosen script as follows:

```shell
shell> mysql -u root -p < install_rewriter.sql
Enter password: (enter root password here)
```

The example here uses the `install_rewriter.sql` installation script. Substitute `uninstall_rewriter.sql` if you are uninstalling the plugin.

Running an installation script should install and enable the plugin. To verify that, connect to the server and execute this statement:
### 5.6.4.2 Using the Rewriter Query Rewrite Plugin

To enable or disable the plugin, enable or disable the `rewriter_enabled` system variable. By default, the Rewriter plugin is enabled when you install it (see Section 5.6.4.1, “Installing or Uninstalling the Rewriter Query Rewrite Plugin”). To set the initial plugin state explicitly, you can set the variable at server startup. For example, to enable the plugin in an option file, use these lines:

```sql
[mysqld]
rewriter_enabled=ON
```

It is also possible to enable or disable the plugin at runtime:

```sql
SET GLOBAL rewriter_enabled = ON;
SET GLOBAL rewriter_enabled = OFF;
```

Assuming that the Rewriter plugin is enabled, it examines and possibly modifies each rewritable statement received by the server. The plugin determines whether to rewrite statements based on its in-memory cache of rewriting rules, which are loaded from the rewrite_rules table in the query_rewrite database.

These statements are subject to rewriting:

- **As of MySQL 8.0.12:** `SELECT`, `INSERT`, `REPLACE`, `UPDATE`, and `DELETE`.
- **Prior to MySQL 8.0.12:** `SELECT` only.

Standalone statements and prepared statements are subject to rewriting. Statements occurring within view definitions or stored programs are not subject to rewriting.

- Adding Rewrite Rules
- How Statement Matching Works
- Rewriting Prepared Statements
- Rewriter Plugin Operational Information
- Rewriter Plugin Use of Character Sets

### Adding Rewrite Rules

To add rules for the Rewriter plugin, add rows to the rewrite_rules table, then invoke the `flush_rewrite_rules()` stored procedure to load the rules from the table into the plugin. The following example creates a simple rule to match statements that select a single literal value:

```sql
INSERT INTO query_rewrite.rewrite_rules (pattern, replacement) VALUES('SELECT ?', 'SELECT ? + 1');
```

The resulting table contents look like this:

```sql
mysql> SELECT * FROM query_rewrite.rewrite_rules\G
*************************** 1. row ***************************
```

For usage instructions, see Section 5.6.4.2, “Using the Rewriter Query Rewrite Plugin”. For reference information, see Section 5.6.4.3, “Rewriter Query Rewrite Plugin Reference”.

---

```sql
SHOW GLOBAL VARIABLES LIKE 'rewriter_enabled';
+------------------+-------+
| Variable_name    | Value |
+------------------+-------+
| rewriter_enabled | ON    |
+------------------+-------+
```

---

504
The rule specifies a pattern template indicating which `SELECT` statements to match, and a replacement template indicating how to rewrite matching statements. However, adding the rule to the `rewrite_rules` table is not sufficient to cause the Rewriter plugin to use the rule. You must invoke `flush_rewrite_rules()` to load the table contents into the plugin in-memory cache:

```sql
mysql> CALL query_rewrite.flush_rewrite_rules();
```

Tip

If your rewrite rules seem not to be working properly, make sure that you have reloaded the rules table by calling `flush_rewrite_rules()`.

When the plugin reads each rule from the rules table, it computes a normalized (statement digest) form from the pattern and a digest hash value, and uses them to update the `normalized_pattern` and `pattern_digest` columns:

```sql
mysql> SELECT * FROM query_rewrite.rewrite_rules\G
```

<table>
<thead>
<tr>
<th>id</th>
<th>pattern</th>
<th>pattern_database</th>
<th>replacement</th>
<th>enabled</th>
<th>message</th>
<th>pattern_digest</th>
<th>normalized_pattern</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SELECT ?</td>
<td>NULL</td>
<td>SELECT ? + 1</td>
<td>YES</td>
<td>NULL</td>
<td>d1b44b0c19af710b5a679907e284acd2d285201794bc69a2389d77baedddae</td>
<td>select ?</td>
</tr>
</tbody>
</table>

For information about statement digesting, normalized statements, and digest hash values, see Section 26.10, “Performance Schema Statement Digests and Sampling”.

If a rule cannot be loaded due to some error, calling `flush_rewrite_rules()` produces an error:

```sql
mysql> CALL query_rewrite.flush_rewrite_rules();
ERROR 1644 (45000): Loading of some rule(s) failed.
```

When this occurs, the plugin writes an error message to the `message` column of the rule row to communicate the problem. Check the `rewrite_rules` table for rows with non-NULL `message` column values to see what problems exist.

Patterns use the same syntax as prepared statements (see Section 13.5.1, “PREPARE Statement”). Within a pattern template, `?` characters act as parameter markers that match data values. Parameter markers can be used only where data values should appear, not for SQL keywords, identifiers, and so forth. The `?` characters should not be enclosed within quotation marks.

Like the pattern, the replacement can contain `?` characters. For a statement that matches a pattern template, the plugin rewrites it, replacing `?` parameter markers in the replacement using data values matched by the corresponding markers in the pattern. The result is a complete statement string. The plugin asks the server to parse it, and returns the result to the server as the representation of the rewritten statement.

After adding and loading the rule, check whether rewriting occurs according to whether statements match the rule pattern:
No rewriting occurs for the first `SELECT` statement, but does for the second. The second statement illustrates that when the `Rewriter` plugin rewrites a statement, it produces a warning message. To view the message, use `SHOW WARNINGS`:

```
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
    Level: Note
   Code: 1105
Message: Query 'SELECT 10' rewritten to 'SELECT 10 + 1' by a query rewrite plugin
```

A statement need not be rewritten to a statement of the same type. The following example loads a rule that rewrites `DELETE` statements to `UPDATE` statements:

```
INSERT INTO query_rewrite.rewrite_rules (pattern, replacement)
VALUES('DELETE FROM db1.t1 WHERE col = ?',
       'UPDATE db1.t1 SET col = NULL WHERE col = ?');
CALL query_rewrite.flush_rewrite_rules();
```

To enable or disable an existing rule, modify its `enabled` column and reload the table into the plugin. To disable rule 1:

```
UPDATE query_rewrite.rewrite_rules SET enabled = 'NO' WHERE id = 1;
CALL query_rewrite.flush_rewrite_rules();
```

This enables you to deactivate a rule without removing it from the table.

To re-enable rule 1:

```
UPDATE query_rewrite.rewrite_rules SET enabled = 'YES' WHERE id = 1;
CALL query_rewrite.flush_rewrite_rules();
```

The `rewrite_rules` table contains a `pattern_database` column that `Rewriter` uses for matching table names that are not qualified with a database name:

- Qualified table names in statements match qualified names in the pattern if corresponding database and table names are identical.
- Unqualified table names in statements match unqualified names in the pattern only if the default database is the same as `pattern_database` and the table names are identical.

Suppose that a table named `appdb.users` has a column named `id` and that applications are expected to select rows from the table using a query of one of these forms, where the second can be used only if `appdb` is the default database:

```
SELECT * FROM users WHERE appdb.id = id_value;
SELECT * FROM users WHERE id = id_value;
```
Suppose also that the `id` column is renamed to `user_id` (perhaps the table must be modified to add another type of ID and it is necessary to indicate more specifically what type of ID the `id` column represents).

The change means that applications must refer to `user_id` rather than `id` in the `WHERE` clause. But if there are old applications that cannot be written to change the `SELECT` queries they generate, they no longer work properly. The Rewriter plugin can solve this problem. To match and rewrite statements whether or not they qualify the table name, add the following two rules and reload the rules table:

```sql
INSERT INTO query_rewrite.rewrite_rules
(pattern, replacement) VALUES(
  'SELECT * FROM appdb.users WHERE id = ?',
  'SELECT * FROM appdb.users WHERE user_id = ?'
);

INSERT INTO query_rewrite.rewrite_rules
(pattern, replacement, pattern_database) VALUES(
  'SELECT * FROM users WHERE id = ?',
  'SELECT * FROM users WHERE user_id = ?',
  'appdb'
);

CALL query_rewrite.flush_rewrite_rules();
```

Rewriter uses the first rule to match statements that use the qualified table name. It uses the second to match statements that used the unqualified name, but only if the default database is `appdb` (the value in `pattern_database`).

How Statement Matching Works

The Rewriter plugin uses statement digests and digest hash values to match incoming statements against rewrite rules in stages. The `max_digest_length` system variable determines the size of the buffer used for computing statement digests. Larger values enable computation of digests that distinguish longer statements. Smaller values use less memory but increase the likelihood of longer statements colliding with the same digest value.

The plugin matches each statement to the rewrite rules as follows:

1. Compute the statement digest hash value and compare it to the rule digest hash values. This is subject to false positives, but serves as a quick rejection test.

2. If the statement digest hash value matches any pattern digest hash values, match the normalized (statement digest) form of the statement to the normalized form of the matching rule patterns.

3. If the normalized statement matches a rule, compare the literal values in the statement and the pattern. A `?` character in the pattern matches any literal value in the statement. If the statement prepares a statement, `?` in the pattern also matches `?` in the statement. Otherwise, corresponding literals must be the same.

If multiple rules match a statement, it is nondeterministic which one the plugin uses to rewrite the statement.

If a pattern contains more markers than the replacement, the plugin discards excess data values. If a pattern contains fewer markers than the replacement, it is an error. The plugin notices this when the rules table is loaded, writes an error message to the `message` column of the rule row to communicate the problem, and sets the `Rewriter_reload_error` status variable to ON.

Rewriting Prepared Statements

Prepared statements are rewritten at parse time (that is, when they are prepared), not when they are executed later.
Prepared statements differ from nonprepared statements in that they may contain `?` characters as parameter markers. To match a `?` in a prepared statement, a Rewriter pattern must contain `?` in the same location. Suppose that a rewrite rule has this pattern:

```sql
SELECT ?, 3
```

The following table shows several prepared `SELECT` statements and whether the rule pattern matches them.

<table>
<thead>
<tr>
<th>Prepared Statement</th>
<th>Whether Pattern Matches Statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>PREPARE s AS 'SELECT 3, 3'</td>
<td>Yes</td>
</tr>
<tr>
<td>PREPARE s AS 'SELECT ?, 3'</td>
<td>Yes</td>
</tr>
<tr>
<td>PREPARE s AS 'SELECT 3, ?'</td>
<td>No</td>
</tr>
<tr>
<td>PREPARE s AS 'SELECT ?, ?'</td>
<td>No</td>
</tr>
</tbody>
</table>

### Rewriter Plugin Operational Information

The Rewriter plugin makes information available about its operation by means of several status variables:

```sql
mysql> SHOW GLOBAL STATUS LIKE 'Rewriter%';
+-----------------------------------+-------+
| Variable_name                     | Value |
+-----------------------------------+-------+
| Rewriter_number_loaded_rules      | 1     |
| Rewriter_number_reloads           | 5     |
| Rewriter_number_rewritten_queries | 1     |
| Rewriter_reload_error             | ON    |
+-----------------------------------+-------+
```

For descriptions of these variables, see Rewriter Query Rewrite Plugin Status Variables.

When you load the rules table by calling the `flush_rewrite_rules()` stored procedure, if an error occurs for some rule, the CALL statement produces an error, and the plugin sets the `Rewriter_reload_error` status variable to ON:

```sql
mysql> CALL query_rewrite.flush_rewrite_rules();
ERROR 1644 (45000): Loading of some rule(s) failed.
```

```sql
mysql> SHOW GLOBAL STATUS LIKE 'Rewriter_reload_error';
+-----------------------+-------+
| Variable_name         | Value |
+-----------------------+-------+
| Rewriter_reload_error | ON    |
+-----------------------+-------+
```

In this case, check the rewrite_rules table for rows with non-NULL message column values to see what problems exist.

### Rewriter Plugin Use of Character Sets

When the rewrite_rules table is loaded into the Rewriter plugin, the plugin interprets statements using the current global value of the `character_set_client` system variable. If the global `character_set_client` value is changed subsequently, the rules table must be reloaded.

A client must have a session `character_set_client` value identical to what the global value was when the rules table was loaded or rule matching does not work for that client.
5.6.4.3 Rewriter Query Rewrite Plugin Reference

The following discussion serves as a reference to these elements associated with the Rewriter query rewrite plugin:

- The Rewriter rules table in the query_rewrite database
- Rewriter procedures and functions
- Rewriter system and status variables

Rewriter Query Rewrite Plugin Rules Table

The rewrite_rules table in the query_rewrite database provides persistent storage for the rules that the Rewriter plugin uses to decide whether to rewrite statements.

Users communicate with the plugin by modifying the set of rules stored in this table. The plugin communicates information to users by setting the table's message column.

Note

The rules table is loaded into the plugin by the flush_rewrite_rules stored procedure. Unless that procedure has been called following the most recent table modification, the table contents do not necessarily correspond to the set of rules the plugin is using.

The rewrite_rules table has these columns:

- id
  The rule ID. This column is the table primary key. You can use the ID to uniquely identify any rule.
- pattern
  The template that indicates the pattern for statements that the rule matches. Use ? to represent parameter markers that match data values.
- pattern_database
  The database used to match unqualified table names in statements. Qualified table names in statements match qualified names in the pattern if corresponding database and table names are identical. Unqualified table names in statements match unqualified names in the pattern only if the default database is the same as pattern_database and the table names are identical.
- replacement
  The template that indicates how to rewrite statements matching the pattern column value. Use ? to represent parameter markers that match data values. In rewritten statements, the plugin replaces ? parameter markers in replacement using data values matched by the corresponding markers in pattern.
- enabled
  Whether the rule is enabled. Load operations (performed by invoking the flush_rewrite_rules() stored procedure) load the rule from the table into the Rewriter in-memory cache only if this column is YES.

This column makes it possible to deactivate a rule without removing it: Set the column to a value other than YES and reload the table into the plugin.
The plugin uses this column for communicating with users. If no error occurs when the rules table is loaded into memory, the plugin sets the `message` column to NULL. A non-NULL value indicates an error and the column contents are the error message. Errors can occur under these circumstances:

- Either the pattern or the replacement is an incorrect SQL statement that produces syntax errors.
- The replacement contains more ? parameter markers than the pattern.

If a load error occurs, the plugin also sets the `Rewriter_reload_error` status variable to ON.

- **pattern_digest**

  This column is used for debugging and diagnostics. If the column exists when the rules table is loaded into memory, the plugin updates it with the pattern digest. This column may be useful if you are trying to determine why some statement fails to be rewritten.

- **normalized_pattern**

  This column is used for debugging and diagnostics. If the column exists when the rules table is loaded into memory, the plugin updates it with the normalized form of the pattern. This column may be useful if you are trying to determine why some statement fails to be rewritten.

### Rewriter Query Rewrite Plugin Procedures and Functions

- **flush_rewrite_rules()**

  This stored procedure uses the `load_rewrite_rules()` UDF to load the contents of the `rewrite_rules` table into the `Rewriter` in-memory cache.

  Calling `flush_rewrite_rules()` implies COMMIT.

  Invoke this procedure after you modify the rules table to cause the plugin to update its cache from the new table contents. If any errors occur, the plugin sets the `message` column for the appropriate rule rows in the table and sets the `Rewriter_reload_error` status variable to ON.

- **load_rewrite_rules()**

  This UDF is a helper routine used by the `flush_rewrite_rules()` stored procedure.

### Rewriter Query Rewrite Plugin System Variables

The `Rewriter` query rewrite plugin supports the following system variables. These variables are available only if the plugin is installed (see Section 5.6.4.1, “Installing or Uninstalling the Rewriter Query Rewrite Plugin”).

- **rewriter_enabled**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>rewriter_enabled</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>
The **ddl_rewriter Plugin**

<table>
<thead>
<tr>
<th>Set_Var</th>
<th>Hint Applies</th>
<th>No</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
<td></td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
<td></td>
</tr>
</tbody>
</table>

Whether the **Rewriter** query rewrite plugin is enabled.

- **rewriter_verbose**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>rewriter_verbose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Set_Var Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

For internal use.

**Rewriter Query Rewrite Plugin Status Variables**

The **Rewriter** query rewrite plugin supports the following status variables. These variables are available only if the plugin is installed (see Section 5.6.4.1, “Installing or Uninstalling the Rewriter Query Rewrite Plugin”).

- **Rewriter_number_loaded_rules**

  The number of rewrite plugin rewrite rules successfully loaded from the `rewrite_rules` table into memory for use by the **Rewriter** plugin.

- **Rewriter_number_reloaded**

  The number of times the `rewrite_rules` table has been loaded into the in-memory cache used by the **Rewriter** plugin.

- **Rewriter_number_rewritten_queries**

  The number of queries rewritten by the **Rewriter** query rewrite plugin since it was loaded.

- **Rewriter_reload_error**

  Whether an error occurred the most recent time that the `rewrite_rules` table was loaded into the in-memory cache used by the **Rewriter** plugin. If the value is **OFF**, no error occurred. If the value is **ON**, an error occurred; check the `message` column of the `rewrite_rules` table for error messages.

**5.6.5 The **ddl_rewriter Plugin****

MySQL 8.0.16 and higher includes a **ddl_rewriter** plugin that modifies **CREATE TABLE** statements received by the server before it parses and executes them. The plugin removes **ENCRYPTION**, **DATA DIRECTORY**, and **INDEX DIRECTORY** clauses, which may be helpful when restoring tables from SQL dump files created from databases that are encrypted or that have their tables stored outside the data directory. For example, the plugin may enable restoring such dump files into an unencrypted instance or in an environment where the paths outside the data directory are not accessible.

Before using the **ddl_rewriter** plugin, install it according to the instructions provided in Section 5.6.5.1, “Installing or Uninstalling **ddl_rewriter**”.

---

1051
The ddl_rewriter Plugin

ddl_rewriter examines SQL statements received by the server prior to parsing, rewriting them according to these conditions:

- **ddl_rewriter** considers only **CREATE TABLE** statements, and only if they are standalone statements that occur at the beginning of an input line or at the beginning of prepared statement text. **ddl_rewriter** does not consider **CREATE TABLE** statements within stored program definitions. Statements can extend over multiple lines.

- Within statements considered for rewrite, instances of the following clauses are rewritten and each instance replaced by a single space:
  - **ENCRYPTION**
  - **DATA DIRECTORY** (at the table and partition levels)
  - **INDEX DIRECTORY** (at the table and partition levels)

- Rewriting does not depend on lettercase.

If **ddl_rewriter** rewrites a statement, it generates a warning:

```sql
mysql> CREATE TABLE t (i INT) DATA DIRECTORY '/var/mysql/data';
Query OK, 0 rows affected, 1 warning (0.03 sec)
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
  Level: Note
  Code: 1105
  Message: Query 'CREATE TABLE t (i INT) DATA DIRECTORY '/var/mysql/data'' rewritten to 'CREATE TABLE t (i INT) ' by a query rewrite plugin
  1 row in set (0.00 sec)
```

If the general query log or binary log is enabled, the server writes to it statements as they appear after any rewriting by **ddl_rewriter**.

When installed, **ddl_rewriter** exposes the Performance Schema **memory/rewriter/ddl_rewriter** instrument for tracking plugin memory use. See Section 26.12.18.10, “Memory Summary Tables”

### 5.6.5.1 Installing or Uninstalling **ddl_rewriter**

This section describes how to install or uninstall the **ddl_rewriter** plugin. For general information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

**Note**

If installed, the **ddl_rewriter** plugin involves some minimal overhead even when disabled. To avoid this overhead, install **ddl_rewriter** only for the period during which you intend to use it.

The primary use case is modification of statements restored from dump files, so the typical usage pattern is: 1) Install the plugin; 2) restore the dump file or files; 3) uninstall the plugin.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the **plugin_dir** system variable). If necessary, configure the plugin directory location by setting the value of **plugin_dir** at server startup.

The plugin library file base name is **ddl_rewriter**. The file name suffix differs per platform (for example, **.so** for Unix and Unix-like systems, **.dll** for Windows).
To install the *ddl_rewriter* plugin, use the `INSTALL PLUGIN` statement, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN ddl_rewriter SONAME 'ddl_rewriter.so';
```

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```sql
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS, PLUGIN_TYPE
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE 'ddl%';
```

<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>PLUGIN_STATUS</th>
<th>PLUGIN_TYPE</th>
</tr>
</thead>
<tbody>
<tr>
<td>ddl_rewriter</td>
<td>ACTIVE</td>
<td>AUDIT</td>
</tr>
</tbody>
</table>

As the preceding result shows, `ddl_rewriter` is implemented as an audit plugin.

If the plugin fails to initialize, check the server error log for diagnostic messages.

Once installed as just described, `ddl_rewriter` remains installed until uninstalled. To remove it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN ddl_rewriter;
```

If `ddl_rewriter` is installed, you can use the `--ddl-rewriter` option for subsequent server startups to control `ddl_rewriter` plugin activation. For example, to prevent the plugin from being enabled at runtime, use this option:

```
[mysqld]
ddl-rewriter=OFF
```

### 5.6.5.2 ddl_rewriter Plugin Options

This section describes the command options that control operation of the `ddl_rewriter` plugin. If values specified at startup time are incorrect, the `ddl_rewriter` plugin may fail to initialize properly and the server does not load it.

To control activation of the `ddl_rewriter` plugin, use this option:

- `--ddl-rewriter[=value]`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--ddl-rewriter[=value]</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.16</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ON, OFF, FORCE, FORCE_PLUS_PERMANENT</td>
</tr>
</tbody>
</table>

This option controls how the server loads the `ddl_rewriter` plugin at startup. It is available only if the plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load` or `--plugin-load-add`. See Section 5.6.5.1, “Installing or Uninstalling `ddl_rewriter`”.
The option value should be one of those available for plugin-loading options, as described in Section 5.6.1, “Installing and Uninstalling Plugins”. For example, --ddl-rewriter=OFF disables the plugin at server startup.

5.6.6 Version Tokens

MySQL includes Version Tokens, a feature that enables creation of and synchronization around server tokens that applications can use to prevent accessing incorrect or out-of-date data.

The Version Tokens interface has these characteristics:

- Version tokens are pairs consisting of a name that serves as a key or identifier, plus a value.
- Version tokens can be locked. An application can use token locks to indicate to other cooperating applications that tokens are in use and should not be modified.
- Version token lists are established per server (for example, to specify the server assignment or operational state). In addition, an application that communicates with a server can register its own list of tokens that indicate the state it requires the server to be in. An SQL statement sent by the application to a server not in the required state produces an error. This is a signal to the application that it should seek a different server in the required state to receive the SQL statement.

The following sections describe the elements of Version Tokens, discuss how to install and use it, and provide reference information for its elements.

5.6.6.1 Version Tokens Elements

Version Tokens is based on a plugin library that implements these elements:

- A server-side plugin named version_tokens holds the list of version tokens associated with the server and subscribes to notifications for statement execution events. The version_tokens plugin uses the audit plugin API to monitor incoming statements from clients and matches each client's session-specific version token list against the server version token list. If there is a match, the plugin lets the statement through and the server continues to process it. Otherwise, the plugin returns an error to the client and the statement fails.

- A set of user-defined functions (UDFs) provides an SQL-level API for manipulating and inspecting the list of server version tokens maintained by the plugin. The VERSION_TOKEN_ADMIN privilege (or the deprecated SUPER privilege) is required to call any of the Version Token UDFs.

- When the version_tokens plugin loads, it defines the VERSION_TOKEN_ADMIN dynamic privilege. This privilege can be granted to users of the UDFs.

- A system variable enables clients to specify the list of version tokens that register the required server state. If the server has a different state when a client sends a statement, the client receives an error.

5.6.6.2 Installing or Uninstalling Version Tokens

Note

If installed, Version Tokens involves some overhead. To avoid this overhead, do not install it unless you plan to use it.

This section describes how to install or uninstall Version Tokens, which is implemented in a plugin library file containing a plugin and user-defined functions (UDFs). For general information about installing or uninstalling plugins and UDFs, see Section 5.6.1, “Installing and Uninstalling Plugins”, and Section 5.7.1, “ Installing and Uninstalling User-Defined Functions”.

1054
To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `version_tokens`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To install the Version Tokens plugin and UDFs, use the `INSTALL PLUGIN` and `CREATE FUNCTION` statements, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN version_tokens SONAME 'version_token.so';
CREATE FUNCTION version_tokens_set RETURNS STRING
  SONAME 'version_token.so';
CREATE FUNCTION version_tokens_show RETURNS STRING
  SONAME 'version_token.so';
CREATE FUNCTION version_tokens_edit RETURNS STRING
  SONAME 'version_token.so';
CREATE FUNCTION version_tokens_delete RETURNS STRING
  SONAME 'version_token.so';
CREATE FUNCTION version_tokens_lock_shared RETURNS INT
  SONAME 'version_token.so';
CREATE FUNCTION version_tokens_lock_exclusive RETURNS INT
  SONAME 'version_token.so';
CREATE FUNCTION version_tokens_unlock RETURNS INT
  SONAME 'version_token.so';
```

You must install the UDFs to manage the server's version token list, but you must also install the plugin because the UDFs do not work correctly without it.

If the plugin and UDFs are used on a replication source server, install them on all replica servers as well to avoid replication problems.

Once installed as just described, the plugin and UDFs remain installed until uninstalled. To remove them, use the `UNINSTALL PLUGIN` and `DROP FUNCTION` statements:

```
UNINSTALL PLUGIN version_tokens;
DROP FUNCTION version_tokens_set;
DROP FUNCTION version_tokens_show;
DROP FUNCTION version_tokens_edit;
DROP FUNCTION version_tokens_delete;
DROP FUNCTION version_tokens_lock_shared;
DROP FUNCTION version_tokens_lock_exclusive;
DROP FUNCTION version_tokens_unlock;
```

### 5.6.6.3 Using Version Tokens

Before using Version Tokens, install it according to the instructions provided at Section 5.6.6.2, “Installing or Uninstalling Version Tokens”.

A scenario in which Version Tokens can be useful is a system that accesses a collection of MySQL servers but needs to manage them for load balancing purposes by monitoring them and adjusting server assignments according to load changes. Such a system comprises these elements:

- The collection of MySQL servers to be managed.
- An administrative or management application that communicates with the servers and organizes them into high-availability groups. Groups serve different purposes, and servers within each group may have different assignments. Assignment of a server within a certain group can change at any time.
- Client applications that access the servers to retrieve and update data, choosing servers according to the purposes assigned them. For example, a client should not send an update to a read-only server.
Version Tokens permit server access to be managed according to assignment without requiring clients to repeatedly query the servers about their assignments:

- The management application performs server assignments and establishes version tokens on each server to reflect its assignment. The application caches this information to provide a central access point to it.

  If at some point the management application needs to change a server assignment (for example, to change it from permitting writes to read only), it changes the server's version token list and updates its cache.

- To improve performance, client applications obtain cache information from the management application, enabling them to avoid having to retrieve information about server assignments for each statement. Based on the type of statements it issues (for example, reads versus writes), a client selects an appropriate server and connects to it.

  In addition, the client sends to the server its own client-specific version tokens to register the assignment it requires of the server. For each statement sent by the client to the server, the server compares its own token list with the client token list. If the server token list contains all tokens present in the client token list with the same values, there is a match and the server executes the statement.

  On the other hand, perhaps the management application has changed the server assignment and its version token list. In this case, the new server assignment may now be incompatible with the client requirements. A token mismatch between the server and client token lists occurs and the server returns an error in reply to the statement. This is an indication to the client to refresh its version token information from the management application cache, and to select a new server to communicate with.

The client-side logic for detecting version token errors and selecting a new server can be implemented different ways:

- The client can handle all version token registration, mismatch detection, and connection switching itself.

  The logic for those actions can be implemented in a connector that manages connections between clients and MySQL servers. Such a connector might handle mismatch error detection and statement resending itself, or it might pass the error to the application and leave it to the application to resend the statement.

The following example illustrates the preceding discussion in more concrete form.

When Version Tokens initializes on a given server, the server's version token list is empty. Token list maintenance is performed by calling user-defined functions (UDFs). The VERSION_TOKEN_ADMIN privilege (or the deprecated SUPER privilege) is required to call any of the Version Token UDFs, so token list modification is expected to be done by a management or administrative application that has that privilege.

Suppose that a management application communicates with a set of servers that are queried by clients to access employee and product databases (named emp and prod, respectively). All servers are permitted to process data retrieval statements, but only some of them are permitted to make database updates. To handle this on a database-specific basis, the management application establishes a list of version tokens on each server. In the token list for a given server, token names represent database names and token values are read or write depending on whether the database must be used in read-only fashion or whether it can take reads and writes.

Client applications register a list of version tokens they require the server to match by setting a system variable. Variable setting occurs on a client-specific basis, so different clients can register different requirements. By default, the client token list is empty, which matches any server token list. When a client
set its token list to a nonempty value, matching may succeed or fail, depending on the server version token list.

To define the version token list for a server, the management application calls the `version_tokens_set()` UDF. (There are also UDFs for modifying and displaying the token list, described later.) For example, the application might send these statements to a group of three servers:

**Server 1:**

```
mysql> SELECT version_tokens_set('emp=read;prod=read');
+------------------------------------------+
<p>| version_tokens_set('emp=read;prod=read') |</p>
<table>
<thead>
<tr>
<th>2 version tokens set.</th>
</tr>
</thead>
</table>
```

**Server 2:**

```
mysql> SELECT version_tokens_set('emp=write;prod=read');
+-------------------------------------------+
<p>| version_tokens_set('emp=write;prod=read') |</p>
<table>
<thead>
<tr>
<th>2 version tokens set.</th>
</tr>
</thead>
</table>
```

**Server 3:**

```
mysql> SELECT version_tokens_set('emp=read;prod=write');
+-------------------------------------------+
<p>| version_tokens_set('emp=read;prod=write') |</p>
<table>
<thead>
<tr>
<th>2 version tokens set.</th>
</tr>
</thead>
</table>
```

The token list in each case is specified as a semicolon-separated list of `name=value` pairs. The resulting token list values result in these server assignments:

- Any server accepts reads for either database.
- Only server 2 accepts updates for the `emp` database.
- Only server 3 accepts updates for the `prod` database.

In addition to assigning each server a version token list, the management application also maintains a cache that reflects the server assignments.

Before communicating with the servers, a client application contacts the management application and retrieves information about server assignments. Then the client selects a server based on those assignments. Suppose that a client wants to perform both reads and writes on the `emp` database. Based on the preceding assignments, only server 2 qualifies. The client connects to server 2 and registers its server requirements there by setting its `version_tokens_session` system variable:

```
mysql> SET @@SESSION.version_tokens_session = 'emp=write';
```

For subsequent statements sent by the client to server 2, the server compares its own version token list to the client list to check whether they match. If so, statements execute normally:

```
mysql> UPDATE emp.employee SET salary = salary * 1.1 WHERE id = 4981;
Query OK, 1 row affected (0.07 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT last_name, first_name FROM emp.employee WHERE id = 4981;
+-----------+------------+
<table>
<thead>
<tr>
<th>last_name</th>
<th>first_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1057</td>
<td></td>
</tr>
</tbody>
</table>
```
Discrepancies between the server and client version token lists can occur two ways:

- A token name in the `version_tokens_session` value is not present in the server token list. In this case, an `ER_VTOKEN_PLUGIN_TOKEN_NOT_FOUND` error occurs.
- A token value in the `version_tokens_session` value differs from the value of the corresponding token in the server token list. In this case, an `ER_VTOKEN_PLUGIN_TOKEN_MISMATCH` error occurs.

As long as the assignment of server 2 does not change, the client continues to use it for reads and writes. But suppose that the management application wants to change server assignments so that writes for the `emp` database must be sent to server 1 instead of server 2. To do this, it uses `version_tokens_edit()` to modify the `emp` token value on the two servers (and updates its cache of server assignments):

**Server 1:**

```sql
mysql> SELECT version_tokens_edit('emp=write');
```

```
+----------------------------------+
| version_tokens_edit('emp=write') |
| 1 version tokens updated.        |
+----------------------------------+
```

**Server 2:**

```sql
mysql> SELECT version_tokens_edit('emp=read');
```

```
+----------------------------------+
| version_tokens_edit('emp=read')  |
| 1 version tokens updated.        |
+----------------------------------+
```

`version_tokens_edit()` modifies the named tokens in the server token list and leaves other tokens unchanged.

The next time the client sends a statement to server 2, its own token list no longer matches the server token list and an error occurs:

```sql
mysql> UPDATE emp.employee SET salary = salary * 1.1 WHERE id = 4982;
ERROR 3136 (42000): Version token mismatch for emp. Correct value read
```

In this case, the client should contact the management application to obtain updated information about server assignments, select a new server, and send the failed statement to the new server.

**Note**

Each client must cooperate with Version Tokens by sending only statements in accordance with the token list that it registers with a given server. For example, if a client registers a token list of `emp=read`, there is nothing in Version Tokens to prevent the client from sending updates for the `emp` database. The client itself must refrain from doing so.

For each statement received from a client, the server implicitly uses locking, as follows:

- Take a shared lock for each token named in the client token list (that is, in the `version_tokens_session` value)
• Perform the comparison between the server and client token lists
• Execute the statement or produce an error depending on the comparison result
• Release the locks

The server uses shared locks so that comparisons for multiple sessions can occur without blocking, while preventing changes to the tokens for any session that attempts to acquire an exclusive lock before it manipulates tokens of the same names in the server token list.

The preceding example uses only a few of the user-defined included in the Version Tokens plugin library, but there are others. One set of UDFs permits the server’s list of version tokens to be manipulated and inspected. Another set of UDFs permits version tokens to be locked and unlocked.

These UDFs permit the server’s list of version tokens to be created, changed, removed, and inspected:

• `version_tokens_set()` completely replaces the current list and assigns a new list. The argument is a semicolon-separated list of \texttt{name=value} pairs.

• `version_tokens_edit()` enables partial modifications to the current list. It can add new tokens or change the values of existing tokens. The argument is a semicolon-separated list of \texttt{name=value} pairs.

• `version_tokens_delete()` deletes tokens from the current list. The argument is a semicolon-separated list of token names.

• `version_tokens_show()` displays the current token list. It takes no argument.

Each of those functions, if successful, returns a binary string indicating what action occurred. The following example establishes the server token list, modifies it by adding a new token, deletes some tokens, and displays the resulting token list:

```
mysql> SELECT version_tokens_set('tok1=a;tok2=b');
+-------------------------------------+
| version_tokens_set('tok1=a;tok2=b') |
+-------------------------------------+
| 2 version tokens set.               |
+-------------------------------------+
mysql> SELECT version_tokens_edit('tok3=c');
+-------------------------------+
| version_tokens_edit('tok3=c') |
+-------------------------------+
| 1 version tokens updated.     |
+-------------------------------+
mysql> SELECT version_tokens_delete('tok2;tok1');
+------------------------------------+
| version_tokens_delete('tok2;tok1') |
+------------------------------------+
| 2 version tokens deleted.          |
+------------------------------------+
mysql> SELECT version_tokens_show();
+-----------------------+
| version_tokens_show()  |
+-----------------------+
| tok3=c;               |
+-----------------------+
```

Warnings occur if a token list is malformed:

```
mysql> SELECT version_tokens_set('tok1=a; =c');
+----------------------------------+
| version_tokens_set('tok1=a; =c') |
+----------------------------------+ 1059
```

1059
As mentioned previously, version tokens are defined using a semicolon-separated list of \texttt{name=value} pairs. Consider this invocation of \texttt{version_tokens_set()}:

\begin{verbatim}
mysql> SELECT version_tokens_set('tok1=b;;; tok2= a = b ; tok1 = 1\'2 3"4')
+---------------------------------------------------------------+
| version_tokens_set('tok1=b;;; tok2= a = b ; tok1 = 1\'2 3"4') |
+---------------------------------------------------------------+
| 3 version tokens set.                                         |
+---------------------------------------------------------------+
\end{verbatim}

Version Tokens interprets the argument as follows:

- Whitespace around names and values is ignored. Whitespace within names and values is permitted. (For \texttt{version_tokens_delete()}, which takes a list of names without values, whitespace around names is ignored.)
- There is no quoting mechanism.
- Order of tokens is not significant except that if a token list contains multiple instances of a given token name, the last value takes precedence over earlier values.

Given those rules, the preceding \texttt{version_tokens_set()} call results in a token list with two tokens: \texttt{tok1} has the value \texttt{1'2 3"4}, and \texttt{tok2} has the value \texttt{a = b}. To verify this, call \texttt{version_tokens_show()}:

\begin{verbatim}
mysql> SELECT version_tokens_show();
+--------------------------+
| version_tokens_show()    |
+--------------------------+
| tok2=a = b;tok1=1'2 3"4; |
+--------------------------+
\end{verbatim}

If the token list contains two tokens, why did \texttt{version_tokens_set()} return the value \texttt{3 version tokens set}? That occurred because the original token list contained two definitions for \texttt{tok1}, and the second definition replaced the first.

The Version Tokens token-manipulation UDFs place these constraints on token names and values:

- Token names cannot contain \texttt{=} or ; characters and have a maximum length of 64 characters.
- Token values cannot contain ; characters. Length of values is constrained by the value of the \texttt{max_allowed_packet} system variable.
- Version Tokens treats token names and values as binary strings, so comparisons are case-sensitive.

Version Tokens also includes a set of UDFs enabling tokens to be locked and unlocked:

- \texttt{version_tokens_lock_exclusive()} acquires exclusive version token locks. It takes a list of one or more lock names and a timeout value.
• `version_tokens_lock_shared()` acquires shared version token locks. It takes a list of one or more lock names and a timeout value.

• `version_tokens_unlock()` releases version token locks (exclusive and shared). It takes no argument.

Each locking function returns nonzero for success. Otherwise, an error occurs:

```
mysql> SELECT version_tokens_lock_shared('lock1', 'lock2', 0); +-------------------------------------------------+
| version_tokens_lock_shared('lock1', 'lock2', 0) |
+-------------------------------------------------+
|                                               1 |
+-------------------------------------------------+
```

```
mysql> SELECT version_tokens_lock_shared(NULL, 0);
ERROR 3131 (42000): Incorrect locking service lock name '(null)'.
```

Locking using Version Tokens locking functions is advisory; applications must agree to cooperate.

It is possible to lock nonexisting token names. This does not create the tokens.

```
mysql> SELECT version_tokens_lock_shared(NULL, 0);
```

Note

Version Tokens locking functions are based on the locking service described at Section 5.6.8.1, “The Locking Service”, and thus have the same semantics for shared and exclusive locks. (Version Tokens uses the locking service routines built into the server, not the locking service UDF interface, so those UDFs need not be installed to use Version Tokens.) Locks acquired by Version Tokens use a locking service namespace of `version_token_locks`. Locking service locks can be monitored using the Performance Schema, so this is also true for Version Tokens locks. For details, see Locking Service Monitoring.

For the Version Tokens locking functions, token name arguments are used exactly as specified. Surrounding whitespace is not ignored and = and ; characters are permitted. This is because Version Tokens simply passes the token names to be locked as is to the locking service.

5.6.6.4 Version Tokens Reference

The following discussion serves as a reference to these Version Tokens elements:

• Version Tokens Functions

• Version Tokens System Variables

Version Tokens Functions

The Version Tokens plugin library includes several user-defined functions. One set of UDFs permits the server’s list of version tokens to be manipulated and inspected. Another set of UDFs permits version tokens to be locked and unlocked. The `VERSION_TOKEN_ADMIN` privilege (or the deprecated `SUPER` privilege) is required to invoke any Version Tokens UDF.

The following UDFs permit the server’s list of version tokens to be created, changed, removed, and inspected. Interpretation of `name_list` and `token_list` arguments (including whitespace handling) occurs as described in Section 5.6.6.3, “Using Version Tokens”, which provides details about the syntax for specifying tokens, as well as additional examples.

• `version_tokens_delete(name_list)`
Deletes tokens from the server’s list of version tokens using the `name_list` argument and returns a binary string that indicates the outcome of the operation. `name_list` is a semicolon-separated list of version token names to delete.

```
mysql> SELECT version_tokens_delete('tok1;tok3');
+------------------------------------+
| version_tokens_delete('tok1;tok3') |
| 2 version tokens deleted.          |
+------------------------------------+
```

An argument of `NULL` is treated as an empty string, which has no effect on the token list.

```
version_tokens_delete() deletes the tokens named in its argument, if they exist. (It is not an error to delete nonexisting tokens.) To clear the token list entirely without knowing which tokens are in the list, pass `NULL` or a string containing no tokens to `version_tokens_set()`:

```
mysql> SELECT version_tokens_set(NULL);
+------------------------------+
| version_tokens_set(NULL)     |
| Version tokens list cleared. |
+------------------------------+
mysql> SELECT version_tokens_set('');
+------------------------------+
| version_tokens_set('')       |
| Version tokens list cleared. |
+------------------------------+
```

• `version_tokens_edit(token_list)`

Modifies the server’s list of version tokens using the `token_list` argument and returns a binary string that indicates the outcome of the operation. `token_list` is a semicolon-separated list of `name=value` pairs specifying the name of each token to be defined and its value. If a token exists, its value is updated with the given value. If a token does not exist, it is created with the given value. If the argument is `NULL` or a string containing no tokens, the token list remains unchanged.

```
mysql> SELECT version_tokens_set('tok1=value1;tok2=value2');
+-----------------------------------------------+
| version_tokens_set('tok1=value1;tok2=value2') |
| 2 version tokens set.                         |
+-----------------------------------------------+
mysql> SELECT version_tokens_edit('tok2=new_value2;tok3=new_value3');
+--------------------------------------------------------+
| version_tokens_edit('tok2=new_value2;tok3=new_value3') |
| 2 version tokens updated.                      |
+--------------------------------------------------------+
```

• `version_tokens_set(token_list)`

Replaces the server’s list of version tokens with the tokens defined in the `token_list` argument and returns a binary string that indicates the outcome of the operation. `token_list` is a semicolon-separated list of `name=value` pairs specifying the name of each token to be defined and its value. If the argument is `NULL` or a string containing no tokens, the token list is cleared.

```
mysql> SELECT version_tokens_set('tok1=value1;tok2=value2');
+-----------------------------------------------+
| version_tokens_set('tok1=value1;tok2=value2') |
+-----------------------------------------------+
```

1062
Version Tokens

| 2 version tokens set. |
+-----------------------|

version_tokens_show()

Returns the server's list of version tokens as a binary string containing a semicolon-separated list of name=value pairs.

```
mysql> SELECT version_tokens_show();
+--------------------------+
| version_tokens_show()    |
+--------------------------+
| tok2=value2;tok1=value1; |
+--------------------------+
```

The following UDFs permit version tokens to be locked and unlocked:

version_tokens_lock_exclusive(token_name[, token_name] ... , timeout)

Acquires exclusive locks on one or more version tokens, specified by name as strings, timing out with an error if the locks are not acquired within the given timeout value.

```
mysql> SELECT version_tokens_lock_exclusive('lock1', 'lock2', 10);
+-----------------------------------------------------+
| version_tokens_lock_exclusive('lock1', 'lock2', 10) |
+-----------------------------------------------------+
|                                                   1 |
+-----------------------------------------------------+
```

version_tokens_lock_shared(token_name[, token_name] ... , timeout)

Acquires shared locks on one or more version tokens, specified by name as strings, timing out with an error if the locks are not acquired within the given timeout value.

```
mysql> SELECT version_tokens_lock_shared('lock1', 'lock2', 10);
+--------------------------------------------------+
| version_tokens_lock_shared('lock1', 'lock2', 10) |
+--------------------------------------------------+
|                                                1 |
+--------------------------------------------------+
```

version_tokens_unlock()

Releases all locks that were acquired within the current session using version_tokens_lock_exclusive() and version_tokens_lock_shared().

```
mysql> SELECT version_tokens_unlock();
+-------------------------+
| version_tokens_unlock() |
|                       1 |
+-------------------------+
```

The locking functions share these characteristics:

- The return value is nonzero for success. Otherwise, an error occurs.
- Token names are strings.
- In contrast to argument handling for the UDFs that manipulate the server token list, whitespace surrounding token name arguments is not ignored and = and ; characters are permitted.
- It is possible to lock nonexisting token names. This does not create the tokens.
Version Tokens

- Timeout values are nonnegative integers representing the time in seconds to wait to acquire locks before timing out with an error. If the timeout is 0, there is no waiting and the function produces an error if locks cannot be acquired immediately.

- Version Tokens locking functions are based on the locking service described at Section 5.6.8.1, “The Locking Service”.

Version Tokens System Variables

Version Tokens supports the following system variables. These variables are unavailable unless the Version Tokens plugin is installed (see Section 5.6.6.2, “Installing or Uninstalling Version Tokens”).

System variables:

- `version_tokens_session`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--version-tokens-session=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>version_tokens_session</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The session value of this variable specifies the client version token list and indicates the tokens that the client session requires the server version token list to have.

If the `version_tokens_session` variable is `NULL` (the default) or has an empty value, any server version token list matches. (In effect, an empty value disables matching requirements.)

If the `version_tokens_session` variable has a nonempty value, any mismatch between its value and the server version token list results in an error for any statement the session sends to the server. A mismatch occurs under these conditions:

- A token name in the `version_tokens_session` value is not present in the server token list. In this case, an `ER_VTOKEN_PLUGIN_TOKEN_NOT_FOUND` error occurs.

- A token value in the `version_tokens_session` value differs from the value of the corresponding token in the server token list. In this case, an `ER_VTOKEN_PLUGIN_TOKEN_MISMATCH` error occurs.

It is not a mismatch for the server version token list to include a token not named in the `version_tokens_session` value.

Suppose that a management application has set the server token list as follows:

```
mysql> SELECT version_tokens_set('tok1=a;tok2=b;tok3=c');
+--------------------------------------------+
| version_tokens_set('tok1=a;tok2=b;tok3=c') |
| 3 version tokens set.                     |
+--------------------------------------------+
```

A client registers the tokens it requires the server to match by setting its `version_tokens_session` value. Then, for each subsequent statement sent by the client, the server checks its token list against the client `version_tokens_session` value and produces an error if there is a mismatch:
The first `SELECT` succeeds because the client tokens `tok1` and `tok2` are present in the server token list and each token has the same value in the server list. The second `SELECT` fails because, although `tok1` is present in the server token list, it has a different value than specified by the client.

At this point, any statement sent by the client fails, unless the server token list changes such that it matches again. Suppose that the management application changes the server token list as follows:

```
mysql> SELECT version_tokens_edit('tok1=b');
+-------------------------------+
| version_tokens_edit('tok1=b') |
| 1 version tokens updated.     |
+-------------------------------+
mysql> SELECT version_tokens_show();
+-----------------------+
| version_tokens_show()   |
| tok3=c;tok1=b;tok2=b;    |
+-----------------------+
```

Now the client `version_tokens_session` value matches the server token list and the client can once again successfully execute statements:

```
mysql> SELECT 1;
+---+
| 1 |
+---+
| 1 |
+---+
```

- `version_tokens_session_number`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--version-tokens-session-number=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>version_tokens_session_number</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

This variable is for internal use.

### 5.6.7 The Clone Plugin

The clone plugin permits cloning data locally or from a remote MySQL server instance. Cloned data is a physical snapshot of data stored in **InnoDB** that includes schemas, tables, tablespaces, and data...
dictionary metadata. The cloned data comprises a fully functional data directory, which permits using the clone plugin for MySQL server provisioning.

**Figure 5.1 Local Cloning Operation**

A local cloning operation clones data from the MySQL server instance where the cloning operation is initiated to a directory on the same server or node where MySQL server instance runs.

**Figure 5.2 Remote Cloning Operation**

A remote cloning operation involves a local MySQL server instance (the “recipient”) where the cloning operation is initiated, and a remote MySQL server instance (the “donor”) where the source data is located. When a remote cloning operation is initiated on the recipient, cloned data is transferred over the network from the donor to the recipient. By default, a remote cloning operation removes the data in the recipient data directory and replaces it with the cloned data. Optionally, you can clone data to a different directory on the recipient to avoid removing existing data.

There is no difference with respect to data that is cloned by a local cloning operation as compared to a remote cloning operation. Both operations clone the same data.

The clone plugin supports replication. In addition to cloning data, a cloning operation extracts and transfers replication coordinates from the donor and applies them on the recipient, which enables using the clone
The Clone Plugin

The clone plugin supports cloning of encrypted and page-compressed data. See Section 5.6.7.4, "Cloning Encrypted Data", and Section 5.6.7.5, "Cloning Compressed Data".

The clone plugin must be installed before you can use it. For installation instructions, see Section 5.6.7.1, "Installing the Clone Plugin". For cloning instructions, see Section 5.6.7.2, "Cloning Data Locally", and Section 5.6.7.3, "Cloning Remote Data".

Performance Schema tables and instrumentation are provided for monitoring cloning operations. See Section 5.6.7.9, "Monitoring Cloning Operations".

5.6.7.1 Installing the Clone Plugin

This section describes how to install and configure the clone plugin. For remote cloning operations, the clone plugin must be installed on the donor and recipient MySQL server instances.

For general information about installing or uninstalling plugins, see Section 5.6.1, "Installing and Uninstalling Plugins".

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the plugin_dir system variable). If necessary, set the value of plugin_dir at server startup to tell the server the plugin directory location.

The plugin library file base name is mysql_clone.so. The file name suffix differs by platform (for example, .so for Unix and Unix-like systems, .dll for Windows).

To load the plugin at server startup, use the --plugin-load-add option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in your my.cnf file, adjusting the .so suffix for your platform as necessary:

```ini
[mysqld]
plugin-load-add=mysql_clone.so
```

After modifying my.cnf, restart the server to cause the new settings to take effect.

Note

The --plugin-load-add option cannot be used to load the clone plugin when restarting the server during an upgrade from a previous MySQL version. For example, after upgrading binaries or packages from MySQL 5.7 to MySQL 8.0, attempting to restart the server with plugin-load-add=mysql_clone.so causes this error: [ERROR] [MY-013238] [Server] Error installing plugin 'clone': Cannot install during upgrade. The workaround is to upgrade the server before attempting to start the server with plugin-load-add=mysql_clone.so.

Alternatively, to load the plugin at runtime, use this statement, adjusting the .so suffix for your platform as necessary:

```sql
INSTALL PLUGIN clone SONAME 'mysql_clone.so';
```

INSTALL PLUGIN loads the plugin, and also registers it in the mysql.plugins system table to cause the plugin to be loaded for each subsequent normal server startup without the need for --plugin-load-add.
To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```sql
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME = 'clone';
```

<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>PLUGIN_STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>clone</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>

If the plugin fails to initialize, check the server error log for clone or plugin-related diagnostic messages.

If the plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load-add`, you can use the `--clone` option at server startup to control the plugin activation state. For example, to load the plugin at startup and prevent it from being removed at runtime, use these options:

```ini
[mysqld]
plugin-load-add=mysql_clone.so
clone=FORCE_PLUS_PERMANENT
```

If you want to prevent the server from running without the clone plugin, use `--clone` with a value of `FORCE` or `FORCE_PLUS_PERMANENT` to force server startup to fail if the plugin does not initialize successfully.

For more information about plugin activation states, see Controlling Plugin Activation State.

### 5.6.7.2 Cloning Data Locally

The clone plugin supports the following syntax for cloning data locally; that is, cloning data from the local MySQL data directory to another directory on the same server or node where the MySQL server instance runs:

```sql
CLONE LOCAL DATA DIRECTORY [-] 'clone_dir';
```

To use `CLONE` syntax, the clone plugin must be installed. For installation instructions, see Section 5.6.7.1, “Installing the Clone Plugin”.

The `BACKUP_ADMIN` privilege is required to execute `CLONE LOCAL DATA DIRECTORY` statements.

```sql
mysql> GRANT BACKUP_ADMIN ON *.* TO 'clone_user';
```

where `clone_user` is the MySQL user that performs the cloning operation. The user you select to perform the cloning operation can be any MySQL user with the `BACKUP_ADMIN` privilege on `*.*`.

The following example demonstrates cloning data locally:

```sql
mysql> CLONE LOCAL DATA DIRECTORY = '/path/to/clone_dir';
```

where `/path/to/clone_dir` is the full path of the local directory that data is cloned to. An absolute path is required, and the specified directory ("clone_dir") must not exist, but the specified path must be an existent path. The MySQL server must have the necessary write access to create the directory.

**Note**

A local cloning operation does not support cloning of user-created tables or tablespaces that reside outside of the data directory. Attempting to clone such tables or tablespaces causes the following error: `ERROR 1086 (HY000): File '/path/to/tablespace_name.ibd' already exists`. Cloning a tablespace with the same path as the source tablespace would cause a conflict and is therefore prohibited.
The Clone Plugin

All other user-created InnoDB tables and tablespaces, the InnoDB system tablespace, redo logs, and undo tablespaces are cloned to the specified directory.

If desired, you can start the MySQL server on the cloned directory after the cloning operation is complete.

```
shell> mysqld_safe --datadir=clone_dir
```

where `clone_dir` is the directory that data was cloned to.

For information about monitoring cloning operation status and progress, see Section 5.6.7.9, “Monitoring Cloning Operations”.

5.6.7.3 Cloning Remote Data

The clone plugin supports the following syntax for cloning remote data; that is, cloning data from a remote MySQL server instance (the donor) and transferring it to the MySQL instance where the cloning operation was initiated (the recipient).

```
CLONE INSTANCE FROM 'user'@'host':port
IDENTIFIED BY 'password'
[DATA DIRECTORY [=] 'clone_dir']
[REQUIRE [NO] SSL];
```

where:

- `user` is the clone user on the donor MySQL server instance.
- `password` is the `user` password.
- `host` is the hostname address of the donor MySQL server instance. Internet Protocol version 6 (IPv6) address format is not supported. An alias to the IPv6 address can be used instead. An IPv4 address can be used as is.
- `port` is the port number of the donor MySQL server instance. (The X Protocol port specified by `mysqlx_port` is not supported. Connecting to the donor MySQL server instance through MySQL Router is also not supported.)
- DATA DIRECTORY [=] 'clone_dir' is an optional clause used to specify a directory on the recipient for the data you are cloning. Use this option if you do not want to remove existing data in the recipient data directory. An absolute path is required, and the directory must not exist. The MySQL server must have the necessary write access to create the directory.

When the optional DATA DIRECTORY [=] 'clone_dir' clause is not used, a cloning operation removes existing data in the recipient data directory, replaces it with the cloned data, and automatically restarts the server afterward.

- [REQUIRE [NO] SSL] explicitly specifies whether an encrypted connection is to be used or not when transferring cloned data over the network. An error is returned if the explicit specification cannot be satisfied. If an SSL clause is not specified, clone attempts to establish an encrypted connection by default, falling back to an insecure connection if the secure connection attempt fails. A secure connection is required when cloning encrypted data regardless of whether this clause is specified. For more information, see Configuring an Encrypted Connection for Cloning.

**Note**

By default, user-created InnoDB tables and tablespaces that reside in the data directory on the donor MySQL server instance are cloned to the data directory on the recipient MySQL server instance. If the DATA DIRECTORY [=] 'clone_dir' clause is specified, they are cloned to the specified directory.
User-created InnoDB tables and tablespaces that reside outside of the data directory on the donor MySQL server instance are cloned to the same path on the recipient MySQL server instance. An error is reported if a table or tablespace already exists.

By default, the InnoDB system tablespace, redo logs, and undo tablespaces are cloned to the same locations that are configured on the donor (as defined by `innodb_data_home_dir` and `innodb_data_file_path`, `innodb_log_group_home_dir`, and `innodb_undo_directory`, respectively). If the `DATA DIRECTORY [=] 'clone_dir'` clause is specified, those tablespaces and logs are cloned to the specified directory.

Remote Cloning Prerequisites

To perform a cloning operation, the clone plugin must be active on both the donor and recipient MySQL server instances. For installation instructions, see Section 5.6.7.1, “Installing the Clone Plugin”.

A MySQL user on the donor and recipient is required for executing the cloning operation (the “clone user”).

- On the donor, the clone user requires the `BACKUP_ADMIN` privilege for accessing and transferring data from the donor, and for blocking DDL during the cloning operation.
- On the recipient, the clone user requires the `CLONE_ADMIN` privilege for replacing recipient data, blocking DDL during the cloning operation, and automatically restarting the server. The `CLONE_ADMIN` privilege includes `BACKUP_ADMIN` and `SHUTDOWN` privileges implicitly.

Instructions for creating the clone user and granting the required privileges are included in the remote cloning example that follows this prerequisite information.

The following prerequisites are checked when the `CLONE INSTANCE` statement is executed:

- The donor and recipient must have the same MySQL server version. The clone plugin is supported in MYSQL 8.0.17 and higher.

```
mysql> SHOW VARIABLES LIKE 'version';
+---------------+--------+
| Variable_name | Value  |
+---------------+--------+
| version       | 8.0.17 |
+---------------+--------+
```

- The donor and recipient MySQL server instances must run on the same operating system and platform. For example, if the donor instance runs on a Linux 64-bit platform, the recipient instance must also run on that platform. Refer to your operating system documentation for information about how to determine your operating system platform.

- The recipient must have enough disk space for the cloned data. By default, recipient data is removed prior to cloning the donor data, so you only require enough space for the donor data. If you clone to a named directory using the `DATA DIRECTORY` clause, you must have enough disk space for the existing recipient data and the cloned data. You can estimate the size of your data by checking the data directory size on your file system and the size of any tablespaces that reside outside of the data directory. When estimating data size on the donor, remember that only InnoDB data is cloned. If you store data in other storage engines, adjust your data size estimate accordingly.

- InnoDB permits creating some tablespace types outside of the data directory. If the donor MySQL server instance has tablespaces that reside outside of the data directory, the cloning operation must be able access those tablespaces. You can query the `INFORMATION_SCHEMA.FILES` table to identify
tablespaces that reside outside of the data directory. Files that reside outside of the data directory have a fully qualified path to a directory other than the data directory.

```
mysql> SELECT FILE_NAME FROM INFORMATION_SCHEMA.FILES;
```

• Plugins that are active on the donor, including any keyring plugin, must also be active on the recipient. You can identify active plugins by issuing a `SHOW PLUGINS` statement or by querying the `INFORMATION_SCHEMA.PLUGINS` table.

• The donor and recipient must have the same MySQL server character set and collation. For information about MySQL server character set and collation configuration, see Section 10.15, “Character Set Configuration”.

• The same `innodb_page_size` and `innodb_data_file_path` settings are required on the donor and recipient. The `innodb_data_file_path` setting on the donor and recipient must specify the same number of data files of an equivalent size. You can check variable settings using `SHOW VARIABLES` syntax.

```
mysql> SHOW VARIABLES LIKE 'innodb_page_size';
mysql> SHOW VARIABLES LIKE 'innodb_data_file_path';
```

• If cloning encrypted or page-compressed data, the donor and recipient must have the same file system block size. For page-compressed data, the recipient file system must support sparse files and hole punching for hole punching to occur on the recipient. For information about these features and how to identify tables and tablespaces that use them, see Section 5.6.7.4, “Cloning Encrypted Data”, and Section 5.6.7.5, “Cloning Compressed Data”. To determine your file system block size, refer to your operating system documentation.

• A secure connection is required if you are cloning encrypted data. See Configuring an Encrypted Connection for Cloning.

• The `clone_valid_donor_list` setting on the recipient must include the host address of the donor MySQL server instance. You can only clone data from a host on the valid donor list. A MySQL user with the `SYSTEM_VARIABLES_ADMIN` privilege is required to configure this variable. Instructions for setting the `clone_valid_donor_list` variable are provided in the remote cloning example that follows this section. You can check the `clone_valid_donor_list` setting using `SHOW VARIABLES` syntax.

```
mysql> SHOW VARIABLES LIKE 'clone_valid_donor_list';
```

• There must be no other cloning operation running. Only a single cloning operation is permitted at a time. To determine if a clone operation is running, query the `clone_status` table. See Monitoring Cloning Operations using Performance Schema Clone Tables.

• The clone plugin transfers data in 1MB packets plus metadata. The minimum required `max_allowed_packet` value is therefore 2MB on the donor and the recipient MySQL server instances. A `max_allowed_packet` value less than 2MB results in an error. Use the following query to check your `max_allowed_packet` setting:

```
mysql> SHOW VARIABLES LIKE 'max_allowed_packet';
```

The following prerequisites also apply:

• Undo tablespace file names on the donor must be unique. When data is cloned to the recipient, undo tablespaces, regardless of their location on the donor, are cloned to the `innodb_undo_directory` location on the recipient or to the directory specified by the `DATA DIRECTORY [=] 'clone_dir'` clause, if used. Duplicate undo tablespace file names on the donor are not permitted for this reason. As of MySQL 8.0.18, an error is reported if duplicate undo tablespace file names are encountered during a cloning operation. Prior to MySQL 8.0.18, cloning undo tablespaces with the same file name could result in undo tablespace files being overwritten on the recipient.
To view undo tablespace file names on the donor to ensure that they are unique, query

```
INFORMATION_SCHEMA.FILES:
```

```
mysql> SELECT TABLESPACE_NAME, FILE_NAME FROM INFORMATION_SCHEMA.FILES
WHERE FILE_TYPE LIKE 'UNDO LOG';
```

For information about dropping and adding undo tablespace files, see Section 15.6.3.4, “Undo Tablespaces”.

- By default, the recipient MySQL server instance is restarted (stopped and started) automatically after the data is cloned. For an automatic restart to occur, a monitoring process must be available on the recipient to detect server shutdowns. Otherwise, the cloning operation halts with the following error after the data is cloned, and the recipient MySQL server instance is shut down:

```
ERROR 3707 (HY000): Restart server failed (mysqld is not managed by supervisor process).
```

This error does not indicate a cloning failure. It means that the recipient MySQL server instance must be started again manually after the data is cloned. After starting the server manually, you can connect to the recipient MySQL server instance and check the Performance Schema clone tables to verify that the cloning operation completed successfully (see Monitoring Cloning Operations using Performance Schema Clone Tables.) The **RESTART** statement has the same monitoring process requirement. For more information, see Section 13.7.8.8, “RESTART Statement”. This requirement is not applicable if cloning to a named directory using the **DATA DIRECTORY** clause, as an automatic restart is not performed in this case.

- Several variables control various aspects of a remote cloning operation. Before performing a remote cloning operation, review the variables and adjust settings as necessary to suit your computing environment. Clone variables are set on recipient MySQL server instance where the cloning operation is executed. See Section 5.6.7.12, “Clone System Variables”.

### Cloning Remote Data

The following example demonstrates cloning remote data. By default, a remote cloning operation removes the data in the recipient data directory, replaces it with the cloned data, and restarts the MySQL server afterward.

The example assumes that remote cloning prerequisites are met. See Remote Cloning Prerequisites.

1. Login to the donor MySQL server instance with an administrative user account.
   a. Create a clone user with the **BACKUP_ADMIN** privilege.

```
mysql> CREATE USER 'donor_clone_user'@'example.donor.host.com' IDENTIFIED BY 'password';
mysql> GRANT BACKUP_ADMIN on *.* to 'donor_clone_user'@'example.donor.host.com';
```

   b. Install the clone plugin:

```
mysql> INSTALL PLUGIN clone SONAME 'mysql_clone.so';
```

2. Login to the recipient MySQL server instance with an administrative user account.
   a. Create a clone user with the **CLONE_ADMIN** privilege.

```
mysql> CREATE USER 'recipient_clone_user'@'example.recipient.host.com' IDENTIFIED BY 'password';
mysql> GRANT CLONE_ADMIN on *.* to 'recipient_clone_user'@'example.recipient.host.com';
```

   b. Install the clone plugin:

```
mysql> INSTALL PLUGIN clone SONAME 'mysql_clone.so';
```
c. Add the host address of the donor MySQL server instance to the `clone_valid_donor_list` variable setting.

```sql
mysql> SET GLOBAL clone_valid_donor_list = 'example.donor.host.com:3306';
```

3. Log on to the recipient MySQL server instance as the clone user you created previously (`recipient_clone_user'@'example.recipient.host.com`) and execute the `CLONE INSTANCE` statement.

```sql
mysql> CLONE INSTANCE FROM 'donor_clone_user'@'example.donor.host.com':3306 IDENTIFIED BY 'password';
```

After the data is cloned, the MySQL server instance on the recipient is restarted automatically.

For information about monitoring cloning operation status and progress, see Section 5.6.7.9, "Monitoring Cloning Operations".

**Cloning to a Named Directory**

By default, a remote cloning operation removes the data in the recipient data directory and replaces it with the cloned data. By cloning to a named directory, you can avoid removing existing data from the recipient data directory.

The procedure for cloning to a named directory is the same procedure described in Cloning Remote Data with one exception: The `CLONE INSTANCE` statement must include the `DATA DIRECTORY` clause. For example:

```sql
mysql> CLONE INSTANCE FROM 'user'@'example.donor.host.com':3306 IDENTIFIED BY 'password'
   DATA DIRECTORY = '/path/to/clone_dir';
```

An absolute path is required, and the directory must not exist. The MySQL server must have the necessary write access to create the directory.

When cloning to a named directory, the recipient MySQL server instance is not restarted automatically after the data is cloned. If you want to restart the MySQL server on the named directory, you must do so manually:

```shell
shell> mysqld_safe --datadir=/path/to/clone_dir
```

where `/path/to/clone_dir` is the path to the named directory on the recipient.

**Configuring an Encrypted Connection for Cloning**

You can configure an encrypted connection for remote cloning operations to protect data as it is cloned over the network. An encrypted connection is required by default when cloning encrypted data. (see Section 5.6.7.4, "Cloning Encrypted Data").

The instructions that follow describe how to configure the recipient MySQL server instance to use an encrypted connection. It is assumed that the donor MySQL server instance is already configured to use encrypted connections. If not, refer to Section 6.3.1, "Configuring MySQL to Use Encrypted Connections" for server-side configuration instructions.

To configure the recipient MySQL server instance to use an encrypted connection:

1. Make the client certificate and key files of the donor MySQL server instance available to the recipient host. Either distribute the files to the recipient host using a secure channel or place them on a mounted
partition that is accessible to the recipient host. The client certificate and key files to make available include:

- **ca.pem**
  The self-signed certificate authority (CA) file.
- **client-cert.pem**
  The client public key certificate file.
- **client-key.pem**
  The client private key file.

2. Configure the following SSL options on the recipient MySQL server instance.

- **clone_ssl_ca**
  Specifies the path to the self-signed certificate authority (CA) file.
- **clone_ssl_cert**
  Specifies the path to the client public key certificate file.
- **clone_ssl_key**
  Specifies the path to the client private key file.

For example:

```
close_ssl_ca=/path/to/ca.pem
clone_ssl_cert=/path/to/client-cert.pem
clone_ssl_key=/path/to/client-key.pem
```

3. To require that an encrypted connection is used, include the `REQUIRE SSL` clause when issuing the `CLONE` statement on the recipient.

```
mysql> CLONE INSTANCE FROM 'user'@'example.donor.host.com':3306
    IDENTIFIED BY 'password'
    DATA DIRECTORY = '/path/to/clone_dir'
    REQUIRE SSL;
```

If an SSL clause is not specified, the clone plugin attempts to establish an encrypted connection by default, falling back to an unencrypted connection if the encrypted connection attempt fails.

**Note**

If you are cloning encrypted data, an encrypted connection is required by default regardless of whether the `REQUIRE SSL` clause is specified. Using `REQUIRE NO SSL` causes an error if you attempt to clone encrypted data.

### 5.6.7.4 Cloning Encrypted Data

Cloning of encrypted data is supported. The following requirements apply:

- A secure connection is required when cloning remote data to ensure safe transfer of unencrypted tablespace keys over the network. Tablespace keys are decrypted at the donor before transport and re-encrypted at the recipient using the recipient master key. An error is reported if an encrypted connection
is not available or the `REQUIRE NO SSL` clause is used in the `CLONE INSTANCE` statement. For information about configuring an encrypted connection for cloning, see Configuring an Encrypted Connection for Cloning.

- When cloning data to a local data directory that uses a locally managed keyring, the same keyring must be used when starting the MySQL server on the clone directory.

- When cloning data to a remote data directory (the recipient directory) that uses a locally managed keyring, the recipient keyring must be used when starting the MySQL server on the cloned directory.

**Note**

The `innodb_redo_log_encrypt` and `innodb_undo_log_encrypt` variable settings cannot be modified while a cloning operation is in progress.

For information about the data encryption feature, see Section 15.13, “InnoDB Data-at-Rest Encryption”.

## 5.6.7.5 Cloning Compressed Data

Cloning of page-compressed data is supported. The following requirements apply when cloning remote data:

- The recipient file system must support sparse files and hole punching for hole punching to occur on the recipient.

- The donor and recipient file systems must have the same block size. If file system block sizes differ, an error similar to the following is reported: ERROR 3868 (HY000): Clone Configuration FS Block Size: Donor value: 114688 is different from Recipient value: 4096.

For information about the page compression feature, see Section 15.9.2, “InnoDB Page Compression”.

## 5.6.7.6 Cloning for Replication

The clone plugin supports replication. In addition to cloning data, a cloning operation extracts replication coordinates from the donor and transfers them to the recipient, which enables using the clone plugin for provisioning Group Replication members and replicas. Using the clone plugin for provisioning is considerably faster and more efficient than replicating a large number of transactions.

Group Replication members can also be configured to use the clone plugin as an option for distributed recovery, in which case joining members automatically choose the most efficient way to retrieve group data from existing group members. For more information, see Section 18.4.3.2, “Cloning for Distributed Recovery”.

During the cloning operation, both the binary log position (filename, offset) and the `gtid_executed` GTID set are extracted and transferred from the donor MySQL server instance to the recipient. This data permits initiating replication at a consistent position in the replication stream. The binary logs and relay logs, which are held in files, are not copied from the donor to the recipient. To initiate replication, the binary logs required for the recipient to catch up to the donor must not be purged between the time that the data is cloned and the time that replication is started. If the required binary logs are not available, a replication handshake error is reported. A cloned instance should therefore be added to a replication group without excessive delay to avoid required binary logs being purged or the new member lagging behind significantly, requiring more recovery time.

- Issue this query on a cloned MySQL server instance to check the binary log position that was transferred to the recipient:

```sql
mysql> SELECT BINLOG_FILE, BINLOG_POSITION FROM performance_schema.clone_status;
```
• Issue this query on a cloned MySQL server instance to check the `gtid_executed` GTID set that was transferred to the recipient:

```sql
mysql> SELECT @@GLOBAL.GTID_EXECUTED;
```

When `master_info_repository=TABLE` and `relay_log_info_repository=TABLE` are set on the recipient (which is the default in MySQL 8.0), the replication metadata repositories are held in tables that are copied from the donor to the recipient during the cloning operation. The replication metadata repositories hold replication-related configuration settings that can be used to resume replication correctly after the cloning operation.

• In MySQL 8.0.17 and 8.0.18, only the table `mysql.slave_master_info` (the connection metadata repository) is copied.

• From MySQL 8.0.19, the tables `mysql.slave_relay_log_info` (the applier metadata repository) and `mysql.slave_worker_info` (the applier worker metadata repository) are also copied.

For a list of what is included in each table, see Section 17.2.4.2, “Replication Metadata Repositories”. Note that if `master_info_repository=FILE` and `relay_log_info_repository=FILE` are set on the server (which is not the default in MySQL 8.0 and is deprecated), the replication metadata repositories are not cloned; they are only cloned if `TABLE` is set.

To clone for replication, perform the following steps:

1. For a new group member for Group Replication, first configure the MySQL Server instance for Group Replication, following the instructions in Section 18.2.1.6, “Adding Instances to the Group”. Also set up the prerequisites for cloning described in Section 18.4.3.2, “Cloning for Distributed Recovery”. When you issue `START GROUP_REPLICATION` on the joining member, the cloning operation is managed automatically by Group Replication, so you do not need to carry out the operation manually, and you do not need to perform any further setup steps on the joining member.

2. For a replica in a source/replica MySQL replication topology, first clone the data from the donor MySQL server instance to the recipient manually. The donor must be a source or replica in the replication topology. For cloning instructions, see Section 5.6.7.3, “Cloning Remote Data”.

3. After the cloning operation completes successfully, if you want to use the same replication channels on the recipient MySQL server instance that were present on the donor, verify which of them can resume replication automatically in the source/replica MySQL replication topology, and which need to be set up manually.

• For GTID-based replication, if the recipient is configured with `gtid_mode=ON` and has cloned from a donor with `gtid_mode=ON, ON_PERMISSIVE, or OFF_PERMISSIVE`, the `gtid_executed` GTID set from the donor is applied on the recipient. If the recipient is cloned from a replica already in the topology, replication channels on the recipient that use GTID auto-positioning (as specified by the `MASTER_AUTO_POSITION` option on the `CHANGE MASTER TO` statement) can resume replication automatically after the cloning operation when the channel is started. You do not need to perform any manual setup if you just want to use these same channels.

• For binary log file position based replication, if the recipient is at MySQL 8.0.17 or 8.0.18, the binary log position from the donor is not applied on the recipient, only recorded in the Performance Schema `clone_status` table. Replication channels on the recipient that use binary log file position based replication must therefore be set up manually to resume replication after the cloning operation. Ensure that these channels are not configured to start replication automatically at server startup, as they do not yet have the binary log position and attempt to start replication from the beginning.

• For binary log file position based replication, if the recipient is at MySQL 8.0.19 or above, the binary log position from the donor is applied on the recipient. Replication channels on the recipient
The Clone Plugin

that use binary log file position based replication automatically attempt to carry out the relay log recovery process, using the cloned relay log information, before restarting replication. For a single-threaded replica (\texttt{slave_parallel_workers} is set to 0), relay log recovery should succeed in the absence of any other issues, enabling the channel to resume replication with no further setup. For a multithreaded replica (\texttt{slave_parallel_workers} is greater than 0), relay log recovery is likely to fail because it cannot usually be completed automatically. In this case, an error message is issued, and you must set the channel up manually.

4. If you need to set up cloned replication channels manually, or want to use different replication channels on the recipient, the following instructions provide a summary and abbreviated examples for adding a recipient MySQL server instance to a replication topology. Also refer to the detailed instructions that apply to your replication setup.

- To add a recipient MySQL server instance to a MySQL replication topology that uses GTID-based transactions as the replication data source, configure the instance as required, following the instructions in Section 17.1.3.4, “Setting Up Replication Using GTIDs”. Add replication channels for the instance as shown in the following abbreviated example. The \texttt{CHANGE MASTER TO} statement must define the host address and port number of the source, and the \texttt{MASTER_AUTO_POSITION} option should be enabled, as shown:

```sql
mysql> CHANGE MASTER TO MASTER_HOST = 'source_host_name', MASTER_PORT = source_port_num, ...
    ... MASTER_AUTO_POSITION = 1,
    ... FOR CHANNEL 'setup_channel';
mysql> START SLAVE USER = 'user_name' PASSWORD = 'password' FOR CHANNEL 'setup_channel';
```

Or from MySQL 8.0.22:

```sql
mysql> START REPLICA USER = 'user_name' PASSWORD = 'password' FOR CHANNEL 'setup_channel';
```

- To add a recipient MySQL server instance to a MySQL replication topology that uses binary log file position based replication, configure the instance as required, following the instructions in Section 17.1.2, “Setting Up Binary Log File Position Based Replication”. Add replication channels for the instance as shown in the following abbreviated example, using the binary log position that was transferred to the recipient during the cloning operation:

```sql
mysql> SELECT BINLOG_FILE, BINLOG_POSITION FROM performance_schema.clone_status;
mysql> CHANGE MASTER TO MASTER_HOST = 'source_host_name', MASTER_PORT = source_port_num, ...
    ... MASTER_LOG_FILE = 'source_log_name',
    ... MASTER_LOG_POS = source_log_pos,
    ... FOR CHANNEL 'setup_channel';
mysql> START SLAVE USER = 'user_name' PASSWORD = 'password' FOR CHANNEL 'setup_channel';
```

Or from MySQL 8.0.22:

```sql
mysql> START REPLICA USER = 'user_name' PASSWORD = 'password' FOR CHANNEL 'setup_channel';
```

5.6.7.7 Directories and Files Created During a Cloning Operation

When data is cloned, the following directories and files are created for internal use. They should not be modified.

- \texttt{#clone}: Contains internal clone files used by the cloning operation. Created in the directory that data is cloned to.
- \texttt{#ib_archive}: Contains internally archived log files, archived on the donor during the cloning operation.
- *.*\texttt{clone} files: Temporary data files created on the recipient while the existing data directory is replaced by a remote cloning operation.

5.6.7.8 Remote Cloning Operation Failure Handling

This section describes failure handling at different stages of a cloning operation.
1. Prerequisites are checked (see Remote Cloning Prerequisites).
   • If a failure occurs during the prerequisite check, the `CLONE INSTANCE` operation reports an error.

2. A backup lock is taken to block DDL operations.
   • If the cloning operation is unable to obtain a DDL lock within the time limit specified by the `clone_ddl_timeout` variable, an error is reported.

3. User-created data (schemas, tables, tablespaces) and binary logs on the recipient are removed before data is cloned to the recipient data directory.
   • When user created data is removed from the recipient during a remote cloning operation, existing data in the recipient data directory is not saved and may be lost if a failure occurs. If the data to be replaced on the recipient is of importance, a backup should be taken before initiating a remote cloning operation.

   For informational purposes, warnings are printed to the server error log to specify when data removal starts and finishes:

   ![Warning] [MY-013453] [InnoDB] Clone removing all user data for provisioning: Started...
   ![Warning] [MY-013453] [InnoDB] Clone removing all user data for provisioning: Finished

   If a failure occurs while removing data, the recipient may be left with a partial set of schemas, tables, and tablespaces that existed before the cloning operation. Any time during the execution of a cloning operation or after a failure, the server is always in a consistent state.

4. Data is cloned from the donor. User-created data, dictionary metadata, and other system data are cloned.
   • If a failure occurs while cloning data, the cloning operation is rolled back and all cloned data removed. At this stage, the previously existing data on the recipient has also been removed, which leaves the recipient with no user data.

   Should this scenario occur, you can either rectify the cause of the failure and re-execute the cloning operation, or forgo the cloning operation and restore the recipient data from a backup taken before the cloning operation.

5. The server is restarted automatically (applies to remote cloning operations that do not clone to a named directory). During startup, typical server startup tasks are performed.
   • If the automatic server restart fails, you can restart the server manually to complete the cloning operation.

   If a network error occurs during a cloning operation, the operation resumes if the error is resolved within five minutes. Otherwise, the operation aborts and returns an error.

**5.6.7.9 Monitoring Cloning Operations**

This section describes options for monitoring cloning operations.

- Monitoring Cloning Operations using Performance Schema Clone Tables
- Monitoring Cloning Operations Using Performance Schema Stage Events
- Monitoring Cloning Operations Using Performance Schema Clone Instrumentation
Monitoring Cloning Operations using Performance Schema Clone Tables

A cloning operation may take some time to complete, depending on the amount of data and other factors related to data transfer. You can monitor the status and progress of a cloning operation on the recipient MySQL server instance using the `clone_status` and `clone_progress` Performance Schema tables.

The `clone_status` and `clone_progress` Performance Schema tables can be used to monitor a cloning operation on the recipient MySQL server instance only. To monitor a cloning operation on the donor MySQL server instance, use the clone stage events, as described in Monitoring Cloning Operations Using Performance Schema Stage Events.

- The `clone_status` table provides the state of the current or last executed cloning operation. A clone operation has four possible states: Not Started, In Progress, Completed, and Failed.

- The `clone_progress` table provides progress information for the current or last executed clone operation, by stage. The stages of a cloning operation include DROP DATA, FILE COPY, PAGE_COPY, REDO_COPY, FILE_SYNC, RESTART, and RECOVERY.

The `SELECT` and `EXECUTE` privileges on the Performance Schema is required to access the Performance Schema clone tables.

To check the state of a cloning operation:
1. Connect to the recipient MySQL server instance.
2. Query the `clone_status` table:

```sql
mysql> SELECT STATE FROM performance_schema.clone_status;
+-----------+
| STATE     |
+-----------+
| Completed |
```

Should a failure occur during a cloning operation, you can query the `clone_status` table for error information:

```sql
mysql> SELECT STATE, ERROR_NO, ERROR_MESSAGE FROM performance_schema.clone_status;
+-----------+----------+---------------+
| STATE     | ERROR_NO | ERROR_MESSAGE |
+-----------+----------+---------------+
| Failed    | xxx      | "xxxxxxxxxxx" |
```

To review the details of each stage of a cloning operation:
1. Connect to the recipient MySQL server instance.
2. Query the `clone_progress` table. For example, the following query provides state and end time data for each stage of the cloning operation:

```sql
mysql> SELECT STAGE, STATE, END_TIME FROM performance_schema.clone_progress;
+-----------+-----------+----------------------------+
| stage     | state     | end_time                   |
+-----------+-----------+----------------------------+
| DROP DATA | Completed | 2019-01-27 22:45:43.141261 |
```
Monitoring Cloning Operations Using Performance Schema Stage Events

A cloning operation may take some time to complete, depending on the amount of data and other factors related to data transfer. There are three stage events for monitoring the progress of a cloning operation. Each stage event reports \texttt{WORK\_COMPLETED} and \texttt{WORK\_ESTIMATED} values. Reported values are revised as the operation progresses.

This method of monitoring a cloning operation can be used on the donor or recipient MySQL server instance.

In order of occurrence, cloning operation stage events include:

- \texttt{stage/innodb/clone\%\% (file copy)}: Indicates progress of the file copy phase of the cloning operation. \texttt{WORK\_ESTIMATED} and \texttt{WORK\_COMPLETED} units are file chunks. The number of files to be transferred is known at the start of the file copy phase, and the number of chunks is estimated based on the number of files. \texttt{WORK\_ESTIMATED} is set to the number of estimated file chunks. \texttt{WORK\_COMPLETED} is updated after each chunk is sent.

- \texttt{stage/innodb/clone\%\% (page copy)}: Indicates progress of the page copy phase of cloning operation. \texttt{WORK\_ESTIMATED} and \texttt{WORK\_COMPLETED} units are pages. Once the file copy phase is completed, the number of pages to be transferred is known, and \texttt{WORK\_ESTIMATED} is set to this value. \texttt{WORK\_COMPLETED} is updated after each page is sent.

- \texttt{stage/innodb/clone\%\% (redo copy)}: Indicates progress of the redo copy phase of cloning operation. \texttt{WORK\_ESTIMATED} and \texttt{WORK\_COMPLETED} units are redo chunks. Once the page copy phase is completed, the number of redo chunks to be transferred is known, and \texttt{WORK\_ESTIMATED} is set to this value. \texttt{WORK\_COMPLETED} is updated after each chunk is sent.

The following example demonstrates how to enable \texttt{stage/innodb/clone\%\% event instruments} and related consumer tables to monitor a cloning operation. For information about Performance Schema stage event instruments and related consumers, see \autoref{sec:performance-schema-stage-event-tables}.

1. Enable the \texttt{stage/innodb/clone\%\% instruments}:
   ```sql
   mysql> UPDATE performance_schema.setup_instruments SET ENABLED = 'YES'
        WHERE NAME LIKE 'stage/innodb/clone%';
   ```

2. Enable the stage event consumer tables, which include \texttt{events\_stages\_current}, \texttt{events\_stages\_history}, and \texttt{events\_stages\_history\_long}.
   ```sql
   mysql> UPDATE performance_schema.setup_consumers SET ENABLED = 'YES'
        WHERE NAME LIKE '%stages%';
   ```

3. Run a cloning operation. In this example, a local data directory is cloned to a directory named \texttt{cloned\_dir}.
   ```sql
   mysql> CLONE LOCAL DATA DIRECTORY = '/path/to/cloned\_dir';
   ```
4. Check the progress of the cloning operation by querying the Performance Schema `events_stages_current` table. The stage event shown differs depending on the cloning phase that is in progress. The `WORK_COMPLETED` column shows the work completed. The `WORK_ESTIMATED` column shows the work required in total.

```sql
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED FROM performance_schema.events_stages_current
WHERE EVENT_NAME LIKE 'stage/innodb/clone%';
+----------------+----------------+----------------+
| EVENT_NAME      | WORK_COMPLETED | WORK_ESTIMATED |
+----------------+----------------+----------------+
| stage/innodb/clone (redo copy) |              1 |              1 |
+----------------+----------------+----------------+
```

The `events_stages_current` table returns an empty set if the cloning operation has finished. In this case, you can check the `events_stages_history` table to view event data for the completed operation. For example:

```sql
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED FROM events_stages_history
WHERE EVENT_NAME LIKE 'stage/innodb/clone%';
+----------------+----------------+----------------+
| EVENT_NAME      | WORK_COMPLETED | WORK_ESTIMATED |
+----------------+----------------+----------------+
| stage/innodb/clone (file copy) |            301 |            301 |
| stage/innodb/clone (page copy) |              0 |              0 |
| stage/innodb/clone (redo copy) |              1 |              1 |
+----------------+----------------+----------------+
```

**Monitoring Cloning Operations Using Performance Schema Clone Instrumentation**

Performance Schema provides instrumentation for advanced performance monitoring of clone operations. To view the available clone instrumentation, issue the following query:

```sql
mysql> SELECT * FROM performance_schema.setup_instruments
WHERE NAME LIKE '%clone%';
+-----------------------------+-------+
| NAME                        | ENABLED |
+-----------------------------+-------+
| wait/synch/mutex/innodb/clone_snapshot_mutex | NO    |
| wait/synch/mutex/innodb/clone_sys_mutex | NO    |
| wait/synch/mutex/innodb/clone_task_mutex | NO    |
| wait/io/file/innodb/innodb_clone_file | YES   |
| stage/innodb/clone (file copy) | YES   |
| stage/innodb/clone (redo copy) | YES   |
| stage/innodb/clone (page copy) | YES   |
| statement/abstract/clone    | YES   |
| statement/clone/local       | YES   |
| statement/clone/client      | YES   |
| statement/clone/server      | YES   |
| memory/innodb/clone         | YES   |
| memory/clone/data           | YES   |
+-----------------------------+-------+
```

**Wait Instruments**

Performance schema wait instruments track events that take time. Clone wait event instruments include:

- **wait/synch/mutex/innodb/clone_snapshot_mutex**: Tracks wait events for the clone snapshot mutex, which synchronizes access to the dynamic snapshot object (on the donor and recipient) between multiple clone threads.

- **wait/synch/mutex/innodb/clone_sys_mutex**: Tracks wait events for the clone sys mutex. There is one clone system object in a MySQL server instance. This mutex synchronizes access to the clone
system object on the donor and recipient. It is acquired by clone threads and other foreground and background threads.

- **wait/synch/mutex/innodb/clone_task_mutex**: Tracks wait events for the clone task mutex, used for clone task management. The `clone_task_mutex` is acquired by clone threads.

- **wait/io/file/innodb/innodb_clone_file**: Tracks all I/O wait operations for files that clone operates on.

For information about monitoring InnoDB mutex waits, see Section 15.16.2, “Monitoring InnoDB Mutex Waits Using Performance Schema”. For information about monitoring wait events in general, see Section 26.12.4, “Performance Schema Wait Event Tables”.

### Stage Instruments

Performance Schema stage events track steps that occur during the statement-execution process. Clone stage event instruments include:

- **stage/innodb/clone (file copy)**: Indicates progress of the file copy phase of the cloning operation.

- **stage/innodb/clone (redo copy)**: Indicates progress of the redo copy phase of cloning operation.

- **stage/innodb/clone (page copy)**: Indicates progress of the page copy phase of cloning operation.

For information about monitoring cloning operations using stage events, see Monitoring Cloning Operations Using Performance Schema Stage Events. For general information about monitoring stage events, see Section 26.12.5, “Performance Schema Stage Event Tables”.

### Statement Instruments

Performance Schema statement events track statement execution. When a clone operation is initiated, the different statement types tracked by clone statement instruments may be executed in parallel. You can observe these statement events in the Performance Schema statement event tables. The number of statements that execute depends on the `clone_max_concurrency` and `clone_autotune_concurrency` settings.

Clone statement event instruments include:

- **statement/abstract/clone**: Tracks statement events for any clone operation before it is classified as a local, client, or server operation type.

- **statement/clone/local**: Tracks clone statement events for local clone operations; generated when executing a `CLONE LOCAL` statement.

- **statement/clone/client**: Tracks remote cloning statement events that occur on the recipient MySQL server instance; generated when executing a `CLONE INSTANCE` statement on the recipient.

- **statement/clone/server**: Tracks remote cloning statement events that occur on the donor MySQL server instance; generated when executing a `CLONE INSTANCE` statement on the recipient.

For information about monitoring Performance Schema statement events, see Section 26.12.6, “Performance Schema Statement Event Tables”.

### Memory Instruments

Performance Schema memory instruments track memory usage. Clone memory usage instruments include:
The Clone Plugin

- **memory/innodb/clone**: Tracks memory allocated by InnoDB for the dynamic snapshot.
- **memory/clone/data**: Tracks memory allocated by the clone plugin during a clone operation.

For information about monitoring memory usage using Performance Schema, see Section 26.12.18.10, “Memory Summary Tables”.

The Com_clone Status Variable

The Com_clone status variable provides a count of CLONE statement executions.

For more information, refer to the discussion about Com_xxx statement counter variables in Section 5.1.10, “Server Status Variables”.

5.6.7.10 Stopping a Cloning Operation

If necessary, you can stop a cloning operation with a KILL QUERY processlist_id statement.

On the recipient MySQL server instance, you can retrieve the processlist identifier (PID) for a cloning operation from the PID column of the clone_status table.

```
mysql> SELECT * FROM performance_schema.clone_status
```

<table>
<thead>
<tr>
<th>ID</th>
<th>PID</th>
<th>STATE</th>
<th>BEGIN_TIME</th>
<th>END_TIME</th>
<th>SOURCE</th>
<th>DESTINATION</th>
<th>ERROR_NO</th>
<th>ERROR_MESSAGE</th>
<th>BINLOG_FILE</th>
<th>BINLOG_POSITION</th>
<th>GTID_EXECUTED</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>8</td>
<td>In Progress</td>
<td>2019-07-15</td>
<td>NULL</td>
<td>LOCAL INSTANCE</td>
<td>/path/to/clone_dir/</td>
<td>0</td>
<td></td>
<td></td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

You can also retrieve the processlist identifier from the ID column of the INFORMATION_SCHEMA PROCESSLIST table, the Id column of SHOW PROCESSLIST output, or the PROCESSLIST_ID column of the Performance Schema threads table. These methods of obtaining the PID information can be used on the donor or recipient MySQL server instance.

5.6.7.12 Clone System Variables

This section describes the system variables that control operation of the clone plugin. If values specified at startup are incorrect, the clone plugin may fail to initialize properly and the server does not load it. In this case, the server may also produce error messages for other clone settings because it does not recognize them.

Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. They can be changed dynamically at runtime using the SET statement, which enables you to modify operation of the server without having to stop and restart it.

Setting a global system variable runtime value normally requires the SYSTEM_VARIABLES_ADMIN privilege (or the deprecated SUPER privilege). For more information, see Section 5.1.9.1, “System Variable Privileges”.

Clone variables are configured on the recipient MySQL server instance where the cloning operation is executed.

• `clone_autotune_concurrency`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--clone-autotune-concurrency</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.17</td>
</tr>
<tr>
<td>System Variable</td>
<td>clone_autotune_concurrency</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

When `clone_autotune_concurrency` is enabled (the default), additional threads for remote cloning operations are spawned dynamically to optimize data transfer speed. The setting is applicable to recipient MySQL server instance only.

During a cloning operation, the number of threads increases incrementally toward a target of double the current thread count. The effect on the data transfer speed is evaluated at each increment. The process either continues or stops according to the following rules:

• If the data transfer speed degrades more than 5% with an incremental increase, the process stops.

• If there is at least a 5% improvement after reaching 25% of the target, the process continues. Otherwise, the process stops.

• If there is at least a 10% improvement after reaching 50% of the target, the process continues. Otherwise, the process stops.

• If there is at least a 25% improvement after reaching the target, the process continues toward a new target of double the current thread count. Otherwise, the process stops.

The autotuning process does not support decreasing the number of threads.
The clone plugin

The `clone_max_concurrency` variable defines the maximum number of threads that can be spawned. If `clone_autotune_concurrency` is disabled, `clone_max_concurrency` defines the number of threads spawned for a remote cloning operation.

- **clone_buffer_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--clone-buffer-size</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.17</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>clone_buffer_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4194304</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1048576</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>268435456</td>
</tr>
</tbody>
</table>

  Defines the size of the intermediate buffer used when transferring data during a local cloning operation. This setting is not applicable to remote cloning operations. The default value is 4 mebibytes (MiB). A larger buffer size may permit I/O device drivers to fetch data in parallel, which can improve cloning performance.

- **clone_ddl_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--clone-ddl-timeout</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.17</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>clone_ddl_timeout</code></td>
</tr>
<tr>

<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>300</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2592000</td>
</tr>
</tbody>
</table>

  The time in seconds to wait for a backup lock when executing a cloning operation. This setting is applied on both the donor and recipient MySQL server instances. A cloning operation cannot run concurrently with DDL operations. A backup lock is required on the donor and recipient MySQL server instances. The cloning operation waits for current DDL operations to finish. Once backup locks are acquired, DDL operations must wait for the cloning operation to finish. A value of 0 means that no backup lock is to be taken for the cloning operation. In this case, the cloning operation fails with an error if a DDL operation is attempted concurrently.

- **clone_enable_compression**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--clone-enable-compression</code></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The Clone Plugin

<table>
<thead>
<tr>
<th>Introduced</th>
<th>8.0.17</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>clone_enable_compression</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Enables compression of data at the network layer during a remote cloning operation. Compression saves network bandwidth at the cost of CPU. Enabling compression may improve the data transfer rate. This setting is only applied on the recipient MySQL server instance.

- **clone_max_concurrency**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--clone-max-concurrency</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.17</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>clone_max_concurrency</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>16</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>128</td>
</tr>
</tbody>
</table>

Defines the maximum number of concurrent threads for a remote cloning operation. The default value is 16. A greater number of threads can improve cloning performance but also reduces the number of permitted simultaneous client connections, which can affect the performance of existing client connections. This setting is only applied on the recipient MySQL server instance.

If `clone_autotune_concurrency` is enabled (the default), `clone_max_concurrency` is the maximum number of threads that can be dynamically spawned for a remote cloning operation. If `clone_autotune_concurrency` is disabled, `clone_max_concurrency` defines the number of threads spawned for a remote cloning operation.

A minimum data transfer rate of 1 mebibyte (MiB) per thread is recommended for remote cloning operations. The data transfer rate for a remote cloning operation is controlled by the `clone_max_data_bandwidth` variable.

- **clone_max_data_bandwidth**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--clone-max-data-bandwidth</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.17</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>clone_max_data_bandwidth</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET VAR</code> Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>
The Clone Plugin

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

Defines the maximum data transfer rate in mebibytes (MiB) per second for a remote cloning operation. This variable helps manage the performance impact of a cloning operation. A limit should be set only when donor disk I/O bandwidth is saturated, affecting performance. A value of 0 means “unlimited”, which permits cloning operations to run at the highest possible data transfer rate. This setting is only applicable to the recipient MySQL server instance.

The minimum data transfer rate is 1 MiB per second, per thread. For example, if there are 8 threads, the minimum transfer rate is 8 MiB per second. The `clone_max_concurrency` variable controls the maximum number threads spawned for a remote cloning operation.

The requested data transfer rate specified by `clone_max_data_bandwidth` may differ from the actual data transfer rate reported by the `DATA_SPEED` column in the `performance_schema.clone_progress` table. If your cloning operation is not achieving the desired data transfer rate and you have available bandwidth, check I/O usage on the recipient and donor. If there is underutilized bandwidth, I/O is the next most likely bottleneck.

• `clone_max_network_bandwidth`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--clone-max-network-bandwidth</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.17</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>clone_max_network_bandwidth</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

Specifies the maximum approximate network transfer rate in mebibytes (MiB) per second for a remote cloning operation. This variable can be used to manage the performance impact of a cloning operation on network bandwidth. It should be set only when network bandwidth is saturated, affecting performance on the donor instance. A value of 0 means “unlimited”, which permits cloning at the highest possible data transfer rate over the network, providing the best performance. This setting is only applicable to the recipient MySQL server instance.

• `clone_ssl_ca`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--clone-ssl-ca=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.14</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>clone_ssl_ca</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>
The Clone Plugin

<table>
<thead>
<tr>
<th>SET_VAR</th>
<th>Hint Applies</th>
<th>No</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>File name</td>
<td></td>
</tr>
<tr>
<td>Default Value</td>
<td>empty string</td>
<td></td>
</tr>
</tbody>
</table>

Specifies the path to the certificate authority (CA) file. Used to configure an encrypted connection for a remote cloning operation. This setting configured on the recipient and used when connecting to the donor.

- **clone_ssl_cert**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--clone-ssl-cert=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.14</td>
</tr>
<tr>
<td>System Variable</td>
<td>clone_ssl_cert</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>empty string</td>
</tr>
</tbody>
</table>

Specifies the path to the public key certificate. Used to configure an encrypted connection for a remote cloning operation. This setting configured on the recipient and used when connecting to the donor.

- **clone_ssl_key**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--clone-ssl-key=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.14</td>
</tr>
<tr>
<td>System Variable</td>
<td>clone_ssl_key</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>empty string</td>
</tr>
</tbody>
</table>

Specifies the path to the private key file. Used to configure an encrypted connection for a remote cloning operation. This setting configured on the recipient and used when connecting to the donor.

- **clone_valid_donor_list**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--clone-valid-donor-list=value</th>
</tr>
</thead>
<tbody>
<tr>

<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>
MySQL Plugin Services

| Default Value | NULL |

Defines valid donor host addresses for remote cloning operations. This setting is applied on the recipient MySQL server instance. A comma-separated list of values is permitted in the following format: "HOST1:PORT1,HOST2:PORT2,HOST3:PORT3". Spaces are not permitted.

The clone_valid_donor_list variable adds a layer of security by providing control over the sources of cloned data. The privilege required to configure clone_valid_donor_list is different from the privilege required to execute remote cloning operations, which permits assigning those responsibilities to different roles. Configuring clone_valid_donor_list requires the SYSTEM_VARIABLES_ADMIN privilege, whereas executing a remote cloning operation requires the CLONE_ADMIN privilege.

Internet Protocol version 6 (IPv6) address format is not supported. Internet Protocol version 6 (IPv6) address format is not supported. An alias to the IPv6 address can be used instead. An IPv4 address can be used as is.

5.6.7.13 Clone Plugin Limitations

The clone plugin is subject to these limitations:

- DDL, including TRUNCATE TABLE, is not permitted during a cloning operation. This limitation should be considered when selecting data sources. A workaround is to use dedicated donor instances, which can accommodate DDL operations being blocked while data is cloned. Concurrent DML is permitted.

- An instance cannot be cloned from a different MySQL server version or release. The donor and recipient must have exactly the same MySQL server version and release. For example, you cannot clone between MySQL 5.7 and MySQL 8.0, or between MySQL 8.0.19 and MySQL 8.0.20. The clone plugin is only supported in MySQL 8.0.17 and higher.

- Only a single MySQL instance can be cloned at a time. Cloning multiple MySQL instances in a single cloning operation is not supported.

- The X Protocol port specified by mysqlx_port is not supported for remote cloning operations (when specifying the port number of the donor MySQL server instance in a CLONE INSTANCE statement).

- The clone plugin does not support cloning of MySQL server configurations. The recipient MySQL server instance retains its configuration, including persisted system variable settings (see Section 5.1.9.3, "Persisted System Variables".)

- The clone plugin does not support cloning of binary logs.

- The clone plugin only clones data stored in InnoDB. Other storage engine data is not cloned. MyISAM and CSV tables stored in any schema including the sys schema are cloned as empty tables.

- Connecting to the donor MySQL server instance through MySQL Router is not supported.

- Local cloning operations do not support cloning of general tablespaces that were created with an absolute path. A cloned tablespace file with the same path as the source tablespace file would cause a conflict.

5.6.8 MySQL Plugin Services

MySQL server plugins have access to server “plugin services.” The plugin services interface complements the plugin API by exposing server functionality that plugins can call. For developer information about writing plugin services, see MySQL Services for Plugins. The following sections describe plugin services available at the SQL and C-language levels.
5.6.8.1 The Locking Service

MySQL distributions provide a locking interface that is accessible at two levels:

- At the SQL level, as a set of user-defined functions (UDFs) that map onto calls to the service routines.
- As a C language interface, callable as a plugin service from server plugins or user-defined functions.

For general information about plugin services, see Section 5.6.8, "MySQL Plugin Services". For general information about user-defined functions, see Adding a User-Defined Function.

The locking interface has these characteristics:

- Locks have three attributes: Lock namespace, lock name, and lock mode:
  - Locks are identified by the combination of namespace and lock name. The namespace enables different applications to use the same lock names without colliding by creating locks in separate namespaces. For example, if applications A and B use namespaces of ns1 and ns2, respectively, each application can use lock names lock1 and lock2 without interfering with the other application.
  - A lock mode is either read or write. Read locks are shared: If a session has a read lock on a given lock identifier, other sessions can acquire a read lock on the same identifier. Write locks are exclusive: If a session has a write lock on a given lock identifier, other sessions cannot acquire a read or write lock on the same identifier.
  - Namespace and lock names must be non-NULL, nonempty, and have a maximum length of 64 characters. A namespace or lock name specified as NULL, the empty string, or a string longer than 64 characters results in an ER_LOCKING_SERVICE_WRONG_NAME error.
  - The locking interface treats namespace and lock names as binary strings, so comparisons are case-sensitive.
  - The locking interface provides functions to acquire locks and release locks. No special privilege is required to call these functions. Privilege checking is the responsibility of the calling application.
  - Locks can be waited for if not immediately available. Lock acquisition calls take an integer timeout value that indicates how many seconds to wait to acquire locks before giving up. If the timeout is reached without successful lock acquisition, an ER_LOCKING_SERVICE_TIMEOUT error occurs. If the timeout is 0, there is no waiting and the call produces an error if locks cannot be acquired immediately.
  - The locking interface detects deadlock between lock-acquisition calls in different sessions. In this case, the locking service chooses a caller and terminates its lock-acquisition request with an ER_LOCKING_SERVICE_DEADLOCK error. This error does not cause transactions to roll back. To choose a session in case of deadlock, the locking service prefers sessions that hold read locks over sessions that hold write locks.
  - A session can acquire multiple locks with a single lock-acquisition call. For a given call, lock acquisition is atomic: The call succeeds if all locks are acquired. If acquisition of any lock fails, the call acquires no locks and fails, typically with an ER_LOCKING_SERVICE_TIMEOUT or ER_LOCKING_SERVICE_DEADLOCK error.
  - A session can acquire multiple locks for the same lock identifier (namespace and lock name combination). These lock instances can be read locks, write locks, or a mix of both.
  - Locks acquired within a session are released explicitly by calling a release-locks function, or implicitly when the session terminates (either normally or abnormally). Locks are not released when transactions commit or roll back.
Within a session, all locks for a given namespace when released are released together.

The interface provided by the locking service is distinct from that provided by `GET_LOCK()` and related SQL functions (see Section 12.15, “Locking Functions”). For example, `GET_LOCK()` does not implement namespaces and provides only exclusive locks, not distinct read and write locks.

### The Locking Service C Interface

This section describes how to use the locking service C language interface. To use the UDF interface instead, see The Locking Service UDF Interface. For general characteristics of the locking service interface, see Section 5.6.8.1, “The Locking Service”. For general information about plugin services, see Section 5.6.8, “MySQL Plugin Services”.

Source files that use the locking service should include this header file:

```c
#include <mysql/service_locking.h>
```

To acquire one or more locks, call this function:

```c
int mysql_acquire_locking_service_locks(MYSQL_THD opaque_thd, const char* lock_namespace, const char**lock_names, size_t lock_num, enum enum_locking_service_lock_type lock_type, unsigned long lock_timeout);
```

The arguments have these meanings:

- **opaque_thd**: A thread handle. If specified as `NULL`, the handle for the current thread is used.
- **lock_namespace**: A null-terminated string that indicates the lock namespace.
- **lock_names**: An array of null-terminated strings that provides the names of the locks to acquire.
- **lock_num**: The number of names in the `lock_names` array.
- **lock_type**: The lock mode, either `LOCKING_SERVICE_READ` or `LOCKING_SERVICE_WRITE` to acquire read locks or write locks, respectively.
- **lock_timeout**: An integer number of seconds to wait to acquire the locks before giving up.

To release locks acquired for a given namespace, call this function:

```c
int mysql_release_locking_service_locks(MYSQL_THD opaque_thd, const char* lock_namespace);
```

The arguments have these meanings:

- **opaque_thd**: A thread handle. If specified as `NULL`, the handle for the current thread is used.
- **lock_namespace**: A null-terminated string that indicates the lock namespace.

Locks acquired or waited for by the locking service can be monitored at the SQL level using the Performance Schema. For details, see Locking Service Monitoring.

### The Locking Service UDF Interface

This section describes how to use the locking service user-defined function (UDF) interface. To use the C language interface instead, see The Locking Service C Interface. For general characteristics of the locking service interface, see Section 5.6.8.1, “The Locking Service”. For general information about user-defined functions, see Adding a User-Defined Function.
Installing or Uninstalling the UDF Locking Interface

The locking service routines described in The Locking Service C Interface need not be installed because they are built into the server. The same is not true of the user-defined functions (UDFs) that map onto calls to the service routines: The UDFs must be installed before use. This section describes how to do that. For general information about UDF installation, see Section 5.7.1, “Installing and Uninstalling User-Defined Functions”.

The locking service UDFs are implemented in a plugin library file located in the directory named by the `plugin_dir` system variable. The file base name is `locking_service`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To install the locking service UDFs, use the `CREATE FUNCTION` statement, adjusting the `.so` suffix for your platform as necessary:

```
CREATE FUNCTION service_get_read_locks RETURNS INT SONAME 'locking_service.so';
CREATE FUNCTION service_get_write_locks RETURNS INT SONAME 'locking_service.so';
CREATE FUNCTION service_release_locks RETURNS INT SONAME 'locking_service.so';
```

If the UDFs are used on a source replication server, install them on all replica servers as well to avoid replication problems.

Once installed, the UDFs remain installed until uninstalled. To remove them, use the `DROP FUNCTION` statement:

```
DROP FUNCTION service_get_read_locks;
DROP FUNCTION service_get_write_locks;
DROP FUNCTION service_release_locks;
```

Using the UDF Locking Interface

Before using the locking service UDFs, install them according to the instructions provided at Installing or Uninstalling the UDF Locking Interface.

