Ranges for the month and day specifiers begin with zero due to the fact that MySQL permits the storing of incomplete dates such as '2014-00-00'.

The language used for day and month names and abbreviations is controlled by the value of the lc_time_names system variable (Section 10.16, "MySQL Server Locale Support").

For the %U, %u, %V, and %v specifiers, see the description of the WEEK() function for information about the mode values. The mode affects how week numbering occurs.

DATE_FORMAT() returns a string with a character set and collation given by character_set_connection and collation_connection so that it can return month and weekday names containing non-ASCII characters.

```sql
mysql> SELECT DATE_FORMAT('2009-10-04 22:23:00', '%W %M %Y');
-> 'Sunday October 2009'
mysql> SELECT DATE_FORMAT('2007-10-04 22:23:00', '%H:%i:%s');
-> '22:23:00'
mysql> SELECT DATE_FORMAT('1900-10-04 22:23:00', '%D %y %a %d %m %b %j');
-> '4th 00 Thu 04 10 Oct 277'
mysql> SELECT DATE_FORMAT('1997-10-04 22:23:00', '%H %k %I %i %T %S %w');
-> '22 22 10 23:00 PM 22:23:00 00 6'
mysql> SELECT DATE_FORMAT('1999-01-01', '%X %V');
-> '1998 52'
mysql> SELECT DATE_FORMAT('2006-06-00', '%d');
-> '00'
```

• DATE_SUB(date, INTERVAL expr unit)

See the description for DATE_ADD().

• DAY(date)

DAY() is a synonym for DAYOFMONTH().
Date and Time Functions

- **DAYNAME(date)**
  Returns the name of the weekday for `date`. The language used for the name is controlled by the value of the `lc_time_names` system variable (see Section 10.16, "MySQL Server Locale Support"). Returns NULL if `date` is NULL.
  
  ```
  mysql> SELECT DAYNAME('2007-02-03');
  -> 'Saturday'
  ```

- **DAYOFMONTH(date)**
  Returns the day of the month for `date`, in the range 1 to 31, or 0 for dates such as '0000-00-00' or '2008-00-00' that have a zero day part. Returns NULL if `date` is NULL.
  
  ```
  mysql> SELECT DAYOFMONTH('2007-02-03');
  -> 3
  ```

- **DAYOFWEEK(date)**
  Returns the weekday index for `date` (1 = Sunday, 2 = Monday, ..., 7 = Saturday). These index values correspond to the ODBC standard. Returns NULL if `date` is NULL.
  
  ```
  mysql> SELECT DAYOFWEEK('2007-02-03');
  -> 7
  ```

- **DAYOFYEAR(date)**
  Returns the day of the year for `date`, in the range 1 to 366. Returns NULL if `date` is NULL.
  
  ```
  mysql> SELECT DAYOFYEAR('2007-02-03');
  -> 34
  ```

- **EXTRACT(unit FROM date)**
  The `EXTRACT()` function uses the same kinds of `unit` specifiers as `DATE_ADD()` or `DATE_SUB()`, but extracts parts from the date rather than performing date arithmetic. For information on the `unit` argument, see Temporal Intervals. Returns NULL if `date` is NULL.
  
  ```
  mysql> SELECT EXTRACT(YEAR FROM '2019-07-02');
  -> 2019
  mysql> SELECT EXTRACT(YEAR_MONTH FROM '2019-07-02 01:02:03');
  -> 201907
  mysql> SELECT EXTRACT(DAY_MINUTE FROM '2019-07-02 01:02:03');
  -> 20102
  mysql> SELECT EXTRACT(MICROSECOND FROM '2003-01-02 10:30:00.000123');
  -> 123
  ```

- **FROM_DAYS(N)**
  Given a day number `N`, returns a `DATE` value. Returns NULL if `N` is NULL.
  
  ```
  mysql> SELECT FROM_DAYS(730669);
  -> '2000-07-03'
  ```

  Use `FROM_DAYS()` with caution on old dates. It is not intended for use with values that precede the advent of the Gregorian calendar (1582). See Section 11.2.7, “What Calendar Is Used By MySQL?”.

- **FROM_UNIXTIME(unix_timestamp[, format])**
  Returns a representation of `unix_timestamp` as a datetime or character string value. The value returned is expressed using the session time zone. (Clients can set the session time zone as described
in Section 5.1.15, "MySQL Server Time Zone Support".) \textit{unix_timestamp} is an internal timestamp value representing seconds since '1970-01-01 00:00:00' UTC, such as produced by the \textit{UNIX_TIMESTAMP()} function.

If \textit{format} is omitted, this function returns a \textit{DATETIME} value.

If \textit{unix_timestamp} or \textit{format} is NULL, this function returns NULL.

If \textit{unix_timestamp} is an integer, the fractional seconds precision of the \textit{DATETIME} is zero. When \textit{unix_timestamp} is a decimal value, the fractional seconds precision of the \textit{DATETIME} is the same as the precision of the decimal value, up to a maximum of 6. When \textit{unix_timestamp} is a floating point number, the fractional seconds precision of the datetime is 6.

On 32-bit platforms, the maximum useful value for \textit{unix_timestamp} is 2147483647.999999, which returns '2038-01-19 03:14:07.999999' UTC. On 64-bit platforms, the effective maximum is 3253677199.999999, which returns '3001-01-18 23:59:59.999999' UTC. Regardless of platform or version, a greater value for \textit{unix_timestamp} than the effective maximum returns 0.

\textit{format} is used to format the result in the same way as the format string used for the \textit{DATE_FORMAT()} function. If \textit{format} is supplied, the value returned is a \textit{VARCHAR}.

```
| mysql> SELECT FROM_UNIXTIME(1447430881); |
| -> '2015-11-13 10:08:01' |
| mysql> SELECT FROM_UNIXTIME(1447430881) + 0; |
| -> 20151113100801 |
| mysql> SELECT FROM_UNIXTIME(1447430881, '%%Y %D %M %h:%i:%s %x'); |
| -> '2015 13th November 10:08:01 2015' |
```

\textbf{Note}

If you use \textit{UNIX_TIMESTAMP()} and \textit{FROM_UNIXTIME()} to convert between values in a non-UTC time zone and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For details, see the description of the \textit{UNIX_TIMESTAMP()} function.

\* \textbf{GET_FORMAT(\textit{(DATE|TIME|DATETIME)}, \{'EUR'|'USA'|'JIS'|'ISO'|'INTERNAL'\})}

Returns a format string. This function is useful in combination with the \textit{DATE_FORMAT()} and the \textit{STR_TO_DATE()} functions.

If \textit{format} is \textbf{NULL}, this function returns \textbf{NULL}.

The possible values for the first and second arguments result in several possible format strings (for the specifiers used, see the table in the \textit{DATE_FORMAT()} function description). ISO format refers to ISO 9075, not ISO 8601.

<td>'%H%i%s'</td>
</tr>
</tbody>
</table>

TIMESTAMP can also be used as the first argument to GET_FORMAT(), in which case the function returns the same values as for DATETIME.

mysql> SELECT DATE_FORMAT('2003-10-03',GET_FORMAT(DATE,'EUR'));
-> '03.10.2003'

mysql> SELECT STR_TO_DATE('10.31.2003',GET_FORMAT(DATE,'USA'));
-> '2003-10-31'

• HOUR(time)

Returns the hour for time. The range of the return value is 0 to 23 for time-of-day values. However, the range of TIME values actually is much larger, so HOUR can return values greater than 23. Returns NULL if time is NULL.

mysql> SELECT HOUR('10:05:03');
-> 10
mysql> SELECT HOUR('272:59:59');
-> 272

• LAST_DAY(date)

Takes a date or datetime value and returns the corresponding value for the last day of the month. Returns NULL if the argument is invalid or NULL.

mysql> SELECT LAST_DAY('2003-02-05');
-> '2003-02-28'
mysql> SELECT LAST_DAY('2004-02-05');
-> '2004-02-29'
mysql> SELECT LAST_DAY('2004-01-01 01:01:01');
-> '2004-01-31'
mysql> SELECT LAST_DAY('2003-03-32');
-> NULL

• LOCALTIME, LOCALTIME([fsp])

LOCALTIME and LOCALTIME() are synonyms for NOW().

• LOCALTIMESTAMP, LOCALTIMESTAMP([fsp])

LOCALTIMESTAMP and LOCALTIMESTAMP() are synonyms for NOW().

• MAKEDATE(year, dayofyear)

Returns a date, given year and day-of-year values. dayofyear must be greater than 0 or the result is NULL. The result is also NULL if either argument is NULL.
**Date and Time Functions**

- **MAKETIME(hour, minute, second)**
  Returns a time value calculated from the `hour`, `minute`, and `second` arguments. Returns `NULL` if any of its arguments are `NULL`.
  The `second` argument can have a fractional part.

  ```
  mysql> SELECT MAKETIME(12,15,30);
  -> '12:15:30'
  ```

- **MICROSECOND(expr)**
  Returns the microseconds from the time or datetime expression `expr` as a number in the range from 0 to 999999. Returns `NULL` if `expr` is `NULL`.

  ```
  mysql> SELECT MICROSECOND('12:00:00.123456');
  -> 123456
  mysql> SELECT MICROSECOND('2019-12-31 23:59:59.000010');
  -> 10
  ```

- **MINUTE(time)**
  Returns the minute for `time`, in the range 0 to 59, or `NULL` if `time` is `NULL`.

  ```
  mysql> SELECT MINUTE('2008-02-03 10:05:03');
  -> 5
  ```

- **MONTH(date)**
  Returns the month for `date`, in the range 1 to 12 for January to December, or 0 for dates such as '0000-00-00' or '2008-00-00' that have a zero month part. Returns `NULL` if `date` is `NULL`.

  ```
  mysql> SELECT MONTH('2008-02-03');
  -> 2
  ```

- **MONTHNAME(date)**
  Returns the full name of the month for `date`. The language used for the name is controlled by the value of the `lc_time_names` system variable (Section 10.16, “MySQL Server Locale Support”). Returns `NULL` if `date` is `NULL`.

  ```
  mysql> SELECT MONTHNAME('2008-02-03');
  -> 'February'
  ```

- **NOW([fsp])**
  Returns the current date and time as a value in 'YYYY-MM-DD hh:mm:ss' or 'YYMMDDhhmmss' format, depending on whether the function is used in string or numeric context. The value is expressed in the session time zone.
  If the `fsp` argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

  ```
  mysql> SELECT NOW();
  ```
**NOW()** returns a constant time that indicates the time at which the statement began to execute. (Within a stored function or trigger, **NOW()** returns the time at which the function or triggering statement began to execute.) This differs from the behavior for **SYSDATE()**, which returns the exact time at which it executes.

```sql
mysql> SELECT NOW(), SLEEP(2), NOW();
+---------------------+----------+---------------------+
| NOW()               | SLEEP(2) | NOW()               |
|---------------------+----------+---------------------|
+---------------------+----------+---------------------+
mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
+---------------------+----------+---------------------+
| SYSDATE()           | SLEEP(2) | SYSDATE()           |
|---------------------+----------+---------------------|
+---------------------+----------+---------------------+
```

In addition, the **SET TIMESTAMP** statement affects the value returned by **NOW()** but not by **SYSDATE()**. This means that timestamp settings in the binary log have no effect on invocations of **SYSDATE()**. Setting the timestamp to a nonzero value causes each subsequent invocation of **NOW()** to return that value. Setting the timestamp to zero cancels this effect so that **NOW()** once again returns the current date and time.

See the description for **SYSDATE()** for additional information about the differences between the two functions.

- **PERIOD_ADD** (*P*, *N*)

  Adds *N* months to period *P* (in the format **YYMM** or **YYYYMM**). Returns a value in the format **YYYYMM**.

  ```sql
  mysql> SELECT PERIOD_ADD(200801,2);
  -> 200803
  ```

  - **Note**
    
    The period argument *P* is not a date value.

  This function returns **NULL** if *P* or *N* is **NULL**.

- **PERIOD_DIFF** (*P*1, *P*2)

  Returns the number of months between periods *P*1 and *P*2. *P*1 and *P*2 should be in the format **YYMM** or **YYYYMM**. Note that the period arguments *P*1 and *P*2 are not date values.

  ```sql
  mysql> SELECT PERIOD_DIFF(200802,200703);
  -> 11
  ```

  This function returns **NULL** if *P*1 or *P*2 is **NULL**.

- **QUARTER**(*date*)

  Returns the quarter of the year for *date*, in the range 1 to 4, or **NULL** if *date* is **NULL**.

  ```sql
  mysql> SELECT QUARTER('2008-04-01');
  -> 2
  ```
• **SECOND(time)**

  Returns the second for time, in the range 0 to 59, or NULL if time is NULL.

  
  mysql> SELECT SECOND('10:05:03');
  -> 3

• **SEC_TO_TIME(seconds)**

  Returns the seconds argument, converted to hours, minutes, and seconds, as a TIME value. The range of the result is constrained to that of the TIME data type. A warning occurs if the argument corresponds to a value outside that range.

  The function returns NULL if seconds is NULL.

  mysql> SELECT SEC_TO_TIME(2378);
  -> '00:39:38'
  mysql> SELECT SEC_TO_TIME(2378) + 0;
  -> 3938

• **STR_TO_DATE(str, format)**

  This is the inverse of the DATE_FORMAT() function. It takes a string str and a format string format. STR_TO_DATE() returns a DATETIME value if the format string contains both date and time parts, or a DATE or TIME value if the string contains only date or time parts. If str or format is NULL, the function returns NULL. If the date, time, or datetime value extracted from str cannot be parsed according to the rules followed by the server, STR_TO_DATE() returns NULL and produces a warning.

  The server scans str attempting to match format to it. The format string can contain literal characters and format specifiers beginning with %. Literal characters in format must match literally in str. Format specifiers in format must match a date or time part in str. For the specifiers that can be used in format, see the DATE_FORMAT() function description.

  mysql> SELECT STR_TO_DATE('01,5,2013','%d,%m,%Y');
  -> '2013-05-01'
  mysql> SELECT STR_TO_DATE('May 1, 2013','%M %d,%Y');
  -> '2013-05-01'

  Scanning starts at the beginning of str and fails if format is found not to match. Extra characters at the end of str are ignored.

  mysql> SELECT STR_TO_DATE('a09:30:17','a%h:%i:%s');
  -> '09:30:17'
  mysql> SELECT STR_TO_DATE('a09:30:17','%h:%i:%s');
  -> NULL
  mysql> SELECT STR_TO_DATE('09:30:17a','%h:%i:%s');
  -> '09:30:17'

  Unspecified date or time parts have a value of 0, so incompletely specified values in str produce a result with some or all parts set to 0:

  mysql> SELECT STR_TO_DATE('abc','abc');
  -> '0000-00-00'
  mysql> SELECT STR_TO_DATE('9','%m');
  -> '0000-09-00'
  mysql> SELECT STR_TO_DATE('9','%s');
  -> '00:00:09'

  Range checking on the parts of date values is as described in Section 11.2.2, “The DATE, DATETIME, and TIMESTAMP Types”. This means, for example, that “zero” dates or dates with part values of 0 are permitted unless the SQL mode is set to disallow such values.
If the NO_ZERO_DATE SQL mode is enabled, zero dates are disallowed. In that case, STR_TO_DATE() returns NULL and generates a warning:

```sql
mysql> SET sql_mode = '';
mysql> SELECT STR_TO_DATE('00/00/0000', '%m/%d/%Y');
+---------------------------------------+
| STR_TO_DATE('00/00/0000', '%m/%d/%Y') |
+---------------------------------------+
| 0000-00-00                            |
+---------------------------------------+
mysql> SET sql_mode = 'NO_ZERO_DATE';
mysql> SELECT STR_TO_DATE('00/00/0000', '%m/%d/%Y');
+---------------------------------------+
| STR_TO_DATE('00/00/0000', '%m/%d/%Y') |
| NULL                                  |
+---------------------------------------+
mysql> SHOW WARNINGS;
*************************** 1. row ***************************
Level: Warning
Code: 1411
Message: Incorrect datetime value: '00/00/0000' for function str_to_date
```

In some previous versions of MySQL, it was possible to pass an invalid date string such as '2021-11-31' to this function. In MySQL 8.2.0 (and later Innovation releases), STR_TO_DATE() performs complete range checking and raises an error if the date after conversion would be invalid.

**Note**

You cannot use format "%X%V" to convert a year-week string to a date because the combination of a year and week does not uniquely identify a year and month if the week crosses a month boundary. To convert a year-week to a date, you should also specify the weekday:

```sql
mysql> SELECT STR_TO_DATE('200442 Monday', '%X%V %W');
-> '2004-10-18'
```

You should also be aware that, for dates and the date portions of datetime values, STR_TO_DATE() checks (only) the individual year, month, and day of month values for validity. More precisely, this means that the year is checked to be sure that it is in the range 0-9999 inclusive, the month is checked to ensure that it is in the range 1-12 inclusive, and the day of month is checked to make sure that it is in the range 1-31 inclusive, but the server does not check the values in combination. For example, SELECT STR_TO_DATE('23-2-31', '%Y-%m-%d') returns 2023-02-31. Enabling or disabling the ALLOW_INVALID_DATES server SQL mode has no effect on this behavior. See Section 11.2.2, “The DATE, DATETIME, and TIMESTAMP Types”, for more information.

- **SUBDATE(date, INTERVAL expr unit)**, **SUBDATE(expr, days)**

When invoked with the INTERVAL form of the second argument, SUBDATE() is a synonym for DATE_SUB(). For information on the INTERVAL unit argument, see the discussion for DATE_ADD().

```sql
mysql> SELECT DATE_SUB('2008-01-02', INTERVAL 31 DAY);
-> '2007-12-02'
mysql> SELECT SUBDATE('2008-01-02', INTERVAL 31 DAY);
2299
```
Date and Time Functions

The second form enables the use of an integer value for \textit{days}. In such cases, it is interpreted as the number of days to be subtracted from the date or datetime expression \textit{expr}.

\begin{verbatim}
mysql> SELECT SUBDATE('2008-01-02 12:00:00', 31);
-> '2007-12-02 12:00:00'
\end{verbatim}

This function returns \textbf{NULL} if any of its arguments are \textbf{NULL}.

\begin{itemize}
  \item **SUBTIME(\textit{expr1}, \textit{expr2})**
  \end{itemize}

\textbf{SUBTIME()} returns \textit{expr1} $-$ \textit{expr2} expressed as a value in the same format as \textit{expr1}. \textit{expr1} is a time or datetime expression, and \textit{expr2} is a time expression.

Resolution of this function's return type is performed as it is for the \textbf{ADDTIME()} function; see the description of that function for more information.

\begin{verbatim}
mysql> SELECT SUBTIME('2007-12-31 23:59:59.999999','1 1:1:1.000002');
-> '2007-12-30 22:58:58.999997'
mysql> SELECT SUBTIME('01:00:00.999999', '02:00:00.999998');
-> '-00:59:59.999999'
\end{verbatim}

This function returns \textbf{NULL} if \textit{expr1} or \textit{expr2} is \textbf{NULL}.

\begin{itemize}
  \item **SYSDATE([\textit{fsp}])**
  \end{itemize}

Returns the current date and time as a value in 'YYYY-MM-DD hh:mm:ss' or YYYYMMDDhhmmss format, depending on whether the function is used in string or numeric context.

If the \textit{fsp} argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

\textbf{SYSDATE()} returns the time at which it executes. This differs from the behavior for \textbf{NOW()}, which returns a constant time that indicates the time at which the statement began to execute. (Within a stored function or trigger, \textbf{NOW()} returns the time at which the function or triggering statement began to execute.)

\begin{verbatim}
mysql> SELECT NOW(), SLEEP(2), NOW();
+---------------------+----------+---------------------+
| NOW()               | SLEEP(2) | NOW()               |
+---------------------+----------+---------------------+
+---------------------+----------+---------------------+
mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
+---------------------+----------+---------------------+
| SYSDATE()           | SLEEP(2) | SYSDATE()           |
+---------------------+----------+---------------------+
+---------------------+----------+---------------------+
\end{verbatim}
In addition, the `SET_TIMESTAMP` statement affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`.

Because `SYSDATE()` can return different values even within the same statement, and is not affected by `SET_TIMESTAMP`, it is nondeterministic and therefore unsafe for replication if statement-based binary logging is used. If that is a problem, you can use row-based logging.

Alternatively, you can use the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`. This works if the option is used on both the replication source server and the replica.

The nondeterministic nature of `SYSDATE()` also means that indexes cannot be used for evaluating expressions that refer to it.

### TIME(expr)

Extracts the time part of the time or datetime expression `expr` and returns it as a string. Returns `NULL` if `expr` is `NULL`.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

```sql
mysql> SELECT TIME('2003-12-31 01:02:03');
-> '01:02:03'
```

```sql
mysql> SELECT TIME('2003-12-31 01:02:03.000123');
-> '01:02:03.000123'
```

### TIMEDIFF(expr1, expr2)

`TIMEDIFF()` returns `expr1 - expr2` expressed as a time value. `expr1` and `expr2` are strings which are converted to `TIME` or `DATETIME` expressions; these must be of the same type following conversion. Returns `NULL` if `expr1` or `expr2` is `NULL`.

The result returned by `TIMEDIFF()` is limited to the range allowed for `TIME` values. Alternatively, you can use either of the functions `TIMESTAMPDIFF()` and `UNIX_TIMESTAMP()`, both of which return integers.

```sql
mysql> SELECT TIMEDIFF('2000-01-01 00:00:00', '2000-01-01 00:00:00.000001');
-> '-00:00:00.000001'
```

```sql
mysql> SELECT TIMEDIFF('2008-12-31 23:59:59.000001', '2008-12-30 01:01:01.000002');
-> '46:58:57.999999'
```

### TIMESTAMP(expr), TIMESTAMP(expr1, expr2)

With a single argument, this function returns the date or datetime expression `expr` as a datetime value. With two arguments, it adds the time expression `expr2` to the date or datetime expression `expr1` and returns the result as a datetime value. Returns `NULL` if `expr`, `expr1`, or `expr2` is `NULL`.

```sql
mysql> SELECT TIMESTAMP('2003-12-31 00:00:00');
-> '2003-12-31 00:00:00'
```

```sql
mysql> SELECT TIMESTAMP('2003-12-31 01:01:01', '01:01:01');
-> '2003-12-31 02:02:02'
```
Date and Time Functions

- **TIMESTAMPADD(unit, interval, datetime_expr)**

  Adds the integer expression `interval` to the date or datetime expression `datetime_expr`. The unit for `interval` is given by the `unit` argument, which should be one of the following values: `MICROSECOND` (microseconds), `SECOND`, `MINUTE`, `HOUR`, `DAY`, `WEEK`, `MONTH`, `QUARTER`, or `YEAR`.

  The `unit` value may be specified using one of keywords as shown, or with a prefix of `SQL_TSI_`. For example, `DAY` and `SQL_TSI_DAY` both are legal.

  This function returns `NULL` if `interval` or `datetime_expr` is `NULL`.

  ```
  mysql> SELECT TIMESTAMPADD(MINUTE, 1, '2003-01-02');
  -> '2003-01-02 00:01:00'
  mysql> SELECT TIMESTAMPADD(WEEK,1,'2003-01-02');
  -> '2003-01-09'
  ```

  When adding a `MONTH` interval to a `DATE` or `DATETIME` value, and the resulting date includes a day that does not exist in the given month, the day is adjusted to the last day of the month, as shown here:

  ```
  mysql> SELECT TIMESTAMPADD(MONTH, 1, DATE '2024-03-30') AS t1,
  -> TIMESTAMPADD(MONTH, 1, DATE '2024-03-31') AS t2;
  +------------+------------+
  | t1         | t2         |
  +------------+------------+
  | 2024-04-30 | 2024-04-30 |
  +------------+------------+
  1 row in set (0.00 sec)
  ```

- **TIMESTAMPDIFF(unit, datetime_expr1, datetime_expr2)**

  Returns `datetime_expr2 - datetime_expr1`, where `datetime_expr1` and `datetime_expr2` are date or datetime expressions. One expression may be a date and the other a datetime; a date value is treated as a datetime having the time part `00:00:00` where necessary. The unit for the result (an integer) is given by the `unit` argument. The legal values for `unit` are the same as those listed in the description of the `TIMESTAMPADD()` function.

  This function returns `NULL` if `datetime_expr1` or `datetime_expr2` is `NULL`.

  ```
  mysql> SELECT TIMESTAMPDIFF(MONTH,'2003-02-01','2003-05-01');
  -> 3
  mysql> SELECT TIMESTAMPDIFF(YEAR,'2002-05-01','2001-01-01');
  -> -1
  mysql> SELECT TIMESTAMPDIFF(MINUTE,'2003-02-01','2003-05-01 12:05:55');
  -> 128885
  ```

  **Note**

  The order of the date or datetime arguments for this function is the opposite of that used with the `TIMESTAMP()` function when invoked with 2 arguments.
• **TIME_FORMAT**(time, format)

This is used like the **DATE_FORMAT()** function, but the **format** string may contain format specifiers only for hours, minutes, seconds, and microseconds. Other specifiers produce a NULL or 0. **TIME_FORMAT()** returns NULL if time or format is NULL.

If the time value contains an hour part that is greater than 23, the %H and %k hour format specifiers produce a value larger than the usual range of 0..23. The other hour format specifiers produce the hour value modulo 12.

```sql
mysql> SELECT TIME_FORMAT('100:00:00', '%H %k %h %I %l');
-> '100 100 04 04 4'
```

• **TIME_TO_SEC**(time)

Returns the time argument, converted to seconds. Returns NULL if time is NULL.

```sql
mysql> SELECT TIME_TO_SEC('22:23:00');
-> 80580
mysql> SELECT TIME_TO_SEC('00:39:38');
-> 2378
```

• **TO_DAYS**(date)

Given a date date, returns a day number (the number of days since year 0). Returns NULL if date is NULL.

```sql
mysql> SELECT TO_DAYS(950501);
-> 728779
mysql> SELECT TO_DAYS('2007-10-07');
-> 733321
```

**TO_DAYS()** is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable. See Section 11.2.7, “What Calendar Is Used By MySQL?”, for details.