To acquire one or more read locks, call this function:

```
mysql> SELECT service_get_read_locks('mynamespace', 'rlock1', 'rlock2', 10);
+---------------------------------------------------------------+
| service_get_read_locks('mynamespace', 'rlock1', 'rlock2', 10) |
|                                                             1 |
+---------------------------------------------------------------+
```

The first argument is the lock namespace. The final argument is an integer timeout indicating how many seconds to wait to acquire the locks before giving up. The arguments in between are the lock names.

For the example just shown, the function acquires locks with lock identifiers `(mynamespace, rlock1)` and `(mynamespace, rlock2)`.
To acquire write locks rather than read locks, call this function:

```
mysql> SELECT service_get_write_locks('mynamespace', 'wlock1', 'wlock2', 10);
+----------------------------------------------------------------+
| service_get_write_locks('mynamespace', 'wlock1', 'wlock2', 10) |
| 1 |
+----------------------------------------------------------------+
```

In this case, the lock identifiers are `(mynamespace, wlock1)` and `(mynamespace, wlock2)`.

To release all locks for a namespace, use this function:

```
mysql> SELECT service_release_locks('mynamespace');
+--------------------------------------+
| service_release_locks('mynamespace') |
| 1 |
+--------------------------------------+
```

Each locking function returns nonzero for success. If the function fails, an error occurs. For example, the following error occurs because lock names cannot be empty:

```
mysql> SELECT service_get_read_locks('mynamespace', '', 10);
ERROR 3131 (42000): Incorrect locking service lock name ''.
```

A session can acquire multiple locks for the same lock identifier. As long as a different session does not have a write lock for an identifier, the session can acquire any number of read or write locks. Each lock request for the identifier acquires a new lock. The following statements acquire three write locks with the same identifier, then three read locks for the same identifier:

```
SELECT service_get_write_locks('ns', 'lock1', 'lock1', 'lock1', 0);
SELECT service_get_read_locks('ns', 'lock1', 'lock1', 'lock1', 0);
```

If you examine the Performance Schema `metadata_locks` table at this point, you should find that the session holds six distinct locks with the same `(ns, lock1)` identifier. (For details, see Locking Service Monitoring.)

Because the session holds at least one write lock on `(ns, lock1)`, no other session can acquire a lock for it, either read or write. If the session held only read locks for the identifier, other sessions could acquire read locks for it, but not write locks.

Locks for a single lock-acquisition call are acquired atomically, but atomicity does not hold across calls. Thus, for a statement such as the following, where `service_get_write_locks()` is called once per row of the result set, atomicity holds for each individual call, but not for the statement as a whole:

```
SELECT service_get_write_locks('ns', 'lock1', 'lock2', 0) FROM t1 WHERE ...
```

---

**Caution**

Because the locking service returns a separate lock for each successful request for a given lock identifier, it is possible for a single statement to acquire a large number of locks. For example:

```
INSERT INTO ... SELECT service_get_write_locks('ns', t1.col_name, 0) FROM t1;
```

These types of statements may have certain adverse effects. For example, if the statement fails part way through and rolls back, locks acquired up to the point of failure still exist. If the intent is for there to be a correspondence between rows inserted and locks acquired, that intent is not satisfied. Also, if it is important that locks are granted in a certain order, be aware that result set order may differ.
MySQL Plugin Services

depending on which execution plan the optimizer chooses. For these reasons, it may be best to limit applications to a single lock-acquisition call per statement.

Locking Service Monitoring

The locking service is implemented using the MySQL Server metadata locks framework, so you monitor locking service locks acquired or waited for by examining the Performance Schema metadata_locks table.

First, enable the metadata lock instrument:

```
mysql> UPDATE performance_schema.setup_instruments SET ENABLED = 'YES'
 WHERE NAME = 'wait/lock/metadata/sql/mdl';
```

Then acquire some locks and check the contents of the metadata_locks table:

```
mysql> SELECT service_get_write_locks('mynamespace', 'lock1', 0);
+----------------------------------------------------+
| service_get_write_locks('mynamespace', 'lock1', 0) |
| 1                                                  |
+----------------------------------------------------+
mysql> SELECT service_get_read_locks('mynamespace', 'lock2', 0);
+---------------------------------------------------+
| service_get_read_locks('mynamespace', 'lock2', 0) |
| 1                                                 |
+---------------------------------------------------+
mysql> SELECT OBJECT_TYPE, OBJECT_SCHEMA, OBJECT_NAME, LOCK_TYPE, LOCK_STATUS
 FROM performance_schema.metadata_locks
 WHERE OBJECT_TYPE = 'LOCKING SERVICE'
```

```
* 1. row ******************************************************
 OBJECT_TYPE: LOCKING SERVICE
 OBJECT_SCHEMA: mynamespace
 OBJECT_NAME: lock1
 LOCK_TYPE: EXCLUSIVE
 LOCK_STATUS: GRANTED
* 2. row ******************************************************
 OBJECT_TYPE: LOCKING SERVICE
 OBJECT_SCHEMA: mynamespace
 OBJECT_NAME: lock2
 LOCK_TYPE: SHARED
 LOCK_STATUS: GRANTED
```

Locking service locks have an OBJECT_TYPE value of LOCKING SERVICE. This is distinct from, for example, locks acquired with the GET_LOCK() function, which have an OBJECT_TYPE of USER LEVEL LOCK.

The lock namespace, name, and mode appear in the OBJECT_SCHEMA, OBJECT_NAME, and LOCK_TYPE columns. Read and write locks have LOCK_TYPE values of SHARED and EXCLUSIVE, respectively.

The LOCK_STATUS value is GRANTED for an acquired lock, PENDING for a lock that is being waited for. You can expect to see PENDING if one session holds a write lock and another session is attempting to acquire a lock having the same identifier.

Locking Service UDF Interface Reference

The SQL interface to the locking service implements the user-defined functions described in this section. For usage examples, see Using the UDF Locking Interface.

The functions share these characteristics:

- The return value is nonzero for success. Otherwise, an error occurs.
• Namespace and lock names must be non-NULL, nonempty, and have a maximum length of 64 characters.

• Timeout values must be integers indicating how many seconds to wait to acquire locks before giving up with an error. If the timeout is 0, there is no waiting and the function produces an error if locks cannot be acquired immediately.

These locking service UDFs are available:

• `service_get_read_locks(namespace, lock_name[, lock_name] ..., timeout)`

  Acquires one or more read (shared) locks in the given namespace using the given lock names, timing out with an error if the locks are not acquired within the given timeout value.

• `service_get_write_locks(namespace, lock_name[, lock_name] ..., timeout)`

  Acquires one or more write (exclusive) locks in the given namespace using the given lock names, timing out with an error if the locks are not acquired within the given timeout value.

• `service_release_locks(namespace)`

  For the given namespace, releases all locks that were acquired within the current session using `service_get_read_locks()` and `service_get_write_locks()`.

  It is not an error for there to be no locks in the namespace.

5.6.8.2 The Keyring Service

MySQL Server supports a keyring service that enables internal server components and plugins to securely store sensitive information for later retrieval. MySQL distributions provide a keyring interface that is accessible at two levels:

• At the SQL level, as a set of user-defined functions (UDFs) that map onto calls to the service routines.

• As a C language interface, callable as a plugin service from server plugins or user-defined functions.

This section describes how to use the keyring service functions to store, retrieve, and remove keys in the MySQL keyring keystore. For information about the SQL interface that uses UDFs, Section 6.4.4.10, “General-Purpose Keyring Key-Management Functions”. For general keyring information, see Section 6.4.4, “The MySQL Keyring”.

The keyring service uses whatever underlying keyring plugin is enabled, if any. If no keyring plugin is enabled, keyring service calls fail.

A “record” in the keystore consists of data (the key itself) and a unique identifier through which the key is accessed. The identifier has two parts:

• `key_id`: The key ID or name. `key_id` values that begin with `mysql_` are reserved by MySQL Server.

• `user_id`: The session effective user ID. If there is no user context, this value can be NULL. The value need not actually be a “user”; the meaning depends on the application.

Functions that implement the keyring UDF interface pass the value of `CURRENT_USER()` as the `user_id` value to keyring service functions.

The keyring service functions have these characteristics in common:

• Each function returns 0 for success, 1 for failure.
MySQL Plugin Services

- The `key_id` and `user_id` arguments form a unique combination indicating which key in the keyring to use.
- The `key_type` argument provides additional information about the key, such as its encryption method or intended use.
- Keyring service functions treat key IDs, user names, types, and values as binary strings, so comparisons are case sensitive. For example, IDs of `MyKey` and `mykey` refer to different keys.

These keyring service functions are available:

- **my_key_fetch()**

  Deobfuscates and retrieves a key from the keyring, along with its type. The function allocates the memory for the buffers used to store the returned key and key type. The caller should zero or obfuscate the memory when it is no longer needed, then free it.

  Syntax:

  ```c
  bool my_key_fetch(const char *key_id, const char **key_type,
                      const char* user_id, void **key, size_t *key_len)
  ```

  Arguments:

  - `key_id, user_id`: Null-terminated strings that as a pair form a unique identifier indicating which key to fetch.
  - `key_type`: The address of a buffer pointer. The function stores into it a pointer to a null-terminated string that provides additional information about the key (stored when the key was added).
  - `key`: The address of a buffer pointer. The function stores into it a pointer to the buffer containing the fetched key data.
  - `key_len`: The address of a variable into which the function stores the size in bytes of the `*key` buffer.

  Return value:

  Returns 0 for success, 1 for failure.

- **my_key_generate()**

  Generates a new random key of a given type and length and stores it in the keyring. The key has a length of `key_len` and is associated with the identifier formed from `key_id` and `user_id`. The type and length values must be consistent with the values supported by the underlying keyring plugin. See Section 6.4.4.8, “Supported Keyring Key Types and Lengths”.

  Syntax:

  ```c
  bool my_key_generate(const char *key_id, const char *key_type,
                       const char *user_id, size_t key_len)
  ```

  Arguments:

  - `key_id, user_id`: Null-terminated strings that as a pair form a unique identifier for the key to be generated.
  - `key_type`: A null-terminated string that provides additional information about the key.
  - `key_len`: The size in bytes of the key to be generated.
MySQL Server User-Defined Functions

Return value:
Returns 0 for success, 1 for failure.

- **my_key_remove()**

  Removes a key from the keyring.

  Syntax:
  ```c
  bool my_key_remove(const char *key_id, const char* user_id)
  ```

  Arguments:
  - **key_id, user_id**: Null-terminated strings that as a pair form a unique identifier for the key to be removed.

  Return value:
  Returns 0 for success, 1 for failure.

- **my_key_store()**

  Obfuscates and stores a key in the keyring.

  Syntax:
  ```c
  bool my_key_store(const char *key_id, const char *key_type, const char* user_id, void *key, size_t key_len)
  ```

  Arguments:
  - **key_id, user_id**: Null-terminated strings that as a pair form a unique identifier for the key to be stored.
  - **key_type**: A null-terminated string that provides additional information about the key.
  - **key**: The buffer containing the key data to be stored.
  - **key_len**: The size in bytes of the key buffer.

  Return value:
  Returns 0 for success, 1 for failure.

5.7 MySQL Server User-Defined Functions

MySQL Server enables user-defined functions (UDFs) to be created and loaded into the server to extend server capabilities. Server capabilities can be implemented in whole or in part using UDFs. In addition, you can write your own UDFs.

The following sections describe how to install and uninstall UDFs, and how to determine at runtime which UDFs are installed and obtain information about them. For a table listing user-defined functions, see Section 12.2, "User-Defined Function Reference". For information about writing UDFs, see Adding Functions to MySQL.

5.7.1 Installing and Uninstalling User-Defined Functions
User-defined functions (UDFs) must be loaded into the server before they can be used. MySQL supports manual UDF loading at runtime and automatic loading during server startup.

While a UDF is loaded, information about it is available as described in Section 5.7.2, “Obtaining User-Defined Function Information”.

- Installing User-Defined Functions
- Uninstalling User-Defined Functions
- Reinstalling or Upgrading User-Defined Functions

**Installing User-Defined Functions**

To load a UDF manually, use the `CREATE FUNCTION` statement. For example:

```sql
CREATE FUNCTION metaphon
  RETURNS STRING
  SONAME 'udf_example.so';
```

The UDF file base name depends on your platform. Common suffixes are `.so` for Unix and Unix-like systems, `.dll` for Windows.

`CREATE FUNCTION` has these effects:

- It loads the UDF into the server to make it available immediately.
- It registers the UDF in the `mysql.func` system table to make it persistent across server restarts. For this reason, `CREATE FUNCTION` requires the `INSERT` privilege for the `mysql` system database.
- It adds the UDF to the Performance Schema `user_defined_functions` table that provides runtime information about installed UDFs. See Section 5.7.2, “Obtaining User-Defined Function Information”.

Automatic UDF loading occurs during the normal server startup sequence:

- UDFs registered in the `mysql.func` table are installed.
- Server components or plugins that are installed at startup may automatically install related UDFs.
- Automatic UDF installation adds the UDFs to the Performance Schema `user_defined_functions` table that provides runtime information about installed UDFs.

If the server is started with the `--skip-grant-tables` option, UDFs registered in the `mysql.func` table are not loaded and are unavailable. This does not apply to UDFs installed automatically by a component or plugin.

**Uninstalling User-Defined Functions**

To remove a UDF, use the `DROP FUNCTION` statement. For example:

```sql
DROP FUNCTION metaphon;
```

`DROP FUNCTION` has these effects:

- It unloads the UDF to make it unavailable.
- It removes the UDF from the `mysql.func` system table. For this reason, `DROP FUNCTION` requires the `DELETE` privilege for the `mysql` system database. With the UDF no longer registered in the `mysql.func` table, the server does not load the UDF during subsequent restarts.
- It removes the UDF from the Performance Schema `user_defined_functions` table that provides runtime information about installed UDFs.
Obtaining User-Defined Function Information

**DROP FUNCTION** cannot be used to drop a UDF that is installed automatically by server components or plugins rather than by using **CREATE FUNCTION**. Such a UDF is also dropped automatically, when the component or plugin that installed it is uninstalled.

Reinstalling or Upgrading User-Defined Functions

To reinstall or upgrade the shared library associated with a UDF, issue a **DROP FUNCTION** statement, upgrade the shared library, and then issue a **CREATE FUNCTION** statement. If you upgrade the shared library first and then use **DROP FUNCTION**, the server may unexpectedly shut down.

**5.7.2 Obtaining User-Defined Function Information**

The Performance Schema **user_defined_functions** table contains information about the currently installed user-defined functions (UDFs):

```sql
SELECT * FROM performance_schema.user_defined_functions;
```

The **mysql.func** system table also lists installed UDFs, but only those installed using **CREATE FUNCTION**. The **user_defined_functions** table lists UDFs installed using **CREATE FUNCTION** as well as UDFs installed automatically by server components or plugins. This difference makes **user_defined_functions** preferable to **mysql.func** for checking which UDFs are installed. See Section 26.12.19.9, “The user_defined_functions Table”.

**5.8 Running Multiple MySQL Instances on One Machine**

In some cases, you might want to run multiple instances of MySQL on a single machine. You might want to test a new MySQL release while leaving an existing production setup undisturbed. Or you might want to give different users access to different **mysqld** servers that they manage themselves. (For example, you might be an Internet Service Provider that wants to provide independent MySQL installations for different customers.)

It is possible to use a different MySQL server binary per instance, or use the same binary for multiple instances, or any combination of the two approaches. For example, you might run a server from MySQL 5.7 and one from MySQL 8.0, to see how different versions handle a given workload. Or you might run multiple instances of the current production version, each managing a different set of databases.

Whether or not you use distinct server binaries, each instance that you run must be configured with unique values for several operating parameters. This eliminates the potential for conflict between instances. Parameters can be set on the command line, in option files, or by setting environment variables. See Section 4.2.2, “Specifying Program Options”. To see the values used by a given instance, connect to it and execute a **SHOW VARIABLES** statement.

The primary resource managed by a MySQL instance is the data directory. Each instance should use a different data directory, the location of which is specified using the **--datadir=dir_name** option. For methods of configuring each instance with its own data directory, and warnings about the dangers of failing to do so, see Section 5.8.1, “Setting Up Multiple Data Directories”.

In addition to using different data directories, several other options must have different values for each server instance:

- **--port=port_num**

  **--port** controls the port number for TCP/IP connections. Alternatively, if the host has multiple network addresses, you can set the **bind_address** system variable to cause each server to listen to a different address.
--socket={file_name|pipe_name}

--socket controls the Unix socket file path on Unix or the named-pipe name on Windows. On Windows, it is necessary to specify distinct pipe names only for those servers configured to permit named-pipe connections.

--shared-memory-base-name=name

This option is used only on Windows. It designates the shared-memory name used by a Windows server to permit clients to connect using shared memory. It is necessary to specify distinct shared-memory names only for those servers configured to permit shared-memory connections.

--pid-file=file_name

This option indicates the path name of the file in which the server writes its process ID.

If you use the following log file options, their values must differ for each server:

--general_log_file=file_name
--log-bin[]=file_name
--slow_query_log_file=file_name
--log-error[]=file_name

For further discussion of log file options, see Section 5.4, “MySQL Server Logs”.

To achieve better performance, you can specify the following option differently for each server, to spread the load between several physical disks:

--tmpdir=dir_name

Having different temporary directories also makes it easier to determine which MySQL server created any given temporary file.

If you have multiple MySQL installations in different locations, you can specify the base directory for each installation with the --basedir=dir_name option. This causes each instance to automatically use a different data directory, log files, and PID file because the default for each of those parameters is relative to the base directory. In that case, the only other options you need to specify are the --socket and --port options. Suppose that you install different versions of MySQL using tar file binary distributions. These install in different locations, so you can start the server for each installation using the command bin/mysql_safe under its corresponding base directory. mysql_safe determines the proper --basedir option to pass to mysqld, and you need specify only the --socket and --port options to mysql_safe.

As discussed in the following sections, it is possible to start additional servers by specifying appropriate command options or by setting environment variables. However, if you need to run multiple servers on a more permanent basis, it is more convenient to use option files to specify for each server those option values that must be unique to it. The --defaults-file option is useful for this purpose.

### 5.8.1 Setting Up Multiple Data Directories

Each MySQL Instance on a machine should have its own data directory. The location is specified using the --datadir=dir_name option.

There are different methods of setting up a data directory for a new instance:
Setting Up Multiple Data Directories

- Create a new data directory.
- Copy an existing data directory.

The following discussion provides more detail about each method.

**Warning**

Normally, you should never have two servers that update data in the same databases. This may lead to unpleasant surprises if your operating system does not support fault-free system locking. If (despite this warning) you run multiple servers using the same data directory and they have logging enabled, you must use the appropriate options to specify log file names that are unique to each server. Otherwise, the servers try to log to the same files.

Even when the preceding precautions are observed, this kind of setup works only with MyISAM and MERGE tables, and not with any of the other storage engines. Also, this warning against sharing a data directory among servers always applies in an NFS environment. Permitting multiple MySQL servers to access a common data directory over NFS is a very bad idea. The primary problem is that NFS is the speed bottleneck. It is not meant for such use. Another risk with NFS is that you must devise a way to ensure that two or more servers do not interfere with each other. Usually NFS file locking is handled by the lockd daemon, but at the moment there is no platform that performs locking 100% reliably in every situation.

**Create a New Data Directory**

With this method, the data directory is in the same state as when you first install MySQL, and has the default set of MySQL accounts and no user data.

On Unix, initialize the data directory. See Section 2.10, “Postinstallation Setup and Testing”.

On Windows, the data directory is included in the MySQL distribution:

- MySQL Zip archive distributions for Windows contain an unmodified data directory. You can unpack such a distribution into a temporary location, then copy it to where you are setting up the new instance.

- Windows MSI package installers create and set up the data directory that the installed server uses, but also create a pristine “template” data directory named data under the installation directory. After an installation has been performed using an MSI package, the template data directory can be copied to set up additional MySQL instances.

**Copy an Existing Data Directory**

With this method, any MySQL accounts or user data present in the data directory are carried over to the new data directory.

1. Stop the existing MySQL instance using the data directory. This must be a clean shutdown so that the instance flushes any pending changes to disk.

2. Copy the data directory to the location where the new data directory should be.

3. Copy the my.cnf or my.ini option file used by the existing instance. This serves as a basis for the new instance.

4. Modify the new option file so that any pathnames referring to the original data directory refer to the new data directory. Also, modify any other options that must be unique per instance, such as the
5. Start the new instance, telling it to use the new option file.

5.8.2 Running Multiple MySQL Instances on Windows

You can run multiple servers on Windows by starting them manually from the command line, each with appropriate operating parameters, or by installing several servers as Windows services and running them that way. General instructions for running MySQL from the command line or as a service are given in Section 2.3, “Installing MySQL on Microsoft Windows”. The following sections describe how to start each server with different values for those options that must be unique per server, such as the data directory. These options are listed in Section 5.8, “Running Multiple MySQL Instances on One Machine”.

5.8.2.1 Starting Multiple MySQL Instances at the Windows Command Line

The procedure for starting a single MySQL server manually from the command line is described in Section 2.3.4.6, “Starting MySQL from the Windows Command Line”. To start multiple servers this way, you can specify the appropriate options on the command line or in an option file. It is more convenient to place the options in an option file, but it is necessary to make sure that each server gets its own set of options. To do this, create an option file for each server and tell the server the file name with a --defaults-file option when you run it.

Suppose that you want to run one instance of mysqld on port 3307 with a data directory of C:\mydata1, and another instance on port 3308 with a data directory of C:\mydata2. Use this procedure:

1. Make sure that each data directory exists, including its own copy of the mysql database that contains the grant tables.

2. Create two option files. For example, create one file named C:\my-opts1.cnf that looks like this:

```ini
[mysqld]
datadir = C:/mydata1
port = 3307
```

Create a second file named C:\my-opts2.cnf that looks like this:

```ini
[mysqld]
datadir = C:/mydata2
port = 3308
```

3. Use the --defaults-file option to start each server with its own option file:

```
C:\> C:\mysql\bin\mysqld --defaults-file=C:\my-opts1.cnf
C:\> C:\mysql\bin\mysqld --defaults-file=C:\my-opts2.cnf
```

Each server starts in the foreground (no new prompt appears until the server exits later), so you will need to issue those two commands in separate console windows.

To shut down the servers, connect to each using the appropriate port number:

```
C:\> C:\mysql\bin\mysqladmin --port=3307 --host=127.0.0.1 --user=root --password shutdown
C:\> C:\mysql\bin\mysqladmin --port=3308 --host=127.0.0.1 --user=root --password shutdown
```

Servers configured as just described permit clients to connect over TCP/IP. If your version of Windows supports named pipes and you also want to permit named-pipe connections, specify options that enable the named pipe and specify its name. Each server that supports named-pipe connections must use a unique pipe name. For example, the C:\my-opts1.cnf file might be written like this:

```ini
[mysqld]
1102
```
Running Multiple MySQL Instances on Windows

```
datadir = C:/mydata1
port = 3307
enable-named-pipe
socket = mypipe1
```

Modify `C:\my-opts2.cnf` similarly for use by the second server. Then start the servers as described previously.

A similar procedure applies for servers that you want to permit shared-memory connections. Enable such connections by starting the server with the `shared_memory` system variable enabled and specify a unique shared-memory name for each server by setting the `shared_memory_base_name` system variable.

### 5.8.2.2 Starting Multiple MySQL Instances as Windows Services

On Windows, a MySQL server can run as a Windows service. The procedures for installing, controlling, and removing a single MySQL service are described in Section 2.3.4.8, “Starting MySQL as a Windows Service”.

To set up multiple MySQL services, you must make sure that each instance uses a different service name in addition to the other parameters that must be unique per instance.

For the following instructions, suppose that you want to run the `mysqld` server from two different versions of MySQL that are installed at `C:\mysql-5.5.9` and `C:\mysql-8.0.24`, respectively. (This might be the case if you are running 5.5.9 as your production server, but also want to conduct tests using 8.0.24.)

To install MySQL as a Windows service, use the `--install` or `--install-manual` option. For information about these options, see Section 2.3.4.8, “Starting MySQL as a Windows Service”.

Based on the preceding information, you have several ways to set up multiple services. The following instructions describe some examples. Before trying any of them, shut down and remove any existing MySQL services.

- **Approach 1**: Specify the options for all services in one of the standard option files. To do this, use a different service name for each server. Suppose that you want to run the 5.5.9 `mysqld` using the service name of `mysqld1` and the 8.0.24 `mysqld` using the service name `mysqld2`. In this case, you can use the `[mysqld1]` group for 5.5.9 and the `[mysqld2]` group for 8.0.24. For example, you can set up `C:\my.cnf` like this:

  ```ini
  # options for mysqld1 service
  [mysqld1]
  basedir = C:/mysql-5.5.9
  port = 3307
  enable-named-pipe
  socket = mypipe1
  
  # options for mysqld2 service
  [mysqld2]
  basedir = C:/mysql-8.0.24
  port = 3308
  enable-named-pipe
  socket = mypipe2
  ```

Install the services as follows, using the full server path names to ensure that Windows registers the correct executable program for each service:

```
C:\> C:\mysql-5.5.9\bin\mysqld --install mysqld1
C:\> C:\mysql-8.0.24\bin\mysqld --install mysqld2
```

To start the services, use the services manager, or `NET START` or `SC START` with the appropriate service names:
Running Multiple MySQL Instances on Unix

To stop the services, use the services manager, or use **NET STOP** or **SC STOP** with the appropriate service names:

```
C:\> NET STOP
C:\> SC STOP
```

**Approach 2:** Specify options for each server in separate files and use `--defaults-file` when you install the services to tell each server what file to use. In this case, each file should list options using a `[mysqld]` group.

With this approach, to specify options for the 5.5.9 `mysqld`, create a file `C:\my-opts1.cnf` that looks like this:

```
[mysqld]
basedir = C:/mysql-5.5.9
port = 3307
enable-named-pipe
socket = mypipe1
```

For the 8.0.24 `mysqld`, create a file `C:\my-opts2.cnf` that looks like this:

```
[mysqld]
basedir = C:/mysql-8.0.24
port = 3308
enable-named-pipe
socket = mypipe2
```

Install the services as follows (enter each command on a single line):

```
C:\> C:\mysql-5.5.9\bin\mysqld --install mysqld1 --defaults-file=C:\my-opts1.cnf
C:\> C:\mysql-8.0.24\bin\mysqld --install mysqld2 --defaults-file=C:\my-opts2.cnf
```

When you install a MySQL server as a service and use a `--defaults-file` option, the service name must precede the option.

After installing the services, start and stop them the same way as in the preceding example.

To remove multiple services, use `SC DELETE mysqld_service_name` for each one. Alternatively, use `mysqld --remove` for each one, specifying a service name following the `--remove` option. If the service name is the default (MySQL), you can omit it when using `mysqld --remove`.

### 5.8.3 Running Multiple MySQL Instances on Unix

**Note**

The discussion here uses `mysqld_safe` to launch multiple instances of MySQL. For MySQL installation using an RPM distribution, server startup and shutdown is managed by systemd on several Linux platforms. On these platforms, `mysqld_safe` is not installed because it is unnecessary. For information about using systemd to handle multiple MySQL instances, see Section 2.5.9, “Managing MySQL Server with systemd”.

One way is to run multiple MySQL instances on Unix is to compile different servers with different default TCP/IP ports and Unix socket files so that each one listens on different network interfaces. Compiling in
Running Multiple MySQL Instances on Unix

different base directories for each installation also results automatically in a separate, compiled-in data
directory, log file, and PID file location for each server.

Assume that an existing 5.7 server is configured for the default TCP/IP port number (3306) and Unix
socket file (/tmp/mysql.sock). To configure a new 8.0.24 server to have different operating parameters,
use a CMake command something like this:

```
shell> cmake . -DMYSQL_TCP_PORT=port_number \
   -DMYSQL_UNIX_ADDR=file_name \
   -DCMAKE_INSTALL_PREFIX=/usr/local/mysql-8.0.24
```

Here, `port_number` and `file_name` must be different from the default TCP/IP port number and Unix
socket file path name, and the `CMAKE_INSTALL_PREFIX` value should specify an installation directory
different from the one under which the existing MySQL installation is located.

If you have a MySQL server listening on a given port number, you can use the following command to find
out what operating parameters it is using for several important configurable variables, including the base
directory and Unix socket file name:

```
shell> mysqladmin --host=host_name --port=port_number variables
```

With the information displayed by that command, you can tell what option values not to use when
configuring an additional server.

If you specify `localhost` as the host name, `mysqladmin` defaults to using a Unix socket file rather than
TCP/IP. To explicitly specify the transport protocol, use the `--protocol={TCP|SOCKET|PIPE|MEMORY}`
option.

You need not compile a new MySQL server just to start with a different Unix socket file and TCP/IP port
number. It is also possible to use the same server binary and start each invocation of it with different
parameter values at runtime. One way to do so is by using command-line options:

```
shell> mysqld_safe --socket=file_name --port=port_number
```

To start a second server, provide different --socket and --port option values, and pass a --
datadir=dir_name option to mysqld_safe so that the server uses a different data directory.

Alternatively, put the options for each server in a different option file, then start each server using a --
defaults-file option that specifies the path to the appropriate option file. For example, if the option files
for two server instances are named /usr/local/mysql/my.cnf and /usr/local/mysql/my.cnf2,
start the servers like this: command:

```
shell> mysqld_safe --defaults-file=/usr/local/mysql/my.cnf
shell> mysqld_safe --defaults-file=/usr/local/mysql/my.cnf2
```

Another way to achieve a similar effect is to use environment variables to set the Unix socket file name and
TCP/IP port number:

```
shell> MYSQL_UNIX_PORT=/tmp/mysqld-new.sock
shell> MYSQL_TCP_PORT=3307
shell> export MYSQL_UNIX_PORT MYSQL_TCP_PORT
shell> bin/mysqld --initialize --user=mysql
shell> mysqld_safe --datadir=/path/to/datadir &
```

This is a quick way of starting a second server to use for testing. The nice thing about this method is that
the environment variable settings apply to any client programs that you invoke from the same shell. Thus,
connections for those clients are automatically directed to the second server.

Section 4.9, “Environment Variables”, includes a list of other environment variables you can use to affect
MySQL programs.
On Unix, the `mysqld_multi` script provides another way to start multiple servers. See Section 4.3.4, “`mysqld_multi` — Manage Multiple MySQL Servers”.

### 5.8.4 Using Client Programs in a Multiple-Server Environment

To connect with a client program to a MySQL server that is listening to different network interfaces from those compiled into your client, you can use one of the following methods:

- Start the client with `--host=host_name --port=port_number` to connect using TCP/IP to a remote server, with `--host=127.0.0.1 --port=port_number` to connect using TCP/IP to a local server, or with `--host=localhost --socket=file_name` to connect to a local server using a Unix socket file or a Windows named pipe.

- Start the client with `--protocol=TCP` to connect using TCP/IP, `--protocol=SOCKET` to connect using a Unix socket file, `--protocol=PIPE` to connect using a named pipe, or `--protocol=MEMORY` to connect using shared memory. For TCP/IP connections, you may also need to specify `--host` and `--port` options. For the other types of connections, you may need to specify a `--socket` option to specify a Unix socket file or Windows named-pipe name, or a `--shared-memory-base-name` option to specify the shared-memory name. Shared-memory connections are supported only on Windows.

- On Unix, set the `MYSQL_UNIX_PORT` and `MYSQL_TCP_PORT` environment variables to point to the Unix socket file and TCP/IP port number before you start your clients. If you normally use a specific socket file or port number, you can place commands to set these environment variables in your `.login` file so that they apply each time you log in. See Section 4.9, “Environment Variables”.

- Specify the default Unix socket file and TCP/IP port number in the `[client]` group of an option file. For example, you can use `C:\my.cnf` on Windows, or the `.my.cnf` file in your home directory on Unix. See Section 4.2.2.2, “Using Option Files”.

- In a C program, you can specify the socket file or port number arguments in the `mysql_real_connect()` call. You can also have the program read option files by calling `mysql_options()`. See C API Function Descriptions.

- If you are using the Perl `DBD::mysql` module, you can read options from MySQL option files. For example:

```perl
$dsn = "DBI:mysql:test;mysql_read_default_group=client;"
    ."mysql_read_default_file=/usr/local/mysql/data/my.cnf";
$dbh = DBI->connect($dsn, $user, $password);

See Section 28.9, “MySQL Perl API”.
```

Other programming interfaces may provide similar capabilities for reading option files.

### 5.9 Debugging MySQL

This section describes debugging techniques that assist efforts to track down problems in MySQL.

#### 5.9.1 Debugging a MySQL Server

If you are using some functionality that is very new in MySQL, you can try to run `mysqld` with the `--skip-new` option (which disables all new, potentially unsafe functionality). See Section B.3.3.3, “What to Do If MySQL Keeps Crashing”.

If `mysqld` does not want to start, verify that you have no `my.cnf` files that interfere with your setup! You can check your `my.cnf` arguments with `mysqld --print-defaults` and avoid using them by starting with `mysqld --no-defaults` ....
Debugging a MySQL Server

If `mysqld` starts to eat up CPU or memory or if it “hangs,” you can use `mysqladmin processlist status` to find out if someone is executing a query that takes a long time. It may be a good idea to run `mysqladmin -i10 processlist status` in some window if you are experiencing performance problems or problems when new clients cannot connect.

The command `mysqladmin debug` dumps some information about locks in use, used memory and query usage to the MySQL log file. This may help solve some problems. This command also provides some useful information even if you have not compiled MySQL for debugging!

If the problem is that some tables are getting slower and slower you should try to optimize the table with `OPTIMIZE TABLE` or `myisamchk`. See Chapter 5, MySQL Server Administration. You should also check the slow queries with `EXPLAIN`.

You should also read the OS-specific section in this manual for problems that may be unique to your environment. See Section 2.1, “General Installation Guidance”.

### 5.9.1.1 Compiling MySQL for Debugging

If you have some very specific problem, you can always try to debug MySQL. To do this you must configure MySQL with the `-DWITH_DEBUG=1` option. You can check whether MySQL was compiled with debugging by doing: `mysqld --help`. If the `--debug` flag is listed with the options then you have debugging enabled. `mysqladmin ver` also lists the `mysqld` version as `mysql ... --debug` in this case.

If `mysqld` stops crashing when you configure it with the `-DWITH_DEBUG=1` CMake option, you probably have found a compiler bug or a timing bug within MySQL. In this case, you can try to add `-g` using the `CMAKE_C_FLAGS` and `CMAKE_CXX_FLAGS` CMake options and not use `-DWITH_DEBUG=1`. If `mysqld` dies, you can at least attach to it with `gdb` or use `gdb` on the core file to find out what happened.

When you configure MySQL for debugging you automatically enable a lot of extra safety check functions that monitor the health of `mysqld`. If they find something “unexpected,” an entry is written to `stderr`, which `mysqld_safe` directs to the error log! This also means that if you are having some unexpected problems with MySQL and are using a source distribution, the first thing you should do is to configure MySQL for debugging. If you believe that you have found a bug, please use the instructions at Section 1.6, “How to Report Bugs or Problems”.

In the Windows MySQL distribution, `mysqld.exe` is by default compiled with support for trace files.

### 5.9.1.2 Creating Trace Files

If the `mysqld` server does not start or it crashes easily, you can try to create a trace file to find the problem.

To do this, you must have a `mysqld` that has been compiled with debugging support. You can check this by executing `mysqld -V`. If the version number ends with `-debug`, it is compiled with support for trace files. (On Windows, the debugging server is named `mysqld-debug` rather than `mysqld`.)

Start the `mysqld` server with a trace log in `/tmp/mysqld.trace` on Unix or `\mysqld.trace` on Windows:

```
shell> mysqld --debug
```

On Windows, you should also use the `--standalone` flag to not start `mysqld` as a service. In a console window, use this command:

```
C:\> mysqld-debug --debug --standalone
```
Debugging a MySQL Server

After this, you can use the `mysql.exe` command-line tool in a second console window to reproduce the problem. You can stop the `mysqld` server with `mysqladmin shutdown`.

The trace file can become very large! To generate a smaller trace file, you can use debugging options something like this:

```
mysqld --debug=d,info,error,query,general,where:O,/tmp/mysqld.trace
```

This only prints information with the most interesting tags to the trace file.

If you file a bug, please add only those lines from the trace file to the bug report that indicate where something seems to go wrong. If you cannot locate the wrong place, open a bug report and upload the whole trace file to the report, so that a MySQL developer can take a look at it. For instructions, see Section 1.6, "How to Report Bugs or Problems".

The trace file is made with the `DBG` package by Fred Fish. See Section 5.9.4, “The DBUG Package”.

### 5.9.1.3 Using WER with PDB to create a Windows crashdump

Program Database files (with suffix `.pdb`) are included in the ZIP Archive Debug Binaries & Test Suite distribution of MySQL. These files provide information for debugging your MySQL installation in the event of a problem. This is a separate download from the standard MSI or Zip file.

**Note**

The PDB files are available in a separate file labeled “ZIP Archive Debug Binaries & Test Suite”.

The PDB file contains more detailed information about `mysqld` and other tools that enables more detailed trace and dump files to be created. You can use these with WinDbg or Visual Studio to debug `mysqld`.

For more information on PDB files, see Microsoft Knowledge Base Article 121366. For more information on the debugging options available, see Debugging Tools for Windows.

To use WinDbg, either install the full Windows Driver Kit (WDK) or install the standalone version.

**Important**

The `.exe` and `.pdb` files must be an exact match (both version number and MySQL server edition); otherwise, or WinDBG complains while attempting to load the symbols.

1. To generate a minidump `mysqld.dmp`, enable the `core-file` option under the `[mysqld]` section in `my.ini`. Restart the MySQL server after making these changes.

2. Create a directory to store the generated files, such as `c:\symbols`

3. Determine the path to your `windbg.exe` executable using the Find GUI or from the command line, for example: `dir /s /b windbg.exe` -- a common default is `C:\Program Files\Debugging Tools for Windows (x64)\windbg.exe`

4. Launch `windbg.exe` giving it the paths to `mysql.exe,mysqld.pdb,mysqld.dmp`, and the source code. Alternatively, pass in each path from the WinDbg GUI. For example:

```
w windbg.exe -i "C:\mysql-8.0.24-winx64\bin"^ -z "C:\mysql-8.0.24-winx64\data\mysqld.dmp"^ -srcpath "E:\ade\mysql_archives\8.0A8.0.24\mysql-8.0.24"^ -y "C:\mysql-8.0.24-winx64\bin;SRV*c:\symbols*http://msdl.microsoft.com/download/symbols"
```
Debugging a MySQL Server

5.9.1.4 Debugging mysqld under gdb

On most systems you can also start mysqld from gdb to get more information if mysqld crashes.

With some older gdb versions on Linux you must use run --one-thread if you want to be able to debug mysqld threads. In this case, you can only have one thread active at a time.

NPTL threads (the new thread library on Linux) may cause problems while running mysqld under gdb. Some symptoms are:

- mysqld hangs during startup (before it writes ready for connections).
- mysqld crashes during a pthread_mutex_lock() or pthread_mutex_unlock() call.

In this case, you should set the following environment variable in the shell before starting gdb:

```bash
LD_ASSUME_KERNEL=2.4.1
export LD_ASSUME_KERNEL
```

When running mysqld under gdb, you should disable the stack trace with --skip-stack-trace to be able to catch segfaults within gdb.

Use the --gdb option to mysqld to install an interrupt handler for SIGINT (needed to stop mysqld with ^C to set breakpoints) and disable stack tracing and core file handling.

It is very hard to debug MySQL under gdb if you do a lot of new connections the whole time as gdb does not free the memory for old threads. You can avoid this problem by starting mysqld with thread_cache_size set to a value equal to max_connections + 1. In most cases just using --thread_cache_size=5' helps a lot!

If you want to get a core dump on Linux if mysqld dies with a SIGSEGV signal, you can start mysqld with the --core-file option. This core file can be used to make a backtrace that may help you find out why mysqld died:

```bash
shell> gdb mysqld core
gdb> backtrace full
gdb> quit
```

See Section B.3.3.3, “What to Do If MySQL Keeps Crashing”.

If you are using gdb on Linux, you should install a .gdb file, with the following information, in your current directory:

```bash
set print sevenbit off
handle SIGUSR1 nostop nopr
handle SIGUSR2 nostop nopr
handle SIGSYS nostop nopr
handle SIGPIPE nostop nopr
handle SIGALRM nostop
handle SIGTERM nostop
handle SIGHUP nostop
handle SIGINT nostop
```

Here is an example how to debug mysqld:
shell> gdb /usr/local/libexec/mysqld
    gdb> run
    ...
    backtrace full # Do this when mysqld crashes

Include the preceding output in a bug report, which you can file using the instructions in Section 1.6, “How to Report Bugs or Problems”.

If mysqld hangs, you can try to use some system tools like strace or /usr/proc/bin/pstack to examine where mysqld has hung.

strace /tmp/log libexec/mysqld

If you are using the Perl DBI interface, you can turn on debugging information by using the trace method or by setting the DBI_TRACE environment variable.

5.9.1.5 Using a Stack Trace

On some operating systems, the error log contains a stack trace if mysqld dies unexpectedly. You can use this to find out where (and maybe why) mysqld died. See Section 5.4.2, “The Error Log”. To get a stack trace, you must not compile mysqld with the -fomit-frame-pointer option to gcc. See Section 5.9.1.1, “Compiling MySQL for Debugging”.

A stack trace in the error log looks something like this:

```
mysqld got signal 11;
Attempting backtrace. You can use the following information to find out where mysqld died. If you see no messages after this, something went terribly wrong...

    stack_bottom = 0x41fd0110 thread_stack 0x400000
    mysqld(my_print_stacktrace+0x32)[0x9da402]
    mysqld(handle_segfault+0x28a)[0x6648e9]
    /lib/libpthread.so.0[0x7f1a5af000f0]
    /lib/libc.so.6[strcmp+0x2][0x7f1a5a10f0f2]
    mysqld(_ZN16set_var_password5checkEP3THD+0xd0)[0x688354]
    mysqld(_ZN17sql_set_variablesP3THD+0x68)[0x67a170]
    mysqld(_Z11mysql_parseP3THD+0x282)[0x67f0ad]
    mysqld(_Z11dump_plugin+0xa)[0x67f71f]
    mysqld(_Z11shutdown)+0x2c[0x67f67]
    mysqld(_Z11shutdown)+0x320[0x67f170]
    mysqld(_Z11shutdown)+0x320[0x67f170]
```

If resolution of function names for the trace fails, the trace contains less information:

```
mysqld got signal 11;
Attempting backtrace. You can use the following information to find out where mysqld died. If you see no messages after this, something went terribly wrong...

    stack_bottom = 0x41fd0110 thread_stack 0x400000
    [0x9da402]
    [0x6648e9]
    [0x7f1a5af000f0]
    [0x7f1a5a10f0f2]
    [0x7412cb]
    [0x688354]
    [0x688494]
    [0x67a170]
    [0x67f0ad]
    [0x67f71f]
    [0x67f67]
```

1110
Debugging a MySQL Server

Newer versions of glibc stack trace functions also print the address as relative to the object. On glibc-based systems (Linux), the trace for an unexpected exit within a plugin looks something like:

```
plugin/auth/auth_test_plugin.so(+0x9a6)[0x7ff4d11c29a6]
```

To translate the relative address (+0x9a6) into a file name and line number, use this command:

```
shell> addr2line -fie auth_test_plugin.so 0x9a6
auth_test_plugin
mysql-trunk/plugin/auth/test_plugin.c:65
```

The `addr2line` utility is part of the binutils package on Linux.

On Solaris, the procedure is similar. The Solaris `printstack()` already prints relative addresses:

```
plugin/auth/auth_test_plugin.so:0x1510
```

To translate, use this command:

```
shell> gaddr2line -fie auth_test_plugin.so 0x1510
mysql-trunk/plugin/auth/test_plugin.c:88
```

Windows already prints the address, function name and line:

```
000007FEF07E10A4 auth_test_plugin.dll!auth_test_plugin()[test_plugin.c:72]
```

5.9.1.6 Using Server Logs to Find Causes of Errors in mysqld

Note that before starting `mysqld` with the general query log enabled, you should check all your tables with `myisamchk`. See Chapter 5, MySQL Server Administration.

If `mysqld` dies or hangs, you should start `mysqld` with the general query log enabled. See Section 5.4.3, “The General Query Log”. When `mysqld` dies again, you can examine the end of the log file for the query that killed `mysqld`.

If you use the default general query log file, the log is stored in the database directory as `host_name.log`. In most cases it is the last query in the log file that killed `mysqld`, but if possible you should verify this by restarting `mysqld` and executing the found query from the `mysql` command-line tools. If this works, you should also test all complicated queries that did not complete.

You can also try the command `EXPLAIN` on all `SELECT` statements that takes a long time to ensure that `mysqld` is using indexes properly. See Section 13.8.2, “EXPLAIN Statement”.

You can find the queries that take a long time to execute by starting `mysqld` with the slow query log enabled. See Section 5.4.5, “The Slow Query Log”.

If you find the text `mysqld restarted` in the error log (normally a file named `host_name.err`) you probably have found a query that causes `mysqld` to fail. If this happens, you should check all your tables with `myisamchk` (see Chapter 5, MySQL Server Administration), and test the queries in the MySQL log files to see whether one fails. If you find such a query, try first upgrading to the newest MySQL version. If this does not help, report a bug, see Section 1.6, “How to Report Bugs or Problems”.

If you have started `mysqld` with the `myisam_recover_options` system variable set, MySQL automatically checks and tries to repair MyISAM tables if they are marked as 'not closed properly' or 'crashed'. If this happens, MySQL writes an entry in the `hostname.err` file 'Warning: Checking table ...' which is followed by Warning: Repairing table if the table needs to be repaired. If you get a lot of these errors, without `mysqld` having died unexpectedly just before, then something is wrong and needs to be investigated further. See Section 5.1.7, “Server Command Options".
When the server detects MyISAM table corruption, it writes additional information to the error log, such as the name and line number of the source file, and the list of threads accessing the table. Example: Got an error from thread_id=1, mi_dynrec.c:368. This is useful information to include in bug reports.

It is not a good sign if mysqld did die unexpectedly, but in this case, you should not investigate the Checking table... messages, but instead try to find out why mysqld died.

### 5.9.1.7 Making a Test Case If You Experience Table Corruption

The following procedure applies to MyISAM tables. For information about steps to take when encountering InnoDB table corruption, see Section 1.6, “How to Report Bugs or Problems”.

If you encounter corrupted MyISAM tables or if mysqld always fails after some update statements, you can test whether the issue is reproducible by doing the following:

1. Stop the MySQL daemon with `mysqladmin shutdown`.
2. Make a backup of the tables to guard against the very unlikely case that the repair does something bad.
3. Check all tables with `myisamchk -s database/*.MYI`. Repair any corrupted tables with `myisamchk -r database/table.MYI`.
4. Make a second backup of the tables.
5. Remove (or move away) any old log files from the MySQL data directory if you need more space.
6. Start mysqld with the binary log enabled. If you want to find a statement that crashes mysqld, you should start the server with the general query log enabled as well. See Section 5.4.3, “The General Query Log”, and Section 5.4.4, “The Binary Log”.
7. When you have gotten a crashed table, stop the mysqld server.
8. Restore the backup.
9. Restart the mysqld server without the binary log enabled.
10. Re-execute the statements with `mysqlbinlog binary-log-file | mysql`. The binary log is saved in the MySQL database directory with the name `hostname-bin.NNNNNN`.
11. If the tables are corrupted again or you can get mysqld to die with the above command, you have found a reproducible bug. FTP the tables and the binary log to our bugs database using the instructions given in Section 1.6, “How to Report Bugs or Problems”. If you are a support customer, you can use the MySQL Customer Support Center (https://www.mysql.com/support/) to alert the MySQL team about the problem and have it fixed as soon as possible.

### 5.9.2 Debugging a MySQL Client

To be able to debug a MySQL client with the integrated debug package, you should configure MySQL with `--WITH_DEBUG=1`. See Section 2.9.7, “MySQL Source-Configuration Options”.

Before running a client, you should set the MYSQL_DEBUG environment variable:

```
shell> MYSQL_DEBUG=d:t:O,/tmp/client.trace
shell> export MYSQL_DEBUG
```

This causes clients to generate a trace file in /tmp/client.trace.
If you have problems with your own client code, you should attempt to connect to the server and run your query using a client that is known to work. Do this by running `mysql` in debugging mode (assuming that you have compiled MySQL with debugging on):

```
shell> mysql --debug=d:t:O,/tmp/client.trace
```

This provides useful information in case you mail a bug report. See Section 1.6, "How to Report Bugs or Problems".

If your client crashes at some 'legal' looking code, you should check that your `mysql.h` include file matches your MySQL library file. A very common mistake is to use an old `mysql.h` file from an old MySQL installation with new MySQL library.

### 5.9.3 The LOCK_ORDER Tool

The MySQL server is a multithreaded application that uses numerous internal locking and lock-related primitives, such as mutexes, rwlocks (including prlocks and sxlocks), conditions, and files. Within the server, the set of lock-related objects changes with implementation of new features and code refactoring for performance improvements. As with any multithreaded application that uses locking primitives, there is always a risk of encountering a deadlock during execution when multiple locks are held at once. For MySQL, the effect of a deadlock is catastrophic, causing a complete loss of service.

As of MySQL 8.0.17, to enable detection of lock-acquisition deadlocks and enforcement that runtime execution is free of them, MySQL supports LOCK_ORDER tooling. This enables a lock-order dependency graph to be defined as part of server design, and server runtime checking to ensure that lock acquisition is acyclic and that execution paths comply with the graph.

This section provides information about using the LOCK_ORDER tool, but only at a basic level. For complete details, see the Lock Order section of the MySQL Server Doxygen documentation, available at https://dev.mysql.com/doc/index-other.html.

The LOCK_ORDER tool is intended for debugging the server, not for production use.

To use the LOCK_ORDER tool, follow this procedure:

1. Build MySQL from source, configuring it with the `--WITH_LOCK_ORDER=ON` CMake option so that the build includes LOCK_ORDER tooling.

   ```
   Note
   With the `WITH_LOCK_ORDER` option enabled, MySQL builds require the `flex` program.
   ```

2. To run the server with the LOCK_ORDER tool enabled, enable the `lock_order` system variable at server startup. Several other system variables for LOCK_ORDER configuration are available as well.

3. For MySQL test suite operation, `mysql-test-run.pl` has a `--lock-order` option that controls whether to enable the LOCK_ORDER tool during test case execution.

The system variables described following configure operation of the LOCK_ORDER tool, assuming that MySQL has been built to include LOCK_ORDER tooling. The primary variable is `lock_order`, which indicates whether to enable the LOCK_ORDER tool at runtime:

- If `lock_order` is disabled (the default), no other LOCK_ORDER system variables have any effect.
- If `lock_order` is enabled, the other system variables configure which LOCK_ORDER features to enable.
The LOCK_ORDER Tool

Note
In general, it is intended that the LOCK_ORDER tool be configured by executing mysql-test-run.pl with the --lock-order option, and for mysql-test-run.pl to set LOCK_ORDER system variables to appropriate values.

All LOCK_ORDER system variables must be set at server startup. At runtime, their values are visible but cannot be changed.

Some system variables exist in pairs, such as lock_order_debug_loop and lock_order_trace_loop. For such pairs, the variables are distinguished as follows when the condition occurs with which they are associated:

- If the _debug_ variable is enabled, a debug assertion is raised.
- If the _trace_ variable is enabled, an error is printed to the logs.

Table 5.7 LOCK_ORDER System Variable Summary

<table>

- **lock_order**

  Command-Line Format
  
  --lock-order[={OFF|ON}]

  Introduced 8.0.17

  System Variable  lock_order
  Scope  Global
  Dynamic  No
  SET_VAR Hint Applies  No
  Type  Boolean
  Default Value  OFF

  Whether to enable the LOCK_ORDER tool at runtime. If lock_order is disabled (the default), no other LOCK_ORDER system variables have any effect. If lock_order is enabled, the other system variables configure which LOCK_ORDER features to enable.
The LOCK_ORDER Tool

If `lock_order` is enabled, an error is raised if the server encounters a lock-acquisition sequence that is not declared in the lock-order graph.

- **lock_order_debug_loop**

  | Command-Line Format | `--lock-order-debug-loop[{OFF|ON}]` |
  |--------------------|----------------------------------|
  | Introduced         | 8.0.17                           |
  | System Variable    | `lock_order_debug_loop`          |
  | Scope              | Global                           |
  | Dynamic            | No                               |
  | `SET_VAR` Hint Applies | No                             |
  | Type               | Boolean                          |
  | Default Value      | `OFF`                            |

Whether the LOCK_ORDER tool causes a debug assertion failure when it encounters a dependency that is flagged as a loop in the lock-order graph.

- **lock_order_debug_missing_arc**

  | Command-Line Format | `--lock-order-debug-missing-arc[{OFF|ON}]` |
  |--------------------|------------------------------------------|
  | Introduced         | 8.0.17                                   |
  | System Variable    | `lock_order_debug_missing_arc`           |
  | Scope              | Global                                   |
  | Dynamic            | No                                       |
  | `SET_VAR` Hint Applies | No                                |
  | Type               | Boolean                                  |
  | Default Value      | `OFF`                                    |

Whether the LOCK_ORDER tool causes a debug assertion failure when it encounters a dependency that is not declared in the lock-order graph.

- **lock_order_debug_missing_key**

  | Command-Line Format | `--lock-order-debug-missing-key[{OFF|ON}]` |
  |--------------------|------------------------------------------|
  | Introduced         | 8.0.17                                   |
  | System Variable    | `lock_order_debug_missing_key`           |
  | Scope              | Global                                   |
  | Dynamic            | No                                       |
  | `SET_VAR` Hint Applies | No                                |
  | Type               | Boolean                                  |
  | Default Value      | `OFF`                                    |

Whether the LOCK_ORDER tool causes a debug assertion failure when it encounters an object that is not properly instrumented with the Performance Schema.

- **lock_order_debug_missing_unlock**
The LOCK_ORDER Tool

| Command-Line Format       | --lock-order-debug-missing-unlock=[OFF|ON] |
|---------------------------|-------------------------------------------|
| Introduced                | 8.0.17                                    |
| System Variable           | lock_order_debug_missing_unlock           |
| Scope                     | Global                                    |
| Dynamic                   | No                                        |
| SET_VAR Hint Applies      | No                                        |
| Type                      | Boolean                                   |
| Default Value             | OFF                                       |

Whether the LOCK_ORDER tool causes a debug assertion failure when it encounters a lock that is destroyed while still held.

- **lock_order_dependencies**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--lock-order-dependencies=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.17</td>
</tr>
<tr>
<td>System Variable</td>
<td>lock_order_dependencies</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>empty string</td>
</tr>
</tbody>
</table>

The path to the `lock_order_dependencies.txt` file that defines the server lock-order dependency graph.

It is permitted to specify no dependencies. An empty dependency graph is used in this case.

- **lock_order_extra_dependencies**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--lock-order-extra-dependencies=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.17</td>
</tr>
<tr>
<td>System Variable</td>
<td>lock_order_extra_dependencies</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>empty string</td>
</tr>
</tbody>
</table>

The path to a file containing additional dependencies for the lock-order dependency graph. This is useful to amend the primary server dependency graph, defined in the `lock_order_dependencies.txt` file, with additional dependencies describing the behavior of third party code. (The alternative is to modify `lock_order_dependencies.txt` itself, which is not encouraged.)

If this variable is not set, no secondary file is used.
### lock_order_output_directory

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--lock-order-output-directory=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.17</td>
</tr>
<tr>
<td>System Variable</td>
<td>lock_order_output_directory</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td>empty string</td>
</tr>
</tbody>
</table>

The directory where the LOCK_ORDER tool writes its logs. If this variable is not set, the default is the current directory.

### lock_order_print_txt

| Command-Line Format                  | --lock-order-print-txt={OFF|ON} |
|--------------------------------------|---------------------------------|
| Introduced                           | 8.0.17                          |
| System Variable                      | lock_order_print_txt            |
| Scope                                | Global                          |
| Dynamic                              | No                              |
| SET_VAR Hint Applies                 | No                              |
| Type                                 | Boolean                         |
| Default Value                        | OFF                             |

Whether the LOCK_ORDER tool performs a lock-order graph analysis and prints a textual report. The report includes any lock-acquisition cycles detected.

### lock_order_trace_loop

| Command-Line Format                  | --lock-order-trace-loop={OFF|ON} |
|--------------------------------------|---------------------------------|
| Introduced                           | 8.0.17                          |
| System Variable                      | lock_order_trace_loop           |
| Scope                                | Global                          |
| Dynamic                              | No                              |
| SET_VAR Hint Applies                 | No                              |
| Type                                 | Boolean                         |
| Default Value                        | OFF                             |

Whether the LOCK_ORDER tool prints a trace in the log file when it encounters a dependency that is flagged as a loop in the lock-order graph.

### lock_order_trace_missing_arc

| Command-Line Format                  | --lock-order-trace-missing-arc={OFF|ON} |
|--------------------------------------|----------------------------------------|
| Introduced                           | 8.0.17                                 |
### System Variable

<table>
<thead>
<tr>
<th>lock_order_trace_missing_arc</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
</tr>
<tr>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
</tr>
<tr>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
</tr>
<tr>
<td>No</td>
</tr>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
</tr>
<tr>
<td>ON</td>
</tr>
</tbody>
</table>

Whether the LOCK_ORDER tool prints a trace in the log file when it encounters a dependency that is not declared in the lock-order graph.

- **lock_order_trace_missing_key**

| Command-Line Format | `--lock-order-trace-missing-key[={OFF|ON}]` |
|---------------------|------------------------------------------|
| Introduced          | 8.0.17                                   |
| System Variable     | lock_order_trace_missing_key             |
| Scope               | Global                                   |
| Dynamic             | No                                       |
| SET_VAR Hint Applies| No                                       |
| Type                | Boolean                                 |
| Default Value       | OFF                                      |

Whether the LOCK_ORDER tool prints a trace in the log file when it encounters an object that is not properly instrumented with the Performance Schema.

- **lock_order_trace_missing_unlock**

| Command-Line Format | `--lock-order-trace-missing-unlock[={OFF|ON}]` |
|---------------------|-----------------------------------------------|
| Introduced          | 8.0.17                                        |
| System Variable     | lock_order_trace_missing_unlock              |
| Scope               | Global                                       |
| Dynamic             | No                                            |
| SET_VAR Hint Applies| No                                            |
| Type                | Boolean                                      |
| Default Value       | ON                                            |

Whether the LOCK_ORDER tool prints a trace in the log file when it encounters a lock that is destroyed while still held.

### 5.9.4 The DBUG Package

The MySQL server and most MySQL clients are compiled with the DBUG package originally created by Fred Fish. When you have configured MySQL for debugging, this package makes it possible to get a trace file of what the program is doing. See Section 5.9.1.2, “Creating Trace Files”.

This section summarizes the argument values that you can specify in debug options on the command line for MySQL programs that have been built with debugging support.
The DBUG package can be used by invoking a program with the `--debug[=debug_options]` or `--debug[=debug_options]` option. If you specify the `--debug` or `--debug[=debug_options]` option without a `debug_options` value, most MySQL programs use a default value. The server default is `d:t:i:o,/tmp/mysqld.trace` on Unix and `d:t:i:o,/mysqld.trace` on Windows. The effect of this default is:

- **d**: Enable output for all debug macros
- **t**: Trace function calls and exits
- **i**: Add PID to output lines
- **o,/tmp/mysqld.trace,0,/mysqld.trace**: Set the debug output file.

Most client programs use a default `debug_options` value of `d:t:o,/tmp/program_name.trace`, regardless of platform.

Here are some example debug control strings as they might be specified on a shell command line:

```plaintext
--debug=d:t
--debug=d:f,main,subr1:F:L:t,20
--debug=d,input,output,files:n
--debug=d:t:i:O,\mysqld.trace
```

For `mysqld`, it is also possible to change DBUG settings at runtime by setting the `debug` system variable. This variable has global and session values:

```plaintext
mysql> SET GLOBAL debug = 'debug_options';
```

Changing the global `debug` value requires privileges sufficient to set global system variables. Changing the session `debug` value requires privileges sufficient to set restricted session system variables. See Section 5.1.9.1, “System Variable Privileges”.

The `debug_options` value is a sequence of colon-separated fields:

```plaintext
field_1:field_2:...:field_N
```

Each field within the value consists of a mandatory flag character, optionally preceded by a + or - character, and optionally followed by a comma-separated list of modifiers:

```plaintext
[+|-]flag[,modifier,modifier,...,modifier]
```

The following table describes the permitted flag characters. Unrecognized flag characters are silently ignored.

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>d</strong></td>
<td>Enable output from DBUG_XXX macros for the current state. May be followed by a list of keywords, which enables output only for the DBUG macros with that keyword. An empty list of keywords enables output for all macros.</td>
</tr>
</tbody>
</table>

In MySQL, common debug macro keywords to enable are `enter`, `exit`, `error`, `warning`, `info`, and `loop`.

| **D** | Delay after each debugger output line. The argument is the delay, in tenths of seconds, subject to machine capabilities. For example, `D,20` specifies a delay of two seconds. |

| **f** | Limit debugging, tracing, and profiling to the list of named functions. An empty list enables all functions. The appropriate **d** or **t** flags must still be given; this flag only limits their actions if they are enabled. |
### Flag | Description
---|---
F | Identify the source file name for each line of debug or trace output.
i | Identify the process with the PID or thread ID for each line of debug or trace output.
L | Identify the source file line number for each line of debug or trace output.
n | Print the current function nesting depth for each line of debug or trace output.
N | Number each line of debug output.
○ | Redirect the debugger output stream to the specified file. The default output is `stderr`.
○ | Like ○, but the file is really flushed between each write. When needed, the file is closed and reopened between each write.
P | Limit debugger actions to specified processes. A process must be identified with the `DEBUG_PROCESS` macro and match one in the list for debugger actions to occur.
P | Print the current process name for each line of debug or trace output.
r | When pushing a new state, do not inherit the previous state’s function nesting level. Useful when the output is to start at the left margin.
S | Do function `_sanity(_file_,_line_)` at each debugged function until `_sanity()` returns something that differs from 0.
t | Enable function call/exit trace lines. May be followed by a list (containing only one modifier) giving a numeric maximum trace level, beyond which no output occurs for either debugging or tracing macros. The default is a compile time option.

The leading + or - character and trailing list of modifiers are used for flag characters such as `d` or `f` that can enable a debug operation for all applicable modifiers or just some of them:

- With no leading + or -, the flag value is set to exactly the modifier list as given.
- With a leading + or -, the modifiers in the list are added to or subtracted from the current modifier list.

The following examples show how this works for the `d` flag. An empty `d` list enabled output for all debug macros. A nonempty `d` list enables output only for the macro keywords in the list.

These statements set the `d` value to the modifier list as given:

```sql
mysql> SET debug = 'd';
mysql> SELECT @@debug;
```

| +---------+
| @@debug  |
| +---------+
| d        |

```sql
mysql> SET debug = 'd,error,warning';
mysql> SELECT @@debug;
```

| +-----------------+
| @@debug          |
| +-----------------+
| d,error,warning  |

A leading + or - adds to or subtracts from the current `d` value:

```sql
mysql> SET debug = '+d,loop';
mysql> SELECT @@debug;
```

| +------------------------------------------------+
| @@debug                                        |
| +------------------------------------------------+
| d,loop                                         |
The DBUG Package

mysql> SET debug = '-d,error,loop';
+----------------------+
| @debug               |
| d,warning            |
| d,loop               |
|                     |
|                     |
|                     |
|                     |

Adding to “all macros enabled” results in no change:

mysql> SET debug = 'd';
+---------+
| @debug  |
| d       |
+---------+

mysql> SET debug = '+d,loop';
+---------+
| @debug  |
| d       |
+---------+

Disabling all enabled macros disables the d flag entirely:

mysql> SET debug = 'd,error,loop';
+----------------------+
| @debug               |
| d,error,loop         |
+----------------------+

mysql> SET debug = '-d,error,loop';
+---------+
| @debug  |
|         |
+---------+

  6.5.2 Installing or Uninstalling MySQL Enterprise Data Masking and De-Identification ........................ 1494
When thinking about security within a MySQL installation, you should consider a wide range of possible topics and how they affect the security of your MySQL server and related applications:

• General factors that affect security. These include choosing good passwords, not granting unnecessary privileges to users, ensuring application security by preventing SQL injections and data corruption, and others. See Section 6.1, “General Security Issues”.

• Security of the installation itself. The data files, log files, and the all the application files of your installation should be protected to ensure that they are not readable or writable by unauthorized parties. For more information, see Section 2.10, “Postinstallation Setup and Testing”.

• Access control and security within the database system itself, including the users and databases granted with access to the databases, views and stored programs in use within the database. For more information, see Section 6.2, “Access Control and Account Management”.

• The features offered by security-related plugins. See Section 6.4, “Security Components and Plugins”.

• Network security of MySQL and your system. The security is related to the grants for individual users, but you may also wish to restrict MySQL so that it is available only locally on the MySQL server host, or to a limited set of other hosts.

• Ensure that you have adequate and appropriate backups of your database files, configuration and log files. Also be sure that you have a recovery solution in place and test that you are able to successfully recover the information from your backups. See Chapter 7, Backup and Recovery.

6.1 General Security Issues

This section describes general security issues to be aware of and what you can do to make your MySQL installation more secure against attack or misuse. For information specifically about the access control system that MySQL uses for setting up user accounts and checking database access, see Section 2.10, “Postinstallation Setup and Testing”.

For answers to some questions that are often asked about MySQL Server security issues, see Section A.9, “MySQL 8.0 FAQ: Security”.

6.1.1 Security Guidelines
Anyone using MySQL on a computer connected to the Internet should read this section to avoid the most common security mistakes.

In discussing security, it is necessary to consider fully protecting the entire server host (not just the MySQL server) against all types of applicable attacks: eavesdropping, altering, playback, and denial of service. We do not cover all aspects of availability and fault tolerance here.

MySQL uses security based on Access Control Lists (ACLs) for all connections, queries, and other operations that users can attempt to perform. There is also support for SSL-encrypted connections between MySQL clients and servers. Many of the concepts discussed here are not specific to MySQL at all; the same general ideas apply to almost all applications.

When running MySQL, follow these guidelines:

• Do not ever give anyone (except MySQL root accounts) access to the user table in the mysql system database! This is critical.

• Learn how the MySQL access privilege system works (see Section 6.2, “Access Control and Account Management”). Use the GRANT and REVOKE statements to control access to MySQL. Do not grant more privileges than necessary. Never grant privileges to all hosts.

Checklist:

• Try mysql -u root. If you are able to connect successfully to the server without being asked for a password, anyone can connect to your MySQL server as the MySQL root user with full privileges! Review the MySQL installation instructions, paying particular attention to the information about setting a root password. See Section 2.10.4, “Securing the Initial MySQL Account”.

• Use the SHOW GRANTS statement to check which accounts have access to what. Then use the REVOKE statement to remove those privileges that are not necessary.

• Do not store cleartext passwords in your database. If your computer becomes compromised, the intruder can take the full list of passwords and use them. Instead, use SHA2() or some other one-way hashing function and store the hash value. To prevent password recovery using rainbow tables, do not use these functions on a plain password; instead, choose some string to be used as a salt, and use hash(hash(password)+salt) values.

• Do not choose passwords from dictionaries. Special programs exist to break passwords. Even passwords like “xfish98” are very bad. Much better is “duag98” which contains the same word “fish” but typed one key to the left on a standard QWERTY keyboard. Another method is to use a password that is taken from the first characters of each word in a sentence (for example, “Four score and seven years ago” results in a password of “Fsasya”). The password is easy to remember and type, but difficult to guess for someone who does not know the sentence. In this case, you can additionally substitute digits for the number words to obtain the phrase “4 score and 7 years ago”, yielding the password “4sa7ya” which is even more difficult to guess.

• Invest in a firewall. This protects you from at least 50% of all types of exploits in any software. Put MySQL behind the firewall or in a demilitarized zone (DMZ).

Checklist:

• Try to scan your ports from the Internet using a tool such as nmap. MySQL uses port 3306 by default. This port should not be accessible from untrusted hosts. As a simple way to check whether your MySQL port is open, try the following command from some remote machine, where server_host is the host name or IP address of the host on which your MySQL server runs:
Keeping Passwords Secure

If `telnet` hangs or the connection is refused, the port is blocked, which is how you want it to be. If you get a connection and some garbage characters, the port is open, and should be closed on your firewall or router, unless you really have a good reason to keep it open.

- Applications that access MySQL should not trust any data entered by users, and should be written using proper defensive programming techniques. See Section 6.1.7, “Client Programming Security Guidelines”.

- Do not transmit plain (unencrypted) data over the Internet. This information is accessible to everyone who has the time and ability to intercept it and use it for their own purposes. Instead, use an encrypted protocol such as SSL or SSH. MySQL supports internal SSL connections. Another technique is to use SSH port-forwarding to create an encrypted (and compressed) tunnel for the communication.

- Learn to use the `tcpdump` and `strings` utilities. In most cases, you can check whether MySQL data streams are unencrypted by issuing a command like the following:

  ```bash
  shell> tcpdump -l -i eth0 -w - src or dst port 3306 | strings
  ```

  This works under Linux and should work with small modifications under other systems.

  **Warning**

  If you do not see cleartext data, this does not always mean that the information actually is encrypted. If you need high security, consult with a security expert.

6.1.2 Keeping Passwords Secure

Passwords occur in several contexts within MySQL. The following sections provide guidelines that enable end users and administrators to keep these passwords secure and avoid exposing them. In addition, the `validate_password` plugin can be used to enforce a policy on acceptable password. See Section 6.4.3, “The Password Validation Component”.

6.1.2.1 End-User Guidelines for Password Security

MySQL users should use the following guidelines to keep passwords secure.

When you run a client program to connect to the MySQL server, it is inadvisable to specify your password in a way that exposes it to discovery by other users. The methods you can use to specify your password when you run client programs are listed here, along with an assessment of the risks of each method. In short, the safest methods are to have the client program prompt for the password or to specify the password in a properly protected option file.

- Use the `mysql_config_editor` utility, which enables you to store authentication credentials in an encrypted login path file named `.mylogin.cnf`. The file can be read later by MySQL client programs to obtain authentication credentials for connecting to MySQL Server. See Section 4.6.7, “`mysql_config_editor` — MySQL Configuration Utility”.

- Use a `--password=password` or `-p password` option on the command line. For example:

  ```bash
  shell> mysql -u francis -p frank db_name
  ```

  **Warning**

  This is convenient but insecure. On some systems, your password becomes visible to system status programs such as `ps` that may be invoked by other users.
to display command lines. MySQL clients typically overwrite the command-line password argument with zeros during their initialization sequence. However, there is still a brief interval during which the value is visible. Also, on some systems this overwriting strategy is ineffective and the password remains visible to `ps`. (SystemV Unix systems and perhaps others are subject to this problem.)

If your operating environment is set up to display your current command in the title bar of your terminal window, the password remains visible as long as the command is running, even if the command has scrolled out of view in the window content area.

- Use the `--password` or `-p` option on the command line with no password value specified. In this case, the client program solicits the password interactively:

  ```shell
  mysql -u francis -p db_name
  Enter password: ********
  ```

  The `*` characters indicate where you enter your password. The password is not displayed as you enter it.

  It is more secure to enter your password this way than to specify it on the command line because it is not visible to other users. However, this method of entering a password is suitable only for programs that you run interactively. If you want to invoke a client from a script that runs noninteractively, there is no opportunity to enter the password from the keyboard. On some systems, you may even find that the first line of your script is read and interpreted (incorrectly) as your password.

- Store your password in an option file. For example, on Unix, you can list your password in the `[client]` section of the `.my.cnf` file in your home directory:

  ```
  [client]
  password=password
  ```

  To keep the password safe, the file should not be accessible to anyone but yourself. To ensure this, set the file access mode to `400` or `600`. For example:

  ```shell
  chmod 600 .my.cnf
  ```

  To name from the command line a specific option file containing the password, use the `--defaults-file=file_name` option, where `file_name` is the full path name to the file. For example:

  ```shell
  mysql --defaults-file=/home/francis/mysql-opts
  ```

  Section 4.2.2.2, "Using Option Files", discusses option files in more detail.

On Unix, the `mysql` client writes a record of executed statements to a history file (see Section 4.5.1.3, "mysql Client Logging"). By default, this file is named `.mysql_history` and is created in your home directory. Passwords can be written as plain text in SQL statements such as `CREATE USER` and `ALTER USER`, so if you use these statements, they are logged in the history file. To keep this file safe, use a restrictive access mode, the same way as described earlier for the `.my.cnf` file.

If your command interpreter maintains a history, any file in which the commands are saved contains MySQL passwords entered on the command line. For example, `bash` uses `~/.bash_history`. Any such file should have a restrictive access mode.

### 6.1.2.2 Administrator Guidelines for Password Security

Database administrators should use the following guidelines to keep passwords secure.

MySQL stores passwords for user accounts in the `mysql.user` system table. Access to this table should never be granted to any nonadministrative accounts.
Account passwords can be expired so that users must reset them. See Section 6.2.15, “Password Management”, and Section 6.2.16, “Server Handling of Expired Passwords”.

The `validate_password` plugin can be used to enforce a policy on acceptable password. See Section 6.4.3, “The Password Validation Component”.

A user who has access to modify the plugin directory (the value of the `plugin_dir` system variable) or the `my.cnf` file that specifies the plugin directory location can replace plugins and modify the capabilities provided by plugins, including authentication plugins.

Files such as log files to which passwords might be written should be protected. See Section 6.1.2.3, “Passwords and Logging”.

### 6.1.2.3 Passwords and Logging

Passwords can be written as plain text in SQL statements such as `CREATE USER`, `GRANT` and `SET PASSWORD`. If such statements are logged by the MySQL server as written, passwords in them become visible to anyone with access to the logs.

Statement logging avoids writing passwords as cleartext for the following statements:

```
CREATE USER ... IDENTIFIED BY ...
ALTER USER ... IDENTIFIED BY ...
SET PASSWORD ...
START SLAVE ... PASSWORD = ...
START REPLICA ... PASSWORD = ...
CREATE SERVER ... OPTIONS(... PASSWORD ...) 
ALTER SERVER ... OPTIONS(... PASSWORD ...)
```

Passwords in those statements are rewritten to not appear literally in statement text written to the general query log, slow query log, and binary log. Rewriting does not apply to other statements. In particular, `INSERT` or `UPDATE` statements for the `mysql.user` system table that refer to literal passwords are logged as is, so you should avoid such statements. (Direct modification of grant tables is discouraged, anyway.)

For the general query log, password rewriting can be suppressed by starting the server with the `--log-raw` option. For security reasons, this option is not recommended for production use. For diagnostic purposes, it may be useful to see the exact text of statements as received by the server.

By default, contents of audit log files produced by the audit log plugin are not encrypted and may contain sensitive information, such as the text of SQL statements. For security reasons, audit log files should be written to a directory accessible only to the MySQL server and to users with a legitimate reason to view the log. See Section 6.4.5.3, “MySQL Enterprise Audit Security Considerations”.

Statements received by the server may be rewritten if a query rewrite plugin is installed (see Query Rewrite Plugins). In this case, the `--log-raw` option affects statement logging as follows:

- Without `--log-raw`, the server logs the statement returned by the query rewrite plugin. This may differ from the statement as received.
- With `--log-raw`, the server logs the original statement as received.

An implication of password rewriting is that statements that cannot be parsed (due, for example, to syntax errors) are not written to the general query log because they cannot be known to be password free. Use cases that require logging of all statements including those with errors should use the `--log-raw` option, bearing in mind that this also bypasses password rewriting.

Password rewriting occurs only when plain text passwords are expected. For statements with syntax that expect a password hash value, no rewriting occurs. If a plain text password is supplied erroneously for such syntax, the password is logged as given, without rewriting.
To guard log files against unwarranted exposure, locate them in a directory that restricts access to the server and the database administrator. If the server logs to tables in the `mysql` database, grant access to those tables only to the database administrator.

Replicas store the password for the replication source server in their connection metadata repository, which by default is a table in the `mysql` database named `slave_master_info`. The use of a file in the data directory for the connection metadata repository is now deprecated, but still possible (see Section 17.2.4, “Relay Log and Replication Metadata Repositories”). Ensure that the connection metadata repository can be accessed only by the database administrator. An alternative to storing the password in the connection metadata repository is to use the `START REPLICA | SLAVE` or `START GROUP_REPLICATION` statement to specify credentials for connecting to the source.

Use a restricted access mode to protect database backups that include log tables or log files containing passwords.

### 6.1.3 Making MySQL Secure Against Attackers

When you connect to a MySQL server, you should use a password. The password is not transmitted as cleartext over the connection.

All other information is transferred as text, and can be read by anyone who is able to watch the connection. If the connection between the client and the server goes through an untrusted network, and you are concerned about this, you can use the compressed protocol to make traffic much more difficult to decipher. You can also use MySQL's internal SSL support to make the connection even more secure. See Section 6.3, “Using Encrypted Connections”. Alternatively, use SSH to get an encrypted TCP/IP connection between a MySQL server and a MySQL client. You can find an Open Source SSH client at [http://www.openssh.org/](http://www.openssh.org/), and a comparison of both Open Source and Commercial SSH clients at [http://en.wikipedia.org/wiki/Comparison_of_SSH_clients](http://en.wikipedia.org/wiki/Comparison_of_SSH_clients).

To make a MySQL system secure, you should strongly consider the following suggestions:

- Require all MySQL accounts to have a password. A client program does not necessarily know the identity of the person running it. It is common for client/server applications that the user can specify any user name to the client program. For example, anyone can use the `mysql` program to connect as any other person simply by invoking it as `mysql -u other_user db_name` if `other_user` has no password. If all accounts have a password, connecting using another user's account becomes much more difficult.

  For a discussion of methods for setting passwords, see Section 6.2.14, “Assigning Account Passwords”.

- Make sure that the only Unix user account with read or write privileges in the database directories is the account that is used for running `mysqld`.

- Never run the MySQL server as the Unix `root` user. This is extremely dangerous, because any user with the `FILE` privilege is able to cause the server to create files as `root` (for example, `~root/.bashrc`). To prevent this, `mysqld` refuses to run as `root` unless that is specified explicitly using the `--user=root` option.

  `mysqld` can (and should) be run as an ordinary, unprivileged user instead. You can create a separate Unix account named `mysql` to make everything even more secure. Use this account only for administering MySQL. To start `mysqld` as a different Unix user, add a `user` option that specifies the user name in the `[mysqld]` group of the `my.cnf` option file where you specify server options. For example:

```
[mysqld]
user=mysql
```
This causes the server to start as the designated user whether you start it manually or by using `mysqld_safe` or `mysql.server`. For more details, see Section 6.1.5, "How to Run MySQL as a Normal User".

Running `mysqld` as a Unix user other than `root` does not mean that you need to change the `root` user name in the `user` table. *User names for MySQL accounts have nothing to do with user names for Unix accounts.*

- Do not grant the `FILE` privilege to nonadministrative users. Any user that has this privilege can write a file anywhere in the file system with the privileges of the `mysqld` daemon. This includes the server's data directory containing the files that implement the privilege tables. To make `FILE`-privilege operations a bit safer, files generated with `SELECT ... INTO OUTFILE` do not overwrite existing files and are writable by everyone.

The `FILE` privilege may also be used to read any file that is world-readable or accessible to the Unix user that the server runs as. With this privilege, you can read any file into a database table. This could be abused, for example, by using `LOAD DATA` to load `/etc/passwd` into a table, which then can be displayed with `SELECT`.

To limit the location in which files can be read and written, set the `secure_file_priv` system to a specific directory. See Section 5.1.8, "Server System Variables".

- Encrypt binary log files and relay log files. Encryption helps to protect these files and the potentially sensitive data contained in them from being misused by outside attackers, and also from unauthorized viewing by users of the operating system where they are stored. You enable encryption on a MySQL server by setting the `binlog_encryption` system variable to `ON`. For more information, see Section 17.3.2, "Encrypting Binary Log Files and Relay Log Files".

- Do not grant the `PROCESS` or `SUPER` privilege to nonadministrative users. The output of `mysqladmin processlist` and `SHOW PROCESSLIST` shows the text of any statements currently being executed, so any user who is permitted to see the server process list might be able to see statements issued by other users.

  `mysqld` reserves an extra connection for users who have the `CONNECTION_ADMIN` or `SUPER` privilege, so that a MySQL `root` user can log in and check server activity even if all normal connections are in use.

  The `SUPER` privilege can be used to terminate client connections, change server operation by changing the value of system variables, and control replication servers.

- Do not permit the use of symlinks to tables. (This capability can be disabled with the `--skip-symbolic-links` option.) This is especially important if you run `mysqld` as `root`, because anyone that has write access to the server's data directory then could delete any file in the system! See Section 8.12.2.2, "Using Symbolic Links for MyISAM Tables on Unix".

- Stored programs and views should be written using the security guidelines discussed in Section 24.6, "Stored Object Access Control".

- If you do not trust your DNS, you should use IP addresses rather than host names in the grant tables. In any case, you should be very careful about creating grant table entries using host name values that contain wildcards.

- If you want to restrict the number of connections permitted to a single account, you can do so by setting the `max_user_connections` variable in `mysqld`. The `CREATE USER` and `ALTER USER` statements also support resource control options for limiting the extent of server use permitted to an account. See Section 13.7.1.3, "CREATE USER Statement", and Section 13.7.1.1, "ALTER USER Statement".
• If the plugin directory is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making `plugin_dir` read only to the server or by setting `secure_file_priv` to a directory where `SELECT` writes can be made safely.

### 6.1.4 Security-Related `mysqld` Options and Variables

The following table shows `mysqld` options and system variables that affect security. For descriptions of each of these, see Section 5.1.7, “Server Command Options”, and Section 5.1.8, “Server System Variables”.

### 6.1.5 How to Run MySQL as a Normal User

On Windows, you can run the server as a Windows service using a normal user account.

On Linux, for installations performed using a MySQL repository or RPM packages, the MySQL server `mysqld` should be started by the local `mysql` operating system user. Starting by another operating system user is not supported by the init scripts that are included as part of the MySQL repositories.

On Unix (or Linux for installations performed using `tar.gz` packages), the MySQL server `mysqld` can be started and run by any user. However, you should avoid running the server as the Unix `root` user for security reasons. To change `mysqld` to run as a normal unprivileged Unix user `user_name`, you must do the following:

1. Stop the server if it is running (use `mysqldadmin shutdown`).
2. Change the database directories and files so that `user_name` has privileges to read and write files in them (you might need to do this as the Unix `root` user):

   ```shell
   shell> chown -R user_name /path/to/mysql/datadir
   ```

   If you do not do this, the server cannot access databases or tables when it runs as `user_name`.

   If directories or files within the MySQL data directory are symbolic links, `chown -R` might not follow symbolic links for you. If it does not, you must also follow those links and change the directories and files they point to.

3. Start the server as user `user_name`. Another alternative is to start `mysqld` as the Unix `root` user and use the `--user=user_name` option. `mysqld` starts, then switches to run as the Unix user `user_name` before accepting any connections.
4. To start the server as the given user automatically at system startup time, specify the user name by adding a `user` option to the `[mysqld]` group of the `/etc/my.cnf` option file or the `my.cnf` option file in the server's data directory. For example:

```
[mysqld]
user=user_name
```

If your Unix machine itself is not secured, you should assign passwords to the MySQL root account in the grant tables. Otherwise, any user with a login account on that machine can run the `mysql` client with a `--user=root` option and perform any operation. (It is a good idea to assign passwords to MySQL accounts in any case, but especially so when other login accounts exist on the server host.) See Section 2.10.4, “Securing the Initial MySQL Account”.

**6.1.6 Security Considerations for LOAD DATA LOCAL**

The `LOAD DATA` statement loads a data file into a table. The statement can load a file located on the server host, or, if the `LOCAL` keyword is specified, on the client host.

The `LOCAL` version of `LOAD DATA` has two potential security issues:

- Because `LOAD DATA LOCAL` is an SQL statement, parsing occurs on the server side, and transfer of the file from the client host to the server host is initiated by the MySQL server, which tells the client the file named in the statement. In theory, a patched server could tell the client program to transfer a file of the server's choosing rather than the file named in the statement. Such a server could access any file on the client host to which the client user has read access. (A patched server could in fact reply with a file-transfer request to any statement, not just `LOAD DATA LOCAL`, so a more fundamental issue is that clients should not connect to untrusted servers.)

- In a Web environment where the clients are connecting from a Web server, a user could use `LOAD DATA LOCAL` to read any files that the Web server process has read access to (assuming that a user could run any statement against the SQL server). In this environment, the client with respect to the MySQL server actually is the Web server, not a remote program being run by users who connect to the Web server.

To avoid connecting to untrusted servers, clients can establish a secure connection and verify the server identity by connecting using the `--ssl-mode=VERIFY_IDENTITY` option and the appropriate CA certificate.

To avoid `LOAD DATA` issues, clients should avoid using `LOCAL` unless proper client-side precautions have been taken.

For control over local data loading, MySQL permits the capability to be enabled or disabled. In addition, as of MySQL 8.0.21, MySQL enables clients to restrict local data loading operations to files located in a designated directory.

- Enabling or Disabling Local Data Loading Capability
- Restricting Files Permitted for Local Data Loading

**Enabling or Disabling Local Data Loading Capability**

Administrators and applications can configure whether to permit local data loading as follows:

- On the server side:

  - The `local_infile` system variable controls server-side `LOCAL` capability. Depending on the `local_infile` setting, the server refuses or permits local data loading by clients that request local data loading.
• By default, local_infile is disabled. To explicitly cause the server to refuse or permit LOAD DATA LOCAL statements (regardless of how client programs and libraries are configured at build time or runtime), start mysqld with local_infile disabled or enabled. local_infile can also be set at runtime.

• On the client side:

  • The ENABLED_LOCAL_INFILE CMake option controls the compiled-in default LOCAL capability for the MySQL client library (see Section 2.9.7, “MySQL Source-Configuration Options”). Clients that make no explicit arrangements therefore have LOCAL capability disabled or enabled according to the ENABLED_LOCAL_INFILE setting specified at MySQL build time.

  • By default, the client library in MySQL binary distributions is compiled with ENABLED_LOCAL_INFILE disabled. If you compile MySQL from source, configure it with ENABLED_LOCAL_INFILE disabled or enabled based on whether clients that make no explicit arrangements should have LOCAL capability disabled or enabled.

  • For client programs that use the C API, local data loading capability is determined by the default compiled into the MySQL client library. To enable or disable it explicitly, invoke the mysql_options() C API function to disable or enable the MYSQL_OPT_LOCAL_INFILE option. See mysql_options().

  • For the mysql client, local data loading capability is determined by the default compiled into the MySQL client library. To disable or enable it explicitly, use the --local-infile=0 or --local-infile[=1] option.

  • For the mysqlimport client, local data loading is not used by default. To disable or enable it explicitly, use the --local=0 or --local[=1] option.

  • If you use LOAD DATA LOCAL in Perl scripts or other programs that read the [client] group from option files, you can add a local-infile option setting to that group. To prevent problems for programs that do not understand this option, specify it using the loose- prefix:

    
    ```
    [client]
    loose-local-infile=0
    ```
    
    or:

    ```
    [client]
    loose-local-infile=1
    ```

  • In all cases, successful use of a LOCAL load operation by a client also requires that the server permits local loading.

If LOCAL capability is disabled, on either the server or client side, a client that attempts to issue a LOAD DATA LOCAL statement receives the following error message:

```
ERROR 3950 (42000): Loading local data is disabled; this must be enabled on both the client and server side
```

### Restricting Files Permitted for Local Data Loading

As of MySQL 8.0.21, the MySQL client library enables client applications to restrict local data loading operations to files located in a designated directory. Certain MySQL client programs take advantage of this capability.
Client programs that use the C API can control which files to permit for load data loading using the `MYSQL_OPT_LOCAL_INFILE` and `MYSQL_OPT_LOAD_DATA_LOCAL_DIR` options of the `mysql_options()` C API function (see `mysql_options()`).

The effect of `MYSQL_OPT_LOAD_DATA_LOCAL_DIR` depends on whether `LOCAL` data loading is enabled or disabled:

- If `LOCAL` data loading is enabled, either by default in the MySQL client library or by explicitly enabling `MYSQL_OPT_LOCAL_INFILE`, the `MYSQL_OPT_LOAD_DATA_LOCAL_DIR` option has no effect.

- If `LOCAL` data loading is disabled, either by default in the MySQL client library or by explicitly disabling `MYSQL_OPT_LOCAL_INFILE`, the `MYSQL_OPT_LOAD_DATA_LOCAL_DIR` option can be used to designate a permitted directory for locally loaded files. In this case, `LOCAL` data loading is permitted but restricted to files located in the designated directory. Interpretation of the `MYSQL_OPT_LOAD_DATA_LOCAL_DIR` value is as follows:
  
  - If the value is the null pointer (the default), it names no directory, with the result that no files are permitted for `LOCAL` data loading.
  
  - If the value is a directory path name, `LOCAL` data loading is permitted but restricted to files located in the named directory. Comparison of the directory path name and the path name of files to be loaded is case-sensitive regardless of the case-sensitivity of the underlying file system.

MySQL client programs use the preceding `mysql_options()` options as follows:

- The `mysql` client has a `--load-data-local-dir` option that takes a directory path or an empty string. `mysql` uses the option value to set the `MYSQL_OPT_LOAD_DATA_LOCAL_DIR` option (with an empty string setting the value to the null pointer). The effect of `--load-data-local-dir` depends on whether `LOCAL` data loading is enabled:
  
  - If `LOCAL` data loading is enabled, either by default in the MySQL client library or by specifying `--local-infile[=1]`, the `--load-data-local-dir` option is ignored.
  
  - If `LOCAL` data loading is disabled, either by default in the MySQL client library or by specifying `--local-infile=0`, the `--load-data-local-dir` option applies.

When `--load-data-local-dir` applies, the option value designates the directory in which local data files must be located. Comparison of the directory path name and the path name of files to be loaded is case-sensitive regardless of the case-sensitivity of the underlying file system. If the option value is the empty string, it names no directory, with the result that no files are permitted for local data loading.

- `mysqlimport` sets `MYSQL_OPT_LOAD_DATA_LOCAL_DIR` for each file that it processes so that the directory containing the file is the permitted local loading directory.

- For data loading operations corresponding to LOAD DATA statements, `mysqlbinlog` extracts the files from the binary log events, writes them as temporary files to the local file system, and writes LOAD DATA LOCAL statements to cause the files to be loaded. By default, `mysqlbinlog` writes these temporary files to an operating system-specific directory. The `--local-load` option can be used to explicitly specify the directory where `mysqlbinlog` should prepare local temporary files.

Because other processes can write files to the default system-specific directory, it is advisable to specify the `--local-load` option to `mysqlbinlog` to designate a different directory for data files, and then designate that same directory by specifying the `--load-data-local-dir` option to `mysql` when processing the output from `mysqlbinlog`. 
6.1.7 Client Programming Security Guidelines

Applications that access MySQL should not trust any data entered by users, who can try to trick your code by entering special or escaped character sequences in Web forms, URLs, or whatever application you have built. Be sure that your application remains secure if a user enters something like `DROP DATABASE mysql;`. This is an extreme example, but large security leaks and data loss might occur as a result of hackers using similar techniques, if you do not prepare for them.

A common mistake is to protect only string data values. Remember to check numeric data as well. If an application generates a query such as `SELECT * FROM table WHERE ID=234` when a user enters the value `234`, the user can enter the value `234 OR 1=1` to cause the application to generate the query `SELECT * FROM table WHERE ID=234 OR 1=1`. As a result, the server retrieves every row in the table. This exposes every row and causes excessive server load. The simplest way to protect from this type of attack is to use single quotation marks around the numeric constants: `SELECT * FROM table WHERE ID='234'`. If the user enters extra information, it all becomes part of the string. In a numeric context, MySQL automatically converts this string to a number and strips any trailing nonnumeric characters from it.

Sometimes people think that if a database contains only publicly available data, it need not be protected. This is incorrect. Even if it is permissible to display any row in the database, you should still protect against denial of service attacks (for example, those that are based on the technique in the preceding paragraph that causes the server to waste resources). Otherwise, your server becomes unresponsive to legitimate users.

Checklist:

- Enable strict SQL mode to tell the server to be more restrictive of what data values it accepts. See Section 5.1.11, "Server SQL Modes".
- Try to enter single and double quotation marks (‘ and ”) in all of your Web forms. If you get any kind of MySQL error, investigate the problem right away.
- Try to modify dynamic URLs by adding `%22 ("), %23 (#), and %27 (‘) to them.
- Try to modify data types in dynamic URLs from numeric to character types using the characters shown in the previous examples. Your application should be safe against these and similar attacks.
- Try to enter characters, spaces, and special symbols rather than numbers in numeric fields. Your application should remove them before passing them to MySQL or else generate an error. Passing unchecked values to MySQL is very dangerous!
- Check the size of data before passing it to MySQL.
- Have your application connect to the database using a user name different from the one you use for administrative purposes. Do not give your applications any access privileges they do not need.

Many application programming interfaces provide a means of escaping special characters in data values. Properly used, this prevents application users from entering values that cause the application to generate statements that have a different effect than you intend:

- MySQL C API: Use the `mysql_real_escape_string_quote()` API call.
- MySQL++: Use the `escape` and `quote` modifiers for query streams.
- PHP: Use either the `mysqli` or `pdo_mysql` extensions, and not the older `ext/mysql` extension. The preferred API’s support the improved MySQL authentication protocol and passwords, as well as prepared statements with placeholders. See also Choosing an API.
If the older ext/mysql extension must be used, then for escaping use the mysql_real_escape_string_quote() function and not mysql_escape_string() or addslashes() because only mysql_real_escape_string_quote() is character set-aware; the other functions can be “bypassed” when using (invalid) multibyte character sets.

- Perl DBI: Use placeholders or the quote() method.
- Ruby DBI: Use placeholders or the quote() method.
- Java JDBC: Use a PreparedStatement object and placeholders.

Other programming interfaces might have similar capabilities.

### 6.2 Access Control and Account Management

MySQL enables the creation of accounts that permit client users to connect to the server and access data managed by the server. The primary function of the MySQL privilege system is to authenticate a user who connects from a given host and to associate that user with privileges on a database such as SELECT, INSERT, UPDATE, and DELETE. Additional functionality includes the ability to grant privileges for administrative operations.

To control which users can connect, each account can be assigned authentication credentials such as a password. The user interface to MySQL accounts consists of SQL statements such as CREATE USER, GRANT, and REVOKE. See Section 13.7.1, “Account Management Statements”.

The MySQL privilege system ensures that all users may perform only the operations permitted to them. As a user, when you connect to a MySQL server, your identity is determined by the host from which you connect and the user name you specify. When you issue requests after connecting, the system grants privileges according to your identity and what you want to do.

MySQL considers both your host name and user name in identifying you because there is no reason to assume that a given user name belongs to the same person on all hosts. For example, the user joe who connects from office.example.com need not be the same person as the user joe who connects from home.example.com. MySQL handles this by enabling you to distinguish users on different hosts that happen to have the same name: You can grant one set of privileges for connections by joe from office.example.com, and a different set of privileges for connections by joe from home.example.com. To see what privileges a given account has, use the SHOW GRANTS statement. For example:

```sql
SHOW GRANTS FOR 'joe'@'office.example.com';
SHOW GRANTS FOR 'joe'@'home.example.com';
```

Internally, the server stores privilege information in the grant tables of the mysql system database. The MySQL server reads the contents of these tables into memory when it starts and bases access-control decisions on the in-memory copies of the grant tables.

MySQL access control involves two stages when you run a client program that connects to the server:

**Stage 1:** The server accepts or rejects the connection based on your identity and whether you can verify your identity by supplying the correct password.

**Stage 2:** Assuming that you can connect, the server checks each statement you issue to determine whether you have sufficient privileges to perform it. For example, if you try to select rows from a table in a database or drop a table from the database, the server verifies that you have the SELECT privilege for the table or the DROP privilege for the database.
For a more detailed description of what happens during each stage, see Section 6.2.6, “Access Control, Stage 1: Connection Verification”, and Section 6.2.7, “Access Control, Stage 2: Request Verification”. For help in diagnosing privilege-related problems, see Section 6.2.21, “Troubleshooting Problems Connecting to MySQL”.

If your privileges are changed (either by yourself or someone else) while you are connected, those changes do not necessarily take effect immediately for the next statement that you issue. For details about the conditions under which the server reloads the grant tables, see Section 6.2.13, “When Privilege Changes Take Effect”.

There are some things that you cannot do with the MySQL privilege system:

- You cannot explicitly specify that a given user should be denied access. That is, you cannot explicitly match a user and then refuse the connection.
- You cannot specify that a user has privileges to create or drop tables in a database but not to create or drop the database itself.
- A password applies globally to an account. You cannot associate a password with a specific object such as a database, table, or routine.

### 6.2.1 Account User Names and Passwords

MySQL stores accounts in the `user` table of the `mysql` system database. An account is defined in terms of a user name and the client host or hosts from which the user can connect to the server. For information about account representation in the `user` table, see Section 6.2.3, “Grant Tables”.

An account may also have authentication credentials such as a password. The credentials are handled by the account authentication plugin. MySQL supports multiple authentication plugins. Some of them use built-in authentication methods, whereas others enable authentication using external authentication methods. See Section 6.2.17, “Pluggable Authentication”.

There are several distinctions between the way user names and passwords are used by MySQL and your operating system:

- User names, as used by MySQL for authentication purposes, have nothing to do with user names (login names) as used by Windows or Unix. On Unix, most MySQL clients by default try to log in using the current Unix user name as the MySQL user name, but that is for convenience only. The default can be overridden easily, because client programs permit any user name to be specified with a `-u` or `--user` option. This means that anyone can attempt to connect to the server using any user name, so you cannot make a database secure in any way unless all MySQL accounts have passwords. Anyone who specifies a user name for an account that has no password can connect successfully to the server.
- MySQL user names are up to 32 characters long. Operating system user names may have a different maximum length.

**Warning**

The MySQL user name length limit is hardcoded in MySQL servers and clients, and trying to circumvent it by modifying the definitions of the tables in the `mysql` database does not work.

You should never alter the structure of tables in the `mysql` database in any manner whatsoever except by means of the procedure that is described in Section 2.11, “Upgrading MySQL”. Attempting to redefine MySQL's system tables in any other fashion results in undefined and unsupported behavior. The server is free to ignore rows that become malformed as a result of such modifications.
• To authenticate client connections for accounts that use built-in authentication methods, the server uses passwords stored in the `user` table. These passwords are distinct from passwords for logging in to your operating system. There is no necessary connection between the “external” password you use to log in to a Windows or Unix machine and the password you use to access the MySQL server on that machine.

If the server authenticates a client using some other plugin, the authentication method that the plugin implements may or may not use a password stored in the `user` table. In this case, it is possible that an external password is also used to authenticate to the MySQL server.

• Passwords stored in the `user` table are encrypted using plugin-specific algorithms.

• If the user name and password contain only ASCII characters, it is possible to connect to the server regardless of character set settings. To enable connections when the user name or password contain non-ASCII characters, client applications should call the `mysql_options()` C API function with the `MYSQL_SET_CHARSET_NAME` option and appropriate character set name as arguments. This causes authentication to take place using the specified character set. Otherwise, authentication fails unless the server default character set is the same as the encoding in the authentication defaults.

Standard MySQL client programs support a `--default-character-set` option that causes `mysql_options()` to be called as just described. In addition, character set autodetection is supported as described in Section 10.4, “Connection Character Sets and Collations”. For programs that use a connector that is not based on the C API, the connector may provide an equivalent to `mysql_options()` that can be used instead. Check the connector documentation.

The preceding notes do not apply for `ucs2`, `utf16`, and `utf32`, which are not permitted as client character sets.

The MySQL installation process populates the grant tables with an initial `root` account, as described in Section 2.10.4, “Securing the Initial MySQL Account”, which also discusses how to assign a password to it. Thereafter, you normally set up, modify, and remove MySQL accounts using statements such as `CREATE USER`, `DROP USER`, `GRANT`, and `REVOKE`. See Section 6.2.8, “Adding Accounts, Assigning Privileges, and Dropping Accounts”, and Section 13.7.1, “Account Management Statements”.

To connect to a MySQL server with a command-line client, specify user name and password options as necessary for the account that you want to use:

```
shell> mysql --user=finley --password db_name
```

If you prefer short options, the command looks like this:

```
shell> mysql -u finley -p db_name
```

If you omit the password value following the `--password` or `-p` option on the command line (as just shown), the client prompts for one. Alternatively, the password can be specified on the command line:

```
shell> mysql --user=finley --password=password db_name
shell> mysql -u finley -p password db_name
```

If you use the `-p` option, there must be no space between `-p` and the following password value.

Specifying a password on the command line should be considered insecure. See Section 6.1.2.1, “End-User Guidelines for Password Security”. To avoid giving the password on the command line, use an option file or a login path file. See Section 4.2.2.2, “Using Option Files”, and Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”.

For additional information about specifying user names, passwords, and other connection parameters, see Section 4.2.4, “Connecting to the MySQL Server Using Command Options”.
Privileges Provided by MySQL

6.2.2 Privileges Provided by MySQL

The privileges granted to a MySQL account determine which operations the account can perform. MySQL privileges differ in the contexts in which they apply and at different levels of operation:

• Administrative privileges enable users to manage operation of the MySQL server. These privileges are global because they are not specific to a particular database.

• Database privileges apply to a database and to all objects within it. These privileges can be granted for specific databases, or globally so that they apply to all databases.

• Privileges for database objects such as tables, indexes, views, and stored routines can be granted for specific objects within a database, for all objects of a given type within a database (for example, all tables in a database), or globally for all objects of a given type in all databases.

Privileges also differ in terms of whether they are static (built in to the server) or dynamic (defined at runtime). Whether a privilege is static or dynamic affects its availability to be granted to user accounts and roles. For information about the differences between static and dynamic privileges, see Static Versus Dynamic Privileges.

Information about account privileges is stored in the grant tables in the `mysql` system database. For a description of the structure and contents of these tables, see Section 6.2.3, “Grant Tables”. The MySQL server reads the contents of the grant tables into memory when it starts, and reloads them under the circumstances indicated in Section 6.2.13, “When Privilege Changes Take Effect”. The server bases access-control decisions on the in-memory copies of the grant tables.

![Important](image)

Some MySQL releases introduce changes to the grant tables to add new privileges or features. To make sure that you can take advantage of any new capabilities, update your grant tables to the current structure whenever you upgrade MySQL. See Section 2.11, “Upgrading MySQL”.

The following sections summarize the available privileges, provide more detailed descriptions of each privilege, and offer usage guidelines.

• Summary of Available Privileges

• Static Privilege Descriptions

• Dynamic Privilege Descriptions

• Privilege-Granting Guidelines

• Static Versus Dynamic Privileges

• Migrating Accounts from SUPER to Dynamic Privileges

Summary of Available Privileges

The following table shows the static privilege names used in `GRANT` and `REVOKE` statements, along with the column name associated with each privilege in the grant tables and the context in which the privilege applies.

### Static Privilege Descriptions

Static privileges are built in to the server, in contrast to dynamic privileges, which are defined at runtime. The following list describes each static privilege available in MySQL.

Particular SQL statements might have more specific privilege requirements than indicated here. If so, the description for the statement in question provides the details.

- ALL, ALL PRIVILEGES
Privileges Provided by MySQL

These privilege specifiers are shorthand for “all privileges available at a given privilege level” (except `GRANT OPTION`). For example, granting `ALL` at the global or table level grants all global privileges or all table-level privileges, respectively.

- **ALTER**

  Enables use of the `ALTER TABLE` statement to change the structure of tables. `ALTER TABLE` also requires the `CREATE` and `INSERT` privileges. Renaming a table requires `ALTER` and `DROP` on the old table, `CREATE`, and `INSERT` on the new table.

- **ALTER ROUTINE**

  Enables use of statements that alter or drop stored routines (stored procedures and functions). For routines that fall within the scope at which the privilege is granted and for which the user is not the user named as the routine `DEFINER`, also enables access to routine properties other than the routine definition.

- **CREATE**

  Enables use of statements that create new databases and tables.

- **CREATE ROLE**

  Enables use of the `CREATE ROLE` statement. (The `CREATE USER` privilege also enables use of the `CREATE ROLE` statement.) See Section 6.2.10, “Using Roles”.

  The `CREATE ROLE` and `DROP ROLE` privileges are not as powerful as `CREATE USER` because they can be used only to create and drop accounts. They cannot be used as `CREATE USER` can be modify account attributes or rename accounts. See User and Role Interchangeability.

- **CREATE ROUTINE**

  Enables use of statements that create stored routines (stored procedures and functions). For routines that fall within the scope at which the privilege is granted and for which the user is not the user named as the routine `DEFINER`, also enables access to routine properties other than the routine definition.

- **CREATE TABLESPACE**

  Enables use of statements that create, alter, or drop tablespaces and log file groups.

- **CREATE TEMPORARY TABLES**

  Enables the creation of temporary tables using the `CREATE TEMPORARY TABLE` statement.

  After a session has created a temporary table, the server performs no further privilege checks on the table. The creating session can perform any operation on the table, such as `DROP TABLE`, `INSERT`, `UPDATE`, or `SELECT`. For more information, see Section 13.1.20.2, “CREATE TEMPORARY TABLE Statement”.

- **CREATE USER**

  Enables use of the `ALTER USER`, `CREATE ROLE`, `CREATE USER`, `DROP ROLE`, `DROP USER`, `RENAME USER`, and `REVOKE ALL PRIVILEGES` statements.

- **CREATE VIEW**

  Enables use of the `CREATE VIEW` statement.
• **DELETE**

Enables rows to be deleted from tables in a database.

• **DROP**

Enables use of statements that drop (remove) existing databases, tables, and views. The DROP privilege is required to use the `ALTER TABLE ... DROP PARTITION` statement on a partitioned table. The DROP privilege is also required for `TRUNCATE TABLE`.

• **DROP ROLE**

Enables use of the DROP ROLE statement. (The CREATE USER privilege also enables use of the DROP ROLE statement.) See Section 6.2.10, "Using Roles".

The CREATE ROLE and DROP ROLE privileges are not as powerful as CREATE USER because they can be used only to create and drop accounts. They cannot be used as CREATE USER can be modify account attributes or rename accounts. See User and Role Interchangeability.

• **EVENT**

Enables use of statements that create, alter, drop, or display events for the Event Scheduler.

• **EXECUTE**

Enables use of statements that execute stored routines (stored procedures and functions). For routines that fall within the scope at which the privilege is granted and for which the user is not the user named as the routine DEFINER, also enables access to routine properties other than the routine definition.