Remember that MySQL converts two-digit year values in dates to four-digit form using the rules in Section 11.2, “Date and Time Data Types”. For example, '2008-10-07' and '08-10-07' are seen as identical dates:

```sql
mysql> SELECT TO_DAYS('2008-10-07'), TO_DAYS('08-10-07');
-> 733687, 733687
```

In MySQL, the zero date is defined as '0000-00-00', even though this date is itself considered invalid. This means that, for '0000-00-00' and '0000-01-01', **TO_DAYS()** returns the values shown here:

```sql
mysql> SELECT TO_DAYS('0000-00-00');
+-----------------------+
| to_days('0000-00-00') |
+-----------------------+
|                  NULL  |
+-----------------------+
1 row in set, 1 warning (0.00 sec)
```

```sql
mysql> SHOW WARNINGS;
+---------+------+----------------------------------------+
| Level   | Code | Message                                |
+---------+------+----------------------------------------+
| Warning | 1292 | Incorrect datetime value: '0000-00-00' |
+---------+------+----------------------------------------+
1 row in set (0.00 sec)
```
Date and Time Functions

mysql> SELECT TO_DAYS('0000-01-01');
+-----------------------+
| to_days('0000-01-01') |
| 1                     |
+-----------------------+
1 row in set (0.00 sec)

This is true whether or not the ALLOW_INVALID_DATES SQL server mode is enabled.

- **TO_SECONDS(expr)**

Given a date or datetime `expr`, returns the number of seconds since the year 0. If `expr` is not a valid date or datetime value (including NULL), it returns NULL.

```
mysql> SELECT TO_SECONDS(950501);
-> 62966505600
mysql> SELECT TO_SECONDS('2009-11-29');
-> 63426672000
mysql> SELECT TO_SECONDS('2009-11-29 13:43:32');
-> 63426721412
mysql> SELECT TO_SECONDS( NOW() );
-> 63426721458
```

Like `TO_DAYS()`, `TO_SECONDS()` is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable. See Section 11.2.7, "What Calendar Is Used By MySQL?", for details.

Like `TO_DAYS()`, `TO_SECONDS()`, converts two-digit year values in dates to four-digit form using the rules in Section 11.2, "Date and Time Data Types".

In MySQL, the zero date is defined as `’0000-00-00’`, even though this date is itself considered invalid. This means that, for `’0000-00-00’` and `’0000-01-01’`, `TO_SECONDS()` returns the values shown here:

```
mysql> SELECT TO_SECONDS('0000-00-00');
+--------------------------+
| TO_SECONDS('0000-00-00') |
| NULL                    |
+--------------------------+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+---------+------+----------------------------------------+
| Level   | Code | Message                                |
| Warning | 1292 | Incorrect datetime value: ’0000-00-00’ |
+---------+------+----------------------------------------+
1 row in set (0.00 sec)

mysql> SELECT TO_SECONDS('0000-01-01');
+--------------------------+
| TO_SECONDS('0000-01-01') |
| 86400                   |
+--------------------------+
```

This is true whether or not the ALLOW_INVALID_DATES SQL server mode is enabled.

- **UNIX_TIMESTAMP([date])**

If `UNIX_TIMESTAMP()` is called with no `date` argument, it returns a Unix timestamp representing seconds since '1970-01-01 00:00:00' UTC.

If `UNIX_TIMESTAMP()` is called with a `date` argument, it returns the value of the argument as seconds since '1970-01-01 00:00:00' UTC. The server interprets `date` as a value in the session time zone and converts it to an internal Unix timestamp value in UTC. (Clients can set the session time zone as described in Section 5.1.15, “MySQL Server Time Zone Support”.) The `date` argument may be a DATE, DATETIME, or TIMESTAMP string, or a number in YYYYMMDD, YMMDDhhmmss, YYYYMMDD, or YYYYMMDDhhmmss format. If the argument includes a time part, it may optionally include a fractional seconds part.

The return value is an integer if no argument is given or the argument does not include a fractional seconds part, or DECIMAL if an argument is given that includes a fractional seconds part.

When the `date` argument is a TIMESTAMP column, `UNIX_TIMESTAMP()` returns the internal timestamp value directly, with no implicit “string-to-Unix-timestamp” conversion.

The valid range of argument values is the same as for the TIMESTAMP data type: '1970-01-01 00:00:01.000000' UTC to '2038-01-19 03:14:07.999999' UTC for 32-bit platforms; for MySQL running on 64-bit platforms, the valid range of argument values for `UNIX_TIMESTAMP()` is '1970-01-01 00:00:01.000000' UTC to '3001-01-19 03:14:07.999999' UTC (corresponding to 32536771199.999999 seconds).

Regardless of MySQL version or platform architecture, if you pass an out-of-range date to `UNIX_TIMESTAMP()`, it returns 0. If `date` is NULL, it returns NULL.

```sql
mysql> SELECT UNIX_TIMESTAMP();
-> 1447431666

mysql> SELECT UNIX_TIMESTAMP('2015-11-13 10:20:19');
-> 1447431619

mysql> SELECT UNIX_TIMESTAMP('2015-11-13 10:20:19.012');
-> 1447431619.012
```

If you use `UNIX_TIMESTAMP()` and `FROM_UNIXTIME()` to convert between values in a non-UTC time zone and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For example, due to conventions for local time zone changes such as Daylight Saving Time (DST), it is possible for `UNIX_TIMESTAMP()` to map two values that are distinct in a non-UTC time zone to the same Unix timestamp value. `FROM_UNIXTIME()` maps that value back to only one of the original values. Here is an example, using values that are distinct in the MET time zone:

```sql
mysql> SET time_zone = 'MET';

mysql> SELECT UNIX_TIMESTAMP('2005-03-27 03:00:00');
+---------------------+
| UNIX_TIMESTAMP('2005-03-27 03:00:00') |
| 1111885200           |
+---------------------+

mysql> SELECT UNIX_TIMESTAMP('2005-03-27 02:00:00');
+---------------------+
| UNIX_TIMESTAMP('2005-03-27 02:00:00') |
| 1111885200           |
+---------------------+
```
### Date and Time Functions

```sql
mysql> SELECT FROM_UNIXTIME(1111885200);
+---------------------------+
| FROM_UNIXTIME(1111885200) |
+---------------------------+
| 2005-03-27 03:00:00       |
+---------------------------+
```

**Note**

To use named time zones such as 'MET' or 'Europe/Amsterdam', the time zone tables must be properly set up. For instructions, see Section 5.1.15, "MySQL Server Time Zone Support".

If you want to subtract `UNIX_TIMESTAMP()` columns, you might want to cast them to signed integers. See Section 12.10, "Cast Functions and Operators".

- **UTC_DATE, UTC_DATE()**

  Returns the current UTC date as a value in 'YYYY-MM-DD' or 'YYYYMMDD' format, depending on whether the function is used in string or numeric context.

  ```sql
  mysql> SELECT UTC_DATE(), UTC_DATE() + 0;
  -> '2003-08-14', 20030814
  ```

- **UTC_TIME, UTC_TIME([fsp])**

  Returns the current UTC time as a value in 'hh:mm:ss' or 'hhmmss' format, depending on whether the function is used in string or numeric context.

  If the `fsp` argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

  ```sql
  mysql> SELECT UTC_TIME(), UTC_TIME() + 0;
  -> '18:07:53', 180753.000000
  ```

- **UTC_TIMESTAMP, UTC_TIMESTAMP([fsp])**

  Returns the current UTC date and time as a value in 'YYYY-MM-DD hh:mm:ss' or 'YYYYMMDDhhmmss' format, depending on whether the function is used in string or numeric context.

  If the `fsp` argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

  ```sql
  mysql> SELECT UTC_TIMESTAMP(), UTC_TIMESTAMP() + 0;
  -> '2003-08-14 18:08:04', 20030814180804.000000
  ```

- **WEEK(date[, mode])**

  This function returns the week number for `date`. The two-argument form of `WEEK()` enables you to specify whether the week starts on Sunday or Monday and whether the return value should be in the range from 0 to 53 or from 1 to 53. If the `mode` argument is omitted, the value of the
**default_week_format** system variable is used. See Section 5.1.8, “Server System Variables”. For a *NULL* date value, the function returns *NULL*.

The following table describes how the *mode* argument works.

<table>
<thead>
<tr>
<th>Mode</th>
<th>First day of week</th>
<th>Range</th>
<th>Week 1 is the first week ...</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Sunday</td>
<td>0-53</td>
<td>with a Sunday in this year</td>
</tr>
<tr>
<td>1</td>
<td>Monday</td>
<td>0-53</td>
<td>with 4 or more days this year</td>
</tr>
<tr>
<td>2</td>
<td>Sunday</td>
<td>1-53</td>
<td>with a Sunday in this year</td>
</tr>
<tr>
<td>3</td>
<td>Monday</td>
<td>1-53</td>
<td>with 4 or more days this year</td>
</tr>
<tr>
<td>4</td>
<td>Sunday</td>
<td>0-53</td>
<td>with 4 or more days this year</td>
</tr>
<tr>
<td>5</td>
<td>Monday</td>
<td>0-53</td>
<td>with a Monday in this year</td>
</tr>
<tr>
<td>6</td>
<td>Sunday</td>
<td>1-53</td>
<td>with 4 or more days this year</td>
</tr>
<tr>
<td>7</td>
<td>Monday</td>
<td>1-53</td>
<td>with a Monday in this year</td>
</tr>
</tbody>
</table>

For *mode* values with a meaning of “with 4 or more days this year,” weeks are numbered according to ISO 8601:1988:

- If the week containing January 1 has 4 or more days in the new year, it is week 1.
- Otherwise, it is the last week of the previous year, and the next week is week 1.

```sql
mysql> SELECT WEEK('2008-02-20');
-> 7
mysql> SELECT WEEK('2008-02-20',0);   
-> 7
mysql> SELECT WEEK('2008-02-20',1);   
-> 8
mysql> SELECT WEEK('2008-12-31',1);   
-> 53
```

If a date falls in the last week of the previous year, MySQL returns 0 if you do not use 2, 3, 6, or 7 as the optional *mode* argument:

```sql
mysql> SELECT YEAR('2000-01-01'), WEEK('2000-01-01',0);
-> 2000, 0
```

One might argue that `WEEK()` should return 52 because the given date actually occurs in the 52nd week of 1999. `WEEK()` returns 0 instead so that the return value is “the week number in the given year.” This
makes use of the \texttt{WEEK()} function reliable when combined with other functions that extract a date part from a date.

If you prefer a result evaluated with respect to the year that contains the first day of the week for the given date, use 0, 2, 5, or 7 as the optional \textit{mode} argument.

\begin{verbatim}
mysql> SELECT WEEK('2000-01-01',2);
-> 52
\end{verbatim}

Alternatively, use the \texttt{YEARWEEK()} function:

\begin{verbatim}
mysql> SELECT YEARWEEK('2000-01-01');
-> 199952
mysql> SELECT MID(YEARWEEK('2000-01-01'),5,2);
-> '52'
\end{verbatim}

\begin{itemize}
\item \texttt{WEEKDAY(date)}
\end{itemize}

Returns the weekday index for \textit{date} (0 = Monday, 1 = Tuesday, \ldots 6 = Sunday). Returns \texttt{NULL} if \textit{date} is \texttt{NULL}.

\begin{verbatim}
mysql> SELECT WEEKDAY('2008-02-03 22:23:00');
-> 6
mysql> SELECT WEEKDAY('2007-11-06');
-> 1
\end{verbatim}

\begin{itemize}
\item \texttt{WEEKOFYEAR(date)}
\end{itemize}

Returns the calendar week of the date as a number in the range from 1 to 53. Returns \texttt{NULL} if \textit{date} is \texttt{NULL}.

\texttt{WEEKOFYEAR()} is a compatibility function that is equivalent to \texttt{WEEK(date,3)}.

\begin{verbatim}
mysql> SELECT WEEKOFYEAR('2008-02-20');
-> 8
\end{verbatim}

\begin{itemize}
\item \texttt{YEAR(date)}
\end{itemize}

Returns the year for \textit{date}, in the range 1000 to 9999, or 0 for the “zero” date. Returns \texttt{NULL} if \textit{date} is \texttt{NULL}.

\begin{verbatim}
mysql> SELECT YEAR('1987-01-01');
-> 1987
\end{verbatim}

\begin{itemize}
\item \texttt{YEARWEEK(date), YEARWEEK(date,mode)}
\end{itemize}

Returns year and week for a date. The year in the result may be different from the year in the date argument for the first and the last week of the year. Returns \texttt{NULL} if \textit{date} is \texttt{NULL}.

The \textit{mode} argument works exactly like the \textit{mode} argument to \texttt{WEEK()}. For the single-argument syntax, a \textit{mode} value of 0 is used. Unlike \texttt{WEEK()}, the value of \texttt{default_week_format} does not influence \texttt{YEARWEEK()}.

\begin{verbatim}
mysql> SELECT YEARWEEK('1987-01-01');
-> 198652
\end{verbatim}

The week number is different from what the \texttt{WEEK()} function would return (0) for optional arguments 0 or 1, as \texttt{WEEK()} then returns the week in the context of the given year.

12.8 String Functions and Operators
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASCII()</td>
<td>Return numeric value of left-most character</td>
</tr>
<tr>
<td>BIN()</td>
<td>Return a string containing binary representation of a number</td>
</tr>
<tr>
<td>BIT_LENGTH()</td>
<td>Return length of argument in bits</td>
</tr>
<tr>
<td>CHAR()</td>
<td>Return the character for each integer passed</td>
</tr>
<tr>
<td>CHAR_LENGTH()</td>
<td>Return number of characters in argument</td>
</tr>
<tr>
<td>CHARACTER_LENGTH()</td>
<td>Synonym for CHAR_LENGTH()</td>
</tr>
<tr>
<td>CONCAT()</td>
<td>Return concatenated string</td>
</tr>
<tr>
<td>CONCAT_WS()</td>
<td>Return concatenate with separator</td>
</tr>
<tr>
<td>ELT()</td>
<td>Return string at index number</td>
</tr>
<tr>
<td>EXPORT_SET()</td>
<td>Return a string such that for every bit set in the value bits, you get an on string and for every unset bit, you get an off string</td>
</tr>
<tr>
<td>FIELD()</td>
<td>Index (position) of first argument in subsequent arguments</td>
</tr>
<tr>
<td>FIND_IN_SET()</td>
<td>Index (position) of first argument within second argument</td>
</tr>
<tr>
<td>FORMAT()</td>
<td>Return a number formatted to specified number of decimal places</td>
</tr>
<tr>
<td>HEX()</td>
<td>Hexadecimal representation of decimal or string value</td>
</tr>
<tr>
<td>INSERT()</td>
<td>Insert substring at specified position up to specified number of characters</td>
</tr>
<tr>
<td>INSTR()</td>
<td>Return the index of the first occurrence of substring</td>
</tr>
<tr>
<td>LCASE()</td>
<td>Synonym for LOWER()</td>
</tr>
<tr>
<td>LEFT()</td>
<td>Return the leftmost number of characters as specified</td>
</tr>
<tr>
<td>LENGTH()</td>
<td>Return the length of a string in bytes</td>
</tr>
<tr>
<td>LIKE</td>
<td>Simple pattern matching</td>
</tr>
<tr>
<td>LOAD_FILE()</td>
<td>Load the named file</td>
</tr>
<tr>
<td>LOCATE()</td>
<td>Return the position of the first occurrence of substring</td>
</tr>
<tr>
<td>LOWER()</td>
<td>Return the argument in lowercase</td>
</tr>
<tr>
<td>LPAD()</td>
<td>Return the string argument, left-padded with the specified string</td>
</tr>
<tr>
<td>LTRIM()</td>
<td>Remove leading spaces</td>
</tr>
<tr>
<td>MAKE_SET()</td>
<td>Return a set of comma-separated strings that have the corresponding bit in bits set</td>
</tr>
<tr>
<td>MATCH()</td>
<td>Perform full-text search</td>
</tr>
</tbody>
</table>
### String Functions and Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MID()</td>
<td>Return a substring starting from the specified position</td>
</tr>
<tr>
<td>NOT LIKE</td>
<td>Negation of simple pattern matching</td>
</tr>
<tr>
<td>NOT REGEXP</td>
<td>Negation of REGEXP</td>
</tr>
<tr>
<td>OCT()</td>
<td>Return a string containing octal representation of a number</td>
</tr>
<tr>
<td>OCTET_LENGTH()</td>
<td>Synonym for LENGTH()</td>
</tr>
<tr>
<td>ORD()</td>
<td>Return character code for leftmost character of the argument</td>
</tr>
<tr>
<td>POSITION()</td>
<td>Synonym for LOCATE()</td>
</tr>
<tr>
<td>QUOTE()</td>
<td>Escape the argument for use in an SQL statement</td>
</tr>
<tr>
<td>REGEXP</td>
<td>Whether string matches regular expression</td>
</tr>
<tr>
<td>REGEXP_INSTR()</td>
<td>Starting index of substring matching regular expression</td>
</tr>
<tr>
<td>REGEXP_LIKE()</td>
<td>Whether string matches regular expression</td>
</tr>
<tr>
<td>REGEXP_REPLACE()</td>
<td>Replace substrings matching regular expression</td>
</tr>
<tr>
<td>REGEXP_SUBSTR()</td>
<td>Return substring matching regular expression</td>
</tr>
<tr>
<td>REPEAT()</td>
<td>Repeat a string the specified number of times</td>
</tr>
<tr>
<td>REPLACE()</td>
<td>Replace occurrences of a specified string</td>
</tr>
<tr>
<td>REVERSE()</td>
<td>Reverse the characters in a string</td>
</tr>
<tr>
<td>RIGHT()</td>
<td>Return the specified rightmost number of characters</td>
</tr>
<tr>
<td>RLIKE</td>
<td>Whether string matches regular expression</td>
</tr>
<tr>
<td>RPAD()</td>
<td>Append string the specified number of times</td>
</tr>
<tr>
<td>RTRIM()</td>
<td>Remove trailing spaces</td>
</tr>
<tr>
<td>SOUNDEX()</td>
<td>Return a soundex string</td>
</tr>
<tr>
<td>SOUNDS LIKE</td>
<td>Compare sounds</td>
</tr>
<tr>
<td>SPACE()</td>
<td>Return a string of the specified number of spaces</td>
</tr>
<tr>
<td>STRCMP()</td>
<td>Compare two strings</td>
</tr>
<tr>
<td>SUBSTR()</td>

<tr>
<td>WEIGHT_STRING()</td>
<td>Return the weight string for a string</td>
</tr>
</tbody>
</table>
String-valued functions return **NULL** if the length of the result would be greater than the value of the `max_allowed_packet` system variable. See Section 5.1.1, "Configuring the Server".

For functions that operate on string positions, the first position is numbered 1.

For functions that take length arguments, noninteger arguments are rounded to the nearest integer.

- **ASCII**(*str*)

  Returns the numeric value of the leftmost character of the string *str*. Returns 0 if *str* is the empty string. Returns **NULL** if *str* is **NULL**. ASCII() works for 8-bit characters.

  ```
  mysql> SELECT ASCII('2');
  -> 50
  mysql> SELECT ASCII(2);
  -> 50
  mysql> SELECT ASCII('dx');
  -> 100
  
  See also the **ORD**() function.
  ```

- **BIN**(*N*)

  Returns a string representation of the binary value of *N*, where *N* is a longlong (BIGINT) number. This is equivalent to `CONV(N,10,2)` . Returns **NULL** if *N* is **NULL**.

  ```
  mysql> SELECT BIN(12);
  -> '1100'
  ```

- **BIT_LENGTH**(*str*)

  Returns the length of the string *str* in bits. Returns **NULL** if *str* is **NULL**.

  ```
  mysql> SELECT BIT_LENGTH('text');
  -> 32
  ```

- **CHAR**(*N*,... [USING charset_name])

  **CHAR**() interprets each argument *N* as an integer and returns a string consisting of the characters given by the code values of those integers. **NULL** values are skipped.

  ```
  mysql> SELECT CHAR(77,121,83,81,'76');
  +--------------------------------------------------+
  | CHAR(77,121,83,81,'76')                          |
  +--------------------------------------------------+
  | 0x4D7953514C                                     |
  +--------------------------------------------------+
  1 row in set (0.00 sec)
  mysql> SELECT CHAR(77,77.3,'77.3');
  +--------------------------------------------+
  | CHAR(77,77.3,'77.3')                       |
  +--------------------------------------------+
  | 0x4D4D                                   |
  +--------------------------------------------+
  1 row in set (0.00 sec)
  
  By default, **CHAR**() returns a binary string. To produce a string in a given character set, use the optional **USING** clause:

  ```
  mysql> SELECT CHAR(77,121,83,81,'76' USING utf8mb4);
  +---------------------------------------+
  | CHAR(77,121,83,81,'76' USING utf8mb4) |
  +---------------------------------------+
  ```
If `USING` is given and the result string is illegal for the given character set, a warning is issued. Also, if strict SQL mode is enabled, the result from `CHAR()` becomes `NULL`.

If `CHAR()` is invoked from within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 4.5.1, “`mysql` — The MySQL Command-Line Client”.

`CHAR()` arguments larger than 255 are converted into multiple result bytes. For example, `CHAR(256)` is equivalent to `CHAR(1,0)`, and `CHAR(256*256)` is equivalent to `CHAR(1,0,0)`:

```sql
mysql> SELECT HEX(CHAR(1,0)), HEX(CHAR(256));
+----------------+----------------+
| HEX(CHAR(1,0)) | HEX(CHAR(256)) |
+----------------+----------------+
| 0100           | 0100           |
+----------------+----------------+
1 row in set (0.00 sec)
mysql> SELECT HEX(CHAR(1,0,0)), HEX(CHAR(256*256));
+------------------+--------------------+
| HEX(CHAR(1,0,0)) | HEX(CHAR(256*256)) |
+------------------+--------------------+
| 010000           | 010000             |
+------------------+--------------------+
1 row in set (0.00 sec)
```

- **CHAR_LENGTH(str)**

  Returns the length of the string `str`, measured in code points. A multibyte character counts as a single code point. This means that, for a string containing two 3-byte characters, `LENGTH()` returns 6, whereas `CHAR_LENGTH()` returns 2, as shown here:

```sql
mysql> SET @dolphin:='海豚';
Query OK, 0 rows affected (0.01 sec)
mysql> SELECT LENGTH(@dolphin), CHAR_LENGTH(@dolphin);
+------------------+-----------------------+
| LENGTH(@dolphin) | CHAR_LENGTH(@dolphin) |
+------------------+-----------------------+
|                6 |                     2 |
+------------------+-----------------------+
```

<td>Returns the <code>N</code>th element of the list of strings: <code>str1</code> if <code>N = 1</code>, <code>str2</code> if <code>N = 2</code>, and so on.</td>
<td><code>ELT()</code> returns the <code>N</code>th element of the list of strings: <code>str1</code> if <code>N = 1</code>, <code>str2</code> if <code>N = 2</code> , and so on. Returns <strong>NULL</strong> if <code>N</code> is less than <code>1</code>, greater than the number of arguments, or <strong>NULL</strong>. <code>ELT()</code> is the complement of <code>FIELD()</code> .</td>
</tr>
</tbody>
</table>
String Functions and Operators

- **EXPORT_SET**

  Returns a string such that for every bit set in the value \textit{bits}, you get an \textit{on} string and for every bit not set in the value, you get an \textit{off} string. Bits in \textit{bits} are examined from right to left (from low-order to high-order bits). Strings are added to the result from left to right, separated by the \textit{separator} string (the default being the comma character, \texttt{,}). The number of bits examined is given by \textit{number_of_bits}, which has a default of 64 if not specified. \textit{number_of_bits} is silently clipped to 64 if larger than 64. It is treated as an unsigned integer, so a value of $-1$ is effectively the same as 64.

  ```
  mysql> SELECT EXPORT_SET(5, 'Y', 'N', ',', 4);
  -> 'Y,N,Y,N'
  mysql> SELECT EXPORT_SET(6, '1', '0', ',', 10);
  -> '0,1,1,0,0,0,0,0,0,0'
  ```

- **FIELD**

  Returns the index (position) of \textit{str} in the \textit{str1, str2, str3, ...} list. Returns 0 if \textit{str} is not found.

  If all arguments to \textit{FIELD() are strings, all arguments are compared as strings. If all arguments are numbers, they are compared as numbers. Otherwise, the arguments are compared as double.}

  If \textit{str} is NULL, the return value is 0 because NULL fails equality comparison with any value. \textit{FIELD()} is the complement of \textit{ELT()}.

  ```
  mysql> SELECT FIELD('Bb', 'Aa', 'Bb', 'Cc', 'Dd', 'Ff');
  -> 2
  mysql> SELECT FIELD('Gg', 'Aa', 'Bb', 'Cc', 'Dd', 'Ff');
  -> 0
  ```

- **FIND_IN_SET**

  Returns a value in the range of 1 to \textit{N} if the string \textit{str} is in the string list \textit{strlist} consisting of \textit{N} substrings. A string list is a string composed of substrings separated by \texttt{,} characters. If the first argument is a constant string and the second is a column of type SET, the \textit{FIND_IN_SET()} function is optimized to use bit arithmetic. Returns 0 if \textit{str} is not in \textit{strlist} or if \textit{strlist} is the empty string. Returns NULL if either argument is NULL. This function does not work properly if the first argument contains a comma (\texttt{,}) character.

  ```
  mysql> SELECT FIND_IN_SET('b','a,b,c,d');
  -> 2
  ```

- **FORMAT**

  Formats the number \textit{X} to a format like '\#,\#,\#,\#.\#', rounded to \textit{D} decimal places, and returns the result as a string. If \textit{D} is 0, the result has no decimal point or fractional part. If \textit{X} or \textit{D} is NULL, the function returns NULL.

  The optional third parameter enables a locale to be specified to be used for the result number's decimal point, thousands separator, and grouping between separators. Permissible locale values are the same as the legal values for the \texttt{lc_time_names} system variable (see Section 10.16, "MySQL Server Locale Support"). If the locale is NULL or not specified, the default locale is 'en_US'.

  ```
  mysql> SELECT FORMAT(12332.123456, 4);
  -> '12,332.1235'
  mysql> SELECT FORMAT(12332.1,4);
  -> '12,332.1000'
  mysql> SELECT FORMAT(12332.2,0);
  -> '12,332'
  mysql> SELECT FORMAT(12332.2,2,'de_DE');
  -> '12.332,20'
  ```
String Functions and Operators

- **FROM_BASE64**

  Takes a string encoded with the base-64 encoded rules used by `TO_BASE64()` and returns the decoded result as a binary string. The result is **NULL** if the argument is **NULL** or not a valid base-64 string. See the description of `TO_BASE64()` for details about the encoding and decoding rules.

  ```sql
  mysql> SELECT TO_BASE64('abc'), FROM_BASE64(TO_BASE64('abc'));
  -> 'JWJj', 'abc'
  ```

  If `FROM_BASE64()` is invoked from within the `mysql` client, binary strings display using hexadecimal notation. You can disable this behavior by setting the value of the `--binary-as-hex` to 0 when starting the `mysql` client. For more information about that option, see Section 4.5.1, "mysql — The MySQL Command-Line Client".

- **HEX**

  For a string argument `str`, `HEX()` returns a hexadecimal string representation of `str` where each byte of each character in `str` is converted to two hexadecimal digits. (Multibyte characters therefore become more than two digits.) The inverse of this operation is performed by the `UNHEX()` function.

  For a numeric argument `N`, `HEX()` returns a hexadecimal string representation of the value of `N` treated as a longlong (BIGINT) number. This is equivalent to `CONV(N,10,16)`. The inverse of this operation is performed by `CONV(HEX(N),16,10)`.

  For a **NULL** argument, this function returns **NULL**.

  ```sql
  mysql> SELECT X'616263', HEX('abc'), UNHEX(HEX('abc'));
  -> 'abc', 616263, 'abc'
  ```

- **INSERT**

  Returns the string `str`, with the substring beginning at position `pos` and `len` characters long replaced by the string `newstr`. Returns the original string if `pos` is not within the length of the string. Replaces the rest of the string from position `pos` if `len` is not within the length of the rest of the string. Returns **NULL** if any argument is **NULL**.

  ```sql
  mysql> SELECT INSERT('Quadratic', 3, 4, 'What');
  -> 'QuWhattic'
  ```

  This function is multibyte safe.

- **INSTR**

  Returns the position of the first occurrence of substring `substr` in string `str`. This is the same as the two-argument form of `LOCATE()`, except that the order of the arguments is reversed.

  ```sql
  mysql> SELECT INSTR('foobarbar', 'bar');
  -> 4
  ```

  This function is multibyte safe, and is case-sensitive only if at least one argument is a binary string. If either argument is **NULL**, this function returns **NULL**.
String Functions and Operators

- **LCASE**(str)**

  LCASE() is a synonym for LOWER().

  LCASE() used in a view is rewritten as LOWER() when storing the view's definition. (Bug #12844279)

- **LEFT**(str, len)**

  Returns the leftmost len characters from the string str, or NULL if any argument is NULL.

  ```
  mysql> SELECT LEFT('foobarbar', 5);
  -> 'fooba'
  ```

  This function is multibyte safe.

- **LENGTH**(str)**

  Returns the length of the string str, measured in bytes. A multibyte character counts as multiple bytes. This means that for a string containing five 2-byte characters, LENGTH() returns 10, whereas CHAR_LENGTH() returns 5. Returns NULL if str is NULL.

  ```
  mysql> SELECT LENGTH('text');
  -> 4
  ```

  **Note**

  The Length() OpenGIS spatial function is named ST_Length() in MySQL.

- **LOAD_FILE**(file_name)**

  Reads the file and returns the file contents as a string. To use this function, the file must be located on the server host, you must specify the full path name to the file, and you must have the FILE privilege. The file must be readable by the server and its size less than max_allowed_packet bytes. If the secure_file_priv system variable is set to a nonempty directory name, the file to be loaded must be located in that directory.

  If the file does not exist or cannot be read because one of the preceding conditions is not satisfied, the function returns NULL.

  The character_set_filesystem system variable controls interpretation of file names that are given as literal strings.

  ```
  mysql> UPDATE t
  SET blob_col=LOAD_FILE('/tmp/picture')
  WHERE id=1;
  ```

- **LOCATE**(substr, str), LOCATE(substr, str, pos)**

  The first syntax returns the position of the first occurrence of substring substr in string str. The second syntax returns the position of the first occurrence of substring substr in string str, starting at position pos. Returns 0 if substr is not in str. Returns NULL if any argument is NULL.

  ```
  mysql> SELECT LOCATE('bar', 'foobebar');
  -> 4
  mysql> SELECT LOCATE('xbar', 'foobebar');
  -> 0
  mysql> SELECT LOCATE('bar', 'foobebar', 5);
  -> 7
  ```

  This function is multibyte safe, and is case-sensitive only if at least one argument is a binary string.
String Functions and Operators

- **LOWER(str)**

  Returns the string *str* with all characters changed to lowercase according to the current character set mapping, or NULL if *str* is NULL. The default character set is utf8mb4.

  ```
  mysql> SELECT LOWER('QUADRATICALLY');
  -> 'quadratically'
  ```

  LOWER() (and UPPER()) are ineffective when applied to binary strings (BINARY, VARBINARY, BLOB). To perform lettercase conversion of a binary string, first convert it to a nonbinary string using a character set appropriate for the data stored in the string:

  ```
  mysql> SET @str = BINARY 'New York';
  mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING utf8mb4));
  +-------------+------------------------------------+
  | LOWER(@str) | LOWER(CONVERT(@str USING utf8mb4)) |
  +-------------+------------------------------------+
  | New York    | new york                           |
  +-------------+------------------------------------+
  ```

  For collations of Unicode character sets, LOWER() and UPPER() work according to the Unicode Collation Algorithm (UCA) version in the collation name, if there is one, and UCA 4.0.0 if no version is specified. For example, utf8mb4_0900_ai_ci and utf8mb3_unicode_520_ci work according to UCA 9.0.0 and 5.2.0, respectively, whereas utf8mb3_unicode_ci works according to UCA 4.0.0. See Section 10.10.1, “Unicode Character Sets”.

  This function is multibyte safe.

- **LCASE()** used within views is rewritten as LOWER().

- **LPAD(str, len, padstr)**

  Returns the string *str*, left-padded with the string *padstr* to a length of *len* characters. If *str* is longer than *len*, the return value is shortened to *len* characters.

  ```
  mysql> SELECT LPAD('hi',4,'??');
  -> '??hi'
  mysql> SELECT LPAD('hi',1,'??');
  -> 'h'
  ```

  Returns NULL if any of its arguments are NULL.

- **LTRIM(str)**

  Returns the string *str* with leading space characters removed. Returns NULL if *str* is NULL.

  ```
  mysql> SELECT LTRIM('  barbar');
  -> 'barbar'
  ```

  This function is multibyte safe.

- **MAKE_SET(bits, str1, str2, ...)**

  Returns a set value (a string containing substrings separated by , characters) consisting of the strings that have the corresponding bit in *bits* set. *str1* corresponds to bit 0, *str2* to bit 1, and so on. NULL values in *str1, str2, ...* are not appended to the result.

  ```
  mysql> SELECT MAKE_SET(1,'a','b','c');
  -> 'a'
  mysql> SELECT MAKE_SET(1 | 4,'hello','nice','world');
  -> 'hello,world'
  ```

2317
String Functions and Operators

- **MID**(str, pos, len)

  MID**(str, pos, len)** is a synonym for SUBSTRING**(str, pos, len)**.

- **OCT**(N)

  Returns a string representation of the octal value of **N**, where **N** is a longlong (**BIGINT**) number. This is equivalent to **CONV**(N, 10, 8). Returns NULL if **N** is NULL.

  ```
  mysql> SELECT OCT(12);
  -> '14'
  ```

- **OCTET_LENGTH**(str)

  OCTET_LENGTH() is a synonym for LENGTH().

- **ORD**(str)

  If the leftmost character of the string **str** is a multibyte character, returns the code for that character, calculated from the numeric values of its constituent bytes using this formula:

  \[
  \text{(1st byte code)} + (\text{2nd byte code} \times 256) + (\text{3rd byte code} \times 256^2) \ldots
  \]

  If the leftmost character is not a multibyte character, **ORD()** returns the same value as the **ASCII()** function. The function returns NULL if **str** is NULL.

  ```
  mysql> SELECT ORD('2');
  -> 50
  ```

- **POSITION**(substr IN str)

  POSITION**(substr IN str)** is a synonym for LOCATE**(substr, str)**.

- **QUOTE**(str)

  Quotes a string to produce a result that can be used as a properly escaped data value in an SQL statement. The string is returned enclosed by single quotation marks and with each instance of backslash (\), single quote ('), ASCII NUL, and Control+Z preceded by a backslash. If the argument is NULL, the return value is the word “NULL” without enclosing single quotation marks.

  ```
  mysql> SELECT QUOTE('Don\'t!');
  -> 'Don\'t!'
  ```

  For comparison, see the quoting rules for literal strings and within the C API in Section 9.1.1, “String Literals”, and mysql_real_escape_string_quote().

- **REPEAT**(str, count)

  Returns a string consisting of the string **str** repeated **count** times. If **count** is less than 1, returns an empty string. Returns NULL if **str** or **count** is NULL.

  ```
  mysql> SELECT REPEAT('MySQL', 3);
  ```
String Functions and Operators

• REPLACE(str, from_str, to_str)

Returns the string str with all occurrences of the string from_str replaced by the string to_str. REPLACE() performs a case-sensitive match when searching for from_str.

mysql> SELECT REPLACE('www.mysql.com', 'w', 'Ww');
-> 'WwWwWw.mysql.com'

This function is multibyte safe. It returns NULL if any of its arguments are NULL.

• REVERSE(str)

Returns the string str with the order of the characters reversed, or NULL if str is NULL.

mysql> SELECT REVERSE('abc');
-> 'cba'

This function is multibyte safe.

• RIGHT(str, len)

Returns the rightmost len characters from the string str, or NULL if any argument is NULL.

mysql> SELECT RIGHT('foobarbar', 4);
-> 'rbar'

This function is multibyte safe.

• RPAD(str, len, padstr)

Returns the string str, right-padded with the string padstr to a length of len characters. If str is longer than len, the return value is shortened to len characters. If str, padstr, or len is NULL, the function returns NULL.

mysql> SELECT RPAD('hi',5,'?');
-> 'hi???'

mysql> SELECT RPAD('hi',1,'?');
-> 'h'

This function is multibyte safe.

• RTRIM(str)

Returns the string str with trailing space characters removed.

mysql> SELECT RTRIM('barbar   ');
-> 'barbar'

This function is multibyte safe, and returns NULL if str is NULL.

• SOUNDEX(str)

Returns a soundex string from str, or NULL if str is NULL. Two strings that sound almost the same should have identical soundex strings. A standard soundex string is four characters long, but the SOUNDEX() function returns an arbitrarily long string. You can use SUBSTRING() on the result to get
a standard soundex string. All nonalphabetic characters in \textit{str} are ignored. All international alphabetic characters outside the A-Z range are treated as vowels.

\begin{itemize}
\item \textbf{Important}

When using \texttt{SOUNDEX()}, you should be aware of the following limitations:

\begin{itemize}
\item This function, as currently implemented, is intended to work well with strings that are in the English language only. Strings in other languages may not produce reliable results.
\item This function is not guaranteed to provide consistent results with strings that use multibyte character sets, including utf-8. See Bug \#22638 for more information.
\end{itemize}

\begin{Verbatim}
\sql> SELECT SOUNDEX('Hello');
-> 'H400'
\sql> SELECT SOUNDEX('Quadratically');
-> 'Q36324'
\end{Verbatim}

\item \textbf{Note}

This function implements the original Soundex algorithm, not the more popular enhanced version (also described by D. Knuth). The difference is that original version discards vowels first and duplicates second, whereas the enhanced version discards duplicates first and vowels second.

\begin{itemize}
\item \texttt{expr1 SOUNDS LIKE expr2}

This is the same as \texttt{SOUNDEX(expr1) = SOUNDEX(expr2)}.
\item \texttt{SPACE(N)}

Returns a string consisting of \texttt{N} space characters, or \texttt{NULL} if \texttt{N} is \texttt{NULL}.

\begin{Verbatim}
\sql> SELECT SPACE(6);
-> '      '
\end{Verbatim}
\item \texttt{SUBSTR(str,pos), SUBSTR(str FROM pos), SUBSTR(str,pos,len), SUBSTR(str FROM pos FOR len)}

\texttt{SUBSTR()} is a synonym for \texttt{SUBSTRING()}.  
\item \texttt{SUBSTRING(str,pos), SUBSTRING(str FROM pos), SUBSTRING(str,pos,len), SUBSTRING(str FROM pos FOR len)}

The forms without a \texttt{len} argument return a substring from string \texttt{str} starting at position \texttt{pos}. The forms with a \texttt{len} argument return a substring \texttt{len} characters long from string \texttt{str}, starting at position \texttt{pos}. The forms that use \texttt{FROM} are standard SQL syntax. It is also possible to use a negative value for \texttt{pos}. In this case, the beginning of the substring is \texttt{pos} characters from the end of the string, rather than the beginning. A negative value may be used for \texttt{pos} in any of the forms of this function. A value of 0 for \texttt{pos} returns an empty string.

For all forms of \texttt{SUBSTRING()}, the position of the first character in the string from which the substring is to be extracted is reckoned as 1.

\begin{Verbatim}
\sql> SELECT SUBSTRING('Quadratically',5);
-> 'ratically'
\sql> SELECT SUBSTRING('foobarbar' FROM 4);
-> 'barbar'
\sql> SELECT SUBSTRING('Quadratically',5,6);
\end{Verbatim}
String Functions and Operators

```
-> 'atica'
mysql> SELECT SUBSTRING('Sakila', -3);
-> 'ila'
mysql> SELECT SUBSTRING('Sakila', -5, 3);
-> 'aki'
mysql> SELECT SUBSTRING('Sakila' FROM -4 FOR 2);
-> 'ki'
```

This function is multibyte safe. It returns `NULL` if any of its arguments are `NULL`.

If `len` is less than 1, the result is the empty string.

- **SUBSTRING_INDEX**(str, delim, count)

  Returns the substring from string `str` before `count` occurrences of the delimiter `delim`. If `count` is positive, everything to the left of the final delimiter (counting from the left) is returned. If `count` is negative, everything to the right of the final delimiter (counting from the right) is returned.

  `SUBSTRING_INDEX()` performs a case-sensitive match when searching for `delim`.

```
mysql> SELECT SUBSTRING_INDEX('www.mysql.com', '.', 2);
-> 'www.mysql'
mysql> SELECT SUBSTRING_INDEX('www.mysql.com', '.', -2);
-> 'mysql.com'
```

This function is multibyte safe.

`SUBSTRING_INDEX()` returns `NULL` if any of its arguments are `NULL`.

- **TO_BASE64**(str)

  Converts the string argument to base-64 encoded form and returns the result as a character string with the connection character set and collation. If the argument is not a string, it is converted to a string before conversion takes place. The result is `NULL` if the argument is `NULL`. Base-64 encoded strings can be decoded using the `FROM_BASE64()` function.

```
mysql> SELECT TO_BASE64('abc'), FROM_BASE64(TO_BASE64('abc'));
-> 'JWJj', 'abc'
```

Different base-64 encoding schemes exist. These are the encoding and decoding rules used by `TO_BASE64()` and `FROM_BASE64()`:

- The encoding for alphabet value 62 is `+'.
- The encoding for alphabet value 63 is `/`.
- Encoded output consists of groups of 4 printable characters. Each 3 bytes of the input data are encoded using 4 characters. If the last group is incomplete, it is padded with `=' characters to a length of 4.
- A newline is added after each 76 characters of encoded output to divide long output into multiple lines.
- Decoding recognizes and ignores newline, carriage return, tab, and space.

- **TRIM([{BOTH | LEADING | TRAILING} [remstr] FROM] str), TRIM([remstr FROM] str)**

  Returns the string `str` with all `remstr` prefixes or suffixes removed. If none of the specifiers `BOTH`, `LEADING`, or `TRAILING` is given, `BOTH` is assumed. `remstr` is optional and, if not specified, spaces are removed.

```
mysql> SELECT TRIM(' bar ');
```
This function is multibyte safe. It returns NULL if any of its arguments are NULL.

- **UCASE(str)**

  `UCASE()` is a synonym for `UPPER()`.

  `UCASE()` used within views is rewritten as `UPPER()`.

- **UNHEX(str)**

  For a string argument `str`, `UNHEX(str)` interprets each pair of characters in the argument as a hexadecimal number and converts it to the byte represented by the number. The return value is a binary string.

  mysql> SELECT UNHEX('4D7953514C');
  -> 'MySQL'

  mysql> SELECT HEX('string');
  -> 'string'

  mysql> SELECT HEX(UNHEX('1267'));
  -> '1267'

  The characters in the argument string must be legal hexadecimal digits: '0' .. '9', 'A' .. 'F', 'a' .. 'f'. If the argument contains any nonhexadecimal digits, or is itself NULL, the result is NULL:

  mysql> SELECT UNHEX('GG');
  +---------------+
  | UNHEX('GG')   |
  +---------------+
  | NULL          |
  +---------------+

  mysql> SELECT UNHEX(NULL);
  +---------------+
  | UNHEX(NULL)   |
  +---------------+
  | NULL          |
  +---------------+

  A NULL result can also occur if the argument to `UNHEX()` is a BINARY column, because values are padded with 0x00 bytes when stored but those bytes are not stripped on retrieval. For example, '41' is stored into a CHAR(3) column as '41 ' and retrieved as '41 ' (with the trailing pad space stripped), so `UNHEX()` for the column value returns X'41'. By contrast, '41' is stored into a BINARY(3) column as '41\0' and retrieved as '41\0' (with the trailing pad 0x00 byte not stripped). '\0' is not a legal hexadecimal digit, so `UNHEX()` for the column value returns NULL.

  For a numeric argument `N`, the inverse of `HEX(N)` is not performed by `UNHEX()`. Use `CONV(HEX(N),16,10)` instead. See the description of `HEX()`.

  If `UNHEX()` is invoked from within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

2322
String Functions and Operators

• **UPPER**(str)

  Returns the string `str` with all characters changed to uppercase according to the current character set mapping, or `NULL` if `str` is `NULL`. The default character set is `utf8mb4`.

  ```sql
  mysql> SELECT UPPER('Hej');
  -> 'HEJ'
  ```

  See the description of **LOWER()** for information that also applies to **UPPER()**. This included information about how to perform lettercase conversion of binary strings (`BINARY`, `VARBINARY`, `BLOB`) for which these functions are ineffective, and information about case folding for Unicode character sets.

  This function is multibyte safe.

  **UCASE()** used within views is rewritten as **UPPER()**.

• **WEIGHT_STRING**(str `[AS {CHAR|BINARY}(N)] [flags]`)

  This function returns the weight string for the input string. The return value is a binary string that represents the comparison and sorting value of the string, or `NULL` if the argument is `NULL`. It has these properties:

  • If `WEIGHT_STRING(str1) = WEIGHT_STRING(str2)`, then `str1 = str2` (`str1` and `str2` are considered equal)

  • If `WEIGHT_STRING(str1) < WEIGHT_STRING(str2)`, then `str1 < str2` (`str1` sorts before `str2`)

  **WEIGHT_STRING()** is a debugging function intended for internal use. Its behavior can change without notice between MySQL versions. It can be used for testing and debugging of collations, especially if you are adding a new collation. See Section 10.14, “Adding a Collation to a Character Set”.

  This list briefly summarizes the arguments. More details are given in the discussion following the list.

  • `str`: The input string expression.

  • `AS` clause: Optional; cast the input string to a given type and length.

  • `flags`: Optional; unused.

  The input string, `str`, is a string expression. If the input is a nonbinary (character) string such as a `CHAR`, `VARCHAR`, or `TEXT` value, the return value contains the collation weights for the string. If the input is a binary (byte) string such as a `BINARY`, `VARBINARY`, or `BLOB` value, the return value is the same as the input (the weight for each byte in a binary string is the byte value). If the input is `NULL`, **WEIGHT_STRING()** returns `NULL`.

  Examples:

  ```sql
  mysql> SET @s = _utf8mb4 'AB' COLLATE utf8mb4_0900_ai_ci;
  mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
  +------+---------+------------------------+
  | @s   | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
  +------+---------+------------------------+
  | AB   | 4142    | 1C471C60               |
  +------+---------+------------------------+
  mysql> SET @s = _utf8mb4 'ab' COLLATE utf8mb4_0900_ai_ci;
  mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
  +------+---------+------------------------+
  | @s   | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
  +------+---------+------------------------+
  | AB   | 4142    | 1C471C60               |
  +------+---------+------------------------+
  ```
The preceding examples use `HEX()` to display the `WEIGHT_STRING()` result. Because the result is a binary value, `HEX()` can be especially useful when the result contains nonprinting values, to display it in printable form:

```sql
mysql> SET @s = CONVERT(X'C39F' USING utf8mb4) COLLATE utf8mb4_czech_ci;
```
```
mysql> SELECT HEX(WEIGHT_STRING(@s));
+-------------------------------------+
<table>
<thead>
<tr>
<th>HEX(WEIGHT_STRING(@s))</th>
</tr>
</thead>
<tbody>
<tr>
<td>0FEA0FEA</td>
</tr>
</tbody>
</table>
+-------------------------------------+
```

For non-NULL return values, the data type of the value is `VARBINARY` if its length is within the maximum length for `VARBINARY`, otherwise the data type is `BLOB`.

The `AS` clause may be given to cast the input string to a nonbinary or binary string and to force it to a given length:

- **`AS CHAR(N)`** casts the string to a nonbinary string and pads it on the right with spaces to a length of `N` characters. `N` must be at least 1. If `N` is less than the length of the input string, the string is truncated to `N` characters. No warning occurs for truncation.

- **`AS BINARY(N)`** is similar but casts the string to a binary string, `N` is measured in bytes (not characters), and padding uses `0x00` bytes (not spaces).
The flags clause currently is unused.

If WEIGHT_STRING() is invoked from within the mysql client, binary strings display using hexadecimal notation, depending on the value of the --binary-as-hex. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

### 12.8.1 String Comparison Functions and Operators

#### Table 12.13 String Comparison Functions and Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LIKE</td>
<td>Simple pattern matching</td>
</tr>
<tr>
<td>NOT LIKE</td>
<td>Negation of simple pattern matching</td>
</tr>
<tr>
<td>STRCMP()</td>
<td>Compare two strings</td>
</tr>
</tbody>
</table>

If a string function is given a binary string as an argument, the resulting string is also a binary string. A number converted to a string is treated as a binary string. This affects only comparisons.

Normally, if any expression in a string comparison is case-sensitive, the comparison is performed in case-sensitive fashion.

If a string function is invoked from within the mysql client, binary strings display using hexadecimal notation, depending on the value of the --binary-as-hex. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

- expr LIKE pat [ESCAPE 'escape_char']

Pattern matching using an SQL pattern. Returns 1 (TRUE) or 0 (FALSE). If either expr or pat is NULL, the result is NULL.

The pattern need not be a literal string. For example, it can be specified as a string expression or table column. In the latter case, the column must be defined as one of the MySQL string types (see Section 11.3, “String Data Types”).

Per the SQL standard, LIKE performs matching on a per-character basis, thus it can produce results different from the = comparison operator:

```
mysql> SELECT 'ä' LIKE 'ae' COLLATE latin1_german2_ci;
+---------------+------------+
| 'ä' LIKE 'ae' COLLATE latin1_german2_ci |   0         |
|---------------+------------|
mysql> SELECT 'ä' = 'ae' COLLATE latin1_german2_ci;
+---------------+------------+
| 'ä' = 'ae' COLLATE latin1_german2_ci |   1         |
|---------------+------------|
```

In particular, trailing spaces are always significant. This differs from comparisons performed with the = operator, for which the significance of trailing spaces in nonbinary strings (CHAR, VARCHAR, and TEXT values) depends on the pad attribute of the collation used for the comparison. For more information, see Trailing Space Handling in Comparisons.
With `LIKE` you can use the following two wildcard characters in the pattern:

- `%` matches any number of characters, even zero characters.
- `_` matches exactly one character.

```sql
mysql> SELECT 'David!' LIKE 'David_';
-> 1
mysql> SELECT 'David!' LIKE '%D%v%';
-> 1
```

To test for literal instances of a wildcard character, precede it by the escape character. If you do not specify the `ESCAPE` character, `\` is assumed, unless the `NO_BACKSLASH_ESCAPES` SQL mode is enabled. In that case, no escape character is used.

- `\%` matches one `%` character.
- `\_` matches one `_` character.

```sql
mysql> SELECT 'David!' LIKE 'David\_';
-> 0
mysql> SELECT 'David_' LIKE 'David\_';
-> 1
```

To specify a different escape character, use the `ESCAPE` clause:

```sql
mysql> SELECT 'David_' LIKE 'David|_' ESCAPE '|';
-> 1
```

The escape sequence should be one character long to specify the escape character, or empty to specify that no escape character is used. The expression must evaluate as a constant at execution time. If the `NO_BACKSLASH_ESCAPES` SQL mode is enabled, the sequence cannot be empty.

The following statements illustrate that string comparisons are not case-sensitive unless one of the operands is case-sensitive (uses a case-sensitive collation or is a binary string):

```sql
mysql> SELECT 'abc' LIKE 'ABC';
-> 1
mysql> SELECT 'abc' LIKE _utf8mb4 'ABC' COLLATE utf8mb4_0900_as_cs;
-> 0
mysql> SELECT 'abc' LIKE _utf8mb4 'ABC' COLLATE utf8mb4_bin;
-> 0
mysql> SELECT 'abc' LIKE BINARY 'ABC';
-> 0
```

As an extension to standard SQL, MySQL permits `LIKE` on numeric expressions.