• **FILE**

Affects the following operations and server behaviors:

- Enables reading and writing files on the server host using the LOAD DATA and SELECT ... INTO OUTFILE statements and the `LOAD_FILE()` function. A user who has the FILE privilege can read any file on the server host that is either world-readable or readable by the MySQL server. (This implies the user can read any file in any database directory, because the server can access any of those files.)

- Enables creating new files in any directory where the MySQL server has write access. This includes the server's data directory containing the files that implement the privilege tables.

- Enables use of the DATA DIRECTORY or INDEX DIRECTORY table option for the CREATE TABLE statement.

As a security measure, the server does not overwrite existing files.

To limit the location in which files can be read and written, set the `secure_file_priv` system variable to a specific directory. See Section 5.1.8, "Server System Variables".

• **GRANT OPTION**

Enables you to grant to or revoke from other users those privileges that you yourself possess.
Privileges Provided by MySQL

- **INDEX**
  Enables use of statements that create or drop (remove) indexes. **INDEX** applies to existing tables. If you have the **CREATE** privilege for a table, you can include index definitions in the **CREATE TABLE** statement.

- **INSERT**
  Enables rows to be inserted into tables in a database. **INSERT** is also required for the **ANALYZE TABLE**, **OPTIMIZE TABLE**, and **REPAIR TABLE** table-maintenance statements.

- **LOCK TABLES**
  Enables use of explicit **LOCK TABLES** statements to lock tables for which you have the **SELECT** privilege. This includes use of write locks, which prevents other sessions from reading the locked table.

- **PROCESS**
  The **PROCESS** privilege controls access to information about threads executing within the server (that is, information about statements being executed by sessions). Thread information available using the **SHOW PROCESSLIST** statement, the **mysqladmin processlist** command, the **INFORMATION_SCHEMA.PROCESSLIST** table, and the Performance Schema **processlist** table is accessible as follows:

  - With the **PROCESS** privilege, a user has access to information about all threads, even those belonging to other users.
  - Without the **PROCESS** privilege, nonanonymous users have access to information about their own threads but not threads for other users, and anonymous users have no access to thread information.

  **Note**
  The Performance Schema **threads** table also provides thread information, but table access uses a different privilege model. See Section 26.12.19.7, “The threads Table”.

  The **PROCESS** privilege also enables use of the **SHOW ENGINE** statement, access to the **INFORMATION_SCHEMA InnoDB** tables (tables with names that begin with **INNODB_**), and (as of MySQL 8.0.21) access to the **INFORMATION_SCHEMA FILES** table.

- **PROXY**
  Enables one user to impersonate or become known as another user. See Section 6.2.18, “Proxy Users”.

- **REFERENCES**
  Creation of a foreign key constraint requires the **REFERENCES** privilege for the parent table.
Privileges Provided by MySQL

• **RELOAD**

  The **RELOAD** enables the following operations:

  • Use of the **FLUSH** statement.

  • Use of **mysqladmin** commands that are equivalent to **FLUSH** operations: **flush-hosts**, **flush-logs**, **flush-privileges**, **flush-status**, **flush-tables**, **flush-threads**, **refresh**, and **reload**.

  The **reload** command tells the server to reload the grant tables into memory. **flush-privileges** is a synonym for **reload**. The **refresh** command closes and reopens the log files and flushes all tables. The other **flush-xxx** commands perform functions similar to **refresh**, but are more specific and may be preferable in some instances. For example, if you want to flush just the log files, **flush-logs** is a better choice than **refresh**.

  • Use of **mysqldump** options that perform various **FLUSH** operations: **--flush-logs** and **--master-data**.

  • Use of the **RESET MASTER** and **RESET REPLICA | SLAVE** statements.

• **REPLICATION CLIENT**

  Enables use of the **SHOW MASTER STATUS, SHOW REPLICA | SLAVE STATUS, and SHOW BINARY LOGS** statements. Grant this privilege to accounts that are used by replicas to connect to the current server as their replication source server.

• **REPLICATION SLAVE**

  Enables the account to request updates that have been made to databases on the replication source server, using the **SHOW REPLICA | SLAVE HOSTS, SHOW RELAYLOG EVENTS, and SHOW BINLOG EVENTS** statements. This privilege is also required to use the **mysqlbinlog** options **--read-from-remote-server (-R)** and **--read-from-remote-master**. Grant this privilege to accounts that are used by replicas to connect to the current server as their replication source server.

• **SELECT**

  Enables rows to be selected from tables in a database. **SELECT** statements require the **SELECT** privilege only if they actually access tables. Some **SELECT** statements do not access tables and can be executed without permission for any database. For example, you can use **SELECT** as a simple calculator to evaluate expressions that make no reference to tables:

  ```sql
  SELECT 1+1;
  SELECT PI()*2;
  ```

  The **SELECT** privilege is also needed for other statements that read column values. For example, **SELECT** is needed for columns referenced on the right hand side of **col_name=expr** assignment in **UPDATE** statements or for columns named in the **WHERE** clause of **DELETE** or **UPDATE** statements.

  The **SELECT** privilege is needed for tables or views used with **EXPLAIN**, including any underlying tables in view definitions.
- **SHOW DATABASES**

   Enables the account to see database names by issuing the `SHOW DATABASE` statement. Accounts that do not have this privilege see only databases for which they have some privileges, and cannot use the statement at all if the server was started with the `--skip-show-database` option.

   **Caution**

   Because any static global privilege is considered a privilege for all databases, any static global privilege enables a user to see all database names with `SHOW DATABASES` or by examining the `SCHEMATA` table of `INFORMATION_SCHEMA`, except databases that have been restricted at the database level by partial revokes.

- **SHOW VIEW**

   Enables use of the `SHOW CREATE VIEW` statement. This privilege is also needed for views used with `EXPLAIN`.

- **SHUTDOWN**

   Enables use of the `SHUTDOWN` and `RESTART` statements, the `mysqladmin shutdown` command, and the `mysql_shutdown()` C API function.

- **SUPER**

   **SUPER** is a powerful and far-reaching privilege and should not be granted lightly. If an account needs to perform only a subset of **SUPER** operations, it may be possible to achieve the desired privilege set by
instead granting one or more dynamic privileges, each of which confers more limited capabilities. See Dynamic Privilege Descriptions.

**Note**

SUPER is deprecated, and you should expect it to be removed in a future version of MySQL. See Migrating Accounts from SUPER to Dynamic Privileges.

SUPER affects the following operations and server behaviors:

- Enables system variable changes at runtime:
  - Enables server configuration changes to global system variables with `SET GLOBAL` and `SET PERSIST`.
    
    The corresponding dynamic privilege is `SYSTEM_VARIABLES_ADMIN`.
  - Enables setting restricted session system variables that require a special privilege.
    
    The corresponding dynamic privilege is `SESSION_VARIABLES_ADMIN`.

  See also Section 5.1.9.1, “System Variable Privileges”.
- Enables changes to global transaction characteristics (see Section 13.3.7, “SET TRANSACTION Statement”).
  
  The corresponding dynamic privilege is `SYSTEM_VARIABLES_ADMIN`.
- Enables the account to start and stop replication, including Group Replication.
  
  The corresponding dynamic privilege is `REPLICATION_SLAVE_ADMIN` for regular replication, `GROUP_REPLICATION_ADMIN` for Group Replication.
- Enables use of the `CHANGE MASTER TO` and `CHANGE REPLICATION FILTER` statements.
  
  The corresponding dynamic privilege is `REPLICATION_SLAVE_ADMIN`.
- Enables binary log control by means of the `PURGE BINARY LOGS` and `BINLOG` statements.
  
  The corresponding dynamic privilege is `BINLOG_ADMIN`.
- Enables setting the effective authorization ID when executing a view or stored program. A user with this privilege can specify any account in the `DEFINER` attribute of a view or stored program.
  
  The corresponding dynamic privilege is `SET_USER_ID`.
- Enables use of the `CREATE SERVER`, `ALTER SERVER`, and `DROP SERVER` statements.
- Enables use of the `mysqladmin debug` command.
- Enables InnoDB encryption key rotation.
  
  The corresponding dynamic privilege is `ENCRYPTION_KEY_ADMIN`.
- Enables execution of Version Tokens user-defined functions.
  
  The corresponding dynamic privilege is `VERSION_TOKEN_ADMIN`. 
Privileges Provided by MySQL

- Enables granting and revoking roles, use of the `WITH ADMIN OPTION` clause of the `GRANT` statement, and nonempty `<graphml>` element content in the result from the `ROLES_GRAPHML()` function.

  The corresponding dynamic privilege is `ROLE_ADMIN`.

- Enables control over client connections not permitted to non-`SUPER` accounts:
  - Enables use of the `KILL` statement or `mysqladmin kill` command to kill threads belonging to other accounts. (An account can always kill its own threads.)
  - The server does not execute `init_connect` system variable content when `SUPER` clients connect.
  - The server accepts one connection from a `SUPER` client even if the connection limit configured by the `max_connections` system variable is reached.
  - A server in offline mode (`offline_mode` enabled) does not terminate `SUPER` client connections at the next client request, and accepts new connections from `SUPER` clients.
  - Updates can be performed even when the `read_only` system variable is enabled. This applies to explicit table updates, and to use of account-management statements such as `GRANT` and `REVOKE` that update tables implicitly.

  The corresponding dynamic privilege for the preceding connection-control operations is `CONNECTION_ADMIN`.

You may also need the `SUPER` privilege to create or alter stored functions if binary logging is enabled, as described in Section 24.7, “Stored Program Binary Logging”.

- `TRIGGER`

  Enables trigger operations. You must have this privilege for a table to create, drop, execute, or display triggers for that table.

  When a trigger is activated (by a user who has privileges to execute `INSERT`, `UPDATE`, or `DELETE` statements for the table associated with the trigger), trigger execution requires that the user who defined the trigger still have the `TRIGGER` privilege for the table.

- `UPDATE`

  Enables rows to be updated in tables in a database.

- `USAGE`

  This privilege specifier stands for “no privileges.” It is used at the global level with `GRANT` to specify clauses such as `WITH GRANT OPTION` without naming specific account privileges in the privilege list. `SHOW GRANTS` displays `USAGE` to indicate that an account has no privileges at a privilege level.

**Dynamic Privilege Descriptions**

Dynamic privileges are defined at runtime, in contrast to static privileges, which are built in to the server. The following list describes each dynamic privilege available in MySQL.

Most dynamic privileges are defined at server startup. Others are defined by a particular server component or plugin, as indicated in the privilege descriptions. In such cases, the privilege is unavailable unless the component or plugin that defines it is enabled.
Particular SQL statements might have more specific privilege requirements than indicated here. If so, the description for the statement in question provides the details.

- **APPLICATION_PASSWORD_ADMIN** (added in MySQL 8.0.14)

  For dual-password capability, this privilege enables use of the `RETAIN CURRENT PASSWORD` and `DISCARD OLD PASSWORD` clauses for `ALTER USER` and `SET PASSWORD` statements that apply to your own account. This privilege is required to manipulate your own secondary password because most users require only one password.

  If an account is to be permitted to manipulate secondary passwords for all accounts, it should be granted the `CREATE USER` privilege rather than `APPLICATION_PASSWORD_ADMIN`.

  For more information about use of dual passwords, see Section 6.2.15, “Password Management”.

- **AUDIT_ADMIN**

  Enables audit log configuration. This privilege is defined by the `audit_log` plugin; see Section 6.4.5, “MySQL Enterprise Audit”.

- **BACKUP_ADMIN**

  Enables execution of the `LOCK INSTANCE FOR BACKUP` statement and access to the Performance Schema `log_status` table.

  **Note**

  Besides `BACKUP_ADMIN`, the `SELECT` privilege on the `log_status` table is also needed for its access.

  The `BACKUP_ADMIN` privilege is automatically granted to users with the `RELOAD` privilege when performing an in-place upgrade to MySQL 8.0 from an earlier version.

- **BINLOG_ADMIN**

  Enables binary log control by means of the `PURGE BINARY LOGS` and `BINLOG` statements.

- **BINLOG_ENCRYPTION_ADMIN**

  Enables setting the system variable `binlog_encryption`, which activates or deactivates encryption for binary log files and relay log files. This ability is not provided by the `BINLOG_ADMIN`, `SYSTEM_VARIABLES_ADMIN`, or `SESSION_VARIABLES_ADMIN` privileges. The related system variable `binlog_rotate_encryption_master_key_at_startup`, which rotates the binary log master key automatically when the server is restarted, does not require this privilege.

- **CLONE_ADMIN**

  Enables execution of the `CLONE` statements. Includes `BACKUP_ADMIN` and `SHUTDOWN` privileges.
• **CONNECTION_ADMIN**

Enables use of the `KILL` statement or `mysqladmin kill` command to kill threads belonging to other accounts. (An account can always kill its own threads.)

Enables setting system variables related to client connections, or circumventing restrictions related to client connections. `CONNECTION_ADMIN` applies to the effects of these system variables:

- `init_connect`: The server does not execute `init_connect` system variable content when `CONNECTION_ADMIN` clients connect.

- `max_connections`: The server accepts one connection from a `CONNECTION_ADMIN` client even if the connection limit configured by the `max_connections` system variable is reached.

- `offline_mode`: A server in offline mode (`offline_mode` enabled) does not terminate `CONNECTION_ADMIN` client connections at the next client request, and accepts new connections from `CONNECTION_ADMIN` clients.

- `read_only`: Updates can be performed even when the `read_only` system variable is enabled. This applies to explicit table updates, and to use of account-management statements such as `GRANT` and `REVOKE` that update tables implicitly.

• **ENCRYPTION_KEY_ADMIN**

Enables InnoDB encryption key rotation.

• **FIREWALL_ADMIN**

Enables a user to administer firewall rules for any user. This privilege is defined by the `MYSQL_FIREWALL` plugin; see Section 6.4.7, “MySQL Enterprise Firewall”.

• **FIREWALL_USER**

Enables users to update their own firewall rules. This privilege is defined by the `MYSQL_FIREWALL` plugin; see Section 6.4.7, “MySQL Enterprise Firewall”.

• **FLUSH_OPTIMIZER_COSTS** (added in MySQL 8.0.23)

Enables use of the `FLUSH OPTIMIZER_COSTS` statement.

• **FLUSH_STATUS** (added in MySQL 8.0.23)

Enables use of the `FLUSH STATUS` statement.

• **FLUSH_TABLES** (added in MySQL 8.0.23)

Enables use of the `FLUSH TABLES` statement.

• **FLUSH_USER_RESOURCES** (added in MySQL 8.0.23)

Enables use of the `FLUSH USER_RESOURCES` statement.

• **GROUP_REPLICATION_ADMIN**

Enables the account to start and stop Group Replication using the `START GROUP REPLICATION` and `STOP GROUP REPLICATION` statements, to change the global setting for the `group_replication_consistency` system variable, and to use the `group_replication_set_write_concurrency()` and
Privileges Provided by MySQL

- `group_replication_set_communication_protocol()` UDFs. Grant this privilege to accounts that are used to administer servers that are members of a replication group.

- **INNODB_REDO_LOG_ARCHIVE**
  
  Enables the account to activate and deactivate redo log archiving.

- **INNODB_REDO_LOG_ENABLE**
  
  Enables use of the `ALTER INSTANCE {ENABLE|DISABLE} INNODB REDO_LOG` statement to enable or disable redo logging. Introduced in MySQL 8.0.21.
  
  See Disabling Redo Logging.

- **NDB_STORED_USER**
  
  Enables the user or role and its privileges to be shared and synchronized between all NDB-enabled MySQL servers as soon as they join a given NDB Cluster. This privilege is available only if the NDB storage engine is enabled.

  Any changes to or revocations of privileges made for the given user or role are synchronized immediately with all connected MySQL servers (SQL nodes). You should be aware that there is no guarantee that multiple statements affecting privileges originating from different SQL nodes are executed on all SQL nodes in the same order. For this reason, it is highly recommended that all user administration be done from a single designated SQL node.

  `NDB_STORED_USER` is a global privilege and must be granted or revoked using ON `*.*`. Trying to set any other scope for this privilege results in an error. This privilege can be given to most application and administrative users, but it cannot be granted to system reserved accounts such as `mysql.session@localhost` or `mysql.infoschema@localhost`.

  A user that has been granted the `NDB_STORED_USER` privilege is stored in NDB (and thus shared by all SQL nodes), as is a role with this privilege. A user that is merely granted a role that has `NDB_STORED_USER` is not stored in NDB; each NDB stored user must be granted the privilege explicitly.

  For more detailed information about how this works in NDB, see Section 22.5.12, “Distributed MySQL Privileges with NDB_STORED_USER”.

  The `NDB_STORED_USER` privilege is available beginning with NDB 8.0.18.

- **PERSIST_RO_VARIABLES_ADMIN**
  
  For users who also have `SYSTEM_VARIABLES_ADMIN`, `PERSIST_RO_VARIABLES_ADMIN` enables use of `SET PERSIST_ONLY` to persist global system variables to the `mysqld-auto.cnf` option file in the data directory. This statement is similar to `SET PERSIST` but does not modify the runtime global system variable value. This makes `SET PERSIST_ONLY` suitable for configuring read-only system variables that can be set only at server startup.

  See also Section 5.1.9.1, “System Variable Privileges”.

- **REPLICATION_APPLIER**
  
  Enables the account to act as the `PRIVILEGE_CHECKS_USER` for a replication channel, and to execute `BINLOG` statements in `mysqlbinlog` output. Grant this privilege to accounts that are assigned using `CHANGE MASTER TO` to provide a security context for replication channels, and to handle replication errors on those channels. As well as the `REPLICATION_APPLIER` privilege, you must also give the account the required privileges to execute the transactions received by the replication channel or
Privileges Provided by MySQL

contains in the `mysqlbinlog` output, for example to update the affected tables. For more information, see Section 17.3.3, “Replication Privilege Checks”.

- **REPLICATION_SLAVE_ADMIN**
  Enables the account to connect to the replication source server, start and stop replication using the `START REPLICA | SLAVE` and `STOP REPLICA | SLAVE` statements, and use the `CHANGE MASTER TO` and `CHANGE_REPLICATION_FILTER` statements. Grant this privilege to accounts that are used by replicas to connect to the current server as their replication source server. This privilege does not apply to Group Replication; use `GROUP_REPLICATION_ADMIN` for that.

- **RESOURCE_GROUP_ADMIN**
  Enables resource group management, consisting of creating, altering, and dropping resource groups, and assignment of threads and statements to resource groups. A user with this privilege can perform any operation relating to resource groups.

- **RESOURCE_GROUP_USER**
  Enables assigning threads and statements to resource groups. A user with this privilege can use the `SET RESOURCE GROUP` statement and the `RESOURCE_GROUP` optimizer hint.

- **ROLE_ADMIN**
  Enables granting and revoking roles, use of the `WITH ADMIN OPTION` clause of the `GRANT` statement, and nonempty `<graphml>` element content in the result from the `ROLES_GRAPHML()` function. Required to set the value of the `mandatory_roles` system variable.

- **SERVICE_CONNECTION_ADMIN**
  Enables connections to the network interface that permits only administrative connections (see Section 5.1.12.1, “Connection Interfaces”).

- **SESSION_VARIABLES_ADMIN** (added in MySQL 8.0.14)
  For most system variables, setting the session value requires no special privileges and can be done by any user to affect the current session. For some system variables, setting the session value can have effects outside the current session and thus is a restricted operation. For these, the `SESSION_VARIABLES_ADMIN` privilege enables the user to set the session value.

  If a system variable is restricted and requires a special privilege to set the session value, the variable description indicates that restriction. Examples include `binlog_format`, `sql_log_bin`, and `sql_log_off`.

  Prior to MySQL 8.0.14 when `SESSION_VARIABLES_ADMIN` was added, restricted session system variables can be set only by users who have the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege.

  The `SESSION_VARIABLES_ADMIN` privilege is a subset of the `SYSTEM_VARIABLES_ADMIN` and `SUPER` privileges. A user who has either of those privileges is also permitted to set restricted session variables and effectively has `SESSION_VARIABLES_ADMIN` by implication and need not be granted `SESSION_VARIABLES_ADMIN` explicitly.

  See also Section 5.1.9.1, “System Variable Privileges”.

- **SET_USER_ID**
  Enables setting the effective authorization ID when executing a view or stored program. A user with this privilege can specify any account as the `DEFINER` attribute of a view or stored program.
As of MySQL 8.0.22, `SET_USER_ID` also enables overriding security checks designed to prevent operations that (perhaps inadvertently) cause stored objects to become orphaned or that cause adoption of stored objects that are currently orphaned. For details, see Orphan Stored Objects.

- **SHOW_ROUTINE** (added in MySQL 8.0.20)

  Enables a user to access definitions and properties of all stored routines (stored procedures and functions), even those for which the user is not named as the routine `DEFINER`. This access includes:

  - The contents of the `INFORMATION_SCHEMA.ROUTINES` table.
  - The `SHOW CREATE FUNCTION` and `SHOW CREATE PROCEDURE` statements.
  - The `SHOW FUNCTION CODE` and `SHOW PROCEDURE CODE` statements.
  - The `SHOW FUNCTION STATUS` and `SHOW PROCEDURE STATUS` statements.

Prior to MySQL 8.0.20, for a user to access definitions of routines the user did not define, the user must have the global `SELECT` privilege, which is very broad. As of 8.0.20, `SHOW_ROUTINE` may be granted instead as a privilege with a more restricted scope that permits access to routine definitions. (That is, an administrator can rescind global `SELECT` from users that do not otherwise require it and grant `SHOW_ROUTINE` instead.) This enables an account to back up stored routines without requiring a broad privilege.

- **SYSTEM_USER** (added in MySQL 8.0.16)

  The `SYSTEM_USER` privilege distinguishes system users from regular users:
  
  - A user with the `SYSTEM_USER` privilege is a system user.
  - A user without the `SYSTEM_USER` privilege is a regular user.

  The `SYSTEM_USER` privilege has an effect on the accounts to which a given user can apply its other privileges, as well as whether the user is protected from other accounts:

  - A system user can modify both system and regular accounts. That is, a user who has the appropriate privileges to perform a given operation on regular accounts is enabled by possession of `SYSTEM_USER` to also perform the operation on system accounts. A system account can be modified only by system users with appropriate privileges, not by regular users.
  - A regular user with appropriate privileges can modify regular accounts, but not system accounts. A regular account can be modified by both system and regular users with appropriate privileges.

  For more information, see Section 6.2.11, "Account Categories".

  The protection against modification by regular accounts that is afforded to system accounts by the `SYSTEM_USER` privilege does not apply to regular accounts that have privileges on the `mysql` system schema and thus can directly modify the grant tables in that schema. For full protection, do not grant `mysql` schema privileges to regular accounts. See Protecting System Accounts Against Manipulation by Regular Accounts.
• **SYSTEM_VARIABLES_ADMIN**

Affects the following operations and server behaviors:

• Enables system variable changes at runtime:
  
  • Enables server configuration changes to global system variables with `SET GLOBAL` and `SET PERSIST`.

  • Enables server configuration changes to global system variables with `SET PERSIST_ONLY`, if the user also has `PERSIST_RO_VARIABLES_ADMIN`.

  • Enables setting restricted session system variables that require a special privilege. In effect, `SYSTEM_VARIABLES_ADMIN` implies `SESSION_VARIABLES_ADMIN` without explicitly granting `SESSION_VARIABLES_ADMIN`.

  See also Section 5.1.9.1, “System Variable Privileges”.

• Enables changes to global transaction characteristics (see Section 13.3.7, “SET TRANSACTION Statement”).

• **TABLE_ENCRYPTION_ADMIN** (added in MySQL 8.0.16)

  Enables a user to override default encryption settings when `table_encryption_privilege_check` is enabled; see Defining an Encryption Default for Schemas and General Tablespaces.

• **VERSION_TOKEN_ADMIN**

  Enables execution of Version Tokens user-defined functions. This privilege is defined by the `version_tokens` plugin; see Section 5.6.6, “Version Tokens”.

• **XA_RECOVER_ADMIN**

  Enables execution of the `XA RECOVER` statement; see Section 13.3.8.1, “XA Transaction SQL Statements”.

Prior to MySQL 8.0, any user could execute the `XA RECOVER` statement to discover the XID values for outstanding prepared XA transactions, possibly leading to commit or rollback of an XA transaction by a user other than the one who started it. In MySQL 8.0, `XA RECOVER` is permitted only to users who have the `XA_RECOVER_ADMIN` privilege, which is expected to be granted only to administrative users who have need for it. This might be the case, for example, for administrators of an XA application if it has crashed and it is necessary to find outstanding transactions started by the application so they can be rolled back. This privilege requirement prevents users from discovering the XID values for outstanding prepared XA transactions other than their own. It does not affect normal commit or rollback of an XA transaction because the user who started it knows its XID.

Privilege-Granting Guidelines

It is a good idea to grant to an account only those privileges that it needs. You should exercise particular caution in granting the **FILE** and administrative privileges:

• **FILE** can be abused to read into a database table any files that the MySQL server can read on the server host. This includes all world-readable files and files in the server’s data directory. The table can then be accessed using `SELECT` to transfer its contents to the client host.

• **GRANT OPTION** enables users to give their privileges to other users. Two users that have different privileges and with the **GRANT OPTION** privilege are able to combine privileges.
• **ALTER** may be used to subvert the privilege system by renaming tables.

• **SHUTDOWN** can be abused to deny service to other users entirely by terminating the server.

• **PROCESS** can be used to view the plain text of currently executing statements, including statements that set or change passwords.

• **SUPER** can be used to terminate other sessions or change how the server operates.

• Privileges granted for the **mysql** system database itself can be used to change passwords and other access privilege information:

  • Passwords are stored encrypted, so a malicious user cannot simply read them to know the plain text password. However, a user with write access to the **mysql.user** system table `authentication_string` column can change an account's password, and then connect to the MySQL server using that account.

  • **INSERT** or **UPDATE** granted for the **mysql** system database enable a user to add privileges or modify existing privileges, respectively.

  • **DROP** for the **mysql** system database enables a user to remote privilege tables, or even the database itself.

### Static Versus Dynamic Privileges

MySQL supports static and dynamic privileges:

• Static privileges are built in to the server. They are always available to be granted to user accounts and cannot be unregistered.

• Dynamic privileges can be registered and unregistered at runtime. This affects their availability: A dynamic privilege that has not been registered cannot be granted.

For example, the **SELECT** and **INSERT** privileges are static and always available, whereas a dynamic privilege becomes available only if the server component that implements it has been enabled.

The remainder of this section describes how dynamic privileges work in MySQL. The discussion uses the term “components” but applies equally to plugins.

#### Note

Server administrators should be aware of which server components define dynamic privileges. For MySQL distributions, documentation of components that define dynamic privileges describes those privileges.

Third-party components may also define dynamic privileges; an administrator should understand those privileges and not install components that might conflict or compromise server operation. For example, one component conflicts with another if both define a privilege with the same name. Component developers can reduce the likelihood of this occurrence by choosing privilege names having a prefix based on the component name.

The server maintains the set of registered dynamic privileges internally in memory. Unregistration occurs at server shutdown.

Normally, a server component that defines dynamic privileges registers them when it is installed, during its initialization sequence. When uninstalled, a server component does not unregister its registered dynamic privileges.
Privileges Provided by MySQL

privileges. (This is current practice, not a requirement. That is, components could, but do not, unregister at any time privileges they register.)

No warning or error occurs for attempts to register an already registered dynamic privilege. Consider the following sequence of statements:

```
INSTALL COMPONENT 'my_component';
UNINSTALL COMPONENT 'my_component';
INSTALL COMPONENT 'my_component';
```

The first `INSTALL COMPONENT` statement registers any privileges defined by server component `my_component`, but `UNINSTALL COMPONENT` does not unregister them. For the second `INSTALL COMPONENT` statement, the component privileges it registers are found to be already registered, but no warnings or errors occur.

Dynamic privileges apply only at the global level. The server stores information about current assignments of dynamic privileges to user accounts in the `mysql.global_grants` system table:

- The server automatically registers privileges named in `global_grants` during server startup (unless the `--skip-grant-tables` option is given).
- The `GRANT` and `REVOKE` statements modify the contents of `global_grants`.
- Dynamic privilege assignments listed in `global_grants` are persistent. They are not removed at server shutdown.

Example: The following statement grants to user `u1` the privileges required to control replication (including Group Replication) on a replica, and to modify system variables:

```
GRANT REPLICATION_SLAVE_ADMIN, GROUP_REPLICATION_ADMIN, BINLOG_ADMIN
ON '.' TO 'u1'@'localhost';
```

Granted dynamic privileges appear in the output from the `SHOW GRANTS` statement and the `INFORMATION_SCHEMA.USER_PRIVILEGES` table.

For `GRANT` and `REVOKE` at the global level, any named privileges not recognized as static are checked against the current set of registered dynamic privileges and granted if found. Otherwise, an error occurs to indicate an unknown privilege identifier.

For `GRANT` and `REVOKE` the meaning of `ALL [PRIVILEGES]` at the global level includes all static global privileges, as well as all currently registered dynamic privileges:

- `GRANT ALL` at the global level grants all static global privileges and all currently registered dynamic privileges. A dynamic privilege registered subsequent to execution of the `GRANT` statement is not granted retroactively to any account.

- `REVOKE ALL` at the global level revokes all granted static global privileges and all granted dynamic privileges.

The `FLUSH PRIVILEGES` statement reads the `global_grants` table for dynamic privilege assignments and registers any unregistered privileges found there.

For descriptions of the dynamic privileges provided by MySQL Server and server components included in MySQL distributions, see Section 6.2.2, “Privileges Provided by MySQL”.

**Migrating Accounts from SUPER to Dynamic Privileges**

In MySQL 8.0, many operations that previously required the `SUPER` privilege are also associated with a dynamic privilege of more limited scope. (For descriptions of these privileges, see Section 6.2.2, “Privileges
Grant Tables

Provided by MySQL. Each such operation can be permitted to an account by granting the associated dynamic privilege rather than SUPER. This change improves security by enabling DBAs to avoid granting SUPER and tailor user privileges more closely to the operations permitted. SUPER is now deprecated; expect it to be removed in a future version of MySQL.

When removal of SUPER occurs, operations that formerly required SUPER fail unless accounts granted SUPER are migrated to the appropriate dynamic privileges. Use the following instructions to accomplish that goal so that accounts are ready prior to SUPER removal:

1. Execute this query to identify accounts that are granted SUPER:

   ```
   SELECT GRANTEE FROM INFORMATION_SCHEMA.USER_PRIVILEGES
   WHERE PRIVILEGE_TYPE = 'SUPER';
   ```

2. For each account identified by the preceding query, determine the operations for which it needs SUPER. Then grant the dynamic privileges corresponding to those operations, and revoke SUPER.

   For example, if 'u1'@'localhost' requires SUPER for binary log purging and system variable modification, these statements make the required changes to the account:

   ```
   GRANT BINLOG_ADMIN, SYSTEM_VARIABLES_ADMIN ON *.* TO 'u1'@'localhost';
   REVOKE SUPER ON *.* FROM 'u1'@'localhost';
   ```

   After you have modified all applicable accounts, the INFORMATION_SCHEMA query in the first step should produce an empty result set.

6.2.3 Grant Tables

The mysql system database includes several grant tables that contain information about user accounts and the privileges held by them. This section describes those tables. For information about other tables in the system database, see Section 5.3, “The mysql System Schema”.

The discussion here describes the underlying structure of the grant tables and how the server uses their contents when interacting with clients. However, normally you do not modify the grant tables directly. Modifications occur indirectly when you use account-management statements such as CREATE USER, GRANT, and REVOKE to set up accounts and control the privileges available to each one. See Section 13.7.1, “Account Management Statements”. When you use such statements to perform account manipulations, the server modifies the grant tables on your behalf.

Note

Direct modification of grant tables using statements such as INSERT, UPDATE, or DELETE is discouraged and done at your own risk. The server is free to ignore rows that become malformed as a result of such modifications.

For any operation that modifies a grant table, the server checks whether the table has the expected structure and produces an error if not. To update the tables to the expected structure, perform the MySQL upgrade procedure. See Section 2.11, “Upgrading MySQL”.

- Grant Table Overview
- The user and db Grant Tables
- The tables_priv and columns_priv Grant Tables
- The procs_priv Grant Table
Grant Tables

• The proxies_priv Grant Table
• The global_grants Grant Table
• The default_roles Grant Table
• The role_edges Grant Table
• The password_history Grant Table
• Grant Table Scope Column Properties
• Grant Table Privilege Column Properties
• Grant Table Concurrency

Grant Table Overview

These `mysql` database tables contain grant information:

• `user`: User accounts, static global privileges, and other nonprivilege columns.
• `global_grants`: Dynamic global privileges.
• `db`: Database-level privileges.
• `tables_priv`: Table-level privileges.
• `columns_priv`: Column-level privileges.
• `procs_priv`: Stored procedure and function privileges.
• `proxies_priv`: Proxy-user privileges.
• `default_roles`: Default user roles.
• `role_edges`: Edges for role subgraphs.
• `password_history`: Password change history.

For information about the differences between static and dynamic global privileges, see Static Versus Dynamic Privileges.)

In MySQL 8.0, grant tables use the InnoDB storage engine and are transactional. Before MySQL 8.0, grant tables used the MyISAM storage engine and were nontransactional. This change of grant table storage engine enables an accompanying change to the behavior of account-management statements such as CREATE USER or GRANT. Previously, an account-management statement that named multiple users could succeed for some users and fail for others. Now, each statement is transactional and either succeeds for all named users or rolls back and has no effect if any error occurs.

Each grant table contains scope columns and privilege columns:

• Scope columns determine the scope of each row in the tables; that is, the context in which the row applies. For example, a `user` table row with Host and User values of 'h1.example.net' and 'bob' applies to authenticating connections made to the server from the host `h1.example.net` by a client that specifies a user name of `bob`. Similarly, a `db` table row with Host, User, and Db column values of 'h1.example.net', 'bob' and 'reports' applies when `bob` connects from the host `h1.example.net` to access the `reports` database. The `tables_priv` and `columns_priv` tables
Grant Tables

contain scope columns indicating tables or table/column combinations to which each row applies. The `procs_priv` scope columns indicate the stored routine to which each row applies.

- Privilege columns indicate which privileges a table row grants; that is, which operations it permits to be performed. The server combines the information in the various grant tables to form a complete description of a user's privileges. Section 6.2.7, “Access Control, Stage 2: Request Verification”, describes the rules for this.

In addition, a grant table may contain columns used for purposes other than scope or privilege assessment.

The server uses the grant tables in the following manner:

- The `user` table scope columns determine whether to reject or permit incoming connections. For permitted connections, any privileges granted in the `user` table indicate the user's static global privileges. Any privileges granted in this table apply to all databases on the server.

  **Caution**

  Because any static global privilege is considered a privilege for all databases, any static global privilege enables a user to see all database names with `SHOW DATABASES` or by examining the `SCHEMATA` table of `INFORMATION_SCHEMA`, except databases that have been restricted at the database level by partial revokes.

- The `global_grants` table lists current assignments of dynamic global privileges to user accounts. For each row, the scope columns determine which user has the privilege named in the privilege column.

- The `db` table scope columns determine which users can access which databases from which hosts. The privilege columns determine the permitted operations. A privilege granted at the database level applies to the database and to all objects in the database, such as tables and stored programs.

- The `tables_priv` and `columns_priv` tables are similar to the `db` table, but are more fine-grained: They apply at the table and column levels rather than at the database level. A privilege granted at the table level applies to the table and to all its columns. A privilege granted at the column level applies only to a specific column.

- The `procs_priv` table applies to stored routines (stored procedures and functions). A privilege granted at the routine level applies only to a single procedure or function.

- The `proxies_priv` table indicates which users can act as proxies for other users and whether a user can grant the `PROXY` privilege to other users.

- The `default_roles` and `role_edges` tables contain information about role relationships.

- The `password_history` table retains previously chosen passwords to enable restrictions on password reuse. See Section 6.2.15, “Password Management”.

The server reads the contents of the grant tables into memory when it starts. You can tell it to reload the tables by issuing a `FLUSH PRIVILEGES` statement or executing a `mysqladmin flush-privileges` or `mysqladmin reload` command. Changes to the grant tables take effect as indicated in Section 6.2.13, “When Privilege Changes Take Effect”.

When you modify an account, it is a good idea to verify that your changes have the intended effect. To check the privileges for a given account, use the `SHOW GRANTS` statement. For example, to determine the privileges that are granted to an account with user name and host name values of `bob` and `pc84.example.com`, use this statement:
Grant Tables

SHOW GRANTS FOR 'bob'@'pc84.example.com';

To display nonprivilege properties of an account, use SHOW CREATE USER:
SHOW CREATE USER 'bob'@'pc84.example.com';

The user and db Grant Tables

The server uses the user and db tables in the mysql database at both the first and second stages of access control (see Section 6.2, “Access Control and Account Management”). The columns in the user and db tables are shown here.

</table>
The `user` table `plugin` and `authentication_string` columns store authentication plugin and credential information.

The server uses the plugin named in the `plugin` column of an account row to authenticate connection attempts for the account.

The `plugin` column must be nonempty. At startup, and at runtime when `FLUSH PRIVILEGES` is executed, the server checks `user` table rows. For any row with an empty `plugin` column, the server writes a warning to the error log of this form:

> [Warning] User entry 'user_name'@'host_name' has an empty plugin value. The user will be ignored and no one can login with this user anymore.

To assign a plugin to an account that is missing one, use the `ALTER USER` statement.

The `password_expired` column permits DBAs to expire account passwords and require users to reset their password. The default `password_expired` value is 'N', but can be set to 'Y' with the `ALTER USER` statement. After an account's password has been expired, all operations performed by the account in subsequent connections to the server result in an error until the user issues an `ALTER USER` statement to establish a new account password.

</tbody>
</table>
Note

Although it is possible to “reset” an expired password by setting it to its current value, it is preferable, as a matter of good policy, to choose a different password. DBAs can enforce non-reuse by establishing an appropriate password-reuse policy. See Password Reuse Policy.

`password_last_changed` is a TIMESTAMP column indicating when the password was last changed. The value is non-NULL only for accounts that use a MySQL built-in authentication plugin (`mysql_native_password`, `sha256_password`, or `caching_sha2_password`). The value is NULL for other accounts, such as those authenticated using an external authentication system.

`password_last_changed` is updated by the `CREATE USER`, `ALTER USER`, and `SET PASSWORD` statements, and by `GRANT` statements that create an account or change an account password.

`password_lifetime` indicates the account password lifetime, in days. If the password is past its lifetime (assessed using the `password_last_changed` column), the server considers the password expired when clients connect using the account. A value of $N$ greater than zero means that the password must be changed every $N$ days. A value of 0 disables automatic password expiration. If the value is NULL (the default), the global expiration policy applies, as defined by the `default_password_lifetime` system variable.

`account_locked` indicates whether the account is locked (see Section 6.2.19, “Account Locking”).

`Password_reuse_history` is the value of the `PASSWORD HISTORY` option for the account, or NULL for the default history.

`Password_reuse_time` is the value of the `PASSWORD REUSE INTERVAL` option for the account, or NULL for the default interval.

`Password_require_current` (added in MySQL 8.0.13) corresponds to the value of the `PASSWORD REQUIRE` option for the account, as shown by the following table.

Table 6.5 Permitted `Password_require_current` Values

<table>
<thead>
<tr>
<th><code>Password_require_current</code> Value</th>
<th>Corresponding <code>PASSWORD REQUIRE</code> Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Y'</td>
<td><code>PASSWORD REQUIRE CURRENT</code></td>
</tr>
<tr>
<td>'N'</td>
<td><code>PASSWORD REQUIRE CURRENT OPTIONAL</code></td>
</tr>
<tr>
<td>NULL</td>
<td><code>PASSWORD REQUIRE CURRENT DEFAULT</code></td>
</tr>
</tbody>
</table>

`User_attributes` (added in MySQL 8.0.14) is a JSON-format column that stores account attributes not stored in other columns:

- `additional_password`: The secondary password, if any. See Dual Password Support.
- `Restrictions`: Restriction lists, if any. Restrictions are added by partial-revoke operations. The attribute value is an array of elements that each have `Database` and `Restrictions` keys indicating the name of a restricted database and the applicable restrictions on it (see Section 6.2.12, “Privilege Restriction Using Partial Revokes”).
- `Password_locking`: The conditions for failed-login tracking and temporary account locking, if any (see Failed-Login Tracking and Temporary Account Locking). The `Password_locking` attribute is updated according to the `FAILED_LOGIN_ATTEMPTS` and `PASSWORD_LOCK_TIME` options of the `CREATE USER` and `ALTER USER` statements. The attribute value is a hash with `failed_login_attempts`
Grant Tables

and **password_lock_time_days** keys indicating the value of such options as have been specified for the account. If a key is missing, its value is implicitly 0. If a key value is implicitly or explicitly 0, the corresponding capability is disabled. This attribute was added in MySQL 8.0.19.

If no attributes apply, **User_attributes** is NULL.

Example: An account that has a secondary password and partially revoked database privileges has **additional_password** and **Restrictions** attributes in the column value:

```sql
mysql> SELECT User_attributes FROM mysql.User WHERE User = 'u'
```

```
+--------------------------------------+
| User_attributes: {
| "Restrictions": {
| ["Database": "mysql", "Privileges": ["SELECT"]],
| "additional_password": "hashed_credentials"})
+--------------------------------------+
```

To determine which attributes are present, use the **JSON_KEYS()** function:

```sql
SELECT User, Host, JSON_KEYS(User_attributes)
FROM mysql.user WHERE User_attributes IS NOT NULL;
```

To extract a particular attribute, such as **Restrictions**, do this:

```sql
SELECT User, Host, User_attributes->>'$.Restrictions'
FROM mysql.user WHERE User_attributes->>'$.Restrictions' <> ' beneficiaries';
```

The **tables_priv** and **columns_priv** Grant Tables

During the second stage of access control, the server performs request verification to ensure that each client has sufficient privileges for each request that it issues. In addition to the **user** and **db** grant tables, the server may also consult the **tables_priv** and **columns_priv** tables for requests that involve tables. The latter tables provide finer privilege control at the table and column levels. They have the columns shown in the following table.

<table>
<thead>
<tr>
<th>Table Name</th>
<th>tables_priv</th>
<th>columns_priv</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Scope columns</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Host</td>
<td>Host</td>
<td></td>
</tr>
<tr>
<td>Db</td>
<td>Db</td>
<td></td>
</tr>
<tr>
<td>User</td>
<td>User</td>
<td></td>
</tr>
<tr>
<td>Table_name</td>
<td>Table_name</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Column_name</td>
<td></td>
</tr>
<tr>
<td><strong>Privilege columns</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Table_priv</td>
<td>Column_priv</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Other columns</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Timestamp</td>
<td>Timestamp</td>
<td></td>
</tr>
<tr>
<td>Grantor</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The **Timestamp** and **Grantor** columns are set to the current timestamp and the `CURRENT_USER` value, respectively, but are otherwise unused.

The **procs_priv** Grant Table

For verification of requests that involve stored routines, the server may consult the **procs_priv** table, which has the columns shown in the following table.
Table 6.7 procs_priv Table Columns

<table>
<thead>
<tr>
<th>Table Name</th>
<th>procs_priv</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope columns</td>
<td></td>
</tr>
<tr>
<td>Host</td>
<td></td>
</tr>
<tr>
<td>Db</td>
<td></td>
</tr>
<tr>
<td>User</td>
<td></td>
</tr>
<tr>
<td>Routine_name</td>
<td></td>
</tr>
<tr>
<td>Routine_type</td>
<td></td>
</tr>
<tr>
<td>Privilege columns</td>
<td>Proc_priv</td>
</tr>
<tr>
<td>Other columns</td>
<td>Timestamp</td>
</tr>
</tbody>
</table>

The `Routine_type` column is an `ENUM` column with values of 'FUNCTION' or 'PROCEDURE' to indicate the type of routine the row refers to. This column enables privileges to be granted separately for a function and a procedure with the same name.

The `Timestamp` and `Grantor` columns are unused.

The proxies_priv Grant Table

The `proxies_priv` table records information about proxy accounts. It has these columns:

- **Host**, **User**: The proxy account; that is, the account that has the `PROXY` privilege for the proxied account.
- **Proxied_host**, **Proxied_user**: The proxied account.
- **Grantor**, **Timestamp**: Unused.
- **With_grant**: Whether the proxy account can grant the `PROXY` privilege to other accounts.

For an account to be able to grant the `PROXY` privilege to other accounts, it must have a row in the `proxies_priv` table with `With_grant` set to 1 and `Proxied_host` and `Proxied_user` set to indicate the account or accounts for which the privilege can be granted. For example, the `'root'@'localhost'` account created during MySQL installation has a row in the `proxies_priv` table that enables granting the `PROXY` privilege for `'@'`, that is, for all users and all hosts. This enables `root` to set up proxy users, as well as to delegate to other accounts the authority to set up proxy users. See Section 6.2.18, “Proxy Users”.

The global_grants Grant Table

The `global_grants` table lists current assignments of dynamic global privileges to user accounts. The table has these columns:

- **USER**, **HOST**: The user name and host name of the account to which the privilege is granted.
- **PRIV**: The privilege name.
- **WITH_GRANT_OPTION**: Whether the account can grant the privilege to other accounts.

The default_roles Grant Table

The `default_roles` table lists default user roles. It has these columns:

- **HOST**, **USER**: The account or role to which the default role applies.
Grant Tables

• DEFAULT_ROLE_HOST, DEFAULT_ROLE_USER: The default role.

The role_edges Grant Table

The role_edges table lists edges for role subgraphs. It has these columns:

• FROM_HOST, FROM_USER: The account that is granted a role.
• TO_HOST, TO_USER: The role that is granted to the account.
• WITH_ADMIN_OPTION: Whether the account can grant the role to and revoke it from other accounts by using WITH ADMIN OPTION.

The password_history Grant Table

The password_history table contains information about password changes. It has these columns:

• Host, User: The account for which the password change occurred.
• Password_timestamp: The time when the password change occurred.
• Password: The new password hash value.

The password_history table accumulates a sufficient number of nonempty passwords per account to enable MySQL to perform checks against both the account password history length and reuse interval. Automatic pruning of entries that are outside both limits occurs when password-change attempts occur.

Note

The empty password does not count in the password history and is subject to reuse at any time.

If an account is renamed, its entries are renamed to match. If an account is dropped or its authentication plugin is changed, its entries are removed.

Grant Table Scope Column Properties

Scope columns in the grant tables contain strings. The default value for each is the empty string. The following table shows the number of characters permitted in each column.

Table 6.8 Grant Table Scope Column Lengths

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Maximum Permitted Characters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host, Proxied_host</td>
<td>255 (60 prior to MySQL 8.0.17)</td>
</tr>
<tr>
<td>User, Proxied_user</td>
<td>32</td>
</tr>
<tr>
<td>Db</td>
<td>64</td>
</tr>
<tr>
<td>Table_name</td>
<td>64</td>
</tr>
<tr>
<td>Column_name</td>
<td>64</td>
</tr>
<tr>
<td>Routine_name</td>
<td>64</td>
</tr>
</tbody>
</table>

Host and Proxied_host values are converted to lowercase before being stored in the grant tables.

For access-checking purposes, comparisons of User, Proxied_user, authentication_string, Db, and Table_name values are case-sensitive. Comparisons of Host, Proxied_host, Column_name, and Routine_name values are not case-sensitive.
Grant Table Privilege Column Properties

The `user` and `db` tables list each privilege in a separate column that is declared as `ENUM('N', 'Y') DEFAULT 'N'`. In other words, each privilege can be disabled or enabled, with the default being disabled.

The `tables_priv`, `columns_priv`, and `procs_priv` tables declare the privilege columns as `SET` columns. Values in these columns can contain any combination of the privileges controlled by the table. Only those privileges listed in the column value are enabled.

### Table 6.9 Set-Type Privilege Column Values

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Column Name</th>
<th>Possible Set Elements</th>
</tr>
</thead>
<tbody>
<tr>

<td>'Select', 'Insert', 'Update', 'Delete', 'Create', 'Drop', 'Grant', 'References', 'Index', 'Alter', 'Create View', 'Show view', 'Trigger'</td>
</tr>
<tr>
<td><code>tables_priv</code></td>
<td><code>Column_priv</code></td>
<td>'Select', 'Insert', 'Update', 'References'</td>
</tr>
<tr>
<td><code>columns_priv</code></td>
<td><code>Column_priv</code></td>
<td>'Select', 'Insert', 'Update', 'References'</td>
</tr>
<tr>
<td><code>procs_priv</code></td>
<td><code>Proc_priv</code></td>
<td>'Execute', 'Alter Routine', 'Grant'</td>
</tr>
</tbody>
</table>

Only the `user` and `global_grants` tables specify administrative privileges, such as `RELOAD`, `SHUTDOWN`, and `SYSTEM_VARIABLES_ADMIN`. Administrative operations are operations on the server itself and are not database-specific, so there is no reason to list these privileges in the other grant tables. Consequently, the server need consult only the `user` and `global_grants` tables to determine whether a user can perform an administrative operation.

The `FILE` privilege also is specified only in the `user` table. It is not an administrative privilege as such, but a user’s ability to read or write files on the server host is independent of the database being accessed.

Grant Table Concurrency

As of MySQL 8.0.22, to permit concurrent DML and DDL operations on MySQL grant tables, read operations that previously acquired row locks on MySQL grant tables are executed as non-locking reads. Operations that are performed as non-locking reads on MySQL grant tables include:

- `SELECT` statements and other read-only statements that read data from grant tables through join lists and subqueries, including `SELECT ... FOR SHARE` statements, using any transaction isolation level.

- DML operations that read data from grant tables (through join lists or subqueries) but do not modify them, using any transaction isolation level.

Statements that no longer acquire row locks when reading data from grant tables report a warning if executed while using statement-based replication.

When using `-binlog_format=mixed`, DML operations that read data from grant tables are written to the binary log as row events to make the operations safe for mixed-mode replication.

`SELECT ... FOR SHARE` statements that read data from grant tables report a warning. With the `FOR SHARE` clause, read locks are not supported on grant tables.
DML operations that read data from grant tables and are executed using the `SERIALIZABLE` isolation level report a warning. Read locks that would normally be acquired when using the `SERIALIZABLE` isolation level are not supported on grant tables.

### 6.2.4 Specifying Account Names

MySQL account names consist of a user name and a host name, which enables creation of distinct accounts for users with the same user name who can connect from different hosts. This section describes how to write account names, including special values and wildcard rules.

MySQL role names are similar to account names, with some differences described at Section 6.2.5, “Specifying Role Names”.

In SQL statements such as `CREATE USER`, `GRANT`, and `SET PASSWORD`, account names follow these rules:

- Account name syntax is `'user_name'@'host_name'`.
- An account name consisting only of a user name is equivalent to `'user_name'@'%'`. For example, `'me'` is equivalent to `'me'@'%'`.
- The user name and host name need not be quoted if they are legal as unquoted identifiers. Quotes are necessary to specify a `user_name` string containing special characters (such as space or `-`), or a `host_name` string containing special characters or wildcard characters (such as `.` or `%`). For example, in the account name `'test-user'@'%.com'`, both the user name and host name parts require quotes.
- Quote user names and host names as identifiers or as strings, using either backticks (` `), single quotation marks (`' `), or double quotation marks (`" `). For string-quoting and identifier-quoting guidelines, see Section 9.1.1, “String Literals”, and Section 9.2, “Schema Object Names”.
- The user name and host name parts, if quoted, must be quoted separately. That is, write `'me'@'localhost'`, not `'me@localhost'`. The latter is actually equivalent to `'me@localhost'@'%'`.
- A reference to the `CURRENT_USER` or `CURRENT_USER()` function is equivalent to specifying the current client's user name and host name literally.

MySQL stores account names in grant tables in the `mysql` system database using separate columns for the user name and host name parts:

- The `user` table contains one row for each account. The `User` and `Host` columns store the user name and host name. This table also indicates which global privileges the account has.
- Other grant tables indicate privileges an account has for databases and objects within databases. These tables have `User` and `Host` columns to store the account name. Each row in these tables associates with the account in the `user` table that has the same `User` and `Host` values.
- For access-checking purposes, comparisons of User values are case-sensitive. Comparisons of Host values are not case sensitive.

For additional detail about the properties of user names and host names as stored in the grant tables, such as maximum length, see Grant Table Scope Column Properties.

User names and host names have certain special values or wildcard conventions, as described following.

The user name part of an account name is either a nonblank value that literally matches the user name for incoming connection attempts, or a blank value (empty string) that matches any user name. An account
Specifying Account Names

with a blank user name is an anonymous user. To specify an anonymous user in SQL statements, use a quoted empty user name part, such as '@localhost'.

The host name part of an account name can take many forms, and wildcards are permitted:

- A host value can be a host name or an IP address (IPv4 or IPv6). The name 'localhost' indicates the local host. The IP address '127.0.0.1' indicates the IPv4 loopback interface. The IP address '::1' indicates the IPv6 loopback interface.

- The % and _ wildcard characters are permitted in host name or IP address values. These have the same meaning as for pattern-matching operations performed with the LIKE operator. For example, a host value of '%mysql.com' matches any host in the mysql.com domain. '198.51.100.%' matches any host in the 198.51.100 class C network.

Because IP wildcard values are permitted in host values (for example, '198.51.100.%' to match every host on a subnet), someone could try to exploit this capability by naming a host 198.51.100.somewhere.com. To foil such attempts, MySQL does not perform matching on host names that start with digits and a dot. For example, if a host is named 1.2.example.com, its name never matches the host part of account names. An IP wildcard value can match only IP addresses, not host names.

- For a host value specified as an IPv4 address, a netmask can be given to indicate how many address bits to use for the network number. Netmask notation cannot be used for IPv6 addresses.

The syntax is host_ip/netmask. For example:

```
CREATE USER 'david'@'198.51.100.0/255.255.255.0';
```

This enables david to connect from any client host having an IP address client_ip for which the following condition is true:

`client_ip & netmask = host_ip`

That is, for the CREATE USER statement just shown:

```
client_ip & 255.255.255.0 = 198.51.100.0
```

IP addresses that satisfy this condition range from 198.51.100.0 to 198.51.100.255.

A netmask typically begins with bits set to 1, followed by bits set to 0. Examples:

- 198.0.0.0/255.0.0.0: Any host on the 198 class A network
- 198.51.100.0/255.255.0.0: Any host on the 198.51 class B network
- 198.51.100.0/255.255.255.0: Any host on the 198.51.100 class C network
- 198.51.100.1: Only the host with this specific IP address

The server performs matching of host values in account names against the client host using the value returned by the system DNS resolver for the client host name or IP address. Except in the case that the account host value is specified using netmask notation, the server performs this comparison as a string match, even for an account host value given as an IP address. This means that you should specify account host values in the same format used by DNS. Here are examples of problems to watch out for:

- Suppose that a host on the local network has a fully qualified name of host1.example.com. If DNS returns name lookups for this host as host1.example.com, use that name in account host values. If DNS returns just host1, use host1 instead.
Specifying Role Names

- If DNS returns the IP address for a given host as 198.51.100.2, that matches an account host value of 198.51.100.2 but not 198.051.100.2. Similarly, it matches an account host pattern like 198.51.100.% but not 198.051.100.%. 

To avoid problems like these, it is advisable to check the format in which your DNS returns host names and addresses. Use values in the same format in MySQL account names.

6.2.5 Specifying Role Names

MySQL role names refer to roles, which are named collections of privileges. For role usage examples, see Section 6.2.10, “Using Roles”.

Role names have syntax and semantics similar to account names; see Section 6.2.4, “Specifying Account Names”. As stored in the grant tables, they have the same properties as account names, which are described in Grant Table Scope Column Properties.

Role names differ from account names in these respects:

- The user part of role names cannot be blank. Thus, there is no “anonymous role” analogous to the concept of “anonymous user.”

- As for an account name, omitting the host part of a role name results in a host part of '%'. But unlike '%', in an account name, a host part of '%' in a role name has no wildcard properties. For example, for a name 'me'@'%', used as a role name, the host part ('%') is just a literal value; it has no “any host” matching property.

- Netmask notation in the host part of a role name has no significance.

- An account name is permitted to be CURRENT_USER() in several contexts. A role name is not.

It is possible for a row in the mysql.user system table to serve as both an account and a role. In this case, any special user or host name matching properties do not apply in contexts for which the name is used as a role name. For example, you cannot execute the following statement with the expectation that it sets the current session roles using all roles that have a user part of myrole and any host name:

```sql
SET ROLE 'myrole'@'%';
```

Instead, the statement sets the active role for the session to the role with exactly the name 'myrole'@'%'.

For this reason, role names are often specified using only the user name part and letting the host name part implicitly be '%'. Specifying a role with a non-% host part can be useful if you intend to create a name that works both as a role as an account that is permitted to connect from the given host.

6.2.6 Access Control, Stage 1: Connection Verification

When you attempt to connect to a MySQL server, the server accepts or rejects the connection based on these conditions:

- Your identity and whether you can verify your identity by supplying the correct password
- Whether your account is locked or unlocked

The server checks credentials first, then account locking state. A failure for either step causes the server to deny access to you completely. Otherwise, the server accepts the connection, and then enters Stage 2 and waits for requests.
Credential checking is performed using the three user table scope columns (Host, User, and authentication_string). Locking state is recorded in the user table account_locked column. The server accepts the connection only if the Host and User columns in some user table row match the client host name and user name, the client supplies the password specified in that row, and the account_locked value is 'N'. The rules for permissible Host and User values are given in Section 6.2.4, "Specifying Account Names". Account locking can be changed with the ALTER USER statement.

Your identity is based on two pieces of information:

- The client host from which you connect
- Your MySQL user name

If the User column value is nonblank, the user name in an incoming connection must match exactly. If the User value is blank, it matches any user name. If the user table row that matches an incoming connection has a blank user name, the user is considered to be an anonymous user with no name, not a user with the name that the client actually specified. This means that a blank user name is used for all further access checking for the duration of the connection (that is, during Stage 2).

The authentication_string column can be blank. This is not a wildcard and does not mean that any password matches. It means that the user must connect without specifying a password. If the server authenticates a client using a plugin, the authentication method that the plugin implements may or may not use the password in the authentication_string column. In this case, it is possible that an external password is also used to authenticate to the MySQL server.

Nonblank authentication_string values in the user table represent encrypted passwords. MySQL does not store passwords as cleartext for anyone to see. Rather, the password supplied by a user who is attempting to connect is encrypted (using the password hashing method implemented by the account authentication plugin). The encrypted password then is used during the connection process when checking whether the password is correct. This is done without the encrypted password ever traveling over the connection. See Section 6.2.1, "Account User Names and Passwords".

From MySQL's point of view, the encrypted password is the real password, so you should never give anyone access to it. In particular, do not give nonadministrative users read access to tables in the mysql system database.

The following table shows how various combinations of User and Host values in the user table apply to incoming connections.

<table>
<thead>
<tr>
<th>User Value</th>
<th>Host Value</th>
<th>Permissible Connections</th>
</tr>
</thead>
<tbody>
<tr>
<td>'fred'</td>
<td>'h1.example.net'</td>
<td>fred, connecting from h1.example.net</td>
</tr>
<tr>
<td>''</td>
<td>'h1.example.net'</td>
<td>Any user, connecting from h1.example.net</td>
</tr>
<tr>
<td>'fred'</td>
<td>'%'</td>
<td>fred, connecting from any host</td>
</tr>
<tr>
<td>''</td>
<td>'%'</td>
<td>Any user, connecting from any host</td>
</tr>
<tr>
<td>'fred'</td>
<td>'%.example.net'</td>
<td>fred, connecting from any host in the example.net domain</td>
</tr>
<tr>
<td>'fred'</td>
<td>'x.example.%'</td>
<td>fred, connecting from x.example.net, x.example.com, x.example.edu, and so on; this is probably not useful</td>
</tr>
<tr>
<td>'fred'</td>
<td>'198.51.100.177'</td>
<td>fred, connecting from the host with IP address 198.51.100.177</td>
</tr>
</tbody>
</table>
Access Control, Stage 1: Connection Verification

<table>
<thead>
<tr>
<th>User Value</th>
<th>Host Value</th>
<th>Permissible Connections</th>
</tr>
</thead>
<tbody>
<tr>
<td>'fred'</td>
<td>'198.51.100.%'</td>
<td>fred, connecting from any host in the 198.51.100 class C subnet</td>
</tr>
<tr>
<td>'fred'</td>
<td>'198.51.100.0/255.255.255.0'</td>
<td>Same as previous example</td>
</tr>
</tbody>
</table>

It is possible for the client host name and user name of an incoming connection to match more than one row in the user table. The preceding set of examples demonstrates this: Several of the entries shown match a connection from h1.example.net by fred.

When multiple matches are possible, the server must determine which of them to use. It resolves this issue as follows:

- Whenever the server reads the user table into memory, it sorts the rows.
- When a client attempts to connect, the server looks through the rows in sorted order.
- The server uses the first row that matches the client host name and user name.

The server uses sorting rules that order rows with the most-specific Host values first. Literal host names and IP addresses are the most specific. (The specificity of a literal IP address is not affected by whether it has a netmask, so 198.51.100.13 and 198.51.100.0/255.255.255.0 are considered equally specific.) The pattern '%%' means "any host" and is least specific. The empty string '' also means "any host" but sorts after '%'. Rows with the same Host value are ordered with the most-specific User values first (a blank User value means "any user" and is least specific). For rows with equally-specific Host and User values, the order is nondeterministic.

To see how this works, suppose that the user table looks like this:

```
+-----------+----------+-
| Host      | User     | ...   |
+-----------+----------+-
| %         | root     | ...   |
| %         | jeffrey  | ...   |
| localhost | root     | ...   |
| localhost |          | ...   |
+-----------+----------+-
```

When the server reads the table into memory, it sorts the rows using the rules just described. The result after sorting looks like this:

```
+-----------+----------+-
| Host      | User     | ...   |
+-----------+----------+-
| localhost | root     | ...   |
| localhost |          | ...   |
| %         | jeffrey  | ...   |
| %         | root     | ...   |
+-----------+----------+-
```

When a client attempts to connect, the server looks through the sorted rows and uses the first match found. For a connection from localhost by jeffrey, two of the rows from the table match: the one with Host and User values of 'localhost' and '', and the one with values of '%' and 'jeffrey'. The 'localhost' row appears first in sorted order, so that is the one the server uses.

Here is another example. Suppose that the user table looks like this:

```
+-----------+----------+-
| Host      | User     | ...   |
+-----------+----------+-
```

1171
A connection by *jeffrey* from *h1.example.net* is matched by the first row, whereas a connection by *jeffrey* from any host is matched by the second.

**Note**

It is a common misconception to think that, for a given user name, all rows that explicitly name that user are used first when the server attempts to find a match for the connection. This is not true. The preceding example illustrates this, where a connection from *h1.example.net* by *jeffrey* is first matched not by the row containing '*jeffrey*' as the User column value, but by the row with no user name. As a result, *jeffrey* is authenticated as an anonymous user, even though he specified a user name when connecting.

If you are able to connect to the server, but your privileges are not what you expect, you probably are being authenticated as some other account. To find out what account the server used to authenticate you, use the `CURRENT_USER()` function. (See Section 12.16, “Information Functions”.) It returns a value in `user_name@host_name` format that indicates the User and Host values from the matching user table row. Suppose that *jeffrey* connects and issues the following query:

```sql
mysql> SELECT CURRENT_USER();
+----------------+
| CURRENT_USER() |
+----------------+
| @localhost     |
```

The result shown here indicates that the matching user table row had a blank User column value. In other words, the server is treating *jeffrey* as an anonymous user.

Another way to diagnose authentication problems is to print out the user table and sort it by hand to see where the first match is being made.

### 6.2.7 Access Control, Stage 2: Request Verification

After you establish a connection, the server enters Stage 2 of access control. For each request that you issue through that connection, the server determines what operation you want to perform, then checks whether you have sufficient privileges to do so. This is where the privilege columns in the grant tables come into play. These privileges can come from any of the `user`, `global_grants`, `db`, `tables_priv`, `columns_priv`, or `procs_priv` tables. (You may find it helpful to refer to Section 6.2.3, “Grant Tables”, which lists the columns present in each grant table.)

The `user` and `global_grants` tables grant global privileges. The rows in these tables for a given account indicate the account privileges that apply on a global basis no matter what the default database is. For example, if the `user` table grants you the `DELETE` privilege, you can delete rows from any table in any database on the server host. It is wise to grant privileges in the `user` table only to people who need them, such as database administrators. For other users, leave all privileges in the `user` table set to 'N'
Access Control, Stage 2: Request Verification

and grant privileges at more specific levels only (for particular databases, tables, columns, or routines). It is also possible to grant database privileges globally but use partial revokes to restrict them from being exercised on specific databases (see Section 6.2.12, “Privilege Restriction Using Partial Revokes”).

The `db` table grants database-specific privileges. Values in the scope columns of this table can take the following forms:

- A blank `User` value matches the anonymous user. A nonblank value matches literally; there are no wildcards in user names.

- The wildcard characters `%` and `_` can be used in the `Host` and `Db` columns. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. If you want to use either character literally when granting privileges, you must escape it with a backslash. For example, to include the underscore character (`_`) as part of a database name, specify it as `\_` in the `GRANT` statement.

- A `'%'` or blank `Host` value means “any host.”

- A `'%'` or blank `Db` value means “any database.”

The server reads the `db` table into memory and sorts it at the same time that it reads the `user` table. The server sorts the `db` table based on the `Host`, `Db`, and `User` scope columns. As with the `user` table, sorting puts the most-specific values first and least-specific values last, and when the server looks for matching rows, it uses the first match that it finds.

The `tables_priv`, `columns_priv`, and `procs_priv` tables grant table-specific, column-specific, and routine-specific privileges. Values in the scope columns of these tables can take the following forms:

- The wildcard characters `%` and `_` can be used in the `Host` column. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator.

- A `'%'` or blank `Host` value means “any host.”

- The `Db`, `Table_name`, `Column_name`, and `Routine_name` columns cannot contain wildcards or be blank.

The server sorts the `tables_priv`, `columns_priv`, and `procs_priv` tables based on the `Host`, `Db`, and `User` columns. This is similar to `db` table sorting, but simpler because only the `Host` column can contain wildcards.

The server uses the sorted tables to verify each request that it receives. For requests that require administrative privileges such as `SHUTDOWN` or `RELOAD`, the server checks only the `user` and `global_privilege` tables because those are the only tables that specify administrative privileges. The server grants access if a row for the account in those tables permits the requested operation and denies access otherwise. For example, if you want to execute `mysqladmin shutdown` but your `user` table row does not grant the `SHUTDOWN` privilege to you, the server denies access without even checking the `db` table. (The latter table contains no `Shutdown_priv` column, so there is no need to check it.)

For database-related requests (`INSERT`, `UPDATE`, and so on), the server first checks the user's global privileges in the `user` table row (less any privilege restrictions imposed by partial revokes). If the row permits the requested operation, access is granted. If the global privileges in the `user` table are insufficient, the server determines the user's database-specific privileges from the `db` table:

The server looks in the `db` table for a match on the `Host`, `Db`, and `User` columns. The `Host` and `User` columns are matched to the connecting user's host name and MySQL user name. The `Db` column is matched to the database that the user wants to access. If there is no row for the `Host` and `User`, access is denied.
After determining the database-specific privileges granted by the `db` table rows, the server adds them to the global privileges granted by the `user` table. If the result permits the requested operation, access is granted. Otherwise, the server successively checks the user's table and column privileges in the `tables_priv` and `columns_priv` tables, adds those to the user's privileges, and permits or denies access based on the result. For stored-routine operations, the server uses the `procs_priv` table rather than `tables_priv` and `columns_priv`.

Expressed in boolean terms, the preceding description of how a user's privileges are calculated may be summarized like this:

```
global privileges
OR (database privileges AND host privileges)
OR table privileges
OR column privileges
OR routine privileges
```

It may not be apparent why, if the global privileges are initially found to be insufficient for the requested operation, the server adds those privileges to the database, table, and column privileges later. The reason is that a request might require more than one type of privilege. For example, if you execute an `INSERT INTO ... SELECT` statement, you need both the `INSERT` and the `SELECT` privileges. Your privileges might be such that the `user` table row grants one privilege global and the `db` table row grants the other specifically for the relevant database. In this case, you have the necessary privileges to perform the request, but the server cannot tell that from either your global or database privileges alone. It must make an access-control decision based on the combined privileges.

### 6.2.8 Adding Accounts, Assigning Privileges, and Dropping Accounts

To manage MySQL accounts, use the SQL statements intended for that purpose:

- `CREATE USER` and `DROP USER` create and remove accounts.
- `GRANT` and `REVOKE` assign privileges to and revoke privileges from accounts.
- `SHOW GRANTS` displays account privilege assignments.

Account-management statements cause the server to make appropriate modifications to the underlying grant tables, which are discussed in Section 6.2.3, “Grant Tables”.

**Note**

Direct modification of grant tables using statements such as `INSERT`, `UPDATE`, or `DELETE` is discouraged and done at your own risk. The server is free to ignore rows that become malformed as a result of such modifications.

For any operation that modifies a grant table, the server checks whether the table has the expected structure and produces an error if not. To update the tables to the expected structure, perform the MySQL upgrade procedure. See Section 2.11, “Upgrading MySQL”.

Another option for creating accounts is to use the GUI tool MySQL Workbench. Also, several third-party programs offer capabilities for MySQL account administration. `phpMyAdmin` is one such program.

This section discusses the following topics:

- Creating Accounts and Granting Privileges
- Checking Account Privileges and Properties
• Revoking Account Privileges

• Dropping Accounts

For additional information about the statements discussed here, see Section 13.7.1, “Account Management Statements”.

Creating Accounts and Granting Privileges

The following examples show how to use the mysql client program to set up new accounts. These examples assume that the MySQL root account has the CREATE USER privilege and all privileges that it grants to other accounts.

At the command line, connect to the server as the MySQL root user, supplying the appropriate password at the password prompt:

```
shell> mysql -u root -p
Enter password: (enter root password here)
```

After connecting to the server, you can add new accounts. The following example uses CREATE USER and GRANT statements to set up four accounts (where you see 'password', substitute an appropriate password):

```
CREATE USER 'finley'@'localhost'
    IDENTIFIED BY 'password';
GRANT ALL
    ON *.*
    TO 'finley'@'localhost'
    WITH GRANT OPTION;
CREATE USER 'finley'@'%.example.com'
    IDENTIFIED BY 'password';
GRANT ALL
    ON *.*
    TO 'finley'@'%.example.com'
    WITH GRANT OPTION;
CREATE USER 'admin'@'localhost'
    IDENTIFIED BY 'password';
GRANT RELOAD,PROCESS
    ON *.*
    TO 'admin'@'localhost';
CREATE USER 'dummy'@'localhost';
```

The accounts created by those statements have the following properties:

• Two accounts have a user name of finley. Both are superuser accounts with full global privileges to do anything. The 'finley'@'localhost' account can be used only when connecting from the local host. The 'finley'@'%.example.com' account uses the '%' wildcard in the host part, so it can be used to connect from any host in the example.com domain.

The 'finley'@'localhost' account is necessary if there is an anonymous-user account for localhost. Without the 'finley'@'localhost' account, that anonymous-user account takes precedence when finley connects from the local host and finley is treated as an anonymous user. The reason for this is that the anonymous-user account has a more specific Host column value than the 'finley'@'%' account and thus comes earlier in the user table sort order. (For information about user table sorting, see Section 6.2.6, “Access Control, Stage 1: Connection Verification”.)

• The 'admin'@'localhost' account can be used only by admin to connect from the local host. It is granted the global RELOAD and PROCESS administrative privileges. These privileges enable the admin
Adding Accounts, Assigning Privileges, and Dropping Accounts

user to execute the `mysqladmin reload`, `mysqladmin refresh`, and `mysqladmin flush-xxx` commands, as well as `mysqladmin processlist`. No privileges are granted for accessing any databases. You could add such privileges using `GRANT` statements.

- The 'dummy@localhost' account has no password (which is insecure and not recommended). This account can be used only to connect from the local host. No privileges are granted. It is assumed that you grant specific privileges to the account using `GRANT` statements.

The previous example grants privileges at the global level. The next example creates three accounts and grants them access at lower levels; that is, to specific databases or objects within databases. Each account has a user name of `custom`, but the host name parts differ:

```
CREATE USER 'custom'@'localhost'
    IDENTIFIED BY 'password';
GRANT ALL
    ON bankaccount.*
    TO 'custom'@'localhost';

CREATE USER 'custom'@'host47.example.com'
    IDENTIFIED BY 'password';
GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
    ON expenses.*
    TO 'custom'@'host47.example.com';

CREATE USER 'custom'@'%.example.com'
    IDENTIFIED BY 'password';
GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
    ON customer.addresses
    TO 'custom'@'%.example.com';
```

The three accounts can be used as follows:

- The 'custom@localhost' account has all database-level privileges to access the `bankaccount` database. The account can be used to connect to the server only from the local host.

- The 'custom@host47.example.com' account has specific database-level privileges to access the `expenses` database. The account can be used to connect to the server only from the host `host47.example.com`.

- The 'custom@%.example.com' account has specific table-level privileges to access the `addresses` table in the `customer` database, from any host in the `example.com` domain. The account can be used to connect to the server from all machines in the domain due to use of the `%` wildcard character in the host part of the account name.

Checking Account Privileges and Properties

To see the privileges for an account, use `SHOW GRANTS`:

```
mysql> SHOW GRANTS FOR 'admin'@'localhost';
+---------------------------------------------+
| Grants for admin@localhost                |
| GRANT RELOAD, PROCESS ON *.* TO 'admin'@'localhost' |
+---------------------------------------------+
```

To see nonprivilege properties for an account, use `SHOW CREATE USER`:

```
mysql> SET print_identified_with_as_hex = ON;
mysql> SHOW CREATE USER 'admin'@'localhost'
+---------------------------------------------+
| CREATE USER for admin@localhost: CREATE USER 'admin'@'localhost' |
+---------------------------------------------+
```
Reserved Accounts

Identified with 'caching_sha2_password'
As 0x24412430303524301D0E17054E2241362B1419313C3E44326F294133734B30792F436E77764270373039612E324452786D43594F45354532324B6169794F47457852796E32

Require none password expire default account unlock
Password history default
Password reuse interval default
Password require current default

Enabling the `print_identified_with_as_hex` system variable (available as of MySQL 8.0.17) causes `SHOW CREATE USER` to display hash values that contain unprintable characters as hexadecimal strings rather than as regular string literals.

Revoking Account Privileges

To revoke account privileges, use the `REVOKE` statement. Privileges can be revoked at different levels, just as they can be granted at different levels.

Revoke global privileges:

```
REVOKE ALL
ON *.*
FROM 'finley'@'%.example.com';
```

```
REVOKE RELOAD
ON *.*
FROM 'admin'@'localhost';
```

Revoke database-level privileges:

```
REVOKE CREATE,DROP
ON expenses.*
FROM 'custom'@'host47.example.com';
```

Revoke table-level privileges:

```
REVOKE INSERT,UPDATE,DELETE
ON customer.addresses
FROM 'custom'@'%.example.com';
```

To check the effect of privilege revocation, use `SHOW GRANTS`:

```
mysql> SHOW GRANTS FOR 'admin'@'localhost';
+---------------------------------------------+
| Grants for admin@localhost                  |
+---------------------------------------------+
| GRANT PROCESS ON *.* TO 'admin'@'localhost' |
+---------------------------------------------+
```

Dropping Accounts

To remove an account, use the `DROP USER` statement. For example, to drop some of the accounts created previously:

```
DROP USER 'finley'@'localhost';
DROP USER 'finley'@'%.example.com';
DROP USER 'admin'@'localhost';
DROP USER 'dummy'@'localhost';
```

6.2.9 Reserved Accounts

One part of the MySQL installation process is data directory initialization (see Section 2.10.1, "Initializing the Data Directory"). During data directory initialization, MySQL creates user accounts that should be considered reserved:
Using Roles

- `'root'@'localhost'`: Used for administrative purposes. This account has all privileges, is a system account, and can perform any operation.

  Strictly speaking, this account name is not reserved, in the sense that some installations rename the root account to something else to avoid exposing a highly privileged account with a well-known name.

- `'mysql.sys'@'localhost'`: Used as the DEFINER for sys schema objects. Use of the mysql.sys account avoids problems that occur if a DBA renames or removes the root account. This account is locked so that it cannot be used for client connections.

- `'mysql.session'@'localhost'`: Used internally by plugins to access the server. This account is locked so that it cannot be used for client connections. The account is a system account.

- `'mysql.infoschema'@'localhost'`: Used as the DEFINER for INFORMATION_SCHEMA views. Use of the mysql.infoschema account avoids problems that occur if a DBA renames or removes the root account. This account is locked so that it cannot be used for client connections.

### 6.2.10 Using Roles

A MySQL role is a named collection of privileges. Like user accounts, roles can have privileges granted to and revoked from them.

A user account can be granted roles, which grants to the account the privileges associated with each role. This enables assignment of sets of privileges to accounts and provides a convenient alternative to granting individual privileges, both for conceptualizing desired privilege assignments and implementing them.

The following list summarizes role-management capabilities provided by MySQL:

- **CREATE ROLE** and **DROP ROLE** create and remove roles.
- **GRANT** and **REVOKE** assign privileges to revoke privileges from user accounts and roles.
- **SHOW GRANTS** displays privilege and role assignments for user accounts and roles.
- **SET DEFAULT ROLE** specifies which account roles are active by default.
- **SET ROLE** changes the active roles within the current session.
- The **CURRENT_ROLE()** function displays the active roles within the current session.
- The **mandatory_roles** and **activate_all_roles_on_login** system variables enable defining mandatory roles and automatic activation of granted roles when users log in to the server.

For descriptions of individual role-manipulation statements (including the privileges required to use them), see Section 13.7.1, “Account Management Statements”. The following discussion provides examples of role usage. Unless otherwise specified, SQL statements shown here should be executed using a MySQL account with sufficient administrative privileges, such as the root account.

- **Creating Roles and Granting Privileges to Them**
- **Defining Mandatory Roles**
- **Checking Role Privileges**
- **Activating Roles**
- **Revoking Roles or Role Privileges**
Using Roles

• Dropping Roles

• User and Role Interchangeability

Creating Roles and Granting Privileges to Them

Consider this scenario:

• An application uses a database named app_db.

• Associated with the application, there can be accounts for developers who create and maintain the application, and for users who interact with it.

• Developers need full access to the database. Some users need only read access, others need read/write access.

To avoid granting privileges individually to possibly many user accounts, create roles as names for the required privilege sets. This makes it easy to grant the required privileges to user accounts, by granting the appropriate roles.

To create the roles, use the CREATE ROLE statement:

```sql
CREATE ROLE 'app_developer', 'app_read', 'app_write';
```

Role names are much like user account names and consist of a user part and host part in 'user_name'@'host_name' format. The host part, if omitted, defaults to '%'. The user and host parts can be unquoted unless they contain special characters such as - or %. Unlike account names, the user part of role names cannot be blank. For additional information, see Section 6.2.5, “Specifying Role Names”.

To assign privileges to the roles, execute GRANT statements using the same syntax as for assigning privileges to user accounts:

```sql
GRANT ALL ON app_db.* TO 'app_developer';
GRANT SELECT ON app_db.* TO 'app_read';
GRANT INSERT, UPDATE, DELETE ON app_db.* TO 'app_write';
```

Now suppose that initially you require one developer account, two user accounts that need read-only access, and one user account that needs read/write access. Use CREATE USER to create the accounts:

```sql
CREATE USER 'dev1'@'localhost' IDENTIFIED BY 'dev1pass';
CREATE USER 'read_user1'@'localhost' IDENTIFIED BY 'read_user1pass';
CREATE USER 'read_user2'@'localhost' IDENTIFIED BY 'read_user2pass';
CREATE USER 'rw_user1'@'localhost' IDENTIFIED BY 'rw_user1pass';
```

To assign each user account its required privileges, you could use GRANT statements of the same form as just shown, but that requires enumerating individual privileges for each user. Instead, use an alternative GRANT syntax that permits granting roles rather than privileges:

```sql
GRANT 'app_developer' TO 'dev1'@'localhost';
GRANT 'app_read' TO 'read_user1'@'localhost', 'read_user2'@'localhost';
GRANT 'app_read', 'app_write' TO 'rw_user1'@'localhost';
```

The GRANT statement for the rw_user1 account grants the read and write roles, which combine to provide the required read and write privileges.

The GRANT syntax for granting roles to an account differs from the syntax for granting privileges: There is an ON clause to assign privileges, whereas there is no ON clause to assign roles. Because the syntaxes
are distinct, you cannot mix assigning privileges and roles in the same statement. (It is permitted to assign both privileges and roles to an account, but you must use separate GRANT statements, each with syntax appropriate to what is to be granted.) As of MySQL 8.0.16, roles cannot be granted to anonymous users.

A role when created is locked, has no password, and is assigned the default authentication plugin. (These role attributes can be changed later with the ALTER USER statement, by users who have the global CREATE USER privilege.)

While locked, a role cannot be used to authenticate to the server. If unlocked, a role can be used to authenticate. This is because roles and users are both authorization identifiers with much in common and little to distinguish them. See also User and Role Interchangeability.

Defining Mandatory Roles

It is possible to specify roles as mandatory by naming them in the value of the mandatory_roles system variable. The server treats a mandatory role as granted to all users, so that it need not be granted explicitly to any account.

To specify mandatory roles at server startup, define mandatory_roles in your server my.cnf file:

```
[mysqld]
mandatory_roles='role1,role2@localhost,r3@%.example.com'
```

To set and persist mandatory_roles at runtime, use a statement like this:

```
SET PERSIST mandatory_roles = 'role1,role2@localhost,r3@%.example.com';
```

SET PERSIST sets the value for the running MySQL instance. It also saves the value, causing it to carry over to subsequent server restarts. To change the value for the running MySQL instance without having it carry over to subsequent restarts, use the GLOBAL keyword rather than PERSIST. See Section 13.7.6.1, “SET Syntax for Variable Assignment”.

Setting mandatory_roles requires the ROLE_ADMIN privilege, in addition to the SYSTEM_VARIABLES_ADMIN privilege (or the deprecated SUPER privilege) normally required to set a global system variable.

Mandatory roles, like explicitly granted roles, do not take effect until activated (see Activating Roles). At login time, role activation occurs for all granted roles if the activate_all_roles_on_login system variable is enabled, or for roles that are set as default roles otherwise. At runtime, SET ROLE activates roles.

Roles named in the value of mandatory_roles cannot be revoked with REVOKE or dropped with DROP ROLE or DROP USER.

To prevent sessions from being made system sessions by default, a role that has the SYSTEM_USER privilege cannot be listed in the value of the mandatory_roles system variable:

- If mandatory_roles is assigned a role at startup that has the SYSTEM_USER privilege, the server writes a message to the error log and exits.
- If mandatory_roles is assigned a role at runtime that has the SYSTEM_USER privilege, an error occurs and the mandatory_roles value remains unchanged.

If a role named in mandatory_roles is not present in the mysql.user system table, the role is not granted to users. When the server attempts role activation for a user, it does not treat the nonexistent role as mandatory and writes a warning to the error log. If the role is created later and thus becomes valid, FLUSH PRIVILEGES may be necessary to cause the server to treat it as mandatory.
SHOW GRANTS displays mandatory roles according to the rules described in Section 13.7.7.21, “SHOW GRANTS Statement”.

Checking Role Privileges

To verify the privileges assigned to an account, use SHOW GRANTS. For example:

```sql
mysql> SHOW GRANTS FOR 'dev1'@'localhost';
```

```
+-------------------------------------------------+
| Grants for dev1@localhost                       |
+-------------------------------------------------+
| GRANT USAGE ON *.* TO `dev1`@`localhost`        |
| GRANT `app_developer`@`%` TO `dev1`@`localhost` |
+-------------------------------------------------+
```

However, that shows each granted role without “expanding” it to the privileges the role represents. To show role privileges as well, add a USING clause naming the granted roles for which to display privileges:

```sql
mysql> SHOW GRANTS FOR 'dev1'@'localhost' USING 'app_developer';
```

```
+----------------------------------------------------------+
| Grants for dev1@localhost                                |
+----------------------------------------------------------+
| GRANT USAGE ON *.* TO `dev1`@`localhost`                 |
| GRANT ALL PRIVILEGES ON `app_db`.* TO `dev1`@`localhost` |
| GRANT `app_developer`@`%` TO `dev1`@`localhost`          |
+----------------------------------------------------------+
```

Verify each other type of user similarly:

```sql
mysql> SHOW GRANTS FOR 'read_user1'@'localhost' USING 'app_read';
```

```
+--------------------------------------------------------+
| Grants for read_user1@localhost                        |
+--------------------------------------------------------+
| GRANT USAGE ON *.* TO `read_user1`@`localhost`         |
| GRANT SELECT ON `app_db`.* TO `read_user1`@`localhost` |
| GRANT `app_read`@`%` TO `read_user1`@`localhost`       |
+--------------------------------------------------------+

mysql> SHOW GRANTS FOR 'rw_user1'@'localhost' USING 'app_read', 'app_write';
```

```
+------------------------------------------------------------------------------+
| Grants for rw_user1@localhost                                                |
+------------------------------------------------------------------------------+
| GRANT USAGE ON *.* TO `rw_user1`@`localhost`                                 |
| GRANT SELECT, INSERT, UPDATE, DELETE ON `app_db`.* TO `rw_user1`@`localhost` |
| GRANT `app_read`@`%`,`app_write`@`%` TO `rw_user1`@`localhost`               |
+------------------------------------------------------------------------------+
```

SHOW GRANTS displays mandatory roles according to the rules described in Section 13.7.7.21, “SHOW GRANTS Statement”.

Activating Roles

Roles granted to a user account can be active or inactive within account sessions. If a granted role is active within a session, its privileges apply; otherwise, they do not. To determine which roles are active within the current session, use the CURRENT_ROLE() function.

By default, granting a role to an account or naming it in the mandatory_roles system variable value does not automatically cause the role to become active within account sessions. For example, because thus far in the preceding discussion no rw_user1 roles have been activated, if you connect to the server as rw_user1 and invoke the CURRENT_ROLE() function, the result is NONE (no active roles):

```sql
mysql> SELECT CURRENT_ROLE();
```

```
+----------------+
| CURRENT_ROLE() |
+----------------+
| NONE           |
+----------------+
```
Using Roles

To specify which roles should become active each time a user connects to the server and authenticates, use SET DEFAULT ROLE. To set the default to all assigned roles for each account created earlier, use this statement:

```sql
SET DEFAULT ROLE ALL TO
  'dev1'@'localhost',
  'read_user1'@'localhost',
  'read_user2'@'localhost',
  'rw_user1'@'localhost';
```

Now if you connect as `rw_user1`, the initial value of `CURRENT_ROLE()` reflects the new default role assignments:

```sql
mysql> SELECT CURRENT_ROLE();
+----------------+
| CURRENT_ROLE() |
+----------------+
| `app_read`@`%`, `app_write`@`%` |
+----------------+
```

To cause all explicitly granted and mandatory roles to be automatically activated when users connect to the server, enable the `activate_all_roles_on_login` system variable. By default, automatic role activation is disabled.

Within a session, a user can execute `SET ROLE` to change the set of active roles. For example, for `rw_user1`:

```sql
mysql> SET ROLE NONE; SELECT CURRENT_ROLE();
+----------------+
| CURRENT_ROLE() |
+----------------+
| NONE           |
+----------------+
mysql> SET ROLE ALL EXCEPT 'app_write'; SELECT CURRENT_ROLE();
+----------------+
| CURRENT_ROLE() |
+----------------+
| `app_read`@`%` |
+----------------+
mysql> SET ROLE DEFAULT; SELECT CURRENT_ROLE();
+----------------+
| CURRENT_ROLE() |
+----------------+
| `app_read`@`%`, `app_write`@`%` |
+----------------+
```

The first `SET ROLE` statement deactivates all roles. The second makes `rw_user1` effectively read only. The third restores the default roles.

The effective user for stored program and view objects is subject to the `DEFINER` and `SQL SECURITY` attributes, which determine whether execution occurs in invoker or definer context (see Section 24.6, "Stored Object Access Control"):

- Stored program and view objects that execute in invoker context execute with the roles that are active within the current session.
- Stored program and view objects that execute in definer context execute with the default roles of the user named in their `DEFINER` attribute. If `activate_all_roles_on_login` is enabled, such objects
Using Roles

execute with all roles granted to the DEFINER user, including mandatory roles. For stored programs, if execution should occur with roles different from the default, the program body should execute SET ROLE to activate the required roles.

Revoking Roles or Role Privileges

Just as roles can be granted to an account, they can be revoked from an account:

REVOKE role FROM user;

Roles named in the mandatory_roles system variable value cannot be revoked.

REVOKE can also be applied to a role to modify the privileges granted to it. This affects not only the role itself, but any account granted that role. Suppose that you want to temporarily make all application users read only. To do this, use REVOKE to revoke the modification privileges from the app_write role:

REVOKE INSERT, UPDATE, DELETE ON app_db.* FROM 'app_write';

As it happens, that leaves the role with no privileges at all, as can be seen using SHOW GRANTS (which demonstrates that this statement can be used with roles, not just users):

mysql> SHOW GRANTS FOR 'app_write';

+---------------------------------------+
<table>
<thead>
<tr>
<th>Grants for app_write@%</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANT USAGE ON <em>.</em> TO <code>app_write</code>@<code>%</code></td>
</tr>
</tbody>
</table>
+---------------------------------------+

Because revoking privileges from a role affects the privileges for any user who is assigned the modified role, rw_user1 now has no table modification privileges (INSERT, UPDATE, and DELETE are no longer present):

mysql> SHOW GRANTS FOR 'rw_user1'@'localhost'

+----------------------------------------------------------------+
<table>
<thead>
<tr>
<th>Grants for rw_user1@localhost</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANT USAGE ON <em>.</em> TO <code>rw_user1</code>@<code>localhost</code></td>
</tr>
<tr>
<td>GRANT SELECT ON <code>app_db</code>.* TO <code>rw_user1</code>@<code>localhost</code></td>
</tr>
<tr>
<td>GRANT <code>app_read</code>@<code>%</code>,<code>app_write</code>@<code>%</code> TO <code>rw_user1</code>@<code>localhost</code></td>
</tr>
</tbody>
</table>
+----------------------------------------------------------------+

In effect, the rw_user1 read/write user has become a read-only user. This also occurs for any other accounts that are granted the app_write role, illustrating how use of roles makes it unnecessary to modify privileges for individual accounts.

To restore modification privileges to the role, simply re-grant them:

GRANT INSERT, UPDATE, DELETE ON app_db.* TO 'app_write';

Now rw_user1 again has modification privileges, as do any other accounts granted the app_write role.

Dropping Roles

To drop roles, use DROP ROLE:

DROP ROLE 'app_read', 'app_write';

Dropping a role revokes it from every account to which it was granted.

Roles named in the mandatory_roles system variable value cannot be dropped.
User and Role Interchangeability

As has been hinted at earlier for `SHOW GRANTS`, which displays grants for user accounts or roles, accounts and roles can be used interchangeably.

One difference between roles and users is that `CREATE ROLE` creates an authorization identifier that is locked by default, whereas `CREATE USER` creates an authorization identifier that is unlocked by default. However, distinction is not immutable because a user with appropriate privileges can lock or unlock roles or users after they have been created.

If a database administrator has a preference that a specific authorization identifier must be a role, a name scheme can be used to communicate this intention. For example, you could use a `r_` prefix for all authorization identifiers that you intend to be roles and nothing else.

Another difference between roles and users lies in the privileges available for administering them:

- The `CREATE ROLE` and `DROP ROLE` privileges enable only use of the `CREATE ROLE` and `DROP ROLE` statements, respectively.
- The `CREATE USER` privilege enables use of the `ALTER USER`, `CREATE ROLE`, `CREATE USER`, `DROP ROLE`, `DROP USER`, `RENAME USER`, and `REVOKE ALL PRIVILEGES` statements.

Thus, the `CREATE ROLE` and `DROP ROLE` privileges are not as powerful as `CREATE USER` and may be granted to users who should only be permitted to create and drop roles, and not perform more general account manipulation.

With regard to privileges and interchangeability of users and roles, you can treat a user account like a role and grant that account to another user or a role. The effect is to grant the account's privileges and roles to the other user or role.

This set of statements demonstrates that you can grant a user to a user, a role to a user, a user to a role, or a role to a role:

```sql
CREATE USER 'u1';
CREATE ROLE 'r1';
GRANT SELECT ON db1.* TO 'u1';
GRANT SELECT ON db2.* TO 'r1';
CREATE USER 'u2';
CREATE ROLE 'r2';
GRANT 'u1', 'r1' TO 'u2';
GRANT 'u1', 'r1' TO 'r2';
```

The result in each case is to grant to the grantee object the privileges associated with the granted object. After executing those statements, each of `u2` and `r2` have been granted privileges from a user (`u1`) and a role (`r1`):

```sql
mysql> SHOW GRANTS FOR 'u2' USING 'u1', 'r1';
+-------------------------------------+
<table>
<thead>
<tr>
<th>Grants for u2@%</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANT USAGE ON <em>.</em> TO <code>u2</code>'@<code>%</code></td>
</tr>
<tr>
<td>GRANT SELECT ON <code>db1</code>.* TO <code>u2</code>'@<code>%</code></td>
</tr>
<tr>
<td>GRANT SELECT ON <code>db2</code>.* TO <code>u2</code>'@<code>%</code></td>
</tr>
<tr>
<td>GRANT <code>u1</code>'@<code>%</code>,<code>r1</code>'@<code>%</code> TO <code>u2</code>'@<code>%</code></td>
</tr>
</tbody>
</table>
+-------------------------------------+
mysql> SHOW GRANTS FOR 'r2' USING 'u1', 'r1';
+-------------------------------------+
<table>
<thead>
<tr>
<th>Grants for r2@%</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANT USAGE ON <em>.</em> TO <code>r2</code>'@<code>%</code></td>
</tr>
<tr>
<td>GRANT SELECT ON <code>db1</code>.* TO <code>r2</code>'@<code>%</code></td>
</tr>
</tbody>
</table>
```
The preceding example is illustrative only, but interchangeability of user accounts and roles has practical application, such as in the following situation: Suppose that a legacy application development project began before the advent of roles in MySQL, so all user accounts associated with the project are granted privileges directly (rather than granted privileges by virtue of being granted roles). One of these accounts is a developer account that was originally granted privileges as follows:

```
CREATE USER 'old_app_dev'@'localhost' IDENTIFIED BY 'old_app_devpass';
GRANT ALL ON old_app.* TO 'old_app_dev'@'localhost';
```

If this developer leaves the project, it becomes necessary to assign the privileges to another user, or perhaps multiple users if development activities have expanded. Here are some ways to deal with the issue:

- Without using roles: Change the account password so the original developer cannot use it, and have a new developer use the account instead:

  ```
  ALTER USER 'old_app_dev'@'localhost' IDENTIFIED BY 'new_password';
  ```

- Using roles: Lock the account to prevent anyone from using it to connect to the server:

  ```
  ALTER USER 'old_app_dev'@'localhost' ACCOUNT LOCK;
  ```

  Then treat the account as a role. For each developer new to the project, create a new account and grant to it the original developer account:

  ```
  CREATE USER 'new_app_dev1'@'localhost' IDENTIFIED BY 'new_password';
  GRANT 'old_app_dev'@'localhost' TO 'new_app_dev1'@'localhost';
  ```

  The effect is to assign the original developer account privileges to the new account.

### 6.2.11 Account Categories

As of MySQL 8.0.16, MySQL incorporates the concept of user account categories, based on the `SYSTEM_USER` privilege.

- **System and Regular Accounts**
- **Operations Affected by the SYSTEM_USER Privilege**
- **System and Regular Sessions**
- **Protecting System Accounts Against Manipulation by Regular Accounts**

#### System and Regular Accounts

MySQL incorporates the concept of user account categories, with system and regular users distinguished according to whether they have the `SYSTEM_USER` privilege:

- A user with the `SYSTEM_USER` privilege is a system user.
- A user without the `SYSTEM_USER` privilege is a regular user.

The `SYSTEM_USER` privilege has an effect on the accounts to which a given user can apply its other privileges, as well as whether the user is protected from other accounts:

- A system user can modify both system and regular accounts. That is, a user who has the appropriate privileges to perform a given operation on regular accounts is enabled by possession of `SYSTEM_USER`
Account Categories

to also perform the operation on system accounts. A system account can be modified only by system users with appropriate privileges, not by regular users.

• A regular user with appropriate privileges can modify regular accounts, but not system accounts. A regular account can be modified by both system and regular users with appropriate privileges.

If a user has the appropriate privileges to perform a given operation on regular accounts, \texttt{SYSTEM\_USER} enables the user to also perform the operation on system accounts. \texttt{SYSTEM\_USER} does not imply any other privilege, so the ability to perform a given account operation remains predicated on possession of any other required privileges. For example, if a user can grant the \texttt{SELECT} and \texttt{UPDATE} privileges to regular accounts, then with \texttt{SYSTEM\_USER} the user can also grant \texttt{SELECT} and \texttt{UPDATE} to system accounts.

The distinction between system and regular accounts enables better control over certain account administration issues by protecting accounts that have the \texttt{SYSTEM\_USER} privilege from accounts that do not have the privilege. For example, the \texttt{CREATE\_USER} privilege enables not only creation of new accounts, but modification and removal of existing accounts. Without the system user concept, a user who has the \texttt{CREATE\_USER} privilege can modify or drop any existing account, including the \texttt{root} account. The concept of system user enables restricting modifications to the \texttt{root} account (itself a system account) so they can be made only by system users. Regular users with the \texttt{CREATE\_USER} privilege can still modify or drop existing accounts, but only regular accounts.

Operations Affected by the \texttt{SYSTEM\_USER} Privilege

The \texttt{SYSTEM\_USER} privilege affects these operations:

• Account manipulation.

Account manipulation includes creating and dropping accounts, granting and revoking privileges, changing account authentication characteristics such as credentials or authentication plugin, and changing other account characteristics such as password expiration policy.

The \texttt{SYSTEM\_USER} privilege is required to manipulate system accounts using account-management statements such as \texttt{CREATE\_USER} and \texttt{GRANT}. To prevent an account from modifying system accounts this way, make it a regular account by not granting it the \texttt{SYSTEM\_USER} privilege. (However, to fully protect system accounts against regular accounts, you must also withhold modification privileges for the \texttt{mysql} system schema from regular accounts. See Protecting System Accounts Against Manipulation by Regular Accounts.)

• Killing current sessions and statements executing within them.

To kill a session or statement that is executing with the \texttt{SYSTEM\_USER} privilege, your own session must have the \texttt{SYSTEM\_USER} privilege, in addition to any other required privilege (\texttt{CONNECTION\_ADMIN} or the deprecated \texttt{SUPER} privilege).

Prior to MySQL 8.0.16, \texttt{CONNECTION\_ADMIN} privilege (or the deprecated \texttt{SUPER} privilege) is sufficient to kill any session or statement.

• Setting the \texttt{DEFINER} attribute for stored objects.

To set the \texttt{DEFINER} attribute for a stored object to an account that has the \texttt{SYSTEM\_USER} privilege, you must have the \texttt{SYSTEM\_USER} privilege, in addition to any other required privilege (\texttt{SET\_USER\_ID} or the deprecated \texttt{SUPER} privilege).

Prior to MySQL 8.0.16, the \texttt{SET\_USER\_ID} privilege (or the deprecated \texttt{SUPER} privilege) is sufficient to specify any \texttt{DEFINER} value for stored objects.
• Specifying mandatory roles.

A role that has the `SYSTEM_USER` privilege cannot be listed in the value of the `mandatory_roles` system variable.

Prior to MySQL 8.0.16, any role can be listed in `mandatory_roles`.

**System and Regular Sessions**

Sessions executing within the server are distinguished as system or regular sessions, similar to the distinction between system and regular users:

• A session that possesses the `SYSTEM_USER` privilege is a system session.

• A session that does not possess the `SYSTEM_USER` privilege is a regular session.

A regular session is able to perform only operations permitted to regular users. A system session is additionally able to perform operations permitted only to system users.

The privileges possessed by a session are those granted directly to its underlying account, plus those granted to all roles currently active within the session. Thus, a session may be a system session because its account has been granted the `SYSTEM_USER` privilege directly, or because the session has activated a role that has the `SYSTEM_USER` privilege. Roles granted to an account that are not active within the session do not affect session privileges.

Because activating and deactivating roles can change the privileges possessed by sessions, a session may change from a regular session to a system session or vice versa. If a session activates or deactivates a role that has the `SYSTEM_USER` privilege, the appropriate change between regular and system session takes place immediately, for that session only:

• If a regular session activates a role with the `SYSTEM_USER` privilege, the session becomes a system session.

• If a system session deactivates a role with the `SYSTEM_USER` privilege, the session becomes a regular session, unless some other role with the `SYSTEM_USER` privilege remains active.

These operations have no effect on existing sessions:

• If the `SYSTEM_USER` privilege is granted to or revoked from an account, existing sessions for the account do not change between regular and system sessions. The grant or revoke operation affects only sessions for subsequent connections by the account.

• Statements executed by a stored object invoked within a session execute with the system or regular status of the parent session, even if the object `DEFINER` attribute names a system account.

Because role activation affects only sessions and not accounts, granting a role that has the `SYSTEM_USER` privilege to a regular account does not protect that account against regular users. The role protects only sessions for the account in which the role has been activated, and protects the session only against being killed by regular sessions.

**Protecting System Accounts Against Manipulation by Regular Accounts**

Account manipulation includes creating and dropping accounts, granting and revoking privileges, changing account authentication characteristics such as credentials or authentication plugin, and changing other account characteristics such as password expiration policy.
Account manipulation can be done two ways:

- By using account-management statements such as `CREATE USER` and `GRANT`. This is the preferred method.
- By direct grant-table modification using statements such as `INSERT` and `UPDATE`. This method is discouraged but possible for users with the appropriate privileges on the `mysql` system schema that contains the grant tables.

To fully protect system accounts against modification by a given account, make it a regular account and do not grant it modification privileges for the `mysql` schema:

- The `SYSTEM_USER` privilege is required to manipulate system accounts using account-management statements. To prevent an account from modifying system accounts this way, make it a regular account by not granting `SYSTEM_USER` to it. This includes not granting `SYSTEM_USER` to any roles granted to the account.
- Privileges for the `mysql` schema enable manipulation of system accounts through direct modification of the grant tables, even if the modifying account is a regular account. To restrict unauthorized direct modification of system accounts by a regular account, do not grant modification privileges for the `mysql` schema to the account (or any roles granted to the account). If a regular account must have global privileges that apply to all schemas, `mysql` schema modifications can be prevented using privilege restrictions imposed using partial revokes. See Section 6.2.12, “Privilege Restriction Using Partial Revokes”.

**Note**

Unlike withholding the `SYSTEM_USER` privilege, which prevents an account from modifying system accounts but not regular accounts, withholding `mysql` schema privileges prevents an account from modifying system accounts as well as regular accounts. This should not be an issue because, as mentioned, direct grant-table modification is discouraged.

Suppose that you want to create a user `u1` who has all privileges on all schemas, except that `u1` should be a regular user without the ability to modify system accounts. Assuming that the `partial_revokes` system variable is enabled, configure `u1` as follows:

```sql
CREATE USER u1 IDENTIFIED BY 'password';
GRANT ALL ON *.* TO u1 WITH GRANT OPTION;
-- GRANT ALL includes SYSTEM_USER, so at this point
-- u1 can manipulate system or regular accounts
REVOKE SYSTEM_USER ON *.* FROM u1;
-- Revoking SYSTEM_USER makes u1 a regular user;
-- now u1 can use account-management statements
-- to manipulate only regular accounts
REVOKE ALL ON mysql.* FROM u1;
-- This partial revoke prevents u1 from directly
-- modifying grant tables to manipulate accounts
```

To prevent all `mysql` system schema access by an account, revoke all its privileges on the `mysql` schema, as just shown. It is also possible to permit partial `mysql` schema access, such as read-only access. The following example creates an account that has `SELECT`, `INSERT`, `UPDATE`, and `DELETE` privileges globally for all schemas, but only `SELECT` for the `mysql` schema:

```sql
CREATE USER u2 IDENTIFIED BY 'password';
GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO u2;
REVOKE INSERT, UPDATE, DELETE ON mysql.* FROM u2;
```
Another possibility is to revoke all `mysql` schema privileges but grant access to specific `mysql` tables or columns. This can be done even with a partial revoke on `mysql`. The following statements enable read-only access to `u1` within the `mysql` schema, but only for the `db` table and the `Host` and `User` columns of the `user` table:

```sql
CREATE USER u3 IDENTIFIED BY 'password';
GRANT ALL ON *.* TO u3;
REVOKE ALL ON mysql.* FROM u3;
GRANT SELECT ON mysql.db TO u3;
GRANT SELECT(Host,User) ON mysql.user TO u3;
```

### 6.2.12 Privilege Restriction Using Partial Revokes

Prior to MySQL 8.0.16, it is not possible to grant privileges that apply globally except for certain schemas. As of MySQL 8.0.16, that is possible if the `partial_revokes` system variable is enabled. Specifically, for users who have privileges at the global level, `partial_revokes` enables privileges for specific schemas to be revoked while leaving the privileges in place for other schemas. Privilege restrictions thus imposed may be useful for administration of accounts that have global privileges but should not be permitted to access certain schemas. For example, it is possible to permit an account to modify any table except those in the `mysql` system schema.

- **Using Partial Revokes**
- **Partial Revokes Versus Explicit Schema Grants**
- **Disabling Partial Revokes**
- **Partial Revokes and Replication**

**Note**

For brevity, `CREATE USER` statements shown here do not include passwords. For production use, always assign account passwords.

### Using Partial Revokes

The `partial_revokes` system variable controls whether privilege restrictions can be placed on accounts. By default, `partial_revokes` is disabled and attempts to partially revoke global privileges produce an error:

```sql
mysql> CREATE USER u1;
mysql> GRANT SELECT, INSERT ON *.* TO u1;
mysql> REVOKE INSERT ON world.* FROM u1;
ERROR 1141 (42000): There is no such grant defined for user 'u1' on host '%'
```

To permit the `REVOKE` operation, enable `partial_revokes`:

```sql
SET PERSIST partial_revokes = ON;
```

`SET PERSIST` sets the value for the running MySQL instance. It also saves the value, causing it to carry over to subsequent server restarts. To change the value for the running MySQL instance without having it carry over to subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`. See Section 13.7.6.1, “SET Syntax for Variable Assignment”.