```sql
mysql> SELECT 10 LIKE '1%';
-> 1
```

MySQL attempts in such cases to perform implicit conversion of the expression to a string. See Section 12.3, "Type Conversion in Expression Evaluation".

---

**Note**

MySQL uses C escape syntax in strings (for example, \n to represent the newline character). If you want a `LIKE` string to contain a literal \, you must double it. (Unless the `NO_BACKSLASH_ESCAPES` SQL mode is enabled, in which case no escape character is used.) For example, to search for \n, specify it as ```\n```. To search for \, specify it as ```\\```. This is because the backslashes are
stripped once by the parser and again when the pattern match is made, leaving a single backslash to be matched against.

Exception: At the end of the pattern string, backslash can be specified as `\`. At the end of the string, backslash stands for itself because there is nothing following to escape. Suppose that a table contains the following values:

```sql
mysql> SELECT filename FROM t1;
+--------------+
| filename     |
+--------------+
| C:           |
| C:\          |
| C:\Programs  |
| C:\Programs\|
+--------------+
```

To test for values that end with backslash, you can match the values using either of the following patterns:

```sql
mysql> SELECT filename, filename LIKE '%\' FROM t1;
+--------------+---------------------+
| filename     | filename LIKE '%\' |
+--------------+---------------------+
| C:           |                    0 |
| C:\          |                    1 |
| C:\Programs  |                    0 |
| C:\Programs\|                    1 |
+--------------+---------------------+
mysql> SELECT filename, filename LIKE '%\\' FROM t1;
+--------------+-----------------------+
| filename     | filename LIKE '%\\' |
+--------------+-----------------------+
| C:           |                     0 |
| C:\          |                     1 |
| C:\Programs  |                     0 |
| C:\Programs\|                     1 |
+--------------+-----------------------+
```

- `expr NOT LIKE pat [ESCAPE 'escape_char']`

  This is the same as `NOT (expr LIKE pat [ESCAPE 'escape_char'])`.

**Note**

Aggregate queries involving `NOT LIKE` comparisons with columns containing `NULL` may yield unexpected results. For example, consider the following table and data:

```sql
CREATE TABLE foo (bar VARCHAR(10));
INSERT INTO foo VALUES (NULL), (NULL);
```

The query `SELECT COUNT(*) FROM foo WHERE bar LIKE '%baz%';` returns 0. You might assume that `SELECT COUNT(*) FROM foo WHERE bar NOT LIKE '%baz%';` would return 2. However, this is not the case: The second query returns 0. This is because `NULL NOT LIKE expr` always returns `NULL`, regardless of the value of `expr`. The same is true for aggregate queries involving...
NULL and comparisons using NOT RLIKE or NOT REGEXP. In such cases, you must test explicitly for NOT NULL using OR (and not AND), as shown here:

```sql
SELECT COUNT(*) FROM foo WHERE bar NOT LIKE '%baz%' OR bar IS NULL;
```

- **STRCMP(expr1, expr2)**

  **STRCMP()** returns 0 if the strings are the same, -1 if the first argument is smaller than the second according to the current sort order, and NULL if either argument is NULL. It returns 1 otherwise.

  ```sql
  mysql> SELECT STRCMP('text', 'text2');
  -> -1
  mysql> SELECT STRCMP('text2', 'text');
  -> 1
  mysql> SELECT STRCMP('text', 'text');
  -> 0
  ```

  **STRCMP()** performs the comparison using the collation of the arguments.

  ```sql
  mysql> SET @s1 = _utf8mb4 'x' COLLATE utf8mb4_0900_ai_ci;
  mysql> SET @s2 = _utf8mb4 'X' COLLATE utf8mb4_0900_ai_ci;
  mysql> SET @s3 = _utf8mb4 'x' COLLATE utf8mb4_0900_as_cs;
  mysql> SET @s4 = _utf8mb4 'X' COLLATE utf8mb4_0900_as_cs;
  mysql> SELECT STRCMP(@s1, @s2), STRCMP(@s3, @s4);
  +------------------ +------------------+
  | STRCMP(@s1, @s2) | STRCMP(@s3, @s4) |
  +------------------ +------------------+
  |                0  |               -1 |
  +------------------ +------------------+
  ```

  If the collations are incompatible, one of the arguments must be converted to be compatible with the other. See Section 10.8.4, “Collation Coercibility in Expressions”.

  ```sql
  mysql> SET @s1 = _utf8mb4 'x' COLLATE utf8mb4_0900_ai_ci;
  mysql> SET @s2 = _utf8mb4 'X' COLLATE utf8mb4_0900_ai_ci;
  mysql> SET @s3 = _utf8mb4 'x' COLLATE utf8mb4_0900_as_cs;
  mysql> SET @s4 = _utf8mb4 'X' COLLATE utf8mb4_0900_as_cs;
  mysql> SELECT STRCMP(@s1, @s3);
  ERROR 1267 (HY000): Illegal mix of collations (utf8mb4_0900_ai_ci, IMPLICIT) and (utf8mb4_0900_as_cs, IMPLICIT) for operation 'strcmp'
  +------------------ +------------------+
  | STRCMP(@s1, @s3 COLLABE utf8mb4_0900_ai_ci) |
  +------------------ +------------------+
  |                0  |               -1 |
  +------------------ +------------------+
  ```

### 12.8.2 Regular Expressions

**Table 12.14 Regular Expression Functions and Operators**

Regular Expressions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RLIKE</td>
<td>Whether string matches regular expression</td>
</tr>
</tbody>
</table>

A regular expression is a powerful way of specifying a pattern for a complex search. This section discusses the functions and operators available for regular expression matching and illustrates, with examples, some of the special characters and constructs that can be used for regular expression operations. See also Section 3.3.4.7, “Pattern Matching”.

MySQL implements regular expression support using International Components for Unicode (ICU), which provides full Unicode support and is multibyte safe.

Use of a binary string with any of the MySQL regular expression functions is rejected with ER_CHARACTER_SET_MISMATCH.

- **Regular Expression Function and Operator Descriptions**
- **Regular Expression Syntax**
- **Regular Expression Resource Control**

### Regular Expression Function and Operator Descriptions

- $expr$ NOT REGEXP $pat$, $expr$ NOT RLIKE $pat$

  This is the same as NOT ($expr$ REGEXP $pat$).

- $expr$ REGEXP $pat$, $expr$ RLIKE $pat$

  Returns 1 if the string $expr$ matches the regular expression specified by the pattern $pat$, 0 otherwise. If $expr$ or $pat$ is NULL, the return value is NULL.

  REGEXP and RLIKE are synonyms for REGEXP_LIKE().

  For additional information about how matching occurs, see the description for REGEXP_LIKE().

  ```sql
  mysql> SELECT 'Michael!' REGEXP '.*';
  +------------------------+
  | 'Michael!' REGEXP '.*' |
  +------------------------+
  |                      1 |
  +------------------------+
  mysql> SELECT 'new\n*line' REGEXP 'new\*.\*line';
  +---------------------------------------+
  | 'new\n*line' REGEXP 'new\*.\*line'     |
  +---------------------------------------+
  |                                     0 |
  +---------------------------------------+
  mysql> SELECT 'a' REGEXP '^[a-d]';
  +---------------------+
  | 'a' REGEXP '^[a-d]'  |
  +---------------------+
  |                   1 |
  +---------------------+
  
  • REGEXP_INSTR($expr$, $pat$[, $pos$[, occurrence[, return_option[, match_type]]]]))

  Returns the starting index of the substring of the string $expr$ that matches the regular expression specified by the pattern $pat$, 0 if there is no match. If $expr$ or $pat$ is NULL, the return value is NULL. Character indexes begin at 1.

  REGEXP_INSTR() takes these optional arguments:
• **pos**: The position in `expr` at which to start the search. If omitted, the default is 1.

• **occurrence**: Which occurrence of a match to search for. If omitted, the default is 1.

• **return_option**: Which type of position to return. If this value is 0, `REGEXP_INSTR()` returns the position of the matched substring's first character. If this value is 1, `REGEXP_INSTR()` returns the position following the matched substring. If omitted, the default is 0.

• **match_type**: A string that specifies how to perform matching. The meaning is as described for `REGEXP_LIKE()`.

For additional information about how matching occurs, see the description for `REGEXP_LIKE()`.
Regular Expressions

• REGEXP_LIKE(expr, pat[, match_type])

Returns 1 if the string expr matches the regular expression specified by the pattern pat, 0 otherwise. If expr or pat is NULL, the return value is NULL.

The pattern can be an extended regular expression, the syntax for which is discussed in Regular Expression Syntax. The pattern need not be a literal string. For example, it can be specified as a string expression or table column.

The optional match_type argument is a string that may contain any or all the following characters specifying how to perform matching:

• c: Case-sensitive matching.
• i: Case-insensitive matching.
• m: Multiple-line mode. Recognize line terminators within the string. The default behavior is to match line terminators only at the start and end of the string expression.
• n: The . character matches line terminators. The default is for . matching to stop at the end of a line.
• u: Unix-only line endings. Only the newline character is recognized as a line ending by the ., ^, and $ match operators.

If characters specifying contradictory options are specified within match_type, the rightmost one takes precedence.

By default, regular expression operations use the character set and collation of the expr and pat arguments when deciding the type of a character and performing the comparison. If the arguments have different character sets or collations, coercibility rules apply as described in Section 10.8.4, “Collation Coercibility in Expressions”. Arguments may be specified with explicit collation indicators to change comparison behavior.

```
mysql> SELECT REGEXP_LIKE('CamelCase', 'CAMELCASE');
+---------------------------------------+
| REGEXP_LIKE('CamelCase', 'CAMELCASE') | 1 |
|---------------------------------------|

mysql> SELECT REGEXP_LIKE('CamelCase', 'CAMELCASE' COLLATE utf8mb4_0900_as_cs);
+------------------------------------------------------------------+
| REGEXP_LIKE('CamelCase', 'CAMELCASE' COLLATE utf8mb4_0900_as_cs) | 0 |
|------------------------------------------------------------------|
```

match_type may be specified with the c or i characters to override the default case sensitivity. Exception: If either argument is a binary string, the arguments are handled in case-sensitive fashion as binary strings, even if match_type contains the i character.

---

Note

MySQL uses C escape syntax in strings (for example, \n to represent the newline character). If you want your expr or pat argument to contain a literal \n, you must double it. (Unless the NO_BACKSLASH_ESCAPES SQL mode is enabled, in which case no escape character is used.)

```
mysql> SELECT REGEXP_LIKE('Michael!', '\.*');
+-------------------------------+
<table>
<thead>
<tr>
<th>REGEXP_LIKE('Michael!', '.*')</th>
</tr>
</thead>
</table>
```

2331
Regular Expressions

<table>
<thead>
<tr>
<th>REGEXP_LIKE('Michael!', '.*')</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql&gt; SELECT REGEXP_LIKE('new\n<em>line', 'new\n</em>line');</td>
<td></td>
</tr>
<tr>
<td>REGEXP_LIKE('new\n<em>line', 'new\n</em>line')</td>
<td>0</td>
</tr>
<tr>
<td>mysql&gt; SELECT REGEXP_LIKE('a', '^[a-d]');</td>
<td></td>
</tr>
<tr>
<td>REGEXP_LIKE('a', '^[a-d]')</td>
<td>1</td>
</tr>
<tr>
<td>mysql&gt; SELECT REGEXP_LIKE('abc', 'ABC');</td>
<td></td>
</tr>
<tr>
<td>REGEXP_LIKE('abc', 'ABC')</td>
<td>1</td>
</tr>
<tr>
<td>mysql&gt; SELECT REGEXP_LIKE('abc', 'ABC', 'c');</td>
<td></td>
</tr>
<tr>
<td>REGEXP_LIKE('abc', 'ABC', 'c')</td>
<td>0</td>
</tr>
</tbody>
</table>

- REGEXP_REPLACE(expr, pat, repl[, pos[, occurrence[, match_type]]])

  Replaces occurrences in the string expr that match the regular expression specified by the pattern pat with the replacement string repl, and returns the resulting string. If expr, pat, or repl is NULL, the return value is NULL.

  REGEXP_REPLACE() takes these optional arguments:

  - pos: The position in expr at which to start the search. If omitted, the default is 1.
  - occurrence: Which occurrence of a match to replace. If omitted, the default is 0 (which means “replace all occurrences”).
  - match_type: A string that specifies how to perform matching. The meaning is as described for REGEXP_LIKE().

  The result returned by this function uses the character set and collation of the expression searched for matches.

  For additional information about how matching occurs, see the description for REGEXP_LIKE().

| mysql> SELECT REGEXP_REPLACE('a b c', 'b', 'X'); |
| REGEXP_REPLACE('a b c', 'b', 'X') |
| a X c |
| mysql> SELECT REGEXP_REPLACE('abc def ghi', '[a-z]+', 'X', 1, 3); |
| REGEXP_REPLACE('abc def ghi', '[a-z]+', 'X', 1, 3) |
| abc def X |
Regular Expressions

- **REGEXP_SUBSTR(expr, pat[, pos[, occurrence[, match_type]]])**

  Returns the substring of the string `expr` that matches the regular expression specified by the pattern `pat`. If `expr` or `pat` is NULL, the return value is NULL.

  **REGEXP_SUBSTR()** takes these optional arguments:
  - `pos`: The position in `expr` at which to start the search. If omitted, the default is 1.
  - `occurrence`: Which occurrence of a match to search for. If omitted, the default is 1.
  - `match_type`: A string that specifies how to perform matching. The meaning is as described for `REGEXP_LIKE()`.

  The result returned by this function uses the character set and collation of the expression searched for matches.

  For additional information about how matching occurs, see the description for `REGEXP_LIKE()`.

  ```sql
  mysql> SELECT REGEXP_SUBSTR('abc def ghi', '[a-z]+');
  +----------------------------------------+
  | REGEXP_SUBSTR('abc def ghi', '[a-z]+') |
  +----------------------------------------+
  | abc                                    |
  +----------------------------------------+
  mysql>
  mysql> SELECT REGEXP_SUBSTR('abc def ghi', '[a-z]+', 1, 3);
  +----------------------------------------------+
  | REGEXP_SUBSTR('abc def ghi', '[a-z]+', 1, 3) |
  +----------------------------------------------+
  | ghi                                          |
  +----------------------------------------------+
  ```

**Regular Expression Syntax**

A regular expression describes a set of strings. The simplest regular expression is one that has no special characters in it. For example, the regular expression `hello` matches `hello` and nothing else.

Nontrivial regular expressions use certain special constructs so that they can match more than one string. For example, the regular expression `hello|world` contains the | alternation operator and matches either the `hello` or `world`.

As a more complex example, the regular expression `B[an]*s` matches any of the strings `Bananas`, `Baaaaas`, `Bs`, and any other string starting with a `B`, ending with an `s`, and containing any number of `a` or `n` characters in between.

The following list covers some of the basic special characters and constructs that can be used in regular expressions. For information about the full regular expression syntax supported by the ICU library used to implement regular expression support, visit the International Components for Unicode web site.

- `^` Match the beginning of a string.

  ```sql
  mysql> SELECT REGEXP_LIKE('fo
fo', '^fo$'); -> 0
  mysql> SELECT REGEXP_LIKE('fofo', '^fo'); -> 1
  ```

- `$` Match the end of a string.

  ```sql
  mysql> SELECT REGEXP_LIKE('fo
o', '^fo
o$'); -> 1
  ```
Regular Expressions

- .
  
  Match any character (including carriage return and newline, although to match these in the middle of a string, the \n (multiple line) match-control character or the (?m) within-pattern modifier must be given).

- a*
  
  Match any sequence of zero or more a characters.

- a+
  
  Match any sequence of one or more a characters.

- a?
  
  Match either zero or one a character.

- de|abc
  
  Alternation; match either of the sequences de or abc.

- (abc)*
  
  Match zero or more instances of the sequence abc.

- \{1, 2, 3\}
  
  Repetition; \{n\} and \{m, n\} notation provide a more general way of writing regular expressions that match many occurrences of the previous atom (or "piece") of the pattern. m and n are integers.

- a*
  
  Can be written as a\{0,\}.
Regular Expressions

- **a+**
  
  Can be written as \( a(1,\)\).

- **a?**
  
  Can be written as \( a(0,1)\).

To be more precise, \( a(n) \) matches exactly \( n \) instances of \( a \). \( a(n, ) \) matches \( n \) or more instances of \( a \). \( a(m,n) \) matches \( m \) through \( n \) instances of \( a \), inclusive. If both \( m \) and \( n \) are given, \( m \) must be less than or equal to \( n \).

```
mysql> SELECT REGEXP_LIKE('abcde', 'a[bcd]{2}e'); -> 0
mysql> SELECT REGEXP_LIKE('abcde', 'a[bcd]{3}e'); -> 1
mysql> SELECT REGEXP_LIKE('abcde', 'a[bcd]{1,10}e'); -> 1
```

- **[a-dX], [^a-dX]**

  Matches any character that is (or is not, if \(^\) is used) either \( a, b, c, d \) or \( X \). A – character between two other characters forms a range that matches all characters from the first character to the second. For example, \([0-9]\) matches any decimal digit. To include a literal \( ] \) character, it must immediately follow the opening bracket \([ \). To include a literal \( \) character, it must be written first or last. Any character that does not have a defined special meaning inside a \([ \) pair matches only itself.

```
mysql> SELECT REGEXP_LIKE('aXbc', '[a-dXYZ]'); -> 1
mysql> SELECT REGEXP_LIKE('aXbc', '^[^a-dXYZ]$'); -> 0
mysql> SELECT REGEXP_LIKE('aXbc', '\^[^a-dXYZ]+$'); -> 1
mysql> SELECT REGEXP_LIKE('gheis', '\^[^a-dXYZ]+$'); -> 0
mysql> SELECT REGEXP_LIKE('gheisa', '\^[^a-dXYZ]+$'); -> 0
```

- **[=character_class=]**

  Within a bracket expression (written using \([ \) and \( ] \)), \([=character_class=] \) represents an equivalence class. It matches all characters with the same collation value, including itself. For example, if \( o \) and \( (+) \) are the members of an equivalence class, \([=o]=\), \([=+(]=\), and \([o+(]=\) are all synonymous. An equivalence class may not be used as an endpoint of a range.

- **[::character_class:]**

  Within a bracket expression (written using \([ \) and \( ] \)), \([::character_class:] \) represents a character class that matches all characters belonging to that class. The following table lists the standard class names. These names stand for the character classes defined in the \(\text{ctype}(3)\) manual page. A particular locale may provide other class names. A character class may not be used as an endpoint of a range.

<table>

</tbody>
</table>

mysql> SELECT REGEXP_LIKE('justalnums', '[:alnum:]+');  -> 1
mysql> SELECT REGEXP_LIKE('!!', '[:alnum:]+');           -> 0

To use a literal instance of a special character in a regular expression, precede it by two backslash (\) characters. The MySQL parser interprets one of the backslashes, and the regular expression library interprets the other. For example, to match the string 1+2 that contains the special + character, only the last of the following regular expressions is the correct one:

mysql> SELECT REGEXP_LIKE('1+2', '1+2');               -> 0
mysql> SELECT REGEXP_LIKE('1+2', '1\+2');              -> 0
mysql> SELECT REGEXP_LIKE('1+2', '1\\+2');             -> 1

Regular Expression Resource Control

REGEXP_LIKE() and similar functions use resources that can be controlled by setting system variables:

- The match engine uses memory for its internal stack. To control the maximum available memory for the stack in bytes, set the `regexp_stack_limit` system variable.

- The match engine operates in steps. To control the maximum number of steps performed by the engine (and thus indirectly the execution time), set the `regexp_time_limit` system variable. Because this limit is expressed as number of steps, it affects execution time only indirectly. Typically, it is on the order of milliseconds.

12.8.3 Character Set and Collation of Function Results

MySQL has many operators and functions that return a string. This section answers the question: What is the character set and collation of such a string?

For simple functions that take string input and return a string result as output, the output's character set and collation are the same as those of the principal input value. For example, `UPPER(X)` returns a string with the same character string and collation as `X`. The same applies for `INSTR()`, `LCASE()`, `LOWER()`, `LTRIM()`, `MID()`, `REPEAT()`, `REPLACE()`, `REVERSE()`, `RIGHT()`, `RPAD()`, `RTRIM()`, `SOUNDEX()`, `SUBSTRING()`, `TRIM()`, `UCASE()`, and `UPPER()`.

Note
The `REPLACE()` function, unlike all other functions, always ignores the collation of the string input and performs a case-sensitive comparison.

If a string input or function result is a binary string, the string has the `binary` character set and collation. This can be checked by using the `CHARSET()` and `COLLATION()` functions, both of which return `binary` for a binary string argument:

mysql> SELECT CHARSET(BINARY 'a'), COLLATION(BINARY 'a');
+---------------------+-----------------------+
| CHARSET(BINARY 'a') | COLLATION(BINARY 'a') |
|---------------------+-----------------------|
| binary              | binary                |

2336
Full-Text Search Functions

For operations that combine multiple string inputs and return a single string output, the “aggregation rules” of standard SQL apply for determining the collation of the result:

- If an explicit `COLLATE Y` occurs, use `Y`.
- If explicit `COLLATE Y` and `COLLATE Z` occur, raise an error.
- Otherwise, if all collations are `Y`, use `Y`.
- Otherwise, the result has no collation.

For example, with `CASE ... WHEN a THEN b WHEN b THEN c COLLATE X END`, the resulting collation is `X`. The same applies for `UNION`, `||`, `CONCAT()`, `ELT()`, `GREATEST()`, `IF()`, and `LEAST()`.

For operations that convert to character data, the character set and collation of the strings that result from the operations are defined by the `character_set_connection` and `collation_connection` system variables that determine the default connection character set and collation (see Section 10.4, “Connection Character Sets and Collations”). This applies only to `BIN_TO_UUID()`, `CAST()`, `CONV()`, `FORMAT()`, `HEX()`, and `SPACE()`.

An exception to the preceding principle occurs for expressions for virtual generated columns. In such expressions, the table character set is used for `BIN_TO_UUID()`, `CONV()`, or `HEX()` results, regardless of connection character set.

If there is any question about the character set or collation of the result returned by a string function, use the `CHARSET()` or `COLLATION()` function to find out:

```
mysql> SELECT USER(), CHARSET(USER()), COLLATION(USER());
+----------------+-----------------+--------------------+
| USER()         | CHARSET(USER()) | COLLATION(USER())  |
+----------------+-----------------+--------------------+
| test@localhost | utf8mb3         | utf8mb3_general_ci |
+----------------+-----------------+--------------------+
mysql> SELECT CHARSET(COMPRESS('abc')), COLLATION(COMPRESS('abc'));
+--------------------------+----------------------------+
| CHARSET(COMPRESS('abc')) | COLLATION(COMPRESS('abc')) |
+--------------------------+----------------------------+
| binary                   | binary                     |
+--------------------------+----------------------------+
```

12.9 Full-Text Search Functions

MATCH (coll1, col2, ...) AGAINST (expr [search_modifier])

search_modifier:

```
{ IN NATURAL LANGUAGE MODE |
  IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION |
  IN BOOLEAN MODE |
  WITH QUERY EXPANSION }
```

MySQL has support for full-text indexing and searching:

- A full-text index in MySQL is an index of type `FULLTEXT`.
- Full-text indexes can be used only with `InnoDB` or `MyISAM` tables, and can be created only for `CHAR`, `VARCHAR`, or `TEXT` columns.
Full-Text Search Functions

- MySQL provides a built-in full-text ngram parser that supports Chinese, Japanese, and Korean (CJK), and an installable MeCab full-text parser plugin for Japanese. Parsing differences are outlined in Section 12.9.8, “ngram Full-Text Parser”, and Section 12.9.9, “MeCab Full-Text Parser Plugin”.

- A `FULLTEXT` index definition can be given in the `CREATE TABLE` statement when a table is created, or added later using `ALTER TABLE` or `CREATE INDEX`.

- For large data sets, it is much faster to load your data into a table that has no `FULLTEXT` index and then create the index after that, than to load data into a table that has an existing `FULLTEXT` index.

Full-text searching is performed using `MATCH()` AGAINST() syntax. `MATCH()` takes a comma-separated list that names the columns to be searched. `AGAINST` takes a string to search for, and an optional modifier that indicates what type of search to perform. The search string must be a string value that is constant during query evaluation. This rules out, for example, a table column because that can differ for each row.

MySQL does not permit the use of a rollup column with `MATCH()`; more specifically, any query matching all of the criteria listed here is rejected with `ER_FULLTEXT_WITH_ROLLUP`:

- `MATCH()` appears in the `SELECT` list, `GROUP BY` clause, `HAVING` clause, or `ORDER BY` clause of a query block.

- The query block contains a `GROUP BY ... WITH ROLLUP` clause.

- The argument of the call to the `MATCH()` function is one of the grouping columns.

Some examples of such queries are shown here:

```
# MATCH() in SELECT list...
SELECT MATCH (a) AGAINST ('abc') FROM t GROUP BY a WITH ROLLUP;
SELECT 1 FROM t GROUP BY a, MATCH (a) AGAINST ('abc') WITH ROLLUP;

# ...in HAVING clause...
SELECT 1 FROM t GROUP BY a WITH ROLLUP HAVING MATCH (a) AGAINST ('abc');

# ...and in ORDER BY clause
SELECT 1 FROM t GROUP BY a WITH ROLLUP ORDER BY MATCH (a) AGAINST ('abc');
```

The use of `MATCH()` with a rollup column in the `WHERE` clause is permitted.

There are three types of full-text searches:

- A natural language search interprets the search string as a phrase in natural human language (a phrase in free text). There are no special operators, with the exception of double quote (”) characters. The stopword list applies. For more information about stopword lists, see Section 12.9.4, “Full-Text Stopwords”.

  Full-text searches are natural language searches if the `IN NATURAL LANGUAGE MODE` modifier is given or if no modifier is given. For more information, see Section 12.9.1, “Natural Language Full-Text Searches”.

- A boolean search interprets the search string using the rules of a special query language. The string contains the words to search for. It can also contain operators that specify requirements such that a word must be present or absent in matching rows, or that it should be weighted higher or lower than usual. Certain common words (stopwords) are omitted from the search index and do not match if present in the search string. The `IN BOOLEAN MODE` modifier specifies a boolean search. For more information, see Section 12.9.2, “Boolean Full-Text Searches”.

- A query expansion search is a modification of a natural language search. The search string is used to perform a natural language search. Then words from the most relevant rows returned by the search are
added to the search string and the search is done again. The query returns the rows from the second search. The IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION or WITH QUERY EXPANSION modifier specifies a query expansion search. For more information, see Section 12.9.3, “Full-Text Searches with Query Expansion”.

For information about FULLTEXT query performance, see Section 8.3.5, “Column Indexes”.

For more information about InnoDB FULLTEXT indexes, see Section 15.6.2.4, “InnoDB Full-Text Indexes”.

Constraints on full-text searching are listed in Section 12.9.5, “Full-Text Restrictions”.

The myisam_ftdump utility dumps the contents of a MyISAM full-text index. This may be helpful for debugging full-text queries. See Section 4.6.3, “myisam_ftdump — Display Full-Text Index information”.

### 12.9.1 Natural Language Full-Text Searches

By default or with the IN NATURAL LANGUAGE MODE modifier, the MATCH() function performs a natural language search for a string against a text collection. A collection is a set of one or more columns included in a FULLTEXT index. The search string is given as the argument to AGAINST(). For each row in the table, MATCH() returns a relevance value; that is, a similarity measure between the search string and the text in that row in the columns named in the MATCH() list.

```sql
mysql> CREATE TABLE articles (  
    -> id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,  
    -> title VARCHAR(200),  
    -> body TEXT,  
    -> FULLTEXT (title,body)  
    -> ) ENGINE=InnoDB;
Query OK, 0 rows affected (0.08 sec)
```

```sql
mysql> INSERT INTO articles (title,body) VALUES  
    -> ('MySQL Tutorial','DBMS stands for DataBase ...'),  
    -> ('How To Use MySQL Well','After you went through a ...'),  
    -> ('Optimizing MySQL','In this tutorial, we show ...'),  
    -> ('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),  
    -> ('MySQL vs. YourSQL','In the following database comparison ...'),  
    -> ('MySQL Security','When configured properly, MySQL ...');
Query OK, 6 rows affected (0.01 sec)
```

```sql
mysql> SELECT * FROM articles  
    -> WHERE MATCH (title,body) AGAINST ('database' IN NATURAL LANGUAGE MODE);
```

<table>
<thead>
<tr>
<th>id</th>
<th>title</th>
<th>body</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>MySQL Tutorial</td>
<td>DBMS stands forDataBase ...</td>
</tr>
<tr>
<td>5</td>
<td>MySQL vs. YourSQL</td>
<td>In the following database comparison ...</td>
</tr>
</tbody>
</table>

2 rows in set (0.00 sec)

By default, the search is performed in case-insensitive fashion. To perform a case-sensitive full-text search, use a case-sensitive or binary collation for the indexed columns. For example, a column that uses the utf8mb4 character set of can be assigned a collation of utf8mb4_0900_as_cs or utf8mb4_bin to make it case-sensitive for full-text searches.

When MATCH() is used in a WHERE clause, as in the example shown earlier, the rows returned are automatically sorted with the highest relevance first as long as the following conditions are met:

- There must be no explicit ORDER BY clause.
Natural Language Full-Text Searches

- The search must be performed using a full-text index scan rather than a table scan.
- If the query joins tables, the full-text index scan must be the leftmost non-constant table in the join.

Given the conditions just listed, it is usually less effort to specify using `ORDER BY` an explicit sort order when one is necessary or desired.

Relevance values are nonnegative floating-point numbers. Zero relevance means no similarity. Relevance is computed based on the number of words in the row (document), the number of unique words in the row, the total number of words in the collection, and the number of rows that contain a particular word.

**Note**

The term “document” may be used interchangeably with the term “row”, and both terms refer to the indexed part of the row. The term “collection” refers to the indexed columns and encompasses all rows.

To simply count matches, you could use a query like this:

```sql
mysql> SELECT COUNT(*) FROM articles
    -> WHERE MATCH (title,body)
    -> AGAINST ('database' IN NATURAL LANGUAGE MODE);
```

<table>
<thead>
<tr>
<th>COUNT(*)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
</tr>
</tbody>
</table>

1 row in set (0.00 sec)

You might find it quicker to rewrite the query as follows:

```sql
mysql> SELECT
    -> COUNT(IF(MATCH (title,body) AGAINST ('database' IN NATURAL LANGUAGE MODE), 1, NULL))
    -> AS count
    -> FROM articles;
```

<table>
<thead>
<tr>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
</tr>
</tbody>
</table>

1 row in set (0.03 sec)

The first query does some extra work (sorting the results by relevance) but also can use an index lookup based on the `WHERE` clause. The index lookup might make the first query faster if the search matches few rows. The second query performs a full table scan, which might be faster than the index lookup if the search term was present in most rows.

For natural-language full-text searches, the columns named in the `MATCH()` function must be the same columns included in some `FULLTEXT` index in your table. For the preceding query, note that the columns named in the `MATCH()` function (`title` and `body`) are the same as those named in the definition of the `article` table's `FULLTEXT` index. To search the `title` or `body` separately, you would create separate `FULLTEXT` indexes for each column.

You can also perform a boolean search or a search with query expansion. These search types are described in Section 12.9.2, “Boolean Full-Text Searches”, and Section 12.9.3, “Full-Text Searches with Query Expansion”.

A full-text search that uses an index can name columns only from a single table in the `MATCH()` clause because an index cannot span multiple tables. For `MyISAM` tables, a boolean search can be done in the absence of an index (albeit more slowly), in which case it is possible to name columns from multiple tables.
Natural Language Full-Text Searches

The preceding example is a basic illustration that shows how to use the MATCH() function where rows are returned in order of decreasing relevance. The next example shows how to retrieve the relevance values explicitly. Returned rows are not ordered because the SELECT statement includes neither WHERE nor ORDER BY clauses:

```sql
mysql> SELECT id, MATCH (title,body) -> AGAINST ('Tutorial' IN NATURAL LANGUAGE MODE) AS score -> FROM articles;
```

```
+----+---------------------+
| id | score               |
+----+---------------------+
|  1 | 0.22764469683170319 |
|  3 | 0.22764469683170319 |
|  4 | 0                   |
|  5 | 0                   |
|  6 | 0                   |
+----+---------------------+
6 rows in set (0.00 sec)
```

The following example is more complex. The query returns the relevance values and it also sorts the rows in order of decreasing relevance. To achieve this result, specify MATCH() twice: once in the SELECT list and once in the WHERE clause. This causes no additional overhead, because the MySQL optimizer notices that the two MATCH() calls are identical and invokes the full-text search code only once.

```sql
mysql> SELECT id, body, MATCH (title,body) -> AGAINST ('Security implications of running MySQL as root' -> IN NATURAL LANGUAGE MODE) AS score -> FROM articles -> WHERE MATCH (title,body) -> AGAINST('Security implications of running MySQL as root' -> IN NATURAL LANGUAGE MODE);
```

```
+----+-------------------------------------+-----------------+
| id | body                                | score           |
+----+-------------------------------------+-----------------+
|  4 | 1. Never run mysqld as root. 2. ... | 1.5219271183014 |
|  6 | When configured properly, MySQL ... | 1.3114095926285 |
+----+-------------------------------------+-----------------+
2 rows in set (0.00 sec)
```

A phrase that is enclosed within double quote (""") characters matches only rows that contain the phrase literally, as it was typed. The full-text engine splits the phrase into words and performs a search in the FULLTEXT index for the words. Nonword characters need not be matched exactly: Phrase searching requires only that matches contain exactly the same words as the phrase and in the same order. For example, "test phrase" matches "test, phrase". If the phrase contains no words that are in the index, the result is empty. For example, if all words are either stopwords or shorter than the minimum length of indexed words, the result is empty.

The MySQL FULLTEXT implementation regards any sequence of true word characters (letters, digits, and underscores) as a word. That sequence may also contain apostrophes (""'), but not more than one in a row. This means that "aaa'bbb" is regarded as one word, but "aaa"'bbb" is regarded as two words. Apostrophes at the beginning or the end of a word are stripped by the FULLTEXT parser; "aaa'bbb" would be parsed as "aaa"bbb".

The built-in FULLTEXT parser determines where words start and end by looking for certain delimiter characters; for example, (space), , (comma), and . (period). If words are not separated by delimiters (as in, for example, Chinese), the built-in FULLTEXT parser cannot determine where a word begins or ends. To be able to add words or other indexed terms in such languages to a FULLTEXT index that uses the built-in FULLTEXT parser, you must preprocess them so that they are separated by some arbitrary delimiter. Alternatively, you can create FULLTEXT indexes using the ngram parser plugin (for Chinese, Japanese, or Korean) or the MeCab parser plugin (for Japanese).
It is possible to write a plugin that replaces the built-in full-text parser. For details, see The MySQL Plugin API. For example parser plugin source code, see the plugin/fulltext directory of a MySQL source distribution.

Some words are ignored in full-text searches:

- Any word that is too short is ignored. The default minimum length of words that are found by full-text searches is three characters for InnoDB search indexes, or four characters for MyISAM. You can control the cutoff by setting a configuration option before creating the index: innodb_ft_min_token_size configuration option for InnoDB search indexes, or ft_min_word_len for MyISAM.

  **Note**
  
  This behavior does not apply to FULLTEXT indexes that use the ngram parser. For the ngram parser, token length is defined by the ngram_token_size option.

- Words in the stopword list are ignored. A stopword is a word such as “the” or “some” that is so common that it is considered to have zero semantic value. There is a built-in stopword list, but it can be overridden by a user-defined list. The stopword lists and related configuration options are different for InnoDB search indexes and MyISAM ones. Stopword processing is controlled by the configuration options innodb_ft_enable_stopword, innodb_ft_server_stopword_table, and innodb_ft_user_stopword_table for InnoDB search indexes, and ft_stopword_file for MyISAM ones.

  See Section 12.9.4, “Full-Text Stopwords” to view default stopword lists and how to change them. The default minimum word length can be changed as described in Section 12.9.6, “Fine-Tuning MySQL Full-Text Search”.

Every correct word in the collection and in the query is weighted according to its significance in the collection or query. Thus, a word that is present in many documents has a lower weight, because it has lower semantic value in this particular collection. Conversely, if the word is rare, it receives a higher weight. The weights of the words are combined to compute the relevance of the row. This technique works best with large collections.

**MyISAM Limitation**

For very small tables, word distribution does not adequately reflect their semantic value, and this model may sometimes produce bizarre results for search indexes on MyISAM tables. For example, although the word “MySQL” is present in every row of the articles table shown earlier, a search for the word in a MyISAM search index produces no results:

```
mysql> SELECT * FROM articles
    -> WHERE MATCH (title, body)
    -> AGAINST ('MySQL' IN NATURAL LANGUAGE MODE);
Empty set (0.00 sec)
```

The search result is empty because the word “MySQL” is present in at least 50% of the rows, and so is effectively treated as a stopword. This filtering technique is more suitable for large data sets, where you might not want the result set to return every second row from a 1GB table, than for small data sets where it might cause poor results for popular terms.

The 50% threshold can surprise you when you first try full-text searching to see how it works, and makes InnoDB tables more suited to experimentation with full-text searches. If you create a MyISAM table and insert only one or two rows of text into it, every word in the text occurs in at least 50% of the rows. As a result, no search
returns any results until the table contains more rows. Users who need to bypass the 50% limitation can build search indexes on InnoDB tables, or use the boolean search mode explained in Section 12.9.2, "Boolean Full-Text Searches".

### 12.9.2 Boolean Full-Text Searches

MySQL can perform boolean full-text searches using the `IN BOOLEAN MODE` modifier. With this modifier, certain characters have special meaning at the beginning or end of words in the search string. In the following query, the `+` and `-` operators indicate that a word must be present or absent, respectively, for a match to occur. Thus, the query retrieves all the rows that contain the word “MySQL” but that do not contain the word “YourSQL”:

```sql
mysql> SELECT * FROM articles WHERE MATCH (title,body) AGAINST ('+MySQL -YourSQL' IN BOOLEAN MODE);
```

<table>
<thead>
<tr>
<th>id</th>
<th>title</th>
<th>body</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>MySQL Tutorial</td>
<td>DBMS stands for DataBase ...</td>
</tr>
<tr>
<td>2</td>
<td>How To Use MySQL Well</td>
<td>After you went through a ...</td>
</tr>
<tr>
<td>3</td>
<td>Optimizing MySQL</td>
<td>In this tutorial, we show ...</td>
</tr>
<tr>
<td>4</td>
<td>1001 MySQL Tricks</td>
<td>1. Never run mysqld as root. 2. ...</td>
</tr>
<tr>
<td>6</td>
<td>MySQL Security</td>
<td>When configured properly, MySQL ...</td>
</tr>
</tbody>
</table>

**Note**

In implementing this feature, MySQL uses what is sometimes referred to as implied Boolean logic, in which

- `+` stands for AND
- `-` stands for NOT
- `[no operator]` implies OR

Boolean full-text searches have these characteristics:

- They do not automatically sort rows in order of decreasing relevance.

- **InnoDB** tables require a `FULLTEXT` index on all columns of the `MATCH()` expression to perform boolean queries. Boolean queries against a MyISAM search index can work even without a `FULLTEXT` index, although a search executed in this fashion would be quite slow.

- The minimum and maximum word length full-text parameters apply to `FULLTEXT` indexes created using the built-in `FULLTEXT` parser and MeCab parser plugin. `innodb_ft_min_token_size` and `innodb_ft_max_token_size` are used for InnoDB search indexes. `ft_min_word_len` and `ft_max_word_len` are used for MyISAM search indexes.

Minimum and maximum word length full-text parameters do not apply to `FULLTEXT` indexes created using the ngram parser. ngram token size is defined by the `ngram_token_size` option.

- The stopword list applies, controlled by `innodb_ft_enable_stopword`, `innodb_ft_server_stopword_table`, and `innodb_ft_user_stopword_table` for InnoDB search indexes, and `ft_stopword_file` for MyISAM ones.

- **InnoDB** full-text search does not support the use of multiple operators on a single search word, as in this example: `'++apple'`. Use of multiple operators on a single search word returns a syntax error to standard out. MyISAM full-text search successfully processes the same search, ignoring all operators except for the operator immediately adjacent to the search word.
Boolean Full-Text Searches

- **InnoDB** full-text search only supports leading plus or minus signs. For example, **InnoDB** supports '+apple' but does not support 'apple+'. Specifying a trailing plus or minus sign causes **InnoDB** to report a syntax error.

- **InnoDB** full-text search does not support the use of a leading plus sign with wildcard ('++*'), a plus and minus sign combination ('+-'), or leading a plus and minus sign combination ('+-apple'). These invalid queries return a syntax error.

- **InnoDB** full-text search does not support the use of the @ symbol in boolean full-text searches. The @ symbol is reserved for use by the @distance proximity search operator.

- They do not use the 50% threshold that applies to **MyISAM** search indexes.

The boolean full-text search capability supports the following operators:

- **+**
  
  A leading or trailing plus sign indicates that this word *must* be present in each row that is returned. **InnoDB** only supports leading plus signs.

- **-**
  
  A leading or trailing minus sign indicates that this word *must not* be present in any of the rows that are returned. **InnoDB** only supports leading minus signs.

  Note: The - operator acts only to exclude rows that are otherwise matched by other search terms. Thus, a boolean-mode search that contains only terms preceded by - returns an empty result. It does not return “all rows except those containing any of the excluded terms.”

- **(no operator)**
  
  By default (when neither + nor - is specified), the word is optional, but the rows that contain it are rated higher. This mimics the behavior of MATCH() AGAINST() without the IN BOOLEAN MODE modifier.

- **@distance**
  
  This operator works on **InnoDB** tables only. It tests whether two or more words all start within a specified distance from each other, measured in words. Specify the search words within a double-quoted string immediately before the @distance operator, for example, MATCH(col1) AGAINST('"word1 word2 word3" @8' IN BOOLEAN MODE)

- **> <**
  
  These two operators are used to change a word's contribution to the relevance value that is assigned to a row. The > operator increases the contribution and the < operator decreases it. See the example following this list.

- **( )**
  
  Parentheses group words into subexpressions. Parenthesized groups can be nested.

- **~**
  
  A leading tilde acts as a negation operator, causing the word's contribution to the row's relevance to be negative. This is useful for marking “noise” words. A row containing such a word is rated lower than others, but is not excluded altogether, as it would be with the – operator.

- *****
Boolean Full-Text Searches

The asterisk serves as the truncation (or wildcard) operator. Unlike the other operators, it is appended to the word to be affected. Words match if they begin with the word preceding the * operator.

If a word is specified with the truncation operator, it is not stripped from a boolean query, even if it is too short or a stopword. Whether a word is too short is determined from the innodb_ft_min_token_size setting for InnoDB tables, or ft_min_word_len for MyISAM tables. These options are not applicable to FULLTEXT indexes that use the ngram parser.

The wildcarded word is considered as a prefix that must be present at the start of one or more words. If the minimum word length is 4, a search for '+word +the*' could return fewer rows than a search for '+word +the', because the second query ignores the too-short search term the.

A phrase that is enclosed within double quote (") characters matches only rows that contain the phrase literally, as it was typed. The full-text engine splits the phrase into words and performs a search in the FULLTEXT index for the words. Nonword characters need not be matched exactly: Phrase searching requires only that matches contain exactly the same words as the phrase and in the same order. For example, "test phrase" matches "test, phrase".

If the phrase contains no words that are in the index, the result is empty. The words might not be in the index because of a combination of factors: if they do not exist in the text, are stopwords, or are shorter than the minimum length of indexed words.

The following examples demonstrate some search strings that use boolean full-text operators:

- 'apple banana'
  Find rows that contain at least one of the two words.

- '+apple +juice'
  Find rows that contain both words.

- '+apple macintosh'
  Find rows that contain the word “apple”, but rank rows higher if they also contain “macintosh”.

- '+apple ~macintosh'
  Find rows that contain the word “apple” but not “macintosh”.

- '+apple ~macintosh'
  Find rows that contain the word “apple”, but if the row also contains the word “macintosh”, rate it lower than if row does not. This is “softer” than a search for '+apple ~macintosh', for which the presence of “macintosh” causes the row not to be returned at all.

- '+apple +(>turnover <strudel)'
  Find rows that contain the words “apple” and “turnover”, or “apple” and “strudel” (in any order), but rank “apple turnover” higher than “apple strudel”.

- 'apple*'
  Find rows that contain words such as “apple”, “apples”, “applesauce”, or “applet”.

- '"some words"'
Find rows that contain the exact phrase “some words” (for example, rows that contain “some words of wisdom” but not “some noise words”). Note that the " characters that enclose the phrase are operator characters that delimit the phrase. They are not the quotation marks that enclose the search string itself.

### Relevancy Rankings for InnoDB Boolean Mode Search

*InnoDB* full-text search is modeled on the *Sphinx* full-text search engine, and the algorithms used are based on *BM25* and *TF-IDF* ranking algorithms. For these reasons, relevancy rankings for *InnoDB* boolean full-text search may differ from *MyISAM* relevancy rankings.

*InnoDB* uses a variation of the “term frequency-inverse document frequency” (*TF-IDF*) weighting system to rank a document's relevance for a given full-text search query. The *TF-IDF* weighting is based on how frequently a word appears in a document, offset by how frequently the word appears in all documents in the collection. In other words, the more frequently a word appears in a document, and the less frequently the word appears in the document collection, the higher the document is ranked.

### How Relevancy Ranking is Calculated

The term frequency (*TF*) value is the number of times that a word appears in a document. The inverse document frequency (*IDF*) value of a word is calculated using the following formula, where `total_records` is the number of records in the collection, and `matching_records` is the number of records that the search term appears in.

\[
\text{IDF} = \log_{10} \left( \frac{\text{total_records}}{\text{matching_records}} \right)
\]

When a document contains a word multiple times, the IDF value is multiplied by the TF value:

\[
\text{TF} \times \text{IDF}
\]

Using the *TF* and *IDF* values, the relevancy ranking for a document is calculated using this formula:

\[
\text{rank} = \text{TF} \times \text{IDF} \times \text{IDF}
\]

The formula is demonstrated in the following examples.

### Relevancy Ranking for a Single Word Search

This example demonstrates the relevancy ranking calculation for a single-word search.

```
mysql> CREATE TABLE articles (  ->    id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,  ->    title VARCHAR(200),  ->    body TEXT,  ->    FULLTEXT (title,body)  ->) ENGINE=InnoDB;
Query OK, 0 rows affected (1.04 sec)

mysql> INSERT INTO articles (title,body) VALUES  ->    ('MySQL Tutorial','This database tutorial ...'),  ->    ('How To Use MySQL','After you went through a ...'),  ->    ('Optimizing Your Database','In this database tutorial ...'),  ->    ('MySQL vs. YourSQL','When comparing databases ...'),  ->    ('MySQL Security','When configured properly, MySQL ...'),  ->    ('Database, Database, Database','database database database'),  ->    ('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),  ->    ('MySQL Full-Text Indexes','MySQL fulltext indexes use a ...');
Query OK, 8 rows affected (0.06 sec)
Records: 8  Duplicates: 0  Warnings: 0
```
Boolean Full-Text Searches

mysql> SELECT id, title, body, 
  -> MATCH (title, body) AGAINST ('database' IN BOOLEAN MODE) AS score 
  -> FROM articles ORDER BY score DESC;

+----+------------------------------+-------------------------------------+---------------------+
| id | title                        | body                                | score               |
+----+------------------------------+-------------------------------------+---------------------+
|  6 | Database, Database, Database | database database database          | 1.0886961221694946  |
|  3 | Optimizing Your Database     | In this database tutorial ...       | 0.36289870738983154 |
|  1 | MySQL Tutorial               | This database tutorial ...           | 0.18144935369491577 |
|  2 | How To Use MySQL             | After you went through a ...         | 0                   |
|  4 | MySQL vs. YourSQL            | When comparing databases ...         | 0                   |
|  5 | MySQL Security               | When configured properly, MySQL ... | 0                   |
|  7 | 1001 MySQL Tricks            | 1. Never run mysqlld as root. 2. ... | 0                   |
|  8 | MySQL Full-Text Indexes      | MySQL fulltext indexes use a ...     | 0                   |
+----+------------------------------+-------------------------------------+---------------------+
8 rows in set (0.00 sec)

There are 8 records in total, with 3 that match the “database” search term. The first record (id 6) contains the search term 6 times and has a relevancy ranking of $1.0886961221694946$. This ranking value is calculated using a TF value of 6 (the “database” search term appears 6 times in record id 6) and an IDF value of 0.42596873216370745, which is calculated as follows (where 8 is the total number of records and 3 is the number of records that the search term appears in):

$$\text{IDF} = \log_{10}(\frac{8}{3}) = 0.42596873216370745$$

The TF and IDF values are then entered into the ranking formula:

$$\text{rank} = \text{TF} \times \text{IDF} \times \text{IDF}$$

Performing the calculation in the MySQL command-line client returns a ranking value of $1.088696164686938$.

mysql> SELECT 6*LOG10(8/3)*LOG10(8/3);
+-------------------------+
| 6*LOG10(8/3)*LOG10(8/3) |
| 1.088696164686938       |
+-------------------------+
1 row in set (0.00 sec)

Note

You may notice a slight difference in the ranking values returned by the `SELECT ... MATCH ... AGAINST` statement and the MySQL command-line client ($1.0886961221694946$ versus $1.088696164686938$). The difference is due to how the casts between integers and floats/doubles are performed internally by InnoDB (along with related precision and rounding decisions), and how they are performed elsewhere, such as in the MySQL command-line client or other types of calculators.

Relevancy Ranking for a Multiple Word Search

This example demonstrates the relevancy ranking calculation for a multiple-word full-text search based on the `articles` table and data used in the previous example.

If you search on more than one word, the relevancy ranking value is a sum of the relevancy ranking value for each word, as shown in this formula:

$$\text{rank} = \text{TF} \times \text{IDF} \times \text{IDF} + \text{TF} \times \text{IDF} \times \text{IDF}$$

Performing a search on two terms (‘mysql tutorial’) returns the following results:
### Full-Text Searches with Query Expansion

**mysql>** SELECT id, title, body, MATCH (title, body) AGAINST ('mysql tutorial' IN BOOLEAN MODE) AS score FROM articles ORDER BY score DESC;

<table>
<thead>
<tr>
<th>id</th>
<th>title</th>
<th>body</th>
<th>score</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>MySQL Tutorial</td>
<td>This database tutorial ...</td>
<td>0.7405621409416199</td>
</tr>
<tr>
<td>3</td>
<td>Optimizing Your Database</td>
<td>In this database tutorial ...</td>
<td>0.3624762296676636</td>
</tr>
<tr>
<td>5</td>
<td>MySQL Security</td>
<td>When configured properly, MySQL ...</td>
<td>0.031219376251101494</td>
</tr>
<tr>
<td>8</td>
<td>MySQL Full-Text Indexes</td>
<td>MySQL fulltext indexes use a ..</td>
<td>0.031219376251101494</td>
</tr>
<tr>
<td>2</td>
<td>How To Use MySQL</td>
<td>After you went through a ...</td>
<td>0.015609688125550747</td>
</tr>
<tr>
<td>4</td>
<td>MySQL vs. YourSQL</td>
<td>When comparing databases ...</td>
<td>0.015609688125550747</td>
</tr>
<tr>
<td>7</td>
<td>1001 MySQL Tricks</td>
<td>1. Never run mysqld as root. 2. ...</td>
<td>0.015609688125550747</td>
</tr>
<tr>
<td>6</td>
<td>Database, Database, Database</td>
<td>database database database</td>
<td>0</td>
</tr>
</tbody>
</table>

8 rows in set (0.00 sec)

In the first record (id 8), 'mysql' appears once and 'tutorial' appears twice. There are six matching records for 'mysql' and two matching records for 'tutorial'. The MySQL command-line client returns the expected ranking value when inserting these values into the ranking formula for a multiple word search:

mysql> SELECT (1*log10(8/6)*log10(8/6)) + (2*log10(8/2)*log10(8/2));

<table>
<thead>
<tr>
<th>(1*log10(8/6)<em>log10(8/6)) + (2</em>log10(8/2)*log10(8/2))</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.7405621541938003</td>
</tr>
</tbody>
</table>

1 row in set (0.00 sec)

**Note**

The slight difference in the ranking values returned by the `SELECT ... MATCH ... AGAINST` statement and the MySQL command-line client is explained in the preceding example.