With `partial_revokes` enabled, the partial revoke succeeds:

```sql
mysql> REVOKE INSERT ON world.* FROM u1;
mysql> SHOW GRANTS FOR u1;
+------------------------------------------+
| Grants for u1%                          |
+------------------------------------------+
```
Privilege Restriction Using Partial Revokes

```
| GRANT SELECT, INSERT ON *.* TO `u1`@`%` |
| REVOKE INSERT ON `world`.* FROM `u1`@`%` |
```

SHOW GRANTS lists partial revokes as REVOKE statements in its output. The result indicates that `u1` has global SELECT and INSERT privileges, except that INSERT cannot be exercised for tables in the world schema. That is, access by `u1` to `world` tables is read only.

The server records privilege restrictions implemented through partial revokes in the `mysql.user` system table. If an account has partial revokes, its `User_attributes` column value has a `Restrictions` attribute:

```
mysql> SELECT User, Host, User_attributes->>'$.Restrictions'
    FROM mysql.user WHERE User_attributes->>'$.Restrictions' <> '';
```

<table>
<thead>
<tr>
<th>User</th>
<th>Host</th>
<th>User_attributes-&gt;&gt;'$.Restrictions'</th>
</tr>
</thead>
<tbody>
<tr>
<td>u1</td>
<td>%</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>[{&quot;Database&quot;: &quot;world&quot;, &quot;Privileges&quot;: [&quot;INSERT&quot;]}]</td>
</tr>
</tbody>
</table>
```

**Note**

Although partial revokes can be imposed for any schema, privilege restrictions on the `mysql` system schema in particular are useful as part of a strategy for preventing regular accounts from modifying system accounts. See Protecting System Accounts Against Manipulation by Regular Accounts.

Partial revoke operations are subject to these conditions:

- Partial revokes must name the schema literally. Schema names that contain the `%` or `_` SQL wildcard characters (for example, `myschema%`) are not permitted.

- It is possible to use partial revokes to place restrictions on nonexistent schemas, but only if the revoked privilege is granted globally. If a privilege is not granted globally, revoking it for a nonexistent schema produces an error.

- Partial revokes apply at the schema level only. You cannot use partial revokes for privileges that apply only globally (such as `FILE` or `BINLOG_ADMIN`), or for table, column, or routine privileges.

As mentioned previously, partial revokes of schema-level privileges appear in SHOW GRANTS output as REVOKE statements. This differs from how SHOW GRANTS represents “plain” schema-level privileges:

- When granted, schema-level privileges are represented by their own GRANT statements in the output:

```
mysql> CREATE USER u1;
mysql> GRANT UPDATE ON mysql.* TO u1;
mysql> GRANT DELETE ON world.* TO u1;
mysql> SHOW GRANTS FOR u1;
```

```
+---------------------------------------+
| Grants for u1@%                       |
+---------------------------------------+
| GRANT USAGE ON *.* TO `u1`@`%`        |
| GRANT UPDATE ON `mysql`.* TO `u1`@`%` |
| GRANT DELETE ON `world`.* TO `u1`@`%` |
+---------------------------------------+
```

- When revoked, schema-level privileges simply disappear from the output. They do not appear as REVOKE statements:

```
mysql> REVOKE UPDATE ON mysql.* FROM u1;
mysql> REVOKE DELETE ON world.* FROM u1;
mysql> SHOW GRANTS FOR u1;
```
Privilege Restriction Using Partial Revokes

When a user grants a privilege, any restriction the grantor has on the privilege is inherited by the grantee, unless the grantee already has the privilege without the restriction. Consider the following two users, one of whom has the global `SELECT` privilege:

```
CREATE USER u1, u2;
GRANT SELECT ON *.* TO u2;
```

Suppose that an administrative user `admin` has a global but partially revoked `SELECT` privilege:

```
mysql> CREATE USER admin;
mysql> GRANT SELECT ON *.* TO admin WITH GRANT OPTION;
mysql> REVOKE SELECT ON mysql.* FROM admin;
mysql> SHOW GRANTS FOR admin;
+------------------------------------------------------+
| Grants for admin@%                                   |
+------------------------------------------------------+
| GRANT SELECT ON *.* TO `admin`@`%` WITH GRANT OPTION |
| REVOKE SELECT ON `mysql`.* FROM `admin`@`%`          |
+------------------------------------------------------+
```

If `admin` grants `SELECT` globally to `u1` and `u2`, the result differs for each user:

- If `admin` grants `SELECT` globally to `u1`, who has no `SELECT` privilege to begin with, `u1` inherits the `admin` privilege restriction:
  
  ```
  mysql> GRANT SELECT ON *.* TO u1;
  mysql> SHOW GRANTS FOR u1;
  +------------------------------------------+
  | Grants for u1@%                          |
  +------------------------------------------+
  | GRANT SELECT ON *.* TO `u1`@`%`          |
  | REVOKE SELECT ON `mysql`.* FROM `u1`@`%` |
  +------------------------------------------+
  ```

- On the other hand, `u2` already holds a global `SELECT` privilege without restriction. `GRANT` can only add to a grantee's existing privileges, not reduce them, so if `admin` grants `SELECT` globally to `u2`, `u2` does not inherit the `admin` restriction:
  
  ```
  mysql> GRANT SELECT ON *.* TO u2;
  mysql> SHOW GRANTS FOR u2;
  +---------------------------------+
  | Grants for u2@%                 |
  +---------------------------------+
  | GRANT SELECT ON *.* TO `u2`@`%` |
  +---------------------------------+
  ```

If a `GRANT` statement includes an `AS user` clause, the privilege restrictions applied are those on the user/role combination specified by the clause, rather than those on the user who executes the statement. For information about the `AS` clause, see Section 13.7.1.6, “GRANT Statement”.

Restrictions on new privileges granted to an account are added to any existing restrictions for that account:

```
mysql> CREATE USER u1;
mysql> GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO u1;
mysql> REVOKE INSERT ON mysql.* FROM u1;
mysql> SHOW GRANTS FOR u1;
+------------------------------------------------------------------+
| Grants for u1@%                                                   |
+------------------------------------------------------------------+
```
Privilege Restriction Using Partial Revokes

Aggregation of privilege restrictions applies both when privileges are partially revoked explicitly (as just shown) and when restrictions are inherited implicitly from the user who executes the statement or the user mentioned in an AS user clause.

If an account has a privilege restriction on a schema:

- The account cannot grant to other accounts a privilege on the restricted schema or any object within it.
- Another account that does not have the restriction can grant privileges to the restricted account for the restricted schema or objects within it. Suppose that an unrestricted user executes these statements:

  ```sql
  CREATE USER u1;
  GRANT SELECT, INSERT, UPDATE ON *.* TO u1;
  REVOKE SELECT, INSERT, UPDATE ON mysql.* FROM u1;
  GRANT SELECT ON mysql.user TO u1;          -- grant table privilege
  GRANT SELECT(Host,User) ON mysql.db TO u1; -- grant column privileges
  ```

  The resulting account has these privileges, with the ability to perform limited operations within the restricted schema:

  ```sql
  mysql> SHOW GRANTS FOR u1;
  +----------------------------------------------------------+
  | Grants for u1@%                                          |
  +----------------------------------------------------------+
  | GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO `u1`@`%`   |
  | REVOKE SELECT, INSERT, UPDATE ON `mysql`.* FROM `u1`@`%`  |
  | GRANT SELECT (Host, User) ON `mysql`.`db` TO `u1`@`%`    |
  | GRANT SELECT ON `mysql`.`user` TO `u1`@`%`               |
  +----------------------------------------------------------+
  ```

If an account has a restriction on a global privilege, the restriction is removed by any of these actions:

- Granting the privilege globally to the account by an account that has no restriction on the privilege.
- Granting the privilege at the schema level.
- Revoking the privilege globally.

Consider a user `u1` who holds several privileges globally, but with restrictions on INSERT, UPDATE and DELETE:

  ```sql
  mysql> CREATE USER u1;
  mysql> GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO u1;
  mysql> REVOKE INSERT, UPDATE, DELETE ON mysql.* FROM u1;
  mysql> SHOW GRANTS FOR u1;
  +----------------------------------------------------------+
  | Grants for u1@%                                          |
  +----------------------------------------------------------+
  | GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO `u1`@`%`   |
  | REVOKE INSERT, UPDATE, DELETE ON `mysql`.* FROM `u1`@`%`  |
  +----------------------------------------------------------+
  ```
Privilege Restriction Using Partial Revokes

Granting a privilege globally to \texttt{u1} from an account with no restriction removes the privilege restriction. For example, to remove the \texttt{INSERT} restriction:

\begin{verbatim}
mysql> GRANT INSERT ON *.* TO u1;
mysql> SHOW GRANTS FOR u1;
+-------------------------------------------------+
| Grants for u1@%
+-------------------------------------------------+
| GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO `u1`@`%` |
| REVOKE UPDATE, DELETE ON `mysql`.* FROM `u1`@`%` |
+-------------------------------------------------+
\end{verbatim}

Granting a privilege at the schema level to \texttt{u1} removes the privilege restriction. For example, to remove the \texttt{UPDATE} restriction:

\begin{verbatim}
mysql> GRANT UPDATE ON mysql.* TO u1;
mysql> SHOW GRANTS FOR u1;
+-------------------------------------------------+
| Grants for u1@%
+-------------------------------------------------+
| GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO `u1`@`%` |
| REVOKE DELETE ON `mysql`.* FROM `u1`@`%` |
+-------------------------------------------------+
\end{verbatim}

Revoking a global privilege removes the privilege, including any restrictions on it. For example, to remove the \texttt{DELETE} restriction (at the cost of removing all \texttt{DELETE} access):

\begin{verbatim}
mysql> REVOKE DELETE ON *.* FROM u1;
mysql> SHOW GRANTS FOR u1;
+-----------------------------------------+
| Grants for u1@%
+-----------------------------------------+
| GRANT SELECT, INSERT ON *.* TO `u1`@`%` |
+-----------------------------------------+
\end{verbatim}

If an account has a privilege at both the global and schema levels, you must revoke it at the schema level twice to effect a partial revoke. Suppose that \texttt{u1} has these privileges, where \texttt{INSERT} is held both globally and on the \texttt{world} schema:

\begin{verbatim}
mysql> CREATE USER u1;
mysql> GRANT SELECT, INSERT ON *.* TO u1;
mysql> GRANT INSERT ON world.* TO u1;
mysql> SHOW GRANTS FOR u1;
+-----------------------------------------+
| Grants for u1@%
+-----------------------------------------+
| GRANT SELECT, INSERT ON *.* TO `u1`@`%` |
| GRANT INSERT ON `world`.* TO `u1`@`%` |
+-----------------------------------------+
\end{verbatim}

Revoking \texttt{INSERT} on \texttt{world} revokes the schema-level privilege (\texttt{SHOW GRANTS} no longer displays the schema-level \texttt{GRANT} statement):

\begin{verbatim}
mysql> REVOKE INSERT ON world.* FROM u1;
mysql> SHOW GRANTS FOR u1;
+-----------------------------------------+
| Grants for u1@%
+-----------------------------------------+
| GRANT SELECT, INSERT ON *.* TO `u1`@`%` |
+-----------------------------------------+
\end{verbatim}

Revoking \texttt{INSERT} on \texttt{world} again performs a partial revoke of the global privilege (\texttt{SHOW GRANTS} now includes a schema-level \texttt{REVOKE} statement):

\begin{verbatim}
mysql> REVOKE INSERT ON world.* FROM u1;
mysql> SHOW GRANTS FOR u1;
+-----------------------------------------+
| Grants for u1@%
+-----------------------------------------+
| GRANT SELECT, INSERT ON *.* TO `u1`@`%` |
+-----------------------------------------+
\end{verbatim}
Partial Revokes Versus Explicit Schema Grants

To provide access to accounts for some schemas but not others, partial revokes provide an alternative to the approach of explicitly granting schema-level access without granting global privileges. The two approaches have different advantages and disadvantages.

Granting schema-level privileges and not global privileges:

- Adding a new schema: The schema is inaccessible to existing accounts by default. For any account to which the schema should be accessible, the DBA must grant schema-level access.
- Adding a new account: The DBA must grant schema-level access for each schema to which the account should have access.

Granting global privileges in conjunction with partial revokes:

- Adding a new schema: The schema is accessible to existing accounts that have global privileges. For any such account to which the schema should be inaccessible, the DBA must add a partial revoke.
- Adding a new account: The DBA must grant the global privileges, plus a partial revoke on each restricted schema.

The approach that uses explicit schema-level grant is more convenient for accounts for which access is limited to a few schemas. The approach that uses partial revokes is more convenient for accounts with broad access to all schemas except a few.

Disabling Partial Revokes

Once enabled, `partial_revokes` cannot be disabled if any account has privilege restrictions. If any such account exists, disabling `partial_revokes` fails:

- For attempts to disable `partial_revokes` at startup, the server logs an error message and enables `partial_revokes`.
- For attempts to disable `partial_revokes` at runtime, an error occurs and the `partial_revokes` value remains unchanged.

To disable `partial_revokes` when restrictions exist, the restrictions first must be removed:

1. Determine which accounts have partial revokes:

   ```sql
   SELECT User, Host, User_attributes->>'$.Restrictions'
   FROM mysql.user WHERE User_attributes->>'$.Restrictions' <> '';
   ```

2. For each such account, remove its privilege restrictions. Suppose that the previous step shows account `u1` to have these restrictions:

   ```json
   ["Database": "world", "Privileges": ["INSERT", "DELETE"]
   ```

   Restriction removal can be done various ways:
When Privilege Changes Take Effect

- Grant the privileges globally, without restrictions:
  
  ```sql
  GRANT INSERT, DELETE ON *.* TO u1;
  ```

- Grant the privileges at the schema level:
  
  ```sql
  GRANT INSERT, DELETE ON world.* TO u1;
  ```

- Revoke the privileges globally (assuming that they are no longer needed):
  
  ```sql
  REVOKE INSERT, DELETE ON *.* FROM u1;
  ```

- Remove the account itself (assuming that it is no longer needed):
  
  ```sql
  DROP USER u1;
  ```

After all privilege restrictions are removed, it is possible to disable partial revokes:

```sql
SET PERSIST partial_revokes = OFF;
```

Partial Revokes and Replication

In replication scenarios, if `partial_revokes` is enabled on any host, it must be enabled on all hosts. Otherwise, `REVOKE` statements to partially revoke a global privilege do not have the same effect for all hosts on which replication occurs, potentially resulting in replication inconsistencies or errors.

6.2.13 When Privilege Changes Take Effect

If the `mysqld` server is started without the `--skip-grant-tables` option, it reads all grant table contents into memory during its startup sequence. The in-memory tables become effective for access control at that point.

If you modify the grant tables indirectly using an account-management statement, the server notices these changes and loads the grant tables into memory again immediately. Account-management statements are described in Section 13.7.1, "Account Management Statements". Examples include `GRANT`, `REVOKE`, `SET PASSWORD`, and `RENAME USER`.

If you modify the grant tables directly using statements such as `INSERT`, `UPDATE`, or `DELETE` (which is not recommended), the changes have no effect on privilege checking until you either tell the server to reload the tables or restart it. Thus, if you change the grant tables directly but forget to reload them, the changes have no effect until you restart the server. This may leave you wondering why your changes seem to make no difference!

To tell the server to reload the grant tables, perform a flush-privileges operation. This can be done by issuing a `FLUSH PRIVILEGES` statement or by executing a `mysqladmin flush-privileges` or `mysqladmin reload` command.

A grant table reload affects privileges for each existing client session as follows:

- Table and column privilege changes take effect with the client's next request.
- Database privilege changes take effect the next time the client executes a `USE db_name` statement.

**Note**

Client applications may cache the database name; thus, this effect may not be visible to them without actually changing to a different database.
Assigning Account Passwords

- Global privileges and passwords are unaffected for a connected client. These changes take effect only in sessions for subsequent connections.

Changes to the set of active roles within a session take effect immediately, for that session only. The `SET ROLE` statement performs session role activation and deactivation (see Section 13.7.1.11, “SET ROLE Statement”).

If the server is started with the `--skip-grant-tables` option, it does not read the grant tables or implement any access control. Any user can connect and perform any operation, which is insecure. To cause a server thus started to read the tables and enable access checking, flush the privileges.

6.2.14 Assigning Account Passwords

Required credentials for clients that connect to the MySQL server can include a password. This section describes how to assign passwords for MySQL accounts.

MySQL stores credentials in the `user` table in the `mysql` system database. Operations that assign or modify passwords are permitted only to users with the `CREATE USER` privilege, or, alternatively, privileges for the `mysql` database (INSERT privilege to create new accounts, UPDATE privilege to modify existing accounts). If the `read_only` system variable is enabled, use of account-modification statements such as `CREATE USER` or `ALTER USER` additionally requires the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege).

The discussion here summarizes syntax only for the most common password-assignment statements. For complete details on other possibilities, see Section 13.7.1.3, “CREATE USER Statement”, Section 13.7.1.1, “ALTER USER Statement”, and Section 13.7.1.10, “SET PASSWORD Statement”.

MySQL uses plugins to perform client authentication; see Section 6.2.17, “Pluggable Authentication”. In password-assigning statements, the authentication plugin associated with an account performs any hashing required of a cleartext password specified. This enables MySQL to obfuscate passwords prior to storing them in the `mysql.user` system table. For the statements described here, MySQL automatically hashes the password specified. There are also syntax for `CREATE USER` and `ALTER USER` that permits hashed values to be specified literally. For details, see the descriptions of those statements.

To assign a password when you create a new account, use `CREATE USER` and include an `IDENTIFIED BY` clause:

```sql
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
```

`CREATE USER` also supports syntax for specifying the account authentication plugin. See Section 13.7.1.3, “CREATE USER Statement”.

To assign or change a password for an existing account, use the `ALTER USER` statement with an `IDENTIFIED BY` clause:

```sql
ALTER USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
```

If you are not connected as an anonymous user, you can change your own password without naming your own account literally:

```sql
ALTER USER USER() IDENTIFIED BY 'password';
```

To change an account password from the command line, use the `mysqladmin` command:

```bash
mysqladmin -u user_name -h host_name password "password"
```

The account for which this command sets the password is the one with a row in the `mysql.user` system table that matches `user_name` in the `User` column and the client host `from which you connect` in the `Host` column.
Warning

Setting a password using `mysqladmin` should be considered *insecure*. On some systems, your password becomes visible to system status programs such as `ps` that may be invoked by other users to display command lines. MySQL clients typically overwrite the command-line password argument with zeros during their initialization sequence. However, there is still a brief interval during which the value is visible. Also, on some systems this overwriting strategy is ineffective and the password remains visible to `ps`. (SystemV Unix systems and perhaps others are subject to this problem.)

If you are using MySQL Replication, be aware that, currently, a password used by a replica as part of a `CHANGE MASTER TO` statement is effectively limited to 32 characters in length; if the password is longer, any excess characters are truncated. This is not due to any limit imposed by MySQL Server generally, but rather is an issue specific to MySQL Replication. (For more information, see Bug #43439.)

6.2.15 Password Management

MySQL supports these password-management capabilities:

- Password expiration, to require passwords to be changed periodically.
- Password reuse restrictions, to prevent old passwords from being chosen again.
- Password verification, to require that password changes also specify the current password to be replaced.
- Dual passwords, to enable clients to connect using either a primary or secondary password.
- Password strength assessment, to require strong passwords.
- Random password generation, as an alternative to requiring explicit administrator-specified literal passwords.
- Password failure tracking, to enable temporary account locking after too many consecutive incorrect-password login failures.

The following sections describe these capabilities, except password strength assessment, which is implemented using the `validate_password` component and is described in Section 6.4.3, “The Password Validation Component”.

- Internal Versus External Credentials Storage
- Password Expiration Policy
- Password Reuse Policy
- Password Verification-Required Policy
- Dual Password Support
- Random Password Generation
- Failed-Login Tracking and Temporary Account Locking

Important

MySQL implements password-management capabilities using tables in the `mysql` system database. If you upgrade MySQL from an earlier version, your system
Password Management

The tables might not be up to date. In that case, the server writes messages similar to these to the error log during the startup process (the exact numbers may vary):

```
[ERROR] Column count of mysql.user is wrong. Expected 49, found 47. The table is probably corrupted
[Warning] ACL table mysql.password_history missing. Some operations may fail.
```

To correct the issue, perform the MySQL upgrade procedure. See Section 2.11, “Upgrading MySQL”. Until this is done, password changes are not possible.

**Internal Versus External Credentials Storage**

Some authentication plugins store account credentials internally to MySQL, in the `mysql.user` system table:

- `mysql_native_password`
- `caching_sha2_password`
- `sha256_password`

Most discussion in this section applies to such authentication plugins because most password-management capabilities described here are based on internal credentials storage handled by MySQL itself. Other authentication plugins store account credentials externally to MySQL. For accounts that use plugins that perform authentication against an external credentials system, password management must be handled externally against that system as well.

The exception is that the options for failed-login tracking and temporary account locking apply to all accounts, not just accounts that use internal credentials storage, because MySQL is able to assess the status of login attempts for any account no matter whether it uses internal or external credentials storage.

For information about individual authentication plugins, see Section 6.4.1, “Authentication Plugins”.

**Password Expiration Policy**

MySQL enables database administrators to expire account passwords manually, and to establish a policy for automatic password expiration. Expiration policy can be established globally, and individual accounts can be set to either defer to the global policy or override the global policy with specific per-account behavior.

To expire an account password manually, use the `ALTER USER` statement:

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE;
```

This operation marks the password expired in the corresponding row in the `mysql.user` system table.

Password expiration according to policy is automatic and is based on password age, which for a given account is assessed from the date and time of its most recent password change. The `mysql.user` system table indicates for each account when its password was last changed, and the server automatically treats the password as expired at client connection time if its age is greater than its permitted lifetime. This works with no explicit manual password expiration.

To establish automatic password-expiration policy globally, use the `default_password_lifetime` system variable. Its default value is 0, which disables automatic password expiration. If the value of `default_password_lifetime` is a positive integer $N$, it indicates the permitted password lifetime, such that passwords must be changed every $N$ days.
Examples:

• To establish a global policy that passwords have a lifetime of approximately six months, start the server with these lines in a server my.cnf file:

```sql
[mysqld]
default_password_lifetime=180
```

• To establish a global policy such that passwords never expire, set `default_password_lifetime` to 0:

```sql
[mysqld]
default_password_lifetime=0
```

• `default_password_lifetime` can also be set and persisted at runtime:

```sql
SET PERSIST default_password_lifetime = 180;
SET PERSIST default_password_lifetime = 0;
```

`SET PERSIST` sets the value for the running MySQL instance. It also saves the value to carry over to subsequent server restarts; see Section 13.7.6.1, “SET Syntax for Variable Assignment”. To change the value for the running MySQL instance without having it carry over to subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`.

The global password-expiration policy applies to all accounts that have not been set to override it. To establish policy for individual accounts, use the `PASSWORD EXPIRE` option of the `CREATE USER` and `ALTER USER` statements. See Section 13.7.1.3, “CREATE USER Statement”, and Section 13.7.1.1, “ALTER USER Statement”.

Example account-specific statements:

• Require the password to be changed every 90 days:

```sql
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 90 DAY;
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 90 DAY;
```

This expiration option overrides the global policy for all accounts named by the statement.

• Disable password expiration:

```sql
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
```

This expiration option overrides the global policy for all accounts named by the statement.

• Defer to the global expiration policy for all accounts named by the statement:

```sql
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
```

When a client successfully connects, the server determines whether the account password has expired:

• The server checks whether the password has been manually expired.

• Otherwise, the server checks whether the password age is greater than its permitted lifetime according to the automatic password expiration policy. If so, the server considers the password expired.

If the password is expired (whether manually or automatically), the server either disconnects the client or restricts the operations permitted to it (see Section 6.2.16, “Server Handling of Expired Passwords”). Operations performed by a restricted client result in an error until the user establishes a new account password:
After the client resets the password, the server restores normal access for the session, as well as for subsequent connections that use the account. It is also possible for an administrative user to reset the account password, but any existing restricted sessions for that account remain restricted. A client using the account must disconnect and reconnect before statements can be executed successfully.

**Note**

Although it is possible to “reset” an expired password by setting it to its current value, it is preferable, as a matter of good policy, to choose a different password. DBAs can enforce non-reuse by establishing an appropriate password-reuse policy. See [Password Reuse Policy](#).

### Password Reuse Policy

MySQL enables restrictions to be placed on reuse of previous passwords. Reuse restrictions can be established based on number of password changes, time elapsed, or both. Reuse policy can be established globally, and individual accounts can be set to either defer to the global policy or override the global policy with specific per-account behavior.

The password history for an account consists of passwords it has been assigned in the past. MySQL can restrict new passwords from being chosen from this history:

- If an account is restricted on the basis of number of password changes, a new password cannot be chosen from a specified number of the most recent passwords. For example, if the minimum number of password changes is set to 3, a new password cannot be the same as any of the most recent 3 passwords.

- If an account is restricted based on time elapsed, a new password cannot be chosen from passwords in the history that are newer than a specified number of days. For example, if the password reuse interval is set to 60, a new password must not be among those previously chosen within the last 60 days.

**Note**

The empty password does not count in the password history and is subject to reuse at any time.

To establish password-reuse policy globally, use the `password_history` and `password_reuse_interval` system variables.

Examples:

- To prohibit reusing any of the last 6 passwords or passwords newer than 365 days, put these lines in the server `my.cnf` file:
Password Management

```sql
[mysql]
password_history=6
password_reuse_interval=365
```

- To set and persist the variables at runtime, use statements like this:

```sql
SET PERSIST password_history = 6;
SET PERSIST password_reuse_interval = 365;
```

`SET PERSIST` sets the value for the running MySQL instance. It also saves the value to carry over to subsequent server restarts; see Section 13.7.6.1, “SET Syntax for Variable Assignment”. To change the value for the running MySQL instance without having it carry over to subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`.

The global password-reuse policy applies to all accounts that have not been set to override it. To establish policy for individual accounts, use the `PASSWORD HISTORY` and `PASSWORD REUSE INTERVAL` options of the `CREATE USER` and `ALTER USER` statements. See Section 13.7.1.3, “CREATE USER Statement”, and Section 13.7.1.1, “ALTER USER Statement”.

Example account-specific statements:

- Require a minimum of 5 password changes before permitting reuse:

  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD HISTORY 5;
  ALTER USER 'jeffrey'@'localhost' PASSWORD HISTORY 5;
  ```

  This history-length option overrides the global policy for all accounts named by the statement.

- Require a minimum of 365 days elapsed before permitting reuse:

  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL 365 DAY;
  ALTER USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL 365 DAY;
  ```

  This time-elapsed option overrides the global policy for all accounts named by the statement.

- To combine both types of reuse restrictions, use `PASSWORD HISTORY` and `PASSWORD REUSE INTERVAL` together:

  ```sql
  CREATE USER 'jeffrey'@'localhost'
  PASSWORD HISTORY 5
  PASSWORD REUSE INTERVAL 365 DAY;
  ALTER USER 'jeffrey'@'localhost'
  PASSWORD HISTORY 5
  PASSWORD REUSE INTERVAL 365 DAY;
  ```

  These options override both global policy reuse restrictions for all accounts named by the statement.

- Defer to the global policy for both types of reuse restrictions:

  ```sql
  CREATE USER 'jeffrey'@'localhost'
  PASSWORD HISTORY DEFAULT
  PASSWORD REUSE INTERVAL DEFAULT;
  ALTER USER 'jeffrey'@'localhost'
  PASSWORD HISTORY DEFAULT
  PASSWORD REUSE INTERVAL DEFAULT;
  ```

Password Verification-Required Policy

As of MySQL 8.0.13, it is possible to require that attempts to change an account password be verified by specifying the current password to be replaced. This enables DBAs to prevent users from changing
a password without proving that they know the current password. Such changes could otherwise occur, for example, if one user walks away from a terminal session temporarily without logging out, and a malicious user uses the session to change the original user's MySQL password. This can have unfortunate consequences:

- The original user becomes unable to access MySQL until the account password is reset by an administrator.
- Until the password reset occurs, the malicious user can access MySQL with the benign user's changed credentials.

Password-verification policy can be established globally, and individual accounts can be set to either defer to the global policy or override the global policy with specific per-account behavior.

For each account, its `mysql.user` row indicates whether there is an account-specific setting requiring verification of the current password for password change attempts. The setting is established by the `PASSWORD REQUIRE` option of the `CREATE USER` and `ALTER USER` statements:

- If the account setting is `PASSWORD REQUIRE CURRENT`, password changes must specify the current password.
- If the account setting is `PASSWORD REQUIRE CURRENT OPTIONAL`, password changes may but need not specify the current password.
- If the account setting is `PASSWORD REQUIRE CURRENT DEFAULT`, the `password_require_current` system variable determines the verification-required policy for the account:
  - If `password_require_current` is enabled, password changes must specify the current password.
  - If `password_require_current` is disabled, password changes may but need not specify the current password.

In other words, if the account setting is not `PASSWORD REQUIRE CURRENT DEFAULT`, the account setting takes precedence over the global policy established by the `password_require_current` system variable. Otherwise, the account defers to the `password_require_current` setting.

By default, password verification is optional: `password_require_current` is disabled and accounts created with no `PASSWORD REQUIRE` option default to `PASSWORD REQUIRE CURRENT DEFAULT`.

The following table shows how per-account settings interact with `password_require_current` system variable values to determine account password verification-required policy.

Note

Privileged users can change any account password without specifying the current password, regardless of the verification-required policy. A privileged user is one who has the global CREATE_USER privilege or the UPDATE privilege for the mysql system database.

To establish password-verification policy globally, use the password_require_current system variable. Its default value is OFF, so it is not required that account password changes specify the current password.

Examples:

- To establish a global policy that password changes must specify the current password, start the server with these lines in a server my.cnf file:

  ```
  [mysqld]
  password_require_current=ON
  ```

- To set and persist password_require_current at runtime, use a statement such as one of these:

  ```
  SET PERSIST password_require_current = ON;
  SET PERSIST password_require_current = OFF;
  ```

  SET PERSIST sets the value for the running MySQL instance. It also saves the value to carry over to subsequent server restarts; see Section 13.7.6.1, “SET Syntax for Variable Assignment”. To change the value for the running MySQL instance without having it carry over to subsequent restarts, use the GLOBAL keyword rather than PERSIST.

The global password verification-required policy applies to all accounts that have not been set to override it. To establish policy for individual accounts, use the PASSWORD_REQUIRE options of the CREATE_USER and ALTER_USER statements. See Section 13.7.1.3, “CREATE USER Statement”, and Section 13.7.1.1, “ALTER USER Statement”.

Example account-specific statements:

- Require that password changes specify the current password:

  ```
  CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT;
  ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT;
  ```

  This verification option overrides the global policy for all accounts named by the statement.

- Do not require that password changes specify the current password (the current password may but need not be given):

  ```
  CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT OPTIONAL;
  ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT OPTIONAL;
  ```

  This verification option overrides the global policy for all accounts named by the statement.

- Defer to the global password verification-required policy for all accounts named by the statement:

  ```
  CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT DEFAULT;
  ```
ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT DEFAULT;

Verification of the current password comes into play when a user changes a password using the \texttt{ALTER USER} or \texttt{SET PASSWORD} statement. The examples use \texttt{ALTER USER}, which is preferred over \texttt{SET PASSWORD}, but the principles described here are the same for both statements.

In password-change statements, a \texttt{REPLACE} clause specifies the current password to be replaced. Examples:

- Change the current user's password:
  \begin{verbatim}
  ALTER USER USER() IDENTIFIED BY 'auth_string' REPLACE 'current_auth_string';
  \end{verbatim}

- Change a named user's password:
  \begin{verbatim}
  ALTER USER 'jeffrey'@'localhost' IDENTIFIED BY 'auth_string' REPLACE 'current_auth_string';
  \end{verbatim}

- Change a named user's authentication plugin and password:
  \begin{verbatim}
  ALTER USER 'jeffrey'@'localhost' IDENTIFIED WITH caching_sha2_password BY 'auth_string' REPLACE 'current_auth_string';
  \end{verbatim}

The \texttt{REPLACE} clause works like this:

- \texttt{REPLACE} must be given if password changes for the account are required to specify the current password, as verification that the user attempting to make the change actually knows the current password.

- \texttt{REPLACE} is optional if password changes for the account may but need not specify the current password.

- If \texttt{REPLACE} is specified, it must specify the correct current password, or an error occurs. This is true even if \texttt{REPLACE} is optional.

- \texttt{REPLACE} can be specified only when changing the account password for the current user. (This means that in the examples just shown, the statements that explicitly name the account for \texttt{jeffrey} fail unless the current user is \texttt{jeffrey}.) This is true even if the change is attempted for another user by a privileged user; however, such a user can change any password without specifying \texttt{REPLACE}.

- \texttt{REPLACE} is omitted from the binary log to avoid writing cleartext passwords to it.

\section*{Dual Password Support}

As of MySQL 8.0.14, user accounts are permitted to have dual passwords, designated as primary and secondary passwords. Dual-password capability makes it possible to seamlessly perform credential changes in scenarios like this:

- A system has a large number of MySQL servers, possibly involving replication.

- Multiple applications connect to different MySQL servers.

- Periodic credential changes must be made to the account or accounts used by the applications to connect to the servers.

Consider how a credential change must be performed in the preceding type of scenario when an account is permitted only a single password. In this case, there must be close cooperation in the timing of when the
account password change is made and propagated throughout all servers, and when all applications that use the account are updated to use the new password. This process may involve downtime during which servers or applications are unavailable.

With dual passwords, credential changes can be made more easily, in phases, without requiring close cooperation, and without downtime:

1. For each affected account, establish a new primary password on the servers, retaining the current password as the secondary password. This enables servers to recognize either the primary or secondary password for each account, while applications can continue to connect to the servers using the same password as previously (which is now the secondary password).

2. After the password change has propagated to all servers, modify applications that use any affected account to connect using the account primary password.

3. After all applications have been migrated from the secondary passwords to the primary passwords, the secondary passwords are no longer needed and can be discarded. After this change has propagated to all servers, only the primary password for each account can be used to connect. The credential change is now complete.

MySQL implements dual-password capability with syntax that saves and discards secondary passwords:

- The `RETAIN CURRENT PASSWORD` clause for the `ALTER USER` and `SET PASSWORD` statements saves an account current password as its secondary password when you assign a new primary password.

- The `DISCARD OLD PASSWORD` clause for `ALTER USER` discards an account secondary password, leaving only the primary password.

Suppose that, for the previously described credential-change scenario, an account named 'appuser1'@'host1.example.com' is used by applications to connect to servers, and that the account password is to be changed from 'password_a' to 'password_b'.

To perform this change of credentials, use `ALTER USER` as follows:

1. On each server that is not a replica, establish 'password_b' as the new appuser1 primary password, retaining the current password as the secondary password:

   ```sql
   ALTER USER 'appuser1'@'host1.example.com'
   IDENTIFIED BY 'password_b'
   RETAIN CURRENT PASSWORD;
   ```

2. Wait for the password change to replicate throughout the system to all replicas.

3. Modify each application that uses the appuser1 account so that it connects to the servers using a password of 'password_b' rather than 'password_a'.

4. At this point, the secondary password is no longer needed. On each server that is not a replica, discard the secondary password:

   ```sql
   ALTER USER 'appuser1'@'host1.example.com'
   DISCARD OLD PASSWORD;
   ```

5. After the discard-password change has replicated to all replicas, the credential change is complete.

The `RETAIN CURRENT PASSWORD` and `DISCARD OLD PASSWORD` clauses have the following effects:

- `RETAIN CURRENT PASSWORD` retains an account current password as its secondary password, replacing any existing secondary password. The new password becomes the primary password, but clients can use the account to connect to the server using either the primary or secondary password.
Password Management

(Exception: If the new password specified by the ALTER USER or SET PASSWORD statement is empty, the secondary password becomes empty as well, even if RETAIN CURRENT PASSWORD is given.)

• If you specify RETAIN CURRENT PASSWORD for an account that has an empty primary password, the statement fails.

• If an account has a secondary password and you change its primary password without specifying RETAIN CURRENT PASSWORD, the secondary password remains unchanged.

• For ALTER USER, if you change the authentication plugin assigned to the account, the secondary password is discarded. If you change the authentication plugin and also specify RETAIN CURRENT PASSWORD, the statement fails.

• For ALTER USER, DISCARD OLD PASSWORD discards the secondary password, if one exists. The account retains only its primary password, and clients can use the account to connect to the server only with the primary password.

Statements that modify secondary passwords require these privileges:

• The APPLICATION_PASSWORD_ADMIN privilege is required to use the RETAIN CURRENT PASSWORD or DISCARD OLD PASSWORD clause for ALTER USER and SET PASSWORD statements that apply to your own account. The privilege is required to manipulate your own secondary password because most users require only one password.

• If an account is to be permitted to manipulate secondary passwords for all accounts, it should be granted the CREATE USER privilege rather than APPLICATION_PASSWORD_ADMIN.

Random Password Generation

As of MySQL 8.0.18, the CREATE USER, ALTER USER, and SET PASSWORD statements have the capability of generating random passwords for user accounts, as an alternative to requiring explicit administrator-specified literal passwords. See the description of each statement for details about the syntax. This section describes the characteristics common to generated random passwords.

By default, generated random passwords have a length of 20 characters. This length is controlled by the generated_random_password_length system variable, which has a range from 5 to 255.

For each account for which a statement generates a random password, the statement stores the password in the mysql.user system table, hashed appropriately for the account authentication plugin. The statement also returns the cleartext password in a row of a result set to make it available to the user or application executing the statement. The result set columns are named user, host, and generated password, indicating the user name and host name values that identify the affected row in the mysql.user system table, and the cleartext generated password.

```
mysql> CREATE USER
    +---------------------+--------------+----------------------+
    | user | host          | generated password   |
    +---------------------+--------------+----------------------+
    | u1 | localhost     | BA;42VpXqQ@i+y{TDFF |
    | u2 | %.example.com | YX5>XRAJRF@sn9azmD4  |
    | u3 | %.org         | ;GfD44l;)C}PI/6)TwZ  |
    +---------------------+--------------+----------------------+
mysql> ALTER USER
    +---------------------+--------------+----------------------+
    | user | host          | generated password   |
    +---------------------+--------------+----------------------+
    | u1 | localhost     | BA;42VpXqQ@i+y{TDFF |
    | u2 | %.example.com | YX5>XRAJRF@sn9azmD4  |
    | u3 | %.org         | ;GfD44l;)C}PI/6)TwZ  |
    +---------------------+--------------+----------------------+
```
Password Management

A CREATE USER, ALTER USER, or SET PASSWORD statement that generates a random password for an account is written to the binary log as a CREATE USER or ALTER USER statement with an IDENTIFIED WITH auth_plugin AS 'auth_string', clause, where auth_plugin is the account authentication plugin and 'auth_string' is the account hashed password value.

If the validate_password component is installed, the policy that it implements has no effect on generated passwords. (The purpose of password validation is to help humans create better passwords.)

Failed-Login Tracking and Temporary Account Locking

As of MySQL 8.0.19, administrators can configure user accounts such that too many consecutive login failures cause temporary account locking.

“Login failure” in this context means failure of the client to provide a correct password during a connection attempt. It does not include failure to connect for reasons such as unknown user or network issues. For accounts that have dual passwords (see Dual Password Support), either account password counts as correct.

The required number of login failures and the lock time are configurable per account, using the FAILED_LOGIN_ATTEMPTS and PASSWORD_LOCK_TIME options of the CREATE USER and ALTER USER statements. Examples:

CREATE USER 'u1'@'localhost' IDENTIFIED BY 'password'
    FAILED_LOGIN_ATTEMPTS 3 PASSWORD_LOCK_TIME 3;

ALTER USER 'u2'@'localhost'
    FAILED_LOGIN_ATTEMPTS 4 PASSWORD_LOCK_TIME UNBOUNDED;

When too many consecutive login failures occur, the client receives an error that looks like this:

```
ERROR 3957 (HY000): Access denied for user user.
Account is blocked for D day(s) (R day(s) remaining) due to N consecutive failed logins.
```

Use the options as follows:

- **FAILED_LOGIN_ATTEMPTS N**
  
  This option indicates whether to track account login attempts that specify an incorrect password. The number N specifies how many consecutive incorrect passwords cause temporary account locking.

- **PASSWORD_LOCK_TIME (N | UNBOUNDED)**
  
  This option indicates how long to lock the account after too many consecutive login attempts provide an incorrect password. The value is a number N to specify the number of days the account remains locked, or UNBOUNDED to specify that when an account enters the temporarily locked state, the duration of that state is unbounded and does not end until the account is unlocked. The conditions under which unlocking occurs are described later.

  Permitted values of N for each option are in the range from 0 to 32767. A value of 0 disables the option.
Failed-login tracking and temporary account locking have these characteristics:

- For failed-login tracking and temporary locking to occur for an account, its `FAILED_LOGIN_ATTEMPTS` and `PASSWORD_LOCK_TIME` options both must be nonzero.

- For `CREATE USER`, if `FAILED_LOGIN_ATTEMPTS` or `PASSWORD_LOCK_TIME` is not specified, its implicit default value is 0 for all accounts named by the statement. This means that failed-login tracking and temporary account locking are disabled. (These implicit defaults also apply to accounts created prior to the introduction of failed-login tracking.)

- For `ALTER USER`, if `FAILED_LOGIN_ATTEMPTS` or `PASSWORD_LOCK_TIME` is not specified, its value remains unchanged for all accounts named by the statement.

- For temporary account locking to occur, password failures must be consecutive. Any successful login that occurs prior to reaching the `FAILED_LOGIN_ATTEMPTS` value for failed logins causes failure counting to reset. For example, if `FAILED_LOGIN_ATTEMPTS` is 4 and three consecutive password failures have occurred, one more failure is necessary for locking to begin. But if the next login succeeds, failed-login counting for the account is reset so that four consecutive failures are again required for locking.

- Once temporary locking begins, successful login cannot occur even with the correct password until either the lock duration has passed or the account is unlocked by one of the account-reset methods listed in the following discussion.

When the server reads the grant tables, it initializes state information for each account regarding whether failed-login tracking is enabled, whether the account is currently temporarily locked and when locking began if so, and the number of failures before temporary locking occurs if the account is not locked.

An account’s state information can be reset, which means that failed-login counting is reset, and the account is unlocked if currently temporarily locked. Account resets can be global for all accounts or per account:

- A global reset of all accounts occurs for any of these conditions:
  - A server restart.
  - Execution of `FLUSH PRIVILEGES`. (Starting the server with `--skip-grant-tables` causes the grant tables not to be read, which disables failed-login tracking. In this case, the first execution of `FLUSH PRIVILEGES` causes the server to read the grant tables and enable failed-login tracking, in addition to resetting all accounts.)

- A per-account reset occurs for any of these conditions:
  - Successful login for the account.
  - The lock duration passes. In this case, failed-login counting resets at the time of the next login attempt.
  - Execution of an `ALTER USER` statement for the account that sets either `FAILED_LOGIN_ATTEMPTS` or `PASSWORD_LOCK_TIME` (or both) to any value (including the current option value), or execution of an `ALTER USER ... UNLOCK` statement for the account.

Other `ALTER USER` statements for the account have no effect on its current failed-login count or its locking state.

Failed-login tracking is tied to the login account that is used to check credentials. If user proxying is in use, tracking occurs for the proxy user, not the proxied user. That is, tracking is tied to the account indicated by `USER()`, not the account indicated by `CURRENT_USER()`. For information about the distinction between proxy and proxied users, see Section 6.2.18, “Proxy Users”. 
6.2.16 Server Handling of Expired Passwords

MySQL provides password-expiration capability, which enables database administrators to require that users reset their password. Passwords can be expired manually, and on the basis of a policy for automatic expiration (see Section 6.2.15, “Password Management”).

The `ALTER USER` statement enables account password expiration. For example:

```
ALTER USER 'myuser'@'localhost' PASSWORD EXPIRE;
```

For each connection that uses an account with an expired password, the server either disconnects the client or restricts the client to “sandbox mode,” in which the server permits the client to perform only those operations necessary to reset the expired password. Which action is taken by the server depends on both client and server settings, as discussed later.

If the server disconnects the client, it returns an `ER_MUST_CHANGE_PASSWORD_LOGIN` error:

```
shell> mysql -u myuser -p
Password: ******
ERROR 1862 (HY000): Your password has expired. To log in you must change it using a client that supports expired passwords.
```

If the server restricts the client to sandbox mode, these operations are permitted within the client session:

- The client can reset the account password with `ALTER USER` or `SET PASSWORD`. After that has been done, the server restores normal access for the session, as well as for subsequent connections that use the account.

  **Note**

  Although it is possible to “reset” an expired password by setting it to its current value, it is preferable, as a matter of good policy, to choose a different password. DBAs can enforce non-reuse by establishing an appropriate password-reuse policy. See Password Reuse Policy.

- The client can use the `SET` statement.

For any operation not permitted within the session, the server returns an `ER_MUST_CHANGE_PASSWORD` error:

```
mysql> USE performance_schema;
ERROR 1820 (HY000): You must reset your password using ALTER USER statement before executing this statement.

mysql> SELECT 1;
ERROR 1820 (HY000): You must reset your password using ALTER USER statement before executing this statement.
```

That is what normally happens for interactive invocations of the `mysql` client because by default such invocations are put in sandbox mode. To resume normal functioning, select a new password.

For noninteractive invocations of the `mysql` client (for example, in batch mode), the server normally disconnects the client if the password is expired. To permit noninteractive `mysql` invocations to stay connected so that the password can be changed (using the statements permitted in sandbox mode), add the `--connect-expired-password` option to the `mysql` command.

As mentioned previously, whether the server disconnects an expired-password client or restricts it to sandbox mode depends on a combination of client and server settings. The following discussion describes the relevant settings and how they interact.
Note
This discussion applies only for accounts with expired passwords. If a client connects using a nonexpired password, the server handles the client normally.

On the client side, a given client indicates whether it can handle sandbox mode for expired passwords. For clients that use the C client library, there are two ways to do this:

- Pass the `MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS` flag to `mysql_options()` prior to connecting:

  ```
  bool arg = 1;
  mysql_options(mysql,
                 MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS,
                 &arg);
  ```

  This is the technique used within the `mysql` client, which enables `MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS` if invoked interactively or with the `--connect-expired-password` option.

- Pass the `CLIENT_CAN_HANDLE_EXPIRED_PASSWORDS` flag to `mysql_real_connect()` at connect time:

  ```
  MYSQL mysql;
  mysql_init(&mysql);
  if (!mysql_real_connect(&mysql,
                          host, user, password, db,
                          port, unix_socket,
                          CLIENT_CAN_HANDLE_EXPIRED_PASSWORDS))
    {
    ... handle error ...
  }
  ```

Other MySQL Connectors have their own conventions for indicating readiness to handle sandbox mode. See the documentation for the Connector in which you are interested.

On the server side, if a client indicates that it can handle expired passwords, the server puts it in sandbox mode.

If a client does not indicate that it can handle expired passwords (or uses an older version of the client library that cannot so indicate), the server action depends on the value of the `disconnect_on_expired_password` system variable:

- If `disconnect_on_expired_password` is enabled (the default), the server disconnects the client with an `ER_MUST_CHANGE_PASSWORD_LOGIN` error.

- If `disconnect_on_expired_password` is disabled, the server puts the client in sandbox mode.

### 6.2.17 Pluggable Authentication

When a client connects to the MySQL server, the server uses the user name provided by the client and the client host to select the appropriate account row from the `mysql.user` system table. The server then authenticates the client, determining from the account row which authentication plugin applies to the client:

- If the server cannot find the plugin, an error occurs and the connection attempt is rejected.

- Otherwise, the server invokes that plugin to authenticate the user, and the plugin returns a status to the server indicating whether the user provided the correct password and is permitted to connect.

Pluggable authentication enables these important capabilities:
Pluggable Authentication

- **Choice of authentication methods.** Pluggable authentication makes it easy for DBAs to choose and change the authentication method used for individual MySQL accounts.

- **External authentication.** Pluggable authentication makes it possible for clients to connect to the MySQL server with credentials appropriate for authentication methods that store credentials elsewhere than in the `mysql.user` system table. For example, plugins can be created to use external authentication methods such as PAM, Windows login IDs, LDAP, or Kerberos.

- **Proxy users:** If a user is permitted to connect, an authentication plugin can return to the server a user name different from the name of the connecting user, to indicate that the connecting user is a proxy for another user (the proxied user). While the connection lasts, the proxy user is treated, for purposes of access control, as having the privileges of the proxied user. In effect, one user impersonates another. For more information, see Section 6.2.18, “Proxy Users”.

**Note**

If you start the server with the `--skip-grant-tables` option, authentication plugins are not used even if loaded because the server performs no client authentication and permits any client to connect. Because this is insecure, if the server is started with the `--skip-grant-tables` option, it also disables remote connections by enabling `skip_networking`.

- **Available Authentication Plugins**
- **Authentication Plugin Usage**
- **Authentication Plugin Client/Server Compatibility**
- **Authentication Plugin Connector-Writing Considerations**
- **Restrictions on Pluggable Authentication**

**Available Authentication Plugins**

MySQL 8.0 provides these authentication plugins:

- A plugin that performs native authentication; that is, authentication based on the password hashing method in use from before the introduction of pluggable authentication in MySQL. The `mysql_native_password` plugin implements authentication based on this native password hashing method. See Section 6.4.1.1, “Native Pluggable Authentication”.

- Plugins that perform authentication using SHA-256 password hashing. This is stronger encryption than that available with native authentication. See Section 6.4.1.3, “SHA-256 Pluggable Authentication”, and Section 6.4.1.2, “Caching SHA-2 Pluggable Authentication”.

- A client-side plugin that sends the password to the server without hashing or encryption. This plugin is used in conjunction with server-side plugins that require access to the password exactly as provided by the client user. See Section 6.4.1.4, “Client-Side Cleartext Pluggable Authentication”.

- A plugin that performs external authentication using PAM (Pluggable Authentication Modules), enabling MySQL Server to use PAM to authenticate MySQL users. This plugin supports proxy users as well. See Section 6.4.1.5, “PAM Pluggable Authentication”.

- A plugin that performs external authentication on Windows, enabling MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password. This plugin supports proxy users as well. See Section 6.4.1.6, “Windows Pluggable Authentication”.

1211
Pluggable Authentication

- Plugins that perform authentication using LDAP (Lightweight Directory Access Protocol) to authenticate MySQL users by accessing directory services such as X.500. These plugins support proxy users as well. See Section 6.4.1.7, “LDAP Pluggable Authentication”.

- A plugin that prevents all client connections to any account that uses it. Use cases for this plugin include proxied accounts that should never permit direct login but are accessed only through proxy accounts and accounts that must be able to execute stored programs and views with elevated privileges without exposing those privileges to ordinary users. See Section 6.4.1.8, “No-Login Pluggable Authentication”.

- A plugin that authenticates clients that connect from the local host through the Unix socket file. See Section 6.4.1.9, “Socket Peer-Credential Pluggable Authentication”.

- A test plugin that checks account credentials and logs success or failure to the server error log. This plugin is intended for testing and development purposes, and as an example of how to write an authentication plugin. See Section 6.4.1.10, “Test Pluggable Authentication”.

Note

For information about current restrictions on the use of pluggable authentication, including which connectors support which plugins, see Restrictions on Pluggable Authentication.

Third-party connector developers should read that section to determine the extent to which a connector can take advantage of pluggable authentication capabilities and what steps to take to become more compliant.

If you are interested in writing your own authentication plugins, see Writing Authentication Plugins.

Authentication Plugin Usage

This section provides general instructions for installing and using authentication plugins. For instructions specific to a given plugin, see the section that describes that plugin under Section 6.4.1, “Authentication Plugins”.

In general, pluggable authentication uses a pair of corresponding plugins on the server and client sides, so you use a given authentication method like this:

- If necessary, install the plugin library or libraries containing the appropriate plugins. On the server host, install the library containing the server-side plugin, so that the server can use it to authenticate client connections. Similarly, on each client host, install the library containing the client-side plugin for use by client programs. Authentication plugins that are built in need not be installed.

- For each MySQL account that you create, specify the appropriate server-side plugin to use for authentication. If the account is to use the default authentication plugin, the account-creation statement need not specify the plugin explicitly. The default_authentication_plugin system variable configures the default authentication plugin.

- When a client connects, the server-side plugin tells the client program which client-side plugin to use for authentication.

In the case that an account uses an authentication method that is the default for both the server and the client program, the server need not communicate to the client which client-side plugin to use, and a round trip in client/server negotiation can be avoided.

For standard MySQL clients such as mysql and mysqladmin, the --default-auth=plugin_name option can be specified on the command line as a hint about which client-side plugin the program can expect to use, although the server overrides this if the server-side plugin associated with the user account requires a different client-side plugin.
If the client program does not find the client-side plugin library file, specify a `--plugin-dir=dir_name` option to indicate the plugin library directory location.

**Authentication Plugin Client/Server Compatibility**

Pluggable authentication enables flexibility in the choice of authentication methods for MySQL accounts, but in some cases client connections cannot be established due to authentication plugin incompatibility between the client and server.

The general compatibility principle for a successful client connection to a given account on a given server is that the client and server both must support the authentication method required by the account. Because authentication methods are implemented by authentication plugins, the client and server both must support the authentication plugin required by the account.

Authentication plugin incompatibilities can arise in various ways. Examples:

- Connect using a MySQL 5.7 client from 5.7.22 or lower to a MySQL 8.0 server account that authenticates with `caching_sha2_password`. This fails because the 5.7 client does not recognize the plugin, which was introduced in MySQL 8.0. (This issue is addressed in MySQL 5.7 as of 5.7.23, when `caching_sha2_password` client-side support was added to the MySQL client library and client programs.)

- Connect using a MySQL 5.5 client to a MySQL 5.6 server account that authenticates with `sha256_password`. This fails because the 5.5 client does not recognize the plugin, which was introduced in MySQL 5.6.

- Connect using a MySQL 5.7 client to a pre-5.7 server account that authenticates with `mysql_old_password`. This fails for multiple reasons. First, such a connection requires `--secure-auth=0`, which is no longer a supported option. Even were it supported, the 5.7 client does not recognize the plugin because it was removed in MySQL 5.7.

- Connect using a MySQL 5.7 client from a Community distribution to a MySQL 5.7 Enterprise server account that authenticates using one of the Enterprise-only LDAP authentication plugins. This fails because the Community client does not have access to the Enterprise plugin.

In general, these compatibility issues do not arise when connections are made between a client and server from the same MySQL distribution. When connections are made between a client and server from different MySQL series, issues can arise. These issues are inherent in the development process when MySQL introduces new authentication plugins or removes old ones. To minimize the potential for incompatibilities, regularly upgrade the server, clients, and connectors on a timely basis.

**Authentication Plugin Connector-Writing Considerations**

Various implementations of the MySQL client/server protocol exist. The `libmysqlclient` C API client library is one implementation. Some MySQL connectors (typically those not written in C) provide their own implementation. However, not all protocol implementations handle plugin authentication the same way. This section describes an authentication issue that protocol implementors should take into account.

In the client/server protocol, the server tells connecting clients which authentication plugin it considers the default. If the protocol implementation used by the client tries to load the default plugin and that plugin does not exist on the client side, the load operation fails. This is an unnecessary failure if the default plugin is not the plugin actually required by the account to which the client is trying to connect.

If a client/server protocol implementation does not have its own notion of default authentication plugin and always tries to load the default plugin specified by the server, it fails with an error if that plugin is not available.
Pluggable Authentication

To avoid this problem, the protocol implementation used by the client should have its own default plugin and should use it as its first choice (or, alternatively, fall back to this default in case of failure to load the default plugin specified by the server). Example:

- In MySQL 5.7, libmysqlclient uses as its default choice either mysql_native_password or the plugin specified through the MYSQL_DEFAULT_AUTH option for mysql_options().

- When a 5.7 client tries to connect to an 8.0 server, the server specifies caching_sha2_password as its default authentication plugin, but the client still sends credential details per either mysql_native_password or whatever is specified through MYSQL_DEFAULT_AUTH.

- The only time the client loads the plugin specified by the server is for a change-plugin request, but in that case it can be any plugin depending on the user account. In this case, the client must try to load the plugin, and if that plugin is not available, an error is not optional.

Restrictions on Pluggable Authentication

The first part of this section describes general restrictions on the applicability of the pluggable authentication framework described at Section 6.2.17, “Pluggable Authentication”. The second part describes how third-party connector developers can determine the extent to which a connector can take advantage of pluggable authentication capabilities and what steps to take to become more compliant.

The term “native authentication” used here refers to authentication against passwords stored in the mysql.user system table. This is the same authentication method provided by older MySQL servers, before pluggable authentication was implemented. “Windows native authentication” refers to authentication using the credentials of a user who has already logged in to Windows, as implemented by the Windows Native Authentication plugin (“Windows plugin” for short).

- General Pluggable Authentication Restrictions

- Pluggable Authentication and Third-Party Connectors

General Pluggable Authentication Restrictions

- Connector/C++: Clients that use this connector can connect to the server only through accounts that use native authentication.

Exception: A connector supports pluggable authentication if it was built to link to libmysqlclient dynamically (rather than statically) and it loads the current version of libmysqlclient if that version is installed, or if the connector is recompiled from source to link against the current libmysqlclient.

For information about writing connectors to handle information from the server about the default server-side authentication plugin, see Authentication Plugin Connector-Writing Considerations.

- Connector.NET: Clients that use Connector.NET can connect to the server through accounts that use native authentication or Windows native authentication.

- Connector/PHP: Clients that use this connector can connect to the server only through accounts that use native authentication, when compiled using the MySQL native driver for PHP (mysqlnd).

- Windows native authentication: Connecting through an account that uses the Windows plugin requires Windows Domain setup. Without it, NTLM authentication is used and then only local connections are possible; that is, the client and server must run on the same computer.

- Proxy users: Proxy user support is available to the extent that clients can connect through accounts authenticated with plugins that implement proxy user capability (that is, plugins that can return a user
name different from that of the connecting user). For example, the PAM and Windows plugins support proxy users. The `mysql_native_password` and `sha256_password` authentication plugins do not support proxy users by default, but can be configured to do so; see Server Support for Proxy User Mapping.

- **Replication**: Replicas can not only employ replication user accounts using native authentication, but can also connect through replication user accounts that use nonnative authentication if the required client-side plugin is available. If the plugin is built into `libmysqlclient`, it is available by default. Otherwise, the plugin must be installed on the replica side in the directory named by the replica's `plugin_dir` system variable.

- **FEDERATED tables**: A FEDERATED table can access the remote table only through accounts on the remote server that use native authentication.

### Pluggable Authentication and Third-Party Connectors

Third-party connector developers can use the following guidelines to determine readiness of a connector to take advantage of pluggable authentication capabilities and what steps to take to become more compliant:

- An existing connector to which no changes have been made uses native authentication and clients that use the connector can connect to the server only through accounts that use native authentication. However, you should test the connector against a recent version of the server to verify that such connections still work without problem.

  Exception: A connector might work with pluggable authentication without any changes if it links to `libmysqlclient` dynamically (rather than statically) and it loads the current version of `libmysqlclient` if that version is installed.

- To take advantage of pluggable authentication capabilities, a connector that is `libmysqlclient`-based should be relinked against the current version of `libmysqlclient`. This enables the connector to support connections though accounts that require client-side plugins now built into `libmysqlclient` (such as the cleartext plugin needed for PAM authentication and the Windows plugin needed for Windows native authentication). Linking with a current `libmysqlclient` also enables the connector to access client-side plugins installed in the default MySQL plugin directory (typically the directory named by the default value of the local server’s `plugin_dir` system variable).

  If a connector links to `libmysqlclient` dynamically, it must be ensured that the newer version of `libmysqlclient` is installed on the client host and that the connector loads it at runtime.

- Another way for a connector to support a given authentication method is to implement it directly in the client/server protocol. Connector/NET uses this approach to provide support for Windows native authentication.

- If a connector should be able to load client-side plugins from a directory different from the default plugin directory, it must implement some means for client users to specify the directory. Possibilities for this include a command-line option or environment variable from which the connector can obtain the directory name. Standard MySQL client programs such as `mysql` and `mysqladmin` implement a `--plugin-dir` option. See also C API Client Plugin Functions.

- Proxy user support by a connector depends, as described earlier in this section, on whether the authentication methods that it supports permit proxy users.

### 6.2.18 Proxy Users

The MySQL server authenticates client connections using authentication plugins. The plugin that authenticates a given connection may request that the connecting (external) user be treated as a different
user for privilege-checking purposes. This enables the external user to be a proxy for the second user; that is, to assume the privileges of the second user:

- The external user is a “proxy user” (a user who can impersonate or become known as another user).
- The second user is a “proxied user” (a user whose identity and privileges can be assumed by a proxy user).

This section describes how the proxy user capability works. For general information about authentication plugins, see Section 6.2.17, “Pluggable Authentication”. For information about specific plugins, see Section 6.4.1, “Authentication Plugins”. For information about writing authentication plugins that support proxy users, see Implementing Proxy User Support in Authentication Plugins.

- Requirements for Proxy User Support
- Simple Proxy User Example
- Preventing Direct Login to Proxied Accounts
- Granting and Revoking the PROXY Privilege
- Default Proxy Users
- Default Proxy User and Anonymous User Conflicts
- Server Support for Proxy User Mapping
- Proxy User System Variables

**Note**

One administrative benefit to be gained by proxying is that the DBA can set up a single account with a set of privileges and then enable multiple proxy users to have those privileges without having to assign the privileges individually to each of those users. As an alternative to proxy users, DBAs may find that roles provide a suitable way to map users onto specific sets of named privileges. Each user can be granted a given single role to, in effect, be granted the appropriate set of privileges. See Section 6.2.10, “Using Roles”.

**Requirements for Proxy User Support**

For proxying to occur for a given authentication plugin, these conditions must be satisfied:

- Proxying must be supported, either by the plugin itself, or by the MySQL server on behalf of the plugin. In the latter case, server support may need to be enabled explicitly; see Server Support for Proxy User Mapping.

- The account for the external proxy user must be set up to be authenticated by the plugin. Use the CREATE USER statement to associate an account with an authentication plugin, or ALTER USER to change its plugin.

- The account for the proxied user must exist and be granted the privileges to be assumed by the proxy user. Use the CREATE USER and GRANT statements for this.

- Normally, the proxied user is configured so that it can be used only in proxying scenarios and not for direct logins.

- The proxy user account must have the PROXY privilege for the proxied account. Use the GRANT statement for this.
Proxy Users

- For a client connecting to the proxy account to be treated as a proxy user, the authentication plugin must return a user name different from the client user name, to indicate the user name of the proxied account that defines the privileges to be assumed by the proxy user.

Alternatively, for plugins that are provided proxy mapping by the server, the proxied user is determined from the `PROXY` privilege held by the proxy user.

The proxy mechanism permits mapping only the external client user name to the proxied user name. There is no provision for mapping host names:

- When a client connects to the server, the server determines the proper account based on the user name passed by the client program and the host from which the client connects.
- If that account is a proxy account, the server attempts to determine the appropriate proxied account by finding a match for a proxied account using the user name returned by the authentication plugin and the host name of the proxy account. The host name in the proxied account is ignored.

**Simple Proxy User Example**

Consider the following account definitions:

```sql
-- create proxy account
CREATE USER 'employee_ext'@'localhost'
  IDENTIFIED WITH my_auth_plugin
  AS 'my_auth_string';

-- create proxied account and grant its privileges;
-- use mysql_no_login plugin to prevent direct login
CREATE USER 'employee'@'localhost'
  IDENTIFIED WITH mysql_no_login;
GRANT ALL
  ON employees.*
  TO 'employee'@'localhost';

-- grant to proxy account the
-- PROXY privilege for proxied account
GRANT PROXY
  ON 'employee'@'localhost'
  TO 'employee_ext'@'localhost';
```

When a client connects as `employee_ext` from the local host, MySQL uses the plugin named `my_auth_plugin` to perform authentication. Suppose that `my_auth_plugin` returns a user name of `employee` to the server, based on the content of `'my_auth_string'` and perhaps by consulting some external authentication system. The name `employee` differs from `employee_ext`, so returning `employee` serves as a request to the server to treat the `employee_ext` external user, for purposes of privilege checking, as the `employee` local user.

In this case, `employee_ext` is the proxy user and `employee` is the proxied user.

The server verifies that proxy authentication for `employee` is possible for the `employee_ext` user by checking whether `employee_ext` (the proxy user) has the `PROXY` privilege for `employee` (the proxied user). If this privilege has not been granted, an error occurs. Otherwise, `employee_ext` assumes the privileges of `employee`. The server checks statements executed during the client session by `employee_ext` against the privileges granted to `employee`. In this case, `employee_ext` can access tables in the `employees` database.

The proxied account, `employee`, uses the `mysql_no_login` authentication plugin to prevent clients from using the account to log in directly. (This assumes that the plugin is installed. For instructions, see Section 6.4.1.8, “No-Login Pluggable Authentication”.) For alternative methods of protecting proxied accounts against direct use, see Preventing Direct Login to Proxied Accounts.
Proxy Users

When proxying occurs, the `USER()` and `CURRENT_USER()` functions can be used to see the difference between the connecting user (the proxy user) and the account whose privileges apply during the current session (the proxied user). For the example just described, those functions return these values:

```
mysql> SELECT USER(), CURRENT_USER();
+------------------------+--------------------+
| USER()                 | CURRENT_USER()     |
|------------------------+--------------------|
| employee_ext@localhost | employee@localhost |
+------------------------+--------------------+
```

In the `CREATE USER` statement that creates the proxy user account, the `IDENTIFIED WITH` clause that names the proxy-supporting authentication plugin is optionally followed by an `AS 'auth_string'` clause specifying a string that the server passes to the plugin when the user connects. If present, the string provides information that helps the plugin determine how to map the proxy (external) client user name to a proxied user name. It is up to each plugin whether it requires the `AS` clause. If so, the format of the authentication string depends on how the plugin intends to use it. Consult the documentation for a given plugin for information about the authentication string values it accepts.

**Preventing Direct Login to Proxied Accounts**

Proxied accounts generally are intended to be used only by means of proxy accounts. That is, clients connect using a proxy account, then are mapped onto and assume the privileges of the appropriate proxied user.

There are multiple ways to ensure that a proxied account cannot be used directly:

- Associate the account with the `mysql_no_login` authentication plugin. In this case, the account cannot be used for direct logins under any circumstances. This assumes that the plugin is installed. For instructions, see Section 6.4.1.8, "No-Login Pluggable Authentication".

- Include the `ACCOUNT LOCK` option when you create the account. See Section 13.7.1.3, "CREATE USER Statement". With this method, also include a password so that if the account is unlocked later, it cannot be accessed with no password. (If the `validate_password` component is enabled, creating an account without a password is not permitted, even if the account is locked. See Section 6.4.3, "The Password Validation Component").

- Create the account with a password but do not tell anyone else the password. If you do not let anyone know the password for the account, clients cannot use it to connect directly to the MySQL server.

**Granting and Revoking the PROXY Privilege**

The `PROXY` privilege is needed to enable an external user to connect as and have the privileges of another user. To grant this privilege, use the `GRANT` statement. For example:

```
GRANT PROXY ON 'proxied_user' TO 'proxy_user';
```

The statement creates a row in the `mysql.proxies_priv` grant table.

At connect time, `proxy_user` must represent a valid externally authenticated MySQL user, and `proxied_user` must represent a valid locally authenticated user. Otherwise, the connection attempt fails.

The corresponding `REVOKE` syntax is:

```
REVOKE PROXY ON 'proxied_user' FROM 'proxy_user';
```

MySQL `GRANT` and `REVOKE` syntax extensions work as usual. Examples:
**Proxy Users**

-- grant PROXY to multiple accounts
GRANT PROXY ON 'a' TO 'b', 'c', 'd';

-- revoke PROXY from multiple accounts
REVOKE PROXY ON 'a' FROM 'b', 'c', 'd';

-- grant PROXY to an account and enable the account to grant
-- PROXY to the proxied account
GRANT PROXY ON 'a' TO 'd' WITH GRANT OPTION;

-- grant PROXY to default proxy account
GRANT PROXY ON 'a' TO ''@'';

The **PROXY** privilege can be granted in these cases:

- **By a user that has** `GRANT PROXY ... WITH GRANT OPTION` **for** `proxied_user`.  
- **By `proxied_user` for itself**: The value of `USER()` must exactly match `CURRENT_USER()` and `proxied_user`, for both the user name and host name parts of the account name.

The initial **root** account created during MySQL installation has the **PROXY ... WITH GRANT OPTION** privilege for `''@''`, that is, for all users and all hosts. This enables **root** to set up proxy users, as well as to delegate to other accounts the authority to set up proxy users. For example, **root** can do this:

```
CREATE USER 'admin'@'localhost'
  IDENTIFIED BY 'admin_password';
GRANT PROXY
  ON ''@''
  TO 'admin'@'localhost'
  WITH GRANT OPTION;
```

Those statements create an **admin** user that can manage all **GRANT PROXY** mappings. For example, **admin** can do this:

```
GRANT PROXY ON sally TO joe;
```

**Default Proxy Users**

To specify that some or all users should connect using a given authentication plugin, create a “blank” MySQL account with an empty user name and host name (`''@''`), associate it with that plugin, and let the plugin return the real authenticated user name (if different from the blank user). Suppose that there exists a plugin named `ldap_auth` that implements LDAP authentication and maps connecting users onto either a developer or manager account. To set up proxying of users onto these accounts, use the following statements:

```
-- create default proxy account
CREATE USER ''@''
  IDENTIFIED WITH ldap_auth
  AS 'O=Oracle, OU=MySQL';

-- create proxied accounts; use
-- mysql_no_login plugin to prevent direct login
CREATE USER 'developer '@'localhost'
  IDENTIFIED WITH mysql_no_login;
CREATE USER 'manager '@'localhost'
  IDENTIFIED WITH mysql_no_login;

-- grant to default proxy account the
-- PROXY privilege for proxied accounts
GRANT PROXY
  ON 'manager '@'localhost'
  TO ''@'';
```

```
```
Now assume that a client connects as follows:

```
shell> mysql --user=myuser --password ...
Enter password: myuser_password
```

The server does not find `myuser` defined as a MySQL user, but because there is a blank user account (`''@''`) that matches the client user name and host name, the server authenticates the client against that account. The server invokes the `ldap_auth` authentication plugin and passes `myuser` and `myuser_password` to it as the user name and password.

If the `ldap_auth` plugin finds in the LDAP directory that `myuser_password` is not the correct password for `myuser`, authentication fails and the server rejects the connection.

If the password is correct and `ldap_auth` finds that `myuser` is a developer, it returns the user name `developer` to the MySQL server, rather than `myuser`. Returning a user name different from the client user name of `myuser` signals to the server that it should treat `myuser` as a proxy. The server verifies that `''@''` can authenticate as `developer` (because `''@''` has the PROXY privilege to do so) and accepts the connection. The session proceeds with `myuser` having the privileges of the `developer` proxied user. (These privileges should be set up by the DBA using `GRANT` statements, not shown.) The `USER()` and `CURRENT_USER()` functions return these values:

```
mysql> SELECT USER(), CURRENT_USER();
+------------------+---------------------+
| USER()           | CURRENT_USER()      |
|------------------+---------------------|
| myuser@localhost | developer@localhost |
+------------------+---------------------+
```

If the plugin instead finds in the LDAP directory that `myuser` is a manager, it returns `manager` as the user name and the session proceeds with `myuser` having the privileges of the `manager` proxied user.

```
mysql> SELECT USER(), CURRENT_USER();
+------------------+-------------------+
| USER()           | CURRENT_USER()    |
|------------------+-------------------|
| myuser@localhost | manager@localhost |
+------------------+-------------------+
```

For simplicity, external authentication cannot be multilevel: Neither the credentials for `developer` nor those for `manager` are taken into account in the preceding example. However, they are still used if a client tries to connect and authenticate directly as the `developer` or `manager` account, which is why those proxied accounts should be protected against direct login (see Preventing Direct Login to Proxied Accounts).

### Default Proxy User and Anonymous User Conflicts

If you intend to create a default proxy user, check for other existing “match any user” accounts that take precedence over the default proxy user because they can prevent that user from working as intended.

In the preceding discussion, the default proxy user account has `''` in the host part, which matches any host. If you set up a default proxy user, take care to also check whether nonproxy accounts exist with the same user part and `''%''` in the host part, because `''%''` also matches any host, but has precedence over `''` by the rules that the server uses to sort account rows internally (see Section 6.2.6, “Access Control, Stage 1: Connection Verification”).

Suppose that a MySQL installation includes these two accounts:
The first account ("@") is intended as the default proxy user, used to authenticate connections for users who do not otherwise match a more-specific account. The second account ("@%") is an anonymous-user account, which might have been created, for example, to enable users without their own account to connect anonymously.

Both accounts have the same user part (""), which matches any user. And each account has a host part that matches any host. Nevertheless, there is a priority in account matching for connection attempts because the matching rules sort a host of "%" ahead of "". For accounts that do not match any more-specific account, the server attempts to authenticate them against "@%" (the anonymous user) rather than "@" (the default proxy user). As a result, the default proxy account is never used.

To avoid this problem, use one of the following strategies:

• Remove the anonymous account so that it does not conflict with the default proxy user.

• Use a more-specific default proxy user that matches ahead of the anonymous user. For example, to permit only localhost proxy connections, use "@localhost":

```sql
CREATE USER "@localhost"
 IDENTIFIED WITH some_plugin
 AS 'some_auth_string';
```

In addition, modify any GRANT PROXY statements to name "@localhost" rather than "@" as the proxy user.

Be aware that this strategy prevents anonymous-user connections from localhost.

• Use a named default account rather than an anonymous default account. For an example of this technique, consult the instructions for using the authentication_windows plugin. See Section 6.4.1.6, “Windows Pluggable Authentication”.

• Create multiple proxy users, one for local connections and one for “everything else” (remote connections). This can be useful particularly when local users should have different privileges from remote users.

Create the proxy users:

```sql
-- create proxy user for local connections
CREATE USER "@localhost"
 IDENTIFIED WITH some_plugin
 AS 'some_auth_string';

-- create proxy user for remote connections
CREATE USER "@%
 IDENTIFIED WITH some_plugin
 AS 'some_auth_string';
```

Create the proxied users:

```sql
-- create proxied user for local connections
CREATE USER 'developer'@'localhost'
 IDENTIFIED WITH mysql_no_login;

-- create proxied user for remote connections
CREATE USER 'developer'@'%
```
Proxy Users

Grant to each proxy account the **PROXY** privilege for the corresponding proxied account:

```sql
GRANT PROXY
ON 'developer'@'localhost'
TO ''@'localhost';
GRANT PROXY
ON 'developer'@'%' TO ''@'%' ;
```

Finally, grant appropriate privileges to the local and remote proxied users (not shown).

Assume that the `some_plugin/'some_auth_string'` combination causes `some_plugin` to map the client user name to `developer`. Local connections match the `'@'localhost'` proxy user, which maps to the `'developer'@'localhost'` proxied user. Remote connections match the `'@'%'` proxy user, which maps to the `'developer'@'%'` proxied user.

**Server Support for Proxy User Mapping**

Some authentication plugins implement proxy user mapping for themselves (for example, the PAM and Windows authentication plugins). Other authentication plugins do not support proxy users by default. Of these, some can request that the MySQL server itself map proxy users according to granted proxy privileges: `mysql_native_password`, `sha256_password`. If the `check_proxy_users` system variable is enabled, the server performs proxy user mapping for any authentication plugins that make such a request:

- By default, `check_proxy_users` is disabled, so the server performs no proxy user mapping even for authentication plugins that request server support for proxy users.

- If `check_proxy_users` is enabled, it may also be necessary to enable a plugin-specific system variable to take advantage of server proxy user mapping support:
  - For the `mysql_native_password` plugin, enable `mysql_native_password_proxy_users`.
  - For the `sha256_password` plugin, enable `sha256_password_proxy_users`.

For example, to enable all the preceding capabilities, start the server with these lines in the `my.cnf` file:

```ini
[mysqld]
check_proxy_users=ON
mysql_native_password_proxy_users=ON
sha256_password_proxy_users=ON
```

Assuming that the relevant system variables have been enabled, create the proxy user as usual using `CREATE USER`, then grant it the **PROXY** privilege to a single other account to be treated as the proxied user. When the server receives a successful connection request for the proxy user, it finds that the user has the **PROXY** privilege and uses it to determine the proper proxied user.

```sql
-- create proxy account
CREATE USER 'proxy_user'@'localhost'
IDENTIFIED WITH mysql_native_password
BY 'password';
-- create proxied account and grant its privileges;
-- use mysql_no_login plugin to prevent direct login
CREATE USER 'proxied_user'@'localhost'
IDENTIFIED WITH mysql_no_login;
-- grant privileges to proxied account
GRANT ... ON ...
```
Account Locking

TO 'proxied_user'@'localhost';

-- grant to proxy account the
-- PROXY privilege for proxied account
GRANT PROXY
ON 'proxied_user'@'localhost'
TO 'proxy_user'@'localhost';

To use the proxy account, connect to the server using its name and password:

shell> mysql -u proxy_user -p
Enter password: (enter proxy_user password here)

Authentication succeeds, the server finds that proxy_user has the PROXY privilege for proxied_user, and the session proceeds with proxy_user having the privileges of proxied_user.

Proxy user mapping performed by the server is subject to these restrictions:

• The server does not proxy to or from an anonymous user, even if the associated PROXY privilege is granted.

• When a single account has been granted proxy privileges for more than one proxied account, server proxy user mapping is nondeterministic. Therefore, granting to a single account proxy privileges for multiple proxied accounts is discouraged.

Proxy User System Variables

Two system variables help trace the proxy login process:

• proxy_user: This value is NULL if proxying is not used. Otherwise, it indicates the proxy user account. For example, if a client authenticates through the ''@'' proxy account, this variable is set as follows:

mysql> SELECT @@proxy_user;

+--------------+
| @@proxy_user |
+--------------+
| ''@''        |

• external_user: Sometimes the authentication plugin may use an external user to authenticate to the MySQL server. For example, when using Windows native authentication, a plugin that authenticates using the windows API does not need the login ID passed to it. However, it still uses a Windows user ID to authenticate. The plugin may return this external user ID (or the first 512 UTF-8 bytes of it) to the server using the external_user read-only session variable. If the plugin does not set this variable, its value is NULL.

6.2.19 Account Locking

MySQL supports locking and unlocking user accounts using the ACCOUNT LOCK and ACCOUNT UNLOCK clauses for the CREATE USER and ALTER USER statements:

• When used with CREATE USER, these clauses specify the initial locking state for a new account. In the absence of either clause, the account is created in an unlocked state.

If the validate_password component is enabled, creating an account without a password is not permitted, even if the account is locked. See Section 6.4.3, “The Password Validation Component”.

• When used with ALTER USER, these clauses specify the new locking state for an existing account. In the absence of either clause, the account locking state remains unchanged.
As of MySQL 8.0.19, `ALTER USER ... UNLOCK` unlocks any account named by the statement that is temporarily locked due to too many failed logins. See Section 6.2.15, “Password Management”.

Account locking state is recorded in the `account_locked` column of the `mysql.user` system table. The output from `SHOW CREATE USER` indicates whether an account is locked or unlocked.

If a client attempts to connect to a locked account, the attempt fails. The server increments the `Locked_connects` status variable that indicates the number of attempts to connect to a locked account, returns an `ER_ACCOUNT_HAS_BEEN_LOCKED` error, and writes a message to the error log:

```
Access denied for user 'user_name'@'host_name'.
Account is locked.
```

Locking an account does not affect being able to connect using a proxy user that assumes the identity of the locked account. It also does not affect the ability to execute stored programs or views that have a `DEFINER` attribute naming the locked account. That is, the ability to use a proxied account or stored programs or views is not affected by locking the account.

The account-locking capability depends on the presence of the `account_locked` column in the `mysql.user` system table. For upgrades from MySQL versions older than 5.7.6, perform the MySQL upgrade procedure to ensure that this column exists. See Section 2.11, “Upgrading MySQL”. For nonupgraded installations that have no `account_locked` column, the server treats all accounts as unlocked, and using the `ACCOUNT LOCK` or `ACCOUNT UNLOCK` clauses produces an error.

### 6.2.20 Setting Account Resource Limits

One means of restricting client use of MySQL server resources is to set the global `max_user_connections` system variable to a nonzero value. This limits the number of simultaneous connections that can be made by any given account, but places no limits on what a client can do once connected. In addition, setting `max_user_connections` does not enable management of individual accounts. Both types of control are of interest to MySQL administrators.

To address such concerns, MySQL permits limits for individual accounts on use of these server resources:

- The number of queries an account can issue per hour
- The number of updates an account can issue per hour
- The number of times an account can connect to the server per hour
- The number of simultaneous connections to the server by an account

Any statement that a client can issue counts against the query limit. Only statements that modify databases or tables count against the update limit.

An “account” in this context corresponds to a row in the `mysql.user` system table. That is, a connection is assessed against the `User` and `Host` values in the `user` table row that applies to the connection. For example, an account `usera'@'%.example.com'` corresponds to a row in the `user` table that has `User` and `Host` values of `usera` and `%.example.com`, to permit `usera` to connect from any host in the `example.com` domain. In this case, the server applies resource limits in this row collectively to all connections by `usera` from any host in the `example.com` domain because all such connections use the same account.

Before MySQL 5.0, an “account” was assessed against the actual host from which a user connects. This older method of accounting may be selected by starting the server with the `--old-style-`
Setting Account Resource Limits

user-limits option. In this case, if usera connects simultaneously from host1.example.com and host2.example.com, the server applies the account resource limits separately to each connection. If usera connects again from host1.example.com, the server applies the limits for that connection together with the existing connection from that host.

To establish resource limits for an account at account-creation time, use the CREATE_USER statement. To modify the limits for an existing account, use ALTER_USER. Provide a WITH clause that names each resource to be limited. The default value for each limit is zero (no limit). For example, to create a new account that can access the customer database, but only in a limited fashion, issue these statements:

```
mysql> CREATE USER 'francis'@'localhost' IDENTIFIED BY 'frank'
   > WITH MAX_QUERIES_PER_HOUR 20
   > MAX_UPDATES_PER_HOUR 10
   > MAX_CONNECTIONS_PER_HOUR 5
   > MAX_USER_CONNECTIONS 2;
```

The limit types need not all be named in the WITH clause, but those named can be present in any order. The value for each per-hour limit should be an integer representing a count per hour. For MAX_USER_CONNECTIONS, the limit is an integer representing the maximum number of simultaneous connections by the account. If this limit is set to zero, the global max_user_connections system variable value determines the number of simultaneous connections. If max_user_connections is also zero, there is no limit for the account.

To modify limits for an existing account, use an ALTER_USER statement. The following statement changes the query limit for francis to 100:

```
mysql> ALTER USER 'francis'@'localhost' WITH MAX_QUERIES_PER_HOUR 100;
```

The statement modifies only the limit value specified and leaves the account otherwise unchanged.

To remove a limit, set its value to zero. For example, to remove the limit on how many times per hour francis can connect, use this statement:

```
mysql> ALTER USER 'francis'@'localhost' WITH MAX_CONNECTIONS_PER_HOUR 0;
```

As mentioned previously, the simultaneous-connection limit for an account is determined from the MAX_USER_CONNECTIONS limit and the max_user_connections system variable. Suppose that the global max_user_connections value is 10 and three accounts have individual resource limits specified as follows:

```
ALTER USER 'user1'@'localhost' WITH MAX_USER_CONNECTIONS 0;
ALTER USER 'user2'@'localhost' WITH MAX_USER_CONNECTIONS 5;
ALTER USER 'user3'@'localhost' WITH MAX_USER_CONNECTIONS 20;
```

user1 has a connection limit of 10 (the global max_user_connections value) because it has a MAX_USER_CONNECTIONS limit of zero. user2 and user3 have connection limits of 5 and 20, respectively, because they have nonzero MAX_USER_CONNECTIONS limits.

The server stores resource limits for an account in the user table row corresponding to the account. The max_questions, max_updates, and max_connections columns store the per-hour limits, and the max_user_connections column stores the MAX_USER_CONNECTIONS limit. (See Section 6.2.3, "Grant Tables".)

Resource-use counting takes place when any account has a nonzero limit placed on its use of any of the resources.

As the server runs, it counts the number of times each account uses resources. If an account reaches its limit on number of connections within the last hour, the server rejects further connections for the
account until that hour is up. Similarly, if the account reaches its limit on the number of queries or updates, the server rejects further queries or updates until the hour is up. In all such cases, the server issues appropriate error messages.

Resource counting occurs per account, not per client. For example, if your account has a query limit of 50, you cannot increase your limit to 100 by making two simultaneous client connections to the server. Queries issued on both connections are counted together.

The current per-hour resource-use counts can be reset globally for all accounts, or individually for a given account:

- To reset the current counts to zero for all accounts, issue a `FLUSH USER_RESOURCES` statement. The counts also can be reset by reloading the grant tables (for example, with a `FLUSH PRIVILEGES` statement or a `mysqladmin reload` command).
- The counts for an individual account can be reset to zero by setting any of its limits again. Specify a limit value equal to the value currently assigned to the account.

Per-hour counter resets do not affect the `MAX_USER_CONNECTIONS` limit.

All counts begin at zero when the server starts. Counts do not carry over through server restarts.

For the `MAX_USER_CONNECTIONS` limit, an edge case can occur if the account currently has open the maximum number of connections permitted to it: A disconnect followed quickly by a connect can result in an error (`ER_TOO_MANY_USER_CONNECTIONS` or `ER_USER_LIMIT_REACHED`) if the server has not fully processed the disconnect by the time the connect occurs. When the server finishes disconnect processing, another connection is once more permitted.

6.2.21 Troubleshooting Problems Connecting to MySQL

If you encounter problems when you try to connect to the MySQL server, the following items describe some courses of action you can take to correct the problem.

- Make sure that the server is running. If it is not, clients cannot connect to it. For example, if an attempt to connect to the server fails with a message such as one of those following, one cause might be that the server is not running:

  ```
  shell> mysql
  ERROR 2003: Can't connect to MySQL server on 'host_name' (111)
  shell> mysql
  ERROR 2002: Can't connect to local MySQL server through socket '/tmp/mysql.sock' (111)
  ```

- It might be that the server is running, but you are trying to connect using a TCP/IP port, named pipe, or Unix socket file different from the one on which the server is listening. To correct this when you invoke a client program, specify a `--port` option to indicate the proper port number, or a `--socket` option to indicate the proper named pipe or Unix socket file. To find out where the socket file is, you can use this command:

  ```
  shell> netstat -ln | grep mysql
  ```

- Make sure that the server has not been configured to ignore network connections or (if you are attempting to connect remotely) that it has not been configured to listen only locally on its network interfaces. If the server was started with the `skip_networking` system variable enabled, no TCP/IP connections are accepted. If the server was started with the `bind_address` system variable set to `127.0.0.1`, it listens for TCP/IP connections only locally on the loopback interface and does not accept remote connections.
Troubleshooting Problems Connecting to MySQL

- Check to make sure that there is no firewall blocking access to MySQL. Your firewall may be configured on the basis of the application being executed, or the port number used by MySQL for communication (3306 by default). Under Linux or Unix, check your IP tables (or similar) configuration to ensure that the port has not been blocked. Under Windows, applications such as ZoneAlarm or Windows Firewall may need to be configured not to block the MySQL port.

- The grant tables must be properly set up so that the server can use them for access control. For some distribution types (such as binary distributions on Windows, or RPM and DEB distributions on Linux), the installation process initializes the MySQL data directory, including the `mysql` system database containing the grant tables. For distributions that do not do this, you must initialize the data directory manually. For details, see Section 2.10, “Postinstallation Setup and Testing”.

To determine whether you need to initialize the grant tables, look for a `mysql` directory under the data directory. (The data directory normally is named `data` or `var` and is located under your MySQL installation directory.) Make sure that you have a file named `user.MYD` in the `mysql` database directory. If not, initialize the data directory. After doing so and starting the server, you should be able to connect to the server.

- After a fresh installation, if you try to log on to the server as `root` without using a password, you might get the following error message.

  ```shell
  mysql -u root
  ERROR 1045 (28000): Access denied for user 'root'@'localhost' (using password: NO)
  ```

  It means a root password has already been assigned during installation and it has to be supplied. See Section 2.10.4, “Securing the Initial MySQL Account” on the different ways the password could have been assigned and, in some cases, how to find it. If you need to reset the root password, see instructions in Section B.3.3.2, “How to Reset the Root Password”. After you have found or reset your password, log on again as `root` using the `--password` (or `-p`) option:

  ```shell
  mysql -u root -p
  Enter password:
  ```

  However, the server is going to let you connect as `root` without using a password if you have initialized MySQL using `mysqld --initialize-insecure` (see Section 2.10.1, “Initializing the Data Directory” for details). That is a security risk, so you should set a password for the `root` account; see Section 2.10.4, “Securing the Initial MySQL Account” for instructions.

- If you have updated an existing MySQL installation to a newer version, did you perform the MySQL upgrade procedure? If not, do so. The structure of the grant tables changes occasionally when new capabilities are added, so after an upgrade you should always make sure that your tables have the current structure. For instructions, see Section 2.11, “Upgrading MySQL”.

- If a client program receives the following error message when it tries to connect, it means that the server expects passwords in a newer format than the client is capable of generating:

  ```shell
  mysql
  Client does not support authentication protocol requested by server; consider upgrading MySQL client
  ```

- Remember that client programs use connection parameters specified in option files or environment variables. If a client program seems to be sending incorrect default connection parameters when you have not specified them on the command line, check any applicable option files and your environment. For example, if you get `Access denied` when you run a client without any options, make sure that you have not specified an old password in any of your option files!

You can suppress the use of option files by a client program by invoking it with the `--no-defaults` option. For example:
Troubleshooting Problems Connecting to MySQL

shell> mysqladmin --no-defaults -u root version

The option files that clients use are listed in Section 4.2.2.2, “Using Option Files”. Environment variables are listed in Section 4.9, “Environment Variables”.

• If you get the following error, it means that you are using an incorrect root password:

shell> mysqladmin -u root -p
Access denied for user 'root'@'localhost' (using password: YES)

If the preceding error occurs even when you have not specified a password, it means that you have an incorrect password listed in some option file. Try the --no-defaults option as described in the previous item.

For information on changing passwords, see Section 6.2.14, “Assigning Account Passwords”.

If you have lost or forgotten the root password, see Section B.3.3.2, “How to Reset the Root Password”.

• localhost is a synonym for your local host name, and is also the default host to which clients try to connect if you specify no host explicitly.

You can use a --host=127.0.0.1 option to name the server host explicitly. This causes a TCP/IP connection to the local mysqld server. You can also use TCP/IP by specifying a --host option that uses the actual host name of the local host. In this case, the host name must be specified in a user table row on the server host, even though you are running the client program on the same host as the server.

• The Access denied error message tells you who you are trying to log in as, the client host from which you are trying to connect, and whether you were using a password. Normally, you should have one row in the user table that exactly matches the host name and user name that were given in the error message. For example, if you get an error message that contains using password: NO, it means that you tried to log in without a password.

• If you get an Access denied error when trying to connect to the database with mysql -u user_name, you may have a problem with the user table. Check this by executing mysql -u root mysql and issuing this SQL statement:

SELECT * FROM user;

The result should include a row with the Host and User columns matching your client’s host name and your MySQL user name.

• If the following error occurs when you try to connect from a host other than the one on which the MySQL server is running, it means that there is no row in the user table with a Host value that matches the client host:

Host ... is not allowed to connect to this MySQL server

You can fix this by setting up an account for the combination of client host name and user name that you are using when trying to connect.

If you do not know the IP address or host name of the machine from which you are connecting, you should put a row with '%' as the Host column value in the user table. After trying to connect from the client machine, use a SELECT USER() query to see how you really did connect. Then change the '%' in the user table row to the actual host name that shows up in the log. Otherwise, your system is left insecure because it permits connections from any host for the given user name.
Troubleshooting Problems Connecting to MySQL

On Linux, another reason that this error might occur is that you are using a binary MySQL version that is compiled with a different version of the glibc library than the one you are using. In this case, you should either upgrade your operating system or glibc, or download a source distribution of MySQL version and compile it yourself. A source RPM is normally trivial to compile and install, so this is not a big problem.

- If you specify a host name when trying to connect, but get an error message where the host name is not shown or is an IP address, it means that the MySQL server got an error when trying to resolve the IP address of the client host to a name:

  ```shell>
  mysqladmin -u root -pxxxx -h some_hostname ver
  Access denied for user 'root'@'' (using password: YES)
  ```

  If you try to connect as root and get the following error, it means that you do not have a row in the user table with a User column value of 'root' and that mysqld cannot resolve the host name for your client:

  ```shell>
  Access denied for user ''@'unknown'
  ```

  These errors indicate a DNS problem. To fix it, execute `mysqladmin flush-hosts` to reset the internal DNS host cache. See Section 5.1.12.3, "DNS Lookups and the Host Cache".

Some permanent solutions are:

- Determine what is wrong with your DNS server and fix it.
- Specify IP addresses rather than host names in the MySQL grant tables.
- Put an entry for the client machine name in `/etc/hosts` on Unix or `\windows\hosts` on Windows.
- Start `mysqld` with the `skip_name_resolve` system variable enabled.
- Start `mysqld` with the `--skip-host-cache` option.
- On Unix, if you are running the server and the client on the same machine, connect to `localhost`. For connections to `localhost`, MySQL programs attempt to connect to the local server by using a Unix socket file, unless there are connection parameters specified to ensure that the client makes a TCP/IP connection. For more information, see Section 4.2.4, "Connecting to the MySQL Server Using Command Options".

- On Windows, if you are running the server and the client on the same machine and the server supports named pipe connections, connect to the host name . (period). Connections to . use a named pipe rather than TCP/IP.

- If `mysql -u root` works but `mysql -h yourHostname -u root` results in Access denied (where `yourHostname` is the actual host name of the local host), you may not have the correct name for your host in the user table. A common problem here is that the Host value in the user table row specifies an unqualified host name, but your system's name resolution routines return a fully qualified domain name (or vice versa). For example, if you have a row with host 'pluto' in the user table, but your DNS tells MySQL that your host name is 'pluto.example.com', the row does not work. Try adding a row to the user table that contains the IP address of your host as the Host column value. (Alternatively, you could add a row to the user table with a Host value that contains a wildcard (for example, 'pluto.%'). However, use of Host values ending with % is insecure and is not recommended!)
• If `mysql -u user_name` works but `mysql -u user_name some_db` does not, you have not granted access to the given user for the database named `some_db`.

• If `mysql -u user_name` works when executed on the server host, but `mysql -h host_name -u user_name` does not work when executed on a remote client host, you have not enabled access to the server for the given user name from the remote host.

• If you cannot figure out why you get `Access denied`, remove from the `user` table all rows that have `Host` values containing wildcards (rows that contain '%', or '_'). A very common error is to insert a new row with `Host='%'` and `User='some_user'`, thinking that this enables you to specify localhost to connect from the same machine. The reason that this does not work is that the default privileges include a row with `Host='localhost'` and `User=''. Because that row has a `Host` value 'localhost' that is more specific than '%', it is used in preference to the new row when connecting from localhost! The correct procedure is to insert a second row with `Host='localhost'` and `User='some_user'`, or to delete the row with `Host='localhost'` and `User=''. After deleting the row, remember to issue a `FLUSH PRIVILEGES` statement to reload the grant tables. See also Section 6.2.6, “Access Control, Stage 1: Connection Verification”.

• If you are able to connect to the MySQL server, but get an `Access denied` message whenever you issue a `SELECT ... INTO OUTFILE` or `LOAD DATA` statement, your row in the `user` table does not have the `FILE` privilege enabled.

• If you change the grant tables directly (for example, by using `INSERT`, `UPDATE`, or `DELETE` statements) and your changes seem to be ignored, remember that you must execute a `FLUSH PRIVILEGES` statement or a `mysqladmin flush-privileges` command to cause the server to reload the privilege tables. Otherwise, your changes have no effect until the next time the server is restarted. Remember that after you change the `root` password with an `UPDATE` statement, you do not need to specify the new password until after you flush the privileges, because the server does not know until then that you have changed the password.

• If your privileges seem to have changed in the middle of a session, it may be that a MySQL administrator has changed them. Reloading the grant tables affects new client connections, but it also affects existing connections as indicated in Section 6.2.13, “When Privilege Changes Take Effect”.

• If you have access problems with a Perl, PHP, Python, or ODBC program, try to connect to the server with `mysql -u user_name db_name` or `mysql -u user_name -p password db_name`. If you are able to connect using the `mysql` client, the problem lies with your program, not with the access privileges. (There is no space between `-p` and the password; you can also use the `--password=password` syntax to specify the password. If you use the `-p` or `--password` option with no password value, MySQL prompts you for the password.)

• For testing purposes, start the `mysqld` server with the `--skip-grant-tables` option. Then you can change the MySQL grant tables and use the `SHOW GRANTS` statement to check whether your modifications have the desired effect. When you are satisfied with your changes, execute `mysqladmin flush-privileges` to tell the `mysqld` server to reload the privileges. This enables you to begin using the new grant table contents without stopping and restarting the server.

• If everything else fails, start the `mysqld` server with a debugging option (for example, `--debug=d,general,query`). This prints host and user information about attempted connections, as well as information about each command issued. See Section 5.9.4, “The DBUG Package”.

• If you have any other problems with the MySQL grant tables and ask on the MySQL Community Slack, always provide a dump of the MySQL grant tables. You can dump the tables with the `mysqldump` command. To file a bug report, see the instructions at Section 1.6, “How to Report Bugs or Problems”. In some cases, you may need to restart `mysqld` with `--skip-grant-tables` to run `mysqldump`. 
6.2.22 SQL-Based Account Activity Auditing

Applications can use the following guidelines to perform SQL-based auditing that ties database activity to MySQL accounts.

MySQL accounts correspond to rows in the `mysql.user` system table. When a client connects successfully, the server authenticates the client to a particular row in this table. The `User` and `Host` column values in this row uniquely identify the account and correspond to the `'<user_name>'@'host_name'` format in which account names are written in SQL statements.

The account used to authenticate a client determines which privileges the client has. Normally, the `CURRENT_USER()` function can be invoked to determine which account this is for the client user. Its value is constructed from the `User` and `Host` columns of the `user` table row for the account.

However, there are circumstances under which the `CURRENT_USER()` value corresponds not to the client user but to a different account. This occurs in contexts when privilege checking is not based the client's account:

- Stored routines (procedures and functions) defined with the `SQL SECURITY DEFINER` characteristic
- Views defined with the `SQL SECURITY DEFINER` characteristic
- Triggers and events

In those contexts, privilege checking is done against the `DEFINER` account and `CURRENT_USER()` refers to that account, not to the account for the client who invoked the stored routine or view or who caused the trigger to activate. To determine the invoking user, you can call the `USER()` function, which returns a value indicating the actual user name provided by the client and the host from which the client connected. However, this value does not necessarily correspond directly to an account in the `user` table, because the `USER()` value never contains wildcards, whereas account values (as returned by `CURRENT_USER()`) may contain user name and host name wildcards.

For example, a blank user name matches any user, so an account of `''@'localhost'` enables clients to connect as an anonymous user from the local host with any user name. In this case, if a client connects as `user1` from the local host, `USER()` and `CURRENT_USER()` return different values:

```
mysql> SELECT USER(), CURRENT_USER();
+-----------------+----------------+
| USER()          | CURRENT_USER() |
+-----------------+----------------+
| user1@localhost | @localhost     |
+-----------------+----------------+
```

The host name part of an account can also contain wildcards. If the host name contains a `%` or `_` pattern character or uses netmask notation, the account can be used for clients connecting from multiple hosts and the `CURRENT_USER()` value does not indicate which one. For example, the account `user2'@'.example.com'` can be used by `user2` to connect from any host in the `example.com` domain. If `user2` connects from `remote.example.com`, `USER()` and `CURRENT_USER()` return different values:

```
mysql> SELECT USER(), CURRENT_USER();
+--------------------------+---------------------+
| USER()                   | CURRENT_USER()      |
+--------------------------+---------------------+
| user2@remote.example.com | user2@%.example.com |
+--------------------------+---------------------+
```

If an application must invoke `USER()` for user auditing (for example, if it does auditing from within triggers) but must also be able to associate the `USER()` value with an account in the `user` table, it is necessary
Using Encrypted Connections

to avoid accounts that contain wildcards in the User or Host column. Specifically, do not permit User to be empty (which creates an anonymous-user account), and do not permit pattern characters or netmask notation in Host values. All accounts must have a nonempty User value and literal Host value.

With respect to the previous examples, the '@localhost' and 'user2'@'%.example.com' accounts should be changed not to use wildcards:

```
RENAME USER '@localhost' TO 'user1'@'localhost';
RENAME USER 'user2'@'%.example.com' TO 'user2'@'remote.example.com';
```

If user2 must be able to connect from several hosts in the example.com domain, there should be a separate account for each host.

To extract the user name or host name part from a CURRENT_USER() or USER() value, use the SUBSTRING_INDEX() function:

```
mysql> SELECT SUBSTRING_INDEX(CURRENT_USER(),'@',1);
+---------------------------------------+
| SUBSTRING_INDEX(CURRENT_USER(),'@',1) |
+---------------------------------------+
| user1                                 |
+---------------------------------------+

mysql> SELECT SUBSTRING_INDEX(CURRENT_USER(),'@',-1);
+----------------------------------------+
| SUBSTRING_INDEX(CURRENT_USER(),'@',-1) |
+----------------------------------------+
| localhost                              |
+----------------------------------------+
```

6.3 Using Encrypted Connections

With an unencrypted connection between the MySQL client and the server, someone with access to the network could watch all your traffic and inspect the data being sent or received between client and server.

When you must move information over a network in a secure fashion, an unencrypted connection is unacceptable. To make any kind of data unreadable, use encryption. Encryption algorithms must include security elements to resist many kinds of known attacks such as changing the order of encrypted messages or replaying data twice.

MySQL supports encrypted connections between clients and the server using the TLS (Transport Layer Security) protocol. TLS is sometimes referred to as SSL (Secure Sockets Layer) but MySQL does not actually use the SSL protocol for encrypted connections because its encryption is weak (see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”).

TLS uses encryption algorithms to ensure that data received over a public network can be trusted. It has mechanisms to detect data change, loss, or replay. TLS also incorporates algorithms that provide identity verification using the X.509 standard.

X.509 makes it possible to identify someone on the Internet. In basic terms, there should be some entity called a “Certificate Authority” (or CA) that assigns electronic certificates to anyone who needs them. Certificates rely on asymmetric encryption algorithms that have two encryption keys (a public key and a secret key). A certificate owner can present the certificate to another party as proof of identity. A certificate consists of its owner’s public key. Any data encrypted using this public key can be decrypted only using the corresponding secret key, which is held by the owner of the certificate.

Support for encrypted connections in MySQL is provided using OpenSSL. For information about the encryption protocols and ciphers that OpenSSL supports, see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

1232
By default, MySQL programs attempt to connect using encryption if the server supports encrypted connections, falling back to an unencrypted connection if an encrypted connection cannot be established. For information about options that affect use of encrypted connections, see Section 6.3.1, “Configuring MySQL to Use Encrypted Connections” and Command Options for Encrypted Connections.

Encrypted connections can be used between source and replica servers. See Section 17.3.1, “Setting Up Replication to Use Encrypted Connections”.

For information about using encrypted connections from the MySQL C API, see C API Support for Encrypted Connections.

It is also possible to connect using encryption from within an SSH connection to the MySQL server host. For an example, see Section 6.3.4, “Connecting to MySQL Remotely from Windows with SSH”.

### 6.3.1 Configuring MySQL to Use Encrypted Connections

Several configuration parameters are available to indicate whether to use encrypted connections, and to specify the appropriate certificate and key files. This section provides general guidance about configuring the server and clients for encrypted connections:

- Server-Side Startup Configuration for Encrypted Connections
- Server-Side Runtime Configuration and Monitoring for Encrypted Connections
- Client-Side Configuration for Encrypted Connections
- Configuring Encrypted Connections as Mandatory

Encrypted connections also can be used in these contexts:

- Between source and replica replication servers. See Section 17.3.1, “Setting Up Replication to Use Encrypted Connections”.
- Among Group Replication servers. See Section 18.5.2, “Securing Group Communication Connections with Secure Socket Layer (SSL)”.
- By client programs that are based on the MySQL C API. See C API Support for Encrypted Connections.

Instructions for creating any required certificate and key files are available in Section 6.3.3, “Creating SSL and RSA Certificates and Keys”.

### Server-Side Startup Configuration for Encrypted Connections

On the server side, the \(--ssl\) option specifies that the server permits but does not require encrypted connections. This option is enabled by default, so it need not be specified explicitly.
To require that clients connect using encrypted connections, enable the `require_secure_transport` system variable. See Configuring Encrypted Connections as Mandatory.

These system variables on the server side specify the certificate and key files the server uses when permitting clients to establish encrypted connections:

- **ssl_ca**: The path name of the Certificate Authority (CA) certificate file. (`ssl_capath` is similar but specifies the path name of a directory of CA certificate files.)

- **ssl_cert**: The path name of the server public key certificate file. This certificate can be sent to the client and authenticated against the CA certificate that it has.

- **ssl_key**: The path name of the server private key file.

For example, to enable the server for encrypted connections, start it with these lines in the `my.cnf` file, changing the file names as necessary:

```plaintext
[mysqld]
ssl_ca=ca.pem
ssl_cert=server-cert.pem
ssl_key=server-key.pem

require_secure_transport=ON
```

To specify in addition that clients are required to use encrypted connections, enable the `require_secure_transport` system variable:

```plaintext
[mysqld]
ssl_ca=ca.pem
ssl_cert=server-cert.pem
ssl_key=server-key.pem
require_secure_transport=ON
```

Each certificate and key system variable names a file in PEM format. Should you need to create the required certificate and key files, see Section 6.3.3, "Creating SSL and RSA Certificates and Keys". MySQL servers compiled using OpenSSL can generate missing certificate and key files automatically at startup. See Section 6.3.3.1, "Creating SSL and RSA Certificates and Keys using MySQL". Alternatively, if you have a MySQL source distribution, you can test your setup using the demonstration certificate and key files in its `mysql-test/std_data` directory.

The server performs certificate and key file autodiscovery. If no explicit encrypted-connection options are given other than `--ssl` (possibly along with `ssl_cipher`) to configure encrypted connections, the server attempts to enable encrypted-connection support automatically at startup:

- If the server discovers valid certificate and key files named `ca.pem`, `server-cert.pem`, and `server-key.pem` in the data directory, it enables support for encrypted connections by clients. (The files need not have been generated automatically; what matters is that they have those names and are valid.)
- If the server does not find valid certificate and key files in the data directory, it continues executing but without support for encrypted connections.