### 12.9.3 Full-Text Searches with Query Expansion

Full-text search supports query expansion (and in particular, its variant “blind query expansion”). This is generally useful when a search phrase is too short, which often means that the user is relying on implied knowledge that the full-text search engine lacks. For example, a user searching for “database” may really mean that “MySQL”, “Oracle”, “DB2”, and “RDBMS” all are phrases that should match “databases” and should be returned, too. This is implied knowledge.

Blind query expansion (also known as automatic relevance feedback) is enabled by adding `WITH QUERY EXPANSION` or `IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION` following the search phrase. It works by performing the search twice, where the search phrase for the second search is the original search phrase concatenated with the few most highly relevant documents from the first search. Thus, if one of these documents contains the word “databases” and the word “MySQL”, the second search finds the documents that contain the word “MySQL” even if they do not contain the word “database”. The following example shows this difference:

mysql> SELECT * FROM articles WHERE MATCH (title, body) AGAINST ('database' IN NATURAL LANGUAGE MODE);

<table>
<thead>
<tr>
<th>id</th>
<th>title</th>
<th>body</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>MySQL Tutorial</td>
<td>DBMS stands for DataBase ...</td>
</tr>
<tr>
<td>5</td>
<td>MySQL vs. YourSQL</td>
<td>In the following database comparison ...</td>
</tr>
</tbody>
</table>

2 rows in set (0.00 sec)
Another example could be searching for books by Georges Simenon about Maigret, when a user is not sure how to spell “Maigret”. A search for “Megre and the reluctant witnesses” finds only “Maigret and the Reluctant Witnesses” without query expansion. A search with query expansion finds all books with the word “Maigret” on the second pass.

Note
Because blind query expansion tends to increase noise significantly by returning nonrelevant documents, use it only when a search phrase is short.

### 12.9.4 Full-Text Stopwords

The stopword list is loaded and searched for full-text queries using the server character set and collation (the values of the `character_set_server` and `collation_server` system variables). False hits or misses might occur for stopword lookups if the stopword file or columns used for full-text indexing or searches have a character set or collation different from `character_set_server` or `collation_server`.

Case sensitivity of stopword lookups depends on the server collation. For example, lookups are case-insensitive if the collation is `utf8mb4_0900_ai_ci`, whereas lookups are case-sensitive if the collation is `utf8mb4_0900_as_cs` or `utf8mb4_bin`.

- **Stopwords for InnoDB Search Indexes**
- **Stopwords for MyISAM Search Indexes**

#### Stopwords for InnoDB Search Indexes

**InnoDB** has a relatively short list of default stopwords, because documents from technical, literary, and other sources often use short words as keywords or in significant phrases. For example, you might search for “to be or not to be” and expect to get a sensible result, rather than having all those words ignored.

To see the default **InnoDB** stopword list, query the Information Schema `INNODB_FT_DEFAULT_STOPWORD` table.
To define your own stopword list for all InnoDB tables, define a table with the same structure as the `INNODB_FT_DEFAULT_STOPWORD` table, populate it with stopwords, and set the value of the `innodb_ft_server_stopword_table` option to a value in the form `db_name/table_name` before creating the full-text index. The stopword table must have a single VARCHAR column named `value`. The following example demonstrates creating and configuring a new global stopword table for InnoDB.

```
-- Create a new stopword table
mysql> CREATE TABLE my_stopwords(value VARCHAR(30)) ENGINE = INNODB;
Query OK, 0 rows affected (0.01 sec)

-- Insert stopwords (for simplicity, a single stopword is used in this example)
mysql> INSERT INTO my_stopwords(value) VALUES ('Ishmael');
Query OK, 1 row affected (0.00 sec)

-- Create the table
mysql> CREATE TABLE opening_lines (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  opening_line TEXT(500),
  author VARCHAR(200),
  title VARCHAR(200)
) ENGINE=InnoDB;
Query OK, 0 rows affected (0.01 sec)

-- Insert data into the table
mysql> INSERT INTO opening_lines(opening_line,author,title) VALUES
  ('Call me Ishmael.','Herman Melville','Moby-Dick'),
  ('A screaming comes across the sky.','Thomas Pynchon','Gravity\'s Rainbow'),
  ('I am an invisible man.','Ralph Ellison','Invisible Man'),
  ('Where now? Who now? When now?','Samuel Beckett','The Unnamable'),
```

Verifying that the specified stopword ('Ishmael') does not appear by querying the Information Schema INNODB_FT_INDEX_TABLE table.

**Note**

By default, words less than 3 characters in length or greater than 84 characters in length do not appear in a InnoDB full-text search index. Maximum and minimum word length values are configurable using the `innodb_ft_max_token_size` and `innodb_ft_min_token_size` variables. This default behavior does not apply to the ngram parser plugin. ngram token size is defined by the `ngram_token_size` option.

To create stopword lists on a table-by-table basis, create other stopword tables and use the `innodb_ft_user_stopword_table` option to specify the stopword table that you want to use before you create the full-text index.

**Stopwords for MyISAM Search Indexes**

The stopword file is loaded and searched using `latin1` if `character_set_server` is `ucs2`, `utf16`, `utf16le`, or `utf32`. 

---

2351
To override the default stopword list for MyISAM tables, set the `ft_stopword_file` system variable. (See Section 5.1.8, “Server System Variables”.) The variable value should be the path name of the file containing the stopword list, or the empty string to disable stopword filtering. The server looks for the file in the data directory unless an absolute path name is given to specify a different directory. After changing the value of this variable or the contents of the stopword file, restart the server and rebuild your FULLTEXT indexes.

The stopword list is free-form, separating stopwords with any nonalphanumeric character such as newline, space, or comma. Exceptions are the underscore character (_) and a single apostrophe (') which are treated as part of a word. The character set of the stopword list is the server’s default character set; see Section 10.3.2, “Server Character Set and Collation”.

The following list shows the default stopwords for MyISAM search indexes. In a MySQL source distribution, you can find this list in the `storage/myisam/ft_static.c` file.

<table>

12.9.5 Full-Text Restrictions

- Full-text searches are supported for InnoDB and MyISAM tables only.
- Full-text searches are not supported for partitioned tables. See Section 24.6, "Restrictions and Limitations on Partitioning".
Fine-Tuning MySQL Full-Text Search

- Full-text searches can be used with most multibyte character sets. The exception is that for Unicode, the utf8mb3 or utf8mb4 character set can be used, but not the ucs2 character set. Although FULLTEXT indexes on ucs2 columns cannot be used, you can perform IN BOOLEAN MODE searches on a ucs2 column that has no such index.

  The remarks for utf8mb3 also apply to utf8mb4, and the remarks for ucs2 also apply to utf16, utf16le, and utf32.

- Ideographic languages such as Chinese and Japanese do not have word delimiters. Therefore, the built-in full-text parser cannot determine where words begin and end in these and other such languages.

  A character-based ngram full-text parser that supports Chinese, Japanese, and Korean (CJK), and a word-based MeCab parser plugin that supports Japanese are provided for use with InnoDB and MyISAM tables.

  Although the use of multiple character sets within a single table is supported, all columns in a FULLTEXT index must use the same character set and collation.

  The MATCH() column list must match exactly the column list in some FULLTEXT index definition for the table, unless this MATCH() is IN BOOLEAN MODE on a MyISAM table. For MyISAM tables, boolean-mode searches can be done on nonindexed columns, although they are likely to be slow.

  The argument to AGAINST() must be a string value that is constant during query evaluation. This rules out, for example, a table column because that can differ for each row.

  The argument to MATCH() cannot use a rollup column.

  Index hints are more limited for FULLTEXT searches than for non-FULLTEXT searches. See Section 8.9.4, “Index Hints”.

  For InnoDB, all DML operations (INSERT, UPDATE, DELETE) involving columns with full-text indexes are processed at transaction commit time. For example, for an INSERT operation, an inserted string is tokenized and decomposed into individual words. The individual words are then added to full-text index tables when the transaction is committed. As a result, full-text searches only return committed data.

  The ‘%’ character is not a supported wildcard character for full-text searches.

12.9.6 Fine-Tuning MySQL Full-Text Search

MySQL’s full-text search capability has few user-tunable parameters. You can exert more control over full-text searching behavior if you have a MySQL source distribution because some changes require source code modifications. See Section 2.8, “Installing MySQL from Source”.

Full-text search is carefully tuned for effectiveness. Modifying the default behavior in most cases can actually decrease effectiveness. Do not alter the MySQL sources unless you know what you are doing.

Most full-text variables described in this section must be set at server startup time. A server restart is required to change them; they cannot be modified while the server is running.

Some variable changes require that you rebuild the FULLTEXT indexes in your tables. Instructions for doing so are given later in this section.

- Configuring Minimum and Maximum Word Length
- Configuring the Natural Language Search Threshold
- Modifying Boolean Full-Text Search Operators
Fine-Tuning MySQL Full-Text Search

- Character Set Modifications
- Rebuilding InnoDB Full-Text Indexes
- Optimizing InnoDB Full-Text Indexes
- Rebuilding MyISAM Full-Text Indexes

Configuring Minimum and Maximum Word Length

The minimum and maximum lengths of words to be indexed are defined by the `innodb_ft_min_token_size` and `innodb_ft_max_token_size` for InnoDB search indexes, and `ft_min_word_len` and `ft_max_word_len` for MyISAM ones.

**Note**
Minimum and maximum word length full-text parameters do not apply to FULLTEXT indexes created using the ngram parser. Ngram token size is defined by the `ngram_token_size` option.

After changing any of these options, rebuild your FULLTEXT indexes for the change to take effect. For example, to make two-character words searchable, you could put the following lines in an option file:

```sql
[mysqld]
innodb_ft_min_token_size=2
ft_min_word_len=2
```

Then restart the server and rebuild your FULLTEXT indexes. For MyISAM tables, note the remarks regarding `myisamchk` in the instructions that follow for rebuilding MyISAM full-text indexes.

Configuring the Natural Language Search Threshold

For MyISAM search indexes, the 50% threshold for natural language searches is determined by the particular weighting scheme chosen. To disable it, look for the following line in `storage/myisam/ftdefs.h`:

```c
#define GWS_IN_USE GWS_PROB
```

Change that line to this:

```c
#define GWS_IN_USE GWS_FREQ
```

Then recompile MySQL. There is no need to rebuild the indexes in this case.

**Note**
By making this change, you severely decrease MySQL's ability to provide adequate relevance values for the `MATCH()` function. If you really need to search for such common words, it would be better to search using `IN BOOLEAN MODE` instead, which does not observe the 50% threshold.

Modifying Boolean Full-Text Search Operators

To change the operators used for boolean full-text searches on MyISAM tables, set the `ft_boolean_syntax` system variable. (InnoDB does not have an equivalent setting.) This variable can be changed while the server is running, but you must have privileges sufficient to set global system
variables (see Section 5.1.9.1, “System Variable Privileges”). No rebuilding of indexes is necessary in this case.

Character Set Modifications

For the built-in full-text parser, you can change the set of characters that are considered word characters in several ways, as described in the following list. After making the modification, rebuild the indexes for each table that contains any `FULLTEXT` indexes. Suppose that you want to treat the hyphen character (\'-%\') as a word character. Use one of these methods:

- **Modify the MySQL source:** In `storage/innobase/handler/ha_innodb.cc` (for InnoDB), or in `storage/myisam/ftdefs.h` (for MyISAM), see the `true_word_char()` and `misc_word_char()` macros. Add '--' to one of those macros and recompile MySQL.

- **Modify a character set file:** This requires no recompilation. The `true_word_char()` macro uses a “character type” table to distinguish letters and numbers from other characters. You can edit the contents of the `<ctype><map>` array in one of the character set XML files to specify that '-' is a “letter.” Then use the given character set for your `FULLTEXT` indexes. For information about the `<ctype><map>` array format, see Section 10.13.1, “Character Definition Arrays”.

- **Add a new collation for the character set used by the indexed columns, and alter the columns to use that collation.** For general information about adding collations, see Section 10.14, “Adding a Collation to a Character Set”. For an example specific to full-text indexing, see Section 12.9.7, “Adding a User-Defined Collation for Full-Text Indexing”.

Rebuilding InnoDB Full-Text Indexes

For the changes to take effect, `FULLTEXT` indexes must be rebuilt after modifying any of the following full-text index variables: `innodb_ft_min_token_size`; `innodb_ft_max_token_size`; `innodb_ft_server_stopword_table`; `innodb_ft_user_stopword_table`; `innodb_ft_enable_stopword`; `ngram_token_size`. Modifying `innodb_ft_min_token_size`, `innodb_ft_max_token_size`, or `ngram_token_size` requires restarting the server.

To rebuild `FULLTEXT` indexes for an InnoDB table, use `ALTER TABLE` with the `DROP INDEX` and `ADD INDEX` options to drop and re-create each index.

Optimizing InnoDB Full-Text Indexes

Running `OPTIMIZE TABLE` on a table with a full-text index rebuilds the full-text index, removing deleted Document IDs and consolidating multiple entries for the same word, where possible.

To optimize a full-text index, enable `innodb_optimize_fulltext_only` and run `OPTIMIZE TABLE`.

```sql
mysql> set GLOBAL innodb_optimize_fulltext_only=ON;
Query OK, 0 rows affected (0.01 sec)
mysql> OPTIMIZE TABLE opening_lines;
+--------------------+----------+----------+----------+
<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_type</th>
<th>Msg_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.opening_lines</td>
<td>optimize</td>
<td>status</td>
<td>OK</td>
</tr>
</tbody>
</table>
+--------------------+----------+----------+----------+
1 row in set (0.01 sec)
```

To avoid lengthy rebuild times for full-text indexes on large tables, you can use the `innodb_ft_num_word_optimize` option to perform the optimization in stages. The `innodb_ft_num_word_optimize` option defines the number of words that are optimized each time.
Adding a User-Defined Collation for Full-Text Indexing

When \texttt{OPTIMIZE TABLE} is run. The default setting is 2000, which means that 2000 words are optimized each time \texttt{OPTIMIZE TABLE} is run. Subsequent \texttt{OPTIMIZE TABLE} operations continue from where the preceding \texttt{OPTIMIZE TABLE} operation ended.

Rebuilding MyISAM Full-Text Indexes

If you modify full-text variables that affect indexing (\textit{ft\_min\_word\_len}, \textit{ft\_max\_word\_len}, or \textit{ft\_stopword\_file}), or if you change the stopword file itself, you must rebuild your \texttt{FULLTEXT} indexes after making the changes and restarting the server.

To rebuild the \texttt{FULLTEXT} indexes for a \texttt{MyISAM} table, it is sufficient to do a \texttt{QUICK} repair operation:

```
mysql> REPAIR TABLE tbl_name QUICK;
```

Alternatively, use \texttt{ALTER TABLE} as just described. In some cases, this may be faster than a repair operation.

Each table that contains any \texttt{FULLTEXT} index must be repaired as just shown. Otherwise, queries for the table may yield incorrect results, and modifications to the table causes the server to see the table as corrupt and in need of repair.

If you use \texttt{myisamchk} to perform an operation that modifies \texttt{MyISAM} table indexes (such as repair or analyze), the \texttt{FULLTEXT} indexes are rebuilt using the \textit{default} full-text parameter values for minimum word length, maximum word length, and stopword file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in \texttt{MyISAM} index files. To avoid the problem if you have modified the minimum or maximum word length or stopword file values used by the server, specify the same \textit{ft\_min\_word\_len}, \textit{ft\_max\_word\_len}, and \textit{ft\_stopword\_file} values for \texttt{myisamchk} that you use for \texttt{mysqld}. For example, if you have set the minimum word length to 3, you can repair a table with \texttt{myisamchk} like this:

```
myisamchk --recover --ft\_min\_word\_len=3 tbl_name.MYI
```

To ensure that \texttt{myisamchk} and the server use the same values for full-text parameters, place each one in both the \texttt{[mysqld]} and \texttt{[myisamchk]} sections of an option file:

```
[mysqld]
ft\_min\_word\_len=3
[myisamchk]
ft\_min\_word\_len=3
```

An alternative to using \texttt{myisamchk} for \texttt{MyISAM} table index modification is to use the \texttt{REPAIR TABLE}, \texttt{ANALYZE TABLE}, \texttt{OPTIMIZE TABLE}, or \texttt{ALTER TABLE} statements. These statements are performed by the server, which knows the proper full-text parameter values to use.

12.9.7 Adding a User-Defined Collation for Full-Text Indexing

Warning

User-defined collations are deprecated; you should expect support for them to be removed in a future version of MySQL. The server issues a warning for any use of \texttt{COLLATE user\_defined\_collation} in an SQL statement; a warning is also issued when the server is started with \texttt{--collation-server} set equal to the name of a user-defined collation.
Adding a User-Defined Collation for Full-Text Indexing

This section describes how to add a user-defined collation for full-text searches using the built-in full-text parser. The sample collation is like `latin1_swedish_ci` but treats the `-` character as a letter rather than as a punctuation character so that it can be indexed as a word character. General information about adding collations is given in Section 10.14, “Adding a Collation to a Character Set”; it is assumed that you have read it and are familiar with the files involved.

To add a collation for full-text indexing, use the following procedure. The instructions here add a collation for a simple character set, which as discussed in Section 10.14, “Adding a Collation to a Character Set”, can be created using a configuration file that describes the character set properties. For a complex character set such as Unicode, create collations using C source files that describe the character set properties.

1. Add a collation to the `Index.xml` file. The permitted range of IDs for user-defined collations is given in Section 10.14.2, “Choosing a Collation ID”. The ID must be unused, so choose a value different from 1025 if that ID is already taken on your system.

```xml
<charset name="latin1">
...
<collation name="latin1_fulltext_ci" id="1025"/>
</charset>
```

2. Declare the sort order for the collation in the `latin1.xml` file. In this case, the order can be copied from `latin1_swedish_ci`:

```xml
<collation name="latin1_fulltext_ci">
  <map>
    00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F
    10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F
    20 21 22 23 24 25 26 27 28 29 2A 2B 2C 2D 2E 2F
    30 31 32 33 34 35 36 37 38 39 3A 3B 3C 3D 3E 3F
    40 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
    50 51 52 53 54 55 56 57 58 59 5A 5B 5C 5D 5E 5F
    60 61 62 63 64 65 66 67 68 69 6A 6B 6C 6D 6E 6F
    70 71 72 73 74 75 76 77 78 79 7A 7B 7C 7D 7E 7F
    80 81 82 83 84 85 86 87 88 89 8A 8B 8C 8D 8E 8F
    90 91 92 93 94 95 96 97 98 99 9A 9B 9C 9D 9E 9F
    A0 A1 A2 A3 A4 A5 A6 A7 A8 A9 AA AB AC AD AE AF
    B0 B1 B2 B3 B4 B5 B6 B7 B8 B9 BA BB BC BD BE BF
    41 41 41 41 5C 5B 5C 43 45 45 45 45 49 49 49 49
    44 4E 4F 4F 4F 4F 5D D7 D8 55 55 55 59 59 DE DF
    41 41 41 41 5C 5B 5C 43 45 45 45 45 49 49 49 49
    44 4E 4F 4F 4F 4F 5D F7 D8 55 55 55 59 59 DE FF
  </map>
</collation>
```

3. Modify the `ctype` array in `latin1.xml`. Change the value corresponding to 0x2D (which is the code for the `-` character) from 10 (punctuation) to 01 (uppercase letter). In the following array, this is the element in the fourth row down, third value from the end.

```xml
<ctype>
  <map>
    00
    20 20 20 20 20 20 20 20 20 20 28 28 28 28 28 28 28 28 20 20
    20 20 20 20 20 20 20 20 20 20 20 20 20 20 20 20 20 20 20 20
    48 10 10 10 10 10 10 10 10 10 10 10 10 10 10 10 01 10 10
    84 84 84 84 84 84 84 84 84 84 84 84 84 84 84 84 10 10 10 10
    10 10 10 10 84 84 81 81 81 81 81 01 01 01 01 01 01 01 01 01
    01 01 01 01 01 01 01 01 01 01 10 10 10 10 10 10 10 10 10 10
    10 82 82 82 82 82 82 82 82 82 02 02 02 02 02 02 02 02 02 02
    02 02 02 02 02 02 02 02 02 02 02 02 02 02 02 02 02 02 02 02
    10 10 02 02 02 02 10 10 10 10 10 10 10 10 01 10 01 00 01 00
    00 10 10 10 10 10 10 10 10 10 10 10 10 10 10 10 01 01 01 00
    10 10 02 02 02 02 10 10 10 10 10 10 10 10 10 10 10 10 10 10
    48 10 10 10 10 10 10 10 10 10 10 10 10 10 10 10 10 10 10 10
  </map>
</ctype>
```
4. Restart the server.

5. To employ the new collation, include it in the definition of columns that are to use it:

```sql
mysql> DROP TABLE IF EXISTS t1;
Query OK, 0 rows affected (0.13 sec)

mysql> CREATE TABLE t1 (
    a TEXT CHARACTER SET latin1 COLLATE latin1_fulltext_ci,
    FULLTEXT INDEX(a)
) ENGINE=InnoDB;
Query OK, 0 rows affected (0.47 sec)
```

6. Test the collation to verify that hyphen is considered as a word character:

```sql
mysql> INSERT INTO t1 VALUES ('----'),('....'),('abcd');
Query OK, 3 rows affected (0.22 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM t1 WHERE MATCH a AGAINST ('----' IN BOOLEAN MODE);
+------+-------+
| a    | c     |
| c     | c     |
+-------+-------+
```

12.9.8 ngram Full-Text Parser

The built-in MySQL full-text parser uses the white space between words as a delimiter to determine where words begin and end, which is a limitation when working with ideographic languages that do not use word delimiters. To address this limitation, MySQL provides an ngram full-text parser that supports Chinese, Japanese, and Korean (CJK). The ngram full-text parser is supported for use with InnoDB and MyISAM.

An ngram is a contiguous sequence of \( n \) characters from a given sequence of text. The ngram parser tokenizes a sequence of text into a contiguous sequence of \( n \) characters. For example, you can tokenize “abcd” for different values of \( n \) using the ngram full-text parser.

\[
\begin{align*}
n=1: & \ 'a', \ 'b', \ 'c', \ 'd' \\
n=2: & \ 'ab', \ 'bc', \ 'cd' \\
n=3: & \ 'abc', \ 'bcd' \\
n=4: & \ 'abcd'
\end{align*}
\]

The ngram full-text parser is a built-in server plugin. As with other built-in server plugins, it is automatically loaded when the server is started.

The full-text search syntax described in Section 12.9, “Full-Text Search Functions” applies to the ngram parser plugin. Differences in parsing behavior are described in this section. Full-text-related configuration
ngram Full-Text Parser

options, except for minimum and maximum word length options (innodb_ft_min_token_size, innodb_ft_max_token_size, ft_min_word_len, ft_max_word_len) are also applicable.

Configuring ngram Token Size

The ngram parser has a default ngram token size of 2 (bigram). For example, with a token size of 2, the ngram parser parses the string “abc def” into four tokens: “ab”, “bc”, “de” and “ef”.

ngram token size is configurable using the ngram_token_size configuration option, which has a minimum value of 1 and maximum value of 10.

Typically, ngram_token_size is set to the size of the largest token that you want to search for. If you only intend to search for single characters, set ngram_token_size to 1. A smaller token size produces a smaller full-text search index, and faster searches. If you need to search for words comprised of more than one character, set ngram_token_size accordingly. For example, “Happy Birthday” is “生日快乐” in simplified Chinese, where “生日” is “birthday”, and “快乐” translates as “happy”. To search on two-character words such as these, set ngram_token_size to a value of 2 or higher.

As a read-only variable, ngram_token_size may only be set as part of a startup string or in a configuration file:

- Startup string:
  ```
  mysql --ngram_token_size=2
  ```

- Configuration file:
  ```
  [mysqld]
  ngram_token_size=2
  ```

Note

The following minimum and maximum word length configuration options are ignored for FULLTEXT indexes that use the ngram parser: innodb_ft_min_token_size, innodb_ft_max_token_size, ft_min_word_len, and ft_max_word_len.

Creating a FULLTEXT Index that Uses the ngram Parser

To create a FULLTEXT index that uses the ngram parser, specify WITH PARSER ngram with CREATE TABLE, ALTER TABLE, or CREATE INDEX.

The following example demonstrates creating a table with an ngram FULLTEXT index, inserting sample data (Simplified Chinese text), and viewing tokenized data in the Information Schema INNODB_FT_INDEX_CACHE table.

```sql
mysql> USE test;

mysql> CREATE TABLE articles {
  
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  title VARCHAR(200),
  body TEXT,
  FULLTEXT (title, body) WITH PARSER ngram
} ENGINE=InnoDB CHARACTER SET utf8mb4;

mysql> SET NAMES utf8mb4;

mysql> INSERT INTO articles (title, body) VALUES

  ('数据库管理', '本教程中我将向你展示如何管理数据库'),
  ('数据库应用开发', '学习开发数据库应用程序');
```
ngram Full-Text Parser

mysql> SET GLOBAL innodb_ft_aux_table="test/articles";

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE ORDER BY doc_id, position;

To add a FULLTEXT index to an existing table, you can use ALTER TABLE or CREATE INDEX. For example:

CREATE TABLE articles (  
id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,  
title VARCHAR(200),  
body TEXT  
) ENGINE=InnoDB CHARACTER SET utf8mb4;

ALTER TABLE articles ADD FULLTEXT INDEX ft_index (title,body) WITH PARSER ngram;

# Or:
CREATE FULLTEXT INDEX ft_index ON articles (title,body) WITH PARSER ngram;

ngram Parser Space Handling

The ngram parser eliminates spaces when parsing. For example:

- “ab cd” is parsed to “ab”, “cd”
- “a bc” is parsed to “bc”

ngram Parser Stopword Handling

The built-in MySQL full-text parser compares words to entries in the stopword list. If a word is equal to an entry in the stopword list, the word is excluded from the index. For the ngram parser, stopword handling is performed differently. Instead of excluding tokens that are equal to entries in the stopword list, the ngram parser excludes tokens that contain stopwords. For example, assuming `ngram_token_size=2`, a document that contains “a,b” is parsed to “a,” and “,b”. If a comma ("," ) is defined as a stopword, both “a,” and “,b” are excluded from the index because they contain a comma.

By default, the ngram parser uses the default stopword list, which contains a list of English stopwords. For a stopword list applicable to Chinese, Japanese, or Korean, you must create your own. For information about creating a stopword list, see Section 12.9.4, “Full-Text Stopwords”.

Stopwords greater in length than `ngram_token_size` are ignored.

ngram Parser Term Search

For natural language mode search, the search term is converted to a union of ngram terms. For example, the string “abc” (assuming `ngram_token_size=2`) is converted to “ab bc”. Given two documents, one containing “ab” and the other containing “abc”, the search term “ab bc” matches both documents.

For boolean mode search, the search term is converted to an ngram phrase search. For example, the string 'abc' (assuming `ngram_token_size=2`) is converted to "ab bc". Given two documents, one containing 'ab' and the other containing 'abc', the search phrase "ab bc" only matches the document containing 'abc'.

ngram Parser Wildcard Search

Because an ngram FULLTEXT index contains only ngrams, and does not contain information about the beginning of terms, wildcard searches may return unexpected results. The following behaviors apply to wildcard searches using ngram FULLTEXT search indexes:
• If the prefix term of a wildcard search is shorter than ngram token size, the query returns all indexed rows that contain ngram tokens starting with the prefix term. For example, assuming `ngram_token_size=2`, a search on "a*" returns all rows starting with "a".

• If the prefix term of a wildcard search is longer than ngram token size, the prefix term is converted to an ngram phrase and the wildcard operator is ignored. For example, assuming `ngram_token_size=2`, an "abc*" wildcard search is converted to "ab bc".

ngram Parser Phrase Search

Phrase searches are converted to ngram phrase searches. For example, The search phrase “abc” is converted to “ab bc”, which returns documents containing “abc” and “ab bc”.

The search phrase “abc def” is converted to “ab bc de ef”, which returns documents containing “abc def” and “ab bc de ef”. A document that contains “abcdef” is not returned.

12.9.9 MeCab Full-Text Parser Plugin

The built-in MySQL full-text parser uses the white space between words as a delimiter to determine where words begin and end, which is a limitation when working with ideographic languages that do not use word delimiters. To address this limitation for Japanese, MySQL provides a MeCab full-text parser plugin. The MeCab full-text parser plugin is supported for use with InnoDB and MyISAM.

Note

MySQL also provides an ngram full-text parser plugin that supports Japanese. For more information, see Section 12.9.8, “ngram Full-Text Parser”.

The MeCab full-text parser plugin is a full-text parser plugin for Japanese that tokenizes a sequence of text into meaningful words. For example, MeCab tokenizes "データベース管理" ("Database Management") into "データベース" ("Database") and "管理" ("Management"). By comparison, the ngram full-text parser tokenizes text into a contiguous sequence of \( n \) characters, where \( n \) represents a number between 1 and 10.

In addition to tokenizing text into meaningful words, MeCab indexes are typically smaller than ngram indexes, and MeCab full-text searches are generally faster. One drawback is that it may take longer for the MeCab full-text parser to tokenize documents, compared to the ngram full-text parser.

The full-text search syntax described in Section 12.9, “Full-Text Search Functions” applies to the MeCab parser plugin. Differences in parsing behavior are described in this section. Full-text related configuration options are also applicable.

For additional information about the MeCab parser, refer to the MeCab: Yet Another Part-of-Speech and Morphological Analyzer project on Github.

Installing the MeCab Parser Plugin

The MeCab parser plugin requires mecab and mecab-ipadic.

On supported Fedora, Debian and Ubuntu platforms (except Ubuntu 12.04 where the system mecab version is too old), MySQL dynamically links to the system mecab installation if it is installed to the default location. On other supported Unix-like platforms, libmecab.so is statically linked in libpluginmecab.so, which is located in the MySQL plugin directory. mecab-ipadic is included in MySQL binaries and is located in $MYSQL_HOME/lib/mecab.

You can install mecab and mecab-ipadic using a native package management utility (on Fedora, Debian, and Ubuntu), or you can build mecab and mecab-ipadic from source. For information about
installing `mecab` and `mecab-ipadic` using a native package management utility, see Installing MeCab From a Binary Distribution (Optional). If you want to build `mecab` and `mecab-ipadic` from source, see Building MeCab From Source (Optional).

On Windows, `libmecab.dll` is found in the MySQL `bin` directory. `mecab-ipadic` is located in `MYSQL_HOME/lib/mecab`.

To install and configure the MeCab parser plugin, perform the following steps:

1. In the MySQL configuration file, set the `mecab_rc_file` configuration option to the location of the `mecabrc` configuration file, which is the configuration file for MeCab. If you are using the MeCab package distributed with MySQL, the `mecabrc` file is located in `MYSQL_HOME/lib/mecab/etc/`.

   ```
   [mysqld]
   loose-mecab-rc-file=MYSQL_HOME/lib/mecab/etc/mecabrc
   ```

   The `loose` prefix is an option modifier. The `mecab.rc_file` option is not recognized by MySQL until the MeCab parser plugin is installed but it must be set before attempting to install the MeCab parser plugin. The `loose` prefix allows you restart MySQL without encountering an error due to an unrecognized variable.

   If you use your own MeCab installation, or build MeCab from source, the location of the `mecabrc` configuration file may differ.

   For information about the MySQL configuration file and its location, see Section 4.2.2.2, “Using Option Files”.

2. Also in the MySQL configuration file, set the minimum token size to 1 or 2, which are the values recommended for use with the MeCab parser. For InnoDB tables, minimum token size is defined by the `innodb_ft_min_token_size` configuration option, which has a default value of 3. For MyISAM tables, minimum token size is defined by `ft_min_word_len`, which has a default value of 4.

   ```
   [mysqld]
   innodb_ft_min_token_size=1
   ```

3. Modify the `mecabrc` configuration file to specify the dictionary you want to use. The `mecab-ipadic` package distributed with MySQL binaries includes three dictionaries (`ipadic_euc-jp`, `ipadic_sjis`, and `ipadic_utf-8`). The `mecabrc` configuration file packaged with MySQL contains an entry similar to the following:

   ```
   dicdir = /path/to/mysql/lib/mecab/lib/mecab/dic/ipadic_euc-jp
   ```

   To use the `ipadic_utf-8` dictionary, for example, modify the entry as follows:

   ```
   dicdir=MYSQL_HOME/lib/mecab/dic/ipadic_utf-8
   ```

   If you are using your own MeCab installation or have built MeCab from source, the default `dicdir` entry in the `mecabrc` file is likely to differ, as are the dictionaries and their location.

   *Note*

   After the MeCab parser plugin is installed, you can use the `mecab_charset` status variable to view the character set used with MeCab. The three MeCab dictionaries provided with the MySQL binary support the following character sets.

   - The `ipadic_euc-jp` dictionary supports the `ujis` and `eucjpms` character sets.
• The `ipadic_sjis` dictionary supports the `sjis` and `cp932` character sets.

• The `ipadic_utf-8` dictionary supports the `utf8mb3` and `utf8mb4` character sets.

`mecab_charset` only reports the first supported character set. For example, the `ipadic_utf-8` dictionary supports both `utf8mb3` and `utf8mb4`. `mecab_charset` always reports `utf8` when this dictionary is in use.

4. Restart MySQL.

5. Install the MeCab parser plugin:

The MeCab parser plugin is installed using `INSTALL PLUGIN` syntax. The plugin name is `mecab`, and the shared library name is `libpluginmecab.so`. For additional information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

`INSTALL PLUGIN mecab SONAME 'libpluginmecab.so';`

Once installed, the MeCab parser plugin loads at every normal MySQL restart.

6. Verify that the MeCab parser plugin is loaded using the `SHOW PLUGINS` statement.

    `mysql> SHOW PLUGINS;`

    A `mecab` plugin should appear in the list of plugins.

Creating a FULLTEXT Index that uses the MeCab Parser

To create a FULLTEXT index that uses the mecab parser, specify `WITH PARSER ngram` with `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`.

This example demonstrates creating a table with a mecab FULLTEXT index, inserting sample data, and viewing tokenized data in the Information Schema INNODB_FT_INDEX_CACHE table:

```
mysql> USE test;
mysql> CREATE TABLE articles (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  title VARCHAR(200),
  body TEXT,
  FULLTEXT (title,body) WITH PARSER mecab
) ENGINE=InnoDB CHARACTER SET utf8mb4;
mysql> SET NAMES utf8mb4;
mysql> INSERT INTO articles (title,body) VALUES
  ('データベース管理', 'このチュートリアルでは、私はどのようにデータベースを管理する方法を紹介します'),
  ('データベースアプリケーション開発', 'データベースアプリケーションを開発することを学ぶ');
mysql> SET GLOBAL innodb_ft_aux_table="test/articles";
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE ORDER BY doc_id, position;
```

To add a FULLTEXT index to an existing table, you can use `ALTER TABLE` or `CREATE INDEX`. For example:

```
CREATE TABLE articles ( id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
```
MeCab Full-Text Parser Plugin

```sql
ALTER TABLE articles ADD FULLTEXT INDEX ft_index (title,body) WITH PARSER mecab;

# Or:
CREATE FULLTEXT INDEX ft_index ON articles (title,body) WITH PARSER mecab;
```

**MeCab Parser Space Handling**

The MeCab parser uses spaces as separators in query strings. For example, the MeCab parser tokenizes データベース管理 as データベース and 管理.

**MeCab Parser Stopword Handling**

By default, the MeCab parser uses the default stopword list, which contains a short list of English stopwords. For a stopword list applicable to Japanese, you must create your own. For information about creating stopword lists, see Section 12.9.4, “Full-Text Stopwords”.

**MeCab Parser Term Search**

For natural language mode search, the search term is converted to a union of tokens. For example, データベース管理 is converted to データベース 管理.

```sql
SELECT COUNT(*) FROM articles WHERE MATCH(title,body) AGAINST('データベース管理' IN NATURAL LANGUAGE MODE);
```

For boolean mode search, the search term is converted to a search phrase. For example, データベース管理 is converted to データベース 管理.

```sql
SELECT COUNT(*) FROM articles WHERE MATCH(title,body) AGAINST('データベース管理' IN BOOLEAN MODE);
```

**MeCab Parser Wildcard Search**

Wildcard search terms are not tokenized. A search on データベース管理* is performed on the prefix, データベース管理.

```sql
SELECT COUNT(*) FROM articles WHERE MATCH(title,body) AGAINST('データベース管理*' IN BOOLEAN MODE);
```

**MeCab Parser Phrase Search**

Phrases are tokenized. For example, データベース管理 is tokenized as データベース 管理.

```sql
SELECT COUNT(*) FROM articles WHERE MATCH(title,body) AGAINST('データベース管理' IN BOOLEAN MODE);
```

**Installing MeCab From a Binary Distribution (Optional)**

This section describes how to install mecab and mecab-ipadic from a binary distribution using a native package management utility. For example, on Fedora, you can use Yum to perform the installation:

```bash
yum mecab-devel
```

On Debian or Ubuntu, you can perform an APT installation:

```bash
apt-get install mecab
```
Installing MeCab From Source (Optional)

If you want to build `mecab` and `mecab-ipadic` from source, basic installation steps are provided below. For additional information, refer to the MeCab documentation.

1. Download the tar.gz packages for `mecab` and `mecab-ipadic` from http://taku910.github.io/mecab/#download. As of February, 2016, the latest available packages are `mecab-0.996.tar.gz` and `mecab-ipadic-2.7.0-20070801.tar.gz`.

2. Install `mecab`:

   ```
   tar zxfv mecab-0.996.tar
   cd mecab-0.996
   ./configure
   make
   make check
   su
   make install
   ```

3. Install `mecab-ipadic`:

   ```
   tar zxfv mecab-ipadic-2.7.0-20070801.tar
   cd mecab-ipadic-2.7.0-20070801
   ./configure
   make
   su
   make install
   ```

4. Compile MySQL using the `WITH_MECAB` CMake option. Set the `WITH_MECAB` option to `system` if you have installed `mecab` and `mecab-ipadic` to the default location.

   ```
   -DMWITH_MECAB=system
   ```

   If you defined a custom installation directory, set `WITH_MECAB` to the custom directory. For example:

   ```
   -DMWITH_MECAB=/path/to/mecab
   ```

12.10 Cast Functions and Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Deprecated</th>
</tr>
</thead>
<tbody>
<tr>
<td>BINARY</td>
<td>Cast a string to a binary string</td>
<td>Yes</td>
</tr>
<tr>
<td>CAST()</td>
<td>Cast a value as a certain type</td>
<td></td>

<td>Cast a value as a certain type</td>
<td></td>
</tr>
</tbody>
</table>

Cast functions and operators enable conversion of values from one data type to another.

- Cast Function and Operator Descriptions
- Character Set Conversions
- Character Set Conversions for String Comparisons
- Cast Operations on Spatial Types
• Other Uses for Cast Operations

Cast Function and Operator Descriptions

• **BINARY expr**

The **BINARY** operator converts the expression to a binary string (a string that has the **binary** character set and **binary** collation). A common use for **BINARY** is to force a character string comparison to be done byte by byte using numeric byte values rather than character by character. The **BINARY** operator also causes trailing spaces in comparisons to be significant. For information about the differences between the **binary** collation of the **binary** character set and the **_bin** collations of nonbinary character sets, see Section 10.8.5, “The binary Collation Compared to _bin Collations”.

The **BINARY** operator is deprecated; you should expect its removal in a future version of MySQL. Use **CAST(... AS BINARY)** instead.

```sql
mysql> SET NAMES utf8mb4 COLLATE utf8mb4_general_ci;
-> OK
mysql> SELECT 'a' = 'A';
-> 1
mysql> SELECT BINARY 'a' = 'A';
-> 0
mysql> SELECT 'a' = 'a ';
-> 1
mysql> SELECT BINARY 'a' = 'a ';
-> 0
```

In a comparison, **BINARY** affects the entire operation; it can be given before either operand with the same result.

To convert a string expression to a binary string, these constructs are equivalent:

- **CONVERT(expr USING BINARY)**
- **CAST(expr AS BINARY)**
- **BINARY expr**

If a value is a string literal, it can be designated as a binary string without converting it by using the **_binary** character set introducer:

```sql
mysql> SELECT 'a' = 'A';
-> 1
mysql> SELECT _binary 'a' = 'A';
-> 0
```

For information about introducers, see Section 10.3.8, “Character Set Introducers”.

The **BINARY** operator in expressions differs in effect from the **BINARY** attribute in character column definitions. For a character column defined with the **BINARY** attribute, MySQL assigns the table default character set and the binary (**_bin**) collation of that character set. Every nonbinary character set has a **_bin** collation. For example, if the table default character set is **utf8mb4**, these two column definitions are equivalent:

- **CHAR(10) BINARY**
- **CHAR(10) CHARACTER SET utf8mb4 COLLATE utf8mb4_bin**

The use of **CHARACTER SET binary** in the definition of a **CHAR**, **VARCHAR**, or **TEXT** column causes the column to be treated as the corresponding binary string data type. For example, the following pairs of definitions are equivalent:

- **CHAR(10) CHARACTER SET binary**
CAST Function and Operator Descriptions

| BINARY(10) |
| VARCHAR(10) CHARACTER SET binary |
| VARBINARY(10) |
| TEXT CHARACTER SET binary |
| BLOB |

If `BINARY` is invoked from within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

- **CAST(expr AS type [ARRAY])**

- **CAST(timestamp_value AT TIME ZONE timezone_specifier AS DATETIME[(precision)])**

  `timezone_specifier`: [INTERVAL] ‘+00:00’ | ‘UTC’

With `CAST(expr AS type)` syntax, the `CAST()` function takes an expression of any type and produces a result value of the specified type. This operation may also be expressed as `CONVERT(expr, type)`, which is equivalent. If `expr` is `NULL`, `CAST()` returns `NULL`.

These `type` values are permitted:

- **BINARY[(N)]**

  Produces a string with the `VARBINARY` data type, except that when the expression `expr` is empty (zero length), the result type is `BINARY(0)`. If the optional length `N` is given, `BINARY(N)` causes the cast to use no more than `N` bytes of the argument. Values shorter than `N` bytes are padded with `0x00` bytes to a length of `N`. If the optional length `N` is not given, MySQL calculates the maximum length from the expression. If the supplied or calculated length is greater than an internal threshold, the result type is `BLOB`. If the length is still too long, the result type is `LONGBLOB`.

  For a description of how casting to `BINARY` affects comparisons, see Section 11.3.3, “The BINARY and VARBINARY Types”.

- **CHAR[(N)] [charset_info]**

  Produces a string with the `VARCHAR` data type, unless the expression `expr` is empty (zero length), in which case the result type is `CHAR(0)`.

  If the optional length `N` is given, `CHAR(N)` causes the cast to use no more than `N` characters of the argument. No padding occurs for values shorter than `N` characters. If the optional length `N` is not given, MySQL calculates the maximum length from the expression. If the supplied or calculated length is greater than an internal threshold, the result type is `TEXT`. If the length is still too long, the result type is `LONGTEXT`.

  With no `charset_info` clause, `CHAR` produces a string with the default character set. To specify the character set explicitly, these `charset_info` values are permitted:

  - **CHARACTER SET charset_name**: Produces a string with the given character set.
  - **ASCII**: Shorthand for `CHARACTER SET latin1`. 

2368
• **UNICODE**: Shorthand for `CHARACTER SET ucs2`.

In all cases, the string has the character set default collation.

• **DATE**

Produces a **DATE** value.

• **DATETIME[ (M) ]**

Produces a **DATETIME** value. If the optional `M` value is given, it specifies the fractional seconds precision.

• **DECIMAL[ (M[, D]) ]**

Produces a **DECIMAL** value. If the optional `M` and `D` values are given, they specify the maximum number of digits (the precision) and the number of digits following the decimal point (the scale). If `D` is omitted, 0 is assumed. If `M` is omitted, 10 is assumed.

• **DOUBLE**

Produces a **DOUBLE** result.

• **FLOAT[ (p) ]**

If the precision `p` is not specified, produces a result of type **FLOAT**. If `p` is provided and `0 <= < p <= 24`, the result is of type **FLOAT**. If `25 <= p <= 53`, the result is of type **DOUBLE**. If `p < 0` or `p > 53`, an error is returned.

• **JSON**

Produces a **JSON** value. For details on the rules for conversion of values between **JSON** and other types, see *Comparison and Ordering of JSON Values*.

• **NCHAR[ (N) ]**

Like **CHAR**, but produces a string with the national character set. See Section 10.3.7, "The National Character Set".

Unlike **CHAR**, **NCHAR** does not permit trailing character set information to be specified.

• **REAL**

Produces a result of type **REAL**. This is actually **FLOAT** if the **REAL_AS_FLOAT** SQL mode is enabled; otherwise the result is of type **DOUBLE**.

• **SIGNED [INTEGER]**

Produces a signed **BIGINT** value.

• **spatial_type**

**CAST()** and **CONVERT()** support casting geometry values from one spatial type to another, for certain combinations of spatial types. For details, see *Cast Operations on Spatial Types*.

• **TIME[ (M) ]**
### Cast Function and Operator Descriptions

Produce a **TIME** value. If the optional $m$ value is given, it specifies the fractional seconds precision.

- **UNSIGNED [INTEGER]**
  Produces an unsigned **BIGINT** value.

- **YEAR**
  Produces a **YEAR** value. These rules govern conversion to **YEAR** as follows:
  - For a four-digit number in the range 1901-2155 inclusive, or for a string which can be interpreted as a four-digit number in this range, return the corresponding **YEAR** value.
  - For a number consisting of one or two digits, or for a string which can be interpreted as such a number, return a **YEAR** value as follows:
    - If the number is in the range 1-69 inclusive, add 2000 and return the sum.
    - If the number is in the range 70-99 inclusive, add 1900 and return the sum.
  - For a string which evaluates to 0, return 2000.
  - For the number 0, return 0.
  - For a **DATE**, **DATETIME**, or **TIMESTAMP** value, return the **YEAR** portion of the value. For a **TIME** value, return the current year.

If you do not specify the type of a **TIME** argument, you may get a different result from what you expect, as shown here:

```sql
mysql> SELECT CAST("11:35:00" AS YEAR), CAST(TIME "11:35:00" AS YEAR);
+--------------------------+-------------------------------+
<table>
<thead>
<tr>
<th>CAST(&quot;11:35:00&quot; AS YEAR)</th>
<th>CAST(TIME &quot;11:35:00&quot; AS YEAR)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2011</td>
<td>2021</td>
</tr>
</tbody>
</table>
+--------------------------+-------------------------------+
```

- For a **DECIMAL**, **DOUBLE**, **DECIMAL**, or **REAL**, round the value to the nearest integer, then attempt to cast the value to **YEAR** using the rules for integer values, as shown here:

```sql
mysql> SELECT CAST(1944.35 AS YEAR), CAST(1944.50 AS YEAR);
+-----------------------+-----------------------+
<table>
<thead>
<tr>
<th>CAST(1944.35 AS YEAR)</th>
<th>CAST(1944.50 AS YEAR)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1944</td>
<td>1945</td>
</tr>
</tbody>
</table>
+-----------------------+-----------------------+
mysql> SELECT CAST(66.35 AS YEAR), CAST(66.50 AS YEAR);
+---------------------+---------------------+
<table>
<thead>
<tr>
<th>CAST(66.35 AS YEAR)</th>
<th>CAST(66.50 AS YEAR)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2066</td>
<td>2067</td>
</tr>
</tbody>
</table>
+---------------------+---------------------+
```

- An argument of type **GEOMETRY** cannot be converted to **YEAR**.
• For a value that cannot be successfully converted to \texttt{YEAR}, return \texttt{NULL}.

A string value containing non-numeric characters which must be truncated prior to conversion raises a warning, as shown here:

```sql
mysql> SELECT CAST("1979aaa" AS YEAR);
+-------------------------+
| CAST("1979aaa" AS YEAR) |
| 1979                   |
+-------------------------+
1 row in set, 1 warning (0.00 sec)
```

```
mysql> SHOW WARNINGS;
+---------+------+-------------------------------------------+
| Level   | Code | Message                                   |
|---------+------|-------------------------------------------|
| Warning | 1292 | Truncated incorrect YEAR value: '1979aaa' |
+---------+------|-------------------------------------------+
```

\texttt{InnoDB} allows the use of an additional \texttt{ARRAY} keyword for creating a multi-valued index on a \texttt{JSON} array as part of \texttt{CREATE INDEX}, \texttt{CREATE TABLE}, and \texttt{ALTER TABLE} statements. \texttt{ARRAY} is not supported except when used to create a multi-valued index in one of these statements, in which case it is required. The column being indexed must be a column of type \texttt{JSON}. With \texttt{ARRAY}, the \texttt{type} following the \texttt{AS} keyword may specify any of the types supported by \texttt{CAST()}, with the exceptions of \texttt{BINARY}, \texttt{JSON}, and \texttt{YEAR}. For syntax information and examples, as well as other relevant information, see \texttt{Multi-Valued Indexes}.

\textbf{Note}

\texttt{CONVERT()}, unlike \texttt{CAST()}, does \textit{not} support multi-valued index creation or the \texttt{ARRAY} keyword.

\texttt{CAST()} supports retrieval of a \texttt{TIMESTAMP} value as being in UTC, using the \texttt{AT TIMEZONE} operator. The only supported time zone is UTC; this can be specified as either of \texttt{'+00:00'} or \texttt{'UTC'}. The only return type supported by this syntax is \texttt{DATETIME}, with an optional precision specifier in the range of 0 to 6, inclusive.

\texttt{TIMESTAMP} values that use timezone offsets are also supported.

```sql
mysql> SELECT @@system_time_zone;
+--------------------+
| @@system_time_zone |
| EDT                |
+--------------------+
1 row in set (0.00 sec)

mysql> CREATE TABLE tz (c TIMESTAMP);
Query OK, 0 rows affected (0.41 sec)

mysql> INSERT INTO tz VALUES
    > ROW(CURRENT_TIMESTAMP),
    > ROW('2020-07-28 14:50:15+1:00');
Query OK, 1 row affected (0.08 sec)

mysql> TABLE tz;
+---------+
| c       |
+---------+
| 2020-07-28 09:22:41 |
```
Character Set Conversions

If you use 'UTC' as the time zone specifier with this form of CAST(), and the server raises an error such as Unknown or incorrect time zone: 'UTC', you may need to install the MySQL time zone tables (see Populating the Time Zone Tables).

**AT TIME ZONE** does not support the ARRAY keyword, and is not supported by the CONVERT() function.

- **CONVERT(expr USING transcodeing_name)**

  CONVERT(expr USING transcodeing_name) is standard SQL syntax. The non-USING form of CONVERT() is ODBC syntax. Regardless of the syntax used, the function returns NULL if expr is NULL.

CONVERT(expr USING transcodeing_name) converts data between different character sets. In MySQL, transcoding names are the same as the corresponding character set names. For example, this statement converts the string 'abc' in the default character set to the corresponding string in the utf8mb4 character set:

```sql
SELECT CONVERT('abc' USING utf8mb4);
```

CONVERT(expr, type) syntax (without USING) takes an expression and a type value specifying a result type, and produces a result value of the specified type. This operation may also be expressed as CAST(expr AS type), which is equivalent. For more information, see the description of CAST().

## Character Set Conversions

**CONVERT()** with a USING clause converts data between character sets:

- **CONVERT(expr USING transcodeing_name)**

In MySQL, transcoding names are the same as the corresponding character set names.