If the server automatically enables encrypted connection support, it writes a note to the error log. If the server discovers that the CA certificate is self-signed, it writes a warning to the error log. (The certificate is self-signed if created automatically by the server or manually using `mysql_ssl_rsa_setup`.)

MySQL also provides these system variables for server-side encrypted-connection control:

- **ssl_cipher**: The list of permissible ciphers for connection encryption.
- **ssl_crl**: The path name of the file containing certificate revocation lists. (`ssl_crlpath` is similar but specifies the path name of a directory of certificate revocation-list files.)
• \texttt{tls\_version, tls\_ciphersuites}: Which encryption protocols and ciphersuites the server permits for encrypted connections; see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”. For example, you can set \texttt{tls\_version} to prevent clients from using less-secure protocols.

If the server cannot create a valid TLS context from the system variables for server-side encrypted-connection control, the server does not support encrypted connections.

### Server-Side Runtime Configuration and Monitoring for Encrypted Connections

Prior to MySQL 8.0.16, the \texttt{tls\_xxx} and \texttt{ssl\_xxx} system variables that configure encrypted-connection support can be set only at server startup. These system variables therefore determine the TLS context the server uses for all new connections.

As of MySQL 8.0.16, the \texttt{tls\_xxx} and \texttt{ssl\_xxx} system variables are dynamic and can be set at runtime, not just at startup. If changed with \texttt{SET GLOBAL}, the new values apply only until server restart. If changed with \texttt{SET PERSIST}, the new values also carry over to subsequent server restarts. See Section 13.7.6.1, “SET Syntax for Variable Assignment”. However, runtime changes to these variables do not immediately affect the TLS context for new connections, as explained later in this section.

Along with the change in MySQL 8.0.16 that enables runtime changes to the TLS context-related system variables, the server enables runtime updates to the actual TLS context used for new connections. This capability may be useful, for example, to avoid restarting a MySQL server that has been running so long that its SSL certificate has expired.

To create the initial TLS context, the server uses the values that the context-related system variables have at startup. To expose the context values, the server also initializes a set of corresponding status variables. The following table shows the system variables that define the TLS context and the corresponding status variables that expose the currently active context values.

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>Corresponding Status Variable Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{ssl_ca}</td>
<td>\texttt{Current_tls_ca}</td>
</tr>
<tr>
<td>\texttt{ssl_capath}</td>
<td>\texttt{Current_tls_capath}</td>
</tr>
<tr>
<td>\texttt{ssl_cert}</td>
<td>\texttt{Current_tls_cert}</td>
</tr>
<tr>
<td>\texttt{ssl_cipher}</td>
<td>\texttt{Current_tls_cipher}</td>
</tr>

To reconfigure the TLS context at runtime, use this procedure:

1. For any TLS context-related system variables that should be changed, set them to their new values.

2. Execute \texttt{ALTER INSTANCE RELOAD TLS}. This statement reconfigures the active TLS context from the current values of the TLS context-related system variables. It also sets the context-related status variables to reflect the new active context values. The statement requires the \texttt{CONNECTION_ADMIN} privilege.

3. New connections established after execution of \texttt{ALTER INSTANCE RELOAD TLS} use the new TLS context. Existing connections remain unaffected. If existing connections should be terminated, use the \texttt{KILL} statement.
Configuring MySQL to Use Encrypted Connections

The members of each pair of system and status variables may have different values temporarily due to the way the reconfiguration procedure works:

- Changes to the system variables prior to `ALTER INSTANCE RELOAD TLS` do not change the TLS context. At this point, those changes have no effect on new connections, and corresponding context-related system and status variables may have different values. This enables you to make any changes required to individual system variables, then update the active TLS context atomically with `ALTER INSTANCE RELOAD TLS` after all system variable changes have been made.

- After `ALTER INSTANCE RELOAD TLS`, corresponding system and status variables have the same values. This remains true until the next change to the system variables.

In some cases, `ALTER INSTANCE RELOAD TLS` by itself may suffice to reconfigure the TLS context, without changing any system variables. Suppose that the certificate in the file named by `ssl_cert` has expired. It is sufficient to replace the existing file contents with a nonexpired certificate and execute `ALTER INSTANCE RELOAD TLS` to cause the new file contents to be read and used for new connections.

As of MySQL 8.0.21, the server implements independent connection-encryption configuration for the administrative connection interface. See Administrative Interface Support for Encrypted Connections. In addition, `ALTER INSTANCE RELOAD TLS` is extended with a `FOR CHANNEL` clause that enables specifying the channel (interface) for which to reload the TLS context. See Section 13.1.5, “ALTER INSTANCE Statement”. There are no status variables to expose the administrative interface TLS context, but the Performance Schema `tls_channel_status` table exposes TLS properties for both the main and administrative interfaces. See Section 26.12.19.8, “The tls_channel_status Table”.

Updating the main interface TLS context has these effects:

- The update changes the TLS context used for new connections on the main connection interface.

- The update also changes the TLS context used for new connections on the administrative interface unless some nondefault TLS parameter value is configured for that interface.

- The update does not affect the TLS context used by other enabled server plugins or components such as Group Replication or X Plugin:

  - To apply the main interface reconfiguration to Group Replication's group communication connections, which take their settings from the server's TLS context-related system variables, you must execute `STOP GROUP_REPLICATION` followed by `START GROUP_REPLICATION` to stop and restart Group Replication.

  - X Plugin initializes its TLS context at plugin initialization as described at Section 20.5.3, “Using Encrypted Connections with X Plugin”. This context does not change thereafter.

By default, the `RELOAD TLS` action rolls back with an error and has no effect if the configuration values do not permit creation of the new TLS context. The previous context values continue to be used for new connections. If the optional `NO ROLLBACK ON ERROR` clause is given and the new context cannot be created, rollback does not occur. Instead, a warning is generated and encryption is disabled for new connections on the interface to which the statement applies.

Options that enable or disable encrypted connections on a connection interface have an effect only at startup. For example, the `--ssl` and `--admin-ssl` options affect only at startup whether the main and administrative interfaces support encrypted connections. Such options are ignored and have no effect on the operation of `ALTER INSTANCE RELOAD TLS` at runtime. For example, you can use `--ssl=OFF` to start the server with encrypted connections disabled on the main interface, then reconfigure TLS and execute `ALTER INSTANCE RELOAD TLS` to enable encrypted connections at runtime.
Configuring MySQL to Use Encrypted Connections

Client-Side Configuration for Encrypted Connections

For a complete list of client options related to establishment of encrypted connections, see Command Options for Encrypted Connections.

By default, MySQL client programs attempt to establish an encrypted connection if the server supports encrypted connections, with further control available through the `--ssl-mode` option:

- In the absence of an `--ssl-mode` option, clients attempt to connect using encryption, falling back to an unencrypted connection if an encrypted connection cannot be established. This is also the behavior with an explicit `--ssl-mode=REQUIRED` option.
- With `--ssl-mode=REQUIRED`, clients require an encrypted connection and fail if one cannot be established.
- With `--ssl-mode=DISABLED`, clients use an unencrypted connection.
- With `--ssl-mode=VERIFY_CA` or `--ssl-mode=VERIFY_IDENTITY`, clients require an encrypted connection, and also perform verification against the server CA certificate and (with `VERIFY_IDENTITY`) against the server host name in its certificate.

Attempts to establish an unencrypted connection fail if the `require_secure_transport` system variable is enabled on the server side to cause the server to require encrypted connections. See Configuring Encrypted Connections as Mandatory.

The following options on the client side identify the certificate and key files clients use when establishing encrypted connections to the server. They are similar to the `ssl_ca`, `ssl_cert`, and `ssl_key` system variables used on the server side, but `--ssl-cert` and `--ssl-key` identify the client public and private key:

- `--ssl-ca`: The path name of the Certificate Authority (CA) certificate file. This option, if used, must specify the same certificate used by the server. (`--ssl-capath` is similar but specifies the path name of a directory of CA certificate files.)
- `--ssl-cert`: The path name of the client public key certificate file.
- `--ssl-key`: The path name of the client private key file.

For additional security relative to that provided by the default encryption, clients can supply a CA certificate matching the one used by the server and enable host name identity verification. In this way, the server and client place their trust in the same CA certificate and the client verifies that the host to which it connected is the one intended:

- To specify the CA certificate, use `--ssl-ca` (or `--ssl-capath`), and specify `--ssl-mode=VERIFY_CA`.
- To enable host name identity verification as well, use `--ssl-mode=VERIFY_IDENTITY` rather than `--ssl-mode=VERIFY_CA`.

Note

Host name identity verification with `VERIFY_IDENTITY` does not work with self-signed certificates that are created automatically by the server or manually using `mysql_ssl_rsa_setup` (see Section 6.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”). Such self-signed certificates do not contain the server name as the Common Name value.
Host name identity verification also does not work with certificates that specify the Common Name using wildcards because that name is compared verbatim to the server name.

MySQL also provides these options for client-side SSL control:

- `--ssl-cipher`: The list of permissible ciphers for connection encryption.
- `--ssl-crl`: The path name of the file containing certificate revocation lists. (`--ssl-crlpath` is similar but specifies the path name of a directory of certificate revocation-list files.)
- `--tls-version, --tls-ciphersuites`: The permitted encryption protocols and ciphersuites; see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

Depending on the encryption requirements of the MySQL account used by a client, the client may be required to specify certain options to connect using encryption to the MySQL server.

Suppose that you want to connect using an account that has no special encryption requirements or that was created using a `CREATE USER` statement that included the `REQUIRE SSL` clause. Assuming that the server supports encrypted connections, a client can connect using encryption with no `--ssl-mode` option or with an explicit `--ssl-mode=PREFERRED` option:

```
mysql
```

Or:

```
mysql --ssl-mode=PREFERRED
```

For an account created with a `REQUIRE SSL` clause, the connection attempt fails if an encrypted connection cannot be established. For an account with no special encryption requirements, the attempt falls back to an unencrypted connection if an encrypted connection cannot be established. To prevent fallback and fail if an encrypted connection cannot be obtained, connect like this:

```
mysql --ssl-mode=REQUIRED
```

If the account has more stringent security requirements, other options must be specified to establish an encrypted connection:

- For accounts created with a `REQUIRE X509` clause, clients must specify at least `--ssl-cert` and `--ssl-key`. In addition, `--ssl-ca` (or `--ssl-capath`) is recommended so that the public certificate provided by the server can be verified. For example (enter the command on a single line):

  ```
  mysql --ssl-ca=ca.pem
  --ssl-cert=client-cert.pem
  --ssl-key=client-key.pem
  ```

- For accounts created with a `REQUIRE ISSUER` or `REQUIRE SUBJECT` clause, the encryption requirements are the same as for `REQUIRE X509`, but the certificate must match the issue or subject, respectively, specified in the account definition.

For additional information about the `REQUIRE` clause, see Section 13.7.1.3, “CREATE USER Statement”.

To prevent use of encryption and override other `--ssl-xxx` options, invoke the client program with `--ssl-mode=DISABLED`:

```
mysql --ssl-mode=DISABLED
```

To determine whether the current connection with the server uses encryption, check the session value of the `Ssl_cipher` status variable. If the value is empty, the connection is not encrypted. Otherwise, the connection is encrypted and the value indicates the encryption cipher. For example:
Configuring MySQL to Use Encrypted Connections

```
mysql> SHOW SESSION STATUS LIKE 'Ssl_cipher';
+---------------+---------------------------+
| Variable_name | Value                     |
+---------------+---------------------------+
| Ssl_cipher    | DHE-RSA-AES128-GCM-SHA256 |
+---------------+---------------------------+
```

For the `mysql` client, an alternative is to use the `STATUS` or `\s` command and check the `SSL` line:

```
mysql> \s
... SSL: Not in use ...
```

Or:

```
mysql> \s
... SSL: Cipher in use is DHE-RSA-AES128-GCM-SHA256 ...
```

### Configuring Encrypted Connections as Mandatory

For some MySQL deployments it may be not only desirable but mandatory to use encrypted connections (for example, to satisfy regulatory requirements). This section discusses configuration settings that enable you to do this. These levels of control are available:

- You can configure the server to require that clients connect using encrypted connections.
- You can invoke individual client programs to require an encrypted connection, even if the server permits but does not require encryption.
- You can configure individual MySQL accounts to be usable only over encrypted connections.

To require that clients connect using encrypted connections, enable the `require_secure_transport` system variable. For example, put these lines in the server `my.cnf` file:

```
[mysqld]
require_secure_transport=ON
```

Alternatively, to set and persist the value at runtime, use this statement:

```
SET PERSIST require_secure_transport=ON;
```

`SET PERSIST` sets the value for the running MySQL instance. It also saves the value, causing it to be used for subsequent server restarts. See Section 13.7.6.1, “SET Syntax for Variable Assignment”.

With `require_secure_transport` enabled, client connections to the server are required to use some form of secure transport, and the server permits only TCP/IP connections that use SSL, or connections that use a socket file (on Unix) or shared memory (on Windows). The server rejects nonsecure connection attempts, which fail with an `ER_SECURE_TRANSPORT_REQUIRED` error.

To invoke a client program such that it requires an encrypted connection whether or not the server requires encryption, use an `--ssl-mode` option value of `REQUIRED`, `VERIFY_CA`, or `VERIFY_IDENTITY`. For example:

```
mysql --ssl-mode=REQUIRED
mysql --ssl-mode=VERIFY_CA
mysql --ssl-mode=VERIFY_IDENTITY
```
To configure a MySQL account to be usable only over encrypted connections, include a `REQUIRE` clause in the `CREATE USER` statement that creates the account, specifying in that clause the encryption characteristics you require. For example, to require an encrypted connection and the use of a valid X.509 certificate, use `REQUIRE X509`:

```
CREATE USER 'jeffrey'@'localhost' REQUIRE X509;
```

For additional information about the `REQUIRE` clause, see Section 13.7.1.3, “CREATE USER Statement”.

To modify existing accounts that have no encryption requirements, use the `ALTER USER` statement.

### 6.3.2 Encrypted Connection TLS Protocols and Ciphers

MySQL supports multiple TLS protocols and ciphers, and enables configuring which protocols and ciphers to permit for encrypted connections. It is also possible to determine which protocol and cipher the current session uses.

- **Supported Connection TLS Protocols**
- **Connection TLS Protocol Configuration**
- **Connection Cipher Configuration**
- **Connection TLS Protocol Negotiation**
- **Monitoring Current Client Session TLS Protocol and Cipher**

#### Supported Connection TLS Protocols

MySQL supports encrypted connections using the TLSv1, TLSv1.1, TLSv1.2, and TLSv1.3 protocols, listed in order from less secure to more secure. The set of protocols actually permitted for connections is subject to multiple factors:

- **MySQL configuration.** Permitted TLS protocols can be configured on both the server side and client side to include only a subset of the supported TLS protocols. The configuration on both sides must include at least one protocol in common or connection attempts cannot negotiate a protocol to use. For details, see Connection TLS Protocol Negotiation.

- **System-wide host configuration.** The host system may permit only certain TLS protocols, which means that MySQL connections cannot use nonpermitted protocols even if MySQL itself permits them:

  - Suppose that MySQL configuration permits TLSv1, TLSv1.1, and TLSv1.2, but your host system configuration permits only connections that use TLSv1.2 or higher. In this case, you cannot establish MySQL connections that use TLSv1 or TLSv1.1, even though MySQL is configured to permit them, because the host system does not permit them.

  - If MySQL configuration permits TLSv1, TLSv1.1, and TLSv1.2, but your host system configuration permits only connections that use TLSv1.3 or higher, you cannot establish MySQL connections at all, because no protocol permitted by MySQL is permitted by the host system.

  Workarounds for this issue include:

  - Change the system-wide host configuration to permit additional TLS protocols. Consult your operating system documentation for instructions. For example, your system may have an `/etc/ssl/openssl.cnf` file that contains these lines to restrict TLS protocols to TLSv1.2 or higher:

    ```
    [system_default_sect]
    MinProtocol = TLSv1.2
    ```
Changing the value to a lower protocol version or None makes the system more permissive. This workaround has the disadvantage that permitting lower (less secure) protocols may have adverse security consequences.

- If you cannot or prefer not to change the host system TLS configuration, change MySQL applications to use higher (more secure) TLS protocols that are permitted by the host system. This may not be possible for older versions of MySQL that support only lower protocol versions. For example, TLSv1 is the only supported protocol prior to MySQL 5.6.46, so attempts to connect to a pre-5.6.46 server fail even if the client is from a newer MySQL version that supports higher protocol versions. In such cases, an upgrade to a version of MySQL that supports additional TLS versions may be required.

- The SSL library. If the SSL library does not support a particular protocol, neither does MySQL, and any parts of the following discussion that specify that protocol do not apply.

**Note**
Support for the TLSv1.3 protocol is available as of MySQL 8.0.16 (as of MySQL 8.0.18 for the Group Replication component). In addition, to use TLSv1.3, both the MySQL server and the client application must be compiled using OpenSSL 1.1.1 or higher.

### Connection TLS Protocol Configuration

On the server side, the value of the `tls_version` system variable determines which TLS protocols a MySQL server permits for encrypted connections. The `tls_version` value applies to connections from clients, regular source/replica replication connections where this server instance is the source, Group Replication group communication connections, and Group Replication distributed recovery connections where this server instance is the donor. The variable value is a list of one or more comma-separated protocol versions from this list (not case-sensitive): TLSv1, TLSv1.1, TLSv1.2, and (if available) TLSV1.3. By default, this variable lists all protocols supported by the SSL library used to compile MySQL. To determine the value of `tls_version` at runtime, use this statement:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'tls_version';
+---------------+-----------------------+
| Variable_name | Value                 |
+---------------+-----------------------+
| tls_version   | TLSv1,TLSv1.1,TLSv1.2 |
+---------------+-----------------------+
```

To change the value of `tls_version`, set it at server startup. For example, to permit connections that use the TLSv1.1 or TLSv1.2 protocol, but prohibit connections that use the less-secure TLSv1 protocol, use these lines in the server `my.cnf` file:

```
[mysqld]
tls_version=TLSv1.1,TLSv1.2
```

To be even more restrictive and permit only TLSv1.2 connections, set `tls_version` like this:

```
[mysqld]
tls_version=TLSv1.2
```

As of MySQL 8.0.16, `tls_version` can also be changed at runtime. See Server-Side Runtime Configuration and Monitoring for Encrypted Connections.

On the client side, the `--tls-version` option specifies which TLS protocols a client program permits for connections to the server. The format of the option value is the same as for the `tls_version` system variable described previously (a list of one or more comma-separated protocol versions).
For source/replica replication connections where this server instance is the replica, the `MASTER_TLS_VERSION` option for the `CHANGE MASTER TO` statement specifies which TLS protocols the replica permits for connections to the source. The format of the option value is the same as for the `tls_version` system variable described previously. See Section 17.3.1, “Setting Up Replication to Use Encrypted Connections”.

The protocols that can be specified for `MASTER_TLS_VERSION` depend on the SSL library. This option is independent of and not affected by the server `tls_version` value. For example, a server that acts as a replica can be configured with `tls_version` set to TLSv1.3 to permit only incoming connections that use TLSv1.3, but also configured with `MASTER_TLS_VERSION` set to TLSv1.2 to permit only TLSv1.2 for outgoing replica connections to the source.

For Group Replication distributed recovery connections where this server instance is the joining member that initiates distributed recovery (that is, the client), the `group_replication_recovery_tls_version` system variable specifies which protocols are permitted by the client. This option is independent of and not affected by the server `tls_version` value, which applies when this server instance is the donor. A Group Replication server generally participates in distributed recovery both as a donor and as a joining member over the course of its group membership, so both these system variables should be set. See Section 18.5.2, “Securing Group Communication Connections with Secure Socket Layer (SSL)”.

TLS protocol configuration affects which protocol a given connection uses, as described in Connection TLS Protocol Negotiation.

Permitted protocols should be chosen such as not to leave “holes” in the list. For example, these server configuration values do not have holes:

```
tls_version=TLSv1,TLSv1.1,TLSv1.2,TLSv1.3
tls_version=TLSv1.1,TLSv1.2,TLSv1.3
tls_version=TLSv1.2,TLSv1.3
tls_version=TLSv1.3
```

These values do have holes and should not be used:

```
tls_version=TLSv1,TLSv1.2 (TLSv1.1 is missing)
tls_version=TLSv1.1,TLSv1.3 (TLSv1.2 is missing)
```

The prohibition on holes also applies in other configuration contexts, such as for clients or replicas.

The list of permitted protocols should not be empty. If you set a TLS version parameter to the empty string, encrypted connections cannot be established:

- `tls_version`: The server does not permit encrypted incoming connections.
- `--tls-version`: The client does not permit encrypted outgoing connections to the server.
- `MASTER_TLS_VERSION`: The replica does not permit encrypted outgoing connections to the source.

### Connection Cipher Configuration

A default set of ciphers applies to encrypted connections, which can be overridden by explicitly configuring the permitted ciphers. During connection establishment, both sides of a connection must permit some cipher in common or the connection fails. Of the permitted ciphers common to both sides, the SSL library chooses the one supported by the provided certificate that has the highest priority.

To specify a cipher or ciphers applicable for encrypted connections that use TLS protocols up through TLSv1.2:
• Set the `ssl_cipher` system variable on the server side, and use the `--ssl-cipher` option for client programs.

• For regular source/replica replication connections, where this server instance is the source, set the `ssl_cipher` system variable. Where this server instance is the replica, use the `MASTER_SSL_CIPHER` option for the `CHANGE MASTER TO` statement. See Section 17.3.1, “Setting Up Replication to Use Encrypted Connections”.

• For a Group Replication group member, for Group Replication group communication connections and also for Group Replication distributed recovery connections where this server instance is the donor, set the `ssl_cipher` system variable. For Group Replication distributed recovery connections where this server instance is the joining member, use the `group_replication_recovery_ssl_cipher` system variable. See Section 18.5.2, “Securing Group Communication Connections with Secure Socket Layer (SSL)”.

For encrypted connections that use TLSv1.3, OpenSSL 1.1.1 and higher supports the following ciphersuites, the first three of which are enabled by default:

<table>
<thead>
<tr>
<th>Ciphersuites</th>
</tr>
</thead>
<tbody>
<tr>
<td>TLS_AES_128_GCM_SHA256</td>
</tr>
<tr>
<td>TLS_AES_256_GCM_SHA384</td>
</tr>
<tr>
<td>TLS_CHACHA20_POLY1305_SHA256</td>
</tr>
<tr>
<td>TLS_AES_128_CCM_SHA256</td>
</tr>
<tr>
<td>TLS_AES_128_CCM_8_SHA256</td>
</tr>
</tbody>
</table>

To configure the permitted TLSv1.3 ciphersuites explicitly, set the following parameters. In each case, the configuration value is a list of zero or more colon-separated ciphersuite names.

• On the server side, use the `tls_ciphersuites` system variable. If this variable is not set, its default value is `NULL`, which means that the server permits the default set of ciphersuites. If the variable is set to the empty string, no ciphersuites are enabled and encrypted connections cannot be established.

• On the client side, use the `--tls-ciphersuites` option. If this option is not set, the client permits the default set of ciphersuites. If the option is set to the empty string, no ciphersuites are enabled and encrypted connections cannot be established.

• For regular source/replica replication connections, where this server instance is the source, use the `tls_ciphersuites` system variable. Where this server instance is the replica, use the `MASTER_TLS_CIPHERSUITES` option for the `CHANGE MASTER TO` statement. See Section 17.3.1, “Setting Up Replication to Use Encrypted Connections”.

• For a Group Replication group member, for Group Replication group communication connections and also for Group Replication distributed recovery connections where this server instance is the donor, use the `tls_ciphersuites` system variable. For Group Replication distributed recovery connections where this server instance is the joining member, use the `group_replication_recovery_tls_ciphersuites` system variable. See Section 18.5.2, “Securing Group Communication Connections with Secure Socket Layer (SSL)”.

Note

Ciphersuite support is available as of MySQL 8.0.16, but requires that both the MySQL server and the client application be compiled using OpenSSL 1.1.1 or higher.

In MySQL 8.0.16 through 8.0.18, the `MASTER_TLS_CIPHERSUITES` option for the `CHANGE MASTER TO` statement and the `group_replication_recovery_tls_ciphersuites` system variable are not available. In these releases, if TLSv1.3 is used for source/replica replication connections, or in Group Replication for distributed recovery (supported from
MySQL 8.0.18), the replication source or Group Replication donor servers must permit the use of at least one TLSv1.3 ciphersuite that is enabled by default. From MySQL 8.0.19, you can use the options to configure client support for any selection of ciphersuites, including only non-default ciphersuites if you want.

A given cipher may work only with particular TLS protocols, which affects the TLS protocol negotiation process. See Connection TLS Protocol Negotiation.

To determine which ciphers a given server supports, check the session value of the `Ssl_cipher_list` status variable:

```
SHOW SESSION STATUS LIKE 'Ssl_cipher_list';
```

The `Ssl_cipher_list` status variable lists the possible SSL ciphers (empty for non-SSL connections). If MySQL supports TLSv1.3, the value includes the possible TLSv1.3 ciphersuites.

For encrypted connections that use TLSv1.3, MySQL uses the SSL library default ciphersuite list.

For encrypted connections that use TLS protocols up through TLSv1.2, MySQL passes the following default cipher list to the SSL library.

```
ECDHE-ECDSA-AES128-GCM-SHA256
ECDHE-ECDSA-AES256-GCM-SHA384
ECDHE-RSA-AES128-GCM-SHA256

```
Encrypted Connection TLS Protocols and Ciphers

- ECDH-RSA-AES128-GCM-SHA256
- DH-RSA-AES256-GCM-SHA384
- ECDH-RSA-AES256-GCM-SHA384
- DH-RSA-AES128-SHA256
- ECDH-RSA-AES128-SHA256
- DH-RSA-AES256-SHA256
- ECDH-RSA-AES256-SHA384
- ECDHE-RSA-AES128-SHA
- ECDHE-ECDSA-AES128-SHA
- ECDHE-RSA-AES256-SHA
- ECDHE-ECDSA-AES256-SHA
- DHE-DSS-AES128-SHA
- DHE-RSA-AES128-SHA
- TLS_DHE_DSS_WITH_AES_256_CBC_SHA
- DHE-RSA-AES256-SHA
- AES128-SHA
- DH-DSS-AES128-SHA
- ECDH-ECDSA-AES128-SHA
- AES256-SHA
- DH-DSS-AES256-SHA
- ECDH-ECDSA-AES256-SHA
- DH-RSA-AES128-SHA
- ECDH-RSA-AES128-SHA
- DH-RSA-AES256-SHA
- ECDH-RSA-AES256-SHA
- DES-CBC3-SHA

These cipher restrictions are in place:

- The following ciphers are permanently restricted:
  - !DHE-DSS-DES-CBC3-SHA
  - !DHE-RSA-DES-CBC3-SHA
  - !ECDH-RSA-DES-CBC3-SHA
  - !ECDHE-RSA-DES-CBC3-SHA
  - !ECDHE-ECDSA-DES-CBC3-SHA

- The following categories of ciphers are permanently restricted:
  - !aNULL
  - !eNULL
  - !EXPORT
  - !LOW
  - !MD5
  - !DES
  - !RC2
  - !RC4
  - !PSK
  - !SSLv3

If the server is started with the `ssl_cert` system variable set to a certificate that uses any of the preceding restricted ciphers or cipher categories, the server starts with support for encrypted connections disabled.

**Connection TLS Protocol Negotiation**

Connection attempts in MySQL negotiate use of the highest TLS protocol version available on both sides for which a protocol-compatible encryption cipher is available on both sides. The negotiation process depends on factors such as the SSL library used to compile the server and client, the TLS protocol and encryption cipher configuration, and which key size is used:

- For a connection attempt to succeed, the server and client TLS protocol configuration must permit some protocol in common.
• Similarly, the server and client encryption cipher configuration must permit some cipher in common. A given cipher may work only with particular TLS protocols, so a protocol available to the negotiation process is not chosen unless there is also a compatible cipher.

• If TLSv1.3 is available, it is used if possible. (This means that server and client configuration both must permit TLSv1.3, and both must also permit some TLSv1.3-compatible encryption cipher.) Otherwise, MySQL continues through the list of available protocols, using TLSv1.2 if possible, and so forth. Negotiation proceeds from more secure protocols to less secure. Negotiation order is independent of the order in which protocols are configured. For example, negotiation order is the same regardless of whether `tls_version` has a value of `TLSv1,TLSv1.1,TLSv1.2,TLSv1.3` or `TLSv1.3,TLSv1.2,TLSv1.1,TLSv1`.

• TLSv1.2 does not work with all ciphers that have a key size of 512 bits or less. To use this protocol with such a key, set the `ssl_cipher` system variable on the server side or use the `--ssl-cipher` client option to specify the cipher name explicitly:

<table>
<thead>
<tr>
<th>Cipher Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>AES128-SHA</td>
</tr>
<tr>
<td>AES128-SHA256</td>
</tr>
<tr>
<td>AES256-SHA</td>
</tr>
<tr>
<td>AES256-SHA256</td>
</tr>
<tr>
<td>CAMELLIA128-SHA</td>
</tr>
<tr>
<td>CAMELLIA256-SHA</td>
</tr>
<tr>
<td>DES-CBC3-SHA</td>
</tr>
<tr>
<td>DHE-RSA-AES256-SHA</td>
</tr>
<tr>
<td>RC4-MD5</td>
</tr>
<tr>
<td>RC4-SHA</td>
</tr>
<tr>
<td>SEED-SHA</td>
</tr>
</tbody>
</table>

• For better security, use a certificate with an RSA key size of at least 2048 bits.

If the server and client do not have a permitted protocol in common, and a protocol-compatible cipher in common, the server terminates the connection request. Examples:

• If the server is configured with `tls_version=TLSv1.1, TLSv1.2`:
  
  - Connection attempts fail for clients invoked with `--tls-version=TLSv1`, and for older clients that support only TLSv1.

  - Similarly, connection attempts fail for replicas configured with `MASTER_TLS_VERSION = 'TLSv1'`, and for older replicas that support only TLSv1.

• If the server is configured with `tls_version=TLSv1` or is an older server that supports only TLSv1:

  - Connection attempts fail for clients invoked with `--tls-version=TLSv1.1, TLSv1.2`.

  - Similarly, connection attempts fail for replicas configured with `MASTER_TLS_VERSION = 'TLSv1.1, TLSv1.2'`.

MySQL permits specifying a list of protocols to support. This list is passed directly down to the underlying SSL library and is ultimately up to that library what protocols it actually enables from the supplied list. Please refer to the MySQL source code and the OpenSSL `SSL_CTX_new()` documentation for information about how the SSL library handles this.

### Monitoring Current Client Session TLS Protocol and Cipher

To determine which encryption TLS protocol and cipher the current client session uses, check the session values of the `Ssl_version` and `Ssl_cipher` status variables:

```sql
mysql> SELECT * FROM performance_schema.session_status
WHERE VARIABLE_NAME IN ('Ssl_version','Ssl_cipher');
```

1246
Creating SSL and RSA Certificates and Keys

<table>
<thead>
<tr>
<th>VARIABLE_NAME</th>
<th>VARIABLE_VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ssl_cipher</td>
<td>DHE-RSA-AES128-GCM-SHA256</td>
</tr>
<tr>
<td>Ssl_version</td>
<td>TLSv1.2</td>
</tr>
</tbody>
</table>

If the connection is not encrypted, both variables have an empty value.

### 6.3.3 Creating SSL and RSA Certificates and Keys

The following discussion describes how to create the files required for SSL and RSA support in MySQL. File creation can be performed using facilities provided by MySQL itself, or by invoking the `openssl` command directly.

SSL certificate and key files enable MySQL to support encrypted connections using SSL. See Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

RSA key files enable MySQL to support secure password exchange over unencrypted connections for accounts authenticated by the `sha256_password` or `caching_sha2_password` plugin. See Section 6.4.1.3, “SHA-256 Pluggable Authentication”, and Section 6.4.1.2, “Caching SHA-2 Pluggable Authentication”.

#### 6.3.3.1 Creating SSL and RSA Certificates and Keys using MySQL

MySQL provides these ways to create the SSL certificate and key files and RSA key-pair files required to support encrypted connections using SSL and secure password exchange using RSA over unencrypted connections, if those files are missing:

- The server can autogenerate these files at startup, for MySQL distributions.
- Users can invoke the `mysql_ssl_rsa_setup` utility manually.
- For some distribution types, such as RPM and DEB packages, `mysql_ssl_rsa_setup` invocation occurs during data directory initialization. In this case, the MySQL distribution need not have been compiled using OpenSSL as long as the `openssl` command is available.

**Important**

Server autogeneration and `mysql_ssl_rsa_setup` help lower the barrier to using SSL by making it easier to generate the required files. However, certificates generated by these methods are self-signed, which may not be very secure. After you gain experience using such files, consider obtaining certificate/key material from a registered certificate authority.

- **Automatic SSL and RSA File Generation**
- **Manual SSL and RSA File Generation Using mysql_ssl_rsa_setup**
- **SSL and RSA File Characteristics**

#### Automatic SSL and RSA File Generation

For MySQL distributions compiled using OpenSSL, the MySQL server has the capability of automatically generating missing SSL and RSA files at startup. The `auto_generate_certs`, `sha256_password_auto_generate_rsa_keys`, and `caching_sha2_password_auto_generate_rsa_keys` system variables control automatic generation of these files. These variables are enabled by default. They can be enabled at startup and inspected but not set at runtime.
Creating SSL and RSA Certificates and Keys

At startup, the server automatically generates server-side and client-side SSL certificate and key files in the data directory if the `auto_generate_certs` system variable is enabled, no SSL options other than `--ssl` are specified, and the server-side SSL files are missing from the data directory. These files enable encrypted client connections using SSL; see Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

1. The server checks the data directory for SSL files with the following names:

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ca.pem</td>
<td>Self-signed CA certificate</td>
</tr>
<tr>
<td>server-cert.pem</td>
<td>Server certificate</td>
</tr>
<tr>
<td>server-key.pem</td>
<td>Server private key</td>
</tr>
</tbody>
</table>

2. If any of those files are present, the server creates no SSL files. Otherwise, it creates them, plus some additional files:

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ca.pem</td>
<td>CA private key</td>
</tr>
<tr>
<td>ca-key.pem</td>
<td>CA private key</td>
</tr>
<tr>
<td>server-cert.pem</td>
<td>Server certificate</td>
</tr>
<tr>
<td>server-key.pem</td>
<td>Server private key</td>
</tr>
<tr>
<td>client-cert.pem</td>
<td>Client certificate</td>
</tr>
<tr>
<td>client-key.pem</td>
<td>Client private key</td>
</tr>
</tbody>
</table>

3. If the server autogenerates SSL files, it uses the names of the `ca.pem`, `server-cert.pem`, and `server-key.pem` files to set the corresponding system variables (`ssl_ca`, `ssl_cert`, `ssl_key`).

At startup, the server automatically generates RSA private/public key-pair files in the data directory if all of these conditions are true: The `sha256_password_auto_generate_rsa_keys` or `caching_sha2_password_auto_generate_rsa_keys` system variable is enabled; no RSA options are specified; the RSA files are missing from the data directory. These key-pair files enable secure password exchange using RSA over unencrypted connections for accounts authenticated by the `sha256_password` or `caching_sha2_password` plugin; see Section 6.4.1.3, “SHA-256 Pluggable Authentication”, and Section 6.4.1.2, “Caching SHA-2 Pluggable Authentication”.

1. The server checks the data directory for RSA files with the following names:

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>private_key.pem</td>
<td>Private member of private/public key pair</td>
</tr>
<tr>
<td>public_key.pem</td>
<td>Public member of private/public key pair</td>
</tr>
</tbody>
</table>

2. If any of these files are present, the server creates no RSA files. Otherwise, it creates them.

3. If the server autogenerates the RSA files, it uses their names to set the corresponding system variables (`sha256_password_private_key_path` and `sha256_password_public_key_path`; `caching_sha2_password_private_key_path` and `caching_sha2_password_public_key_path`).

Manual SSL and RSA File Generation Using `mysql_ssl_rsa_setup`

MySQL distributions include a `mysql_ssl_rsa_setup` utility that can be invoked manually to generate SSL and RSA files. This utility is included with all MySQL distributions, but it does require that the `openssl` command be available. For usage instructions, see Section 4.4.3, “`mysql_ssl_rsa_setup — Create SSL/RSA Files`”.

SSL and RSA File Characteristics

SSL and RSA files created automatically by the server or by invoking `mysql_ssl_rsa_setup` have these characteristics:

- SSL and RSA keys are have a size of 2048 bits.
• The SSL CA certificate is self signed.

• The SSL server and client certificates are signed with the CA certificate and key, using the `sha256WithRSAEncryption` signature algorithm.

• SSL certificates use these Common Name (CN) values, with the appropriate certificate type (CA, Server, Client):

| ca.pem:         | MySQL_Server_suffix_Auto_Generated_CA_Certificate |
| server-cert.pem: | MySQL_Server_suffix_Auto_Generated_Server_Certificate |
| client-cert.pem: | MySQL_Server_suffix_Auto_Generated_Client_Certificate |

The `suffix` value is based on the MySQL version number. For files generated by `mysql_ssl_rsa_setup`, the suffix can be specified explicitly using the `--suffix` option.

For files generated by the server, if the resulting CN values exceed 64 characters, the `_suffix` portion of the name is omitted.

• SSL files have blank values for Country (C), State or Province (ST), Organization (O), Organization Unit Name (OU) and email address.

• SSL files created by the server or by `mysql_ssl_rsa_setup` are valid for ten years from the time of generation.

• RSA files do not expire.

• SSL files have different serial numbers for each certificate/key pair (1 for CA, 2 for Server, 3 for Client).

• Files created automatically by the server are owned by the account that runs the server. Files created using `mysql_ssl_rsa_setup` are owned by the user who invoked that program. This can be changed on systems that support the `chown()` system call if the program is invoked by root and the `--uid` option is given to specify the user who should own the files.

• On Unix and Unix-like systems, the file access mode is 644 for certificate files (that is, world readable) and 600 for key files (that is, accessible only by the account that runs the server).

To see the contents of an SSL certificate (for example, to check the range of dates over which it is valid), invoke `openssl` directly:

```
openssl x509 -text -in ca.pem
openssl x509 -text -in server-cert.pem
openssl x509 -text -in client-cert.pem
```

It is also possible to check SSL certificate expiration information using this SQL statement:

```sql
mysql> SHOW STATUS LIKE 'Ssl_server_not%';
+-----------------------+--------------------------+
| Variable_name         | Value                    |
+-----------------------+--------------------------+
| Ssl_server_not_after  | Apr 28 14:16:39 2027 GMT |
| Ssl_server_not_before | May  1 14:16:39 2017 GMT |
+-----------------------+--------------------------+
```

### 6.3.3.2 Creating SSL Certificates and Keys Using openssl

This section describes how to use the `openssl` command to set up SSL certificate and key files for use by MySQL servers and clients. The first example shows a simplified procedure such as you might use from the command line. The second shows a script that contains more detail. The first two examples are intended for use on Unix and both use the `openssl` command that is part of OpenSSL. The third example describes how to set up SSL files on Windows.
Creating SSL and RSA Certificates and Keys

Note
There are easier alternatives to generating the files required for SSL than the procedure described here: Let the server autogenerate them or use the mysql_ssl_rsa_setup program. See Section 6.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”.

Important
Whatever method you use to generate the certificate and key files, the Common Name value used for the server and client certificates/keys must each differ from the Common Name value used for the CA certificate. Otherwise, the certificate and key files do not work for servers compiled using OpenSSL. A typical error in this case is:

ERROR 2026 (HY000): SSL connection error:
error:00000001:lib(0):func(0):reason(1)

- Example 1: Creating SSL Files from the Command Line on Unix
- Example 2: Creating SSL Files Using a Script on Unix
- Example 3: Creating SSL Files on Windows

Example 1: Creating SSL Files from the Command Line on Unix

The following example shows a set of commands to create MySQL server and client certificate and key files. You must respond to several prompts by the openssl commands. To generate test files, you can press Enter to all prompts. To generate files for production use, you should provide nonempty responses.

```bash
# Create clean environment
rm -rf newcerts
mkdir newcerts && cd newcerts

# Create CA certificate
openssl genrsa 2048 > ca-key.pem
openssl req -new -x509 -nodes -days 3600 -key ca-key.pem -out ca.pem

# Create server certificate, remove passphrase, and sign it
# server-cert.pem = public key, server-key.pem = private key
openssl req -newkey rsa:2048 -days 3600 -nodes -keyout server-key.pem -out server-req.pem
openssl rsa -in server-key.pem -out server-key.pem
openssl x509 -req -in server-req.pem -days 3600 -key ca-key.pem -CAkey ca-key.pem -set_serial 01 -out server-cert.pem

# Create client certificate, remove passphrase, and sign it
# client-cert.pem = public key, client-key.pem = private key
openssl req -newkey rsa:2048 -days 3600 -nodes -keyout client-key.pem -out client-req.pem
openssl rsa -in client-key.pem -out client-key.pem
openssl x509 -req -in client-req.pem -days 3600 -key ca-key.pem -CAkey ca-key.pem -set_serial 01 -out client-cert.pem
```

After generating the certificates, verify them:

```bash
openssl verify -CAfile ca.pem server-cert.pem client-cert.pem
```

You should see a response like this:

```bash
server-cert.pem: OK
client-cert.pem: OK
```
Creating SSL and RSA Certificates and Keys

To see the contents of a certificate (for example, to check the range of dates over which a certificate is valid), invoke `openssl` like this:

```bash
openssl x509 -text -in ca.pem
openssl x509 -text -in server-cert.pem
openssl x509 -text -in client-cert.pem
```

Now you have a set of files that can be used as follows:

- **ca.pem**: Use this to set the `ssl_ca` system variable on the server side and the `--ssl-ca` option on the client side. (The CA certificate, if used, must be the same on both sides.)

- **server-cert.pem, server-key.pem**: Use these to set the `ssl_cert` and `ssl_key` system variables on the server side.

- **client-cert.pem, client-key.pem**: Use these as the arguments to the `--ssl-cert` and `--ssl-key` options on the client side.

For additional usage instructions, see Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

**Example 2: Creating SSL Files Using a Script on Unix**

Here is an example script that shows how to set up SSL certificate and key files for MySQL. After executing the script, use the files for SSL connections as described in Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

```
DIR=`pwd`/openssl
PRIV=$DIR/private
mkdir $DIR $PRIV $DIR/newcerts
cp /usr/share/ssl/openssl.cnf $DIR
replace ./demoCA $DIR -- $DIR/openssl.cnf

# Create necessary files: $database, $serial and $new_certs_dir
directory (optional)
touch $DIR/index.txt
echo "01" > $DIR/serial

# Generation of Certificate Authority(CA)
openssl req -new -x509 -keyout $PRIV/cakey.pem -out $DIR/ca.pem
  -days 3600 -config $DIR/openssl.cnf

# Sample output:
# Using configuration from /home/jones/openssl/openssl.cnf
# Generating a 1024 bit RSA private key
# ................++++++
# .........++++++
# writing new private key to '/home/jones/openssl/private/cakey.pem'

Example 3: Creating SSL Files on Windows

Download OpenSSL for Windows if it is not installed on your system. An overview of available packages can be seen here:

http://www.slproweb.com/products/Win32OpenSSL.html

Choose the Win32 OpenSSL Light or Win64 OpenSSL Light package, depending on your architecture (32-bit or 64-bit). The default installation location is C:\OpenSSL-Win32 or C:\OpenSSL-Win64, depending on which package you downloaded. The following instructions assume a default location of C:\OpenSSL-Win32. Modify this as necessary if you are using the 64-bit package.

If a message occurs during setup indicating '...critical component is missing: Microsoft Visual C++ 2008 Redistributables', cancel the setup and download one of the following packages as well, again depending on your architecture (32-bit or 64-bit):

- Visual C++ 2008 Redistributables (x86), available at:

- Visual C++ 2008 Redistributables (x64), available at:

After installing the additional package, restart the OpenSSL setup procedure.

During installation, leave the default C:\OpenSSL-Win32 as the install path, and also leave the default option 'Copy OpenSSL DLL files to the Windows system directory' selected.

When the installation has finished, add C:\OpenSSL-Win32\bin to the Windows System Path variable of your server (depending on your version of Windows, the following path-setting instructions might differ slightly):

1. On the Windows desktop, right-click the My Computer icon, and select Properties.
2. Select the Advanced tab from the System Properties menu that appears, and click the Environment Variables button.
3. Under System Variables, select Path, then click the Edit button. The Edit System Variable dialogue should appear.
4. Add ';C:\OpenSSL-Win32\bin' to the end (notice the semicolon).
5. Press OK 3 times.

6. Check that OpenSSL was correctly integrated into the Path variable by opening a new command console (Start>Run>cmd.exe) and verifying that OpenSSL is available:

Microsoft Windows [Version ...]
Copyright (c) 2006 Microsoft Corporation. All rights reserved.
C:\Windows\system32>cd \\
C:\>openssl
OpenSSL> exit <<< If you see the OpenSSL prompt, installation was successful.
C:\>

After OpenSSL has been installed, use instructions similar to those from Example 1 (shown earlier in this section), with the following changes:

- Change the following Unix commands:

```
# Create clean environment
rm -rf newcerts
mkdir newcerts && cd newcerts
```

On Windows, use these commands instead:

```
# Create clean environment
md c:\newcerts
cd c:\newcerts
```

- When a '\ ' character is shown at the end of a command line, this '\ ' character must be removed and the command lines entered all on a single line.

After generating the certificate and key files, to use them for SSL connections, see Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

6.3.3.3 Creating RSA Keys Using openssl

This section describes how to use the **openssl** command to set up the RSA key files that enable MySQL to support secure password exchange over unencrypted connections for accounts authenticated by the **sha256_password** and **caching_sha2_password** plugins.

**Note**

There are easier alternatives to generating the files required for RSA than the procedure described here: Let the server autogenerate them or use the **mysql_ssl_rsa_setup** program. See Section 6.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”.

To create the RSA private and public key-pair files, run these commands while logged into the system account used to run the MySQL server so that the files are owned by that account:

```
openssl genrsa -out private_key.pem 2048
openssl rsa -in private_key.pem -pubout -out public_key.pem
```

Those commands create 2,048-bit keys. To create stronger keys, use a larger value.

Then set the access modes for the key files. The private key should be readable only by the server, whereas the public key can be freely distributed to client users:

```
chmod 400 private_key.pem
```
6.3.4 Connecting to MySQL Remotely from Windows with SSH

This section describes how to get an encrypted connection to a remote MySQL server with SSH. The information was provided by David Carlson <dcarlson@mplcomm.com>.

1. Install an SSH client on your Windows machine. For a comparison of SSH clients, see http://en.wikipedia.org/wiki/Comparison_of_SSH_clients.

2. Start your Windows SSH client. Set Host_Name = yourmysqlserver_URL_or_IP. Set userid=your_userid to log in to your server. This userid value might not be the same as the user name of your MySQL account.

3. Set up port forwarding. Either do a remote forward (Set local_port: 3306, remote_host: yourmysqlservername_or_ip, remote_port: 3306) or a local forward (Set port: 3306, host: localhost, remote port: 3306).

4. Save everything, otherwise you must redo it the next time.

5. Log in to your server with the SSH session you just created.

6. On your Windows machine, start some ODBC application (such as Access).

7. Create a new file in Windows and link to MySQL using the ODBC driver the same way you normally do, except type in localhost for the MySQL host server, not yourmysqlservername.

At this point, you should have an ODBC connection to MySQL, encrypted using SSH.

6.4 Security Components and Plugins

MySQL includes several components and plugins that implement security features:

- Plugins for authenticating attempts by clients to connect to MySQL Server. Plugins are available for several authentication protocols. For general discussion of the authentication process, see Section 6.2.17, “Pluggable Authentication”. For characteristics of specific authentication plugins, see Section 6.4.1, “Authentication Plugins”.

- A password-validation component for implementing password strength policies and assessing the strength of potential passwords. See Section 6.4.3, “The Password Validation Component”.

- Keyring plugins that provide secure storage for sensitive information. See Section 6.4.4, “The MySQL Keyring”.

- (MySQL Enterprise Edition only) MySQL Enterprise Audit, implemented using a server plugin, uses the open MySQL Audit API to enable standard, policy-based monitoring and logging of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines. See Section 6.4.5, “MySQL Enterprise Audit”.

- A user-defined function enables applications to add their own message events to the audit log. See Section 6.4.6, “The Audit Message Component”.

- (MySQL Enterprise Edition only) MySQL Enterprise Firewall, an application-level firewall that enables database administrators to permit or deny SQL statement execution based on matching against lists of accepted statement patterns. This helps harden MySQL Server against attacks such as SQL injection or
6.4.1 Authentication Plugins

The following sections describe pluggable authentication methods available in MySQL and the plugins that implement these methods. For general discussion of the authentication process, see Section 6.2.17, "Pluggable Authentication".

The default plugin is indicated by the value of the `default_authentication_plugin` system variable.

6.4.1.1 Native Pluggable Authentication

MySQL includes a `mysql_native_password` plugin that implements native authentication; that is, authentication based on the password hashing method in use from before the introduction of pluggable authentication.

The following table shows the plugin names on the server and client sides.

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td>mysql_native_password</td>
</tr>
<tr>
<td>Client-side plugin</td>
<td>mysql_native_password</td>
</tr>
<tr>
<td>Library file</td>
<td>None (plugins are built in)</td>
</tr>
</tbody>
</table>

The following sections provide installation and usage information specific to native pluggable authentication:

• Installing Native Pluggable Authentication

• Using Native Pluggable Authentication

For general information about pluggable authentication in MySQL, see Section 6.2.17, “Pluggable Authentication”.

Installing Native Pluggable Authentication

The `mysql_native_password` plugin exists in server and client forms:

• The server-side plugin is built into the server, need not be loaded explicitly, and cannot be disabled by unloading it.

• The client-side plugin is built into the `libmysqlclient` client library and is available to any program linked against `libmysqlclient`.

Using Native Pluggable Authentication

MySQL client programs use `mysql_native_password` by default. The `--default-auth` option can be used as a hint about which client-side plugin the program can expect to use:
6.4.1.2 Caching SHA-2 Pluggable Authentication

MySQL provides two authentication plugins that implement SHA-256 hashing for user account passwords:

- **sha256_password**: Implements basic SHA-256 authentication.
- **caching_sha2_password**: Implements SHA-256 authentication (like sha256_password), but uses caching on the server side for better performance and has additional features for wider applicability.

This section describes the caching SHA-2 authentication plugin. For information about the original basic (noncaching) plugin, see Section 6.4.1.3, “SHA-256 Pluggable Authentication”.

**Important**

In MySQL 8.0, caching_sha2_password is the default authentication plugin rather than mysql_native_password. For information about the implications of this change for server operation and compatibility of the server with clients and connectors, see caching_sha2_password as the Preferred Authentication Plugin.

**Important**

To connect to the server using an account that authenticates with the caching_sha2_password plugin, you must use either a secure connection or an unencrypted connection that supports password exchange using an RSA key pair, as described later in this section. Either way, the caching_sha2_password plugin uses MySQL’s encryption capabilities. See Section 6.3, “Using Encrypted Connections”.

**Note**

In the name sha256_password, “sha256” refers to the 256-bit digest length the plugin uses for encryption. In the name caching_sha2_password, “sha2” refers more generally to the SHA-2 class of encryption algorithms, of which 256-bit encryption is one instance. The latter name choice leaves room for future expansion of possible digest lengths without changing the plugin name.

The caching_sha2_password plugin has these advantages, compared to sha256_password:

- On the server side, an in-memory cache enables faster reauthentication of users who have connected previously when they connect again.

- RSA-based password exchange is available regardless of the SSL library against which MySQL is linked.

- Support is provided for client connections that use the Unix socket-file and shared-memory protocols.

The following table shows the plugin names on the server and client sides.

**Table 6.13 Plugin and Library Names for SHA-2 Authentication**

The following sections provide installation and usage information specific to caching SHA-2 pluggable authentication:

- Installing SHA-2 Pluggable Authentication
- Using SHA-2 Pluggable Authentication
- Cache Operation for SHA-2 Pluggable Authentication

For general information about pluggable authentication in MySQL, see Section 6.2.17, “Pluggable Authentication”.

### Installing SHA-2 Pluggable Authentication

The `caching_sha2_password` plugin exists in server and client forms:

- The server-side plugin is built into the server, need not be loaded explicitly, and cannot be disabled by unloading it.
- The client-side plugin is built into the `libmysqlclient` client library and is available to any program linked against `libmysqlclient`.

The server-side plugin uses the `sha2_cache_cleaner` audit plugin as a helper to perform password cache management. `sha2_cache_cleaner`, like `caching_sha2_password`, is built in and need not be installed.

### Using SHA-2 Pluggable Authentication

To set up an account that uses the `caching_sha2_password` plugin for SHA-256 password hashing, use the following statement, where `password` is the desired account password:

```
CREATE USER 'sha2user'@'localhost'
IDENTIFIED WITH caching_sha2_password BY 'password';
```

The server assigns the `caching_sha2_password` plugin to the account and uses it to encrypt the password using SHA-256, storing those values in the `plugin` and `authentication_string` columns of the `mysql.user` system table.

The preceding instructions do not assume that `caching_sha2_password` is the default authentication plugin. If `caching_sha2_password` is the default authentication plugin, a simpler `CREATE USER` syntax can be used.

To start the server with the default authentication plugin set to `caching_sha2_password`, put these lines in the server option file:

```
[mysqld]
default_authentication_plugin=caching_sha2_password
```

That causes the `caching_sha2_password` plugin to be used by default for new accounts. As a result, it is possible to create the account and set its password without naming the plugin explicitly:

```
CREATE USER 'sha2user'@'localhost' IDENTIFIED BY 'password';
```

Another consequence of setting `default_authentication_plugin` to `caching_sha2_password` is that, to use some other plugin for account creation, you must specify that plugin explicitly. For example, to use the `mysql_native_password` plugin, use this statement:
CREATE USER 'nativeuser'@'localhost'
IDENTIFIED WITH mysql_native_password BY 'password';

The `caching_sha2_password` plugin supports connections over secure transport. If you follow the RSA configuration procedure given later in this section, it also supports encrypted password exchange using RSA over unencrypted connections. RSA support has these characteristics:

- On the server side, two system variables name the RSA private and public key-pair files: `caching_sha2_password_private_key_path` and `caching_sha2_password_public_key_path`. The database administrator must set these variables at server startup if the key files to use have names that differ from the system variable default values.

- The server uses the `caching_sha2_password_auto_generate_rsa_keys` system variable to determine whether to automatically generate the RSA key-pair files. See Section 6.3.3, “Creating SSL and RSA Certificates and Keys”.

- The `Caching_sha2_password_rsa_public_key` status variable displays the RSA public key value used by the `caching_sha2_password` authentication plugin.

- Clients that are in possession of the RSA public key can perform RSA key-pair-based password exchange with the server during the connection process, as described later.

- For connections by accounts that authenticate with `caching_sha2_password` and RSA key-pair-based password exchange, the server does not send the RSA public key to clients by default. Clients can use a client-side copy of the required public key, or request the public key from the server.

Use of a trusted local copy of the public key enables the client to avoid a round trip in the client/server protocol, and is more secure than requesting the public key from the server. On the other hand, requesting the public key from the server is more convenient (it requires no management of a client-side file) and may be acceptable in secure network environments.

- For command-line clients, use the `--server-public-key-path` option to specify the RSA public key file. Use the `--get-server-public-key` option to request the public key from the server.

  The following programs support the two options: *mysql*, *mysqlsh*, *mysqladmin*, *mysqlbinlog*, *mysqlcheck*, *mysqldump*, *mysqlimport*, *mysqlpump*, *mysqlshow*, *mysqldump*, *mysqlslap*, *mysqltest*, *mysql_upgrade*.

- For programs that use the C API, call `mysql_options()` to specify the RSA public key file by passing the `MYSQL_SERVER_PUBLIC_KEY` option and the name of the file, or request the public key from the server by passing the `MYSQL_OPT_GET_SERVER_PUBLIC_KEY` option.

- For replicas, use the `CHANGE MASTER TO` statement with the `MASTER_PUBLIC_KEY_PATH` option to specify the RSA public key file, or the `GET_MASTER_PUBLIC_KEY` option to request the public key from the source. For Group Replication, the `group_replication_recovery_public_key_path` and `group_replication_recovery_get_public_key` system variables serve the same purpose.

  In all cases, if the option is given to specify a valid public key file, it takes precedence over the option to request the public key from the server.

For clients that use the `caching_sha2_password` plugin, passwords are never exposed as cleartext when connecting to the server. How password transmission occurs depends on whether a secure connection or RSA encryption is used:

- If the connection is secure, an RSA key pair is unnecessary and is not used. This applies to TCP connections encrypted using TLS, as well as Unix socket-file and shared-memory connections. The password is sent as cleartext but cannot be snooped because the connection is secure.
• If the connection is not secure, an RSA key pair is used. This applies to TCP connections not encrypted using without TLS and named-pipe connections. RSA is used only for password exchange between client and server, to prevent password snooping. When the server receives the encrypted password, it decrypts it. A scramble is used in the encryption to prevent repeat attacks.

To enable use of an RSA key pair for password exchange during the client connection process, use the following procedure:

1. Create the RSA private and public key-pair files using the instructions in Section 6.3.3, “Creating SSL and RSA Certificates and Keys”.

2. If the private and public key files are located in the data directory and are named private_key.pem and public_key.pem (the default values of the caching_sha2_password_private_key_path and caching_sha2_password_public_key_path system variables), the server uses them automatically at startup.

   Otherwise, to name the key files explicitly, set the system variables to the key file names in the server option file. If the files are located in the server data directory, you need not specify their full path names:

   ```
   [mysqld]
   caching_sha2_password_private_key_path=myprivkey.pem
   caching_sha2_password_public_key_path=mypubkey.pem
   ```

   If the key files are not located in the data directory, or to make their locations explicit in the system variable values, use full path names:

   ```
   [mysqld]
   caching_sha2_password_private_key_path=/usr/local/mysql/myprivkey.pem
   caching_sha2_password_public_key_path=/usr/local/mysql/mypubkey.pem
   ```

3. Restart the server, then connect to it and check the `Caching_sha2_password_rsa_public_key` status variable value. The value actually displayed differs from that shown here, but should be nonempty:

   ```
   mysql> SHOW STATUS LIKE 'Caching_sha2_password_rsa_public_key'
   *************************** 1. row ***************************
   Variable_name: Caching_sha2_password_rsa_public_key
   Value: -----BEGIN PUBLIC KEY-----
   MIGfMA0GCSqGSIb3DQEBAQUAA4GNADCBiQKBgQDO9nRUDd+KvSZgY7cNB2MnpwX6
   NVel1Pbw3kF07u18nJ91wc99Du/E71w6CVxw7VKrXPe8bVQuzg5y45Nz/ckaaJa
   aLqJ08C1dmNvnyU54OT/1/Lcs2xIyfaDme8fcCJ64Zw7NkY2kt1IMJUB5Qd5kJ
   g8a7EtKwyhHbbc3QIDAQAB
   -----END PUBLIC KEY-----
   ```

   If the value is empty, the server found some problem with the key files. Check the error log for diagnostic information.

After the server has been configured with the RSA key files, accounts that authenticate with the caching_sha2_password plugin have the option of using those key files to connect to the server. As mentioned previously, such accounts can use either a secure connection (in which case RSA is not used) or an unencrypted connection that performs password exchange using RSA. Suppose that an unencrypted connection is used. For example:

   ```
   shell> mysql --ssl-mode=DISABLED -u sha2user -p
   Enter password: password
   ```

For this connection attempt by sha2user, the server determines that caching_sha2_password is the appropriate authentication plugin and invokes it (because that was the plugin specified at CREATE USER time). The plugin finds that the connection is not encrypted and thus requires the password to be
transmitted using RSA encryption. However, the server does not send the public key to the client, and the client provided no public key, so it cannot encrypt the password and the connection fails:

```
ERROR 2061 (HY000): Authentication plugin 'caching_sha2_password' reported error: Authentication requires secure connection.
```

To request the RSA public key from the server, specify the `--get-server-public-key` option:

```
shell> mysql --ssl-mode=DISABLED -u sha2user -p --get-server-public-key
Enter password: password
```

In this case, the server sends the RSA public key to the client, which uses it to encrypt the password and returns the result to the server. The plugin uses the RSA private key on the server side to decrypt the password and accepts or rejects the connection based on whether the password is correct.

Alternatively, if the client has a file containing a local copy of the RSA public key required by the server, it can specify the file using the `--server-public-key-path` option:

```
shell> mysql --ssl-mode=DISABLED -u sha2user -p --server-public-key-path=file_name
Enter password: password
```

In this case, the client uses the public key to encrypt the password and returns the result to the server. The plugin uses the RSA private key on the server side to decrypt the password and accepts or rejects the connection based on whether the password is correct.

The public key value in the file named by the `--server-public-key-path` option should be the same as the key value in the server-side file named by the `caching_sha2_password_public_key_path` system variable. If the key file contains a valid public key value but the value is incorrect, an access-denied error occurs. If the key file does not contain a valid public key, the client program cannot use it.

Client users can obtain the RSA public key two ways:

- The database administrator can provide a copy of the public key file.
- A client user who can connect to the server some other way can use a `SHOW STATUS LIKE 'Caching_sha2_password_rsa_public_key'` statement and save the returned key value in a file.

**Cache Operation for SHA-2 Pluggable Authentication**

On the server side, the `caching_sha2_password` plugin uses an in-memory cache for faster authentication of clients who have connected previously. Entries consist of account-name/password-hash pairs. The cache works like this:

1. When a client connects, `caching_sha2_password` checks whether the client and password match some cache entry. If so, authentication succeeds.

2. If there is no matching cache entry, the plugin attempts to verify the client against the credentials in the `mysql.user` system table. If this succeeds, `caching_sha2_password` adds an entry for the client to the hash. Otherwise, authentication fails and the connection is rejected.

In this way, when a client first connects, authentication against the `mysql.user` system table occurs. When the client connects subsequently, faster authentication against the cache occurs.

Password cache operations other than adding entries are handled by the `sha2_cache_cleaner` audit plugin, which performs these actions on behalf of `caching_sha2_password`:

- It clears the cache entry for any account that is renamed or dropped, or any account for which the credentials or authentication plugin are changed.

- It empties the cache when the `FLUSH PRIVILEGES` statement is executed.
• It empties the cache at server shutdown. (This means the cache is not persistent across server restarts.)

Cache clearing operations affect the authentication requirements for subsequent client connections. For each user account, the first client connection for the user after any of the following operations must use a secure connection (made using TCP using TLS credentials, a Unix socket file, or shared memory) or RSA key pair-based password exchange:

• After account creation.

• After a password change for the account.

• After `RENAME USER` for the account.

• After `FLUSH PRIVILEGES`.

`FLUSH PRIVILEGES` clears the entire cache and affects all accounts that use the `caching_sha2_password` plugin. The other operations clear specific cache entries and affect only accounts that are part of the operation.

Once the user authenticates successfully, the account is entered into the cache and subsequent connections do not require a secure connection or the RSA key pair, until another cache clearing event occurs that affects the account. (When the cache can be used, the server uses a challenge-response mechanism that does not use cleartext password transmission and does not require a secure connection.)

### 6.4.1.3 SHA-256 Pluggable Authentication

MySQL provides two authentication plugins that implement SHA-256 hashing for user account passwords:

• `sha256_password`: Implements basic SHA-256 authentication.

• `caching_sha2_password`: Implements SHA-256 authentication (like `sha256_password`), but uses caching on the server side for better performance and has additional features for wider applicability.

This section describes the original noncaching SHA-2 authentication plugin. For information about the caching plugin, see Section 6.4.1.2, “Caching SHA-2 Pluggable Authentication”.

---

**Important**

In MySQL 8.0, `caching_sha2_password` is the default authentication plugin rather than `mysql_native_password`. For information about the implications of this change for server operation and compatibility of the server with clients and connectors, see `caching_sha2_password` as the Preferred Authentication Plugin.

Because `caching_sha2_password` is the default authentication plugin in MySQL 8.0 and provides a superset of the capabilities of the `sha256_password` authentication plugin, `sha256_password` is deprecated; expect it to be removed in a future version of MySQL. MySQL accounts that authenticate using `sha256_password` should be migrated to use `caching_sha2_password` instead.

---

**Important**

To connect to the server using an account that authenticates with the `sha256_password` plugin, you must use either a TLS connection or an unencrypted connection that supports password exchange using an RSA key pair, as described later in this section. Either way, the `sha256_password` plugin uses MySQL’s encryption capabilities. See Section 6.3, “Using Encrypted Connections”.

---
Authentication Plugins

Note

In the name `sha256_password`, “sha256” refers to the 256-bit digest length the plugin uses for encryption. In the name `caching_sha2_password`, “sha2” refers more generally to the SHA-2 class of encryption algorithms, of which 256-bit encryption is one instance. The latter name choice leaves room for future expansion of possible digest lengths without changing the plugin name.

The following table shows the plugin names on the server and client sides.

Table 6.14 Plugin and Library Names for SHA-256 Authentication

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td><code>sha256_password</code></td>
</tr>
<tr>
<td>Client-side plugin</td>
<td><code>sha256_password</code></td>
</tr>
<tr>
<td>Library file</td>
<td>None (plugins are built in)</td>
</tr>
</tbody>
</table>

The following sections provide installation and usage information specific to SHA-256 pluggable authentication:

- Installing SHA-256 Pluggable Authentication
- Using SHA-256 Pluggable Authentication

For general information about pluggable authentication in MySQL, see Section 6.2.17, “Pluggable Authentication”.

Installing SHA-256 Pluggable Authentication

The `sha256_password` plugin exists in server and client forms:

- The server-side plugin is built into the server, need not be loaded explicitly, and cannot be disabled by unloading it.
- The client-side plugin is built into the `libmysqlclient` client library and is available to any program linked against `libmysqlclient`.

Using SHA-256 Pluggable Authentication

To set up an account that uses the `sha256_password` plugin for SHA-256 password hashing, use the following statement, where `password` is the desired account password:

```
CREATE USER 'sha256user'@'localhost'
IDENTIFIED WITH sha256_password BY 'password';
```

The server assigns the `sha256_password` plugin to the account and uses it to encrypt the password using SHA-256, storing those values in the `plugin` and `authentication_string` columns of the `mysql.user` system table.

The preceding instructions do not assume that `sha256_password` is the default authentication plugin. If `sha256_password` is the default authentication plugin, a simpler `CREATE USER` syntax can be used.

To start the server with the default authentication plugin set to `sha256_password`, put these lines in the server option file:

```
[mysqld]
default_authentication_plugin=sha256_password
```
Authentication Plugins

That causes the `sha256_password` plugin to be used by default for new accounts. As a result, it is possible to create the account and set its password without naming the plugin explicitly:

```sql
CREATE USER 'sha256user'@'localhost' IDENTIFIED BY 'password';
```

Another consequence of setting `default_authentication_plugin` to `sha256_password` is that, to use some other plugin for account creation, you must specify that plugin explicitly. For example, to use the `mysql_native_password` plugin, use this statement:

```sql
CREATE USER 'nativeuser'@'localhost' IDENTIFIED WITH mysql_native_password BY 'password';
```

`sha256_password` supports connections over secure transport. `sha256_password` also supports encrypted password exchange using RSA over unencrypted connections if MySQL is compiled using OpenSSL, and the MySQL server to which you wish to connect is configured to support RSA (using the RSA configuration procedure given later in this section).

RSA support has these characteristics:

- On the server side, two system variables name the RSA private and public key-pair files: `sha256_password_private_key_path` and `sha256_password_public_key_path`. The database administrator must set these variables at server startup if the key files to use have names that differ from the system variable default values.

- The server uses the `sha256_password_auto_generate_rsa_keys` system variable to determine whether to automatically generate the RSA key-pair files. See Section 6.3.3, “Creating SSL and RSA Certificates and Keys”.

- The `Rsa_public_key` status variable displays the RSA public key value used by the `sha256_password` authentication plugin.

- Clients that are in possession of the RSA public key can perform RSA key pair-based password exchange with the server during the connection process, as described later.

- For connections by accounts that authenticate with `sha256_password` and RSA public key pair-based password exchange, the server sends the RSA public key to the client as needed. However, if a copy of the public key is available on the client host, the client can use it to save a round trip in the client/server protocol:

  - For these command-line clients, use the `--server-public-key-path` option to specify the RSA public key file: `mysql, mysqladmin, mysqlbinlog, mysqlcheck, mysqldump, mysqlimport, mysqlpump, mysqlshow, mysqlslap, mysqltest, mysql_upgrade`.

  - For programs that use the C API, call `mysql_options()` to specify the RSA public key file by passing the `MYSQL_SERVER_PUBLIC_KEY` option and the name of the file.

  - For replicas, use the `CHANGE MASTER TO` statement with the `MASTER_PUBLIC_KEY_PATH` option to specify the RSA public key file. For Group Replication, the `group_replication_recovery_get_public_key` system variable serves the same purpose.

For clients that use the `sha256_password` plugin, passwords are never exposed as cleartext when connecting to the server. How password transmission occurs depends on whether a secure connection or RSA encryption is used:

- If the connection is secure, an RSA key pair is unnecessary and is not used. This applies to connections encrypted using TLS. The password is sent as cleartext but cannot be snooped because the connection is secure.
Authentication Plugins

Note
Unlike caching_sha2_password, the sha256_password plugin does not treat shared-memory connections as secure, even though share-memory transport is secure by default.

- If the connection is not secure, and an RSA key pair is available, the connection remains unencrypted. This applies to connections not encrypted using TLS. RSA is used only for password exchange between client and server, to prevent password snooping. When the server receives the encrypted password, it decrypts it. A scramble is used in the encryption to prevent repeat attacks.

- If a secure connection is not used and RSA encryption is not available, the connection attempt fails because the password cannot be sent without being exposed as cleartext.

Note
To use RSA password encryption with sha256_password, the client and server both must be compiled using OpenSSL, not just one of them.

Assuming that MySQL has been compiled using OpenSSL, use the following procedure to enable use of an RSA key pair for password exchange during the client connection process:

1. Create the RSA private and public key-pair files using the instructions in Section 6.3.3, “Creating SSL and RSA Certificates and Keys”.

2. If the private and public key files are located in the data directory and are named private_key.pem and public_key.pem (the default values of the sha256_password_private_key_path and sha256_password_public_key_path system variables), the server uses them automatically at startup.

   Otherwise, to name the key files explicitly, set the system variables to the key file names in the server option file. If the files are located in the server data directory, you need not specify their full path names:

   ```
   [mysqld]
   sha256_password_private_key_path=myprivkey.pem
   sha256_password_public_key_path=mypubkey.pem
   ```

   If the key files are not located in the data directory, or to make their locations explicit in the system variable values, use full path names:

   ```
   [mysqld]
   sha256_password_private_key_path=/usr/local/mysql/myprivkey.pem
   sha256_password_public_key_path=/usr/local/mysql/mypubkey.pem
   ```

3. Restart the server, then connect to it and check the Rsa_public_key status variable value. The value actually displayed differs from that shown here, but should be nonempty:

   ```
   mysql> SHOW STATUS LIKE 'Rsa_public_key'
   *************************** 1. row ***************************
   Variable_name: Rsa_public_key
   Value: -----BEGIN PUBLIC KEY-----
   MIGfMA0GCSqGSIb3DQEBAQUAA4GNADCBiQKBgQDO9nRUDd+KvSZgY7cNBZMNpwX6
   MvE1PbJFXO7u18nJ91w99DvU71w6CVXw7VKrXPeHzVQUzGyUNKf45Nz/ckaaJa
   aLg3OB CIDmNVnyU54OT/11cs2x1yfafa8fCJ64ZwTnkby2qkt1IMjUAB5og5kJ
   g8a7EtKwyHhB0c3QIDAQAB
   -----END PUBLIC KEY-----
   ```

   If the value is empty, the server found some problem with the key files. Check the error log for diagnostic information.
Authentication Plugins

After the server has been configured with the RSA key files, accounts that authenticate with the `sha256_password` plugin have the option of using those key files to connect to the server. As mentioned previously, such accounts can use either a secure connection (in which case RSA is not used) or an unencrypted connection that performs password exchange using RSA. Suppose that an unencrypted connection is used. For example:

```
shell> mysql --ssl-mode=DISABLED -u sha256user -p
Enter password: password
```

For this connection attempt by `sha256user`, the server determines that `sha256_password` is the appropriate authentication plugin and invokes it (because that was the plugin specified at `CREATE USER` time). The plugin finds that the connection is not encrypted and thus requires the password to be transmitted using RSA encryption. In this case, the plugin sends the RSA public key to the client, which uses it to encrypt the password and returns the result to the server. The plugin uses the RSA private key on the server side to decrypt the password and accepts or rejects the connection based on whether the password is correct.

The server sends the RSA public key to the client as needed. However, if the client has a file containing a local copy of the RSA public key required by the server, it can specify the file using the `--server-public-key-path` option:

```
shell> mysql --ssl-mode=DISABLED -u sha256user -p --server-public-key-path=file_name
Enter password: password
```

The public key value in the file named by the `--server-public-key-path` option should be the same as the key value in the server-side file named by the `sha256_password_public_key_path` system variable. If the key file contains a valid public key value but the value is incorrect, an access-denied error occurs. If the key file does not contain a valid public key, the client program cannot use it. In this case, the `sha256_password` plugin sends the public key to the client as if no `--server-public-key-path` option had been specified.

Client users can obtain the RSA public key two ways:

- The database administrator can provide a copy of the public key file.
- A client user who can connect to the server some other way can use a `SHOW STATUS LIKE 'Rsa_public_key'` statement and save the returned key value in a file.

### 6.4.1.4 Client-Side Cleartext Pluggable Authentication

A client-side authentication plugin is available that enables clients to send passwords to the server as cleartext, without hashing or encryption. This plugin is built into the MySQL client library.

The following table shows the plugin name.

**Table 6.15 Plugin and Library Names for Cleartext Authentication**

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td>None, see discussion</td>
</tr>
<tr>
<td>Client-side plugin</td>
<td><code>mysql_clear_password</code></td>
</tr>
<tr>
<td>Library file</td>
<td>None (plugin is built in)</td>
</tr>
</tbody>
</table>

Many client-side authentication plugins perform hashing or encryption of a password before the client sends it to the server. This enables clients to avoid sending passwords as cleartext.

Hashing or encryption cannot be done for authentication schemes that require the server to receive the password as entered on the client side. In such cases, the client-side `mysql_clear_password` plugin can be used.
Authentication Plugins

plugin is used, which enables the client to send the password to the server as cleartext. There is no corresponding server-side plugin. Rather, mysql_clear_password can be used on the client side in concert with any server-side plugin that needs a cleartext password. (Examples are the PAM and simple LDAP authentication plugins; see Section 6.4.1.5, “PAM Pluggable Authentication”, and Section 6.4.1.7, “LDAP Pluggable Authentication”.)

The following discussion provides usage information specific to cleartext pluggable authentication. For general information about pluggable authentication in MySQL, see Section 6.2.17, “Pluggable Authentication”.

Note

Sending passwords as cleartext may be a security problem in some configurations. To avoid problems if there is any possibility that the password would be intercepted, clients should connect to MySQL Server using a method that protects the password. Possibilities include SSL (see Section 6.3, “Using Encrypted Connections”), IPsec, or a private network.

To make inadvertent use of the mysql_clear_password plugin less likely, MySQL clients must explicitly enable it. This can be done in several ways:

- Set the LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN environment variable to a value that begins with 1, Y, or y. This enables the plugin for all client connections.
- The mysql, mysqladmin, mysqlcheck, mysqldump, mysqlshow, and mysqlslap client programs support an --enable-cleartext-plugin option that enables the plugin on a per-invocation basis.
- The mysql_options() C API function supports a MYSQL_ENABLE_CLEARTEXT_PLUGIN option that enables the plugin on a per-connection basis. Also, any program that uses libmysqlclient and reads option files can enable the plugin by including an enable-cleartext-plugin option in an option group read by the client library.

6.4.1.5 PAM Pluggable Authentication

Note

PAM pluggable authentication is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see https://www.mysql.com/products/.

MySQL Enterprise Edition supports an authentication method that enables MySQL Server to use PAM (Pluggable Authentication Modules) to authenticate MySQL users. PAM enables a system to use a standard interface to access various kinds of authentication methods, such as traditional Unix passwords or an LDAP directory.

PAM pluggable authentication provides these capabilities:

- External authentication: PAM authentication enables MySQL Server to accept connections from users defined outside the MySQL grant tables and that authenticate using methods supported by PAM.
- Proxy user support: PAM authentication can return to MySQL a user name different from the external user name passed by the client program, based on the PAM groups the external user is a member of and the authentication string provided. This means that the plugin can return the MySQL user that defines the privileges the external PAM-authenticated user should have. For example, an operating system user named joe can connect and have the privileges of a MySQL user named developer.

PAM pluggable authentication has been tested on Linux and macOS.
The following table shows the plugin and library file names. The file name suffix might differ on your system. The file must be located in the directory named by the `plugin_dir` system variable. For installation information, see Installing PAM Pluggable Authentication.

**Table 6.16 Plugin and Library Names for PAM Authentication**

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td><code>authentication_pam</code></td>
</tr>
<tr>
<td>Client-side plugin</td>
<td><code>mysql_clear_password</code></td>
</tr>
<tr>
<td>Library file</td>
<td><code>authentication_pam.so</code></td>
</tr>
</tbody>
</table>

The client-side `mysql_clear_password` cleartext plugin that communicates with the server-side PAM plugin is built into the `libmysqlclient` client library and is included in all distributions, including community distributions. Inclusion of the client-side cleartext plugin in all MySQL distributions enables clients from any distribution to connect to a server that has the server-side PAM plugin loaded.

The following sections provide installation and usage information specific to PAM pluggable authentication:

- How PAM Authentication of MySQL Users Works
- Installing PAM Pluggable Authentication
- Uninstalling PAM Pluggable Authentication
- Using PAM Pluggable Authentication
- PAM Unix Password Authentication without Proxy Users
- PAM LDAP Authentication without Proxy Users
- PAM Unix Password Authentication with Proxy Users and Group Mapping
- PAM Authentication Access to Unix Password Store
- PAM Authentication Debugging

For general information about pluggable authentication in MySQL, see Section 6.2.17, “Pluggable Authentication”. For information about the `mysql_clear_password` plugin, see Section 6.4.1.4, “Client-Side Cleartext Pluggable Authentication”. For proxy user information, see Section 6.2.18, “Proxy Users”.

**How PAM Authentication of MySQL Users Works**

This section provides a general overview of how MySQL and PAM work together to authenticate MySQL users. For examples showing how to set up MySQL accounts to use specific PAM services, see Using PAM Pluggable Authentication.

1. The client program and the server communicate, with the client sending to the server the client user name (the operating system user name by default) and password:

   - The client user name is the external user name.

   - For accounts that use the PAM server-side authentication plugin, the corresponding client-side plugin is `mysql_clear_password`. This client-side plugin performs no password hashing, with the result that the client sends the password to the server as cleartext.

2. The server finds a matching MySQL account based on the external user name and the host from which the client connects. The PAM plugin uses the information passed to it by MySQL Server (such as...
user name, host name, password, and authentication string). When you define a MySQL account that authenticates using PAM, the authentication string contains:

- A PAM service name, which is a name that the system administrator can use to refer to an authentication method for a particular application. There can be multiple applications associated with a single database server instance, so the choice of service name is left to the SQL application developer.

- Optionally, if proxying is to be used, a mapping from PAM groups to MySQL user names.

3. The plugin uses the PAM service named in the authentication string to check the user credentials and returns 'Authentication succeeded, Username is user_name' or 'Authentication failed'. The password must be appropriate for the password store used by the PAM service. Examples:

- For traditional Unix passwords, the service looks up passwords stored in the /etc/shadow file.

- For LDAP, the service looks up passwords stored in an LDAP directory.

If the credentials check fails, the server refuses the connection.

4. Otherwise, the authentication string indicates whether proxying occurs. If the string contains no PAM group mapping, proxying does not occur. In this case, the MySQL user name is the same as the external user name.

5. Otherwise, proxying is indicated based on the PAM group mapping, with the MySQL user name determined based on the first matching group in the mapping list. The meaning of “PAM group” depends on the PAM service. Examples:

- For traditional Unix passwords, groups are Unix groups defined in the /etc/group file, possibly supplemented with additional PAM information in a file such as /etc/security/group.conf.

- For LDAP, groups are LDAP groups defined in an LDAP directory.

If the proxy user (the external user) has the PROXY privilege for the proxied MySQL user name, proxying occurs, with the proxy user assuming the privileges of the proxied user.

**Installing PAM Pluggable Authentication**

This section describes how to install the PAM authentication plugin. For general information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the plugin_dir system variable). If necessary, configure the plugin directory location by setting the value of plugin_dir at server startup.

The plugin library file base name is authentication_pam. The file name suffix differs per platform (for example, .so for Unix and Unix-like systems, .dll for Windows).

To load the plugin at server startup, use the --plugin-load-add option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server my.cnf file, adjusting the .so suffix for your platform as necessary:

```ini
[mysqld]
plugin-load-add=authentication_pam.so
```

After modifying my.cnf, restart the server to cause the new settings to take effect.
Alternatively, to load the plugin at runtime, use this statement, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN authentication_pam SONAME 'authentication_pam.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
    FROM INFORMATION_SCHEMA.PLUGINS
    WHERE PLUGIN_NAME LIKE '%pam%';
```

```
+--------------------+---------------+
<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>PLUGIN_STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>authentication_pam</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>
+--------------------+---------------+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the PAM plugin, see Using PAM Pluggable Authentication.

### Uninstalling PAM Pluggable Authentication

The method used to uninstall the PAM authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.
- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN authentication_pam;
```

### Using PAM Pluggable Authentication

This section describes in general terms how to use the PAM authentication plugin to connect from MySQL client programs to the server. The following sections provide instructions for using PAM authentication in specific ways. It is assumed that the server is running with the server-side PAM plugin enabled, as described in Installing PAM Pluggable Authentication.

To refer to the PAM authentication plugin in the `IDENTIFIED WITH` clause of a `CREATE USER` statement, use the name `authentication_pam`. For example:

```
CREATE USER user
    IDENTIFIED WITH authentication_pam
    AS 'auth_string';
```

The authentication string specifies the following types of information:

- The PAM service name (see How PAM Authentication of MySQL Users Works). Examples in the following discussion use a service name of `mysql-unix` for authentication using traditional Unix passwords, and `mysql-ldap` for authentication using LDAP.
- For proxy support, PAM provides a way for a PAM module to return to the server a MySQL user name other than the external user name passed by the client program when it connects to the server. Use the authentication string to control the mapping from external user names to MySQL user names. If you want to take advantage of proxy user capabilities, the authentication string must include this kind of mapping.
For example, if an account uses the mysql-unix PAM service name and should map operating system users in the root and users PAM groups to the developer and data_entry MySQL users, respectively, use a statement like this:

```sql
CREATE USER user
  IDENTIFIED WITH authentication_pam
AS 'mysql-unix, root=developer, users=data_entry';
```

Authentication string syntax for the PAM authentication plugin follows these rules:

- The string consists of a PAM service name, optionally followed by a PAM group mapping list consisting of one or more keyword/value pairs each specifying a PAM group name and a MySQL user name:

  ```plaintext
  pam_service_name[,pam_group_name=mysql_user_name]...
  ```

  The plugin parses the authentication string for each connection attempt that uses the account. To minimize overhead, keep the string as short as possible.

- Each `pam_group_name=mysql_user_name` pair must be preceded by a comma.

- Leading and trailing spaces not inside double quotation marks are ignored.

- Unquoted `pam_service_name`, `pam_group_name`, and `mysql_user_name` values can contain anything except equal sign, comma, or space.

- If a `pam_service_name`, `pam_group_name`, or `mysql_user_name` value is quoted with double quotation marks, everything between the quotation marks is part of the value. This is necessary, for example, if the value contains space characters. All characters are legal except double quotation mark and backslash (\). To include either character, escape it with a backslash.

If the plugin successfully authenticates the external user name (the name passed by the client), it looks for a PAM group mapping list in the authentication string and, if present, uses it to return a different MySQL user name to the MySQL server based on which PAM groups the external user is a member of:

- If the authentication string contains no PAM group mapping list, the plugin returns the external name.

- If the authentication string does contain a PAM group mapping list, the plugin examines each `pam_group_name=mysql_user_name` pair in the list from left to right and tries to find a match for the `pam_group_name` value in a non-MySQL directory of the groups assigned to the authenticated user and returns `mysql_user_name` for the first match it finds. If the plugin finds no match for any PAM group, it returns the external name. If the plugin is not capable of looking up a group in a directory, it ignores the PAM group mapping list and returns the external name.

The following sections describe how to set up several authentication scenarios that use the PAM authentication plugin:

- No proxy users. This uses PAM only to check login names and passwords. Every external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use PAM authentication. (For a MySQL account of `user_name'@'host_name'` to match the external user, `user_name` must be the external user name and `host_name` must match the host from which the client connects.) Authentication can be performed by various PAM-supported methods. Later discussion shows how to authenticate client credentials using traditional Unix passwords, and passwords in LDAP.

  PAM authentication, when not done through proxy users or PAM groups, requires the MySQL user name to be same as the operating system user name. MySQL user names are limited to 32 characters (see Section 6.2.3, “Grant Tables”), which limits PAM nonproxy authentication to Unix accounts with names of at most 32 characters.
• Proxy users only, with PAM group mapping. For this scenario, create one or more MySQL accounts that define different sets of privileges. (Ideally, nobody should connect using those accounts directly.) Then define a default user authenticating through PAM that uses some mapping scheme (usually based on the external PAM groups the users are members of) to map all the external user names to the few MySQL accounts holding the privilege sets. Any client who connects and specifies an external user name as the client user name is mapped to one of the MySQL accounts and uses its privileges. The discussion shows how to set this up using traditional Unix passwords, but other PAM methods such as LDAP could be used instead.

Variations on these scenarios are possible:

• You can permit some users to log in directly (without proxying) but require others to connect through proxy accounts.

• You can use one PAM authentication method for some users, and another method for other users, by using differing PAM service names among your PAM-authenticated accounts. For example, you can use the `mysql-unix` PAM service for some users, and `mysql-ldap` for others.

The examples make the following assumptions. You might need to make some adjustments if your system is set up differently.

• The login name and password are `antonio` and `antonio_password`, respectively. Change these to correspond to the user you want to authenticate.

• The PAM configuration directory is `/etc/pam.d`.

• The PAM service name corresponds to the authentication method (`mysql-unix` or `mysql-ldap` in this discussion). To use a given PAM service, you must set up a PAM file with the same name in the PAM configuration directory (creating the file if it does not exist). In addition, you must name the PAM service in the authentication string of the `CREATE USER` statement for any account that authenticates using that PAM service.

The PAM authentication plugin checks at initialization time whether the `AUTHENTICATION_PAM_LOG` environment value is set in the server's startup environment. If so, the plugin enables logging of diagnostic messages to the standard output. Depending on how your server is started, the message might appear on the console or in the error log. These messages can be helpful for debugging PAM-related issues that occur when the plugin performs authentication. For more information, see PAM Authentication Debugging.

**PAM Unix Password Authentication without Proxy Users**

This authentication scenario uses PAM to check external users defined in terms of operating system user names and Unix passwords, without proxying. Every such external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use PAM authentication through traditional Unix password store.

```
Note

Traditional Unix passwords are checked using the `/etc/shadow` file. For information regarding possible issues related to this file, see PAM Authentication Access to Unix Password Store.
```

1. Verify that Unix authentication permits logins to the operating system with the user name `antonio` and password `antonio_password`.

2. Set up PAM to authenticate MySQL connections using traditional Unix passwords by creating a `mysql-unix` PAM service file named `/etc/pam.d/mysql-unix`. The file contents are system dependent, so check existing login-related files in the `/etc/pam.d` directory to see what they look like. On Linux, the `mysql-unix` file might look like this:
Authentication Plugins

```pam
#PAM-1.0
auth            include         password-auth
account         include         password-auth
```

For macOS, use `login` rather than `password-auth`.

The PAM file format might differ on some systems. For example, on Ubuntu and other Debian-based systems, use these file contents instead:

```pam
@include common-auth
@include common-account
@include common-session-noninteractive
```

3. Create a MySQL account with the same user name as the operating system user name and define it to authenticate using the PAM plugin and the `mysql-unix` PAM service:

```sql
CREATE USER 'antonio'@'localhost'
  IDENTIFIED WITH authentication_pam
  AS 'mysql-unix';
GRANT ALL PRIVILEGES
  ON mydb.*
  TO 'antonio'@'localhost';
```

Here, the authentication string contains only the PAM service name, `mysql-unix`, which authenticates Unix passwords.

4. Use the `mysql` command-line client to connect to the MySQL server as `antonio`. For example:

```
shell> mysql --user=antonio --password --enable-cleartext-plugin
Enter password: antonio_password
```

The server should permit the connection and the following query returns output as shown:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-------------------+-------------------+--------------+
| USER()            | CURRENT_USER()    | @@proxy_user |
+-------------------+-------------------+--------------+
| antonio@localhost | antonio@localhost | NULL         |
+-------------------+-------------------+--------------+
```

This demonstrates that the `antonio` operating system user is authenticated to have the privileges granted to the `antonio` MySQL user, and that no proxying has occurred.

**Note**

The client-side `mysql_clear_password` authentication plugin leaves the password untouched, so client programs send it to the MySQL server as cleartext. This enables the password to be passed as is to PAM. A cleartext password is necessary to use the server-side PAM library, but may be a security problem in some configurations. These measures minimize the risk:

- To make inadvertent use of the `mysql_clear_password` plugin less likely, MySQL clients must explicitly enable it (for example, with the `--enable-cleartext-plugin` option). See Section 6.4.1.4, "Client-Side Cleartext Pluggable Authentication".

- To avoid password exposure with the `mysql_clear_password` plugin enabled, MySQL clients should connect to the MySQL server using an encrypted connection. See Section 6.3.1, "Configuring MySQL to Use Encrypted Connections".
Authentication Plugins

PAM LDAP Authentication without Proxy Users

This authentication scenario uses PAM to check external users defined in terms of operating system user names and LDAP passwords, without proxying. Every such external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use PAM authentication through LDAP.

To use PAM LDAP pluggable authentication for MySQL, these prerequisites must be satisfied:

- An LDAP server must be available for the PAM LDAP service to communicate with.
- LDAP users to be authenticated by MySQL must be present in the directory managed by the LDAP server.

Note

Another way to use LDAP for MySQL user authentication is to use the LDAP-specific authentication plugins. See Section 6.4.1.7, "LDAP Pluggable Authentication".

Configure MySQL for PAM LDAP authentication as follows:

1. Verify that Unix authentication permits logins to the operating system with the user name antonio and password antonio_password.

2. Set up PAM to authenticate MySQL connections using LDAP by creating a mysql-ldap PAM service file named /etc/pam.d/mysql-ldap. The file contents are system dependent, so check existing login-related files in the /etc/pam.d directory to see what they look like. On Linux, the mysql-ldap file might look like this:

   #%PAM-1.0
   auth        required    pam_ldap.so
   account     required    pam_ldap.so

   If PAM object files have a suffix different from .so on your system, substitute the correct suffix.

   The PAM file format might differ on some systems.

3. Create a MySQL account with the same user name as the operating system user name and define it to authenticate using the PAM plugin and the mysql-ldap PAM service:

   CREATE USER 'antonio'@'localhost' IDENTIFIED WITH authentication_pam AS 'mysql-ldap';
   GRANT ALL PRIVILEGES ON mydb.* TO 'antonio'@'localhost';

   Here, the authentication string contains only the PAM service name, mysql-ldap, which authenticates using LDAP.

4. Connecting to the server is the same as described in PAM Unix Password Authentication without Proxy Users.

PAM Unix Password Authentication with Proxy Users and Group Mapping

The authentication scheme described here uses proxying and PAM group mapping to map connecting MySQL users who authenticate using PAM onto other MySQL accounts that define different sets of privileges. Users do not connect directly through the accounts that define the privileges. Instead, they connect through a default proxy account authenticated using PAM, such that all the external users are mapped to the MySQL accounts that hold the privileges. Any user who connects using the proxy account
is mapped to one of those MySQL accounts, the privileges for which determine the database operations permitted to the external user.

The procedure shown here uses Unix password authentication. To use LDAP instead, see the early steps of PAM LDAP Authentication without Proxy Users.

**Note**

Traditional Unix passwords are checked using the `/etc/shadow` file. For information regarding possible issues related to this file, see PAM Authentication Access to Unix Password Store.

1. Verify that Unix authentication permits logins to the operating system with the user name `antonio` and password `antonio_password`.

2. Verify that `antonio` is a member of the `root` or `users` PAM group.

3. Set up PAM to authenticate the `mysql-unix` PAM service through operating system users by creating a file named `/etc/pam.d/mysql-unix`. The file contents are system dependent, so check existing login-related files in the `/etc/pam.d` directory to see what they look like. On Linux, the `mysql-unix` file might look like this:

   ```
   #%PAM-1.0
   auth            include         password-auth
   account         include         password-auth
   ```

   For macOS, use `login` rather than `password-auth`.

   The PAM file format might differ on some systems. For example, on Ubuntu and other Debian-based systems, use these file contents instead:

   ```
   @include common-auth
   @include common-account
   @include common-session-noninteractive
   ```

4. Create a default proxy user (`''@''`) that maps external PAM users to the proxied accounts:

   ```
   CREATE USER ''@''
   IDENTIFIED WITH authentication_pam
   AS 'mysql-unix, root=developer, users=data_entry';
   ```

   Here, the authentication string contains the PAM service name, `mysql-unix`, which authenticates Unix passwords. The authentication string also maps external users in the `root` and `users` PAM groups to the `developer` and `data_entry` MySQL user names, respectively.

   The PAM group mapping list following the PAM service name is required when you set up proxy users. Otherwise, the plugin cannot tell how to perform mapping from external user names to the proper proxied MySQL user names.

   **Note**

   If your MySQL installation has anonymous users, they might conflict with the default proxy user. For more information about this issue, and ways of dealing with it, see Default Proxy User and Anonymous User Conflicts.

5. Create the proxied accounts and grant to each one the privileges it should have:

   ```
   CREATE USER 'developer'@'localhost'
   IDENTIFIED WITH mysql_no_login;
   CREATE USER 'data_entry'@'localhost'
   ```
The proxied accounts use the `mysql_no_login` authentication plugin to prevent clients from using the accounts to log in directly to the MySQL server. Instead, users who authenticate using PAM are expected to use the `developer` or `data_entry` account by proxy based on their PAM group. (This assumes that the plugin is installed. For instructions, see Section 6.4.1.8, “No-Login Pluggable Authentication”.) For alternative methods of protecting proxied accounts against direct use, see Preventing Direct Login to Proxied Accounts.

6. Grant to the proxy account the `PROXY` privilege for each proxied account:

   ```sql
   GRANT PROXY
   ON 'developer'@'localhost'
   TO ''@'';
   GRANT PROXY
   ON 'data_entry'@'localhost'
   TO ''@'';
   ```

7. Use the `mysql` command-line client to connect to the MySQL server as `antonio`.

   ```shell
   mysql --user=antonio --password --enable-cleartext-plugin
   ```

   Enter password: `antonio_password`

   The server authenticates the connection using the default `''@''` proxy account. The resulting privileges for `antonio` depend on which PAM groups `antonio` is a member of. If `antonio` is a member of the `root` PAM group, the PAM plugin maps `root` to the `developer` MySQL user name and returns that name to the server. The server verifies that `''@''` has the `PROXY` privilege for `developer` and permits the connection. The following query returns output as shown:

   ```sql
   mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
   +-------------------+---------------------+--------------+
   | USER()            | CURRENT_USER()      | @@proxy_user |
   +-------------------+---------------------+--------------+
   | antonio@localhost | developer@localhost | ''@''        |
   +-------------------+---------------------+--------------+
   ```

   This demonstrates that the `antonio` operating system user is authenticated to have the privileges granted to the `developer` MySQL user, and that proxying occurs through the default proxy account.

   If `antonio` is not a member of the `root` PAM group but is a member of the `users` PAM group, a similar process occurs, but the plugin maps `user` PAM group membership to the `data_entry` MySQL user name and returns that name to the server:

   ```sql
   mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
   +-------------------+---------------------+--------------+
   | USER()            | CURRENT_USER()      | @@proxy_user |
   +-------------------+---------------------+--------------+
   | antonio@localhost | data_entry@localhost | ''@''        |
   +-------------------+---------------------+--------------+
   ```

   This demonstrates that the `antonio` operating system user is authenticated to have the privileges of the `data_entry` MySQL user, and that proxying occurs through the default proxy account.
Authentication Plugins

**Note**

The client-side `mysql_clear_password` authentication plugin leaves the password untouched, so client programs send it to the MySQL server as cleartext. This enables the password to be passed as is to PAM. A cleartext password is necessary to use the server-side PAM library, but may be a security problem in some configurations. These measures minimize the risk:

- To make inadvertent use of the `mysql_clear_password` plugin less likely, MySQL clients must explicitly enable it (for example, with the `--enable-cleartext-plugin` option). See Section 6.4.1.4, “Client-Side Cleartext Pluggable Authentication”.

- To avoid password exposure with the `mysql_clear_password` plugin enabled, MySQL clients should connect to the MySQL server using an encrypted connection. See Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

**PAM Authentication Access to Unix Password Store**

On some systems, Unix authentication uses a password store such as `/etc/shadow`, a file that typically has restricted access permissions. This can cause MySQL PAM-based authentication to fail. Unfortunately, the PAM implementation does not permit distinguishing “password could not be checked” (due, for example, to inability to read `/etc/shadow`) from “password does not match.” If you are using Unix password store for PAM authentication, you may be able to enable access to it from MySQL using one of the following methods:

- Assuming that the MySQL server is run from the `mysql` operating system account, put that account in the `shadow` group that has `/etc/shadow` access:

  1. Create a `shadow` group in `/etc/group`.
  2. Add the `mysql` operating system user to the `shadow` group in `/etc/group`.
  3. Assign `/etc/group` to the `shadow` group and enable the group read permission:

     ```
     chgrp shadow /etc/shadow
     chmod g+r /etc/shadow
     ```
  4. Restart the MySQL server.

- If you are using the `pam_unix` module and the `unix_chkpwd` utility, enable password store access as follows:

  ```
  chmod u-s /usr/sbin/unix_chkpwd
  setcap cap_dac_read_search+ep /usr/sbin/unix_chkpwd
  ```

  Adjust the path to `unix_chkpwd` as necessary for your platform.

**PAM Authentication Debugging**

The PAM authentication plugin checks at initialization time whether the `AUTHENTICATION_PAM_LOG` environment value is set (the value does not matter). If so, the plugin enables logging of diagnostic messages to the standard output. These messages may be helpful for debugging PAM-related issues that occur when the plugin performs authentication.

Some messages include reference to PAM plugin source files and line numbers, which enables plugin actions to be tied more closely to the location in the code where they occur.
Another technique for debugging connection failures and determining what is happening during connection attempts is to configure PAM authentication to permit all connections, then check the system log files. This technique should be used only on a temporary basis, and not on a production server.

Configure a PAM service file named `/etc/pam.d/mysql-any-password` with these contents (the format may differ on some systems):

```
# %PAM-1.0
auth required pam_permit.so
account required pam_permit.so
```

Create an account that uses the PAM plugin and names the `mysql-any-password` PAM service:

```
CREATE USER 'testuser'@'localhost' IDENTIFIED WITH authentication_pam AS 'mysql-any-password';
```

The `mysql-any-password` service file causes any authentication attempt to return true, even for incorrect passwords. If an authentication attempt fails, that tells you the configuration problem is on the MySQL side. Otherwise, the problem is on the operating system/PAM side. To see what might be happening, check system log files such as `/var/log/secure`, `/var/log/audit.log`, `/var/log/syslog`, or `/var/log/messages`.

After determining what the problem is, remove the `mysql-any-password` PAM service file to disable any-password access.

6.4.1.6 Windows Pluggable Authentication

**Note**

Windows pluggable authentication is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see [https://www.mysql.com/products/](https://www.mysql.com/products/).

MySQL Enterprise Edition for Windows supports an authentication method that performs external authentication on Windows, enabling MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password.

The client and server exchange data packets in the authentication handshake. As a result of this exchange, the server creates a security context object that represents the identity of the client in the Windows OS. This identity includes the name of the client account. Windows pluggable authentication uses the identity of the client to check whether it is a given account or a member of a group. By default, negotiation uses Kerberos to authenticate, then NTLM if Kerberos is unavailable.

Windows pluggable authentication provides these capabilities:

- External authentication: Windows authentication enables MySQL Server to accept connections from users defined outside the MySQL grant tables who have logged in to Windows.

- Proxy user support: Windows authentication can return to MySQL a user name different from the external user name passed by the client program. This means that the plugin can return the MySQL user that defines the privileges the external Windows-authenticated user should have. For example, a Windows user named `joe` can connect and have the privileges of a MySQL user named `developer`.

The following table shows the plugin and library file names. The file must be located in the directory named by the `plugin_dir` system variable.
Table 6.17 Plugin and Library Names for Windows Authentication

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td><code>authentication_windows</code></td>
</tr>
<tr>
<td>Client-side plugin</td>
<td><code>authentication_windows_client</code></td>
</tr>
<tr>
<td>Library file</td>
<td><code>authentication_windows.dll</code></td>
</tr>
</tbody>
</table>

The library file includes only the server-side plugin. The client-side plugin is built into the `libmysqlclient` client library.

The server-side Windows authentication plugin is included only in MySQL Enterprise Edition. It is not included in MySQL community distributions. The client-side plugin is included in all distributions, including community distributions. This permits clients from any distribution to connect to a server that has the server-side plugin loaded.

The Windows authentication plugin is supported on any version of Windows supported by MySQL 8.0 (see https://www.mysql.com/support/supportedplatforms/database.html).

The following sections provide installation and usage information specific to Windows pluggable authentication:

- Installing Windows Pluggable Authentication
- Uninstalling Windows Pluggable Authentication
- Using Windows Pluggable Authentication

For general information about pluggable authentication in MySQL, see Section 6.2.17, “Pluggable Authentication”. For proxy user information, see Section 6.2.18, “Proxy Users”.

Installing Windows Pluggable Authentication

This section describes how to install the Windows authentication plugin. For general information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

To load the plugin at server startup, use the `--plugin-load-add` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file:

```
[mysqld]
plugin-load-add=authentication_windows.dll
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement:

```
INSTALL PLUGIN authentication_windows SONAME 'authentication_windows.dll';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:
Authentication Plugins

mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS FROM INFORMATION_SCHEMA.PLUGINS WHERE PLUGIN_NAME LIKE '%windows%';
+------------------------+---------------+
| PLUGIN_NAME            | PLUGIN_STATUS |
+------------------------+---------------+
| authentication_windows | ACTIVE        |
+------------------------+---------------+

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the Windows authentication plugin, see Using Windows Pluggable Authentication. Additional plugin control is provided by the `authentication_windows_use_principal_name` and `authentication_windows_log_level` system variables. See Section 5.1.8, “Server System Variables”.

Uninstalling Windows Pluggable Authentication

The method used to uninstall the Windows authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.

- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN authentication_windows;
```

In addition, remove any startup options that set Windows plugin-related system variables.

Using Windows Pluggable Authentication

The Windows authentication plugin supports the use of MySQL accounts such that users who have logged in to Windows can connect to the MySQL server without having to specify an additional password. It is assumed that the server is running with the server-side plugin enabled, as described in Installing Windows Pluggable Authentication. Once the DBA has enabled the server-side plugin and set up accounts to use it, clients can connect using those accounts with no other setup required on their part.

To refer to the Windows authentication plugin in the `IDENTIFIED WITH` clause of a `CREATE USER` statement, use the name `authentication_windows`. Suppose that the Windows users Rafal and Tasha should be permitted to connect to MySQL, as well as any users in the Administrators or Power Users group. To set this up, create a MySQL account named `sql_admin` that uses the Windows plugin for authentication:

```
CREATE USER sql_admin
  IDENTIFIED WITH authentication_windows
AS 'Rafal, Tasha, Administrators, "Power Users"';
```

The plugin name is `authentication_windows`. The string following the `AS` keyword is the authentication string. It specifies that the Windows users named Rafal or Tasha are permitted to authenticate to the server as the MySQL user `sql_admin`, as are any Windows users in the Administrators or Power Users group. The latter group name contains a space, so it must be quoted with double quote characters.

After you create the `sql_admin` account, a user who has logged in to Windows can attempt to connect to the server using that account:

```
C:\> mysql --user=sql_admin
```
No password is required here. The `authentication_windows` plugin uses the Windows security API to check which Windows user is connecting. If that user is named Rafal or Tasha, or is a member of the Administrators or Power Users group, the server grants access and the client is authenticated as sql_admin and has whatever privileges are granted to the sql_admin account. Otherwise, the server denies access.

Authentication string syntax for the Windows authentication plugin follows these rules:

- The string consists of one or more user mappings separated by commas.

- Each user mapping associates a Windows user or group name with a MySQL user name:

  ```
  win_user_or_group_name=mysql_user_name
  win_user_or_group_name
  ```

  For the latter syntax, with no `mysql_user_name` value given, the implicit value is the MySQL user created by the `CREATE USER` statement. Thus, these statements are equivalent:

  ```
  CREATE USER sql_admin
  IDENTIFIED WITH authentication_windows
  AS 'Rafal, Tasha, Administrators, "Power Users"';
  ```

  ```
  CREATE USER sql_admin
  IDENTIFIED WITH authentication_windows
  AS 'Rafal=sql_admin, Tasha=sql_admin, Administrators=sql_admin, "Power Users"=sql_admin';
  ```

- Each backslash character (`\`) in a value must be doubled because backslash is the escape character in MySQL strings.

- Leading and trailing spaces not inside double quotation marks are ignored.

- Unquoted `win_user_or_group_name` and `mysql_user_name` values can contain anything except equal sign, comma, or space.

- If a `win_user_or_group_name` and or `mysql_user_name` value is quoted with double quotation marks, everything between the quotation marks is part of the value. This is necessary, for example, if the name contains space characters. All characters within double quotes are legal except double quotation mark and backslash. To include either character, escape it with a backslash.

- `win_user_or_group_name` values use conventional syntax for Windows principals, either local or in a domain. Examples (note the doubling of backslashes):

  ```
  domain\user
  .\user
  domain\group
  .\group
  BUILTIN\WellKnownGroup
  ```

When invoked by the server to authenticate a client, the plugin scans the authentication string left to right for a user or group match to the Windows user. If there is a match, the plugin returns the corresponding `mysql_user_name` to the MySQL server. If there is no match, authentication fails.

A user name match takes preference over a group name match. Suppose that the Windows user named `win_user` is a member of `win_group` and the authentication string looks like this:

```
'win_group = sql_user1, win_user = sql_user2'
```
Authentication Plugins

Windows authentication always works for connections from the same computer on which the server is running. For cross-computer connections, both computers must be registered with Windows Active Directory. If they are in the same Windows domain, it is unnecessary to specify a domain name. It is also possible to permit connections from a different domain, as in this example:

```
CREATE USER sql_accounting
  IDENTIFIED WITH authentication_windows
  AS 'SomeDomain\Accounting';
```

Here `SomeDomain` is the name of the other domain. The backslash character is doubled because it is the MySQL escape character within strings.

MySQL supports the concept of proxy users whereby a client can connect and authenticate to the MySQL server using one account but while connected has the privileges of another account (see Section 6.2.18, “Proxy Users”). Suppose that you want Windows users to connect using a single user name but be mapped based on their Windows user and group names onto specific MySQL accounts as follows:

- The `local_user` and `MyDomain\domain_user` local and domain Windows users should map to the `local_wlad` MySQL account.

- Users in the `MyDomain\Developers` domain group should map to the `local_dev` MySQL account.

- Local machine administrators should map to the `local_admin` MySQL account.

To set this up, create a proxy account for Windows users to connect to, and configure this account so that users and groups map to the appropriate MySQL accounts (`local_wlad`, `local_dev`, `local_admin`). In addition, grant the MySQL accounts the privileges appropriate to the operations they need to perform. The following instructions use `win_proxy` as the proxy account, and `local_wlad`, `local_dev`, and `local_admin` as the proxied accounts.

1. Create the proxy MySQL account:

```
CREATE USER win_proxy
  IDENTIFIED WITH authentication_windows
  AS 'local_user = local_wlad,
  MyDomain\domain_user = local_wlad,
  MyDomain\Developers = local_dev,
  BUILTIN\Administrators = local_admin';
```

2. For proxying to work, the proxied accounts must exist, so create them:

```
CREATE USER local_wlad
  IDENTIFIED WITH mysql_no_login;
CREATE USER local_dev
  IDENTIFIED WITH mysql_no_login;
CREATE USER local_admin
  IDENTIFIED WITH mysql_no_login;
```

The proxied accounts use the `mysql_no_login` authentication plugin to prevent clients from using the accounts to log in directly to the MySQL server. Instead, users who authenticate using Windows are expected to use the `win_proxy` proxy account. (This assumes that the plugin is installed. For instructions, see Section 6.4.1.8, “No-Login Pluggable Authentication”.) For alternative methods of protecting proxied accounts against direct use, see Preventing Direct Login to Proxied Accounts.

You should also execute `GRANT` statements (not shown) that grant each proxied account the privileges required for MySQL access.

3. Grant to the proxy account the `PROXY` privilege for each proxied account:

```
GRANT PROXY ON local_wlad TO win_proxy;
```
GRANT PROXY ON local_dev TO win_proxy;
GRANT PROXY ON local_admin TO win_proxy;

Now the Windows users local_user and MyDomain\domain_user can connect to the MySQL server as win_proxy and when authenticated have the privileges of the account given in the authentication string (in this case, local_wlad). A user in the MyDomain\Developers group who connects as win_proxy has the privileges of the local_dev account. A user in the BUILTIN\Administrators group has the privileges of the local_admin account.

To configure authentication so that all Windows users who do not have their own MySQL account go through a proxy account, substitute the default proxy account ('''@''') for win_proxy in the preceding instructions. For information about default proxy accounts, see Section 6.2.18, “Proxy Users”.

Note

If your MySQL installation has anonymous users, they might conflict with the default proxy user. For more information about this issue, and ways of dealing with it, see Default Proxy User and Anonymous User Conflicts.

To use the Windows authentication plugin with Connector/NET connection strings in Connector/NET 6.4.4 and higher, see Using the Windows Native Authentication Plugin.

6.4.1.7 LDAP Pluggable Authentication

Note

LDAP pluggable authentication is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see https://www.mysql.com/products/.

MySQL Enterprise Edition supports an authentication method that enables MySQL Server to use LDAP (Lightweight Directory Access Protocol) to authenticate MySQL users by accessing directory services such as X.500. MySQL uses LDAP to fetch user, credential, and group information.

LDAP pluggable authentication provides these capabilities:

- External authentication: LDAP authentication enables MySQL Server to accept connections from users defined outside the MySQL grant tables in LDAP directories.

- Proxy user support: LDAP authentication can return to MySQL a user name different from the external user name passed by the client program, based on the LDAP groups the external user is a member of. This means that an LDAP plugin can return the MySQL user that defines the privileges the external LDAP-authenticated user should have. For example, an LDAP user named joe can connect and have the privileges of a MySQL user named developer, if the LDAP group for joe is developer.

- Security: Using TLS, connections to the LDAP server can be secure.

The following tables show the plugin and library file names for simple and SASL-based LDAP authentication. The file name suffix might differ on your system. The files must be located in the directory named by the plugin_dir system variable.

Table 6.18 Plugin and Library Names for Simple LDAP Authentication

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin name</td>
<td>authentication_ldap_simple</td>
</tr>
<tr>
<td>Client-side plugin name</td>
<td>mysql_clear_password</td>
</tr>
<tr>
<td>Library file name</td>
<td>authentication_ldap_simple.so</td>
</tr>
</tbody>
</table>
Table 6.19 Plugin and Library Names for SASL-Based LDAP Authentication

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin name</td>
<td>authentication_ldap_sasl</td>
</tr>
<tr>
<td>Client-side plugin name</td>
<td>authentication_ldap_sasl_client</td>
</tr>
<tr>
<td>Library file names</td>
<td>authentication_ldap_sasl.so,</td>
</tr>
<tr>
<td></td>
<td>authentication_ldap_sasl_client.so</td>
</tr>
</tbody>
</table>

The library files include only the authentication_ldap_XXX authentication plugins. The client-side mysql_clear_password plugin is built into the libmysqlclient client library.

Each server-side LDAP plugin works with a specific client-side plugin:

- The server-side authentication_ldap_simple plugin performs simple LDAP authentication. For connections by accounts that use this plugin, client programs use the client-side mysql_clear_password plugin, which sends the password to the server as cleartext. No password hashing or encryption is used, so a secure connection between the MySQL client and server is recommended to prevent password exposure.

- The server-side authentication_ldap_sasl plugin performs SASL-based LDAP authentication. For connections by accounts that use this plugin, client programs use the client-side authentication_ldap_sasl_client plugin. The client-side and server-side SASL LDAP plugins use SASL messages for secure transmission of credentials within the LDAP protocol, to avoid sending the cleartext password between the MySQL client and server.

The following sections provide installation and usage information specific to LDAP pluggable authentication:

- Prerequisites for LDAP Pluggable Authentication
- How LDAP Authentication of MySQL Users Works
- Installing LDAP Pluggable Authentication
- Uninstalling LDAP Pluggable Authentication
- LDAP Pluggable Authentication and ldap.conf
- Using LDAP Pluggable Authentication
- Simple LDAP Authentication
- SASL-Based LDAP Authentication
- LDAP Authentication with Proxying
- LDAP Authentication Group Preference and Mapping Specification
- LDAP Authentication User DN Suffixes
- LDAP Authentication Methods
- The GSSAPI/Kerberos Authentication Method
- LDAP Search Referral

For general information about pluggable authentication in MySQL, see Section 6.2.17, “Pluggable Authentication”. For information about the mysql_clear_password plugin, see Section 6.4.1.4, “Client-Side Cleartext Pluggable Authentication”. For proxy user information, see Section 6.2.18, “Proxy Users”.

1285
Authentication Plugins

Note

If your system supports PAM and permits LDAP as a PAM authentication method, another way to use LDAP for MySQL user authentication is to use the server-side `authentication_pam` plugin. See Section 6.4.1.5, “PAM Pluggable Authentication”.

Prerequisites for LDAP Pluggable Authentication

To use LDAP pluggable authentication for MySQL, these prerequisites must be satisfied:

- An LDAP server must be available for the LDAP authentication plugins to communicate with.
- LDAP users to be authenticated by MySQL must be present in the directory managed by the LDAP server.
- An LDAP client library must be available on systems where the server-side `authentication_ldap_sasl` or `authentication_ldap_simple` plugin is used. Currently, supported libraries are the Windows native LDAP library, or the OpenLDAP library on non-Windows systems.
- To use SASL-based LDAP authentication:
  - The LDAP server must be configured to communicate with a SASL server.
  - A SASL client library must be available on systems where the client-side `authentication_ldap_sasl_client` plugin is used. Currently, the only supported library is the Cyrus SASL library.
  - To use a particular SASL authentication method, any other services required by that method must be available. For example, to use GSSAPI/Kerberos, a GSSAPI library and Kerberos services must be available.

How LDAP Authentication of MySQL Users Works

This section provides a general overview of how MySQL and LDAP work together to authenticate MySQL users. For examples showing how to set up MySQL accounts to use specific LDAP authentication plugins, see Using LDAP Pluggable Authentication. For information about authentication methods available to the LDAP plugins, see LDAP Authentication Methods.

The client connects to the MySQL server, providing the MySQL client user name and a password:

- For simple LDAP authentication, the client-side and server-side plugins communicate the password as cleartext. A secure connection between the MySQL client and server is recommended to prevent password exposure.
- For SASL-based LDAP authentication, the client-side and server-side plugins avoid sending the cleartext password between the MySQL client and server. For example, the plugins might use SASL messages for secure transmission of credentials within the LDAP protocol. For the GSSAPI authentication method, the client-side and server-side plugins communicate securely using Kerberos without using LDAP messages directly.

If the client user name and host name match no MySQL account, the connection is rejected.

If there is a matching MySQL account, authentication against LDAP occurs. The LDAP server looks for an entry matching the user and authenticates the entry against the LDAP password:
Authentication Plugins

• If the MySQL account names an LDAP user distinguished name (DN), LDAP authentication uses that value and the LDAP password provided by the client. (To associate an LDAP user DN with a MySQL account, include a `BY` clause that specifies an authentication string in the `CREATE USER` statement that creates the account.)

• If the MySQL account names no LDAP user DN, LDAP authentication uses the user name and LDAP password provided by the client. In this case, the authentication plugin first binds to the LDAP server using the root DN and password as credentials to find the user DN based on the client user name, then authenticates that user DN against the LDAP password. This bind using the root credentials fails if the root DN and password are set to incorrect values, or are empty (not set) and the LDAP server does not permit anonymous connections.

If the LDAP server finds no match or multiple matches, authentication fails and the client connection is rejected.

If the LDAP server finds a single match, LDAP authentication succeeds (assuming that the password is correct), the LDAP server returns the LDAP entry, and the authentication plugin determines the name of the authenticated user based on that entry:

• If the LDAP entry has a group attribute (by default, the `cn` attribute), the plugin returns its value as the authenticated user name.

• If the LDAP entry has no group attribute, the authentication plugin returns the client user name as the authenticated user name.

The MySQL server compares the client user name with the authenticated user name to determine whether proxying occurs for the client session:

• If the names are the same, no proxying occurs: The MySQL account matching the client user name is used for privilege checking.

• If the names differ, proxying occurs: MySQL looks for an account matching the authenticated user name. That account becomes the proxied user, which is used for privilege checking. The MySQL account that matched the client user name is treated as the external proxy user.

Installing LDAP Pluggable Authentication

This section describes how to install the LDAP authentication plugins. For general information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

To be usable by the server, the plugin library files must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The server-side plugin library file base names are `authentication_ldap_simple` and `authentication_ldap_sasl`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To load the plugins at server startup, use `--plugin-load-add` options to name the library files that contain them. With this plugin-loading method, the options must be given each time the server starts. Also, specify values for any plugin-provided system variables you wish to configure.

Each server-side LDAP plugin exposes a set of system variables that enable its operation to be configured. Setting most of these is optional, but you must set the variables that specify the LDAP server host (so the plugin knows where to connect) and base distinguished name for LDAP bind operations (to limit the scope of searches and obtain faster searches). For details about all LDAP system variables, see Section 6.4.1.11, “Pluggable Authentication System Variables”.

1287
To load the plugins and set the LDAP server host and base distinguished name for LDAP bind operations, put lines such as these in your `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```
[mysqld]
plugin-load-add=authentication_ldap_simple.so
authentication_ldap_simple_server_host=127.0.0.1
authentication_ldap_simple_bind_base_dn="dc=example,dc=com"
plugin-load-add=authentication_ldap_sasl.so
authentication_ldap_sasl_server_host=127.0.0.1
authentication_ldap_sasl_bind_base_dn="dc=example,dc=com"
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugins at runtime, use these statements, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN authentication_ldap_simple
SONAME 'authentication_ldap_simple.so';
INSTALL PLUGIN authentication_ldap_sasl
SONAME 'authentication_ldap_sasl.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

After installing the plugins at runtime, their system variables become available and you can add settings for them to your `my.cnf` file to configure the plugins for subsequent restarts. For example:

```
[mysqld]
authentication_ldap_simple_server_host=127.0.0.1
authentication_ldap_simple_bind_base_dn="dc=example,dc=com"
authentication_ldap_sasl_server_host=127.0.0.1
authentication_ldap_sasl_bind_base_dn="dc=example,dc=com"
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to set and persist the values at runtime, use these statements:

```
SET PERSIST authentication_ldap_simple_server_host='127.0.0.1';
SET PERSIST authentication_ldap_simple_bind_base_dn='dc=example,dc=com';
SET PERSIST authentication_ldap_sasl_server_host='127.0.0.1';
SET PERSIST authentication_ldap_sasl_bind_base_dn='dc=example,dc=com';
```

`SET PERSIST` sets the value for the running MySQL instance. It also saves the value, causing it to carry over to subsequent server restarts. To change a value for the running MySQL instance without having it carry over to subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`. See Section 13.7.6.1, “SET Syntax for Variable Assignment”.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE '%ldap%';
```

```
+----------------------------+---------------+
| PLUGIN_NAME                | PLUGIN_STATUS |
+----------------------------+---------------+
| authentication_ldap_sasl   | ACTIVE        |
| authentication_ldap_simple | ACTIVE        |
+----------------------------+---------------+
```

If a plugin fails to initialize, check the server error log for diagnostic messages.
To associate MySQL accounts with an LDAP plugin, see Using LDAP Pluggable Authentication.

**Additional Notes for SELinux**

On systems running EL6 or EL that have SELinux enabled, changes to the SELinux policy are required to enable the MySQL LDAP plugins to communicate with the LDAP service:

1. Create a file `mysqlldap.te` with these contents:
   ```
   module mysqlldap 1.0;
   require {
     type ldap_port_t;
     type mysqld_t;
     class tcp_socket name_connect;
   }
   #============= mysqld_t ==============
   allow mysqld_t ldap_port_t:tcp_socket name_connect;
   ```

2. Compile the security policy module into a binary representation:
   ```
   checkmodule -M -m mysqlldap.te -o mysqlldap.mod
   ```

3. Create an SELinux policy module package:
   ```
   semodule_package -m mysqlldap.mod -o mysqlldap.pp
   ```

4. Install the module package:
   ```
   semodule -i mysqlldap.pp
   ```

5. When the SELinux policy changes have been made, restart the MySQL server:
   ```
   service mysqld restart
   ```

**Uninstalling LDAP Pluggable Authentication**

The method used to uninstall the LDAP authentication plugins depends on how you installed them:

- If you installed the plugins at server startup using `--plugin-load-add` options, restart the server without those options.

- If you installed the plugins at runtime using `INSTALL PLUGIN`, they remain installed across server restarts. To uninstall them, use `UNINSTALL PLUGIN`:

  ```
  UNINSTALL PLUGIN authentication_ldap_simple;
  UNINSTALL PLUGIN authentication_ldap_sasl;
  ```

  In addition, remove from your `my.cnf` file any startup options that set LDAP plugin-related system variables. If you used `SET PERSIST` to persist LDAP system variables, use `RESET PERSIST` to remove the settings.

**LDAP Pluggable Authentication and ldap.conf**

For installations that use OpenLDAP, the `ldap.conf` file provides global defaults for LDAP clients. Options can be set in this file to affect LDAP clients, including the LDAP authentication plugins. OpenLDAP uses configuration options in this order of precedence:
Authentication Plugins

- Configuration specified by the LDAP client.
- Configuration specified in the `ldap.conf` file. To disable use of this file, set the `LDAPNOINIT` environment variable.
- OpenLDAP library built-in defaults.

If the library defaults or `ldap.conf` values do not yield appropriate option values, an LDAP authentication plugin may be able to set related variables to affect the LDAP configuration directly. For example, LDAP plugins can override `ldap.conf` for parameters such as these:

- TLS configuration: System variables are available to enable TLS and control CA configuration, such as `authentication_ldap_simple_tls` and `authentication_ldap_simple_ca_path` for simple LDAP authentication, and `authentication_ldap_sasl_tls` and `authentication_ldap_sasl_ca_path` for SASL LDAP authentication.
- LDAP referral. See LDAP Search Referral.

For more information about `ldap.conf` consult the `ldap.conf(5)` man page.

Using LDAP Pluggable Authentication

This section describes how to enable MySQL accounts to connect to the MySQL server using LDAP pluggable authentication. It is assumed that the server is running with the appropriate server-side plugins enabled, as described in Installing LDAP Pluggable Authentication, and that the appropriate client-side plugins are available on the client host.

This section does not describe LDAP configuration or administration. You are assumed to be familiar with those topics.

The two server-side LDAP plugins each work with a specific client-side plugin:

- The server-side `authentication_ldap_simple` plugin performs simple LDAP authentication. For connections by accounts that use this plugin, client programs use the client-side `mysql_clear_password` plugin, which sends the password to the server as cleartext. No password hashing or encryption is used, so a secure connection between the MySQL client and server is recommended to prevent password exposure.

- The server-side `authentication_ldap_sasl` plugin performs SASL-based LDAP authentication. For connections by accounts that use this plugin, client programs use the client-side `authentication_ldap_sasl_client` plugin. The client-side and server-side SASL LDAP plugins use SASL messages for secure transmission of credentials within the LDAP protocol, to avoid sending the cleartext password between the MySQL client and server.

Overall requirements for LDAP authentication of MySQL users:

- There must be an LDAP directory entry for each user to be authenticated.
- There must be a MySQL user account that specifies a server-side LDAP authentication plugin and optionally names the associated LDAP user distinguished name (DN). (To associate an LDAP user DN with a MySQL account, include a `BY` clause in the `CREATE USER` statement that creates the account.) If an account names no LDAP string, LDAP authentication uses the user name specified by the client to find the LDAP entry.
- Client programs connect using the connection method appropriate for the server-side authentication plugin the MySQL account uses. For LDAP authentication, connections require the MySQL user name and LDAP password. In addition, for accounts that use the server-side
The instructions here assume the following scenario:

- MySQL users **betsy** and **boris** authenticate to the LDAP entries for **betsy_ldap** and **boris_ldap**, respectively. (It is not necessary that the MySQL and LDAP user names differ. The use of different names in this discussion helps clarify whether an operation context is MySQL or LDAP.)

- LDAP entries use the **uid** attribute to specify user names. This may vary depending on LDAP server. Some LDAP servers use the **cn** attribute for user names rather than **uid**. To change the attribute, modify the `authentication_ldap_simple_user_search_attr` or `authentication_ldap_sasl_user_search_attr` system variable appropriately.

- These LDAP entries are available in the directory managed by the LDAP server, to provide distinguished name values that uniquely identify each user:

```
uid=betsy_ldap,ou=People,dc=example,dc=com
uid=boris_ldap,ou=People,dc=example,dc=com
```

- `CREATE USER` statements that create MySQL accounts name an LDAP user in the **BY** clause, to indicate which LDAP entry the MySQL account authenticates against.

The instructions for setting up an account that uses LDAP authentication depend on which server-side LDAP plugin is used. The following sections describe several usage scenarios.

### Simple LDAP Authentication

To configure a MySQL account for simple LDAP authentication, the `CREATE USER` statement specifies the `authentication_ldap_simple` plugin, and optionally names the LDAP user distinguished name (DN):

```sql
CREATE USER user IDENTIFIED WITH authentication_ldap_simple [BY 'LDAP user DN'];
```

Suppose that MySQL user **betsy** has this entry in the LDAP directory:

```
uid=betsy_ldap,ou=People,dc=example,dc=com
```

Then the statement to create the MySQL account for **betsy** looks like this:

```sql
CREATE USER 'betsy'@'localhost'
    IDENTIFIED WITH authentication_ldap_simple AS 'uid=betsy_ldap,ou=People,dc=example,dc=com';
```

The authentication string specified in the **BY** clause does not include the LDAP password. That must be provided by the client user at connect time.

Clients connect to the MySQL server by providing the MySQL user name and LDAP password, and by enabling the client-side `mysql_clear_password` plugin:

```bash
shell> mysql --user=betsy --password --enable-cleartext-plugin
Enter password: betsy_password (betsy_ldap LDAP password)
```

**Note**

The client-side `mysql_clear_password` authentication plugin leaves the password untouched, so client programs send it to the MySQL server as cleartext. This enables the password to be passed as is to the LDAP server. A cleartext password is necessary to use the server-side LDAP library without SASL, but may be a security problem in some configurations. These measures minimize the risk:
Authentication Plugins

- To make inadvertent use of the `mysql_clear_password` plugin less likely, MySQL clients must explicitly enable it (for example, with the `--enable-cleartext-plugin` option). See Section 6.4.1.4, "Client-Side Cleartext Pluggable Authentication".

- To avoid password exposure with the `mysql_clear_password` plugin enabled, MySQL clients should connect to the MySQL server using an encrypted connection. See Section 6.3.1, "Configuring MySQL to Use Encrypted Connections".

The authentication process occurs as follows:

1. The client-side plugin sends `betsy` and `betsy_password` as the client user name and LDAP password to the MySQL server.

2. The connection attempt matches the `'betsy'@'localhost'` account. The server-side LDAP plugin finds that this account has an authentication string of `'uid=boris_ldap,ou=People,dc=example,dc=com'` to name the LDAP user DN. The plugin sends this string and the LDAP password to the LDAP server.

3. The LDAP server finds the LDAP entry for `betsy_ldap` and the password matches, so LDAP authentication succeeds.

4. The LDAP entry has no group attribute, so the server-side plugin returns the client user name (betsy) as the authenticated user. This is the same user name supplied by the client, so no proxying occurs and the client session uses the `'betsy'@'localhost'` account for privilege checking.

Had the matching LDAP entry contained a group attribute, that attribute value would have been the authenticated user name and, if the value differed from `betsy`, proxying would have occurred. For examples that use the group attribute, see LDAP Authentication with Proxying.

Had the `CREATE USER` statement contained no `BY` clause to specify the `betsy_ldap` LDAP distinguished name, authentication attempts would use the user name provided by the client (in this case, `betsy`). In the absence of an LDAP entry for `betsy`, authentication would fail.

### SASL-Based LDAP Authentication

To configure a MySQL account for SASL LDAP authentication, the `CREATE USER` statement specifies the `authentication_ldap_sasl` plugin, and optionally names the LDAP user distinguished name (DN):

```sql
CREATE USER user
  IDENTIFIED WITH authentication_ldap_sasl
    [BY 'LDAP user DN'];
```

Suppose that MySQL user `boris` has this entry in the LDAP directory:

```
uid=boris_ldap,ou=People,dc=example,dc=com
```

Then the statement to create the MySQL account for `boris` looks like this:

```sql
CREATE USER 'boris'@'localhost'
  IDENTIFIED WITH authentication_ldap_sasl
    AS 'uid=boris_ldap,ou=People,dc=example,dc=com';
```

The authentication string specified in the `BY` clause does not include the LDAP password. That must be provided by the client user at connect time.

Clients connect to the MySQL server by providing the MySQL user name and LDAP password:
Authentication Plugins

For the server-side authentication_ldap_sasl plugin, clients use the client-side authentication_ldap_sasl_client plugin. If a client program does not find the client-side plugin, specify a --plugin-dir option that names the directory where the plugin library file is installed.

The authentication process for boris is similar to that previously described for betsy with simple LDAP authentication, except that the client-side and server-side SASL LDAP plugins use SASL messages for secure transmission of credentials within the LDAP protocol, to avoid sending the cleartext password between the MySQL client and server.

LDAP Authentication with Proxying

LDAP authentication plugins support proxying, enabling a user to connect to the MySQL server as one user but assume the privileges of a different user. This section describes basic LDAP plugin proxy support. The LDAP plugins also support specification of group preference and proxy user mapping; see LDAP Authentication Group Preference and Mapping Specification.

The proxying implementation described here is based on use of LDAP group attribute values to map connecting MySQL users who authenticate using LDAP onto other MySQL accounts that define different sets of privileges. Users do not connect directly through the accounts that define the privileges. Instead, they connect through a default proxy account authenticated with LDAP, such that all external logins are mapped to the proxied MySQL accounts that hold the privileges. Any user who connects using the proxy account is mapped to one of those proxied MySQL accounts, the privileges for which determine the database operations permitted to the external user.

The instructions here assume the following scenario:

- LDAP entries use the uid and cn attributes to specify user name and group values, respectively. To use different user and group attribute names, set the appropriate plugin-specific system variables:
  - For the authentication_ldap_simple plugin: Set authentication_ldap_simple_user_search_attr and authentication_ldap_simple_group_search_attr.
  - For the authentication_ldap_sasl plugin: Set authentication_ldap_sasl_user_search_attr and authentication_ldap_sasl_group_search_attr.
  - These LDAP entries are available in the directory managed by the LDAP server, to provide distinguished name values that uniquely identify each user:
    
    ```
    uid=basha,ou=People,dc=example,dc=com,cn=accounting
    uid=basil,ou=People,dc=example,dc=com,cn=front_office
    ```

    At connect time, the group attribute values become the authenticated user names, so they name the accounting and front_office proxied accounts.

- The examples assume use of SASL LDAP authentication. Make the appropriate adjustments for simple LDAP authentication.

Create the default proxy MySQL account:

```sql
CREATE USER ''@'%' IDENTIFIED WITH authentication_ldap_sasl;
```

The proxy account definition has no AS 'auth_string' clause to name an LDAP user DN. Thus:
• When a client connects, the client user name becomes the LDAP user name to search for.

• The matching LDAP entry is expected to include a group attribute naming the proxied MySQL account that defines the privileges the client should have.

Note
If your MySQL installation has anonymous users, they might conflict with the default proxy user. For more information about this issue, and ways of dealing with it, see Default Proxy User and Anonymous User Conflicts.

Create the proxied accounts and grant to each one the privileges it should have:

```sql
CREATE USER 'accounting'@'localhost'
    IDENTIFIED WITH mysql_no_login;
CREATE USER 'front_office'@'localhost'
    IDENTIFIED WITH mysql_no_login;

GRANT ALL PRIVILEGES
    ON accountingdb.*
    TO 'accounting'@'localhost';
GRANT ALL PRIVILEGES
    ON frontdb.*
    TO 'front_office'@'localhost';
```

The proxied accounts use the `mysql_no_login` authentication plugin to prevent clients from using the accounts to log in directly to the MySQL server. Instead, users who authenticate using LDAP are expected to use the default `'@'` proxy account. (This assumes that the `mysql_no_login` plugin is installed. For instructions, see Section 6.4.1.8, "No-Login Pluggable Authentication"). For alternative methods of protecting proxied accounts against direct use, see Preventing Direct Login to Proxied Accounts.

Grant to the proxy account the `PROXY` privilege for each proxied account:

```sql
GRANT PROXY
    ON 'accounting'@'localhost'
    TO '@'@'%';
GRANT PROXY
    ON 'front_office'@'localhost'
    TO '@'@'%';
```

Use the `mysql` command-line client to connect to the MySQL server as `basha`.

```
shell> mysql --user=basha --password
Enter password: basha_password (basha LDAP password)
```

Authentication occurs as follows:

1. The server authenticates the connection using the default `'@'` proxy account, for client user `basha`.

2. The matching LDAP entry is:

   `uid=basha,ou=People,dc=example,dc=com,cn=accounting`

3. The matching LDAP entry has group attribute `cn=accounting`, so `accounting` becomes the authenticated proxied user.

4. The authenticated user differs from the client user name `basha`, with the result that `basha` is treated as a proxy for `accounting`, and `basha` assumes the privileges of the proxied `accounting` account. The following query returns output as shown:

   ```sql
   mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
   ```
This demonstrates that `basha` uses the privileges granted to the proxied `accounting` MySQL account, and that proxying occurs through the default proxy user account.

Now connect as `basil` instead:

```
shell> mysql --user=basil --password
Enter password: basil_password (basil LDAP password)
```

The authentication process for `basil` is similar to that previously described for `basha`:

1. The server authenticates the connection using the default `''@'%'` proxy account, for client user `basil`.
2. The matching LDAP entry is:
   ```
   uid=basil,ou=People,dc=example,dc=com,cn=front_office
   ```
3. The matching LDAP entry has group attribute `cn=front_office`, so `front_office` becomes the authenticated proxied user.
4. The authenticated user differs from the client user name `basil`, with the result that `basil` is treated as a proxy for `front_office`, and `basil` assumes the privileges of the proxied `front_office` account. The following query returns output as shown:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----------------+------------------------+--------------+
| USER()          | CURRENT_USER()         | @@proxy_user |
+-----------------+------------------------+--------------+
| basil@localhost | front_office@localhost | ''@'%'       |
```

This demonstrates that `basil` uses the privileges granted to the proxied `front_office` MySQL account, and that proxying occurs through the default proxy user account.

**LDAP Authentication Group Preference and Mapping Specification**

As described in [LDAP Authentication with Proxying](#), basic LDAP authentication proxying works by the principle that the plugin uses the first group name returned by the LDAP server as the MySQL proxied user account name. This simple capability does not enable specifying any preference about which group name to use if the LDAP server returns multiple group names, or specifying any name other than the group name as the proxied user name.

As of MySQL 8.0.14, for MySQL accounts that use LDAP authentication, the authentication string can specify the following information to enable greater proxying flexibility:

- A list of groups in preference order, such that the plugin uses the first group name in the list that matches a group returned by the LDAP server.
- A mapping from group names to proxied user names, such that a group name when matched can provide a specified name to use as the proxied user. This provides an alternative to using the group name as the proxied user.

Consider the following MySQL proxy account definition:

```sql
CREATE USER ''@'%'`
```
The authentication string has a user DN suffix `ou=People,dc=example,dc=com` prefixed by the `+` character. Thus, as described in LDAP Authentication User DN Suffixes, the full user DN is constructed from the user DN suffix as specified, plus the client user name as the `uid` attribute.

The remaining part of the authentication string begins with `#`, which signifies the beginning of group preference and mapping information. This part of the authentication string lists group names in the order `grp1, grp2, grp3`. The LDAP plugin compares that list with the set of group names returned by the LDAP server, looking in list order for a match against the returned names. The plugin uses the first match, or if there is no match, authentication fails.

Suppose that the LDAP server returns groups `grp3, grp2, grp7`. The LDAP plugin uses `grp2` because it is the first group in the authentication string that matches, even though it is not the first group returned by the LDAP server. If the LDAP server returns `grp4, grp2, grp1`, the plugin uses `grp1` even though `grp2` also matches. `grp1` has a precedence higher than `grp2` because it is listed earlier in the authentication string.

Assuming that the plugin finds a group name match, it performs mapping from that group name to the MySQL proxied user name, if there is one. For the example proxy account, mapping occurs as follows:

- If the matching group name is `grp1` or `grp3`, those are associated in the authentication string with user names `usera` and `userc`, respectively. The plugin uses the corresponding associated user name as the proxied user name.
- If the matching group name is `grp2`, there is no associated user name in the authentication string. The plugin uses `grp2` as the proxied user name.

If the LDAP server returns a group in DN format, the LDAP plugin parses the group DN to extract the group name from it.

To specify LDAP group preference and mapping information, these principles apply:

- Begin the group preference and mapping part of the authentication string with a `#` prefix character.
- The group preference and mapping specification is a list of one or more items, separated by commas. Each item has the form `group_name=user_name` or `group_name`. Items should be listed in group name preference order. For a group name selected by the plugin as a match from set of group names returned by the LDAP server, the two syntaxes differ in effect as follows:
  - For an item specified as `group_name=user_name` (with a user name), the group name maps to the user name, which is used as the MySQL proxied user name.
  - For an item specified as `group_name` (with no user name), the group name is used as the MySQL proxied user name.
- To quote a group or user name that contains special characters such as space, surround it by double quote (`"`) characters. For example, if an item has group and user names of `my group name` and `my user name`, it must be written in a group mapping using quotes:

  "my group name"="my user name"

If an item has group and user names of `my_group_name` and `my_user_name` (which contain no special characters), it may but need not be written using quotes. Any of the following are valid:

```
my_group_name=my_user_name
my_group_name="my_user_name"
```
Authentication Plugins

"my_group_name"=my_user_name
"my_group_name"="my_user_name"

- To escape a character, precede it by a backslash (\). This is useful particularly to include a literal double quote or backslash, which are otherwise not included literally.

- A user DN need not be present in the authentication string, but if present, it must precede the group preference and mapping part. A user DN can be given as a full user DN, or as a user DN suffix with a + prefix character. (See LDAP Authentication User DN Suffixes.)

LDAP Authentication User DN Suffixes

LDAP authentication plugins permit the authentication string that provides user DN information to begin with a + prefix character:

- In the absence of a + character, the authentication string value is treated as is without modification.

- If the authentication string begins with +, the plugin constructs the full user DN value from the user name sent by the client, together with the DN specified in the authentication string (with the + removed). In the constructed DN, the client user name becomes the value of the attribute that specifies LDAP user names. This is \texttt{uid} by default; to change the attribute, modify the appropriate system variable (\texttt{authentication_ldap_simple_user_search_attr} or \texttt{authentication_ldap_sasl_user_search_attr}). The authentication string is stored as given in the \texttt{mysql.user} system table, with the full user DN constructed on the fly before authentication.

This account authentication string does not have + at the beginning, so it is taken as the full user DN:

```
CREATE USER 'baldwin'
 IDENTIFIED WITH authentication_ldap_simple
 AS 'uid=admin,ou=People,dc=example,dc=com';
```

The client connects with the user name specified in the account (\texttt{baldwin}). In this case, that name is not used because the authentication string has no prefix and thus fully specifies the user DN.

This account authentication string does have + at the beginning, so it is taken as just part of the user DN:

```
CREATE USER 'accounting'
 IDENTIFIED WITH authentication_ldap_simple
 AS '+ou=People,dc=example,dc=com';
```

The client connects with the user name specified in the account (\texttt{accounting}), which in this case is used as the \texttt{uid} attribute together with the authentication string to construct the user DN:

```
uid=accounting,ou=People,dc=example,dc=com
```

The accounts in the preceding examples have a nonempty user name, so the client always connects to the MySQL server using the same name as specified in the account definition. If an account has an empty user name, such as the default anonymous '@%' proxy account described in LDAP Authentication with Proxying, clients might connect to the MySQL server with varying user names. But the principle is the same: If the authentication string begins with +, the plugin uses the user name sent by the client together with the authentication string to construct the user DN.

LDAP Authentication Methods

The LDAP authentication plugins use a configurable authentication method. The appropriate system variable and available method choices are plugin-specific:

- For the \texttt{authentication_ldap_simple} plugin: Set the \texttt{authentication_ldap_simple_auth_method_name} system variable to configure the method. The permitted choices are \texttt{SIMPLE} and \texttt{AD-FOREST}. 
For the `authentication_ldap_sasl` plugin: Set the `authentication_ldap_sasl_auth_method_name` system variable to configure the method. The permitted choices are SCRAM-SHA-1, SCRAM-SHA-256, and GSSAPI. (To determine which SASL LDAP methods are actually available on the host system, check the value of the `Authentication_ldap_sasl_supported_methods` status variable.)

See the system variable descriptions for information about each permitted method. Also, depending on the method, additional configuration may be needed, as described in the following sections.

The GSSAPI/Kerberos Authentication Method

Generic Security Service Application Program Interface (GSSAPI) is a security abstraction interface. Kerberos is an instance of a specific security protocol that can be used through that abstract interface. Using GSSAPI, applications authenticate to Kerberos to obtain service credentials, then use those credentials in turn to enable secure access to other services.

One such service is LDAP, which is used by the client-side and server-side SASL LDAP authentication plugins. When the `authentication_ldap_sasl_auth_method_name` system variable is set to GSSAPI, these plugins use the GSSAPI/Kerberos authentication method. In this case, the plugins communicate securely using Kerberos without using LDAP messages directly. The server-side plugin then communicates with the LDAP server to interpret LDAP authentication messages and retrieve LDAP groups.

GSSAPI/Kerberos is supported as an authentication method for MySQL clients and servers only on Linux. It is useful in Linux environments where applications access LDAP using Microsoft Active Directory, which has Kerberos enabled by default.

The following discussion provides information about the configuration requirements for using the GSSAPI method. Familiarity is assumed with Kerberos concepts and operation, such as these common Kerberos terms:

- **Principal** = A named entity, such as a user or service.
- **KDC** = The Key Distribution Center, comprising the AS and TGS.
- **AS** = The Authentication Server, part of the KDC. Provides the initial ticket needed to obtain a TGT.
- **TGS** = The ticket-granting service, part of the KDC.
- **TGT** = The ticket-granting ticket, presented to the TGS to obtain service tickets for service access.

Kerberos authentication requires both a KDC server and an LDAP server. This requirement can be satisfied in different ways:

- **Active Directory** includes both servers, with Kerberos authentication enabled by default in the Active Directory LDAP server.
- **OpenLDAP** provides an LDAP server, but a separate KDC server may be needed, with additional Kerberos setup required.

Kerberos must also be available on the client host. A client contacts the AS using a password to obtain a TGT. The client then uses the TGT to obtain access from the TGS to other services, such as LDAP.

The following sections discuss the configuration steps to use GSSAPI/Kerberos for SASL LDAP authentication in MySQL:

- **Check the Kerberos Setup**
Authentication Plugins

- Configure the Server-Side SASL LDAP Authentication Plugin for GSSAPI/Kerberos
- Create a MySQL Account That Uses GSSAPI/Kerberos
- Use the MySQL Account to Connect to the MySQL Server
- /etc/krb5.conf Client Configuration Parameters

Check the Kerberos Setup

The following example shows how to test availability of Kerberos in Active Directory. The example makes these assumptions:

- Active Directory is running on the host named ldap_auth.example.com with IP address 198.51.100.10.
- The MYSQL.LOCAL domain is used for MySQL-related Kerberos authentication and LDAP lookups.
- A principal named bredon@MYSQL.LOCAL is registered with the KDC. (In later discussion, this principal name is also used for the MySQL user that uses GSSAPI/Kerberos to authenticate to the MySQL server.)

With those assumptions satisfied, follow this procedure:

1. Verify that the Kerberos library is installed and configured correctly in the operating system. For example, to configure a MYSQL.LOCAL domain for use during MySQL authentication, the Kerberos configuration file, /etc/krb5.conf, should contain something like this:

```
[realms]
MYSQL.LOCAL = {
    kdc = ldap_auth.example.com
    admin_server = ldap_auth.example.com
    default_domain = MYSQL.LOCAL
}
```

2. You may need to add an entry to /etc/hosts for the server host:

```
198.51.100.10 ldap_auth ldap_auth.example.com
```

3. Check whether Kerberos authentication works correctly:
   a. Use `kinit` to authenticate to Kerberos:

```
kinit bredon@MYSQL.LOCAL
```

   The command authenticates for the Kerberos principal named bredon@MYSQL.LOCAL. Enter the principal's password when the command prompts for it. The KDC returns a TGT that is cached on the client side for use by other Kerberos-aware applications.

   b. Use `klist` to check whether the TGT was obtained correctly. The output should be similar to this:

```
Ticket cache: FILE:/tmp/krb5cc_244306
Default principal: bredon@MYSQL.LOCAL

Valid starting       Expires              Service principal
03/23/2020 08:18:33  03/23/2020 18:18:33  krbtgt/MYSQL.LOCAL@MYSQL.LOCAL
```

4. Check whether `ldapsearch` works with the Kerberos TGT using this command, which searches for users in the MYSQL.LOCAL domain:

```
ldapsearch -h 198.51.100.10 -Y GSSAPI -b "dc=MYS...
Configure the Server-Side SASL LDAP Authentication Plugin for GSSAPI/Kerberos

Assuming that the LDAP server is accessible through Kerberos as just described, configure the server-side SASL LDAP authentication plugin to use the GSSAPI/Kerberos authentication method. (For general LDAP plugin installation information, see Installing LDAP Pluggable Authentication.) Here is an example of plugin-related settings the server `my.cnf` file might contain:

```
[mysqld]
plugin-load-add=authentication_ldap_sasl.so
authentication_ldap_sasl_auth_method_name="GSSAPI"
authentication_ldap_sasl_server_host=198.51.100.10
authentication_ldap_sasl_server_port=389
authentication_ldap_sasl_bind_root_dn="cn=admin,cn=users,dc=MYSQL,dc=LOCAL"
authentication_ldap_sasl_bind_root_pwd="password"
authentication_ldap_sasl_bind_base_dn="cn=users,dc=MYSQL,dc=LOCAL"
authentication_ldap_sasl_user_search_attr="sAMAccountName"
```

Those option file settings configure the SASL LDAP plugin as follows:

- The `--plugin-load-add` option loads the plugin (adjust the `.so` suffix for your platform as necessary). If you loaded the plugin previously using an `INSTALL PLUGIN` statement, this option is unnecessary.

- `authentication_ldap_sasl_auth_method_name` must be set to `GSSAPI` to use GSSAPI/Kerberos as the SASL LDAP authentication method.

- `authentication_ldap_sasl_server_host` and `authentication_ldap_sasl_server_port` indicate the IP address and port number of the Active Directory server host for authentication.

- `authentication_ldap_sasl_bind_root_dn` and `authentication_ldap_sasl_bind_root_pwd` configure the root DN and password for group search capability. This capability is required, but users may not have privileges to search. In such cases, it is necessary to provide root DN information:
  - In the DN option value, `admin` should be the name of an administrative LDAP account that has privileges to perform user searches.
  - In the password option value, `password` should be the `admin` account password.

- `authentication_ldap_sasl_bind_base_dn` indicates the user DN base path, so that searches look for users in the `MYSQL.LOCAL` domain.

- `authentication_ldap_sasl_user_search_attr` specifies a standard Active Directory search attribute, `sAMAccountName`. This attribute is used in searches to match logon names; attribute values are not the same as the user DN values.

Create a MySQL Account That Uses GSSAPI/Kerberos

MySQL authentication using the SASL LDAP authentication plugin with the GSSAPI/Kerberos method is based on a user that is a Kerberos principal. The following discussion uses a principal named `bredon@MYSQL.LOCAL` as this user, which must be registered in several places:

- The Kerberos administrator should register the user name as a Kerberos principal. This name should include a domain name. The principal name and password are used by clients to authenticate with Kerberos and obtain a TGT.

- The LDAP administrator should register the user name in an LDAP entry. For example:
Authentication Plugins

Note

In Active Directory (which uses Kerberos as the default authentication method), creating a user creates both the Kerberos principal and the LDAP entry.

- The MySQL DBA should create an account that has the Kerberos principal name as the user name, and that authenticates using the SASL LDAP plugin.

Assuming that the Kerberos principal and LDAP entry have been registered by the appropriate service administrators, and that the MySQL server has been started using the `my.cnf` settings previously described, create a MySQL account that corresponds to the Kerberos principal name, including the domain name.

Note

The SASL LDAP plugin uses a constant user DN for Kerberos authentication and ignores any user DN configured from MySQL. This has certain implications:

- For any MySQL account that uses GSSAPI/Kerberos authentication, the authentication string in `CREATE USER` or `ALTER USER` statements should contain no user DN because it has no effect.

- Because the authentication string contains no user DN, it should contain group mapping information, to enable the user to be handled as a proxy user that is mapped onto the desired proxied user. For information about proxying with the LDAP authentication plugin, see LDAP Authentication with Proxying.

The following statements create a proxy user named `bredon@MYSQL.LOCAL` that assumes the privileges of the proxied user named `proxied_krb_usr`. Other GSSAPI/Kerberos users that should have the same privileges can similarly be created as proxy users for the same proxied user.

```
-- create proxy account
CREATE USER 'bredon@MYSQL.LOCAL'
  IDENTIFIED WITH authentication_ldap_sasl
  BY '#krb_grp=proxied_krb_user';

-- create proxied account and grant its privileges;
-- use mysql_no_login plugin to prevent direct login
CREATE USER 'proxied_krb_user'
  IDENTIFIED WITH mysql_no_login;
GRANT ALL
  ON krb_user_db.*
  TO 'proxied_krb_user';

-- grant to proxy account the
-- proxy privilege for proxied account
GRANT PROXY
  ON 'proxied_krb_user'
  TO 'bredon@MYSQL.LOCAL';
```

Observe closely the quoting for the proxy account name in the first `CREATE USER` statement and the `GRANT PROXY` statement:

- For most MySQL accounts, the user and host are separate parts of the account name, and thus are quoted separately as `"user_name"@"host_name"`.

- For Kerberos authentication, the user part of the account name includes the principal domain, so `"bredon@MYSQL.LOCAL"` is quoted as a single value. Because no host part is given, the full MySQL account name uses the default of `"%"` as the host part: `"bredon@MYSQL.LOCAL"@"%"`
The proxied account uses the `mysql_no_login` authentication plugin to prevent clients from using the account to log in directly to the MySQL server. Instead, it is expected that users who authenticate using LDAP use the `bredon@MYSQL.LOCAL` proxy account. (This assumes that the `mysql_no_login` plugin is installed. For instructions, see Section 6.4.1.8, “No-Login Pluggable Authentication”.) For alternative methods of protecting proxied accounts against direct use, see Preventing Direct Login to Proxy Accounts.

**Use the MySQL Account to Connect to the MySQL Server**

After a MySQL account that uses GSSAPI/Kerberos has been set up, clients can authenticate to Kerberos and use the account to connect to the MySQL server. Kerberos authentication can take place either prior to or at the time of MySQL client program invocation:

- The client user can obtain a TGT independently of MySQL prior to invoking the MySQL client program. For example, the client user can use `kinit` to authenticate to Kerberos by providing a Kerberos principal name and the principal password. The TGT is cached and becomes available for use by other Kerberos-aware applications, such as the client-side SASL LDAP authentication plugin. In this case, the MySQL client program authenticates to the MySQL server using the TGT, so invoke the client without specifying a user name or password:

  ```
  shell> kinit bredon@MYSQL.LOCAL
  Password for bredon@MYSQL.LOCAL: (enter password here)
  shell> mysql --default-auth=authentication_ldap_sasl_client
  ```

  If the MySQL client command does include credentials, they are handled as follows:

  - If the command includes a user name, authentication fails if that name does not match the principal name in the TGT.
  - If the command includes a password, the password is ignored. Because authentication is based on the TGT, it can succeed even if the user-provided password is incorrect. For this reason, the plugin produces a warning if a valid TGT is found that causes a password to be ignored.
  - If there is no TGT, the client-side SASL LDAP authentication plugin itself can obtain the TGT from the KDC. In this case, to invoke the client, specify the name and password of the Kerberos principal associated with the MySQL account (enter the command on a single line, then enter the principal password at the prompt):

    ```
    shell> mysql --default-auth=authentication_ldap_sasl_client
    --user=bredon@MYSQL.LOCAL
    --password
    Enter password: (enter password here)
    ```

  - If the client command specifies no principal name as the user name and the client-side plugin finds the Kerberos cache empty because there is no TGT, authentication fails.

  If you are uncertain whether a TGT exists, you can use `klist` to check.

  Authentication occurs as follows:

  1. The client uses the TGT to authenticate using Kerberos.
  2. The server finds the LDAP entry for the principal and uses it to authenticate the connection for the `bredon@MYSQL.LOCAL` MySQL proxy account.
  3. The group mapping information in the proxy account authentication string (`'#krb_grp=proxied_krb_user'`) indicates that the authenticated proxied user should be `proxied_krb_user`.

1302
4. `bredon@MYSQL.LOCAL` is treated as a proxy for `proxied_krb_user`, and the following query returns output as shown:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+------------------------------+--------------------+--------------------------+
<table>
<thead>
<tr>
<th>USER()</th>
<th>CURRENT_USER()</th>
<th>@@proxy_user</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="mailto:bredon@MYSQL.LOCAL">bredon@MYSQL.LOCAL</a>@localhost</td>
<td>proxied_krb_user@%</td>
<td>'<a href="mailto:bredon@MYSQL.LOCAL">bredon@MYSQL.LOCAL</a>'@'%'</td>
</tr>
</tbody>
</table>
+------------------------------+--------------------+--------------------------+
```

The `USER()` value indicates the user name used for the client command (`bredon@MYSQL.LOCAL`) and the host from which the client connected (`localhost`).

The `CURRENT_USER()` value is the full name of the proxied user account, which consists of the `proxied_krb_user` user part and the `%` host part.

The `@@proxy_user` value indicates the full name of the account used to make the connection to the MySQL server, which consists of the `bredon@MYSQL.LOCAL` user part and the `%` host part.

This demonstrates that proxying occurs through the `bredon@MYSQL.LOCAL` proxy user account, and that `bredon@MYSQL.LOCAL` assumes the privileges granted to the `proxied_krb_user` proxied user account.

A TGT once obtained is cached on the client side and can be used until it expires without specifying the password again. However the TGT is obtained, the client-side plugin uses it to acquire service tickets and communicate with the server-side plugin.

When the client-side plugin itself obtains the TGT, the client user may not want the TGT to be reused. As described in `/etc/krb5.conf Client Configuration Parameters`, the local `/etc/krb5.conf` file can be used to cause the client-side plugin to destroy the TGT when done with it.

The server-side plugin has no access to the TGT itself or the Kerberos password used to obtain it.

The LDAP authentication plugins have no control over the caching mechanism (storage in a local file, in memory, and so forth), but Kerberos utilities such as `kswitch` may be available for this purpose.

/etc/krb5.conf Client Configuration Parameters

The client-side SASL LDAP plugin reads the local `/etc/krb5.conf` file. If this file is missing or inaccessible, an error occurs. Assuming that the file is accessible, the optional `[appdefaults]` group can be used to provide information used by the plugin. Place such information within the `MySQL` section of the group. For example:

```
[appdefaults]
MySQL = {
  ldap_server_host = "ldap_host.example.com"
  ldap_destroy_tgt = true
}
```

The client-side plugin recognizes these parameters in the `MySQL` section:

- The `ldap_server_host` value specifies the LDAP server host and can be useful when that host differs from the KDC server host specified in the `[realms]` group. By default, the plugin uses the KDC server host as the LDAP server host.

- The `ldap_destroy_tgt` value indicates whether the client-side plugin destroys the TGT after obtaining and using it. By default, `ldap_destroy_tgt` is `false`, but can be set to `true` to avoid TGT reuse. (This setting applies only to TGTs created by the client-side plugin, not TGTs created externally to MySQL.)
**Authentication Plugins**

**LDAP Search Referral**

An LDAP server can be configured to delegate LDAP searches to another LDAP server, a functionality known as LDAP referral. Suppose that the server `a.example.com` holds a "dc=example,dc=com" root DN and wishes to delegate searches to another server `b.example.com`. To enable this, `a.example.com` would be configured with a named referral object having these attributes:

```plaintext
dn: dc=subtree,dc=example,dc=com
objectClass: referral
objectClass: extensibleObject
dc: subtree
ref: ldap://b.example.com/dc=subtree,dc=example,dc=com
```

An issue with enabling LDAP referral is that searches can fail with LDAP operation errors when the search base DN is the root DN, and referral objects are not set. A MySQL DBA might wish to avoid such referral errors for the LDAP authentication plugins, even though LDAP referral might be be set globally in the `ldap.conf` configuration file. To configure on a plugin-specific basis whether the LDAP server should use LDAP referral when communicating with each plugin, set the `authentication_ldap_simple_referral` and `authentication_ldap_sasl_referral` system variables. Setting either variable to `ON` or `OFF` causes the corresponding LDAP authentication plugin to tell the LDAP server whether to use referral during MySQL authentication. Each variable has a plugin-specific effect and does not affect other applications that communicate with the LDAP server. Both variables are `OFF` by default.

### 6.4.1.8 No-Login Pluggable Authentication

The `mysql_no_login` server-side authentication plugin prevents all client connections to any account that uses it. Use cases for this plugin include:

- Accounts that must be able to execute stored programs and views with elevated privileges without exposing those privileges to ordinary users.
- Proxied accounts that should never permit direct login but are intended to be accessed only through proxy accounts.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file must be located in the directory named by the `plugin_dir` system variable.

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td>mysql_no_login</td>
</tr>
<tr>
<td>Client-side plugin</td>
<td>None</td>
</tr>
<tr>
<td>Library file</td>
<td>mysql_no_login.so</td>
</tr>
</tbody>
</table>

The following sections provide installation and usage information specific to no-login pluggable authentication:

- Installing No-Login Pluggable Authentication
- Uninstalling No-Login Pluggable Authentication
- Using No-Login Pluggable Authentication

For general information about pluggable authentication in MySQL, see Section 6.2.17, “Pluggable Authentication”. For proxy user information, see Section 6.2.18, “Proxy Users”.

1304
Installing No-Login Pluggable Authentication

This section describes how to install the no-login authentication plugin. For general information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `mysql_no_login`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To load the plugin at server startup, use the `--plugin-load-add` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```sql
[mysqld]
plugin-load-add=mysql_no_login.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN mysql_no_login SONAME 'mysql_no_login.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE '%login%';
+----------------+---------------+
| PLUGIN_NAME     | PLUGIN_STATUS |
|----------------+---------------|
| mysql_no_login  | ACTIVE        |
+----------------+---------------+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the no-login plugin, see Using No-Login Pluggable Authentication.

Uninstalling No-Login Pluggable Authentication

The method used to uninstall the no-login authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.

- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN mysql_no_login;
```
**Using No-Login Pluggable Authentication**

This section describes how to use the no-login authentication plugin to prevent accounts from being used for connecting from MySQL client programs to the server. It is assumed that the server is running with the no-login plugin enabled, as described in [Installing No-Login Pluggable Authentication](#).

To refer to the no-login authentication plugin in the `IDENTIFIED WITH` clause of a `CREATE USER` statement, use the name `mysql_no_login`.

An account that authenticates using `mysql_no_login` may be used as the `DEFINER` for stored program and view objects. If such an object definition also includes `SQL SECURITY DEFINER`, it executes with that account's privileges. DBAs can use this behavior to provide access to confidential or sensitive data that is exposed only through well-controlled interfaces.

The following example illustrates these principles. It defines an account that does not permit client connections, and associates with it a view that exposes only certain columns of the `mysql.user` system table:

```sql
CREATE DATABASE nologindb;
CREATE USER 'nologin'@'localhost'
  IDENTIFIED WITH mysql_no_login;
GRANT ALL ON nologindb.*
  TO 'nologin'@'localhost';
GRANT SELECT ON mysql.user
  TO 'nologin'@'localhost';
CREATE DEFINER = 'nologin'@'localhost'
  SQL SECURITY DEFINER
  VIEW nologindb.myview
  AS SELECT User, Host FROM mysql.user;
```

To provide protected access to the view to an ordinary user, do this:

```sql
GRANT SELECT ON nologindb.myview
  TO 'ordinaryuser'@'localhost';
```

Now the ordinary user can use the view to access the limited information it presents:

```sql
SELECT * FROM nologindb.myview;
```

Attempts by the user to access columns other than those exposed by the view result in an error, as do attempts to select from the view by users not granted access to it.

---

**Note**

Because the `nologin` account cannot be used directly, the operations required to set up objects that it uses must be performed by `root` or similar account that has the privileges required to create the objects and set `DEFINER` values.

The `mysql_no_login` plugin is also useful in proxying scenarios. (For a discussion of concepts involved in proxying, see [Section 6.2.18, “Proxy Users”](#).) An account that authenticates using `mysql_no_login` may be used as a proxied user for proxy accounts:

```sql
-- create proxied account
CREATE USER 'proxied_user'@'localhost'
  IDENTIFIED WITH mysql_no_login;
-- grant privileges to proxied account
GRANT ...
  ON ... 
  TO 'proxied_user'@'localhost';
-- permit proxy_user to be a proxy account for proxied account
GRANT PROXY ON 'proxied_user'@'localhost'
```
TO 'proxy_user'@'localhost';

This enables clients to access MySQL through the proxy account (proxy_user) but not to bypass the proxy mechanism by connecting directly as the proxied user (proxied_user). A client who connects using the proxy_user account has the privileges of the proxied_user account, but proxied_user itself cannot be used to connect.

For alternative methods of protecting proxied accounts against direct use, see Preventing Direct Login to Proxied Accounts.

### 6.4.1.9 Socket Peer-Credential Pluggable Authentication

The server-side auth_socket authentication plugin authenticates clients that connect from the local host through the Unix socket file. The plugin uses the SO_PEERCRED socket option to obtain information about the user running the client program. Thus, the plugin can be used only on systems that support the SO_PEERCRED option, such as Linux.

The source code for this plugin can be examined as a relatively simple example demonstrating how to write a loadable authentication plugin.

The following table shows the plugin and library file names. The file must be located in the directory named by the plugin_dir system variable.

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td>auth_socket</td>
</tr>
<tr>
<td>Client-side plugin</td>
<td>None, see discussion</td>
</tr>
<tr>
<td>Library file</td>
<td>auth_socket.so</td>
</tr>
</tbody>
</table>

The following sections provide installation and usage information specific to socket pluggable authentication:

- Installing Socket Pluggable Authentication
- Uninstalling Socket Pluggable Authentication
- Using Socket Pluggable Authentication

For general information about pluggable authentication in MySQL, see Section 6.2.17, “Pluggable Authentication”.

#### Installing Socket Pluggable Authentication

This section describes how to install the socket authentication plugin. For general information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the plugin_dir system variable). If necessary, configure the plugin directory location by setting the value of plugin_dir at server startup.

To load the plugin at server startup, use the --plugin-load-add option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server my.cnf file:

```
[mysqld]
plugin-load-add=auth_socket.so
```
Authentication Plugins

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement:

```
INSTALL PLUGIN auth_socket SONAME 'auth_socket.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
               FROM INFORMATION_SCHEMA.PLUGINS
          WHERE PLUGIN_NAME LIKE '%socket%';
```

<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>PLUGIN_STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>auth_socket</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the socket plugin, see Using Socket Pluggable Authentication.

Uninstalling Socket Pluggable Authentication

The method used to uninstall the socket authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.

- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN auth_socket;
```

Using Socket Pluggable Authentication

The socket plugin checks whether the socket user name (the operating system user name) matches the MySQL user name specified by the client program to the server. If the names do not match, the plugin checks whether the socket user name matches the name specified in the `authentication_string` column of the `mysql.user` system table row. If a match is found, the plugin permits the connection. The `authentication_string` value can be specified using an `IDENTIFIED ...AS` clause with `CREATE USER` or `ALTER USER`.

Suppose that a MySQL account is created for an operating system user named `valerie` who is to be authenticated by the `auth_socket` plugin for connections from the local host through the socket file:

```
CREATE USER 'valerie'@'localhost' IDENTIFIED WITH auth_socket;
```

If a user on the local host with a login name of `stefanie` invokes `mysql` with the option `--user=valerie` to connect through the socket file, the server uses `auth_socket` to authenticate the client. The plugin determines that the `--user` option value (`valerie`) differs from the client user’s name (`stephanie`) and refuses the connection. If a user named `valerie` tries the same thing, the plugin finds that the user name and the MySQL user name are both `valerie` and permits the connection. However, the plugin refuses the connection even for `valerie` if the connection is made using a different protocol, such as TCP/IP.
Authentication Plugins

To permit both the valerie and stephanie operating system users to access MySQL through socket file connections that use the account, this can be done two ways:

- Name both users at account-creation time, one following `CREATE USER`, and the other in the authentication string:
  
  ```sql
  CREATE USER 'valerie'@'localhost' IDENTIFIED WITH auth_socket AS 'stephanie';
  ```

- If you have already used `CREATE USER` to create the account for a single user, use `ALTER USER` to add the second user:
  
  ```sql
  CREATE USER 'valerie'@'localhost' IDENTIFIED WITH auth_socket;
  ALTER USER 'valerie'@'localhost' IDENTIFIED WITH auth_socket AS 'stephanie';
  ```

To access the account, both valerie and stephanie specify `--user=valerie` at connect time.

6.4.1.10 Test Pluggable Authentication

MySQL includes a test plugin that checks account credentials and logs success or failure to the server error log. This is a loadable plugin (not built in) and must be installed prior to use.

The test plugin source code is separate from the server source, unlike the built-in native plugin, so it can be examined as a relatively simple example demonstrating how to write a loadable authentication plugin.

**Note**

This plugin is intended for testing and development purposes, and is not for use in production environments or on servers that are exposed to public networks.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file must be located in the directory named by the `plugin_dir` system variable.

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td>test_plugin_server</td>
</tr>
<tr>
<td>Client-side plugin</td>
<td>auth_test_plugin</td>
</tr>
<tr>
<td>Library file</td>
<td>auth_test_plugin.so</td>
</tr>
</tbody>
</table>

The following sections provide installation and usage information specific to test pluggable authentication:

- Installing Test Pluggable Authentication
- Uninstalling Test Pluggable Authentication
- Using Test Pluggable Authentication

For general information about pluggable authentication in MySQL, see Section 6.2.17, “Pluggable Authentication”.

### Installing Test Pluggable Authentication

This section describes how to install the test authentication plugin. For general information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.
Authentication Plugins

To load the plugin at server startup, use the `--plugin-load-add` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```
[mysqld]
plugin-load-add=auth_test_plugin.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN test_plugin_server SONAME 'auth_test_plugin.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE '%test_plugin%';
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the test plugin, see Using Test Pluggable Authentication.

### Uninstalling Test Pluggable Authentication

The method used to uninstall the test authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.

- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN test_plugin_server;
```

### Using Test Pluggable Authentication

To use the test authentication plugin, create an account and name that plugin in the `IDENTIFIED WITH` clause:

```
CREATE USER 'testuser'@'localhost'
IDENTIFIED WITH test_plugin_server
BY 'testpassword';
```

Then provide the `--user` and `--password` options for that account when you connect to the server. For example:

```
shell> mysql --user=testuser --password
Enter password: testpassword
```
The plugin fetches the password as received from the client and compares it with the value stored in the `authentication_string` column of the account row in the `mysql.user` system table. If the two values match, the plugin returns the `authentication_string` value as the new effective user ID.

You can look in the server error log for a message indicating whether authentication succeeded (notice that the password is reported as the “user”):

```
[Note] Plugin test_plugin_server reported: 'successfully authenticated user testpassword'
```

### 6.4.11 Pluggable Authentication System Variables

These variables are unavailable unless the appropriate server-side plugin is installed:

- `authentication_ldap_sasl` for system variables with names of the form `authentication_ldap_sasl_xxx`
- `authentication_ldap_simple` for system variables with names of the form `authentication_ldap_simple_xxx`

For SASL LDAP authentication, the authentication method name. Communication between the authentication plugin and the LDAP server occurs according to this authentication method to ensure password security.

These authentication method values are permitted:

- **SCRAM-SHA-1**: Use a SASL challenge-response mechanism.

  The client-side `authentication_ldap_sasl_client` plugin communicates with the SASL server, using the password to create a challenge and obtain a SASL request buffer, then passes this buffer to the server-side `authentication_ldap_sasl` plugin. The client-side and server-side SASL LDAP plugins use SASL messages for secure transmission of credentials within the LDAP protocol, to avoid sending the cleartext password between the MySQL client and server.

- **SCRAM-SHA-256**: Use a SASL challenge-response mechanism.

  This method is similar to **SCRAM-SHA-1**, but is more secure. It is available in MySQL 8.0.23 and higher. It requires an OpenLDAP server built using Cyrus SASL 2.1.27 or higher.

- **GSSAPI**: Use Kerberos, a passwordless and ticket-based protocol.
GSSAPI/Kerberos is supported as an authentication method for MySQL clients and servers only on Linux. It is useful in Linux environments where applications access LDAP using Microsoft Active Directory, which has Kerberos enabled by default.

The client-side `authentication_ldap_sasl_client` plugin obtains a service ticket using the ticket-granting ticket (TGT) from Kerberos, but does not use LDAP services directly. The server-side `authentication_ldap_sasl` plugin routes Kerberos messages between the client-side plugin and the LDAP server. Using the credentials thus obtained, the server-side plugin then communicates with the LDAP server to interpret LDAP authentication messages and retrieve LDAP groups.

- `authentication_ldap_sasl_bind_base_dn`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--authentication-ldap-sasl-bind-base-dn=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_sasl_bind_base_dn</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>NULL</code></td>
</tr>
</tbody>
</table>

For SASL LDAP authentication, the base distinguished name (DN). This variable can be used to limit the scope of searches by anchoring them at a certain location (the "base") within the search tree.

Suppose that members of one set of LDAP user entries each have this form:

```plaintext
uid=user_name,ou=People,dc=example,dc=com
```

And that members of another set of LDAP user entries each have this form:

```plaintext
uid=user_name,ou=Admin,dc=example,dc=com
```

Then searches work like this for different base DN values:

- If the base DN is `ou=People,dc=example,dc=com`: Searches find user entries only in the first set.
- If the base DN is `ou=Admin,dc=example,dc=com`: Searches find user entries only in the second set.
- If the base DN is `ou=dc=example,dc=com`: Searches find user entries in the first or second set.

In general, more specific base DN values result in faster searches because they limit the search scope more.

- `authentication_ldap_sasl_bind_root_dn`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--authentication-ldap-sasl-bind-root-dn=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_sasl_bind_root_dn</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
For SASL LDAP authentication, the password for the root distinguished name. This variable is used in conjunction with `authentication_ldap_sasl_bind_root_pwd` as the credentials for authenticating to the LDAP server for the purpose of performing searches. Authentication uses either one or two LDAP bind operations, depending on whether the MySQL account names an LDAP user DN:

- If the account does not name a user DN: `authentication_ldap_sasl` performs an initial LDAP binding using `authentication_ldap_sasl_bind_root_dn` and `authentication_ldap_sasl_bind_root_pwd`. (These are both empty by default, so if they are not set, the LDAP server must permit anonymous connections.) The resulting bind LDAP handle is used to search for the user DN, based on the client user name. `authentication_ldap_sasl` performs a second bind using the user DN and client-supplied password.

- If the account does name a user DN: The first bind operation is unnecessary in this case. `authentication_ldap_sasl` performs a single bind using the user DN and client-supplied password. This is faster than if the MySQL account does not specify an LDAP user DN.

`authentication_ldap_sasl_bind_root_pwd`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--authentication-ldap-sasl-bind-root-pwd=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_sasl_bind_root_pwd</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

For SASL LDAP authentication, the absolute path of the certificate authority file. Specify this file if it is desired that the authentication plugin perform verification of the LDAP server certificate.

`authentication_ldap_sasl_ca_path`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--authentication-ldap-sasl-ca-path=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_sasl_ca_path</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

Note

In addition to setting the `authentication_ldap_sasl_ca_path` variable to the file name, you must add the appropriate certificate authority certificates to the file and enable the `authentication_ldap_sasl_tls` system variable. These
variables can be set to override the default OpenLDAP TLS configuration; see LDAP Pluggable Authentication and ldap.conf

• authentication_ldap_sasl_group_search_attr

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--authentication-ldap-sasl-group-search-attr=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>authentication_ldap_sasl_group_search_attr</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>cn</td>
</tr>
</tbody>
</table>

For SASL LDAP authentication, the name of the attribute that specifies group names in LDAP directory entries. If authentication_ldap_sasl_group_search_attr has its default value of cn, searches return the cn value as the group name. For example, if an LDAP entry with a uid value of user1 has a cn attribute of mygroup, searches for user1 return mygroup as the group name.

This variable should be the empty string if you want no group or proxy authentication.

If the group search attribute is isMemberOf, LDAP authentication directly retrieves the user attribute isMemberOf value and assigns it as group information. If the group search attribute is not isMemberOf, LDAP authentication searches for all groups where the user is a member. (The latter is the default behavior.) This behavior is based on how LDAP group information can be stored two ways: 1) A group entry can have an attribute named memberUid or member with a value that is a user name; 2) A user entry can have an attribute named isMemberOf with values that are group names.

• authentication_ldap_sasl_group_search_filter

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--authentication-ldap-sasl-group-search-filter=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>authentication_ldap_sasl_group_search_filter</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>(</td>
</tr>
</tbody>
</table>

For SASL LDAP authentication, the custom group search filter.

The search filter value can contain {UA} and {UD} notation to represent the user name and the full user DN. For example, {UA} is replaced with a user name such as "admin", whereas {UD} is replaced with a use full DN such as "uid=admin,ou=People,dc=example,dc=com". The following value is the default, which supports both OpenLDAP and Active Directory:

```plaintext
(|&{objectClass=posixGroup}(memberUid={UA}))
(|&{objectClass=group}(member={UD}))
```

In some cases for the user scenario, memberOf is a simple user attribute that holds no group information. For additional flexibility, an optional {GA} prefix can be used with the group search attribute. Any group attribute with a {GA} prefix is treated as a user attribute having group names. For example,
Authentication Plugins

with a value of \{(GA)MemberOf\}, if the group value is the DN, the first attribute value from the group DN is returned as the group name.

- **authentication_ldap_sasl_init_pool_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--authentication-ldap-sasl-init-pool-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>authentication_ldap_sasl_init_pool_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR</td>
<td>Hint Applies: No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>32767</td>
</tr>
</tbody>
</table>

For SASL LDAP authentication, the initial size of the pool of connections to the LDAP server. Choose the value for this variable based on the average number of concurrent authentication requests to the LDAP server.

The plugin uses `authentication_ldap_sasl_init_pool_size` and `authentication_ldap_sasl_max_pool_size` together for connection-pool management:

- When the authentication plugin initializes, it creates `authentication_ldap_sasl_init_pool_size` connections, unless `authentication_ldap_sasl_max_pool_size=0` to disable pooling.

- If the plugin receives an authentication request when there are no free connections in the current connection pool, the plugin can create a new connection, up to the maximum connection pool size given by `authentication_ldap_sasl_max_pool_size`.

- If the plugin receives a request when the pool size is already at its maximum and there are no free connections, authentication fails.

- When the plugin unloads, it closes all pooled connections.

Changes to plugin system variable settings may have no effect on connections already in the pool. For example, modifying the LDAP server host, port, or TLS settings does not affect existing connections. However, if the original variable values were invalid and the connection pool could not be initialized, the plugin attempts to reinitialize the pool for the next LDAP request. In this case, the new system variable values are used for the reinitialization attempt.

If `authentication_ldap_sasl_max_pool_size=0` to disable pooling, each LDAP connection opened by the plugin uses the values the system variables have at that time.

- **authentication_ldap_sasl_log_status**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--authentication-ldap-sasl-log-status=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>authentication_ldap_sasl_log_status</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR</td>
<td>Hint Applies: No</td>
</tr>
</tbody>
</table>

1316
Authentication Plugins

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value (≥ 8.0.18)</td>
<td>6</td>
</tr>
<tr>
<td>Maximum Value (≤ 8.0.17)</td>
<td>5</td>
</tr>
</tbody>
</table>

For SASL LDAP authentication, the logging level for messages written to the error log. The following table shows the permitted level values and their meanings.

### Table 6.24 Log Levels for authentication_ldap_sasl_log_status

<table>
<thead>
<tr>
<th>Option Value</th>
<th>Types of Messages Logged</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>No messages</td>
</tr>
<tr>
<td>2</td>
<td>Error messages</td>
</tr>
<tr>
<td>3</td>
<td>Error and warning messages</td>
</tr>
<tr>
<td>4</td>
<td>Error, warning, and information messages</td>
</tr>
<tr>
<td>5</td>
<td>Same as previous level plus debugging messages from MySQL</td>
</tr>
<tr>
<td>6</td>
<td>Same as previous level plus debugging messages from LDAP library</td>
</tr>
</tbody>
</table>

Log level 6 is available as of MySQL 8.0.18.

On the client side, messages can be logged to the standard output by setting the `AUTHENTICATION_LDAP_CLIENT_LOG` environment variable. The permitted and default values are the same as for `authentication_ldap_sasl_log_status`.

The `AUTHENTICATION_LDAP_CLIENT_LOG` environment variable applies only to SASL LDAP authentication. It has no effect for simple LDAP authentication because the client plugin in that case is `mysql_clear_password`, which knows nothing about LDAP operations.

- `authentication_ldap_sasl_max_pool_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--authentication-ldap-sasl-max-pool-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_sasl_max_pool_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>

<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>32767</td>
</tr>
</tbody>
</table>

For SASL LDAP authentication, the maximum size of the pool of connections to the LDAP server. To disable connection pooling, set this variable to 0.

This variable is used in conjunction with `authentication_ldap_sasl_init_pool_size`. See the description of that variable.
• **authentication_ldap_sasl_referral**

| Command-Line Format         | --authentication-ldap-sasl-referral=[{OFF|ON}] |
|-----------------------------|-----------------------------------------------|
| Introduced                  | 8.0.20                                        |
| System Variable             | authentication_ldap_sasl_referral             |
| Scope                       | Global                                        |
| Dynamic                     | Yes                                           |
| SET_VAR Hint Applies        | No                                            |
| Type                        | Boolean                                       |
| Default Value               | OFF                                           |

For SASL LDAP authentication, whether to enable LDAP search referral. See [LDAP Search Referral](#).

This variable can be set to override the default OpenLDAP referral configuration; see [LDAP Pluggable Authentication and ldap.conf](#).

• **authentication_ldap_sasl_server_host**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--authentication-ldap-sasl-server-host=host_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>authentication_ldap_sasl_server_host</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

For SASL LDAP authentication, the LDAP server host. The permitted values for this variable depend on the authentication method:

- For **authentication_ldap_sasl_auth_method_name=SCRAM-SHA-1**: The LDAP server host can be a host name or IP address.

- For **authentication_ldap_sasl_auth_method_name=SCRAM-SHA-256**: The LDAP server host can be a host name or IP address.

• **authentication_ldap_sasl_server_port**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--authentication-ldap-sasl-server-port=port_num</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>authentication_ldap_sasl_server_port</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>389</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
</tbody>
</table>
Authentication Plugins

<table>
<thead>
<tr>
<th>Maximum Value</th>
<th>32376</th>
</tr>
</thead>
</table>

For SASL LDAP authentication, the LDAP server TCP/IP port number.

As of MySQL 8.0.14, if the LDAP port number is configured as 636 or 3269, the plugin uses LDAPS (LDAP over SSL) instead of LDAP. (LDAPS differs from startTLS.)

```
• authentication_ldap_sasl_tls
```

| Command-Line Format | --authentication-ldap-sasl-tls[={OFF|ON}] |
|---------------------|------------------------------------------|
| System Variable     | authentication_ldap_sasl_tls              |
| Scope               | Global                                   |
| Dynamic             | Yes                                      |
| SET_VAR Hint Applies| No                                       |
| Type                | Boolean                                  |
| Default Value       | OFF                                      |

For SASL LDAP authentication, whether connections by the plugin to the LDAP server are secure. If this variable is enabled, the plugin uses TLS to connect securely to the LDAP server. This variable can be set set to override the default OpenLDAP TLS configuration; see LDAP Pluggable Authentication and ldap.conf. If you enable this variable, you may also wish to set the `authentication_ldap_sasl_ca_path` variable.

MySQL LDAP plugins support the StartTLS method, which initializes TLS on top of a plain LDAP connection.

As of MySQL 8.0.14, LDAPS can be used by setting the `authentication_ldap_sasl_server_port` system variable.

```
• authentication_ldap_sasl_user_search_attr
```

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--authentication-ldap-sasl-user-search-attr=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>authentication_ldap_sasl_user_search_attr</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>uid</td>
</tr>
</tbody>
</table>

For SASL LDAP authentication, the name of the attribute that specifies user names in LDAP directory entries. If a user distinguished name is not provided, the authentication plugin searches for the name using this attribute. For example, if the `authentication_ldap_sasl_user_search_attr` value is `uid`, a search for the user name `user1` finds entries with a `uid` value of `user1`.

```
• authentication_ldap_simple_auth_method_name
```

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--authentication-ldap-simple-auth-method-name=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>authentication_ldap_simple_auth_method_name</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>
For simple LDAP authentication, the authentication method name. Communication between the authentication plugin and the LDAP server occurs according to this authentication method.

Note
For all simple LDAP authentication methods, it is recommended to also set TLS parameters to require that communication with the LDAP server take place over secure connections.

These authentication method values are permitted:

- **SIMPLE**: Use simple LDAP authentication. This method uses either one or two LDAP bind operations, depending on whether the MySQL account names an LDAP user distinguished name. See the description of `authentication_ldap_simple_bind_root_dn`.

- **AD-FOREST**: A variation on SIMPLE, such that authentication searches all domains in the Active Directory forest, performing an LDAP bind to each Active Directory domain until the user is found in some domain.

- `authentication_ldap_simple_bind_base_dn`
For simple LDAP authentication, the base distinguished name (DN). This variable can be used to limit the scope of searches by anchoring them at a certain location (the “base”) within the search tree.

Suppose that members of one set of LDAP user entries each have this form:

```
uid=user_name,ou=People,dc=example,dc=com
```

And that members of another set of LDAP user entries each have this form:

```
uid=user_name,ou=Admin,dc=example,dc=com
```

Then searches work like this for different base DN values:

- If the base DN is `ou=People,dc=example,dc=com`: Searches find user entries only in the first set.
- If the base DN is `ou=Admin,dc=example,dc=com`: Searches find user entries only in the second set.
- If the base DN is `ou=dc=example,dc=com`: Searches find user entries in the first or second set.

In general, more specific base DN values result in faster searches because they limit the search scope more.

- `authentication_ldap_simple_bind_root_dn`

```
<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--authentication-ldap-simple-bind-root-dn=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_simple_bind_root_dn</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>
```

For simple LDAP authentication, the root distinguished name (DN). This variable is used in conjunction with `authentication_ldap_simple_bind_root_pwd` as the credentials for authenticating to the LDAP server for the purpose of performing searches. Authentication uses either one or two LDAP bind operations, depending on whether the MySQL account names an LDAP user DN:

- If the account does not name a user DN: `authentication_ldap_simple` performs an initial LDAP binding using `authentication_ldap_simple_bind_root_dn` and `authentication_ldap_simple_bind_root_pwd`. (These are both empty by default, so if they are not set, the LDAP server must permit anonymous connections.) The resulting bind LDAP handle is used to search for the user DN, based on the client user name. `authentication_ldap_simple` performs a second bind using the user DN and client-supplied password.

- If the account does name a user DN: The first bind operation is unnecessary in this case. `authentication_ldap_simple` performs a single bind using the user DN and client-supplied password. This is faster than if the MySQL account does not specify an LDAP user DN.

- `authentication_ldap_simple_bind_root_pwd`

```
| Command-Line Format | --authentication-ldap-simple-bind-root-pwd=value |
```
Authentication Plugins

<tr>
<td>Default Value</td>
<td>`(</td>
</tr>
<tr>
<td></td>
<td><code>(&amp;(objectClass=group)(member=%s)))</code></td>
</tr>
</tbody>
</table>

For simple LDAP authentication, the custom group search filter.

The search filter value can contain `{UA}` and `{UD}` notation to represent the user name and the full user DN. For example, `{UA}` is replaced with a user name such as "admin", whereas `{UD}` is replaced with a use full DN such as "uid=admin,ou=People,dc=example,dc=com". The following value is the default, which supports both OpenLDAP and Active Directory:

```
(|(&(objectClass=posixGroup)(memberUid={UA}))
 |(&(objectClass=group)(member={UD})))
```

In some cases for the user scenario, `memberOf` is a simple user attribute that holds no group information. For additional flexibility, an optional `{GA}` prefix can be used with the group search attribute. Any group attribute with a `{GA}` prefix is treated as a user attribute having group names. For example, with a value of `{GA}MemberOf`, if the group value is the DN, the first attribute value from the group DN is returned as the group name.

• **authentication_ldap_simple_init_pool_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--authentication-ldap-simple-init-pool-size=#</th>
</tr>
</thead>
<tbody>

</table>
For simple LDAP authentication, the initial size of the pool of connections to the LDAP server. Choose the value for this variable based on the average number of concurrent authentication requests to the LDAP server.

The plugin uses `authentication_ldap_simple_init_pool_size` and `authentication_ldap_simple_max_pool_size` together for connection-pool management:

- When the authentication plugin initializes, it creates `authentication_ldap_simple_init_pool_size` connections, unless `authentication_ldap_simple_max_pool_size=0` to disable pooling.

- If the plugin receives an authentication request when there are no free connections in the current connection pool, the plugin can create a new connection, up to the maximum connection pool size given by `authentication_ldap_simple_max_pool_size`.

- If the plugin receives a request when the pool size is already at its maximum and there are no free connections, authentication fails.

- When the plugin unloads, it closes all pooled connections.

Changes to plugin system variable settings may have no effect on connections already in the pool. For example, modifying the LDAP server host, port, or TLS settings does not affect existing connections. However, if the original variable values were invalid and the connection pool could not be initialized, the plugin attempts to reinitialize the pool for the next LDAP request. In this case, the new system variable values are used for the reinitialization attempt.

If `authentication_ldap_simple_max_pool_size=0` to disable pooling, each LDAP connection opened by the plugin uses the values the system variables have at that time.
For simple LDAP authentication, the logging level for messages written to the error log. The following table shows the permitted level values and their meanings.

<table>
<thead>
<tr>
<th>Option Value</th>
<th>Types of Messages Logged</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>No messages</td>
</tr>
<tr>
<td>2</td>
<td>Error messages</td>

<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

For simple LDAP authentication, the LDAP server host. The permitted values for this variable depend on the authentication method:

- For `authentication_ldap_simple_auth_method_name=SIMPLE`: The LDAP server host can be a host name or IP address.

- For `authentication_ldap_simple_auth_method_name=AD-FOREST`: The LDAP server host can be an Active Directory domain name. For example, for an LDAP server URL of `ldap://example.mem.local:389`, the server name can be `mem.local`.

An Active Directory forest setup can have multiple domains (LDAP server IPs), which can be discovered using DNS. On Unix and Unix-like systems, some additional setup may be required to configure your DNS server with SRV records that specify the LDAP servers for the Active Directory domain. For information about DNS SRV, see [RFC 2782](#).

Suppose that your configuration has these properties:

- The name server that provides information about Active Directory domains has IP address `10.172.166.100`.

- The LDAP servers have names `ldap1.mem.local` through `ldap3.mem.local` and IP addresses `10.172.166.101` through `10.172.166.103`.

You want the LDAP servers to be discoverable using SRV searches. For example, at the command line, a command like this should list the LDAP servers:

```
host -t SRV _ldap._tcp.mem.local
```

Perform the DNS configuration as follows:

1. Add a line to `/etc/resolv.conf` to specify the name server that provides information about Active Directory domains:

   ```
   nameserver 10.172.166.100
   ```

2. Configure the appropriate zone file for the name server with SRV records for the LDAP servers:

   ```
   _ldap._tcp.mem.local. 86400 IN SRV 0 100 389 ldap1.mem.local.
   _ldap._tcp.mem.local. 86400 IN SRV 0 100 389 ldap2.mem.local.
   ```
3. It may also be necessary to specify the IP address for the LDAP servers in `/etc/hosts` if the server host cannot be resolved. For example, add lines like this to the file:

```
10.172.166.101 ldap1.mem.local
10.172.166.102 ldap2.mem.local
10.172.166.103 ldap3.mem.local
```

With the DNS configured as just described, the server-side LDAP plugin can discover the LDAP servers and tries to authenticate in all domains until authentication succeeds or there are no more servers.

Windows needs no such settings as just described. Given the LDAP server host in the `authentication_ldap_simple_server_host` value, the Windows LDAP library searches all domains and attempts to authenticate.

- `authentication_ldap_simple_server_port`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--authentication-ldap-simple-server-port=port_num</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_simple_server_port</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>389</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>32376</td>
</tr>
</tbody>
</table>

For simple LDAP authentication, the LDAP server TCP/IP port number.

As of MySQL 8.0.14, if the LDAP port number is configured as 636 or 3269, the plugin uses LDAPS (LDAP over SSL) instead of LDAP. (LDAPS differs from `startTLS`.)

- `authentication_ldap_simple_tls`

| Command-Line Format | `--authentication-ldap-simple-tls={OFF|ON}]` |
|---------------------|-----------------------------------------------|
| System Variable     | `authentication_ldap_simple_tls` |
| Scope               | Global |
| Dynamic             | Yes |
| `SET_VAR` Hint Applies | No |
| Type                | Boolean |
| Default Value       | `OFF` |

For simple LDAP authentication, whether connections by the plugin to the LDAP server are secure. If this variable is enabled, the plugin uses TLS to connect securely to the LDAP server. This variable can be set set to override the default OpenLDAP TLS configuration; see LDAP.
**The Connection-Control Plugins**

**Pluggable Authentication and ldap.conf** If you enable this variable, you may also wish to set the `authentication_ldap_simple_ca_path` variable.

MySQL LDAP plugins support the StartTLS method, which initializes TLS on top of a plain LDAP connection.

As of MySQL 8.0.14, LDAPS can be used by setting the `authentication_ldap_simple_server_port` system variable.

- **`authentication_ldap_simple_user_search_attr`**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--authentication-ldap-simple-user-search-attr=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_simple_user_search_attr</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>uid</code></td>
</tr>
</tbody>
</table>

For simple LDAP authentication, the name of the attribute that specifies user names in LDAP directory entries. If a user distinguished name is not provided, the authentication plugin searches for the name using this attribute. For example, if the `authentication_ldap_simple_user_search_attr` value is `uid`, a search for the user name `user1` finds entries with a `uid` value of `user1`.

### 6.4.2 The Connection-Control Plugins

MySQL Server includes a plugin library that enables administrators to introduce an increasing delay in server response to connection attempts after a configurable number of consecutive failed attempts. This capability provides a deterrent that slows down brute force attacks against MySQL user accounts. The plugin library contains two plugins:

- **CONNECTION_CONTROL** checks incoming connection attempts and adds a delay to server responses as necessary. This plugin also exposes system variables that enable its operation to be configured and a status variable that provides rudimentary monitoring information.

  The `CONNECTION_CONTROL` plugin uses the audit plugin interface (see [Writing Audit Plugins](https://dev.mysql.com/doc/refman/8.0/en/scripting-error.html)). To collect information, it subscribes to the `MYSQL_AUDIT_CONNECTION_CLASSMASK` event class, and processes `MYSQL_AUDIT_CONNECTION_CONNECT` and `MYSQL_AUDIT_CONNECTION_CHANGE_USER` subevents to check whether the server should introduce a delay before responding to connection attempts.

- **CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS** implements an INFORMATION_SCHEMA table that exposes more detailed monitoring information for failed connection attempts.

  The following sections provide information about connection-control plugin installation and configuration. For information about the `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table, see Section 25.53.1, “The INFORMATION_SCHEMA CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS Table”.

### 6.4.2.1 Connection-Control Plugin Installation

This section describes how to install the connection-control plugins, `CONNECTION_CONTROL` and `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS`. For general information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

1328
The Connection-Control Plugins

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `connection_control`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To load the plugins at server startup, use the `--plugin-load-add` option to name the library file that contains them. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```
[mysqld]
plugin-load-add=connection_control.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugins at runtime, use these statements, adjusting the `.so` suffix for your platform as necessary:

```sql
INSTALL PLUGIN CONNECTION_CONTROL
SONAME 'connection_control.so';
INSTALL PLUGIN CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS
SONAME 'connection_control.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```sql
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
    FROM INFORMATION_SCHEMA.PLUGINS
    WHERE PLUGIN_NAME LIKE 'connection%';
```

<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>PLUGIN_STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONNECTION_CONTROL</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>

If a plugin fails to initialize, check the server error log for diagnostic messages.

If the plugins have been previously registered with `INSTALL PLUGIN` or are loaded with `--plugin-load-add`, you can use the `--connection-control` and `--connection-control-failed-login-attempts` options at server startup to control plugin activation. For example, to load the plugins at startup and prevent them from being removed at runtime, use these options:

```
[mysqld]
plugin-load-add=connection_control.so
connection-control=FORCE_PLUS_PERMANENT
connection-control-failed-login-attempts=FORCE_PLUS_PERMANENT
```

If it is desired to prevent the server from running without a given connection-control plugin, use an option value of `FORCE` or `FORCE_PLUS_PERMANENT` to force server startup to fail if the plugin does not initialize successfully.

```
Note
It is possible to install one plugin without the other, but both must be installed for full connection-control capability. In particular, installing only the
```
The Connection-Control Plugins

- Connection Delay Configuration
- Connection Failure Assessment
- Connection Failure Monitoring

Connection Delay Configuration

To enable configuring its operation, the CONNECTION_CONTROL plugin exposes these system variables:

- **connection_control_failed_connections_threshold**: The number of consecutive failed connection attempts permitted to accounts before the server adds a delay for subsequent connection attempts. To disable failed-connection counting, set `connection_control_failed_connections_threshold` to zero.

- **connection_control_min_connection_delay**: The minimum delay in milliseconds for connection failures above the threshold.

- **connection_control_max_connection_delay**: The maximum delay in milliseconds for connection failures above the threshold.

If `connection_control_failed_connections_threshold` is nonzero, failed-connection counting is enabled and has these properties:

- The delay is zero up through `connection_control_failed_connections_threshold` consecutive failed connection attempts.

- Thereafter, the server adds an increasing delay for subsequent consecutive attempts, until a successful connection occurs. The initial unadjusted delays begin at 1000 milliseconds (1 second) and increase by 1000 milliseconds per attempt. That is, once delay has been activated for an account, the unadjusted delays for subsequent failed attempts are 1000 milliseconds, 2000 milliseconds, 3000 milliseconds, and so forth.

- The actual delay experienced by a client is the unadjusted delay, adjusted to lie within the values of the `connection_control_min_connection_delay` and `connection_control_max_connection_delay` system variables, inclusive.

- Once delay has been activated for an account, the first successful connection thereafter by the account also experiences a delay, but failure counting is reset for subsequent connections.

For example, with the default `connection_control_failed_connections_threshold` value of 3, there is no delay for the first three consecutive failed connection attempts by an account. The actual adjusted delays experienced by the account for the fourth and subsequent failed connections depend on the `connection_control_min_connection_delay` and `connection_control_max_connection_delay` values:

- If `connection_control_min_connection_delay` and `connection_control_max_connection_delay` are 1000 and 20000, the adjusted delays are the same as the unadjusted delays, up to a maximum of 20000 milliseconds. The fourth and subsequent failed connections are delayed by 1000 milliseconds, 2000 milliseconds, 3000 milliseconds, and so forth.

- If `connection_control_min_connection_delay` and `connection_control_max_connection_delay` are 1500 and 20000, the adjusted delays for the
The Connection-Control Plugins

fourth and subsequent failed connections are 1500 milliseconds, 2000 milliseconds, 3000 milliseconds, and so forth, up to a maximum of 20000 milliseconds.

• If `connection_control_min_connection_delay` and `connection_control_max_connection_delay` are 2000 and 3000, the adjusted delays for the fourth and subsequent failed connections are 2000 milliseconds, 2000 milliseconds, and 3000 milliseconds, with all subsequent failed connections also delayed by 3000 milliseconds.

You can set the `CONNECTION_CONTROL` system variables at server startup or runtime. Suppose that you want to permit four consecutive failed connection attempts before the server starts delaying its responses, with a minimum delay of 2000 milliseconds. To set the relevant variables at server startup, put these lines in the server `my.cnf` file:

```ini
[mysqld]
plugin-load-add=connection_control.so
connection_control_failed_connections_threshold=4
connection_control_min_connection_delay=2000
```

To set and persist the variables at runtime, use these statements:

```sql
SET PERSIST connection_control_failed_connections_threshold = 4;
SET PERSIST connection_control_min_connection_delay = 2000;
```

`SET PERSIST` sets the value for the running MySQL instance. It also saves the value, causing it to carry over to subsequent server restarts. To change a value for the running MySQL instance without having it carry over to subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`. See Section 13.7.6.1, “SET Syntax for Variable Assignment”.

The `connection_control_min_connection_delay` and `connection_control_max_connection_delay` system variables both have minimum and maximum values of 1000 and 2147483647. In addition, the permitted range of values of each variable also depends on the current value of the other:

• `connection_control_min_connection_delay` cannot be set greater than the current value of `connection_control_max_connection_delay`.

• `connection_control_max_connection_delay` cannot be set less than the current value of `connection_control_min_connection_delay`.

Thus, to make the changes required for some configurations, you might need to set the variables in a specific order. Suppose that the current minimum and maximum delays are 1000 and 2000, and that you want to set them to 3000 and 5000. You cannot first set `connection_control_min_connection_delay` to 3000 because that is greater than the current `connection_control_max_connection_delay` value of 2000. Instead, set `connection_control_max_connection_delay` to 5000, then set `connection_control_min_connection_delay` to 3000.

Connection Failure Assessment

When the `CONNECTION_CONTROL` plugin is installed, it checks connection attempts and tracks whether they fail or succeed. For this purpose, a failed connection attempt is one for which the client user and host match a known MySQL account but the provided credentials are incorrect, or do not match any known account.

Failed-connection counting is based on the user/host combination for each connection attempt. Determination of the applicable user name and host name takes proxying into account and occurs as follows:
The Connection-Control Plugins

• If the client user proxies another user, the account for failed-connection counting is the proxying user, not the proxied user. For example, if `external_user@example.com` proxies `proxy_user@example.com`, connection counting uses the proxying user, `external_user@example.com`, rather than the proxied user, `proxy_user@example.com`. Both `external_user@example.com` and `proxy_user@example.com` must have valid entries in the `mysql.user` system table and a proxy relationship between them must be defined in the `mysql.proxies_priv` system table (see Section 6.2.18, “Proxy Users”).

• If the client user does not proxy another user, but does match a `mysql.user` entry, counting uses the `CURRENT_USER()` value corresponding to that entry. For example, if a user `user1` connecting from a host `host1.example.com` matches a `user1@host1.example.com` entry, counting uses `user1@host1.example.com`. If the user matches a `user1%.example.com`, `user1%.com`, or `user1%` entry instead, counting uses `user1%.example.com`, `user1%.com`, or `user1%`, respectively.

For the cases just described, the connection attempt matches some `mysql.user` entry, and whether the request succeeds or fails depends on whether the client provides the correct authentication credentials. For example, if the client presents an incorrect password, the connection attempt fails.

If the connection attempt matches no `mysql.user` entry, the attempt fails. In this case, no `CURRENT_USER()` value is available and connection-failure counting uses the user name provided by the client and the client host as determined by the server. For example, if a client attempts to connect as user `user2` from host `host2.example.com`, the user name part is available in the client request and the server determines the host information. The user/host combination used for counting is `user2@host2.example.com`.

Note

The server maintains information about which client hosts can possibly connect to the server (essentially the union of host values for `mysql.user` entries). If a client attempts to connect from any other host, the server rejects the attempt at an early stage of connection setup:

```
ERROR 1130 (HY000): Host 'host_name' is not allowed to connect to this MySQL server
```

Because this type of rejection occurs so early, `CONNECTION_CONTROL` does not see it, and does not count it.

Connection Failure Monitoring

To monitor failed connections, use these information sources:

• The `Connection_control_delay_generated` status variable indicates the number of times the server added a delay to its response to a failed connection attempt. This does not count attempts that occur before reaching the threshold defined by the `connection_control_failed_connections_threshold` system variable.

• The `INFORMATION_SCHEMA CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table provides information about the current number of consecutive failed connection attempts per account (user/host combination). This counts all failed attempts, regardless of whether they were delayed.

Assigning a value to `connection_control_failed_connections_threshold` at runtime has these effects:

• All accumulated failed-connection counters are reset to zero.
The Connection-Control Plugins

- The `Connection_control_delay_generated` status variable is reset to zero.
- The `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table becomes empty.

### 6.4.2.2 Connection-Control System and Status Variables

This section describes the system and status variables that the `CONNECTION_CONTROL` plugin provides to enable its operation to be configured and monitored.

- **Connection-Control System Variables**
- **Connection-Control Status Variables**

#### Connection-Control System Variables

If the `CONNECTION_CONTROL` plugin is installed, it exposes these system variables:

- **connection_control_failed_connections_threshold**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--connection-control-failed-connections-threshold=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>connection_control_failed_connections_threshold</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>True</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>3</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

The number of consecutive failed connection attempts permitted to accounts before the server adds a delay for subsequent connection attempts:

- If the variable has a nonzero value $N$, the server adds a delay beginning with consecutive failed attempt $N+1$. If an account has reached the point where connection responses are delayed, a delay also occurs for the next subsequent successful connection.
- Setting this variable to zero disables failed-connection counting. In this case, the server never adds delays.

For information about how `connection_control_failed_connections_threshold` interacts with other connection-control system and status variables, see Section 6.4.2.1, “Connection-Control Plugin Installation”.

- **connection_control_max_connection_delay**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--connection-control-max-connection-delay=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>connection_control_max_connection_delay</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>True</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>
The Password Validation Component

| Default Value | 2147483647 |
| Minimum Value | 1000 |
| Maximum Value | 2147483647 |
| Unit          | milliseconds |

The maximum delay in milliseconds for server response to failed connection attempts, if `connection_control_failed_connections_threshold` is greater than zero.

For information about how `connection_control_max_connection_delay` interacts with other connection-control system and status variables, see Section 6.4.2.1, “Connection-Control Plugin Installation”.

- `connection_control_min_connection_delay`

  | Command-Line Format | `--connection-control-min-connection-delay=#` |
  | System Variable    | `connection_control_min_connection_delay` |
  | Scope              | Global |
  | Dynamic            | Yes |
  | `SET_VAR` Hint Applies | No |
  | Type               | Integer |
  | Default Value      | 1000 |
  | Minimum Value      | 1000 |
  | Maximum Value      | 2147483647 |
  | Unit               | milliseconds |

The minimum delay in milliseconds for server response to failed connection attempts, if `connection_control_failed_connections_threshold` is greater than zero.

For information about how `connection_control_min_connection_delay` interacts with other connection-control system and status variables, see Section 6.4.2.1, “Connection-Control Plugin Installation”.

### Connection-Control Status Variables

If the `CONNECTION_CONTROL` plugin is installed, it exposes this status variable:

- `Connection_control_delay_generated`

  The number of times the server added a delay to its response to a failed connection attempt. This does not count attempts that occur before reaching the threshold defined by the `connection_control_failed_connections_threshold` system variable.

  This variable provides a simple counter. For more detailed connection-control monitoring information, examine the `INFORMATION_SCHEMA CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table; see Section 25.53.1, “The INFORMATION_SCHEMA CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS Table”.

  Assigning a value to `connection_control_failed_connections_threshold` at runtime resets `Connection_control_delay_generated` to zero.

### 6.4.3 The Password Validation Component
The **validate_password** component serves to improve security by requiring account passwords and enabling strength testing of potential passwords. This component exposes system variables that enable you to configure password policy, and status variables for component monitoring.

**Note**

In MySQL 8.0, the **validate_password** plugin was reimplemented as the **validate_password** component. (For general information about server components, see Section 5.5, “MySQL Server Components”.) The following instructions describe how to use the component, not the plugin. For instructions on using the plugin form of **validate_password**, see The Password Validation Plugin in MySQL 5.7 Reference Manual.

The plugin form of **validate_password** is still available but is deprecated; expect it to be removed in a future version of MySQL. MySQL installations that use the plugin should make the transition to using the component instead. See Section 6.4.3.3, “Transitioning to the Password Validation Component”.

The **validate_password** component implements these capabilities:

- For SQL statements that assign a password supplied as a cleartext value, **validate_password** checks the password against the current password policy and rejects the password if it is weak (the statement returns an **ER_NOT_VALID_PASSWORD** error). This applies to the **ALTER USER**, **CREATE USER**, and **SET PASSWORD** statements.

- For **CREATE USER** statements, **validate_password** requires that a password be given, and that it satisfies the password policy. This is true even if an account is locked initially because otherwise unlocking the account later would cause it to become accessible without a password that satisfies the policy.

- **validate_password** implements a **VALIDATE_PASSWORD_STRENGTH()** SQL function that assesses the strength of potential passwords. This function takes a password argument and returns an integer from 0 (weak) to 100 (strong).

**Note**

For statements that assign or modify account passwords (**ALTER USER**, **CREATE USER**, and **SET PASSWORD**), the **validate_password** capabilities described here apply only to accounts that use an authentication plugin that stores credentials internally to MySQL. For accounts that use plugins that perform authentication against a credentials system external to MySQL, password management must be handled externally against that system as well. For more information about internal credentials storage, see Section 6.2.15, “Password Management”.

The preceding restriction does not apply to use of the **VALIDATE_PASSWORD_STRENGTH()** function because it does not affect accounts directly.

**Examples:**

- **validate_password** checks the cleartext password in the following statement. Under the default password policy, which requires passwords to be at least 8 characters long, the password is weak and the statement produces an error:

  ```sql
  mysql> ALTER USER USER() IDENTIFIED BY 'abc';
  ERROR 1819 (HY000): Your password does not satisfy the current policy requirements
  ```
The Password Validation Component

- Passwords specified as hashed values are not checked because the original password value is not available for checking:

  ```mysql
  mysql> ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED WITH mysql_native_password
  AS '*0D3CED9BEC10A777AB23CC1353A8C00A633045E';
  Query OK, 0 rows affected (0.01 sec)
  ```

- This account-creation statement fails, even though the account is locked initially, because it does not include a password that satisfies the current password policy:

  ```mysql
  mysql> CREATE USER 'juanita'@'localhost' ACCOUNT LOCK;
  ERROR 1819 (HY000): Your password does not satisfy the current policy requirements
  ```

- To check a password, use the `VALIDATE_PASSWORD_STRENGTH()` function:

  ```mysql
  mysql> SELECT VALIDATE_PASSWORD_STRENGTH('weak');
  +------------------------------------+
  | VALIDATE_PASSWORD_STRENGTH('weak') |
  +------------------------------------+
  |                                 25 |
  +------------------------------------+
  mysql> SELECT VALIDATE_PASSWORD_STRENGTH('lessweak$_@123');
  +----------------------------------------------+
  | VALIDATE_PASSWORD_STRENGTH('lessweak$_@123') |
  +----------------------------------------------+
  |                                           50 |
  +----------------------------------------------+
  mysql> SELECT VALIDATE_PASSWORD_STRENGTH('N0Tweak$_@123!');
  +----------------------------------------------+
  | VALIDATE_PASSWORD_STRENGTH('N0Tweak$_@123!') |
  +----------------------------------------------+
  |                                          100 |
  +----------------------------------------------+
  ```

To configure password checking, modify the system variables having names of the form `validate_password.xxx`; these are the parameters that control password policy. See Section 6.4.3.2, “Password Validation Options and Variables”.

If `validate_password` is not installed, the `validate_password.xxx` system variables are not available, passwords in statements are not checked, and the `VALIDATE_PASSWORD_STRENGTH()` function always returns 0. For example, without the plugin installed, accounts can be assigned passwords shorter than 8 characters, or no password at all.

Assuming that `validate_password` is installed, it implements three levels of password checking: LOW, MEDIUM, and STRONG. The default is MEDIUM; to change this, modify the value of `validate_password.policy`. The policies implement increasingly strict password tests. The following descriptions refer to default parameter values, which can be modified by changing the appropriate system variables.

- **LOW** policy tests password length only. Passwords must be at least 8 characters long. To change this length, modify `validate_password.length`.

- **MEDIUM** policy adds the conditions that passwords must contain at least 1 numeric character, 1 lowercase character, 1 uppercase character, and 1 special (nonalphanumeric) character. To change these values, modify `validate_password.number_count`, `validate_password.mixed_case_count`, and `validate_password.special_char_count`.

- **STRONG** policy adds the condition that password substrings of length 4 or longer must not match words in the dictionary file, if one has been specified. To specify the dictionary file, modify `validate_password.dictionary_file`. 

1336
In addition, validate_password supports the capability of rejecting passwords that match the user name part of the effective user account for the current session, either forward or in reverse. To provide control over this capability, validate_password exposes a validate_password.check_user_name system variable, which is enabled by default.

6.4.3.1 Password Validation Component Installation and Uninstallation

This section describes how to install and uninstall the validate_password password-validation component. For general information about installing and uninstalling components, see Section 5.5, "MySQL Server Components".

Note

If you install MySQL 8.0 using the MySQL Yum repository, MySQL SLES Repository, or RPM packages provided by Oracle, the validate_password component is enabled by default after you start your MySQL Server for the first time.

Upgrades to MySQL 8.0 from 5.7 using Yum or RPM packages leave the validate_password plugin in place. To make the transition from the validate_password plugin to the validate_password component, see Section 6.4.3.3, “Transitioning to the Password Validation Component”.

To be usable by the server, the component library file must be located in the MySQL plugin directory (the directory named by the plugin_dir system variable). If necessary, configure the plugin directory location by setting the value of plugin_dir at server startup.

To install the validate_password component, use this statement:

```
INSTALL COMPONENT 'file://component_validate_password';
```

Component installation is a one-time operation that need not be done per server startup. INSTALL COMPONENT loads the component, and also registers it in the mysql.component system table to cause it to be loaded during subsequent server startups.

To uninstall the validate_password component, use this statement:

```
UNINSTALL COMPONENT 'file://component_validate_password';
```

UNINSTALL COMPONENT unloads the component, and deregisters it from the mysql.component system table to cause it not to be loaded during subsequent server startups.

6.4.3.2 Password Validation Options and Variables

This section describes the system and status variables that validate_password provides to enable its operation to be configured and monitored.

- Password Validation Component System Variables
- Password Validation Component Status Variables
- Password Validation Plugin Options
- Password Validation Plugin System Variables
- Password Validation Plugin Status Variables

Password Validation Component System Variables
The Password Validation Component

If the `validate_password` component is enabled, it exposes several system variables that enable configuration of password checking:

```sql
mysql> SHOW VARIABLES LIKE 'validate_password.%';
+--------------------------------------+--------+
| Variable_name                        | Value  |
|--------------------------------------+--------|
| validate_password.check_user_name    | ON     |
| validate_password.dictionary_file    |        |
| validate_password.length             | 8      |
| validate_password.mixed_case_count   | 1      |
| validate_password.number_count       | 1      |
| validate_password.policy             | MEDIUM |
| validate_password.special_char_count | 1      |
+--------------------------------------+--------+
```

To change how passwords are checked, you can set these system variables at server startup or at runtime. The following list describes the meaning of each variable.

- **validate_password.check_user_name**

  | Command-Line Format       | --validate-password.check-user-name[={OFF|ON}] |
  |---------------------------|-----------------------------------------------|
  | System Variable           | validate_password.check_user_name             |
  | Scope                     | Global                                         |
  | Dynamic                   | Yes                                            |
  | `SET_VAR` Hint Applies    | No                                             |
  | Type                      | Boolean                                        |
  | Default Value             | ON                                             |

Whether `validate_password` compares passwords to the user name part of the effective user account for the current session and rejects them if they match. This variable is unavailable unless `validate_password` is installed.

By default, `validate_password.check_user_name` is enabled. This variable controls user name matching independent of the value of `validate_password.policy`.

When `validate_password.check_user_name` is enabled, it has these effects:

- Checking occurs in all contexts for which `validate_password` is invoked, which includes use of statements such as `ALTER USER` or `SET PASSWORD` to change the current user’s password, and invocation of functions such as `VALIDATE_PASSWORD_STRENGTH()`.

- The user names used for comparison are taken from the values of the `USER()` and `CURRENT_USER()` functions for the current session. An implication is that a user who has sufficient privileges to set another user’s password can set the password to that user’s name, and cannot set that user’s password to the name of the user executing the statement. For example, `'root'@'localhost'` can set the password for `'jeffrey'@'localhost'` to `'jeffrey'`, but cannot set the password to `'root'`.

- Only the user name part of the `USER()` and `CURRENT_USER()` function values is used, not the host name part. If a user name is empty, no comparison occurs.

- If a password is the same as the user name or its reverse, a match occurs and the password is rejected.
The Password Validation Component

- User-name matching is case-sensitive. The password and user name values are compared as binary strings on a byte-by-byte basis.

- If a password matches the user name, `VALIDATE_PASSWORD_STRENGTH()` returns 0 regardless of how other `validate_password` system variables are set.

- `validate_password.dictionary_file`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--validate-password.dictionary-file=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>validate_password.dictionary_file</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

The path name of the dictionary file that `validate_password` uses for checking passwords. This variable is unavailable unless `validate_password` is installed.

By default, this variable has an empty value and dictionary checks are not performed. For dictionary checks to occur, the variable value must be nonempty. If the file is named as a relative path, it is interpreted relative to the server data directory. File contents should be lowercase, one word per line. Contents are treated as having a character set of `utf8`. The maximum permitted file size is 1MB.

For the dictionary file to be used during password checking, the password policy must be set to 2 (`STRONG`); see the description of the `validate_password.policy` system variable. Assuming that is true, each substring of the password of length 4 up to 100 is compared to the words in the dictionary file. Any match causes the password to be rejected. Comparisons are not case sensitive.

For `VALIDATE_PASSWORD_STRENGTH()`, the password is checked against all policies, including `STRONG`, so the strength assessment includes the dictionary check regardless of the `validate_password.policy` value.

`validate_password.dictionary_file` can be set at runtime and assigning a value causes the named file to be read without a server restart.

- `validate_password.length`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--validate-password.length=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>validate_password.length</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8</td>
</tr>
</tbody>
</table>
The Password Validation Component

| Minimum Value | 0 |

The minimum number of characters that `validate_password` requires passwords to have. This variable is unavailable unless `validate_password` is installed.

The `validate_password.length` minimum value is a function of several other related system variables. The value cannot be set less than the value of this expression:

```
validate_password.number_count + validate_password.special_char_count + (2 * validate_password.mixed_case_count)
```

If `validate_password` adjusts the value of `validate_password.length` due to the preceding constraint, it writes a message to the error log.

- `validate_password.mixed_case_count`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--validate-password.mixed-case-count=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>validate_password.mixed_case_count</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

The minimum number of lowercase and uppercase characters that `validate_password` requires passwords to have if the password policy is `MEDIUM` or stronger. This variable is unavailable unless `validate_password` is installed.

For a given `validate_password.mixed_case_count` value, the password must have that many lowercase characters, and that many uppercase characters.

- `validate_password.number_count`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--validate-password.number-count=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>validate_password.number_count</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

The minimum number of numeric (digit) characters that `validate_password` requires passwords to have if the password policy is `MEDIUM` or stronger. This variable is unavailable unless `validate_password` is installed.
The Password Validation Component

- validate_password.policy

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--validate-password.policy=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>validate_password.policy</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Valid Values</td>
<td>0, 1, 2</td>
</tr>
</tbody>
</table>

The password policy enforced by validate_password. This variable is unavailable unless validate_password is installed.

validate_password.policy affects how validate_password uses its other policy-setting system variables, except for checking passwords against user names, which is controlled independently by validate_password.check_user_name.

The validate_password.policy value can be specified using numeric values 0, 1, 2, or the corresponding symbolic values LOW, MEDIUM, STRONG. The following table describes the tests performed for each policy. For the length test, the required length is the value of the validate_password.length system variable. Similarly, the required values for the other tests are given by other validate_password.xxx variables.

<table>
<thead>
<tr>
<th>Policy</th>
<th>Tests Performed</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 or LOW</td>
<td>Length</td>
</tr>
<tr>
<td>1 or MEDIUM</td>
<td>Length; numeric, lowercase/uppercase, and special characters</td>
</tr>
<tr>
<td>2 or STRONG</td>
<td>Length; numeric, lowercase/uppercase, and special characters; dictionary file</td>
</tr>
</tbody>
</table>

- validate_password.special_char_count

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--validate-password.special-char-count=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>validate_password.special_char_count</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

The minimum number of nonalphanumeric characters that validate_password requires passwords to have if the password policy is MEDIUM or stronger. This variable is unavailable unless validate_password is installed.
Password Validation Component Status Variables

If the validate_password component is enabled, it exposes status variables that provide operational information:

```sql
mysql> SHOW STATUS LIKE 'validate_password.%';
```

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>validate_password.dictionary_file_last_parsed</td>
<td>2019-10-03 08:33:49</td>
</tr>
<tr>
<td>validate_password.dictionary_file_words_count</td>
<td>1902</td>
</tr>
</tbody>
</table>

The following list describes the meaning of each status variable.

- **validate_password.dictionary_file_last_parsed**
  
  When the dictionary file was last parsed. This variable is unavailable unless validate_password is installed.

- **validate_password.dictionary_file_words_count**
  
  The number of words read from the dictionary file. This variable is unavailable unless validate_password is installed.

Password Validation Plugin Options

**Note**

In MySQL 8.0, the validate_password plugin was reimplemented as the validate_password component. The validate_password plugin is deprecated; expect it to be removed in a future version of MySQL. Consequently, its options are also deprecated, and you should expect them to be removed as well. MySQL installations that use the plugin should make the transition to using the component instead. See Section 6.4.3.3, “Transitioning to the Password Validation Component”.

To control activation of the validate_password plugin, use this option:

- **--validate-password [=value]**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--validate-password [=value]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ON, OFF, FORCE, FORCE_PLUS_PERMANENT</td>
</tr>
</tbody>
</table>

This option controls how the server loads the deprecated validate_password plugin at startup. The value should be one of those available for plugin-loading options, as described in Section 5.6.1, "Installing and Uninstalling Plugins". For example, `--validate-password=FORCE_PLUS_PERMANENT` tells the server to load the plugin at startup and prevents it from being removed while the server is running.
This option is available only if the `validate_password` plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load-add`. See Section 6.4.3.1, “Password Validation Component Installation and Uninstallation”.

### Password Validation Plugin System Variables

**Note**

In MySQL 8.0, the `validate_password` plugin was reimplemented as the `validate_password` component. The `validate_password` plugin is deprecated; expect it to be removed in a future version of MySQL. Consequently, its system variables are also deprecated and you should expect them to be removed as well. Use the corresponding system variables of the `validate_password` component instead; see Password Validation Component System Variables. MySQL installations that use the plugin should make the transition to using the component instead. See Section 6.4.3.3, “Transitioning to the Password Validation Component”.

- **validate_password_check_user_name**

  | Command-Line Format          | `--validate-password-check-user-name=[{OFF|ON}]` |
  |-----------------------------|-----------------------------------------------|
  | System Variable             | `validate_password_check_user_name`            |
  | Scope                       | Global                                        |
  | Dynamic                     | Yes                                           |
  | SET_VAR Hint Applies        | No                                            |
  | Type                        | Boolean                                       |
  | Default Value               | `ON`                                          |

This `validate_password` plugin system variable is deprecated; expect it to be removed in a future version of MySQL. Use the corresponding `validate_password.check_user_name` system variable of the `validate_password` component instead.

- **validate_password_dictionary_file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--validate-password-dictionary-file=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>validate_password_dictionary_file</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

This `validate_password` plugin system variable is deprecated; expect it to be removed in a future version of MySQL. Use the corresponding `validate_password.dictionary_file` system variable of the `validate_password` component instead.

- **validate_password_length**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--validate-password-length=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>validate_password_length</code></td>
</tr>
</tbody>
</table>

This `validate_password` plugin system variable is deprecated; expect it to be removed in a future version of MySQL. Use the corresponding `validate_password.length` system variable of the `validate_password` component instead.
The Password Validation Component

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>$SET_VAR$ Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

This `validate_password` plugin system variable is deprecated; expect it to be removed in a future version of MySQL. Use the corresponding `validate_password.length` system variable of the `validate_password` component instead.

- `validate_password.mixed_case_count`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--validate-password-mixed-case-count=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>validate_password_mixed_case_count</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>$SET_VAR$ Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

This `validate_password` plugin system variable is deprecated; expect it to be removed in a future version of MySQL. Use the corresponding `validate_password.mixed_case_count` system variable of the `validate_password` component instead.

- `validate_password.number_count`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--validate-password-number-count=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>validate_password_number_count</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>$SET_VAR$ Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

This `validate_password` plugin system variable is deprecated; expect it to be removed in a future version of MySQL. Use the corresponding `validate_password.number_count` system variable of the `validate_password` component instead.

- `validate_password.policy`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--validate-password-policy=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>validate_password_policy</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>
The Password Validation Component

<table>
<thead>
<tr>
<th>Dynamic</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET_VAR</td>
<td>Hint Applies</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Valid Values</td>
<td>0, 1, 2</td>
</tr>
</tbody>
</table>

This `validate_password` plugin system variable is deprecated; expect it to be removed in a future version of MySQL. Use the corresponding `validate_password.policy` system variable of the `validate_password` component instead.

- `validate_password_special_char_count`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--validate-password-special-char-count=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>validate_password_special_char_count</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR</td>
<td>Hint Applies</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

This `validate_password` plugin system variable is deprecated; expect it to be removed in a future version of MySQL. Use the corresponding `validate_password.special_char_count` system variable of the `validate_password` component instead.

Password Validation Plugin Status Variables

**Note**

In MySQL 8.0, the `validate_password` plugin was reimplemented as the `validate_password` component. The `validate_password` plugin is deprecated; expect it to be removed in a future version of MySQL. Consequently, its status variables are also deprecated; expect it to be removed. Use the corresponding status variables of the `validate_password` component; see Password Validation Component Status Variables. MySQL installations that use the plugin should make the transition to using the component instead. See Section 6.4.3.3, “Transitioning to the Password Validation Component”.

- `validate_password_dictionary_file_last_parsed`

This `validate_password` plugin status variable is deprecated; expect it to be removed in a future version of MySQL. Use the corresponding `validate_password.dictionary_file_last_parsed` status variable of the `validate_password` component instead.

- `validate_password_dictionary_file_words_count`
This validate_password plugin status variable is deprecated; expect it to be removed in a future version of MySQL. Use the corresponding validate_password.dictionary_file_words_count status variable of the validate_password component instead.

6.4.3.3 Transitioning to the Password Validation Component

**Note**

In MySQL 8.0, the validate_password plugin was reimplemented as the validate_password component. The validate_password plugin is deprecated and will be removed in a future version of MySQL.

MySQL installations that currently use the validate_password plugin should make the transition to using the validate_password component instead. To do so, use the following procedure. The procedure installs the component before uninstalling the plugin, to avoid having a time window during which no password validation occurs. (The component and plugin can be installed simultaneously. In this case, the server attempts to use the component, falling back to the plugin if the component is unavailable.)

1. Install the validate_password component:

   ```
   INSTALL COMPONENT 'file://component_validate_password';
   ```

2. Test the validate_password component to ensure that it works as expected. If you need to set any validate_password.xxx system variables, you can do so at runtime using SET GLOBAL. (Any option file changes that must be made are performed in the next step.)

3. Adjust any references to the plugin system and status variables to refer to the corresponding component system and status variables. Suppose that previously you had configured the plugin at startup using an option file like this:

   ```
   [mysqld]
   validate-password=FORCE_PLUS_PERMANENT
   validate_password_dictionary_file=/usr/share/dict/words
   validate_password_length=10
   validate_password_number_count=2
   ```

   Those settings are appropriate for the plugin, but must be modified to apply to the component. To adjust the option file, omit the --validate-password option (it applies only to the plugin, not the component), and modify the system variable references from no-dot names appropriate for the plugin to dotted names appropriate for the component:

   ```
   [mysqld]
   validate_password.dictionary_file=/usr/share/dict/words
   validate_password.length=10
   validate_password.number_count=2
   ```

   Similar adjustments are needed for applications that refer at runtime to validate_password plugin system and status variables. Change the no-dot plugin variable names to the corresponding dotted component variable names.

4. Uninstall the validate_password plugin:

   ```
   UNINSTALL PLUGIN validate_password;
   ```

   If the validate_password plugin is loaded at server startup using a --plugin-load or --plugin-load-add option, omit that option from the server startup procedure. For example, if the option is listed in a server option file, remove it from the file.

5. Restart the server.
6.4.4 The MySQL Keyring

MySQL Server supports a keyring that enables internal server components and plugins to securely store sensitive information for later retrieval. The implementation comprises these elements:

- Keyring plugins that manage a backing store or communicate with a storage back end. These keyring plugins are available:
  - `keyring_file` stores keyring data in a file local to the server host. This plugin is available in MySQL Community Edition and MySQL Enterprise Edition distributions. See Section 6.4.4.2, “Using the `keyring_file` File-Based Plugin”.
  - `keyring_encrypted_file` stores keyring data in an encrypted file local to the server host. This plugin is available in MySQL Enterprise Edition distributions. See Section 6.4.4.3, “Using the `keyring_encrypted_file` Keyring Plugin”.
  - `keyring_okv` is a KMIP 1.1 plugin for use with KMIP-compatible back end keyring storage products such as Oracle Key Vault and Gemalto SafeNet KeySecure Appliance. This plugin is available in MySQL Enterprise Edition distributions. See Section 6.4.4.4, “Using the `keyring_okv` KMIP Plugin”.
  - `keyring_aws` communicates with the Amazon Web Services Key Management Service for key generation and uses a local file for key storage. This plugin is available in MySQL Enterprise Edition distributions. See Section 6.4.4.5, “Using the `keyring_aws` Amazon Web Services Keyring Plugin”.
  - `keyring_hashicorp` communicates with HashiCorp Vault for back end storage. This plugin is available in MySQL Enterprise Edition distributions as of MySQL 8.0.18. See Section 6.4.4.6, “Using the HashiCorp Vault Keyring Plugin”.
  - `keyring_oci` communicates with Oracle Cloud Infrastructure Vault for back end storage. This plugin is available in MySQL Enterprise Edition distributions as of MySQL 8.0.22. See Section 6.4.4.7, “Using the Oracle Cloud Infrastructure Vault Keyring Plugin”.
- A key migration capability. A MySQL server operational mode enables migration of keys between underlying keyring keystores, permitting DBAs to switch a MySQL installation from one keyring plugin to another. See Section 6.4.4.9, “Migrating Keys Between Keyring Keystores”.
- A keyring service interface for keyring key management, accessible at two levels:
  - SQL interface: In SQL statements, call the user-defined functions (UDFs) described in Section 6.4.4.10, “General-Purpose Keyring Key-Management Functions”.
  - C interface: In C-language code, call the keyring service functions described in Section 5.6.8.2, “The Keyring Service”.
- Key metadata access. In MySQL 8.0.16 and higher, the Performance Schema `keyring_keys` table exposes metadata for keys in the keyring. Key metadata includes key IDs, key owners, and backend key IDs. The `keyring_keys` table does not expose any sensitive keyring data such as key contents. See Section 26.12.19.3, “The `keyring_keys` table”.

**Warning**

The `keyring_file` and `keyring_encrypted_file` plugins for encryption key management are not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).
Within MySQL, uses of the keyring include:

- The InnoDB storage engine uses the keyring to store its key for tablespace encryption. InnoDB can use any supported keyring plugin. See Section 15.13, "InnoDB Data-at-Rest Encryption".

- MySQL Enterprise Audit uses the keyring to store the audit log file encryption password. The audit log plugin can use any supported keyring plugin. See Encrypting Audit Log Files.

- Binary log and relay log management supports keyring-based encryption of log files. With log file encryption activated, the keys used to encrypt passwords for the binary log files and relay log files are stored in the keyring. This capability can use any supported keyring plugin. See Section 17.3.2, "Encrypting Binary Log Files and Relay Log Files".

For general keyring installation instructions, see Section 6.4.4.1, “Keyring Plugin Installation”. For installation and configuration information specific to a given keyring plugin, see the section describing that plugin.

For information about using the keyring UDFs, see Section 6.4.4.10, “General-Purpose Keyring Key-Management Functions”.

Keyring plugins and UDFs access a keyring service that provides the interface for server components to the keyring. For information about accessing the keyring plugin service and writing keyring plugins, see Section 5.6.8.2, “The Keyring Service”; and Writing Keyring Plugins.

### 6.4.4.1 Keyring Plugin Installation

Keyring service consumers require a keyring plugin to be installed. MySQL provides these plugin choices:

- **keyring_file**: Stores keyring data in a file local to the server host. Available in all MySQL distributions.

- **keyring_encrypted_file**: Stores keyring data in an encrypted file local to the server host. Available in MySQL Enterprise Edition distributions.

- **keyring_okv**: Uses KMIP-compatible back end keyring storage products such as Oracle Key Vault and Gemalto SafeNet KeySecure Appliance. Available in MySQL Enterprise Edition distributions.

- **keyring_aws**: Communicates with the Amazon Web Services Key Management Service as a back end for key generation and uses a local file for key storage. Available in MySQL Enterprise Edition distributions.

- **keyring_hashicorp**: Communicates with HashiCorp Vault for back end storage. Available in MySQL Enterprise Edition distributions.

- **For keyring_oci**: Section 6.4.4.7, “Using the Oracle Cloud Infrastructure Vault Keyring Plugin”

This section describes how to install the keyring plugin of your choosing. For general information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

If you intend to use keyring user-defined functions (UDFs) in conjunction with the keyring plugin, install the UDFs after installing the plugin, using the instructions in Section 6.4.4.10, “General-Purpose Keyring Key-Management Functions”.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.
Installation for each keyring plugin is similar. The following instructions use `keyring_file`. Users of a different keyring plugin can substitute its name for `keyring_file`.

The `keyring_file` plugin library file base name is `keyring_file`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

**Note**

Only one keyring plugin should be enabled at a time. Enabling multiple keyring plugins is unsupported and results may not be as anticipated.

The keyring plugin must be loaded early during the server startup sequence so that server components can access it as necessary during their own initialization. For example, the InnoDB storage engine uses the keyring for tablespace encryption, so the keyring plugin must be loaded and available prior to InnoDB initialization.

To load the plugin, use the `--early-plugin-load` option to name the plugin library file that contains it. For example, on platforms where the plugin library file suffix is `.so`, use these lines in the server `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```
[mysqld]
early-plugin-load=keyring_file.so
```

Before starting the server, check the notes for your chosen keyring plugin to see whether it permits or requires additional configuration:

- **keyring_file**: Section 6.4.4.2, "Using the keyring_file File-Based Plugin".
- **keyring_encrypted_file**: Section 6.4.4.3, "Using the keyring_encrypted_file Keyring Plugin".
- **keyring_okv**: Section 6.4.4.4, "Using the keyring_okv KMIP Plugin".
- **keyring_aws**: Section 6.4.4.5, "Using the keyring_aws Amazon Web Services Keyring Plugin"
- **keyring_hashicorp**: Section 6.4.4.6, "Using the HashiCorp Vault Keyring Plugin"

After performing any plugin-specific configuration, verify plugin installation. With the MySQL server running, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.6.2, "Obtaining Server Plugin Information"). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE 'keyring%';
+--------------+---------------+
| PLUGIN_NAME  | PLUGIN_STATUS |
+--------------+---------------+
| keyring_file | ACTIVE        |
+--------------+---------------+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

Plugins can be loaded by methods other than `--early-plugin-load`, such as the `--plugin-load` or `--plugin-load-add` option or the `INSTALL PLUGIN` statement. However, keyring plugins loaded using those methods may be available too late in the server startup sequence for certain server components, such as InnoDB:

- Plugin loading using `--plugin-load` or `--plugin-load-add` occurs after InnoDB initialization.
- Plugins installed using `INSTALL PLUGIN` are registered in the `mysql.plugin` system table and loaded automatically for subsequent server restarts. However, because `mysql.plugin` is an InnoDB table, any plugins named in it can be loaded during startup only after InnoDB initialization.
If no keyring plugin is available when a server component tries to access the keyring service, the service cannot be used by that component. As a result, the component may fail to initialize or may initialize with limited functionality. For example, if InnoDB finds that there are encrypted tablespaces when it initializes, it attempts to access the keyring. If the keyring is unavailable, InnoDB can access only unencrypted tablespaces. To ensure that InnoDB can access encrypted tablespaces as well, use `--early-plugin-load` to load the keyring plugin.

### 6.4.4.2 Using the keyring_file File-Based Plugin

The **keyring_file** keyring plugin stores keyring data in a file local to the server host.

#### Warning

The **keyring_file** plugin for encryption key management is not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).

To install the **keyring_file** plugin, use the general keyring installation instructions found in Section 6.4.4.1, “Keyring Plugin Installation”, together with the configuration information specific to **keyring_file** found here.

To be usable during the server startup process, **keyring_file** must be loaded using the `--early-plugin-load` option. The **keyring_file_data** system variable optionally configures the location of the file used by the **keyring_file** plugin for data storage. The default value is platform specific. To configure the file location explicitly, set the variable value at startup. For example, use these lines in the server `my.cnf` file, adjusting the `.so` suffix and file location for your platform as necessary:

```
[mysqld]
early-plugin-load=keyring_file.so
keyring_file_data=/usr/local/mysql/mysql-keyring/keyring
```

Keyring operations are transactional: The **keyring_file** plugin uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has the same name as the value of the **keyring_file_data** system variable with a suffix of `.backup`.

For additional information about **keyring_file_data**, see Section 6.4.4.13, “Keyring System Variables”.

To ensure that keys are flushed only when the correct keyring storage file exists, **keyring_file** stores a SHA-256 checksum of the keyring in the file. Before updating the file, the plugin verifies that it contains the expected checksum.

The **keyring_file** plugin supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by those functions are accessible at two levels:

- **SQL interface:** In SQL statements, call the user-defined functions (UDFs) described in Section 6.4.4.10, “General-Purpose Keyring Key-Management Functions”.

- **C interface:** In C-language code, call the keyring service functions described in Section 5.6.8.2, “The Keyring Service”.

Example (using UDFs):

```sql
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

For information about the key types permitted by **keyring_file**, see Section 6.4.4.8, “Supported Keyring Key Types and Lengths”.
6.4.4.3 Using the keyring_encrypted_file Keyring Plugin

Note

The `keyring_encrypted_file` plugin is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see https://www.mysql.com/products/.

The `keyring_encrypted_file` keyring plugin stores keyring data in an encrypted file local to the server host.

Warning

The `keyring_encrypted_file` plugin for encryption key management is not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).

To install the `keyring_encrypted_file` plugin, use the general keyring installation instructions found in Section 6.4.4.1, “Keyring Plugin Installation”, together with the configuration information specific to `keyring_encrypted_file` found here.

To be usable during the server startup process, `keyring_encrypted_file` must be loaded using the `--early-plugin-load` option. To specify the password for encrypting the keyring data file, set the `keyring_encrypted_file_password` system variable. (The password is mandatory; if not specified at server startup, `keyring_encrypted_file` initialization fails.) The `keyring_encrypted_file_data` system variable optionally configures the location of the file used by the `keyring_encrypted_file` plugin for data storage. The default value is platform specific. To configure the file location explicitly, set the variable value at startup. For example, use these lines in the server `my.cnf` file, adjusting the `.so` suffix and file location for your platform as necessary and substituting your chosen password:

```
[mysqld]
early-plugin-load=keyring_encrypted_file.so
keyring_encrypted_file_data=/usr/local/mysql/mysql-keyring/keyring-encrypted
keyring_encrypted_file_password=password
```

Because the `my.cnf` file stores a password when written as shown, it should have a restrictive mode and be accessible only to the account used to run the MySQL server.

Keyring operations are transactional: The `keyring_encrypted_file` plugin uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has the same name as the value of the `keyring_encrypted_file_data` system variable with a suffix of `.backup`.

For additional information about the system variables used to configure the `keyring_encrypted_file` plugin, see Section 6.4.4.13, “Keyring System Variables”.

To ensure that keys are flushed only when the correct keyring storage file exists, `keyring_encrypted_file` stores a SHA-256 checksum of the keyring in the file. Before updating the file, the plugin verifies that it contains the expected checksum. In addition, `keyring_encrypted_file` encrypts file contents using AES before writing the file, and decrypts file contents after reading the file.

The `keyring_encrypted_file` plugin supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by those functions are accessible at two levels:

- SQL interface: In SQL statements, call the user-defined functions (UDFs) described in Section 6.4.4.10, “General-Purpose Keyring Key-Management Functions”.
The MySQL Keyring

• C interface: In C-language code, call the keyring service functions described in Section 5.6.8.2, “The Keyring Service”.

Example (using UDFs):

```sql
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

For information about the key types permitted by `keyring_encrypted_file`, see Section 6.4.4.8, “Supported Keyring Key Types and Lengths”.

6.4.4.4 Using the keyring_okv KMIP Plugin

Note

The `keyring_okv` plugin is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see https://www.mysql.com/products/.

The Key Management Interoperability Protocol (KMIP) enables communication of cryptographic keys between a key management server and its clients. The `keyring_okv` keyring plugin uses the KMIP 1.1 protocol to communicate securely as a client of a KMIP back end. Keyring material is generated exclusively by the back end, not by `keyring_okv`. The plugin works with these KMIP-compatible products:

• Oracle Key Vault

• Gemalto SafeNet KeySecure Appliance

• Townsend Alliance Key Manager

The `keyring_okv` plugin supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by those functions are accessible at two levels:

• SQL interface: In SQL statements, call the user-defined functions (UDFs) described in Section 6.4.4.10, “General-Purpose Keyring Key-Management Functions”.

• C interface: In C-language code, call the keyring service functions described in Section 5.6.8.2, “The Keyring Service”.

Example (using UDFs):

```sql
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

For information about the key types permitted by `keyring_okv`, Section 6.4.4.8, “Supported Keyring Key Types and Lengths”.

To install the `keyring_okv` plugin, use the general keyring installation instructions found in Section 6.4.4.1, “Keyring Plugin Installation”, together with the configuration information specific to `keyring_okv` found here.

• General keyring_okv Configuration

• Configuring keyring_okv for Oracle Key Vault

• Configuring keyring_okv for Gemalto SafeNet KeySecure Appliance

• Configuring keyring_okv for Townsend Alliance Key Manager
• Password-Protecting the keyring-okv Key File

General keyring-okv Configuration

Regardless of which KMIP back end the keyring-okv plugin uses for keyring storage, the keyring-okv_conf_dir system variable configures the location of the directory used by keyring-okv for its support files. The default value is empty, so you must set the variable to name a properly configured directory before the plugin can communicate with the KMIP back end. Unless you do so, keyring-okv writes a message to the error log during server startup that it cannot communicate:

[Warning] Plugin keyring-okv reported: 'For keyring-okv to be initialized, please point the keyring-okv_conf_dir variable to a directory containing Oracle Key Vault configuration file and ssl materials'

The keyring-okv_conf_dir variable must name a directory that contains the following items:

• okvclient.ora: A file that contains details of the KMIP back end with which keyring-okv communicates.

• ssl: A directory that contains the certificate and key files required to establish a secure connection with the KMIP back end: CA.pem, cert.pem, and key.pem. If the key file is password-protected, the ssl directory can contain a single-line text file named password.txt containing the password needed to decrypt the key file.

Both the okvclient.ora file and ssl directory with the certificate and key files are required for keyring-okv to work properly. The procedure used to populate the configuration directory with these files depends on the KMIP back end used with keyring-okv, as described elsewhere.

The configuration directory used by keyring-okv as the location for its support files should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use the /usr/local/mysql/mysql-keyring-okv directory, the following commands (executed as root) create the directory and set its mode and ownership:

cd /usr/local/mysql
mkdir mysql-keyring-okv
chmod 750 mysql-keyring-okv
chown mysql mysql-keyring-okv
chgrp mysql mysql-keyring-okv

To be usable during the server startup process, keyring-okv must be loaded using the --early-plugin-load option. Also, set the keyring-okv_conf_dir system variable to tell keyring-okv where to find its configuration directory. For example, use these lines in the server .my.cnf file, adjusting the .so suffix and directory location for your platform as necessary:

[mysqld]
early-plugin-load=keyring-okv.so
keyring-okv_conf_dir=/usr/local/mysql/mysql-keyring-okv

For additional information about keyring-okv_conf_dir, see Section 6.4.4.13, “Keyring System Variables”.

Configuring keyring-okv for Oracle Key Vault

The discussion here assumes that you are familiar with Oracle Key Vault. Some pertinent information sources:

• Oracle Key Vault site

• Oracle Key Vault documentation
In Oracle Key Vault terminology, clients that use Oracle Key Vault to store and retrieve security objects are called endpoints. To communicate with Oracle Key Vault, it is necessary to register as an endpoint and enroll by downloading and installing endpoint support files.

The following procedure briefly summarizes the process of setting up `keyring_okv` for use with Oracle Key Vault:

1. Create the configuration directory for the `keyring_okv` plugin to use.
2. Register an endpoint with Oracle Key Vault to obtain an enrollment token.
3. Use the enrollment token to obtain the `okvclient.jar` client software download.
4. Install the client software to populate the `keyring_okv` configuration directory that contains the Oracle Key Vault support files.

Use the following procedure to configure `keyring_okv` and Oracle Key Vault to work together. This description only summarizes how to interact with Oracle Key Vault. For details, visit the Oracle Key Vault site and consult the Oracle Key Vault Administrator's Guide.

1. Create the configuration directory that contains the Oracle Key Vault support files, and make sure that the `keyring_okv_conf_dir` system variable is set to name that directory (for details, see General `keyring_okv` Configuration).
2. Log in to the Oracle Key Vault management console as a user who has the System Administrator role.
4. Provide the required endpoint information and click Register. The endpoint type should be Other. Successful registration results in an enrollment token.
5. Log out from the Oracle Key Vault server.
6. Connect again to the Oracle Key Vault server, this time without logging in. Use the endpoint enrollment token to enroll and request the `okvclient.jar` software download. Save this file to your system.
7. Install the `okvclient.jar` file using the following command (you must have JDK 1.4 or higher):

   ```
   java -jar okvclient.jar -d dir_name [-v]
   ```

   The directory name following the `–d` option is the location in which to install extracted files. The `–v` option, if given, causes log information to be produced that may be useful if the command fails.

   When the command asks for an Oracle Key Vault endpoint password, do not provide one. Instead, press Enter. (The result is that no password is required when the endpoint connects to Oracle Key Vault.)

8. The preceding command produces an `okvclient.ora` file, which should be in this location under the directory named by the `–d` option in the preceding `java -jar` command:

   ```
   install_dir/conf/okvclient.ora
   ```

   The file contents include lines that look something like this:

   ```
   SERVER=host_ip:port_num
   STANDBY_SERVER=host_ip:port_num
   ```

   The `keyring_okv` plugin attempts to communicate with the server running on the host named by the `SERVER` variable and falls back to `STANDBY_SERVER` if that fails:
The MySQL Keyring

- For the `SERVER` variable, a setting in the `okvclient.ora` file is mandatory.
- For the `STANDBY_SERVER` variable, a setting in the `okvclient.ora` file is optional.

9. Go to the Oracle Key Vault installer directory and test the setup by running this command:

   `okvutil/bin/okvutil list`

   The output should look something like this:

<table>
<thead>
<tr>
<th>Unique ID</th>
<th>Type</th>
<th>Identifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>255AB8DE-C97F-482C-E053-0100007F28B9</td>
<td>Symmetric Key</td>
<td></td>
</tr>
<tr>
<td>264BF6E0-A20E-7C42-E053-0100007FB29C</td>
<td>Symmetric Key</td>
<td></td>
</tr>
</tbody>
</table>

   For a fresh Oracle Key Vault server (a server without any key in it), the output looks like this instead, to indicate that there are no keys in the vault:

   `no objects found`

10. Use this command to extract the `ssl` directory containing SSL materials from the `okvclient.jar` file:

   `jar xf okvclient.jar ssl`

11. Copy the Oracle Key Vault support files (the `okvclient.ora` file and the `ssl` directory) into the configuration directory.

12. (Optional) If you wish to password-protect the key file, use the instructions in Password-Protecting the keyring_okev Key File.

   After completing the preceding procedure, restart the MySQL server. It loads the `keyring_okev` plugin and `keyring_okev` uses the files in its configuration directory to communicate with Oracle Key Vault.

Configuring keyring_okev for Gemalto SafeNet KeySecure Appliance

Gemalto SafeNet KeySecure Appliance uses the KMIP protocol (version 1.1 or 1.2). The `keyring_okev` keyring plugin (which supports KMIP 1.1) can use KeySecure as its KMIP back end for keyring storage.

Use the following procedure to configure `keyring_okev` and KeySecure to work together. The description only summarizes how to interact with KeySecure. For details, consult the section named Add a KMIP Server in the KeySecure User Guide.

1. Create the configuration directory that contains the KeySecure support files, and make sure that the `keyring_okev_conf_dir` system variable is set to name that directory (for details, see General keyring_okev Configuration).

2. In the configuration directory, create a subdirectory named `ssl` to use for storing the required SSL certificate and key files.

3. In the configuration directory, create a file named `okvclient.ora`. It should have following format:

   ```
   SERVER=host_ip:port_num
   STANDBY_SERVER=host_ip:port_num
   ```

   For example, if KeySecure is running on host 198.51.100.20 and listening on port 9002, the `okvclient.ora` file looks like this:

   ```
   SERVER=198.51.100.20:9002
   STANDBY_SERVER=198.51.100.20:9002
   ```
4. Connect to the KeySecure Management Console as an administrator with credentials for Certificate Authorities access.

5. Navigate to Security >> Local CAs and create a local certificate authority (CA).

6. Go to Trusted CA Lists. Select Default and click on Properties. Then select Edit for Trusted Certificate Authority List and add the CA just created.

7. Download the CA and save it in the ssl directory as a file named CA.pem.

8. Navigate to Security >> Certificate Requests and create a certificate. Then you can download a compressed tar file containing certificate PEM files.

9. Extract the PEM files from in the downloaded file. For example, if the file name is csr_w_pk_pkcs8.gz, decompress and unpack it using this command:

```bash
tar xzvf csr_w_pk_pkcs8.gz
```

Two files result from the extraction operation: certificate_request.pem and private_key_pkcs8.pem.

10. Use this openssl command to decrypt the private key and create a file named key.pem:

```bash
openssl pkcs8 -in private_key_pkcs8.pem -out key.pem
```

11. Copy the key.pem file into the ssl directory.

12. Copy the certificate request in certificate_request.pem into the clipboard.

13. Navigate to Security >> Local CAs. Select the same CA that you created earlier (the one you downloaded to create the CA.pem file), and click Sign Request. Paste the Certificate Request from the clipboard, choose a certificate purpose of Client (the keyring is a client of KeySecure), and click Sign Request. The result is a certificate signed with the selected CA in a new page.

14. Copy the signed certificate to the clipboard, then save the clipboard contents as a file named cert.pem in the ssl directory.

15. (Optional) If you wish to password-protect the key file, use the instructions in Password-Protecting the keyring_okv Key File.

After completing the preceding procedure, restart the MySQL server. It loads the keyring_okv plugin and keyring_okv uses the files in its configuration directory to communicate with KeySecure.

**Configuring keyring_okv for Townsend Alliance Key Manager**

Townsend Alliance Key Manager uses the KMIP protocol. The keyring_okv keyring plugin can use Alliance Key Manager as its KMIP back end for keyring storage. For additional information, see Alliance Key Manager for MySQL.

**Password-Protecting the keyring_okv Key File**

You can optionally protect the key file with a password and supply a file containing the password to enable the key file to be decrypted. To so do, change location to the ssl directory and perform these steps:

1. Encrypt the key.pem key file. For example, use a command like this, and enter the encryption password at the prompts:

```bash
shell> openssl rsa -des3 -in key.pem -out key.pem.new
```
2. Save the encryption password in a single-line text file named `password.txt` in the `ssl` directory.

3. Verify that the encrypted key file can be decrypted using the following command. The decrypted file should display on the console:

```bash
shell> openssl rsa -in key.pem.new -passin file:password.txt
```

4. Remove the original `key.pem` file and rename `key.pem.new` to `key.pem`.

5. Change the ownership and access mode of new `key.pem` file and `password.txt` file as necessary to ensure that they have the same restrictions as other files in the `ssl` directory.

### 6.4.4.5 Using the keyring_aws Amazon Web Services Keyring Plugin

#### Note

The `keyring_aws` plugin is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see [https://www.mysql.com/products/](https://www.mysql.com/products/).

The `keyring_aws` keyring plugin communicates with the Amazon Web Services Key Management Service (AWS KMS) as a back end for key generation and uses a local file for key storage. All keyring material is generated exclusively by the AWS server, not by `keyring_aws`.

`keyring_aws` is available on these platforms:

- EL7
- macOS 10.13 and 10.14
- SLES 12
- Ubuntu 14.04 and 16.04
- Windows

The discussion here assumes that you are familiar with AWS in general and KMS in particular. Some pertinent information sources:

- AWS site
- KMS documentation

The following sections provide configuration and usage information for the `keyring_aws` keyring plugin:

- `keyring_aws` Configuration
- `keyring_aws` Operation
- `keyring_aws` Credential Changes

#### keyring_aws Configuration

To install the `keyring_aws` plugin, use the general keyring installation instructions found in Section 6.4.4.1, "Keyring Plugin Installation", together with the plugin-specific configuration information found here.
The MySQL Keyring

The plugin library file contains the `keyring_aws` plugin and two user-defined functions (UDFs), `keyring_aws_rotate_cmk()` and `keyring_aws_rotate_keys()`.

To configure `keyring_aws`, you must obtain a secret access key that provides credentials for communicating with AWS KMS and write it to a configuration file:

1. Create an AWS KMS account.
2. Use AWS KMS to create a secret access key ID and secret access key. The access key serves to verify your identity and that of your applications.
3. Use the AWS KMS account to create a customer master key (CMK) ID. At MySQL startup, set the `keyring_aws_cmk_id` system variable to the CMK ID value. This variable is mandatory and there is no default. (Its value can be changed at runtime if desired using `SET GLOBAL`.)
4. If necessary, create the directory in which the configuration file should be located. The directory should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use `/usr/local/mysql/mysql-keyring/keyring_aws_conf` as the file name, the following commands (executed as `root`) create its parent directory and set the directory mode and ownership:

   ```shell
   cd /usr/local/mysql
   mkdir mysql-keyring
   chmod 750 mysql-keyring
   chown mysql mysql-keyring
   chgrp mysql mysql-keyring
   ```

   At MySQL startup, set the `keyring_aws_conf_file` system variable to `/usr/local/mysql/mysql-keyring/keyring_aws_conf` to indicate the configuration file location to the server.

5. Prepare the `keyring_aws` configuration file, which should contain two lines:
   - Line 1: The secret access key ID
   - Line 2: The secret access key

   For example, if the key ID is `wwwwwwwwwwwwwwEXAMPLE` and the key is `xxxxxxxxxxxxx/yyyyyyy/zzzzzzzzEXAMPLEKEY`, the configuration file looks like this:

   ```plaintext
   wwwwwwwwwwwwwwwEXAMPLE
   xxxxxxxxxxxxxx/yyyyyyy/zzzzzzzzEXAMPLEKEY
   ```

   To be usable during the server startup process, `keyring_aws` must be loaded using the `--early-plugin-load` option. The `keyring_aws_cmk_id` system variable is mandatory and configures the customer master key (CMK) ID obtained from the AWS KMS server. The `keyring_aws_conf_file` and `keyring_aws_data_file` system variables optionally configure the locations of the files used by the `keyring_aws` plugin for configuration information and data storage. The file location variable default values are platform specific. To configure the locations explicitly, set the variable values at startup. For example, use these lines in the server `my.cnf` file, adjusting the `.so` suffix and file locations for your platform as necessary:

   ```ini
   [mysqld]
   early-plugin-load=keyring_aws.so
   keyring_aws_cmk_id='arn:aws:kms:us-west-2:111122223333:key/abcd1234-ef56-ab12-cd34-ef56abcd1234'
   keyring_aws_conf_file=/usr/local/mysql/mysql-keyring/keyring_aws_conf
   keyring_aws_data_file=/usr/local/mysql/mysql-keyring/keyring_aws_data
   ```

   For the `keyring_aws` plugin to start successfully, the configuration file must exist and contain valid secret access key information, initialized as described previously. The storage file need not exist. If it does not, `keyring_aws` attempts to create it (as well as its parent directory, if necessary).
For additional information about the system variables used to configure the `keyring_aws` plugin, see Section 6.4.4.13, “Keyring System Variables”.

Start the MySQL server and install the UDFs associated with the `keyring_aws` plugin. This is a one-time operation, performed by executing the following statements, adjusting the `.so` suffix for your platform as necessary:

```sql
CREATE FUNCTION keyring_aws_rotate_cmk RETURNS INTEGER SONAME 'keyring_aws.so';
CREATE FUNCTION keyring_aws_rotate_keys RETURNS INTEGER SONAME 'keyring_aws.so';
```

For additional information about the `keyring_aws` UDFs, see Section 6.4.4.11, “Plugin-Specific Keyring Key-Management Functions”.

**keyring_aws Operation**

At plugin startup, the `keyring_aws` plugin reads the AWS secret access key ID and key from its configuration file. It also reads any encrypted keys contained in its storage file into its in-memory cache.

During operation, `keyring_aws` maintains encrypted keys in the in-memory cache and uses the storage file as local persistent storage. Each keyring operation is transactional: `keyring_aws` either successfully changes both the in-memory key cache and the keyring storage file, or the operation fails and the keyring state remains unchanged.

To ensure that keys are flushed only when the correct keyring storage file exists, `keyring_aws` stores a SHA-256 checksum of the keyring in the file. Before updating the file, the plugin verifies that it contains the expected checksum.

The `keyring_aws` plugin supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by these functions are accessible at two levels:

- **SQL interface:** In SQL statements, call the user-defined functions (UDFs) described in Section 6.4.4.10, “General-Purpose Keyring Key-Management Functions”.
- **C interface:** In C-language code, call the keyring service functions described in Section 5.6.8.2, “The Keyring Service”.

Example (using UDFs):

```sql
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

In addition, the `keyring_aws_rotate_cmk()` and `keyring_aws_rotate_keys()` UDFs “extend” the keyring plugin interface to provide AWS-related capabilities not covered by the standard keyring service interface. These capabilities are accessible only by calling the UDFs. There are no corresponding C-language key service functions.

For information about the key types permitted by `keyring_aws`, see Section 6.4.4.8, “Supported Keyring Key Types and Lengths”.

**keyring_aws Credential Changes**

Assuming that the `keyring_aws` plugin has initialized properly at server startup, it is possible to change the credentials used for communicating with AWS KMS:

1. Use AWS KMS to create a new secret access key ID and secret access key.
2. Store the new credentials in the configuration file (the file named by the `keyring_aws_conf_file` system variable). The file format is as described previously.

3. Reinitialize the `keyring_aws` plugin so that it rereads the configuration file. Assuming that the new credentials are valid, the plugin should initialize successfully.

There are two ways to reinitialize the plugin:

- Restart the server. This is simpler and has no side effects, but is not suitable for installations that require minimal server downtime with as few restarts as possible.

- Reinitialize the plugin without restarting the server by executing the following statements, adjusting the `.so` suffix for your platform as necessary:

```sql
UNINSTALL PLUGIN keyring_aws;
INSTALL PLUGIN keyring_aws SONAME 'keyring_aws.so';
```

**Note**
In addition to loading a plugin at runtime, `INSTALL PLUGIN` has the side effect of registering the plugin in the `mysql.plugin` system table. Because of this, if you decide to stop using `keyring_aws`, it is not sufficient to remove the `--early-plugin-load` option from the set of options used to start the server. That stops the plugin from loading early, but the server still attempts to load it when it gets to the point in the startup sequence where it loads the plugins registered in `mysql.plugin`.

Consequently, if you execute the `UNINSTALL PLUGIN` plus `INSTALL PLUGIN` sequence just described to change the AWS KMS credentials, then to stop using `keyring_aws`, it is necessary to execute `UNINSTALL PLUGIN` again to unregister the plugin in addition to removing the `--early-plugin-load` option.

### 6.4.4.6 Using the HashiCorp Vault Keyring Plugin

**Note**
The `keyring_hashicorp` plugin is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see [https://www.mysql.com/products/](https://www.mysql.com/products/).

The `keyring_hashicorp` keyring plugin communicates with HashiCorp Vault for back end storage. The plugin supports HashiCorp Vault AppRole authentication. No key information is permanently stored in MySQL server local storage. (An optional in-memory key cache may be used as intermediate storage.) Random key generation is performed on the MySQL server side, and the keys are subsequently stored to Hashicorp Vault.

The `keyring_hashicorp` plugin supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by those functions are accessible at two levels:

- **SQL interface:** In SQL statements, call the user-defined functions (UDFs) described in Section 6.4.4.10, "General-Purpose Keyring Key-Management Functions".

- **C interface:** In C-language code, call the keyring service functions described in Section 5.6.8.2, "The Keyring Service".

Example (using UDFs):
The MySQL Keyring

```sql
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

For information about the key types permitted by keyring_hashicorp, see Section 6.4.4.8, “Supported Keyring Key Types and Lengths”.

To install the keyring_hashicorp plugin, use the general keyring installation instructions found in Section 6.4.4.1, “Keyring Plugin Installation”, together with the configuration information specific to keyring_hashicorp found here. Plugin-specific configuration includes preparation of the certificate and key files needed for connecting to HashiCorp Vault, as well as configuring Vault itself. The following sections provide the necessary instructions.

- Certificate and Key Preparation
- HashiCorp Vault Setup
- keyring_hashicorp Configuration

Certificate and Key Preparation

The keyring_hashicorp plugin requires a secure connection to the HashiCorp Vault server, employing the HTTPS protocol. A typical setup includes a set of certificate and key files:

- `company.crt`: A custom CA certificate belonging to the organization. This file is used both by HashiCorp Vault server and the keyring_hashicorp plugin.

- `vault.key`: The private key of the HashiCorp Vault server instance. This file is used by HashiCorp Vault server.

- `vault.crt`: The certificate of the HashiCorp Vault server instance. This file must be signed by the organization CA certificate.

The following instructions describe how to create the certificate and key files using OpenSSL. (If you already have the files, proceed to HashiCorp Vault Setup.) The instructions as shown apply to Linux platforms and may require adjustment for other platforms.

⚠️ Important

Certificates generated by these instructions are self-signed, which may not be very secure. After you gain experience using such files, consider obtaining certificate/key material from a registered certificate authority.

1. Prepare the company and HashiCorp Vault server keys.

Use the following commands to generate the key files:

```bash
openssl genrsa -aes256 -out company.key 4096
openssl genrsa -aes256 -out vault.key 2048
```

The commands produce files holding the company private key (`company.key`) and the Vault server private key (`vault.key`). The keys are randomly generated RSA keys of 4,096 and 2,048 bits, respectively.

Each command prompts for a password. (For testing purposes, the password is not required. To disable it, omit the `-aes256` argument.)

The key files hold sensitive information and should be stored in a secure location. The password (also sensitive) is required later, so write it down and store it in a secure location.
The MySQL Keyring

(Optional) To check key file content and validity, use the following commands:

```bash
openssl rsa -in company.key -check
openssl rsa -in vault.key -check
```

2. Create the company CA certificate.

Use the following command to create a company CA certificate file named `company.crt` that is valid for 365 days (enter the command on a single line):

```bash
openssl req -x509 -new -nodes -key company.key -sha256 -days 365 -out company.crt
```

If you used the `-aes256` argument to perform key encryption during key generation, you are prompted for the company key password during CA certificate creation. You are also prompted for information about the certificate holder (that is, you or your company), as shown here:

- `Country Name`: AP
- `State or Province Name`: [Some-State]
- `Locality Name`: [Some-City]
- `Organization Name`: [Some-Company]
- `Organizational Unit Name`: [Some-Section]
- `Common Name`: [Some-FQDN or YOUR name]
- `Email Address`

Answer the prompts with appropriate values.

3. Create a certificate signing request.

To create a HashiCorp Vault server certificate, a Certificate Signing Request (CSR) must be prepared for the newly created server key. Create a configuration file named `request.conf` containing the following lines. If the HashiCorp Vault server does not run on the local host, substitute appropriate CN and IP values, and make any other changes required.

```bash
[req]
distinguished_name = vault
x509_extensions = v3_req
prompt = no

[vault]
C = US
ST = CA
L = RWC
O = Company
CN = 127.0.0.1

[v3_req]
subjectAltName = @alternatives
authorityKeyIdentifier = keyid,issuer
basicConstraints = CA:TRUE

[alternatives]
IP = 127.0.0.1
```

Use this command to create the signing request:

```bash
openssl req -new -key vault.key -config request.conf -out request.csr
```

The output file (`request.csr`) is an intermediate file that serves as input for creation of the server certificate.

4. Create the HashiCorp Vault server certificate.
Sign the combined information from the HashiCorp Vault server key (`vault.key`) and the CSR (`request.csr`) with the company certificate (`company.crt`) to create the HashiCorp Vault server certificate (`vault.crt`). Use the following command to do this (enter the command on a single line):

```
openssl x509 -req -in request.csr
-CA company.crt -CAkey company.key -CAcreateserial
-out vault.crt -days 365 -sha256
```

To make the `vault.crt` server certificate useful, append the contents of the `company.crt` company certificate to it. This is required so that the company certificate is delivered along with the server certificate in requests.

```
cat company.crt >> vault.crt
```

If you open the `vault.crt` file with a text editor, its content should look like this:

```
-----BEGIN CERTIFICATE-----
... content of HashiCorp Vault server certificate ...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
... content of company certificate ...
-----END CERTIFICATE-----
```

### HashiCorp Vault Setup

The following instructions describe how to create a HashiCorp Vault setup that facilitates testing the `keyring_hashicorp` plugin.

⚠️ **Important**

A test setup is similar to a production setup, but production use of HashiCorp Vault entails additional security considerations such as use of non-self-signed certificates and storing the company certificate in the system trust store. You must implement whatever additional security steps are needed to satisfy your operational requirements.

These instructions assume availability of the certificate and key files created in Certificate and Key Preparation. See that section if you do not have the files.

1. Fetch the HashiCorp Vault binary.

   Download the HashiCorp Vault binary appropriate for your platform from https://www.vaultproject.io/downloads.html.

   Extract the content of the archive to produce the executable `vault` command, which is used to perform HashiCorp Vault operations. If necessary, add the directory where you install the command to the system path.

   (Optional) HashiCorp Vault supports autocomplete options that make it easier to use. For more information, see https://learn.hashicorp.com/vault/getting-started/install#command-completion.

2. Create the HashiCorp Vault server configuration file.

   Prepare a configuration file named `config.hcl` with the following content. For the `tls_cert_file`, `tls_key_file`, and `path` values, substitute path names appropriate for your system.

```
listener "tcp" {
    address="127.0.0.1:8200"
    tls_cert_file="/home/username/certificates/vault.crt"
```
3. Start the HashiCorp Vault server.

To start the Vault server, use the following command, where the `-config` option specifies the path to the configuration file just created:

```bash
vault server -config=config.hcl
```

During this step, you may be prompted for a password for the Vault server private key stored in the `vault.key` file.

The server should start, displaying some information on the console (IP, port, and so forth).

So that you can enter the remaining commands, put the `vault server` command in the background or open another terminal before continuing.

4. Initialize the HashiCorp Vault server.

   **Note**
   
   The operations described in this step are required only when starting Vault the first time, to obtain the unseal key and root token. Subsequent Vault instance restarts require only unsealing using the unseal key.

   Issue the following commands (assuming Bourne shell syntax):

   ```bash
   export VAULT_SKIP_VERIFY=1
   vault operator init -n 1 -t 1
   ```

   The first command enables the `vault` command to temporarily ignore the fact that no company certificate has been added to the system trust store. It compensates for the fact that our self-signed CA is not added to that store. (For production use, such a certificate should be added.)

   The second command creates a single unseal key with a requirement for a single unseal key to be present for unsealing. (For production use, an instance would have multiple unseal keys with up to that many keys required to be entered to unseal it. The unseal keys should be delivered to key custodians within the company. Use of a single key might be considered a security issue because that permits the vault to be unsealed by a single key custodian.)

   Vault should reply with information about the unseal key and root token, plus some additional text (the actual unseal key and root token values differ from those shown here):

   ```
   ...  
   Unseal Key 1: I2xwcFQc89200Nt2pBiRN1nkH2TUrWS+JybL39BjcOE=  
   Initial Root Token: s.vTvXeo3tPEYehfcd9WH7oUKz  
   ...  
   ```

   Store the unseal key and root token in a secure location.

5. Unseal the HashiCorp Vault server.

   Use this command to unseal the Vault server:
The MySQL Keyring

```
vault operator unseal
```

When prompted to enter the unseal key, use the key obtained previously during Vault initialization.

Vault should produce output indicating that setup is complete and the vault is unsealed.

6. Log in to the HashiCorp Vault server and verify its status.

Prepare the environment variables required for logging in as root:

```
vault login s.vTvXeo3tPEYehfcd9WH7oUKz
```

For the token value in that command, substitute the content of the root token obtained previously during Vault initialization.

Verify the Vault server status:

```
vault status
```

The output should contain these lines (among others):

```
...  
Initialized true
Sealed false
...  
```

7. Set up HashiCorp Vault authentication and storage.

```
Note
The operations described in this step are needed only the first time the Vault instance is run. They need not be repeated afterward.
```

Enable the AppRole authentication method and verify that it is in the authentication method list:

```
vault auth enable approle
vault auth list
```

Enable the Vault KeyValue storage engine:

```
vault secrets enable -version=1 kv
```

Create and set up a role for use with the `keyring_hashicorp` plugin (enter the command on a single line):

```
vault write auth/approle/role/mysql token_num_uses=0
token_ttl=20m token_max_ttl=30m secret_id_num_uses=0
```

8. Add an AppRole security policy.

```
Note
The operations described in this step are needed only the first time the Vault instance is run. They need not be repeated afterward.
```

Prepare a policy that to permit the previously created role to access appropriate secrets. Create a new file named `mysql.hcl` with the following content:

```
path "kv/mysql/**" {  
capabilities = ["create", "read", "update", "delete", "list"]
```

Import the policy file to the Vault server to create a policy named `mysql-policy`, then assign the policy to the new role:

```
vault policy write mysql-policy mysql.hcl
vault write auth/approle/role/mysql policies=mysql-policy
```

Obtain the ID of the newly created role and store it in a secure location:

```
vault read auth/approle/role/mysql/role-id
```

Generate a secret ID for the role and store it in a secure location:

```
vault write -f auth/approle/role/mysql/secret-id
```

After these AppRole role ID and secret ID credentials are generated, they are expected to remain valid indefinitely. They need not be generated again and the `keyring_hashicorp` plugin can be configured with them for use on an ongoing basis. For more information about AuthRole authentication, visit [https://www.vaultproject.io/docs/auth/approle.html](https://www.vaultproject.io/docs/auth/approle.html).

**keyring_hashicorp Configuration**

The plugin library file contains the `keyring_hashicorp` plugin and a user-defined function (UDF), `keyring_hashicorp_update_config()`. When the plugin initializes and terminates, it automatically loads and unloads the UDF, so there is no need to load and unload the UDF manually.

The `keyring_hashicorp` plugin supports the configuration parameters shown in the following table. Specify these parameters by assigning values to the corresponding system variables.

<table>
<thead>
<tr>
<th>Configuration Parameter</th>
<th>System Variable</th>
<th>Mandatory</th>
</tr>
</thead>
<tbody>
<tr>
<td>HashiCorp Server URL</td>
<td>keyring_hashicorp_server_url</td>
<td>No</td>
</tr>
<tr>
<td>AppRole role ID</td>
<td>keyring_hashicorp_role_id</td>
<td>Yes</td>
</tr>
<tr>
<td>AppRole secret ID</td>
<td>keyring_hashicorp_secret_id</td>
<td>Yes</td>
</tr>
<tr>
<td>Store path</td>
<td>keyring_hashicorp_store_path</td>
<td>Yes</td>
</tr>
<tr>
<td>Authorization Path</td>
<td>keyring_hashicorp_auth_path</td>
<td>No</td>
</tr>
<tr>
<td>CA certificate file path</td>
<td>keyring_hashicorp_ca_path</td>
<td>No</td>
</tr>
<tr>
<td>Cache control</td>
<td>keyring_hashicorp_caching</td>
<td>No</td>
</tr>
</tbody>
</table>

To be usable during the server startup process, `keyring_hashicorp` must be loaded using the `--early-plugin-load` option. As indicated by the preceding table, several plugin-related system variables are mandatory and must also be set. For example, use these lines in the server `my.cnf` file, adjusting the `.so` suffix and file locations for your platform as necessary:

```
[mysqld]
early-plugin-load=keyring_hashicorp.so
keyring_hashicorp_role_id='ee3b495c-d0c9-11e9-8881-8444c71c32aa'
keyring_hashicorp_secret_id='0512af29-d0ca-11e9-95ee-0010e00dd718'
keyring_hashicorp_store_path='/v1/kv/mysql'
```

MySQL Server authenticates against HashiCorp Vault using AppRole authentication. Successful authentication requires that two secrets be provided to Vault, a role ID and a secret ID, which are similar in concept to user name and password. The role ID and secret ID values to use are those obtained during the HashiCorp Vault setup procedure performed previously. To specify the two IDs, assign their respective values to the `keyring_hashicorp_role_id` and `keyring_hashicorp_secret_id` system variables.
The MySQL Keyring

The setup procedure also results in a store path of /v1/kv/mysql, which is the value to assign to keyring_hashicorp_commit_store_path.

At plugin initialization time, keyring_hashicorp attempts to connect to the HashiCorp Vault server using the configuration values. If the connection is successful, the plugin stores the values in corresponding system variables that have _commit_ in their name. For example, upon successful connection, the plugin stores the values of keyring_hashicorp_role_id and keyring_hashicorp_store_path in keyring_hashicorp_commit_role_id and keyring_hashicorp_commit_store_path.

Reconfiguration at runtime can be performed with the assistance of the keyring_hashicorp_update_config() UDF:

1. Use SET statements to assign the desired new values to the configuration system variables shown in the preceding table. These assignments in themselves have no effect on ongoing plugin operation.
2. Invoke keyring_hashicorp_update_config() to cause the plugin to reconfigure and reconnect to the HashiCorp Vault server using the new variable values.
3. If the connection is successful, the plugin stores the updated configuration values in corresponding system variables that have _commit_ in their name.

For example, if you have reconfigured HashiCorp Vault to listen on port 8201 rather than the default 8200, reconfigure keyring_hashicorp like this:

```sql
mysql> SET GLOBAL keyring_hashicorp_server_url = 'https://127.0.0.1:8201';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT keyring_hashicorp_update_config();
+----------------------------------------+
| keyring_hashicorp_update_config()    |
+----------------------------------------+
| Configuration update was successful.  |
+----------------------------------------+
1 row in set (0.03 sec)
```

If the plugin is not able to connect to HashiCorp Vault during initialization or reconfiguration and there was no existing connection, the _commit_ system variables are set to 'Not committed' for string-valued variables, and OFF for Boolean-valued variables. If the plugin is not able to connect but there was an existing connection, that connection remains active and the _commit_ variables reflect the values used for it.

**Note**

If you do not set the mandatory system variables at server startup, or if some other plugin initialization error occurs, initialization fails. In this case, you can use the runtime reconfiguration procedure to initialize the plugin without restarting the server.

For additional information about the keyring_hashicorp plugin-specific system variables and UDF, see Section 6.4.4.13, “Keyring System Variables”, and Section 6.4.4.11, “Plugin-Specific Keyring Key-Management Functions”.

6.4.4.7 Using the Oracle Cloud Infrastructure Vault Keyring Plugin

**Note**

The keyring_oci plugin is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see https://www.mysql.com/products/.
The MySQL Keyring

The `keyring oci` plugin is a keyring plugin that communicates with Oracle Cloud Infrastructure Vault for back end storage. No key information is permanently stored in MySQL server local storage. All keys are stored in Oracle Cloud Infrastructure Vault, making this plugin well suited for Oracle Cloud Infrastructure MySQL customers for management of their MySQL Enterprise Edition keys.

The `keyring oci` plugin supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by those functions are accessible at two levels:

- SQL interface: In SQL statements, call the user-defined functions (UDFs) described in Section 6.4.10, "General-Purpose Keyring Key-Management Functions".
- C interface: In C-language code, call the keyring service functions described in Section 5.6.8.2, "The Keyring Service".

Example (using UDFs):

```sql
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

For information about the key types permitted by `keyring oci`, see Section 6.4.8, "Supported Keyring Key Types and Lengths".

To install the `keyring oci` plugin, use the general keyring installation instructions found in Section 6.4.1, "Keyring Plugin Installation", together with the configuration information specific to `keyring oci` found here. Plugin-specific configuration involves setting a number of system variables to indicate the names or values of Oracle Cloud Infrastructure resources.

You are assumed to be familiar with Oracle Cloud Infrastructure concepts, but the following documentation may be helpful when setting up resources to be used by the `keyring oci` plugin:

- Overview of Vault
- Resource Identifiers
- Required Keys and OCIDs
- Managing Keys
- Managing Compartments
- Managing Vaults
- Managing Secrets

The `keyring oci` plugin supports the configuration parameters shown in the following table. Specify these parameters by assigning values to the corresponding system variables.

<table>
<thead>
<tr>
<th>Configuration Parameter</th>
<th>System Variable</th>
<th>Mandatory</th>
</tr>
</thead>
<tbody>
<tr>
<td>User OCID</td>
<td>keyring_oci_user</td>
<td>Yes</td>
</tr>
<tr>
<td>Tenancy OCID</td>
<td>keyring_oci_tenancy</td>
<td>Yes</td>
</tr>
<tr>
<td>Compartment OCID</td>
<td>keyring_oci_compartment</td>
<td>Yes</td>
</tr>
<tr>
<td>Vault OCID</td>
<td>keyring_oci_virtual_vault</td>
<td>Yes</td>
</tr>
<tr>
<td>Master key OCID</td>
<td>keyring_oci_master_key</td>
<td>Yes</td>
</tr>
<tr>
<td>Encryption server endpoint</td>
<td>keyring_oci_encryption_endpoint</td>
<td>Yes</td>
</tr>
<tr>

To be usable during the server startup process, `keyring_oci` must be loaded using the `--early-plugin-load` option. As indicated by the preceding table, several plugin-related system variables are mandatory and must also be set:

- Oracle Cloud Infrastructure uses Oracle Cloud IDs (OCIDs) extensively to designate resources, and several `keyring_oci` parameters specify OCID values of the resources to use. Consequently, prior to using the `keyring_oci` plugin, these prerequisites must be satisfied:
  - A user for connecting to Oracle Cloud Infrastructure must exist. Create the user if necessary and assign the user OCID to the `keyring_oci_user` system variable.
  - The Oracle Cloud Infrastructure tenancy to be used must exist, as well as the MySQL compartment within the tenancy, and the vault within the compartment. Create these resources if necessary and make sure the user is enabled to use them. Assign the OCIDs for the tenancy, compartment and vault to the `keyring_oci_tenancy`, `keyring_oci_compartment`, and `keyring_oci_virtual_vault` system variables.
  - A master key for encryption must exist. Create it if necessary and assign its OCID to the `keyring_oci_master_key` system variable.
  - Several server endpoints must be specified. These endpoints are vault specific and Oracle Cloud Infrastructure assigns them at vault-creation time. Obtain their values from the vault details page and assign them to the `keyring_oci_encryption_endpoint`, `keyring_oci_management_endpoint`, `keyring_oci_vaults_endpoint`, and `keyring_oci_secrets_endpoint` system variables.
  - The Oracle Cloud Infrastructure API uses an RSA private/public key pair for authentication. To create this key pair and obtain the key fingerprint, use the instructions at Required Keys and OCIDs. Assign the private key file name and key fingerprint to the `keyring_oci_key_file` and `keyring_oci_key_fingerprint` system variables.

In addition to the mandatory system variables, `keyring_oci_ca_certificate` optionally may be set to specify a certificate authority (CA) certificate bundle file for peer authentication.

**Important**

If you copy a parameter from the Oracle Cloud Infrastructure Console, the copied value may include an initial `https://` part. Omit that part when setting the corresponding `keyring_oci` system variable.

For example, to load and configure `keyring_oci8`, use these lines in the server `my.cnf` file (adjust the `.so` suffix and file location for your platform as necessary):

```ini
[mysqld]
early-plugin-load=keyring_oci.so
keyring_oci_user=ocid1.user.oc1..longAlphaNumericString
keyring_oci_tenancy=ocid1.tenancy.oc1..longAlphaNumericString
keyring_oci_compartment=ocid1.compartment.oc1..longAlphaNumericString
keyring_oci_virtual_vault=ocid1.vault.oc1.iad.shortAlphaNumericString.longAlphaNumericString
keyring_oci_master_key=ocid1.key.oc1.iad.shortAlphaNumericString.longAlphaNumericString
```
The MySQL Keyring

```
keyring_oci_encryption_endpoint=shortAlphaNumericString-crypto.kms.us-ashburn-1.oraclecloud.com
keyring_oci_management_endpoint=shortAlphaNumericString-management.kms.us-ashburn-1.oraclecloud.com
keyring_oci_vaults_endpoint=vaults.us-ashburn-1.oci.oraclecloud.com
keyring_oci_secrets_endpoint=secrets.vaults.us-ashburn-1.oci.oraclecloud.com
keyring_oci_key_file=file_name
```

For additional information about the `keyring_oci` plugin-specific system variables, see Section 6.4.4.13, "Keyring System Variables".

The `keyring_oci` plugin does not support runtime reconfiguration and none of its system variables can be modified at runtime. To change configuration parameters, do this:

- Modify parameter settings in the `my.cnf` file, or use `SET PERSIST_ONLY` for parameters that are persisted to `mysqld-auto.conf`.
- Restart the server.

### 6.4.4.8 Supported Keyring Key Types and Lengths

MySQL Keyring supports keys of different types (encryption algorithms) and lengths:

- The available key types depend on which keyring plugin is installed.
- The permitted key lengths are subject to multiple factors:
  - General keyring UDF interface limits (for keys managed using one of the keyring UDFs described in Section 6.4.4.10, “General-Purpose Keyring Key-Management Functions”), or limits from back end implementations. These length limits can vary by key operation type.
  - In addition to the general limits, individual plugins may impose restrictions on key lengths per key type.

Table 6.26, “General Keyring Key Length Limits” shows the general key length limits. (The lower limits for `keyring_aws` are imposed by the AWS KMS interface, not the keyring UDFs.) Table 6.27, “Keyring Plugin Key Types and Lengths” shows for each keyring plugin the key types it permits, as well as any plugin-specific key-length restrictions.

#### Table 6.26 General Keyring Key Length Limits

<table>
<thead>
<tr>
<th>Key Operation</th>
<th>Maximum Key Length</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>

The **SECRET** key type, available as of MySQL 8.0.19, is intended for general-purpose storage of sensitive data using the MySQL keyring, and is supported by most keyring plugins. The keyring encrypts and decrypts **SECRET** data as a byte stream upon storage and retrieval.

Example keyring operations involving the **SECRET** key type:

```sql
SELECT keyring_key_generate('MySecret1', 'SECRET', 20);
SELECT keyring_key_remove('MySecret1');
SELECT keyring_key_store('MySecret2', 'SECRET', 'MySecretData');
SELECT keyring_key_fetch('MySecret2');
SELECT keyring_key_length_fetch('MySecret2');
SELECT keyring_key_type_fetch('MySecret2');
SELECT keyring_key_remove('MySecret2');
```

### 6.4.4.9 Migrating Keys Between Keyring Keystores

The MySQL server supports an operational mode that enables migration of keys between underlying keyring keystores, permitting DBAs to switch a MySQL installation from one keyring plugin to another. A migration server (that is, a server started in key migration mode) does not accept client connections. Instead, it runs only long enough to migrate keys, then exits. A migration server reports errors to the console (the standard error output).

It is possible to perform offline or online key migration:

- If you are sure that no running server on the local host is using the source or destination keystore, an offline migration is possible. In this case, the migration server can modify the keystores without possibility of a running server modifying keystore content during the migration.

- If a running server on the local host is using the source or destination keystore, an online migration must be performed. In this case, the migration server connects to the running server and instructs it to pause keyring operations while key migration is in progress.

The result of a key migration operation is that the destination keystore contains the keys it had prior to the migration, plus the keys from the source keystore. The source keystore is the same before and after the migration because keys are copied, not moved. If a key to be copied already exists in the destination keystore, an error occurs and the destination keystore is restored to its premigration state.
The user who invokes the server in key-migration mode must not be the root operating system user, and must have permission to read and write the keyring files.

To perform a key migration operation, determine which key migration options are needed. Migration options indicate which keyring plugins are involved, and whether to perform an offline or online migration:

- To indicate the source and destination keyring plugins, specify these options:
  - `--keyring-migration-source`: The source keyring plugin that manages the keys to be migrated.
  - `--keyring-migration-destination`: The destination keyring plugin to which the migrated keys are to be copied.

These options tell the server to run in key migration mode. Both options are mandatory for all key migration operations. The source and destination plugins must differ, and the migration server must support both plugins.

- For an offline migration, no additional key migration options are needed.

  **Warning**
  Do not perform offline migration involving a keystore that is in use by a running server.

- For an online migration, some running server currently is using the source or destination keystore. Specify the key migration options that indicate how to connect to the running server. This is necessary so that the migration server can connect to the running server and tell it to pause keyring use during the migration operation.

  Use of any of the following options signifies an online migration:

  - `--keyring-migration-host`: The host where the running server is located. This is always the local host.
  - `--keyring-migration-user, --keyring-migration-password`: The user name and password for the account to use to connect to the running server.
  - `--keyring-migration-port`: For TCP/IP connections, the port number to connect to on the running server.
  - `--keyring-migration-socket`: For Unix socket file or Windows named pipe connections, the socket file or named pipe to connect to on the running server.

For additional details about the key migration options, see Section 6.4.4.12, “Keyring Command Options”.

Start the migration server with the key migration options determined as just described, possibly with other options. Keep the following considerations in mind:

- Other server options might be required, such as other configuration parameters for the two keyring plugins. For example, if `keyring_file` is one of the plugins, you must set the `keyring_file_data` system variable if the keyring data file location is not the default location. Other non-keyring options may be required as well. One way to specify these options is by using `--defaults-file` to name an option file that contains the required options.

- If you invoke the migration server from a system account different from that normally used to run MySQL, it might create keyring directories or files that are inaccessible to the server during normal operation. Suppose that `mysqld` normally runs as the `mysql` operating system user, but you invoke the migration server while logged in as `isabel`. Any new directories or files created by the migration server
The MySQL Keyring

are owned by *isabel*. Subsequent startup fails when a server run as the `mysql` operating system user attempts to access file system objects owned by *isabel*

To avoid this issue, start the migration server as the `root` operating system user and provide a `--user=user_name` option, where `user_name` is the system account normally used to run MySQL.

- The migration server expects path name option values to be full paths. Relative path names may not be resolved as you expect.

Example command line for offline key migration:

```bash
mysqld --defaults-file=/usr/local/mysql/etc/my.cnf
    --keyring-migration-source=keyring_file.so
    --keyring-migration-destination=keyring_encrypted_file.so
    --keyring_encrypted_file_password=password
```

Example command line for online key migration:

```bash
mysqld --defaults-file=/usr/local/mysql/etc/my.cnf
    --keyring-migration-source=keyring_file.so
    --keyring-migration-destination=keyring_encrypted_file.so
    --keyring_encrypted_file_password=password
    --keyring-migration-host=localhost
    --keyring-migration-user=root
    --keyring-migration-password=root_password
```

The key migration server performs the migration operation as follows:

1. (Online migration only) Connect to the running server using the connection options. The account used to connect must have the privileges required to modify the global `keyring_operations` system variable (**ENCRYPTION_KEY_ADMIN** in addition to either **SYSTEM_VARIABLES_ADMIN** or the deprecated **SUPER** privilege).

2. (Online migration only) Disable `keyring_operations` on the running server. (The running server must support `keyring_operations`.)

3. Load the source and destination keyring plugins.

4. Copy keys from the source keyring to the destination keyring.

5. Unload the keyring plugins.

6. (Online migration only) Enable `keyring_operations` on the running server.

7. (Online migration only) Disconnect from the running server.

8. Exit.

If an error occurs during key migration, any keys that were copied to the destination plugin are removed, leaving the destination keystore unchanged.

**Important**

For an online migration operation, the migration server takes care of enabling and disabling `keyring_operations` on the running server. If the migration server exits abnormally (for example, if it is forcibly terminated), it is possible that `keyring_operations` is not re-enabled on the running server, leaving it unable to perform keyring operations. In this case, it may be necessary to connect to the running server and enable `keyring_operations` manually.

After a successful online key migration operation, the running server might need to be restarted:
The MySQL Keyring

- If the running server was using the source keystore, it need not be restarted after the migration.

- If the running server was using the source keystore before the migration but should use the destination keystore after the migration, it must be reconfigured to use the destination keyring plugin and restarted.

- If the running server was using the destination keystore and continues to use it, it should be restarted after the migration to load all keys migrated into the destination keystore.

**Note**

MySQL server key migration mode supports pausing a single running server. To perform a key migration if multiple key servers are using the keystores involved, use this procedure:

1. Connect to each running server manually and set `keyring_operations=OFF`.
2. Use the migration server to perform an offline key migration.
3. Connect to each running server manually and set `keyring_operations=ON`.

All running servers must support the `keyring_operations=ON` system variable.

### 6.4.4.10 General-Purpose Keyring Key-Management Functions

MySQL Server supports a keyring service that enables internal server components and plugins to securely store sensitive information for later retrieval.

MySQL Server also includes an SQL interface for keyring key management, implemented as a set of general-purpose user-defined functions (UDFs) that access the functions provided by the internal keyring service. The keyring UDFs are contained in a plugin library file, which also contains a `keyring_udf` plugin that must be enabled prior to UDF invocation. For these UDFs to be used, a keyring plugin such as `keyring_file` or `keyring_okv` must be enabled.

The UDFs described here are general purpose and intended for use with any keyring plugin. A given keyring plugin might have UDFs of its own that are intended for use only with that plugin; see Section 6.4.4.11, “Plugin-Specific Keyring Key-Management Functions”.

The following sections provide installation instructions for the keyring UDFs and demonstrate how to use them. For information about the keyring service functions invoked by the UDFs, see Section 5.6.8.2, “The Keyring Service”. For general keyring information, see Section 6.4.4, “The MySQL Keyring”.

- Installing or Uninstalling General-Purpose Keyring Functions
- Using General-Purpose Keyring Functions
- General-Purpose Keyring Function Reference

#### Installing or Uninstalling General-Purpose Keyring Functions

This section describes how to install or uninstall the keyring user-defined functions (UDFs), which are implemented in a plugin library file that also contains a `keyring_udf` plugin. For general information about installing or uninstalling plugins and UDFs, see Section 5.6.1, “Installing and Uninstalling Plugins”, and Section 5.7.1, “Installing and Uninstalling User-Defined Functions”.

The keyring UDFs enable keyring key management operations, but the `keyring_udf` plugin must also be installed because the UDFs do not work correctly without it. Attempts to use the UDFs without the `keyring_udf` plugin result in an error.
To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `keyring_udf`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To install the `keyring_udf` plugin and the UDFs, use the `INSTALL PLUGIN` and `CREATE FUNCTION` statements, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN keyring_udf SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_generate RETURNS INTEGER
  SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_fetch RETURNS STRING
  SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_length_fetch RETURNS INTEGER
  SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_type_fetch RETURNS STRING
  SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_store RETURNS INTEGER
  SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_remove RETURNS INTEGER
  SONAME 'keyring_udf.so';
```

If the plugin and UDFs are used on a source replication server, install them on all replicas as well to avoid replication issues.

Once installed as just described, the plugin and UDFs remain installed until uninstalled. To remove them, use the `UNINSTALL PLUGIN` and `DROP FUNCTION` statements:

```
UNINSTALL PLUGIN keyring_udf;
DROP FUNCTION keyring_key_generate;
DROP FUNCTION keyring_key_fetch;
DROP FUNCTION keyring_key_length_fetch;
DROP FUNCTION keyring_key_type_fetch;
DROP FUNCTION keyring_key_store;
DROP FUNCTION keyring_key_remove;
```

Using General-Purpose Keyring Functions

Before using the keyring user-defined functions (UDFs), install them according to the instructions provided in Installing or Uninstalling General-Purpose Keyring Functions.

The keyring UDFs are subject to these constraints:

- To use any keyring UDF, the `keyring_udf` plugin must be enabled. Otherwise, an error occurs:

```
ERROR 1123 (HY000): Can't initialize function 'keyring_key_generate';
This function requires keyring_udf plugin which is not installed.
Please install
```

To install the `keyring_udf` plugin, see Installing or Uninstalling General-Purpose Keyring Functions.

- The keyring UDFs invoke keyring service functions (see Section 5.6.8.2, “The Keyring Service”). The service functions in turn use whatever keyring plugin is installed (for example, `keyring_file` or `keyring_okv`). Therefore, to use any keyring UDF, some underlying keyring plugin must be enabled. Otherwise, an error occurs:

```
ERROR 3188 (HY000): Function 'keyring_key_generate' failed because
underlying keyring service returned an error. Please check if a
keyring plugin is installed and that provided arguments are valid
for the keyring you are using.
```
To install a keyring plugin, see Section 6.4.4.1, “Keyring Plugin Installation”.

- To use any keyring UDF, a user must possess the global `EXECUTE` privilege. Otherwise, an error occurs:

```
ERROR 1123 (HY000): Can't initialize function 'keyring_key_generate';
The user is not privileged to execute this function. User needs to have EXECUTE
```

To grant the global `EXECUTE` privilege to a user, use this statement:

```
GRANT EXECUTE ON *.* TO user;
```

Alternatively, should you prefer to avoid granting the global `EXECUTE` privilege while still permitting users to access specific key-management operations, “wrapper” stored programs can be defined (a technique described later in this section).

- A key stored in the keyring by a given user can be manipulated later only by the same user. That is, the value of the `CURRENT_USER()` function at the time of key manipulation must have the same value as when the key was stored in the keyring. (This constraint rules out the use of the keyring UDFs for manipulation of instance-wide keys, such as those created by InnoDB to support tablespace encryption.)

To enable multiple users to perform operations on the same key, “wrapper” stored programs can be defined (a technique described later in this section).

- Keyring UDFs support the key types and lengths supported by the underlying keyring plugin. For information about keys specific to a particular keyring plugin, see Section 6.4.4.8, “Supported Keyring Key Types and Lengths”.

To create a new random key and store it in the keyring, call `keyring_key_generate()`, passing to it an ID for the key, along with the key type (encryption method) and its length in bytes. The following call creates a 2,048-bit DSA-encrypted key named `MyKey`:

```
mysql> SELECT keyring_key_generate('MyKey', 'DSA', 256);
+-------------------------------------------+
| keyring_key_generate('MyKey', 'DSA', 256) |
+-------------------------------------------+
|                                         1 |
+-------------------------------------------+
```

A return value of 1 indicates success. If the key cannot be created, the return value is `NULL` and an error occurs. One reason this might be is that the underlying keyring plugin does not support the specified combination of key type and key length; see Section 6.4.4.8, “Supported Keyring Key Types and Lengths”.

To be able to check the return type regardless of whether an error occurs, use `SELECT ... INTO @var_name` and test the variable value:

```
mysql> SELECT keyring_key_generate('', '', -1) INTO @x;
ERROR 3188 (HY000): Function 'keyring_key_generate' failed because underlying keyring service returned an error. Please check if a keyring plugin is installed and that provided arguments are valid for the keyring you are using.
mysql> SELECT @x;
+------+
| @x   |
+------+
| NULL |
mysql> SELECT keyring_key_generate('x', 'AES', 16) INTO @x;
mysql> SELECT @x;
+------+
| @x   |
| 1376  |
```

1376
This technique also applies to other keyring UDFs that for failure return a value and an error.

The ID passed to `keyring_key_generate()` provides a means by which to refer to the key in subsequent UDF calls. For example, use the key ID to retrieve its type as a string or its length in bytes as an integer:

```sql
mysql> SELECT keyring_key_type_fetch('MyKey');
+---------------------------------+
| keyring_key_type_fetch('MyKey') |
| DSA                             |
+---------------------------------+
mysql> SELECT keyring_key_length_fetch('MyKey');
+-----------------------------------+
| keyring_key_length_fetch('MyKey') |
|                               256 |
+-----------------------------------+
```

To retrieve a key value, pass the key ID to `keyring_key_fetch()`. The following example uses `HEX()` to display the key value because it may contain nonprintable characters. The example also uses a short key for brevity, but be aware that longer keys provide better security:

```sql
mysql> SELECT keyring_key_generate('MyShortKey', 'DSA', 8);
+----------------------------------------------+
| keyring_key_generate('MyShortKey', 'DSA', 8) |
|                                            1 |
+----------------------------------------------+
mysql> SELECT HEX(keyring_key_fetch('MyShortKey'));
+--------------------------------------+
| HEX(keyring_key_fetch('MyShortKey')) |
| 1DB3B0FC3328A24C                     |
+--------------------------------------+
```

Keyring UDFs treat key IDs, types, and values as binary strings, so comparisons are case-sensitive. For example, IDs of `MyKey` and `mykey` refer to different keys.

To remove a key, pass the key ID to `keyring_key_remove()`:

```sql
mysql> SELECT keyring_key_remove('MyKey');
+-----------------------------+
| keyring_key_remove('MyKey') |
|                           1 |
+-----------------------------+
```

To obfuscate and store a key that you provide, pass the key ID, type, and value to `keyring_key_store()`:

```sql
mysql> SELECT keyring_key_store('AES_key', 'AES', 'Secret string');
+------------------------------------------------------+
| keyring_key_store('AES_key', 'AES', 'Secret string') |
|                                                    1 |
+------------------------------------------------------+
```

As indicated previously, a user must have the global `EXECUTE` privilege to call keyring UDFs, and the user who stores a key in the keyring initially must be the same user who performs subsequent operations on
the key later, as determined from the CURRENT_USER() value in effect for each UDF call. To permit key operations to users who do not have the global EXECUTE privilege or who may not be the key “owner,” use this technique:

1. Define “wrapper” stored programs that encapsulate the required key operations and have a DEFINER value equal to the key owner.

2. Grant the EXECUTE privilege for specific stored programs to the individual users who should be able to invoke them.

3. If the operations implemented by the wrapper stored programs do not include key creation, create any necessary keys in advance, using the account named as the DEFINER in the stored program definitions.

This technique enables keys to be shared among users and provides to DBAs more fine-grained control over who can do what with keys, without having to grant global privileges.

The following example shows how to set up a shared key named SharedKey that is owned by the DBA, and a get_shared_key() stored function that provides access to the current key value. The value can be retrieved by any user with the EXECUTE privilege for that function, which is created in the key_schema schema.

From a MySQL administrative account ('root'@'localhost' in this example), create the administrative schema and the stored function to access the key:

```
mysql> CREATE SCHEMA key_schema;
mysql> CREATE DEFINER = 'root'@'localhost'
    
    FUNCTION key_schema.get_shared_key()
    
    RETURNS BLOB READS SQL DATA
    
    RETURN keyring_key_fetch('SharedKey');
```

From the administrative account, ensure that the shared key exists:

```
mysql> SELECT keyring_key_generate('SharedKey', 'DSA', 8);
+---------------------------------------------+
| keyring_key_generate('SharedKey', 'DSA', 8) |
|                                           1 |
+---------------------------------------------+
```

From the administrative account, create an ordinary user account to which key access is to be granted:

```
mysql> CREATE USER 'key_user'@'localhost'
    
    IDENTIFIED BY 'key_user_pwd';
```

From the key_user account, verify that, without the proper EXECUTE privilege, the new account cannot access the shared key:

```
mysql> SELECT HEX(key_schema.get_shared_key());
ERROR 1370 (42000): execute command denied to user 'key_user'@'localhost'
for routine 'key_schema.get_shared_key'
```

From the administrative account, grant EXECUTE to key_user for the stored function:

```
mysql> GRANT EXECUTE ON FUNCTION key_schema.get_shared_key
    
    TO 'key_user'@'localhost';
```

From the key_user account, verify that the key is now accessible:

```
mysql> SELECT HEX(key_schema.get_shared_key());
1378
```
General-Purpose Keyring Function Reference

For each general-purpose keyring user-defined function (UDF), this section describes its purpose, calling sequence, and return value. For information about the conditions under which these UDFs can be invoked, see Using General-Purpose Keyring Functions.

- **keyring_key_fetch(key_id)**

  Given a key ID, deobfuscates and returns the key value.

  Arguments:
  
  - **key_id**: A string that specifies the key ID.

  Return value:

  Returns the key value as a string for success, **NULL** if the key does not exist, or **NULL** and an error for failure.

  **Note**

  Key values retrieved using **keyring_key_fetch()** are subject to the general keyring UDF limits described in Section 6.4.4.8, “Supported Keyring Key Types and Lengths”. A key value longer than that length can be stored using a keyring service function (see Section 5.6.8.2, “The Keyring Service”), but if retrieved using **keyring_key_fetch()** is truncated to the general keyring UDF limit.

  **Example:**

  ```
  mysql> SELECT keyring_key_generate('RSA_key', 'RSA', 16);
  +--------------------------------------------+
  | keyring_key_generate('RSA_key', 'RSA', 16) |
  +--------------------------------------------+
  |                                          1 |
  +--------------------------------------------+

  mysql> SELECT HEX(keyring_key_fetch('RSA_key'));
  +-----------------------------------+
  | HEX(keyring_key_fetch('RSA_key')) |
  +-----------------------------------+
  | 91C2253B696064D3556984B6630F891A  |
  +-----------------------------------+

  mysql> SELECT keyring_key_type_fetch('RSA_key');
  +-----------------------------------+
  | keyring_key_type_fetch('RSA_key') |
  +-----------------------------------+
  | RSA                               |
  +-----------------------------------+

  mysql> SELECT keyring_key_length_fetch('RSA_key');
  +-------------------------------------+
  | keyring_key_length_fetch('RSA_key') |
  +-------------------------------------+
  |                                  16 |
  +-------------------------------------+
  ```

  The example uses **HEX()** to display the key value because it may contain nonprintable characters. The example also uses a short key for brevity, but be aware that longer keys provide better security.
**keyring_key_generate(key_id, key_type, key_length)**

Generates a new random key with a given ID, type, and length, and stores it in the keyring. The type and length values must be consistent with the values supported by the underlying keyring plugin. See Section 6.4.4.8, “Supported Keyring Key Types and Lengths”.

**Arguments:**

- **key_id**: A string that specifies the key ID.
- **key_type**: A string that specifies the key type.
- **key_length**: An integer that specifies the key length in bytes.

**Return value:**

Returns 1 for success, or `NULL` and an error for failure.

**Example:**

```sql
mysql> SELECT keyring_key_generate('RSA_key', 'RSA', 384);
+---------------------------------------------+
| keyring_key_generate('RSA_key', 'RSA', 384) |
+---------------------------------------------+
|                                           1 |
+---------------------------------------------+
```

**keyring_key_length_fetch(key_id)**

Given a key ID, returns the key length.

**Arguments:**

- **key_id**: A string that specifies the key ID.

**Return value:**

Returns the key length in bytes as an integer for success, `NULL` if the key does not exist, or `NULL` and an error for failure.

**Example:**

See the description of `keyring_key_fetch()`.

**keyring_key_remove(key_id)**

Removes the key with a given ID from the keyring.

**Arguments:**

- **key_id**: A string that specifies the key ID.

**Return value:**

Returns 1 for success, or `NULL` for failure.

**Example:**

```sql
mysql> SELECT keyring_key_remove('AES_key');
+-------------------------------+
| 1380                         |
+-------------------------------+
```
The MySQL Keyring

<table>
<thead>
<tr>
<th>keyring_key_remove('AES_key')</th>
<th>........................................</th>
<th>1</th>
</tr>
</thead>
</table>

- `keyring_key_store(key_id, key_type, key)`

Obfuscates and stores a key in the keyring.

Arguments:

- `key_id`: A string that specifies the key ID.
- `key_type`: A string that specifies the key type.
- `key`: A string that specifies the key value.

Return value:

Returns 1 for success, or `NULL` and an error for failure.

Example:

```sql
mysql> SELECT keyring_key_store('new key', 'DSA', 'My key value');
+-----------------------------------------------------+
| keyring_key_store('new key', 'DSA', 'My key value') | 1 |
+-----------------------------------------------------+
```

- `keyring_key_type_fetch(key_id)`

Given a key ID, returns the key type.

Arguments:

- `key_id`: A string that specifies the key ID.

Return value:

Returns the key type as a string for success, `NULL` if the key does not exist, or `NULL` and an error for failure.

Example:

See the description of `keyring_key_fetch()`.

### 6.4.4.11 Plugin-Specific Keyring Key-Management Functions

For each keyring plugin-specific user-defined function (UDF), this section describes its purpose, calling sequence, and return value. For information about general-purpose keyring UDFs, see Section 6.4.4.10, “General-Purpose Keyring Key-Management Functions”.

- `keyring_aws_rotate_cmk()`

Associated keyring plugin: `keyring_aws`

`keyring_aws_rotate_cmk()` rotates the customer master key (CMK). Rotation changes only the key that AWS KMS uses for subsequent data key-encryption operations. AWS KMS maintains previous CMK versions, so keys generated using previous CMKs remain decryptable after rotation.
Rotation changes the CMK value used inside AWS KMS but does not change the ID used to refer to it, so there is no need to change the `keyring_aws_cmk_id` system variable after calling `keyring_aws_rotate_cmk()`.

This UDF requires the `SUPER` privilege.

Arguments:

None.

Return value:

Returns 1 for success, or NULL and an error for failure.

- **keyring_aws_rotate_keys()**

  Associated keyring plugin: `keyring_aws`

  `keyring_aws_rotate_keys()` rotates keys stored in the `keyring_aws` storage file named by the `keyring_aws_data_file` system variable. Rotation sends each key stored in the file to AWS KMS for re-encryption using the value of the `keyring_aws_cmk_id` system variable as the CMK value, and stores the new encrypted keys in the file.

  `keyring_aws_rotate_keys()` is useful for key re-encryption under these circumstances:

  - After rotating the CMK; that is, after invoking the `keyring_aws_rotate_cmk()` UDF
  - After changing the `keyring_aws_cmk_id` system variable to a different key value

  This UDF requires the `SUPER` privilege.

  Arguments:

  None.

  Return value:

  Returns 1 for success, or NULL and an error for failure.

- **keyring_hashicorp_update_config()**

  Associated keyring plugin: `keyring_hashicorp`

  When invoked, the `keyring_hashicorp_update_config()` UDF causes `keyring_hashicorp` to perform a runtime reconfiguration, as described in `keyring_hashicorp Configuration`.

  This UDF requires the `SYSTEM_VARIABLES_ADMIN` privilege because it modifies global system variables.

  Arguments:

  None.

  Return value:

  Returns the string 'Configuration update was successful.' for success, or 'Configuration update failed.' for failure.
6.4.4.12 Keyring Command Options

MySQL supports the following keyring-related command-line options:

• `--keyring-migration-destination=plugin`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-migration-destination=plugin_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The destination keyring plugin for key migration. See Section 6.4.4.9, “Migrating Keys Between Keyring Keystores”. The format and interpretation of the option value is the same as described for the `--keyring-migration-source` option.

Note `--keyring-migration-source` and `--keyring-migration-destination` are mandatory for all keyring migration operations. The source and destination plugins must differ, and the migration server must support both plugins.

• `--keyring-migration-host=host_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-migration-host=host_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>localhost</td>
</tr>
</tbody>
</table>

The host location of the running server that is currently using one of the key migration keystores. See Section 6.4.4.9, “Migrating Keys Between Keyring Keystores”. Migration always occurs on the local host, so the option always specifies a value for connecting to a local server, such as `localhost`, `127.0.0.1`, `::1`, or the local host IP address or host name.

• `--keyring-migration-password[=password]`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-migration-password[=password]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The password for connecting to the running server that is currently using one of the key migration keystores. See Section 6.4.4.9, “Migrating Keys Between Keyring Keystores”. If you omit the `password` value following the option name on the command line, the server prompts for one.

Specifying a password on the command line should be considered insecure. See Section 6.1.2.1, “End-User Guidelines for Password Security”. You can use an option file to avoid giving the password on the command line. In this case, the file should have a restrictive mode and be accessible only to the account used to run the migration server.

• `--keyring-migration-port=port_num`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-migration-port=port_num</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>3306</td>
</tr>
</tbody>
</table>

For TCP/IP connections, the port number for connecting to the running server that is currently using one of the key migration keystores. See Section 6.4.4.9, “Migrating Keys Between Keyring Keystores”.

1383
The MySQL Keyring

Christian F. A. Gerard

MySQL 8.0.21

• **--keyring-migration-socket=path**

  | Command-Line Format | --keyring-migration-socket={file_name|pipe_name} |
  |---------------------|-----------------------------------------------|
  | Type                | String                                        |

  For Unix socket file or Windows named pipe connections, the socket file or named pipe for connecting to the running server that is currently using one of the key migration keystores. See Section 6.4.4.9, “Migrating Keys Between Keyring Keystores”.

• **--keyring-migration-source=plugin**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-migration-source=plugin_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

  The source keyring plugin for key migration. See Section 6.4.4.9, “Migrating Keys Between Keyring Keystores”.

  The option value is similar to that for **--plugin-load**, except that only one plugin library can be specified. The value is given as name=plugin_library or plugin_library. The name is the name of a plugin to load, and plugin_library is the name of the library file that contains the plugin code. If the plugin library is named without any preceding plugin name, the server loads all plugins in the library. The server looks for plugin library files in the directory named by the plugin_dir system variable.

  **Note**
  --keyring-migration-source and --keyring-migration-destination are mandatory for all keyring migration operations. The source and destination plugins must differ, and the migration server must support both plugins.

• **--keyring-migration-user=user_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-migration-user=user_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

  The user name for connecting to the running server that is currently using one of the key migration keystores. See Section 6.4.4.9, “Migrating Keys Between Keyring Keystores”.

6.4.4.13 Keyring System Variables

MySQL Keyring plugins support the following system variables. Use them to configure keyring plugin operation. These variables are unavailable unless the appropriate keyring plugin is installed (see Section 6.4.4.1, “Keyring Plugin Installation”).

• **keyring_aws_cmk_id**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-aws-cmk-id=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>keyring_aws_cmk_id</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
The customer master key (CMK) ID obtained from the AWS KMS server and used by the `keyring_aws` plugin. This variable is unavailable unless that plugin is installed.

This variable is mandatory. If not specified, `keyring_aws` initialization fails.

- **keyring_aws_conf_file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-aws-conf-file=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>keyring_aws_conf_file</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>platform specific</code></td>
</tr>
</tbody>
</table>

  The location of the configuration file for the `keyring_aws` plugin. This variable is unavailable unless that plugin is installed.

  At plugin startup, `keyring_aws` reads the AWS secret access key ID and key from the configuration file. For the `keyring_aws` plugin to start successfully, the configuration file must exist and contain valid secret access key information, initialized as described in Section 6.4.4.5, "Using the `keyring_aws` Amazon Web Services Keyring Plugin".

  The default file name is `keyring_aws_conf`, located in the default keyring file directory. The location of this default directory is the same as for the `keyring_file_data` system variable. See the description of that variable for details, as well as for considerations to take into account if you create the directory manually.

- **keyring_aws_data_file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-aws-data-file</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>keyring_aws_data_file</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>platform specific</code></td>
</tr>
</tbody>
</table>

  The location of the storage file for the `keyring_aws` plugin. This variable is unavailable unless that plugin is installed.

  At plugin startup, if the value assigned to `keyring_aws_data_file` specifies a file that does not exist, the `keyring_aws` plugin attempts to create it (as well as its parent directory, if necessary). If the file does exist, `keyring_aws` reads any encrypted keys contained in the file into its in-memory cache. `keyring_aws` does not cache unencrypted keys in memory.

  The default file name is `keyring_aws_data`, located in the default keyring file directory. The location of this default directory is the same as for the `keyring_file_data` system variable. See the description of that variable for details, as well as for considerations to take into account if you create the directory manually.
• **keyring_aws_region**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-aws-region=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>keyring_aws_region</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>us-east-1</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ap-northeast-1</td>
</tr>
<tr>
<td></td>
<td>ap-northeast-2</td>
</tr>
<tr>
<td></td>
<td>ap-south-1</td>
</tr>
<tr>
<td></td>
<td>ap-southeast-1</td>
</tr>
<tr>
<td></td>
<td>ap-southeast-2</td>
</tr>
<tr>
<td></td>
<td>eu-central-1</td>
</tr>
<tr>
<td></td>
<td>eu-west-1</td>
</tr>
<tr>
<td></td>
<td>sa-east-1</td>
</tr>
<tr>
<td></td>
<td>us-east-1</td>
</tr>
<tr>
<td></td>
<td>us-west-1</td>
</tr>
<tr>
<td></td>
<td>us-west-2</td>
</tr>
</tbody>
</table>

The AWS region for the **keyring_aws** plugin. This variable is unavailable unless that plugin is installed.

• **keyring_encrypted_file_data**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-encrypted-file-data=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>keyring_encrypted_file_data</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>platform specific</td>
</tr>
</tbody>
</table>

The path name of the data file used for secure data storage by the **keyring_encrypted_file** plugin. This variable is unavailable unless that plugin is installed. The file location should be in a directory considered for use only by keyring plugins. For example, do not locate the file under the data directory.

Keyring operations are transactional: The **keyring_encrypted_file** plugin uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has
The same name as the value of the `keyring_encrypted_file_data` system variable with a suffix of `.backup`.

Do not use the same `keyring_encrypted_file` data file for multiple MySQL instances. Each instance should have its own unique data file.

The default file name is `keyring_encrypted`, located in a directory that is platform specific and depends on the value of the `INSTALL_LAYOUT` CMake option, as shown in the following table. To specify the default directory for the file explicitly if you are building from source, use the `INSTALL_MYSQLKEYRINGDIR` CMake option.

<table>
<thead>
<tr>
<th>INSTALL_LAYOUT Value</th>
<th>Default keyring_encrypted_file_data Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEB, RPM, SVR4</td>
<td><code>/var/lib/mysql-keyring/keyring_encrypted</code></td>
</tr>
<tr>
<td>Otherwise</td>
<td><code>keyring/keyring_encrypted</code> under the CMAKE_INSTALL_PREFIX value</td>
</tr>
</tbody>
</table>

At plugin startup, if the value assigned to `keyring_encrypted_file_data` specifies a file that does not exist, the `keyring_encrypted_file` plugin attempts to create it (as well as its parent directory, if necessary).

If you create the directory manually, it should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use the `/usr/local/mysql/mysql-keyring` directory, the following commands (executed as root) create the directory and set its mode and ownership:

```bash
cd /usr/local/mysql
mkdir mysql-keyring
chmod 750 mysql-keyring
chown mysql mysql-keyring
chgrp mysql mysql-keyring
```

If the `keyring_encrypted_file` plugin cannot create or access its data file, it writes an error message to the error log. If an attempted runtime assignment to `keyring_encrypted_file_data` results in an error, the variable value remains unchanged.

---

Important
---

Once the `keyring_encrypted_file` plugin has created its data file and started to use it, it is important not to remove the file. Loss of the file causes data encrypted using its keys to become inaccessible. (It is permissible to rename or move the file, as long as you change the value of `keyring_encrypted_file_data` to match.)

- `keyring_encrypted_file_password`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-encrypted-file-password=password</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>keyring_encrypted_file_password</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>
The MySQL Keyring

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
</table>

The password used by the `keyring_encrypted_file` plugin. This variable is unavailable unless that plugin is installed.

This variable is mandatory. If not specified, `keyring_encrypted_file` initialization fails.

If this variable is specified in an option file, the file should have a restrictive mode and be accessible only to the account used to run the MySQL server.

**Important**

Once the `keyring_encrypted_file_password` value has been set, changing it does not rotate the keyring password and could make the server inaccessible. If an incorrect password is provided, the `keyring_encrypted_file` plugin cannot load keys from the encrypted keyring file.

The password value cannot be displayed at runtime with `SHOW VARIABLES` or the Performance Schema `global_variables` table because the display value is obfuscated.

- `keyring_file_data`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--keyring-file-data=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>keyring_file_data</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>platform specific</code></td>
</tr>
</tbody>
</table>

The path name of the data file used for secure data storage by the `keyring_file` plugin. This variable is unavailable unless that plugin is installed. The file location should be in a directory considered for use only by keyring plugins. For example, do not locate the file under the data directory.

Keyring operations are transactional: The `keyring_file` plugin uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has the same name as the value of the `keyring_file_data` system variable with a suffix of `.backup`.

Do not use the same `keyring_file` data file for multiple MySQL instances. Each instance should have its own unique data file.

The default file name is `keyring`, located in a directory that is platform specific and depends on the value of the `INSTALL_LAYOUT` CMake option, as shown in the following table. To specify the default directory for the file explicitly if you are building from source, use the `INSTALL_MYSQLKEYRINGDIR` CMake option.

<table>
<thead>
<tr>
<th><code>INSTALL_LAYOUT</code> Value</th>
<th>Default <code>keyring_file_data</code> Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEB, RPM, SVR4</td>
<td><code>/var/lib/mysql-keyring/keyring</code></td>
</tr>
</tbody>
</table>
The MySQL Keyring

<table>
<thead>
<tr>
<th>INSTALL_LAYOUT Value</th>
<th>Default keyring_file_data Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Otherwise</td>
<td>keyring/keyring under the CMAKE_INSTALL_PREFIX value</td>
</tr>
</tbody>
</table>

At plugin startup, if the value assigned to keyring_file_data specifies a file that does not exist, the keyring_file plugin attempts to create it (as well as its parent directory, if necessary).

If you create the directory manually, it should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use the /usr/local/mysql/mysql-keyring directory, the following commands (executed as root) create the directory and set its mode and ownership:

```bash
cd /usr/local/mysql
mkdir mysql-keyring
chmod 750 mysql-keyring
chown mysql mysql-keyring
chgrp mysql mysql-keyring
```

If the keyring_file plugin cannot create or access its data file, it writes an error message to the error log. If an attempted runtime assignment to keyring_file_data results in an error, the variable value remains unchanged.

**Important**

Once the keyring_file plugin has created its data file and started to use it, it is important not to remove the file. For example, InnoDB uses the file to store the master key used to decrypt the data in tables that use InnoDB tablespace encryption; see Section 15.13, “InnoDB Data-at-Rest Encryption”. Loss of the file causes data in such tables to become inaccessible. (It is permissible to rename or move the file, as long as you change the value of keyring_file_data to match.) It is recommended that you create a separate backup of the keyring data file immediately after you create the first encrypted table and before and after master key rotation.

- **keyring_hashicorp_auth_path**
  
  Command-Line Format  
  ```
  --keyring-hashicorp-auth-path=value
  ```

  Introduced  
  8.0.18

  System Variable  
  keyring_hashicorp_auth_path

  Scope  
  Global

  Dynamic  
  Yes

  SET_VAR Hint Applies  
  No

  Type  
  String

  Default Value  
  /v1/auth/approle/login

  The authentication path where AppRole authentication is enabled within the HashiCorp Vault server, for use by the keyring_hashicorp plugin. This variable is unavailable unless that plugin is installed.

- **keyring_hashicorp_ca_path**
  
  Command-Line Format  
  ```
  --keyring-hashicorp-ca-path=file_name
  ```

  Introduced  
  8.0.18

  System Variable  
  keyring_hashicorp_ca_path

  The authentication path where AppRole authentication is enabled within the HashiCorp Vault server, for use by the keyring_hashicorp plugin. This variable is unavailable unless that plugin is installed.
The absolute path name of a local file accessible to the MySQL server that contains a properly formatted TLS certificate authority for use by the `keyring_hashicorp` plugin. This variable is unavailable unless that plugin is installed.

If this variable is not set, the `keyring_hashicorp` plugin opens an HTTPS connection without using server certificate verification, and trusts any certificate delivered by the HashiCorp Vault server. For this to be safe, it must be assumed that the Vault server is not malicious and that no man-in-the-middle attack is possible. If those assumptions are invalid, set `keyring_hashicorp_ca_path` to the path of a trusted CA certificate. (For example, for the instructions in Certificate and Key Preparation, this is the `company.crt` file.)

- **keyring_hashicorp_caching**

  Whether to enable the optional in-memory key cache used by the `keyring_hashicorp` plugin to cache keys from the HashiCorp Vault server. This variable is unavailable unless that plugin is installed. If the cache is enabled, the plugin populates it during initialization. Otherwise, the plugin populates only the key list during initialization.

  Enabling the cache is a compromise: It improves performance, but maintains a copy of sensitive key information in memory, which may be undesirable for security purposes.

- **keyring_hashicorp_commit_auth_path**

  This variable is associated with `keyring_hashicorp_auth_path`, from which it takes its value during `keyring_hashicorp` plugin initialization. This variable is unavailable unless that plugin is installed. It
The MySQL Keyring

reflects the “committed” value actually used for plugin operation if initialization succeeds. For additional
information, see keyring_hashicorp Configuration.

<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The OCID of the tenancy compartment that the **keyring oci** plugin uses as the location of the MySQL keys. This variable is unavailable unless that plugin is installed.

Prior to using **keyring oci**, you must create a MySQL compartment or subcompartment if it does not exist. This compartment should contain no vault keys or vault secrets. It should not be used by systems other than MySQL Keyring.

For information about managing compartments and obtaining the OCID, see [Managing Compartments](#).

This variable is mandatory. If not specified, **keyring oci** initialization fails.

- **keyring oci encryption endpoint**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-oci-encryption-endpoint=value</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>
The MySQL Keyring

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
</table>

The endpoint of the Oracle Cloud Infrastructure encryption server that the `keyring_oci` plugin uses for generating ciphertext for new keys. This variable is unavailable unless that plugin is installed.

The encryption endpoint is vault specific and Oracle Cloud Infrastructure assigns it at vault-creation time. To obtain the endpoint OCID, view the configuration details for your `keyring_oci` vault, using the instructions at Managing Vaults.

This variable is mandatory. If not specified, `keyring_oci` initialization fails.

- **keyring_oci_key_file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-oci-key-file=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.22</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>keyring_oci_key_file</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The path name of the file containing the RSA private key that the `keyring_oci` plugin uses for Oracle Cloud Infrastructure authentication. This variable is unavailable unless that plugin is installed.

You must also upload the corresponding RSA public key using the Console. The Console displays the key fingerprint value, which you can use to set the `keyring_oci_key_fingerprint` system variable.

For information about generating and uploading API keys, see Required Keys and OCIDs.

This variable is mandatory. If not specified, `keyring_oci` initialization fails.

- **keyring_oci_key_fingerprint**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-oci-key-fingerprint=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.22</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>keyring_oci_key_fingerprint</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
The fingerprint of the RSA private key that the `keyring_oci` plugin uses for Oracle Cloud Infrastructure authentication. This variable is unavailable unless that plugin is installed.

To obtain the key fingerprint while creating the API keys, execute this command:

```
openssl rsa -pubout -outform DER -in ~/.oci/oci_api_key.pem | openssl md5 -c
```

Alternatively, obtain the fingerprint from the Console, which automatically displays the fingerprint when you upload the RSA public key.

For information about obtaining key fingerprints, see Required Keys and OCIDs.

This variable is mandatory. If not specified, `keyring_oci` initialization fails.

• `keyring_oci_management_endpoint`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--keyring-oci-management-endpoint=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.22</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>keyring_oci_management_endpoint</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The endpoint of the Oracle Cloud Infrastructure key management server that the `keyring_oci` plugin uses for listing existing keys. This variable is unavailable unless that plugin is installed.

The key management endpoint is vault specific and Oracle Cloud Infrastructure assigns it at vault-creation time. To obtain the endpoint OCID, view the configuration details for your `keyring_oci` vault, using the instructions at Managing Vaults.

This variable is mandatory. If not specified, `keyring_oci` initialization fails.

• `keyring_oci_master_key`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--keyring-oci-master-key=ocid</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.22</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>keyring_oci_master_key</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
The OCID of the Oracle Cloud Infrastructure master encryption key that the `keyring_oci` plugin uses for encryption of secrets. This variable is unavailable unless that plugin is installed.

Prior to using `keyring_oci`, you must create a cryptographic key for the Oracle Cloud Infrastructure compartment if it does not exist. Provide a MySQL-specific name for the generated key, and do not use it for other purposes.

For information about key creation, see Managing Keys.

This variable is mandatory. If not specified, `keyring_oci` initialization fails.

- `keyring_oci_secrets_endpoint`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--keyring-oci-secrets-endpoint=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.22</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>keyring_oci_secrets_endpoint</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The endpoint of the Oracle Cloud Infrastructure secrets server that the `keyring_oci` plugin uses for listing, creating, and retiring secrets. This variable is unavailable unless that plugin is installed.

The secrets endpoint is vault specific and Oracle Cloud Infrastructure assigns it at vault-creation time.

To obtain the endpoint OCID, view the configuration details for your `keyring_oci` vault, using the instructions at Managing Vaults.

This variable is mandatory. If not specified, `keyring_oci` initialization fails.

- `keyring_oci_tenancy`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--keyring-oci-tenancy=ocid</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.22</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>keyring_oci_tenancy</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The OCID of the Oracle Cloud Infrastructure tenancy that the `keyring_oci` plugin uses as the location of the MySQL compartment. This variable is unavailable unless that plugin is installed.

Prior to using `keyring_oci`, you must create a tenancy if it does not exist. To obtain the tenancy OCID from the Console, use the instructions at Required Keys and OCIDs.

This variable is mandatory. If not specified, `keyring_oci` initialization fails.

- `keyring_oci_user`
### The MySQL Keyring

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-oci-user=ocid</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.22</td>
</tr>
<tr>
<td>System Variable</td>
<td>keyring oci_user</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The OCID of the Oracle Cloud Infrastructure user that the `keyring_oci` plugin uses for cloud connections. This variable is unavailable unless that plugin is installed.

Prior to using `keyring_oci`, this user must exist and be granted access to use the configured Oracle Cloud Infrastructure tenancy, compartment, and vault resources.

To obtain the user OCID from the Console, use the instructions at Required Keys and OCIDs.

This variable is mandatory. If not specified, `keyring_oci` initialization fails.

- **keyring_oci_vaults_endpoint**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-oci-vaults-endpoint=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.22</td>
</tr>
<tr>
<td>System Variable</td>
<td>keyring_oci_vaults_endpoint</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The endpoint of the Oracle Cloud Infrastructure vaults server that the `keyring_oci` plugin uses for obtaining the value of secrets. This variable is unavailable unless that plugin is installed.

The vaults endpoint is vault specific and Oracle Cloud Infrastructure assigns it at vault-creation time. To obtain the endpoint OCID, view the configuration details for your `keyring_oci` vault, using the instructions at Managing Vaults.

This variable is mandatory. If not specified, `keyring_oci` initialization fails.

- **keyring_oci_virtual_vault**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-oci-virtual-vault=ocid</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.22</td>
</tr>
<tr>
<td>System Variable</td>
<td>keyring_oci_virtual_vault</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>

This variable is mandatory. If not specified, `keyring_oci` initialization fails.
The MySQL Keyring

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
</table>

The OCID of the Oracle Cloud Infrastructure Vault that the `keyring oci` plugin uses for encryption operations. This variable is unavailable unless that plugin is installed.

Prior to using `keyring oci`, you must create a new vault in the MySQL compartment if it does not exist. (Alternatively, you can reuse an existing vault that is in a parent compartment of the MySQL compartment.) Compartment users can see and use only the keys in their respective compartments.

For information about creating a vault and obtaining the vault OCID, see Managing Vaults.

This variable is mandatory. If not specified, `keyring oci` initialization fails.

- `keyring okv_conf_dir`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--keyring-okv-conf-dir=dir_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>keyring_okv_conf_dir</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td>empty string</td>
</tr>
</tbody>
</table>

The path name of the directory that stores configuration information used by the `keyring okv` plugin. This variable is unavailable unless that plugin is installed. The location should be a directory considered for use only by the `keyring okv` plugin. For example, do not locate the directory under the data directory.

The default `keyring okv_conf_dir` value is empty. For the `keyring okv` plugin to be able to access Oracle Key Vault, the value must be set to a directory that contains Oracle Key Vault configuration and SSL materials. For instructions on setting up this directory, see Section 6.4.4.4, “Using the `keyring okv` KMIP Plugin”.

The directory should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use the `/usr/local/mysql/mysql-keyring-okv` directory, the following commands (executed as root) create the directory and set its mode and ownership:

```
cd /usr/local/mysql
mkdir mysql-keyring-okv
chmod 750 mysql-keyring-okv
chown mysql mysql-keyring-okv
chgrp mysql mysql-keyring-okv
```

If the value assigned to `keyring okv_conf_dir` specifies a directory that does not exist, or that does not contain configuration information that enables a connection to Oracle Key Vault to be established, `keyring okv` writes an error message to the error log. If an attempted runtime assignment to `keyring okv_conf_dir` results in an error, the variable value and keyring operation remain unchanged.

- `keyring_operations`

| System Variable | `keyring_operations` |
Whether keyring operations are enabled. This variable is used during key migration operations. See Section 6.4.4.9, “Migrating Keys Between Keyring Keystores”. The privileges required to modify this variable are ENCRYPTION_KEY_ADMIN in addition to either SYSTEM_VARIABLES_ADMIN or the deprecated SUPER privilege.

6.4.5 MySQL Enterprise Audit

MySQL Enterprise Audit is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see https://www.mysql.com/products/.

MySQL Enterprise Edition includes MySQL Enterprise Audit, implemented using a server plugin named audit_log. MySQL Enterprise Audit uses the open MySQL Audit API to enable standard, policy-based monitoring, logging, and blocking of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines.

When installed, the audit plugin enables MySQL Server to produce a log file containing an audit record of server activity. The log contents include when clients connect and disconnect, and what actions they perform while connected, such as which databases and tables they access.

After you install the audit plugin (see Section 6.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”), it writes an audit log file. By default, the file is named audit.log in the server data directory. To change the name of the file, set the audit_log_file system variable at server startup.

By default, audit log file contents are written in new-style XML format, without compression or encryption. To select the file format, set the audit_log_format system variable at server startup. For details on file format and contents, see Section 6.4.5.4, “Audit Log File Formats”.

For more information about controlling how logging occurs, including audit log file naming and format selection, see Section 6.4.5.5, “Configuring Audit Logging Characteristics”. To perform filtering of audited events, see Section 6.4.5.7, “Audit Log Filtering”. For descriptions of the parameters used to configure the audit log plugin, see Audit Log Options and Variables.

If the audit log plugin is enabled, the Performance Schema (see Chapter 26, MySQL Performance Schema) has instrumentation for it. To identify the relevant instruments, use this query:

```
SELECT NAME FROM performance_schema.setup_instruments
WHERE NAME LIKE '*/alog/*';
```

6.4.5.1 Elements of MySQL Enterprise Audit

MySQL Enterprise Audit is based on the audit log plugin and related elements:

- A server-side plugin named audit_log examines auditable events and determines whether to write them to the audit log.
• User-defined functions enable manipulation of filtering definitions that control logging behavior, the encryption password, and log file reading.

• Tables in the `mysql` system database provide persistent storage of filter and user account data.

• System variables enable audit log configuration and status variables provide runtime operational information.

• An `AUDIT_ADMIN` privilege enable users to administer the audit log.

### 6.4.5.2 Installing or Uninstalling MySQL Enterprise Audit

This section describes how to install or uninstall MySQL Enterprise Audit, which is implemented using the audit log plugin and related elements described in Section 6.4.5.1, “Elements of MySQL Enterprise Audit”. For general information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

#### Important
Read this entire section before following its instructions. Parts of the procedure differ depending on your environment.

#### Note
If installed, the `audit_log` plugin involves some minimal overhead even when disabled. To avoid this overhead, do not install MySQL Enterprise Audit unless you plan to use it.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

To install MySQL Enterprise Audit, look in the `share` directory of your MySQL installation and choose the script that is appropriate for your platform. The available scripts differ in the suffix used to refer to the plugin library file:

- `audit_log_filter_win_install.sql`: Choose this script for Windows systems that use `.dll` as the file name suffix.
- `audit_log_filter_linux_install.sql`: Choose this script for Linux and similar systems that use `.so` as the file name suffix.

Run the script as follows. The example here uses the Linux installation script. Make the appropriate substitution for your system.

```
shell> mysql -u root -p < audit_log_filter_linux_install.sql
Enter password: (enter root password here)
```

#### Note
Some MySQL versions have introduced changes to the structure of the MySQL Enterprise Audit tables. To ensure that your tables are up to date for upgrades from earlier versions of MySQL 8.0, perform the MySQL upgrade procedure, making sure to use the option that forces an update (see Section 2.11, “Upgrading MySQL”). If you prefer to run the update statements only for the MySQL Enterprise Audit tables, see the following discussion.

As of MySQL 8.0.12, for new MySQL installations, the `USER` and `HOST` columns in the `audit_log_user` table used by MySQL Enterprise Audit have definitions that better correspond to the definitions of the `User` and `Host` columns in the
**mysql.user** system table. For upgrades to an installation for which MySQL Enterprise Audit is already installed, it is recommended that you alter the table definitions as follows:

```sql
ALTER TABLE mysql.audit_log_user
  DROP FOREIGN KEY audit_log_user_ibfk_1;
ALTER TABLE mysql.audit_log_filter
  CONVERT TO CHARACTER SET utf8mb4 COLLATE utf8mb4_0900_as_ci;
ALTER TABLE mysql.audit_log_user
  CONVERT TO CHARACTER SET utf8mb4 COLLATE utf8mb4_0900_as_ci;
ALTER TABLE mysql.audit_log_user
  MODIFY COLUMN USER VARCHAR(32);
ALTER TABLE mysql.audit_log_user
  ADD FOREIGN KEY (FILTERNAME) REFERENCES mysql.audit_log_filter(NAME);
```

**Note**

To use MySQL Enterprise Audit in the context of source/replica replication, Group Replication, or InnoDB Cluster, you must prepare the replica nodes prior to running the installation script on the source node. This is necessary because the `INSTALL PLUGIN` statement in the script is not replicated.

1. On each replica node, extract the `INSTALL PLUGIN` statement from the installation script and execute it manually.
2. On the source node, run the installation script as described previously.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```sql
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
    FROM INFORMATION_SCHEMA.PLUGINS
    WHERE PLUGIN_NAME LIKE 'audit%';
```

<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>PLUGIN_STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>audit_log</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>

If the plugin fails to initialize, check the server error log for diagnostic messages.

After MySQL Enterprise Audit is installed, you can use the `--audit-log` option for subsequent server startups to control `audit_log` plugin activation. For example, to prevent the plugin from being removed at runtime, use this option:

```
[mysqld]
audit-log=FORCE_PLUS_PERMANENT
```

If it is desired to prevent the server from running without the audit plugin, use `--audit-log` with a value of `FORCE` or `FORCE_PLUS_PERMANENT` to force server startup to fail if the plugin does not initialize successfully.

**Important**

By default, rule-based audit log filtering logs no auditable events for any users. This differs from legacy audit log behavior, which logs all auditable events for all users (see Section 6.4.5.9, “Legacy Mode Audit Log Filtering”). Should you wish to produce log-everything behavior with rule-based filtering, create a simple filter to enable logging and assign it to the default account:

```sql
SELECT audit_log_filter_set_filter('log_all', '{ "filter": { "log": true } }');
```
The filter assigned to `%` is used for connections from any account that has no explicitly assigned filter (which initially is true for all accounts).

Once installed as just described, MySQL Enterprise Audit remains installed until uninstalled. To remove it, execute the following statements:

```
DROP TABLE IF EXISTS mysql.audit_log_user;
DROP TABLE IF EXISTS mysql.audit_log_filter;
UNINSTALL PLUGIN audit_log;
DROP FUNCTION audit_log_filter_set_filter;
DROP FUNCTION audit_log_filter_remove_filter;
DROP FUNCTION audit_log_filter_set_user;
DROP FUNCTION audit_log_filter_remove_user;
DROP FUNCTION audit_log_filter_flush;
DROP FUNCTION audit_log_encryption_password_get;
DROP FUNCTION audit_log_encryption_password_set;
DROP FUNCTION audit_log_read;
DROP FUNCTION audit_log_read_bookmark;
```

### 6.4.5.3 MySQL Enterprise Audit Security Considerations

By default, contents of audit log files produced by the audit log plugin are not encrypted and may contain sensitive information, such as the text of SQL statements. For security reasons, audit log files should be written to a directory accessible only to the MySQL server and to users with a legitimate reason to view the log. The default file name is `audit.log` in the data directory. This can be changed by setting the `audit_log_file` system variable at server startup. Other audit log files may exist due to log rotation.

For additional security, enable audit log file encryption. See Encrypting Audit Log Files.

### 6.4.5.4 Audit Log File Formats

The MySQL server calls the audit log plugin to write an audit record to its log file whenever an auditable event occurs. Typically the first audit record written after plugin startup contains the server description and startup options. Elements following that one represent events such as client connect and disconnect events, executed SQL statements, and so forth. Only top-level statements are logged, not statements within stored programs such as triggers or stored procedures. Contents of files referenced by statements such as `LOAD DATA` are not logged.

To select the log format that the audit log plugin uses to write its log file, set the `audit_log_format` system variable at server startup. These formats are available:

- **New-style XML format** (`audit_log_format=NEW`): An XML format that has better compatibility with Oracle Audit Vault than old-style XML format. MySQL 8.0 uses new-style XML format by default.
- **Old-style XML format** (`audit_log_format=OLD`): The original audit log format used by default in older MySQL series.
- **JSON format** (`audit_log_format=JSON`)

By default, audit log file contents are written in new-style XML format, without compression or encryption.

**Note**

For information about issues to consider when changing the log format, see Selecting Audit Log File Format.

The following sections describe the available audit logging formats:

- **New-Style XML Audit Log File Format**
New-Style XML Audit Log File Format

Here is a sample log file in new-style XML format (audit_log_format=NEW), reformatted slightly for readability:

```xml
<?xml version="1.0" encoding="utf-8"?>
<AUDIT>
  <AUDIT_RECORD>
    <TIMESTAMP>2019-10-03T14:06:33 UTC</TIMESTAMP>
    <RECORD_ID>1_2019-10-03T14:06:33</RECORD_ID>
    <NAME>Audit</NAME>
    <SERVER_ID>1</SERVER_ID>
    <VERSION>1</VERSION>
    <STARTUP_OPTIONS>/usr/local/mysql/bin/mysqld
      --socket=/usr/local/mysql/mysql.sock
      --port=3306</STARTUP_OPTIONS>
    <OS_VERSION>i686-Linux</OS_VERSION>
    <MYSQL_VERSION>5.7.21-log</MYSQL_VERSION>
  </AUDIT_RECORD>

  <AUDIT_RECORD>
    <TIMESTAMP>2019-10-03T14:09:38 UTC</TIMESTAMP>
    <RECORD_ID>2_2019-10-03T14:06:33</RECORD_ID>
    <NAME>Connect</NAME>
    <CONNECTION_ID>5</CONNECTION_ID>
    <STATUS>0</STATUS>
    <STATUS_CODE>0</STATUS_CODE>
    <USER>root</USER>
    <OS_LOGIN/>
    <HOST>localhost</HOST>
    <IP>127.0.0.1</IP>
    <COMMAND_CLASS>connect</COMMAND_CLASS>
    <CONNECTION_TYPE>SSL/TLS</CONNECTION_TYPE>
    <CONNECTION_ATTRIBUTES>
      <ATTRIBUTE>
        <NAME>_pid</NAME>
        <VALUE>42794</VALUE>
      </ATTRIBUTE>
      ...
      <ATTRIBUTE>
        <NAME>program_name</NAME>
        <VALUE>mysqladmin</VALUE>
      </ATTRIBUTE>
    </CONNECTION_ATTRIBUTES>
    <PRIV_USER>root</PRIV_USER>
    <PROXY_USER/>
    <DB>test</DB>
  </AUDIT_RECORD>

  ...

  <AUDIT_RECORD>
    <TIMESTAMP>2019-10-03T14:09:38 UTC</TIMESTAMP>
    <RECORD_ID>6_2019-10-03T14:06:33</RECORD_ID>
    <NAME>Query</NAME>
    <CONNECTION_ID>5</CONNECTION_ID>
    <STATUS>0</STATUS>
    <STATUS_CODE>0</STATUS_CODE>
    <USER>root[root] @ localhost [127.0.0.1]</USER>
    <OS_LOGIN/>
    <HOST>localhost</HOST>
    <IP>127.0.0.1</IP>
    <COMMAND_CLASS>drop_table</COMMAND_CLASS>
  </AUDIT_RECORD>
</AUDIT>
```
The audit log file is written as XML, using UTF-8 (up to 4 bytes per character). The root element is `<AUDIT>`. The root element contains `<AUDIT_RECORD>` elements, each of which provides information about an audited event. When the audit log plugin begins writing a new log file, it writes the XML declaration and opening `<AUDIT>` root element tag. When the plugin closes a log file, it writes the closing `</AUDIT>` root element tag. The closing tag is not present while the file is open.

Elements within `<AUDIT_RECORD>` elements have these characteristics:

- Some elements appear in every `<AUDIT_RECORD>` element. Others are optional and may appear depending on the audit record type.
- Order of elements within an `<AUDIT_RECORD>` element is not guaranteed.
- Element values are not fixed length. Long values may be truncated as indicated in the element descriptions given later.
- The `<`, `>`, `"`, and `&` characters are encoded as `&lt;`, `&gt;`, `&quot;`, and `&amp;`, respectively. NUL bytes (U+00) are encoded as the `?` character.
• Characters not valid as XML characters are encoded using numeric character references. Valid XML characters are:

| #x9 | #xA | #xD | [#x20-#xD7FF] | [#xE000-#xFFFD] | [#x10000-#x10FFFF] |

The following elements are mandatory in every `<AUDIT_RECORD>` element:

• `<NAME>`

A string representing the type of instruction that generated the audit event, such as a command that the server received from a client.

Example:

```xml
<NAME>Query</NAME>
```

Some common `<NAME>` values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Audit</td>
<td>When auditing starts, which may be server startup time</td>
</tr>
<tr>
<td>Connect</td>
<td>When a client connects, also known as logging in</td>
</tr>
<tr>
<td>Query</td>
<td>An SQL statement (executed directly)</td>
</tr>
<tr>
<td>Prepare</td>
<td>Preparation of an SQL statement; usually followed by Execute</td>
</tr>
<tr>
<td>Execute</td>
<td>Execution of an SQL statement; usually follows Prepare</td>
</tr>
<tr>
<td>Shutdown</td>
<td>Server shutdown</td>
</tr>
<tr>
<td>Quit</td>
<td>When a client disconnects</td>
</tr>
<tr>
<td>NoAudit</td>
<td>Auditing has been turned off</td>
</tr>
</tbody>
</table>

The possible values are `Audit, Binlog Dump, Change user, Close stmt, Connect Out, Connect, Create DB, Daemon, Debug, Delayed insert, Drop DB, Execute, Fetch, Field List, Init DB, Kill, Long Data, NoAudit, Ping, Prepare, Processlist, Query, Quit, Refresh, Register Slave, Reset stmt, Set option, Shutdown, Sleep, Statistics, Table Dump, TableDelete, TableInsert, TableRead, TableUpdate, Time`.

Many of these values correspond to the `COM_` command values listed in the `my_command.h` header file. For example, `Create DB` and `Change user` correspond to `COM_CREATE_DB` and `COM_CHANGE_USER`, respectively.

Events having `<NAME>` values of `TableXXX` accompany `Query` events. For example, the following statement generates one `Query` event, two `TableRead` events, and a `TableInsert` event:

```sql
INSERT INTO t3 SELECT t1.* FROM t1 JOIN t2;
```

Each `TableXXX` event contains `<DB>` and `<TABLE>` elements to identify the table to which the event refers.

• `<RECORD_ID>`

A unique identifier for the audit record. The value is composed from a sequence number and timestamp, in the format `SEQ_TIMESTAMP`. When the audit log plugin opens the audit log file, it initializes the sequence number to the size of the audit log file, then increments the sequence by 1 for each record logged. The timestamp is a UTC value in `YYYY-MM-DDThh:mm:ss` format indicating the date and time when the audit log plugin opened the file.

Example:

```xml
<RECORD_ID>12_2019-10-03T14:06:33</RECORD_ID>
```

• `<TIMESTAMP>`
A string representing a UTC value in `YYYY-MM-DDThh:mm:ss UTC` format indicating the date and time when the audit event was generated. For example, the event corresponding to execution of an SQL statement received from a client has a `<TIMESTAMP>` value occurring after the statement finishes, not when it was received.

Example:

```
<TIMESTAMP>2019-10-03T14:09:45 UTC</TIMESTAMP>
```

The following elements are optional in `<AUDIT_RECORD>` elements. Many of them occur only with specific `<NAME>` element values.

- `<COMMAND_CLASS>`

  A string that indicates the type of action performed.

  Example:

  ```
  <COMMAND_CLASS>drop_table</COMMAND_CLASS>
  ```

  The values correspond to the `statement/sql/xxx` command counters. For example, `xxx` is `drop_table` and `select` for `DROP_TABLE` and `SELECT` statements, respectively. The following statement displays the possible names:

  ```
  SELECT REPLACE(EVENT_NAME, 'statement/sql/', '') AS name 
  FROM performance_schema.events_statements_summary_global_by_event_name 
  WHERE EVENT_NAME LIKE 'statement/sql/%' 
  ORDER BY name;
  ```

- `<CONNECTION_ATTRIBUTES>`

  As of MySQL 8.0.19, events with a `<COMMAND_CLASS>` value of `connect` may include a `<CONNECTION_ATTRIBUTES>` element to display the connection attributes passed by the client at connect time. (For information about these attributes, which are also exposed in Performance Schema tables, see Section 26.12.9, “Performance Schema Connection Attribute Tables”.)

  The `<CONNECTION_ATTRIBUTES>` element contains one `<ATTRIBUTE>` element per attribute, each of which contains `<NAME>` and `<VALUE>` elements to indicate the attribute name and value, respectively.

  Example:

  ```
  <CONNECTION_ATTRIBUTES> 
  <ATTRIBUTE> 
  <NAME>_pid</NAME> 
  <VALUE>42794</VALUE> 
  </ATTRIBUTE> 
  <ATTRIBUTE> 
  <NAME>_os</NAME> 
  <VALUE>osx10.14</VALUE> 
  </ATTRIBUTE> 
  <ATTRIBUTE> 
  <NAME>_platform</NAME> 
  <VALUE>x86_64</VALUE> 
  </ATTRIBUTE> 
  <ATTRIBUTE> 
  <NAME>_client_version</NAME> 
  <VALUE>8.0.19</VALUE> 
  </ATTRIBUTE> 
  <ATTRIBUTE> 
  <NAME>_client_name</NAME> 
  <VALUE>libmysql</VALUE> 
  </ATTRIBUTE> 
  ```
If no connection attributes are present in the event, none are logged and no `<CONNECTION_ATTRIBUTES>` element appears. This can occur if the connection attempt is unsuccessful, the client passes no attributes, or the connection occurs internally such as during server startup or when initiated by a plugin.

- `<CONNECTION_ID>`

An unsigned integer representing the client connection identifier. This is the same as the value returned by the `CONNECTION_ID()` function within the session.

Example:

```
<CONNECTION_ID>127</CONNECTION_ID>
```

- `<CONNECTION_TYPE>`

The security state of the connection to the server. Permitted values are `TCP/IP` (TCP/IP connection established without encryption), `SSL/TLS` (TCP/IP connection established with encryption), `Socket` (Unix socket file connection), `Named Pipe` (Windows named pipe connection), and `Shared Memory` (Windows shared memory connection).

Example:

```
<CONNECTION_TYPE>SSL/TLS</CONNECTION_TYPE>
```

- `<DB>`

A string representing the default database name.

Example:

```
<DB>test</DB>
```

- `<HOST>`

A string representing the client host name.

Example:

```
<HOST>localhost</HOST>
```

- `<IP>`

A string representing the client IP address.

Example:

```
<IP>127.0.0.1</IP>
```

- `<MYSQL_VERSION>`

A string representing the MySQL server version. This is the same as the value of the `VERSION()` function or `version` system variable.
Example:

```xml
<MYSQL_VERSION>5.7.21-log</MYSQL_VERSION>
```

• `<OS_LOGIN>`

A string representing the external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this element is empty. The value is the same as that of the `external_user` system variable (see Section 6.2.18, “Proxy Users”).

Example:

```xml
<OS_LOGIN>jeffrey</OS_LOGIN>
```

• `<OS_VERSION>`

A string representing the operating system on which the server was built or is running.

Example:

```xml
<OS_VERSION>x86_64-Linux</OS_VERSION>
```

• `<PRIV_USER>`

A string representing the user that the server authenticated the client as. This is the user name that the server uses for privilege checking, and may differ from the `<USER>` value.

Example:

```xml
<PRIV_USER>jeffrey</PRIV_USER>
```

• `<PROXY_USER>`

A string representing the proxy user (see Section 6.2.18, “Proxy Users”). The value is empty if user proxying is not in effect.

Example:

```xml
<PROXY_USER>developer</PROXY_USER>
```

• `<SERVER_ID>`

An unsigned integer representing the server ID. This is the same as the value of the `server_id` system variable.

Example:

```xml
<SERVER_ID>1</SERVER_ID>
```

• `<SQLTEXT>`

A string representing the text of an SQL statement. The value can be empty. Long values may be truncated. The string, like the audit log file itself, is written using UTF-8 (up to 4 bytes per character), so
the value may be the result of conversion. For example, the original statement might have been received from the client as an SJIS string.

Example:
<pre>&lt;SQLTEXT&gt;DELETE FROM t1&lt;/SQLTEXT&gt;</pre>

• <STARTUP_OPTIONS>

A string representing the options that were given on the command line or in option files when the MySQL server was started. The first option is the path to the server executable.

Example:
<pre>&lt;STARTUP_OPTIONS&gt;/usr/local/mysql/bin/mysqld --port=3306 --log_output=FILE&lt;/STARTUP_OPTIONS&gt;</pre>

• <STATUS>

An unsigned integer representing the command status: 0 for success, nonzero if an error occurred. This is the same as the value of the <code>mysql_errno()</code> C API function. See the description for <STATUS_CODE> for information about how it differs from <STATUS>.

The audit log does not contain the SQLSTATE value or error message. To see the associations between error codes, SQLSTATE values, and messages, see Server Error Message Reference.

Warnings are not logged.

Example:
<pre>&lt;STATUS&gt;1051&lt;/STATUS&gt;</pre>

• <STATUS_CODE>

An unsigned integer representing the command status: 0 for success, 1 if an error occurred.

The <code>STATUS_CODE</code> value differs from the <code>STATUS</code> value: <code>STATUS_CODE</code> is 0 for success and 1 for error, which is compatible with the EZ_collector consumer for Audit Vault. <code>STATUS</code> is the value of the <code>mysql_errno()</code> C API function. This is 0 for success and nonzero for error, and thus is not necessarily 1 for error.

Example:
<pre>&lt;STATUS_CODE&gt;0&lt;/STATUS_CODE&gt;</pre>

• <TABLE>

A string representing a table name.

Example:
<pre>&lt;TABLE&gt;t3&lt;/TABLE&gt;</pre>

• <USER>

A string representing the user name sent by the client. This may differ from the <PRIV_USER> value.

Example:
<pre>&lt;USER&gt;root[root] @ localhost [127.0.0.1]&lt;/USER&gt;</pre>
• <VERSION>

An unsigned integer representing the version of the audit log file format.

Example:

<VERSION>1</VERSION>

Old-Style XML Audit Log File Format

Here is a sample log file in old-style XML format (audit_log_format=OLD), reformatted slightly for readability:

```xml
<?xml version="1.0" encoding="utf-8"?>
<AUDIT>
  <AUDIT_RECORD
    TIMESTAMP="2019-10-03T14:25:00 UTC"
    RECORD_ID="1_2019-10-03T14:25:00"
    NAME="Audit"
    SERVER_ID="1"
    VERSION="1"
    STARTUP_OPTIONS="--port=3306"
    OS_VERSION="i686-Linux"
    MYSQL_VERSION="5.7.21-log"/>
  <AUDIT_RECORD
    TIMESTAMP="2019-10-03T14:25:24 UTC"
    RECORD_ID="2_2019-10-03T14:25:00"
    NAME="Connect"
    CONNECTION_ID="4"
    STATUS="0"
    STATUS_CODE="0"
    USER="root"
    OS_LOGIN=""
    HOST="localhost"
    IP="127.0.0.1"
    COMMAND_CLASS="connect"
    CONNECTION_TYPE="SSL/TLS"
    PRIV_USER="connect"
    PROXY_USER=""
    DB="test"/>
  ...
  <AUDIT_RECORD
    TIMESTAMP="2019-10-03T14:25:24 UTC"
    RECORD_ID="6_2019-10-03T14:25:00"
    NAME="Query"
    CONNECTION_ID="4"
    STATUS="0"
    STATUS_CODE="0"
    USER="root[root] @ localhost [127.0.0.1]"
    OS_LOGIN=""
    HOST="localhost"
    IP="127.0.0.1"
    COMMAND_CLASS="drop_table"
    SQLTEXT="DROP TABLE IF EXISTS t"/>
  ...
  <AUDIT_RECORD
    TIMESTAMP="2019-10-03T14:25:24 UTC"
    RECORD_ID="8_2019-10-03T14:25:00"
    NAME="Quit"
    CONNECTION_ID="4"
    STATUS="0"
    STATUS_CODE="0"
```
The audit log file is written as XML, using UTF-8 (up to 4 bytes per character). The root element is `<AUDIT>`. The root element contains `<AUDIT_RECORD>` elements, each of which provides information about an audited event. When the audit log plugin begins writing a new log file, it writes the XML declaration and opening `<AUDIT>` root element tag. When the plugin closes a log file, it writes the closing `</AUDIT>` root element tag. The closing tag is not present while the file is open.

Attributes of `<AUDIT_RECORD>` elements have these characteristics:

- Some attributes appear in every `<AUDIT_RECORD>` element. Others are optional and may appear depending on the audit record type.
- Order of attributes within an `<AUDIT_RECORD>` element is not guaranteed.
- Attribute values are not fixed length. Long values may be truncated as indicated in the attribute descriptions given later.
- The `<`, `>`, `,`, and `&` characters are encoded as `&lt;`, `&gt;`, `&quot;`, and `&amp;`, respectively. NUL bytes (U+00) are encoded as the `?` character.
- Characters not valid as XML characters are encoded using numeric character references. Valid XML characters are:

```
#x9 | #xA | #xD | [#x20-#xD7FF] | [#xE000-#xFFFD] | [#x10000-#x10FFFF]
```

The following attributes are mandatory in every `<AUDIT_RECORD>` element:

- **NAME**

  A string representing the type of instruction that generated the audit event, such as a command that the server received from a client.

  **Example**: `NAME="Query"`

  Some common `NAME` values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Audit</td>
<td>When auditing starts, which may be server startup time</td>
</tr>
<tr>
<td>Connect</td>
<td>When a client connects, also known as logging in</td>
</tr>
<tr>
<td>Query</td>
<td>An SQL statement (executed directly)</td>
</tr>
<tr>
<td>Prepare</td>
<td>Preparation of an SQL statement; usually followed by Execute</td>
</tr>
<tr>
<td>Execute</td>
<td>Execution of an SQL statement; usually follows Prepare</td>
</tr>
<tr>
<td>Shutdown</td>
<td>Server shutdown</td>
</tr>
<tr>
<td>Quit</td>
<td>When a client disconnects</td>
</tr>
<tr>
<td>NoAudit</td>
<td>Auditing has been turned off</td>
</tr>
</tbody>
</table>

The possible values are Audit, Binlog Dump, Change user, Close stmt, Connect Out, Connect, Create DB, Daemon, Debug, Delayed insert, Drop DB, Execute, Fetch, Field List, Init DB, Kill, Long Data, NoAudit, Ping, Prepare, Processlist, Query, Quit, Refresh, Register Slave, Reset stmt, Set option, Shutdown, Sleep, Statistics, Table Dump, TableDelete, TableInsert, TableRead, TableUpdate, Time.
Many of these values correspond to the COM_xxx command values listed in the my_command.h header file. For example, "Create DB" and "Change user" correspond to COM_CREATE_DB and COM_CHANGE_USER, respectively.

Events having NAME values of TableXXX accompany Query events. For example, the following statement generates one Query event, two TableRead events, and a TableInsert events:

```
INSERT INTO t3 SELECT t1.* FROM t1 JOIN t2;
```

Each TableXXX event has DB and TABLE attributes to identify the table to which the event refers. Connect events for old-style XML audit log format do not include connection attributes.

- RECORD_ID

A unique identifier for the audit record. The value is composed from a sequence number and timestamp, in the format SEQ_TIMESTAMP. When the audit log plugin opens the audit log file, it initializes the sequence number to the size of the audit log file, then increments the sequence by 1 for each record logged. The timestamp is a UTC value in YYYY-MM-DDThh:mm:ss format indicating the date and time when the audit log plugin opened the file.

Example: RECORD_ID="12_2019-10-03T14:25:00"

- TIMESTAMP

A string representing a UTC value in YYYY-MM-DDThh:mm:ss UTC format indicating the date and time when the audit event was generated. For example, the event corresponding to execution of an SQL statement received from a client has a TIMESTAMP value occurring after the statement finishes, not when it was received.

Example: TIMESTAMP="2019-10-03T14:25:32 UTC"

The following attributes are optional in <AUDIT_RECORD> elements. Many of them occur only for elements with specific values of the NAME attribute.

- COMMAND_CLASS

A string that indicates the type of action performed.

Example: COMMAND_CLASS="drop_table"

The values correspond to the statement/sql/xxx command counters. For example, xxx is drop_table and select for DROP TABLE and SELECT statements, respectively. The following statement displays the possible names:

```
SELECT REPLACE(EVENT_NAME, 'statement/sql/', '') AS name
FROM performance_schema.events_statements_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'statement/sql/%'
ORDER BY name;
```

- CONNECTION_ID

An unsigned integer representing the client connection identifier. This is the same as the value returned by the CONNECTION_ID() function within the session.

Example: CONNECTION_ID="127"

- CONNECTION_TYPE
The security state of the connection to the server. Permitted values are TCP/IP (TCP/IP connection established without encryption), SSL/TLS (TCP/IP connection established with encryption), Socket (Unix socket file connection), Named Pipe (Windows named pipe connection), and Shared Memory (Windows shared memory connection).

Example: CONNECTION_TYPE="SSL/TLS"

• **DB**
  A string representing the default database name.
  Example: DB="test"

• **HOST**
  A string representing the client host name.
  Example: HOST="localhost"

• **IP**
  A string representing the client IP address.
  Example: IP="127.0.0.1"

• **MYSQL_VERSION**
  A string representing the MySQL server version. This is the same as the value of the VERSION() function or version system variable.
  Example: MYSQL_VERSION="5.7.21-log"

• **OS_LOGIN**
  A string representing the external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this attribute is empty. The value is the same as that of the external_user system variable (see Section 6.2.18, "Proxy Users").
  Example: OS_LOGIN="jeffrey"

• **OS_VERSION**
  A string representing the operating system on which the server was built or is running.
  Example: OS_VERSION="x86_64-Linux"

• **PRIV_USER**
  A string representing the user that the server authenticated the client as. This is the user name that the server uses for privilege checking, and it may differ from the USER value.
  Example: PRIV_USER="jeffrey"

• **PROXY_USER**
  A string representing the proxy user (see Section 6.2.18, "Proxy Users"). The value is empty if user proxying is not in effect.
Example: `PROXY_USER="developer"`

- **SERVER_ID**

  An unsigned integer representing the server ID. This is the same as the value of the `server_id` system variable.

  Example: `SERVER_ID=1`

- **SQLTEXT**

  A string representing the text of an SQL statement. The value can be empty. Long values may be truncated. The string, like the audit log file itself, is written using UTF-8 (up to 4 bytes per character), so the value may be the result of conversion. For example, the original statement might have been received from the client as an SJIS string.

  Example: `SQLTEXT="DELETE FROM t1"`

- **STARTUP_OPTIONS**

  A string representing the options that were given on the command line or in option files when the MySQL server was started.

  Example: `STARTUP_OPTIONS="--port=3306 --log_output=FILE"`

- **STATUS**

  An unsigned integer representing the command status: 0 for success, nonzero if an error occurred. This is the same as the value of the `mysql_errno()` C API function. See the description for `STATUS_CODE` for information about how it differs from `STATUS`.

  The audit log does not contain the SQLSTATE value or error message. To see the associations between error codes, SQLSTATE values, and messages, see Server Error Message Reference.

  Warnings are not logged.

  Example: `STATUS="1051"`

- **STATUS_CODE**

  An unsigned integer representing the command status: 0 for success, 1 if an error occurred.

  The `STATUS_CODE` value differs from the `STATUS` value: `STATUS_CODE` is 0 for success and 1 for error, which is compatible with the EZ_collector consumer for Audit Vault. `STATUS` is the value of the `mysql_errno()` C API function. This is 0 for success and nonzero for error, and thus is not necessarily 1 for error.

  Example: `STATUS_CODE="0"`

- **TABLE**

  A string representing a table name.

  Example: `TABLE="t3"`

- **USER**

  A string representing the user name sent by the client. This may differ from the `PRIV_USER` value.
MySQL Enterprise Audit

- **VERSION**
  
  An unsigned integer representing the version of the audit log file format.
  
  Example: `VERSION="1"`

**JSON Audit Log File Format**

For JSON-format audit logging (audit_log_format=JSON), the log file contents form a JSON array with each array element representing an audited event as a JSON hash of key-value pairs. Examples of complete event records appear later in this section. The following is an excerpt of partial events:

```json
[
  {
    "timestamp": "2019-10-03 13:50:01",
    "id": 0,
    "class": "audit",
    "event": "startup",
    ...
  },
  {
    "timestamp": "2019-10-03 15:02:32",
    "id": 0,
    "class": "connection",
    "event": "connect",
    ...
  },
  ...
  {
    "timestamp": "2019-10-03 17:37:26",
    "id": 0,
    "class": "table_access",
    "event": "insert",
    ...
  }
]
```

The audit log file is written using UTF-8 (up to 4 bytes per character). When the audit log plugin begins writing a new log file, it writes the opening `]` array marker. When the plugin closes a log file, it writes the closing `]` array marker. The closing marker is not present while the file is open.

Items within audit records have these characteristics:

- Some items appear in every audit record. Others are optional and may appear depending on the audit record type.
- Order of items within an audit record is not guaranteed.
- Item values are not fixed length. Long values may be truncated as indicated in the item descriptions given later.
- The " and \ characters are encoded as ", and \, respectively.

The following examples show the JSON object formats for different event types (as indicated by the class and event items), reformatted slightly for readability:

Auditing startup event:

```json
{
  "timestamp": "2019-10-03 14:21:56",
  "id": 0,
  "class": "audit",
  "event": "startup",
  "connection_id": 0,
  ...
}
```
When the audit log plugin starts as a result of server startup (as opposed to being enabled at runtime), `connection_id` is set to 0, and `account` and `login` are not present.

**Auditing shutdown event:**

```json
{
  "timestamp": "2019-10-03 14:28:20",
  "id": 3,
  "class": "audit",
  "event": "shutdown",
  "connection_id": 0,
  "shutdown_data": { "server_id": 1 }
}
```

When the audit log plugin is uninstalled as a result of server shutdown (as opposed to being disabled at runtime), `connection_id` is set to 0, and `account` and `login` are not present.

**Connect or change-user event:**

```json
{
  "timestamp": "2019-10-03 14:23:18",
  "id": 1,
  "class": "connection",
  "event": "connect",
  "connection_id": 5,
  "account": { "user": "root", "host": "localhost" },
  "login": { "user": "root", "os": "", "ip": "::1", "proxy": "" },
  "connection_data": { "connection_type": "ssl",
    "status": 0,
    "db": "test",
    "connection_attributes": { "_pid": "43236",
      ...
    "program_name": "mysqladmin"
  }
}
```

**Disconnect event:**

```json
{
  "timestamp": "2019-10-03 14:24:45",
  "id": 3,
  "class": "connection",
  "event": "disconnect",
  "connection_id": 5,
  "account": { "user": "root", "host": "localhost" },
  "login": { "user": "root", "os": "", "ip": "::1", "proxy": "" },
  "connection_data": { "connection_type": "ssl" }
}
```

**Query event:**

```json
{
  "timestamp": "2019-10-03 14:23:35",
  "id": 2,
  "class": "general",
  "event": "status",
  "connection_id": 5,
  "account": { "user": "root", "host": "localhost" },
  "login": { "user": "root", "os": "", "ip": "::1", "proxy": "" },
  "general_data": { "command": "Query",
    "sql_command": "show_variables",
    "query": "SHOW VARIABLES",
    "_pid": "43236",
    ...
    "program_name": "mysqladmin"
  }
}
```
Table access event (read, delete, insert, update):

```json
{ "timestamp": "2019-10-03 14:23:41",
  "id": 0,
  "class": "table_access",
  "event": "insert",
  "connection_id": 5,
  "account": { "user": "root", "host": "localhost" },
  "login": { "user": "root", "os": "", "ip": "127.0.0.1", "proxy": "" },
  "table_access_data": { "db": "test",
    "table": "t1",
    "query": "INSERT INTO t1 (i) VALUES(1),(2),(3)"
  }
}
```

The items in the following list appear at the top level of JSON-format audit records: Each item value is either a scalar or a JSON hash. For items that have a hash value, the description lists only the item names within that hash. For more complete descriptions of second-level hash items, see later in this section.

- **account**

  The MySQL account associated with the event. The value is a hash containing these items equivalent to the value of the `CURRENT_USER()` function within the section: `user`, `host`.

  Example:

  ```json
  "account": { "user": "root", "host": "localhost" }
  ```

- **class**

  A string representing the event class. The class defines the type of event, when taken together with the `event` item that specifies the event subclass.

  Example:

  ```json
  "class": "connection"
  ```

  The following table shows the permitted combinations of `class` and `event` values.

  **Table 6.28 Audit Log Class and Event Combinations**

<table>
<thead>
<tr>
<th>Class Value</th>
<th>Permitted Event Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>audit</td>
<td>startup, shutdown</td>
</tr>
<tr>
<td>connection</td>
<td>connect, change_user, disconnect</td>
</tr>
<tr>
<td>general</td>
<td>status</td>
</tr>
<tr>
<td>table_access_data</td>
<td>read, delete, insert, update</td>
</tr>
</tbody>
</table>

- **connection_data**

  Information about a client connection. The value is a hash containing these items: `connection_type`, `status`, `db`, and possibly `connection_attributes`. This item occurs only for audit records with a `class` value of `connection`.

  Example:

  ```json
  "connection_data": { "connection_type": "ssl",
    "status": 0,
    "db": "test" }
  ```
As of MySQL 8.0.19, events with a class value of connection and event value of connect may include a connection_attributes item to display the connection attributes passed by the client at connect time. (For information about these attributes, which are also exposed in Performance Schema tables, see Section 26.12.9, "Performance Schema Connection Attribute Tables").

The connection_attributes value is a hash that represents each attribute by its name and value.

Example:

```
"connection_attributes": {
  "_pid": "43236",
  "_os": "osx10.14",
  "_platform": "x86_64",
  "_client_version": "8.0.19",
  "_client_name": "libmysql",
  "program_name": "mysqladmin"
}
```

If no connection attributes are present in the event, none are logged and no connection_attributes item appears. This can occur if the connection attempt is unsuccessful, the client passes no attributes, or the connection occurs internally such as during server startup or when initiated by a plugin.

- **connection_id**

  An unsigned integer representing the client connection identifier. This is the same as the value returned by the CONNECTION_ID() function within the session.

  Example:

  ```
  "connection_id": 5
  ```

- **event**

  A string representing the subclass of the event class. The subclass defines the type of event, when taken together with the class item that specifies the event class. For more information, see the class item description.

  Example:

  ```
  "event": "connect"
  ```

- **general_data**

  Information about an executed statement or command. The value is a hash containing these items: command, sql_command, query, status. This item occurs only for audit records with a class value of general.

  Example:

  ```
  "general_data": { "command": "Query",
                   "sql_command": "show_variables",
                   "query": "SHOW VARIABLES",
                   "status": 0 }
  ```
• **id**

An unsigned integer representing an event ID.

Example:

```
"id": 2
```

For audit records that have the same `timestamp` value, their `id` values distinguish them and form a sequence. Within the audit log, `timestamp/id` pairs are unique. These pairs are bookmarks that identify event locations within the log.

• **login**

Information indicating how a client connected to the server. The value is a hash containing these items: `user`, `os`, `ip`, `proxy`.

Example:

```
"login": { "user": "root", "os": ", "ip": ":1", "proxy": "" }
```

• **shutdown_data**

Information pertaining to audit log plugin termination. The value is a hash containing these items: `server_id` This item occurs only for audit records with `class` and `event` values of `audit` and `shutdown`, respectively.

Example:

```
"shutdown_data": { "server_id": 1 }
```

• **startup_data**

Information pertaining to audit log plugin initialization. The value is a hash containing these items: `server_id, os_version, mysql_version, args`. This item occurs only for audit records with `class` and `event` values of `audit` and `startup`, respectively.

Example:

```
"startup_data": { "server_id": 1,  
                "os_version": "i686-Linux",  
                "mysql_version": "5.7.21-log",  
                "args": ["/usr/local/mysql/bin/mysqld",  
                          "--loose-audit-log-format=JSON",  
                          "--log-error=logs.err",  
                          "--pid-file=mysqld.pid",  
                          "--port=3306" ] }
```

• **table_access_data**

Information about an access to a table. The value is a hash containing these items: `db, table, query, sql_command`, This item occurs only for audit records with a `class` value of `table_access`.

Example:

```
"table_access_data": { "db": "test",  
                      "table": "t1",  
                      "query": "INSERT INTO t1 (i) VALUES(1),(2),(3)" ,  
                      "sql_command": "insert" }
```

• **timestamp**
A string representing a UTC value in `YYYY-MM-DD hh:mm:ss` format indicating the date and time when the audit event was generated. For example, the event corresponding to execution of an SQL statement received from a client has a `timestamp` value occurring after the statement finishes, not when it was received.

Example:

```
"timestamp": "2019-10-03 13:50:01"
```

For audit records that have the same `timestamp` value, their `id` values distinguish them and form a sequence. Within the audit log, `timestamp/id` pairs are unique. These pairs are bookmarks that identify event locations within the log.

These items appear within hash values associated with top-level items of JSON-format audit records:

- **args**

  An array of options that were given on the command line or in option files when the MySQL server was started. The first option is the path to the server executable.

  Example:

  ```
  "args": ["/usr/local/mysql/bin/mysqld",
  "--loose-audit-log-format=JSON",
  "--log-error=log.err",
  "--pid-file=mysqld.pid",
  "--port=3306" ]
  ```

- **command**

  A string representing the type of instruction that generated the audit event, such as a command that the server received from a client.

  Example:

  ```
  "command": "Query"
  ```

- **connection_type**

  The security state of the connection to the server. Permitted values are `tcp/ip` (TCP/IP connection established without encryption), `ssl` (TCP/IP connection established with encryption), `socket` (Unix socket file connection), `named_pipe` (Windows named pipe connection), and `shared_memory` (Windows shared memory connection).

  Example:

  ```
  "connection_type": "tcp/tcp"
  ```

- **db**

  A string representing a database name. For `connection_data`, it is the default database. For `table_access_data`, it is the table database.

  Example:

  ```
  "db": "test"
  ```

- **host**
A string representing the client host name.

Example:

```
"host": "localhost"
```

- **ip**

A string representing the client IP address.

Example:

```
"ip": "::1"
```

- **mysql_version**

A string representing the MySQL server version. This is the same as the value of the `VERSION()` function or `version` system variable.

Example:

```
"mysql_version": "5.7.21-log"
```

- **os**

A string representing the external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this attribute is empty. The value is the same as that of the `external_user` system variable. See Section 6.2.18, “Proxy Users”.

Example:

```
"os": "jeffrey"
```

- **os_version**

A string representing the operating system on which the server was built or is running.

Example:

```
"os_version": "i686-Linux"
```

- **proxy**

A string representing the proxy user (see Section 6.2.18, “Proxy Users”). The value is empty if user proxying is not in effect.

Example:

```
"proxy": "developer"
```

- **query**

A string representing the text of an SQL statement. The value can be empty. Long values may be truncated. The string, like the audit log file itself, is written using UTF-8 (up to 4 bytes per character), so the value may be the result of conversion. For example, the original statement might have been received from the client as an SJIS string.

Example:
"query": "DELETE FROM t1"

• **server_id**

An unsigned integer representing the server ID. This is the same as the value of the `server_id` system variable.

Example:

"server_id": 1

• **sql_command**

A string that indicates the SQL statement type.

Example:

"sql_command": "insert"

The values correspond to the `statement/sql/xxx` command counters. For example, `xxx` is `drop_table` and `select` for DROP TABLE and SELECT statements, respectively. The following statement displays the possible names:

```
SELECT REPLACE(EVENT_NAME, 'statement/sql/', '') AS name
FROM performance_schema.events_statements_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'statement/sql/%'
ORDER BY name;
```

• **status**

An unsigned integer representing the command status: 0 for success, nonzero if an error occurred. This is the same as the value of the `mysql_errno()` C API function.

The audit log does not contain the SQLSTATE value or error message. To see the associations between error codes, SQLSTATE values, and messages, see [Server Error Message Reference](#).

Warnings are not logged.

Example:

"status": 1051

• **table**

A string representing a table name.

Example:

"table": "t1"

• **user**

A string representing a user name. The meaning differs depending on the item within which `user` occurs:

- Within `account` items, `user` is a string representing the user that the server authenticated the client as. This is the user name that the server uses for privilege checking.

- Within `login` items, `user` is a string representing the user name sent by the client.
6.4.5.5 Configuring Audit Logging Characteristics

This section describes how to configure audit logging characteristics, such as the file to which the audit log plugin writes events, the format of written events, and whether to enable log file compression and encryption.

- Naming Conventions for Audit Log Files
- Selecting Audit Log File Format
- Compressing Audit Log Files
- Encrypting Audit Log Files
- Manually Uncompressing and Decrypting Audit Log Files
- Audit Log File Encryption Prior to MySQL 8.0.17
- Space Management and Name Rotation of Audit Log Files
- Write Strategies for Audit Logging

Note

Encryption capabilities described here apply as of MySQL 8.0.17, with the exception of the section that compares current encryption capabilities to the previous more-limited capabilities; see Audit Log File Encryption Prior to MySQL 8.0.17.

For additional information about the user-defined functions and system variables that affect audit logging, see Audit Log Functions, and Audit Log Options and Variables.

The audit log plugin can also control which audited events are written to the audit log file, based on event content or the account from which events originate. See Section 6.4.5.7, “Audit Log Filtering”.

Naming Conventions for Audit Log Files

To configure the audit log file name, set the `audit_log_file` system variable at server startup. The default name is `audit.log` in the server data directory. For best security, write the audit log to a directory accessible only to the MySQL server and to users with a legitimate reason to view the log.

The plugin interprets the `audit_log_file` value as composed of an optional leading directory name, a base name, and an optional suffix. If compression or encryption are enabled, the effective file name (the name actually used to create the log file) differs from the configured file name because it has additional suffixes:

- If compression is enabled, the plugin adds a suffix of `.gz`.
- If encryption is enabled, the plugin adds a suffix of `.pwd_id.enc`, where `pwd_id` indicates which encryption password to use for log file operations. The audit log plugin stores encryption passwords in the keyring; see Encrypting Audit Log Files.

The effective audit log file name is the name resulting from the addition of applicable compression and encryption suffixes to the configured file name. For example, if the configured `audit_log_file` value is `audit.log`, the effective file name is one of the values shown in the following table.
### MySQL Enterprise Audit

<table>
<thead>
<tr>
<th>Enabled Features</th>
<th>Effective File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>No compression or encryption</td>
<td><code>audit.log</code></td>
</tr>
<tr>
<td>Compression</td>
<td><code>audit.log.gz</code></td>
</tr>
<tr>
<td>Encryption</td>
<td><code>audit.log.pwd_id.enc</code></td>
</tr>
<tr>
<td>Compression, encryption</td>
<td><code>audit.log.gz.pwd_id.enc</code></td>
</tr>
</tbody>
</table>

`pwd_id` indicates the ID of the password used to encrypt or decrypt a file. `pwd_id` format is `pwd_timestamp-seq`, where:

- `pwd_timestamp` is a UTC value in `YYYYMMDDThhmmss` format indicating when the password was created.
- `seq` is a sequence number. Sequence numbers start at 1 and increase for passwords that have the same `pwd_timestamp` value.

Here are some example `pwd_id` password ID values:

```plaintext
20190403T142359-1  
20190403T142400-1  
20190403T142400-2  
```

To construct the corresponding keyring IDs for storing passwords in the keyring, the audit log plugin adds a prefix of `audit_log-` to the `pwd_id` values. For the example password IDs just shown, the corresponding keyring IDs are:

```plaintext
audit_log-20190403T142359-1  
audit_log-20190403T142400-1  
audit_log-20190403T142400-2  
```

The ID of the password currently used for encryption by the audit log plugin is the one having the largest `pwd_timestamp` value. If multiple passwords have that `pwd_timestamp` value, the current password ID is the one with the largest sequence number. For example, in the preceding set of password IDs, two of them have the largest timestamp, `20190403T142400`, so the current password ID is the one with the largest sequence number (2).

The audit log plugin performs certain actions during initialization and termination based on the effective audit log file name:

- During initialization, the plugin checks whether a file with the audit log file name already exists and renames it if so. (In this case, the plugin assumes that the previous server invocation exited unexpectedly with the audit log plugin running.) The plugin then writes to a new empty audit log file.
- During termination, the plugin renames the audit log file.
- File renaming (whether during plugin initialization or termination) occurs according to the usual rules for automatic log file rotation; see Automatic Audit Log File Rotation.

### Selecting Audit Log File Format

To configure the audit log file format, set the `audit_log_format` system variable at server startup. By default, the format is `NEW` (new-style XML format). For details about each format, see Section 6.4.5.4, “Audit Log File Formats”.

If you change `audit_log_format`, it is recommended that you also change `audit_log_file`. Otherwise, the result is that there exist two sets of log files with the same base name but different formats.
Compressing Audit Log Files

Audit log file compression can be enabled for any logging format.

To configure audit log file compression, set the `audit_log_compression` system variable at server startup. Permitted values are `NONE` (no compression; the default) and `GZIP` (GNU Zip compression).

If both compression and encryption are enabled, compression occurs before encryption. To recover the original file manually, first decrypt it, then uncompress it. See Manually Uncompressing and Decrypting Audit Log Files.

Encrypting Audit Log Files

Audit log file encryption can be enabled for any logging format. Encryption is based on user-defined passwords (with the exception of the initial password that the audit log plugin generates). To use this feature, the MySQL keyring must be enabled because audit logging uses it for password storage. Any keyring plugin can be used; for instructions, see Section 6.4.4, “The MySQL Keyring”.

To configure audit log file encryption, set the `audit_log_encryption` system variable at server startup. Permitted values are `NONE` (no encryption; the default) and `AES` (AES-256-CBC cipher encryption).

To set or get an encryption password at runtime, use these user-defined functions (UDFs):

- To set the current encryption password, invoke `audit_log_encryption_password_set()`.
  - This function stores the new password in the keyring. If encryption is enabled, it also performs a log file rotation operation that renames the current log file, and begins a new log file encrypted with the password. File renaming occurs according to the usual rules for automatic log file rotation; see Automatic Audit Log File Rotation.

  If the `audit_log_password_history_keep_days` system variable is nonzero, invoking `audit_log_encryption_password_set()` also causes expiration of old archived audit log encryption passwords. See the description of that variable for information about audit log password history, including password archiving and expiration.

- To get the current encryption password, invoke `audit_log_encryption_password_get()` with no argument. To get a password by ID, pass an argument specifying the keyring ID of the current password or an archived password.

  To determine which audit log keyring IDs exist, query the Performance Schema `keyring_keys` table:

  ```sql
  mysql> SELECT KEY_ID FROM performance_schema.keyring_keys WHERE KEY_ID LIKE 'audit_log%' ORDER BY KEY_ID;
  +-----------------------------+
  | KEY_ID                      |
  +-----------------------------+
  | audit_log-20190415T152248-1 |
  | audit_log-20190415T153507-1 |
  | audit_log-20190416T125122-1 |
  | audit_log-20190416T141608-1 |
  +-----------------------------+
  
  For additional information about audit log encryption UDFs, see Audit Log Functions.

When the audit log plugin initializes, if it finds that log file encryption is enabled, it checks whether the keyring contains an audit log encryption password. If not, the plugin automatically generates a random initial encryption password and stores it in the keyring. To discover this password, invoke `audit_log_encryption_password_get()`.
If both compression and encryption are enabled, compression occurs before encryption. To recover the original file manually, first decrypt it, then uncompress it. See Manually Uncompressing and Decrypting Audit Log Files.

Manually Uncompressing and Decrypting Audit Log Files

Audit log files can be uncompressed and decrypted using standard tools. This should be done only for log files that have been closed (archived) and are no longer in use, not for the log file that the audit log plugin is currently writing. You can recognize archived log files because they have been renamed by the audit log plugin to include a timestamp in the file name just after the base name.

For this discussion, assume that audit_log_file is set to audit.log. In that case, an archived audit log file has one of the names shown in the following table.

<table>
<thead>
<tr>
<th>Enabled Features</th>
<th>Archived File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>No compression or encryption</td>
<td>audit.timestamp.log</td>
</tr>
<tr>
<td>Compression</td>
<td>audit.timestamp.log.gz</td>
</tr>
<tr>
<td>Encryption</td>
<td>audit.timestamp.log.pwd_id.enc</td>
</tr>
<tr>
<td>Compression, encryption</td>
<td>audit.timestamp.log.gz.pwd_id.enc</td>
</tr>
</tbody>
</table>

As discussed in Naming Conventions for Audit Log Files, pwd_id format is pwd_timestamp-seq. Thus, the names of archived encrypted log files actually contain two timestamps. The first indicates file rotation time, and the second indicates when the encryption password was created.

Consider the following set of archived encrypted log file names:

```
audit.20190410T205827.log.20190403T185337-1.enc
audit.20190410T210243.log.20190403T185337-1.enc
audit.20190415T145309.log.20190414T223342-1.enc
audit.20190415T151322.log.20190414T223342-2.enc
```

Each file name has a unique rotation-time timestamp. By contrast, the password timestamps are not unique:

- The first two files have the same password ID and sequence number (20190403T185337-1). They have the same encryption password.

- The second two files have the same password ID (20190414T223342) but different sequence numbers (1, 2). These files have different encryption passwords.

To uncompress a compressed log file manually, use gunzip, gzip -d, or equivalent command. For example:

```
gunzip -c audit.timestamp.log.gz > audit.timestamp.log
```

To decrypt an encrypted log file manually, use the openssl command. For example:

```
openssl enc -d -aes-256-cbc -pass pass:password -md sha256
-in audit.timestamp.log.pwd_id.enc
-out audit.timestamp.log
```

To execute that command, you must obtain password, the encryption password. To do this, use audit_log_encryption_password_get(). For example, if the audit log file name is audit.20190415T151322.log.20190414T223342-2.enc, the password ID is
If both compression and encryption are enabled for audit logging, compression occurs before encryption. In this case, the file name has `.gz` and `.pwd_id.enc` suffixes added, corresponding to the order in which those operations occur. To recover the original file manually, perform the operations in reverse. That is, first decrypt the file, then uncompress it:

```
openssl enc -d -aes-256-cbc -pass pass:password -md sha256 -in audit.timestamp.log.gz.pwd_id.enc
   -out audit.timestamp.log.gz.enc
gunzip -c audit.timestamp.log.gz.enc > audit.timestamp.log
```

### Audit Log File Encryption Prior to MySQL 8.0.17

This section covers the differences in audit log file encryption capabilities prior to and as of MySQL 8.0.17, which is when password history was implemented (which includes password archiving and expiration). It also indicates how the audit log plugin handles upgrades to MySQL 8.0.17 or higher from versions lower than 8.0.17.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Prior to MySQL 8.0.17</th>
<th>As of MySQL 8.0.17</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of passwords</td>
<td>Single password only</td>
<td>Multiple passwords permitted</td>
</tr>
<tr>
<td>Encrypted log file names</td>
<td><code>.enc</code> suffix</td>
<td><code>.pwd_id.enc</code> suffix</td>
</tr>
<tr>
<td>Password keyring ID</td>
<td><code>audit_log</code></td>
<td><code>audit_log-pwd_id</code></td>
</tr>
<tr>
<td>Password history</td>
<td>No</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Prior to MySQL 8.0.17, there is no password history, so setting a new password makes the old password inaccessible, rendering MySQL Enterprise Audit unable to read log files encrypted with the old password. Should you anticipate a need to decrypt those files manually, you must maintain a record of previous passwords.

If audit log file encryption is enabled when you upgrade to MySQL 8.0.17 or higher from a lower version, the audit log plugin performs these upgrade actions:

- During plugin initialization, the plugin checks for an encryption password with a keyring ID of `audit_log`. If it finds one, the plugin duplicates the password using a keyring ID in `audit_log-pwd_id` format and uses it as the current encryption password. (For details about `pwd_id` syntax, see Naming Conventions for Audit Log Files.)

- Existing encrypted log files have a suffix of `.enc`. The plugin does not rename these to have a suffix of `.pwd_id.enc`, but can read them as long as the key with the ID of `audit_log` remains in the keyring.

- When password cleanup occurs, if the plugin expires any password with a keyring ID in `audit_log-pwd_id` format, it also expires the password with a keyring ID of `audit_log`, if it exists. (At this point, encrypted log files that have a suffix of `.enc` rather than `.pwd_id.enc` become unreadable by the plugin, so it is assumed that you no longer need them.)

### Space Management and Name Rotation of Audit Log Files

The audit log file has the potential to grow very large and consume a lot of disk space. To enable management of the space used by its log files, the audit log plugin provides for log file
rotation, either manually or automatically. Rotation capabilities use the `audit_log_flush` and `audit_log_rotate_on_size` system variables:

- By default, `audit_log_rotate_on_size=0` and no log rotation occurs unless performed manually. In this case, use `audit_log_flush` to close and reopen the current log file after manually renaming it.

- If `audit_log_rotate_on_size` is greater than 0, automatic rotation occurs when a write to the current log file causes its size to exceed this value. The audit log plugin closes the file, renames it, and opens a new log file. With automatic rotation enabled, `audit_log_flush` has no effect.

- Automatic rotation also occurs under several other conditions, described later.

**Note**

Renamed log files are not removed automatically. For example, with size-based log file rotation, renamed log files do not rotate off the end of the name sequence. Instead, they have unique names and accumulate indefinitely. To avoid excessive space use, remove old files periodically, backing them up first as necessary. If backed-up log files are encrypted, also back up the corresponding encryption passwords to a safe place, should you need to decrypt the files later.

The following discussion describes log file rotation methods in greater detail.

**Manual Audit Log File Rotation**

If `audit_log_rotate_on_size=0` (the default), no log rotation occurs unless performed manually. In this case, the audit log plugin closes and reopens the log file when the `audit_log_flush` value changes from disabled to enabled. Log file renaming must be done externally to the server. Suppose that the log file name is `audit.log` and you want to maintain the three most recent log files, cycling through the names `audit.log.1` through `audit.log.3`. On Unix, perform rotation manually like this:

1. From the command line, rename the current log files:

   ```sh
   mv audit.log.2 audit.log.3
   mv audit.log.1 audit.log.2
   mv audit.log audit.log.1
   ```

   This strategy overwrites the current `audit.log.3` contents, placing a bound on the number of archived log files and the space they use.

2. At this point, the plugin is still writing to the current log file, which has been renamed to `audit.log.1`. Connect to the server and flush the log file so the plugin closes it and reopens a new `audit.log` file:

   ```sql
   SET GLOBAL audit_log_flush = ON;
   ```

   `audit_log_flush` is special in that its value remains OFF so that you need not disable it explicitly before enabling it again to perform another flush.

**Note**

If compression or encryption are enabled, log file names include suffixes that signify the enabled features, as well as a password ID if encryption is enabled. If file names include a password ID, be sure to retain the ID in the name of any files...
you rename manually so that the password to use for decryption operations can be determined.

**Note**

For JSON-format logging, renaming audit log files manually makes them unavailable to the log-reading functions because the audit log plugin no longer can determine that they are part of the log file sequence (see Section 6.4.5.6, “Reading Audit Log Files”). Consider setting `audit_log_rotate_on_size` greater than 0 to use size-based rotation instead.

**Automatic Audit Log File Rotation**

If `audit_log_rotate_on_size` is greater than 0, setting `audit_log_flush` has no effect. Instead, whenever a write to the current log file causes its size to exceed the `audit_log_rotate_on_size` value, the audit log plugin closes the file, renames it, and opens a new log file.

Automatic rotation also occurs under these conditions:

- During plugin initialization, if a file with the audit log file name already exists (see Naming Conventions for Audit Log Files).
- During plugin termination.
- When the `audit_log_encryption_password_set()` function is called to set the encryption password, if encryption is enabled. (Rotation does not occur if encryption is disabled.)

The plugin renames the original file by inserting a timestamp just after its base name. For example, if the file name is `audit.log`, the plugin renames it to a value such as `audit.20190115T140633.log`. The timestamp is a UTC value in `YYYYMMDDThhmmss` format. The timestamp indicates rotation time for XML logging, and the timestamp of the last event written to the file for JSON logging.

**Write Strategies for Audit Logging**

The audit log plugin can use any of several strategies for log writes. Regardless of strategy, logging occurs on a best-effort basis, with no guarantee of consistency.

To specify a write strategy, set the `audit_log_strategy` system variable at server startup. By default, the strategy value is `ASYNCHRONOUS` and the plugin logs asynchronously to a buffer, waiting if the buffer is full. It's possible to tell the plugin not to wait (PERFORMANCE) or to log synchronously, either using file system caching (SEMISYNCHRONOUS) or forcing output with a `sync()` call after each write request (SYNCHRONOUS).

For asynchronous write strategy, the `audit_log_buffer_size` system variable is the buffer size in bytes. Set this variable at server startup to change the buffer size. The plugin uses a single buffer, which it allocates when it initializes and removes when it terminates. The plugin does not allocate this buffer for nonasynchronous write strategies.

Asynchronous logging strategy has these characteristics:

- Minimal impact on server performance and scalability.
- Blocking of threads that generate audit events for the shortest possible time; that is, time to allocate the buffer plus time to copy the event to the buffer.
- Output goes to the buffer. A separate thread handles writes from the buffer to the log file.
With asynchronous logging, the integrity of the log file may be compromised if a problem occurs during a write to the file or if the plugin does not shut down cleanly (for example, in the event that the server host exits unexpectedly). To reduce this risk, set `audit_log_strategy` to use synchronous logging.

A disadvantage of `PERFORMANCE` strategy is that it drops events when the buffer is full. For a heavily loaded server, the audit log may have events missing.

### 6.4.5.6 Reading Audit Log Files

The audit log plugin supports user-defined functions that provide an SQL interface for reading JSON-format audit log files. (This capability does not apply to log files written in other formats.)

When the audit log plugin initializes and is configured for JSON logging, it uses the directory containing the current audit log file as the location to search for readable audit log files. The plugin determines the file location, base name, and suffix from the value of the `audit_log_file` system variable, then looks for files with names that match the following pattern, where ` [...]` indicates optional file name parts:

```
basename_.timestamp_.suffix[.gz][_.pwd_id].enc
```

If a file name ends with `.enc`, the file is encrypted and reading its unencrypted contents requires a decryption password obtained from the keyring. The audit log plugin determines the keyring ID of the decryption password as follows:

- If `.enc` is preceded by `pwd_id`, the keyring ID is `audit_log-pwd_id`.
- If `.enc` is not preceded by `pwd_id`, the file has an old name from before audit log encryption password history was implemented. The keyring ID is `audit_log`.

For more information about encrypted audit log files, see Encrypting Audit Log Files.

The plugin ignores files that have been renamed manually and do not match the pattern, and files that were encrypted with a password no longer available in the keyring. The plugin opens each remaining candidate file, verifies that the file actually contains JSON audit events, and sorts the files using the timestamps from the first event of each file. The result is a sequence of files that are subject to access using the log-reading user-defined functions (UDFs):

- `audit_log_read()` reads events from the audit log or closes the reading process.
- `audit_log_read_bookmark()` returns a bookmark for the most recently written audit log event. This bookmark is suitable for passing to `audit_log_read()` to indicate where to begin reading.

To use the functions to read the audit log, follow these principles:

- Call `audit_log_read()` to read events beginning from a given position or the current position, or to close reading:
  - To initialize an audit log read sequence, pass an argument that indicates the position at which to begin. One way to do so is to pass the bookmark returned by `audit_log_read_bookmark()`:
    ```sql
    SELECT audit_log_read(audit_log_read_bookmark());
    ```
  - To continue reading from the current position in the sequence, call `audit_log_read()` with no position specified:
SELECT audit_log_read();

- To explicitly close the read sequence, pass a JSON null argument:

SELECT audit_log_read('null');

It is unnecessary to close reading explicitly. Reading is closed implicitly when the session ends or a new read sequence is initialized by calling audit_log_read() with an argument that indicates the position at which to begin.

- A successful call to audit_log_read() to read events returns a JSON string containing an array of audit events:

  - If the final value of the returned array is not a JSON null value, there are more events following those just read and audit_log_read() can be called again to read more of them.
  
  - If the final value of the returned array is a JSON null value, there are no more events left to be read in the current read sequence.

Each non-null array element is an event represented as a JSON hash. For example:

```json
[
  {
    "timestamp": "2020-05-18 13:39:33", "id": 0,
    "class": "connection", "event": "connect",
    ...  
  },
  {
    "timestamp": "2020-05-18 13:39:33", "id": 1,
    "class": "general", "event": "status",
    ...  
  },
  {
    "timestamp": "2020-05-18 13:39:33", "id": 2,
    "class": "connection", "event": "disconnect",
    ...  
  },
  null
]
```

For more information about the content of JSON-format audit events, see JSON Audit Log File Format.

- An audit_log_read() call to read events that does not specify a position produces an error under any of these conditions:
  
  - A read sequence has not yet been initialized by passing a position to audit_log_read().
  
  - There are no more events left to be read in the current read sequence; that is, audit_log_read() previously returned an array ending with a JSON null value.
  
  - The most recent read sequence has been closed by passing a JSON null value to audit_log_read().

  To read events under those conditions, it is necessary to first initialize a read sequence by calling audit_log_read() with an argument that specifies a position.

To specify a position to audit_log_read(), include an argument that indicates where to begin reading. For example, pass a bookmark, which is a JSON hash containing timestamp and id elements that uniquely identify a particular event. Here is an example bookmark, obtained by calling the audit_log_read_bookmark() function:
MySQL Enterprise Audit

```
mysql> SELECT audit_log_read_bookmark();
+-------------------------------------------------+
| audit_log_read_bookmark()                       |
+-------------------------------------------------+
| { "timestamp": "2020-05-18 21:03:44", "id": 0 } |
+-------------------------------------------------+
```

Passing the current bookmark to `audit_log_read()` initializes event reading beginning at the bookmark position:

```
mysql> SELECT audit_log_read(audit_log_read_bookmark());
+-----------------------------------------------------------------------+
| audit_log_read(audit_log_read_bookmark())                             |
+-----------------------------------------------------------------------+
| [ {"timestamp":"2020-05-18 22:41:24","id":0,"class":"connection", ... |
+-----------------------------------------------------------------------+
```

The argument to `audit_log_read()` is optional. If present, it can be a JSON `null` value to close the read sequence, or a JSON hash.

Within a hash argument to `audit_log_read()`, items are optional and control aspects of the read operation such as the position at which to begin reading or how many events to read. The following items are significant (other items are ignored):

- **start**: The position within the audit log of the first event to read. The position is given as a timestamp and the read starts from the first event that occurs on or after the timestamp value. The `start` item has this format, where `value` is a literal timestamp value:

  
  ```
  "start": { "timestamp": "value" }
  ```

  The `start` item is permitted as of MySQL 8.0.22.

- **timestamp, id**: The position within the audit log of the first event to read. The `timestamp` and `id` items together comprise a bookmark that uniquely identify a particular event. If an `audit_log_read()` argument includes either item, it must include both to completely specify a position or an error occurs.

- **max_array_length**: The maximum number of events to read from the log. If this item is omitted, the default is to read to the end of the log or until the read buffer is full, whichever comes first.

To specify a starting position to `audit_log_read()`, pass a hash argument that includes either a `start` item or a bookmark consisting of `timestamp` and `id` items. If a hash argument includes both a `start` item and a bookmark, an error occurs.

If a hash argument specifies no starting position, reading continues from the current position.

If a timestamp value includes no time part, a time part of `00:00:00` is assumed.

Example arguments accepted by `audit_log_read()`:

- Read events starting with the first event that occurs on or after the given timestamp:

  ```
  audit_log_read('{ "start": { "timestamp": "2020-05-24 12:30:00" } }')
  ```

- Like the previous example, but read at most 3 events:

  ```
  audit_log_read('{ "start": { "timestamp": "2020-05-24 12:30:00" }, "max_array_length": 3 }')
  ```

- Read events starting with the first event that occurs on or after `2020-05-24 00:00:00` (the timestamp includes no time part, so `00:00:00` is assumed):
- Read events starting with the event that has the exact timestamp and event ID:

\[
\text{audit_log_read('{' "start": { "timestamp": "2020-05-24" } }')}
\]

- Like the previous example, but read at most 3 events:

\[
\text{audit_log_read('{' "timestamp": "2020-05-24 12:30:00", "id": 0, "max_array_length": 3 }')}
\]

- Read events from the current position in the read sequence:

\[
\text{audit_log_read()}
\]

- Read at most 5 events beginning at the current position in the read sequence:

\[
\text{audit_log_read('{' "max_array_length": 5 }')}
\]

- Close the current read sequence:

\[
\text{audit_log_read('null')}
\]

A JSON string returned from either log-reading function can be manipulated as necessary. Suppose that a call to obtain a bookmark produces this value:

```sql
mysql> SET @mark := audit_log_read_bookmark();
mysql> SELECT @mark;
+---------------------------------------------+
| @mark                                        |
+---------------------------------------------+
| { "timestamp": "2020-05-18 16:10:28", "id": 2 } |
+---------------------------------------------+
```

Calling `audit_log_read()` with that argument can return multiple events. To limit `audit_log_read()` to reading at most \( N \) events, add to the string a `max_array_length` item with that value. For example, to read a single event, modify the string as follows:

```sql
mysql> SET @mark := JSON_SET(@mark, '\$.max_array_length', 1);
mysql> SELECT @mark;
+------------------------------------------------------------------+
| @mark                                                            |
+------------------------------------------------------------------+
| {"id": 2, "timestamp": "2020-05-18 16:10:28", "max_array_length": 1} |
+------------------------------------------------------------------+
```

The modified string, when passed to `audit_log_read()`, produces a result containing at most one event, no matter how many are available.

Prior to MySQL 8.0.19, string return values from audit log UDFs are binary strings. To use a binary string with functions that require a nonbinary string (such as functions that manipulate JSON values), convert it to a nonbinary string. For example, before passing a bookmark to `JSON_SET()`, convert it to `utf8mb4` as follows:

```sql
SET @mark = CONVERT(@mark USING utf8mb4);
```

That statement can be used even for MySQL 8.0.19 and higher; for those versions, it is essentially a no-op and is harmless.

To set a limit on the number of bytes that `audit_log_read()` reads, set the `audit_log_read_buffer_size` system variable. As of MySQL 8.0.12, this variable has
a default of 32KB and can be set at runtime. Each client should set its session value of `audit_log_read_buffer_size` appropriately for its use of `audit_log_read()`. Each call to `audit_log_read()` returns as many available events as fit within the buffer size. Events that do not fit within the buffer size are skipped and generate warnings. Given this behavior, consider these factors when assessing the proper buffer size for an application:

- There is a tradeoff between number of calls to `audit_log_read()` and events returned per call:
  - With a smaller buffer size, calls return fewer events, so more calls are needed.
  - With a larger buffer size, calls return more events, so fewer calls are needed.
- With a smaller buffer size, such as the default size of 32KB, there is a greater chance that events will exceed the buffer size and be skipped.

Prior to MySQL 8.0.12, `audit_log_read_buffer_size` has a default of 1MB, affects all clients, and can be changed only at server startup.

For additional information about audit log-reading functions, see Audit Log Functions.

**6.4.5.7 Audit Log Filtering**

**Note**

This section describes how audit log filtering works if the audit log plugin and the accompanying audit tables and UDFs are installed. If the plugin is installed but not the accompanying audit tables and UDFs, the plugin operates in legacy filtering mode, described in Section 6.4.5.9, “Legacy Mode Audit Log Filtering”. Legacy mode is filtering behavior as it was prior to MySQL 5.7.13; that is, before the introduction of rule-based filtering.

The audit log plugin has the capability of controlling logging of audited events by filtering them:

- Audited events can be filtered using these characteristics:
  - User account
  - Audit event class
  - Audit event subclass
  - Value of event fields such as those that indicate operation status or SQL statement executed
- Audit filtering is rule based:
  - A filter definition creates a set of auditing rules. Definitions can be configured to include or exclude events for logging based on the characteristics just described.
  - Filter rules have the capability of blocking (aborting) execution of qualifying events, in addition to existing capabilities for event logging.
  - Multiple filters can be defined, and any given filter can be assigned to any number of user accounts.
  - It is possible to define a default filter to use with any user account that has no explicitly assigned filter.
- Audit filters can be defined, displayed, and modified using an SQL interface based on user-defined functions (UDFs).
• Audit filter definitions are stored in the tables in the mysql system database.

• Within a given session, the value of the read-only audit_log_filter_id system variable indicates whether a filter has been assigned to the session.

Note

By default, rule-based audit log filtering logs no auditable events for any users. To log all auditable events for all users, use the following statements, which create a simple filter to enable logging and assign it to the default account:

```
SELECT audit_log_filter_set_filter('log_all', '{ "filter": { "log": true } }');
SELECT audit_log_filter_set_user('%', 'log_all');
```

The filter assigned to % is used for connections from any account that has no explicitly assigned filter (which initially is true for all accounts).

The following list briefly summarizes the UDFs that implement the SQL interface for audit filtering control:

• `audit_log_filter_set_filter()`: Define a filter
• `audit_log_filter_remove_filter()`: Remove a filter
• `audit_log_filter_set_user()`: Start filtering a user account
• `audit_log_filter_remove_user()`: Stop filtering a user account
• `audit_log_filter_flush()`: Flush manual changes to the filter tables to affect ongoing filtering

For usage examples and complete details about the filtering functions, see Using Audit Log Filtering Functions, and Audit Log Functions.

Audit log filtering functions are subject to these constraints:

• To use any filtering function, the audit_log plugin must be enabled or an error occurs. In addition, the audit tables must exist or an error occurs. To install the audit_log plugin and its accompanying UDFs and tables, see Section 6.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”.

• To use any filtering function, a user must possess the SUPER privilege or an error occurs. To grant the SUPER privilege to a user account, use this statement:

```
GRANT SUPER ON *.* TO user;
```

Alternatively, should you prefer to avoid granting the SUPER privilege while still permitting users to access specific filtering functions, “wrapper” stored programs can be defined. This technique is described in the context of keyring UDFs in Using General-Purpose Keyring Functions; it can be adapted for use with filtering UDFs.

• The audit_log plugin operates in legacy mode if it is installed but the accompanying audit tables and functions are not created. The plugin writes these messages to the error log at server startup:

```
[Warning] Plugin audit_log reported: 'Failed to open the audit log filter tables.'
[Warning] Plugin audit_log reported: 'Audit Log plugin supports a filtering, which has not been installed yet. Audit Log plugin will run in the legacy mode, which will be disabled in the next release.'
```

In legacy mode, filtering can be done based only on event account or status. For details, see Section 6.4.5.9, “Legacy Mode Audit Log Filtering”.

• Using Audit Log Filtering Functions
Using Audit Log Filtering Functions

Before using the audit log user-defined functions (UDFs), install them according to the instructions provided in Section 6.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”. The `SUPER` privilege is required to use any of these functions.

The audit log filtering functions enable filtering control by providing an interface to create, modify, and remove filter definitions and assign filters to user accounts.

Filter definitions are JSON values. For information about using JSON data in MySQL, see Section 11.5, “The JSON Data Type”. This section shows some simple filter definitions. For more information about filter definitions, see Section 6.4.5.8, “Writing Audit Log Filter Definitions”.

When a connection arrives, the audit log plugin determines which filter to use for the new session by searching for the user account name in the current filter assignments:

- If a filter is assigned to the user, the audit log uses that filter.
- Otherwise, if no user-specific filter assignment exists, but there is a filter assigned to the default account (`%`), the audit log uses the default filter.
- Otherwise, the audit log selects no audit events from the session for processing.

If a change-user operation occurs during a session (see `mysql_change_user()`), filter assignment for the session is updated using the same rules but for the new user.

By default, no accounts have a filter assigned, so no processing of auditable events occurs for any account.

Suppose that instead you want the default to be to log only connection-related activity (for example, to see connect, change-user, and disconnect events, but not the SQL statements users execute while connected). To achieve this, define a filter (shown here named `log_conn_events`) that enables logging only of events in the `connection` class, and assign that filter to the default account, represented by the `%` account name:

```
SET @f = '{ "filter": { "class": { "name": "connection" } } }';
SELECT audit_log_filter_set_filter('log_conn_events', @f);
SELECT audit_log_filter_set_user('%', 'log_conn_events');
```

Now the audit log uses this default account filter for connections from any account that has no explicitly defined filter.

To assign a filter explicitly to a particular user account or accounts, define the filter, then assign it to the relevant accounts:

```
SELECT audit_log_filter_set_filter('log_all', '{ "filter": { "log": true } }');
SELECT audit_log_filter_set_user('user1@localhost', 'log_all');
SELECT audit_log_filter_set_user('user2@localhost', 'log_all');
```

Now full logging is enabled for `user1@localhost` and `user2@localhost`. Connections from other accounts continue to be filtered using the default account filter.

To disassociate a user account from its current filter, either unassign the filter or assign a different filter:

- To unassign the filter from the user account:
  ```
  SELECT audit_log_filter_remove_user('user1@localhost');
  ```

- To assign a different filter to the user account:
  ```
  SELECT audit_log_filter_set_user('user1@localhost', 'log_conn_events');
  ```
Filtering of current sessions for the account remains unaffected. Subsequent connections from the account are filtered using the default account filter if there is one, and are not logged otherwise.

- To assign a different filter to the user account:

```sql
SELECT audit_log_filter_set_filter('log_nothing', '{ "filter": { "log": false } }');
SELECT audit_log_filter_set_user('user1@localhost', 'log_nothing');
```

Filtering of current sessions for the account remains unaffected. Subsequent connections from the account are filtered using the new filter. For the filter shown here, that means no logging for new connections from `user1@localhost`.

For audit log filtering, user name and host name comparisons are case-sensitive. This differs from comparisons for privilege checking, for which host name comparisons are not case-sensitive.

To remove a filter, do this:

```sql
SELECT audit_log_filter_remove_filter('log_nothing');
```

Removing a filter also unassigns it from any users to whom it has been assigned, including any current sessions for those users.

The filtering UDFs just described affect audit filtering immediately and update the audit log tables in the `mysql` system database that store filters and user accounts (see Audit Log Tables). It is also possible to modify the audit log tables directly using statements such as `INSERT`, `UPDATE`, and `DELETE`, but such changes do not affect filtering immediately. To flush your changes and make them operational, call `audit_log_filter_flush()`:

```sql
SELECT audit_log_filter_flush();
```

**Warning**

`audit_log_filter_flush()` should be used only after modifying the audit tables directly, to force reloading all filters. Otherwise, this function should be avoided. It is, in effect, a simplified version of unloading and reloading the `audit_log` plugin with `UNINSTALL PLUGIN` plus `INSTALL PLUGIN`.

`audit_log_filter_flush()` affects all current sessions and detaches them from their previous filters. Current sessions are no longer logged unless they disconnect and reconnect, or execute a change-user operation.

To determine whether a filter has been assigned to the current session, check the session value of the read-only `audit_log_filter_id` system variable. If the value is 0, no filter is assigned. A nonzero value indicates the internally maintained ID of the assigned filter:

```sql
mysql> SELECT @audit_log_filter_id;
+-----------------------+
<table>
<thead>
<tr>
<th>@audit_log_filter_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
</tr>
</tbody>
</table>
+-----------------------+
```

### 6.4.5.8 Writing Audit Log Filter Definitions

Filter definitions are JSON values. For information about using JSON data in MySQL, see Section 11.5, "The JSON Data Type".

Filter definitions have this form, where `actions` indicates how filtering takes place:
The following discussion describes permitted constructs in filter definitions.

- Logging All Events
- Logging Specific Event Classes
- Logging Specific Event Subclasses
- Inclusive and Exclusive Logging
- Testing Event Field Values
- Blocking Execution of Specific Events
- Logical Operators
- Referencing Predefined Variables
- Referencing Predefined Functions
- Replacing a User Filter

Logging All Events

To explicitly enable or disable logging of all events, use a `log` element in the filter:

```json
{ "filter": { "log": true } }
```

The `log` value can be either `true` or `false`.

The preceding filter enables logging of all events. It is equivalent to:

```json
{ "filter": { } }
```

Logging behavior depends on the `log` value and whether `class` or `event` items are specified:

- With `log` specified, its given value is used.
- Without `log` specified, logging is `true` if no `class` or `event` item is specified, and `false` otherwise (in which case, `class` or `event` can include their own `log` item).

Logging Specific Event Classes

To log events of a specific class, use a `class` element in the filter, with its `name` field denoting the name of the class to log:

```json
{ "filter": {   "class": { "name": "connection" } } }
```

The `name` value can be `connection`, `general`, or `table_access` to log connection, general, or table-access events, respectively.
The preceding filter enables logging of events in the `connection` class. It is equivalent to the following filter with `log` items made explicit:

```json
{  
  "filter": {  
    "log": false,  
    "class": { "log": true,  
      "name": "connection" }  
  }  
}
```

To enable logging of multiple classes, define the `class` value as a JSON array element that names the classes:

```json
{  
  "filter": {  
    "class": [  
      { "name": "connection" },  
      { "name": "general" },  
      { "name": "table_access" }  
    ]  
  }  
}
```

**Note**

When multiple instances of a given item appear at the same level within a filter definition, the item values can be combined into a single instance of that item within an array value. The preceding definition can be written like this:

```json
{  
  "filter": {  
    "class": [  
      { "name": [ "connection", "general", "table_access" ] }  
    ]  
  }  
}
```

**Logging Specific Event Subclasses**

To select specific event subclasses, use an `event` item containing a `name` item that names the subclasses. The default action for events selected by an `event` item is to log them. For example, this filter enables logging for the named event subclasses:

```json
{  
  "filter": {  
    "class": [  
      {  
        "name": "connection",  
        "event": [  
          { "name": "connect" },  
          { "name": "disconnect" }  
        ]  
      },  
      { "name": "general" },  
      { "name": "table_access",  
        "event": [  
          { "name": "insert" },  
          { "name": "delete" },  
          { "name": "update" }  
        ]  
      }  
    ]  
  }  
}
```
The `event` item can also contain explicit `log` items to indicate whether to log qualifying events. This `event` item selects multiple events and explicitly indicates logging behavior for them:

```json
"event": [
  { "name": "read", "log": false },
  { "name": "insert", "log": true },
  { "name": "delete", "log": true },
  { "name": "update", "log": true }
]
```

The `event` item can also indicate whether to block qualifying events, if it contains an `abort` item. For details, see Blocking Execution of Specific Events.

Table 6.29, “Event Class and Subclass Combinations” describes the permitted subclass values for each event class.

**Table 6.29 Event Class and Subclass Combinations**

<table>
<thead>
<tr>
<th>Event Class</th>
<th>Event Subclass</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>connection</td>
<td>connect</td>
<td>Connection initiation (successful or unsuccessful)</td>
</tr>
<tr>
<td>connection</td>

</tbody>
</table>
### Inclusive and Exclusive Logging

A filter can be defined in inclusive or exclusive mode:

- **Inclusive mode** logs only explicitly specified items.
- **Exclusive mode** logs everything but explicitly specified items.

To perform inclusive logging, disable logging globally and enable logging for specific classes. This filter logs `connect` and `disconnect` events in the `connection` class, and events in the `general` class:

```json
{
  "filter": {
    "log": false,
    "class": [
      {
        "name": "connection",
        "event": [
          { "name": "connect", "log": true },
          { "name": "disconnect", "log": true }
        ]
      },
      { "name": "general", "log": true }
    ]
  }
}
```

To perform exclusive logging, enable logging globally and disable logging for specific classes. This filter logs everything except events in the `general` class:

```json
{
  "filter": {
    "log": true,
    "class": {
      "name": "general", "log": false
    }
  }
}
```

This filter logs `change_user` events in the `connection` class, `message` events, and `table_access` events, by virtue of *not* logging everything else:

```json
{
  "filter": {
    "log": true,
    "class": [
      {
        "name": "connection",
        "event": [
          { "name": "connect", "log": false },
          { "name": "disconnect", "log": false }
        ]
      },
      { "name": "general", "log": false }
    ]
  }
}
```
Testing Event Field Values

To enable logging based on specific event field values, specify a field item within the log item that indicates the field name and its expected value:

```
{
  "filter": {
    "class": {
      "name": "general",
      "event": {
        "name": "status",
        "log": {
          "field": { "name": "general_command.str", "value": "Query" }
        }
      }
    }
  }
}
```

Each event contains event class-specific fields that can be accessed from within a filter to perform custom filtering.

A connection event indicates when a connection-related activity occurs during a session, such as a user connecting to or disconnecting from the server. Table 6.31, “Connection Event Fields” indicates the permitted fields for connection events.

**Table 6.31 Connection Event Fields**

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Field Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>status</td>
<td>integer</td>
<td>Event status: 0: OK Otherwise: Failed</td>
</tr>
<tr>
<td>connection_id</td>
<td>unsigned integer</td>
<td>Connection ID</td>
</tr>
<tr>
<td>user.str</td>
<td>string</td>
<td>User name specified during authentication</td>
</tr>
<tr>
<td>user.length</td>
<td>unsigned integer</td>
<td>User name length</td>
</tr>
<tr>
<td>priv_user.str</td>
<td>string</td>
<td>Authenticated user name (account user name)</td>
</tr>
<tr>
<td>priv_user.length</td>
<td>unsigned integer</td>
<td>Authenticated user name length</td>
</tr>
<tr>
<td>external_user.str</td>
<td>string</td>
<td>External user name (provided by third-party authentication plugin)</td>
</tr>
<tr>
<td>external_user.length</td>
<td>unsigned integer</td>
<td>External user name length</td>
</tr>
<tr>
<td>proxy_user.str</td>
<td>string</td>
<td>Proxy user name</td>
</tr>
<tr>
<td>proxy_user.length</td>
<td>unsigned integer</td>
<td>Proxy user name length</td>
</tr>
<tr>
<td>host.str</td>
<td>string</td>
<td>Connected user host</td>
</tr>
<tr>
<td>host.length</td>
<td>unsigned integer</td>
<td>Connected user host length</td>
</tr>
<tr>
<td>ip.str</td>
<td>string</td>
<td>Connected user IP address</td>
</tr>
<tr>
<td>ip.length</td>
<td>unsigned integer</td>
<td>Connected user IP address length</td>
</tr>
<tr>
<td>database.str</td>
<td>string</td>
<td>Database name specified at connect time</td>
</tr>
<tr>
<td>Field Name</td>
<td>Field Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>----------------</td>
<td>-------------------------------------------------------</td>
</tr>
<tr>
<td>database.length</td>
<td>unsigned integer</td>
<td>Database name length</td>
</tr>
<tr>
<td>connection_type</td>
<td>integer</td>
<td>Connection type:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>or &quot;::undefined&quot;: Undefined</td>
</tr>
<tr>
<td></td>
<td></td>
<td>or &quot;::tcp/ip&quot;: TCP/IP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>or &quot;::socket&quot;: Socket</td>
</tr>
<tr>
<td></td>
<td></td>
<td>or &quot;::named_pipe&quot;: Named pipe</td>
</tr>
<tr>
<td></td>
<td></td>
<td>or &quot;::ssl&quot;: TCP/IP with encryption</td>
</tr>
<tr>
<td></td>
<td></td>
<td>or &quot;::shared_memory&quot;: Shared memory</td>
</tr>
</tbody>
</table>

The "::xxx" values are symbolic pseudo-constants that may be given instead of the literal numeric values. They must be quoted as strings and are case-sensitive.

A general event indicates the status code of an operation and its details. *Table 6.32, “General Event Fields”* indicates the permitted fields for general events.

**Table 6.32 General Event Fields**

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Field Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>general_error_code</td>
<td>integer</td>
<td>Event status:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0: OK</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Otherwise: Failed</td>
</tr>
<tr>
<td>general_thread_id</td>
<td>unsigned integer</td>
<td>Connection/thread ID</td>
</tr>
<tr>
<td>general_user.str</td>
<td>string</td>
<td>User name specified during authentication</td>
</tr>
<tr>
<td>general_user.length</td>
<td>unsigned integer</td>
<td>User name length</td>
</tr>
<tr>
<td>general_command.str</td>
<td>string</td>
<td>Command name</td>
</tr>
<tr>
<td>general_command.length</td>
<td>unsigned integer</td>
<td>Command name length</td>
</tr>
<tr>
<td>general_query.str</td>
<td>string</td>
<td>SQL statement text</td>
</tr>
<tr>
<td>general_query.length</td>
<td>unsigned integer</td>
<td>SQL statement text length</td>
</tr>
<tr>
<td>general_host.str</td>
<td>string</td>
<td>Host name</td>
</tr>
<tr>
<td>general_host.length</td>
<td>unsigned integer</td>
<td>Host name length</td>
</tr>
<tr>
<td>general_sql_command.str</td>
<td>string</td>
<td>SQL command type name</td>
</tr>
<tr>
<td>general_sql_command.length</td>
<td>unsigned integer</td>
<td>SQL command type name length</td>
</tr>
<tr>
<td>general_external_user.str</td>
<td>string</td>
<td>External user name (provided by third-party authentication plugin)</td>
</tr>
<tr>
<td>general_external_user.length</td>
<td>unsigned integer</td>
<td>External user name length</td>
</tr>
<tr>
<td>general_ip.str</td>
<td>string</td>
<td>Connected user IP address</td>
</tr>
<tr>
<td>general_ip.length</td>
<td>unsigned integer</td>
<td>Connection user IP address length</td>
</tr>
</tbody>
</table>

*general_command.str* indicates a command name: *Query*, *Execute*, *Quit*, or *Change user*. 
A general event with the `general_command.str` field set to `Query` or `Execute` contains `general_sql_command.str` set to a value that specifies the type of SQL command: `alter_db`, `alter_db_upgrade`, `admin_commands`, and so forth. These values can be seen as the last components of the Performance Schema instruments displayed by this statement:

```
mysql> SELECT NAME FROM performance_schema.setup_instruments
    > WHERE NAME LIKE 'statement/sql/%' ORDER BY NAME;
```

<table>
<thead>
<tr>
<th>NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>statement/sql/alter_db</td>
</tr>
<tr>
<td>statement/sql/alter_db_upgrade</td>
</tr>
<tr>
<td>statement/sql/alter_event</td>
</tr>
<tr>
<td>statement/sql/alter_function</td>
</tr>
<tr>
<td>statement/sql/alter_instance</td>
</tr>
<tr>
<td>statement/sql/alter_procedure</td>
</tr>
<tr>
<td>statement/sql/alter_server</td>
</tr>
<tr>
<td>...</td>
</tr>
</tbody>
</table>

A table-access event provides information about specific table accesses. Table 6.33, “Table-Access Event Fields” indicates the permitted fields for table-access events.

**Table 6.33 Table-Access Event Fields**

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Field Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>connection_id</td>
<td>unsigned integer</td>
<td>Event connection ID</td>
</tr>
<tr>
<td>sql_command_id</td>
<td>integer</td>
<td>SQL command ID</td>
</tr>
<tr>
<td>query.str</td>
<td>string</td>
<td>SQL statement text</td>
</tr>
<tr>
<td>query.length</td>
<td>unsigned integer</td>
<td>SQL statement text length</td>
</tr>
<tr>
<td>table_database.str</td>
<td>string</td>
<td>Database name associated with event</td>
</tr>
<tr>
<td>table_database.length</td>
<td>unsigned integer</td>
<td>Database name length</td>
</tr>
<tr>
<td>table_name.str</td>
<td>string</td>
<td>Table name associated with event</td>
</tr>
<tr>
<td>table_name.length</td>
<td>unsigned integer</td>
<td>Table name length</td>
</tr>
</tbody>
</table>

The following list shows which statements produce which table-access events:

- **read event:**
  - `SELECT`
  - `INSERT ... SELECT` (for tables referenced in `SELECT` clause)
  - `REPLACE ... SELECT` (for tables referenced in `SELECT` clause)
  - `UPDATE ... WHERE` (for tables referenced in `WHERE` clause)
  - `HANDLER ... READ`

- **delete event:**
  - `DELETE`
  - `TRUNCATE TABLE`

- **insert event:**
• INSERT
• INSERT ... SELECT (for table referenced in INSERT clause)
• REPLACE
• REPLACE ... SELECT (for table referenced in REPLACE clause)
• LOAD DATA
• LOAD XML
• update event:
  • UPDATE
  • UPDATE ... WHERE (for tables referenced in UPDATE clause)

Blocking Execution of Specific Events

event items can include an abort item that indicates whether to prevent qualifying events from executing. For example, abort enables rules to be written that block execution of specific SQL statements.

The abort item must appear within an event item. For example:

```
"event": {
  "name": qualifying event subclass names
  "abort": condition
}
```

For event subclasses selected by the name item, the abort action is true or false, depending on condition evaluation. If the condition evaluates to true, the event is blocked. Otherwise, the event continues executing.

The condition specification can be as simple as true or false, or it can be more complex such that evaluation depends on event characteristics.

This filter blocks INSERT, UPDATE, and DELETE statements:

```
{
  "filter": {
    "class": {
      "name": "table_access",
      "event": {
        "name": [ "insert", "update", "delete" ],
        "abort": true
      }
    }
  }
}
```

This more complex filter blocks the same statements, but only for a specific table finances.bank_account:

```
{
  "filter": {
    "class": {
      "name": "table_access",
      "event": {  
        "name": [ "insert", "update", "delete" ],
        "abort": true
      }
    }
  }
}
```
Statements matched and blocked by the filter return an error to the client:

```
ERROR 1045 (28000): Statement was aborted by an audit log filter
```

Not all events can be blocked (see Table 6.30, "Log and Abort Characteristics Per Event Class and Subclass Combination"). For an event that cannot, the audit log writes a warning to the error log rather than blocking it.

For attempts to define a filter in which the `abort` item appears elsewhere than in an `event` item, an error occurs.

**Logical Operators**

Logical operators (`and`, `or`, `not`) can be used in log items. This permits construction of more advanced filtering configurations:

```json
{
  "filter": {
    "class": {
      "name": "general",
      "event": {
        "name": "status",
        "log": {
          "or": [
            {
              "and": [
                {
                  "field": { "name": "general_command.str", "value": "Query" } },
                {
                  "field": { "name": "general_command.length", "value": 5 } }
              ]
            },
            {
              "and": [
                {
                  "field": { "name": "general_command.str", "value": "Execute" } },
                {
                  "field": { "name": "general_command.length", "value": 7 } }
              ]
            }
          ]
        }
      }
    }
  }
}
```

**Referencing Predefined Variables**

To refer to a predefined variable in a log condition, use a `variable` item, which tests equality against a given value:

```json
{
  "filter": {
```

1447
Each predefined variable corresponds to a system variable. By writing a filter that tests a predefined variable, you can modify filter operation by setting the corresponding system variable, without having to redefine the filter. For example, by writing a filter that tests the value of the `audit_log_connection_policy_value` predefined variable, you can modify filter operation by changing the value of the `audit_log_connection_policy` system variable.

The `audit_log_***_policy` system variables are used for the legacy mode audit log (see Section 6.4.5.9, “Legacy Mode Audit Log Filtering”). With rule-based audit log filtering, those variables remain visible (for example, using `SHOW VARIABLES`), but changes to them have no effect unless you write filters containing constructs that refer to them.

The following list describes the permitted predefined variables for variable items:

- **audit_log_connection_policy_value**

  This variable corresponds to the value of the `audit_log_connection_policy` system variable. The value is an unsigned integer. Table 6.34, “Audit_log_connection_policy_value Values” shows the permitted values and the corresponding `audit_log_connection_policy` values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Corresponding audit_log_connection_policy Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 or &quot;::none&quot;</td>
<td>NONE</td>
</tr>
<tr>
<td>1 or &quot;::errors&quot;</td>
<td>ERRORS</td>
</tr>
<tr>
<td>2 or &quot;::all&quot;</td>
<td>ALL</td>
</tr>
</tbody>
</table>

The "::***" values are symbolic pseudo-constants that may be given instead of the literal numeric values. They must be quoted as strings and are case-sensitive.

- **audit_log_policy_value**

  This variable corresponds to the value of the `audit_log_policy` system variable. The value is an unsigned integer. Table 6.35, “Audit_log_policy_value Values” shows the permitted values and the corresponding `audit_log_policy` values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Corresponding audit_log_policy Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 or &quot;::none&quot;</td>
<td>NONE</td>
</tr>
<tr>
<td>1 or &quot;::logins&quot;</td>
<td>LOGINS</td>
</tr>
<tr>
<td>2 or &quot;::all&quot;</td>
<td>ALL</td>
</tr>
<tr>
<td>3 or &quot;::queries&quot;</td>
<td>QUERIES</td>
</tr>
</tbody>
</table>
The "::xxx" values are symbolic pseudo-constants that may be given instead of the literal numeric values. They must be quoted as strings and are case-sensitive.

- **audit_log_statement_policy_value**

  This variable corresponds to the value of the `audit_log_statement_policy` system variable. The value is an unsigned integer. Table 6.36, "audit_log_statement_policy_value Values" shows the permitted values and the corresponding `audit_log_statement_policy` values.

  **Table 6.36 audit_log_statement_policy_value Values**

<table>
<thead>
<tr>
<th>Value</th>
<th>Corresponding audit_log_statement_policy Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 or &quot;::none&quot;</td>
<td>NONE</td>
</tr>
<tr>
<td>1 or &quot;::errors&quot;</td>
<td>ERRORS</td>
</tr>
<tr>
<td>2 or &quot;::all&quot;</td>
<td>ALL</td>
</tr>
</tbody>
</table>

  The "::xxx" values are symbolic pseudo-constants that may be given instead of the literal numeric values. They must be quoted as strings and are case-sensitive.

### Referencing Predefined Functions

To refer to a predefined function in a log condition, use a function item, which takes name and args values to specify the function name and its arguments, respectively:

```json
{
    "filter": {
        "class": {
            "name": "general",
            "event": {
                "name": "status",
                "log": {
                    "function": {
                        "name": "find_in_include_list",
                        "args": [ {
                            "string": [ { "field": "user.str" }, {
                                "string": @
                            }, { "field": "host.str" } ] } ]
                    }
                }
            }
        }
    }
}
```

The function as specified in the `name` item should be the function name only, without parentheses or the argument list. Arguments in the `args` item, if there is one, must be given in the order listed in the function description. Arguments can refer to predefined variables, event fields, or string or numeric constants.

The preceding filter determines whether to log `general` class `status` events depending on whether the current user is found in the `audit_log_include_accounts` system variable. That user is constructed using fields in the event.