Examples:

```sql
SELECT CONVERT('test' USING utf8mb4);
SELECT CONVERT(_latin1'Müller' USING utf8mb4);
INSERT INTO utf8mb4_table (utf8mb4_column)
    SELECT CONVERT(latin1_column USING utf8mb4) FROM latin1_table;
```
To convert strings between character sets, you can also use `CONVERT(expr, type)` syntax (without `USING`), or `CAST(expr AS type)`, which is equivalent:

- `CONVERT(string, CHAR[(N)] CHARACTER SET charset_name)`
- `CAST(string AS CHAR[(N)] CHARACTER SET charset_name)`

Examples:

```sql
SELECT CONVERT('test', CHAR CHARACTER SET utf8mb4);
SELECT CAST('test' AS CHAR CHARACTER SET utf8mb4);
```

If you specify `CHARACTER SET charset_name` as just shown, the character set and collation of the result are `charset_name` and the default collation of `charset_name`. If you omit `CHARACTER SET charset_name`, the character set and collation of the result are defined by the `character_set_connection` and `collation_connection` system variables that determine the default connection character set and collation (see Section 10.4, “Connection Character Sets and Collations”).

A `COLLATE` clause is not permitted within a `CONVERT()` or `CAST()` call, but you can apply it to the function result. For example, these are legal:

```sql
SELECT CONVERT('test' USING utf8mb4) COLLATE utf8mb4_bin;
SELECT CONVERT('test', CHAR CHARACTER SET utf8mb4) COLLATE utf8mb4_bin;
SELECT CAST('test' AS CHAR CHARACTER SET utf8mb4) COLLATE utf8mb4_bin;
```

But these are illegal:

```sql
SELECT CONVERT('test' USING utf8mb4 COLLATE utf8mb4_bin);
SELECT CONVERT('test', CHAR CHARACTER SET utf8mb4 COLLATE utf8mb4_bin);
SELECT CAST('test' AS CHAR CHARACTER SET utf8mb4 COLLATE utf8mb4_bin);
```

For string literals, another way to specify the character set is to use a character set introducer. `_latin1` and `_latin2` in the preceding example are instances of introducers. Unlike conversion functions such as `CAST()`, or `CONVERT()`, which convert a string from one character set to another, an introducer designates a string literal as having a particular character set, with no conversion involved. For more information, see Section 10.3.8, “Character Set Introducers”.

Character Set Conversions for String Comparisons

Normally, you cannot compare a `BLOB` value or other binary string in case-insensitive fashion because binary strings use the `binary` character set, which has no collation with the concept of lettercase. To perform a case-insensitive comparison, first use the `CONVERT()` or `CAST()` function to convert the value to a nonbinary string. Comparisons of the resulting string use its collation. For example, if the conversion result collation is not case-sensitive, a `LIKE` operation is not case-sensitive. That is true for the following operation because the default `utf8mb4` collation (`utf8mb4_0900_ai_ci`) is not case-sensitive:

```sql
SELECT 'A' LIKE CONVERT(blob_col USING utf8mb4)
FROM tbl_name;
```

To specify a particular collation for the converted string, use a `COLLATE` clause following the `CONVERT()` call:

```sql
SELECT 'A' LIKE CONVERT(blob_col USING utf8mb4) COLLATE utf8mb4_unicode_ci
FROM tbl_name;
```

To use a different character set, substitute its name for `utf8mb4` in the preceding statements (and similarly to use a different collation).

`CONVERT()` and `CAST()` can be used more generally for comparing strings represented in different character sets. For example, a comparison of these strings results in an error because they have different character sets:
Converting one of the strings to a character set compatible with the other enables the comparison to occur without error:

```sql
mysql> SELECT @s1 = CONVERT(@s2 USING latin1);
+---------------------------------+
| @s1 = CONVERT(@s2 USING latin1) |
+---------------------------------+
| 1                               |
+---------------------------------+
```

Character set conversion is also useful preceding lettercase conversion of binary strings. `LOWER()` and `UPPER()` are ineffective when applied directly to binary strings because the concept of lettercase does not apply. To perform lettercase conversion of a binary string, first convert it to a nonbinary string using a character set appropriate for the data stored in the string:

```sql
mysql> SET @str = BINARY 'New York';
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING utf8mb4));
+-------------+------------------------------------+
| LOWER(@str) | LOWER(CONVERT(@str USING utf8mb4)) |
+-------------+------------------------------------+
| New York    | new york                           |
+-------------+------------------------------------+
```

Be aware that if you apply `BINARY`, `CAST()`, or `CONVERT()` to an indexed column, MySQL may not be able to use the index efficiently.

## Cast Operations on Spatial Types

`CAST()` and `CONVERT()` support casting geometry values from one spatial type to another, for certain combinations of spatial types. The following list shows the permitted type combinations, where “MySQL extension” designates casts implemented in MySQL beyond those defined in the SQL/MM standard:

- **From Point to:**
  - `MultiPoint`
  - `GeometryCollection`
- **From LineString to:**
  - `Polygon` (MySQL extension)
  - `MultiPoint` (MySQL extension)
  - `MultiLineString`
  - `GeometryCollection`
- **From Polygon to:**
  - `LineString` (MySQL extension)
  - `MultiLineString` (MySQL extension)
  - `MultiPolygon`
Cast Operations on Spatial Types

- GeometryCollection
- From MultiPoint to:
  - Point
  - LineString (MySQL extension)
  - GeometryCollection
- From MultiLineString to:
  - LineString
  - Polygon (MySQL extension)
  - MultiPolygon (MySQL extension)
  - GeometryCollection
- From MultiPolygon to:
  - Polygon
  - MultiLineString (MySQL extension)
  - GeometryCollection
- From GeometryCollection to:
  - Point
  - LineString
  - Polygon
  - MultiPoint
  - MultiLineString
  - MultiPolygon

In spatial casts, GeometryCollection and GeomCollection are synonyms for the same result type.

Some conditions apply to all spatial type casts, and some conditions apply only when the cast result is to have a particular spatial type. For information about terms such as "well-formed geometry," see Section 11.4.4, “Geometry Well-Formedness and Validity”.

- General Conditions for Spatial Casts
- Conditions for Casts to Point
- Conditions for Casts to LineString
- Conditions for Casts to Polygon
- Conditions for Casts to MultiPoint
- Conditions for Casts to MultiLineString
Cast Operations on Spatial Types

- Conditions for Casts to MultiPolygon
- Conditions for Casts to GeometryCollection

General Conditions for Spatial Casts

These conditions apply to all spatial casts regardless of the result type:

- The result of a cast is in the same SRS as that of the expression to cast.
- Casting between spatial types does not change coordinate values or order.
- If the expression to cast is NULL, the function result is NULL.
- Casting to spatial types using the JSON_VALUE() function with a RETURNING clause specifying a spatial type is not permitted.
- Casting to an ARRAY of spatial types is not permitted.
- If the spatial type combination is permitted but the expression to cast is not a syntactically well-formed geometry, an ER_GIS_INVALID_DATA error occurs.
- If the spatial type combination is permitted but the expression to cast is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an ER_SRS_NOT_FOUND error occurs.
- If the expression to cast has a geographic SRS but has a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range (−180, 180], an ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE error occurs.
  - If a latitude value is not in the range [−90, 90], an ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

Conditions for Casts to Point

When the cast result type is Point, these conditions apply:

- If the expression to cast is a well-formed geometry of type Point, the function result is that Point.
- If the expression to cast is a well-formed geometry of type MultiPoint containing a single Point, the function result is that Point. If the expression contains more than one Point, an ER_INVALID_CAST_TO_GEOMETRY error occurs.
- If the expression to cast is a well-formed geometry of type GeometryCollection containing only a single Point, the function result is that Point. If the expression is empty, contains more than one Point, or contains other geometry types, an ER_INVALID_CAST_TO_GEOMETRY error occurs.
- If the expression to cast is a well-formed geometry of type other than Point, MultiPoint, GeometryCollection, an ER_INVALID_CAST_TO_GEOMETRY error occurs.

Conditions for Casts to LineString

When the cast result type is LineString, these conditions apply:

- If the expression to cast is a well-formed geometry of type LineString, the function result is that LineString.
Cast Operations on Spatial Types

- If the expression to cast is a well-formed geometry of type `Polygon` that has no inner rings, the function result is a `LineString` containing the points of the outer ring in the same order. If the expression has inner rings, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

- If the expression to cast is a well-formed geometry of type `MultiPoint` containing at least two points, the function result is a `LineString` containing the points of the `MultiPoint` in the order they appear in the expression. If the expression contains only one `Point`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

- If the expression to cast is a well-formed geometry of type `MultiLineString` containing a single `LineString`, the function result is that `LineString`. If the expression contains more than one `LineString`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

- If the expression to cast is a well-formed geometry of type `GeometryCollection`, containing only a single `LineString`, the function result is that `LineString`. If the expression is empty, contains more than one `LineString`, or contains other geometry types, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

- If the expression to cast is a well-formed geometry of type other than `LineString`, `Polygon`, `MultiPoint`, `MultiLineString`, or `GeometryCollection`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

**Conditions for Casts to Polygon**

When the cast result type is `Polygon`, these conditions apply:

- If the expression to cast is a well-formed geometry of type `LineString` that is a ring (that is, the start and end points are the same), the function result is a `Polygon` with an outer ring consisting of the points of the `LineString` in the same order. If the expression is not a ring, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs. If the ring is not in the correct order (the exterior ring must be counter-clockwise), an `ER_INVALID_CAST_POLYGON_RING_DIRECTION` error occurs.

- If the expression to cast is a well-formed geometry of type `Polygon`, the function result is that `Polygon`.

- If the expression to cast is a well-formed geometry of type `MultiLineString` where all elements are rings, the function result is a `Polygon` with the first `LineString` as outer ring and any additional `LineString` values as inner rings. If any element of the expression is not a ring, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs. If any ring is not in the correct order (the exterior ring must be counter-clockwise, interior rings must be clockwise), an `ER_INVALID_CAST_POLYGON_RING_DIRECTION` error occurs.

- If the expression to cast is a well-formed geometry of type `MultiPolygon` containing a single `Polygon`, the function result is that `Polygon`. If the expression contains more than one `Polygon`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

- If the expression to cast is a well-formed geometry of type `GeometryCollection` containing only a single `Polygon`, the function result is that `Polygon`. If the expression is empty, contains more than one `Polygon`, or contains other geometry types, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

- If the expression to cast is a well-formed geometry of type other than `LineString`, `Polygon`, `MultiLineString`, `MultiPolygon`, or `GeometryCollection`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

**Conditions for Casts to MultiPoint**

When the cast result type is `MultiPoint`, these conditions apply:
Cast Operations on Spatial Types

- If the expression to cast is a well-formed geometry of type `Point`, the function result is a `MultiPoint` containing that `Point` as its sole element.

- If the expression to cast is a well-formed geometry of type `LineString`, the function result is a `MultiPoint` containing the points of the `LineString` in the same order.

- If the expression to cast is a well-formed geometry of type `MultiPoint`, the function result is that `MultiPoint`.

- If the expression to cast is a well-formed geometry of type `GeometryCollection` containing only points, the function result is a `MultiPoint` containing those points. If the `GeometryCollection` is empty or contains other geometry types, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

- If the expression to cast is a well-formed geometry of type other than `Point`, `LineString`, `MultiPoint`, or `GeometryCollection`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

**Conditions for Casts to MultiLineString**

When the cast result type is `MultiLineString`, these conditions apply:

- If the expression to cast is a well-formed geometry of type `LineString`, the function result is a `MultiLineString` containing that `LineString` as its sole element.

- If the expression to cast is a well-formed geometry of type `Polygon`, the function result is a `MultiLineString` containing the outer ring of the `Polygon` as its first element and any inner rings as additional elements in the order they appear in the expression.

- If the expression to cast is a well-formed geometry of type `MultiLineString`, the function result is that `MultiLineString`.

- If the expression to cast is a well-formed geometry of type `MultiPolygon` containing only polygons without inner rings, the function result is a `MultiLineString` containing the polygon rings in the order they appear in the expression. If the expression contains any polygons with inner rings, an `ER_WRONG_PARAMETERS_TO_STORED_FCT` error occurs.

- If the expression to cast is a well-formed geometry of type `GeometryCollection` containing only linestrings, the function result is a `MultiLineString` containing those linestrings. If the expression is empty or contains other geometry types, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

- If the expression to cast is a well-formed geometry of type other than `LineString`, `Polygon`, `MultiLineString`, `MultiPolygon`, or `GeometryCollection`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

**Conditions for Casts to MultiPolygon**

When the cast result type is `MultiPolygon`, these conditions apply:

- If the expression to cast is a well-formed geometry of type `Polygon`, the function result is a `MultiPolygon` containing the `Polygon` as its sole element.

- If the expression to cast is a well-formed geometry of type `MultiLineString` where all elements are rings, the function result is a `MultiPolygon` containing a `Polygon` with only an outer ring for each element of the expression. If any element is not a ring, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs. If any ring is not in the correct order (exterior ring must be counter-clockwise), an `ER_INVALID_CAST_POLYGON_RING_DIRECTION` error occurs.

- If the expression to cast is a well-formed geometry of type `MultiPolygon`, the function result is that `MultiPolygon`.
Other Uses for Cast Operations

- If the expression to cast is a well-formed geometry of type `GeometryCollection` containing only polygons, the function result is a `MultiPolygon` containing those polygons. If the expression is empty or contains other geometry types, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

- If the expression to cast is a well-formed geometry of type other than `Polygon`, `MultiLineString`, `MultiPolygon`, or `GeometryCollection`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

Conditions for Casts to `GeometryCollection`

When the cast result type is `GeometryCollection`, these conditions apply:

- `GeometryCollection` and `GeomCollection` are synonyms for the same result type.

- If the expression to cast is a well-formed geometry of type `Point`, the function result is a `GeometryCollection` containing that `Point` as its sole element.

- If the expression to cast is a well-formed geometry of type `LineString`, the function result is a `GeometryCollection` containing that `LineString` as its sole element.

- If the expression to cast is a well-formed geometry of type `Polygon`, the function result is a `GeometryCollection` containing that `Polygon` as its sole element.

- If the expression to cast is a well-formed geometry of type `MultiPoint`, the function result is a `GeometryCollection` containing the points in the order they appear in the expression.

- If the expression to cast is a well-formed geometry of type `MultiLineString`, the function result is a `GeometryCollection` containing the linestrings in the order they appear in the expression.

- If the expression to cast is a well-formed geometry of type `MultiPolygon`, the function result is a `GeometryCollection` containing the elements of the `MultiPolygon` in the order they appear in the expression.

- If the expression to cast is a well-formed geometry of type `GeometryCollection`, the function result is that `GeometryCollection`.

Other Uses for Cast Operations

The cast functions are useful for creating a column with a specific type in a `CREATE TABLE ... SELECT` statement:

```
mysql> CREATE TABLE new_table SELECT CAST('2000-01-01' AS DATE) AS c1;
mysql> SHOW CREATE TABLE new_table\G
*************************** 1. row ***************************
Table: new_table
Create Table: CREATE TABLE `new_table` (
  `c1` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4
```

The cast functions are useful for sorting `ENUM` columns in lexical order. Normally, sorting of `ENUM` columns occurs using the internal numeric values. Casting the values to `CHAR` results in a lexical sort:

```
SELECT enum_col FROM tbl_name ORDER BY CAST(enum_col AS CHAR);
```

`CAST()` also changes the result if you use it as part of a more complex expression such as

```
CONCAT('Date: ',CAST(NOW() AS DATE)).
```

For temporal values, there is little need to use `CAST()` to extract data in different formats. Instead, use a function such as `EXTRACT()`, `DATE_FORMAT()`, or `TIME_FORMAT()`. See Section 12.7, “Date and Time Functions”.

2379
To cast a string to a number, it normally suffices to use the string value in numeric context:

```sql
mysql> SELECT 1+'1';
-> 2
```

That is also true for hexadecimal and bit literals, which are binary strings by default:

```sql
mysql> SELECT X'41', X'41'+0;
-> 'A', 65
mysql> SELECT b'1100001', b'1100001'+0;
-> 'a', 97
```

A string used in an arithmetic operation is converted to a floating-point number during expression evaluation.

A number used in string context is converted to a string:

```sql
mysql> SELECT CONCAT('hello you ',2);
-> 'hello you 2'
```

For information about implicit conversion of numbers to strings, see Section 12.3, “Type Conversion in Expression Evaluation”.

MySQL supports arithmetic with both signed and unsigned 64-bit values. For numeric operators (such as `+` or `-`) where one of the operands is an unsigned integer, the result is unsigned by default (see Section 12.6.1, “Arithmetic Operators”). To override this, use the `SIGNED` or `UNSIGNED` cast operator to cast a value to a signed or unsigned 64-bit integer, respectively.

```sql
mysql> SELECT 1 - 2;
-> -1
mysql> SELECT CAST(1 - 2 AS UNSIGNED);
-> 18446744073709551615
mysql> SELECT CAST(CAST(1 - 2 AS UNSIGNED) AS SIGNED);
-> -1
```

If either operand is a floating-point value, the result is a floating-point value and is not affected by the preceding rule. (In this context, `DECIMAL` column values are regarded as floating-point values.)

```sql
mysql> SELECT CAST(1 AS UNSIGNED) - 2.0;
-> -1.0
```

The SQL mode affects the result of conversion operations (see Section 5.1.11, “Server SQL Modes”). Examples:

- For conversion of a “zero” date string to a date, `CONVERT()` and `CAST()` return `NULL` and produce a warning when the `NO_ZERO_DATE` SQL mode is enabled.
- For integer subtraction, if the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the subtraction result is signed even if any operand is unsigned.

### 12.11 XML Functions

<table>
<thead>

</tr>
</tbody>
</table>

This section discusses XML and related functionality in MySQL.
XML Functions

Note
It is possible to obtain XML-formatted output from MySQL in the *mysql* and *mysqldump* clients by invoking them with the `--xml` option. See Section 4.5.1, "mysql — The MySQL Command-Line Client", and Section 4.5.4, "mysqldump — A Database Backup Program".

Two functions providing basic XPath 1.0 (XML Path Language, version 1.0) capabilities are available. Some basic information about XPath syntax and usage is provided later in this section; however, an in-depth discussion of these topics is beyond the scope of this manual, and you should refer to the XML Path Language (XPath) 1.0 standard for definitive information. A useful resource for those new to XPath or who desire a refresher in the basics is the Zvon.org XPath Tutorial, which is available in several languages.

Note
These functions remain under development. We continue to improve these and other aspects of XML and XPath functionality in MySQL 8.2 and onwards. You may discuss these, ask questions about them, and obtain help from other users with them in the MySQL XML User Forum.

XPath expressions used with these functions support user variables and local stored program variables. User variables are weakly checked; variables local to stored programs are strongly checked (see also Bug #26518):

- **User variables (weak checking).** Variables using the syntax `$@variable_name` (that is, user variables) are not checked. No warnings or errors are issued by the server if a variable has the wrong type or has previously not been assigned a value. This also means the user is fully responsible for any typographical errors, since no warnings are given if (for example) `$@myvariable` is used where `$@myvariable` was intended.

Example:

```sql
mysql> SET @xml = '<a><b>X</b><b>Y</b></a>';  
Query OK, 0 rows affected (0.00 sec)
mysql> SET @i =1, @j = 2;  
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @i, ExtractValue(@xml, '//b[@$i]');  
+------+------------------+
<table>
<thead>
<tr>
<th>@i</th>
<th>ExtractValue(@xml, '//b[@$i]')</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>X</td>
</tr>
</tbody>
</table>
+------+------------------+
1 row in set (0.00 sec)
mysql> SELECT @j, ExtractValue(@xml, '//b[@$j]');  
+------+------------------+
<table>
<thead>
<tr>
<th>@j</th>
<th>ExtractValue(@xml, '//b[@$j]')</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>Y</td>
</tr>
</tbody>
</table>
+------+------------------+
1 row in set (0.00 sec)
mysql> SELECT @k, ExtractValue(@xml, '//b[@$k]');  
+------+------------------+
<table>
<thead>
<tr>
<th>@k</th>
<th>ExtractValue(@xml, '//b[@$k]')</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td></td>
</tr>
</tbody>
</table>
+------+------------------+
1 row in set (0.00 sec)
```
XML Functions

• **Variables in stored programs (strong checking).** Variables using the syntax \$variable_name can be declared and used with these functions when they are called inside stored programs. Such variables are local to the stored program in which they are defined, and are strongly checked for type and value.

Example:

```sql
mysql> DELIMITER |
mysql> CREATE PROCEDURE myproc ()
    -> BEGIN
    -> DECLARE i INT DEFAULT 1;
    -> DECLARE xml VARCHAR(25) DEFAULT '<a>X</a><a>Y</a><a>Z</a>';  
    -> WHILE i < 4 DO
    ->     SELECT xml, i, ExtractValue(xml, '//a[$i]');
    ->     SET i = i+1;
    -> END WHILE;
    -> END |
Query OK, 0 rows affected (0.01 sec)
mysql> DELIMITER ;
mysql> CALL myproc();
+--------------------------+---+------------------------------+
| xml                      | i | ExtractValue(xml, '//a[$i]') |
| <a>X</a><a>Y</a><a>Z</a> | 1 | X                            |
+--------------------------+---+------------------------------+
1 row in set (0.00 sec)

+--------------------------+---+------------------------------+
| xml                      | i | ExtractValue(xml, '//a[$i]') |
| <a>X</a><a>Y</a><a>Z</a> | 2 | Y                            |
+--------------------------+---+------------------------------+
1 row in set (0.01 sec)

+--------------------------+---+------------------------------+
| xml                      | i | ExtractValue(xml, '//a[$i]') |
| <a>X</a><a>Y</a><a>Z</a> | 3 | Z                            |
+--------------------------+---+------------------------------+
1 row in set (0.01 sec)
```

**Parameters.** Variables used in XPath expressions inside stored routines that are passed in as parameters are also subject to strong checking.

Expressions containing user variables or variables local to stored programs must otherwise (except for notation) conform to the rules for XPath expressions containing variables as given in the XPath 1.0 specification.

**Note**

A user variable used to store an XPath expression is treated as an empty string. Because of this, it is not possible to store an XPath expression as a user variable. (Bug #32911)

• `ExtractValue(xml_frag, xpath_expr)`

`ExtractValue()` takes two string arguments, a fragment of XML markup `xml_frag` and an XPath expression `xpath_expr` (also known as a locator); it returns the text (CDATA) of the first text node which is a child of the element or elements matched by the XPath expression.
Using this function is the equivalent of performing a match using the `xpath_expr` after appending `/text()`. In other words, `ExtractValue('<a><b>Sakila</b></a>', '/a/b')` and `ExtractValue('<a><b>Sakila</b></a>', '/a/b/text()')` produce the same result. If `xml_frag` or `xpath_expr` is NULL, the function returns NULL.

If multiple matches are found, the content of the first child text node of each matching element is returned (in the order matched) as a single, space-delimited string.

If no matching text node is found for the expression (including the implicit `/text()`)—for whatever reason, as long as `xpath_expr` is valid, and `xml_frag` consists of elements which are properly nested and closed—an empty string is returned. No distinction is made between a match on an empty element and no match at all. This is by design.

If you need to determine whether no matching element was found in `xml_frag` or such an element was found but contained no child text nodes, you should test the result of an expression that uses the XPath `count()` function. For example, both of these statements return an empty string, as shown here:

```sql
mysql> SELECT ExtractValue('<a><b/></a>', '/a/b');
+-------------------------------------+
| ExtractValue('<a><b/></a>', '/a/b') |
+-------------------------------------+
|                                     |
+-------------------------------------+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a><c/></a>', '/a/b');
+-------------------------------------+
| ExtractValue('<a><c/></a>', '/a/b') |
+-------------------------------------+
|                                     |
+-------------------------------------+
1 row in set (0.00 sec)
```

However, you can determine whether there was actually a matching element using the following:

```sql
mysql> SELECT ExtractValue('<a><b/></a>', 'count(/a/b)');
+-------------------------------------+
| ExtractValue('<a><b/></a>', 'count(/a/b)') |
+-------------------------------------+
| 1                                   |
+-------------------------------------+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a><c/></a>', 'count(/a/b)');
+-------------------------------------+
| ExtractValue('<a><c/></a>', 'count(/a/b)') |
+-------------------------------------+
| 0                                   |
+-------------------------------------+
1 row in set (0.01 sec)
```

---

**Important**

`ExtractValue()` returns only CDATA, and does not return any tags that might be contained within a matching tag, nor any of their content (see the result returned as `val1` in the following example).

```sql
mysql> SELECT
   -> ExtractValue('<a>ccc<b>ddd</b></a>', '/a') AS val1,
   -> ExtractValue('<a>ccc<b>ddd</b></a>', '/a/b') AS val2,
   -> ExtractValue('<a>ccc<b>ddd</b></a>', '//b') AS val3;
+-----+-----+-----+
| val1| val2| val3|
+-----+-----+-----+
| ccc | ccc |    |
|     |     | ddd|
+-----+-----+-----+
3 rows in set (0.00 sec)
```
This function uses the current SQL collation for making comparisons with `contains()`, performing the same collation aggregation as other string functions (such as `CONCAT()`), in taking into account the collation coercibility of their arguments; see Section 10.8.4, “Collation Coercibility in Expressions”, for an explanation of the rules governing this behavior.

(NULL is returned if `xml_frag` contains elements which are not properly nested or closed, and a warning is generated, as shown in this example:

```sql
mysql> SELECT ExtractValue('<a>c</a><b>', '//a');
+-----------------------------------+
| ExtractValue('<a>c</a><b>', '//a') |
| NULL                              |
+-----------------------------------+
1 row in set, 1 warning (0.00 sec)
```

```sql
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Warning
Code: 1525
Message: Incorrect XML value: 'parse error at line 1 pos 11:
   END-OF-INPUT unexpected ('>' wanted)'
1 row in set (0.00 sec)
```

### UpdateXML(xml_target, xpath_expr, new_xml)

This function replaces a single portion of a given fragment of XML markup `xml_target` with a new XML fragment `new_xml`, and then returns the changed XML. The portion of `xml_target` that is replaced matches an XPath expression `xpath_expr` supplied by the user.

If no expression matching `xpath_expr` is found, or if multiple matches are found, the function returns the original `xml_target` XML fragment. All three arguments should be strings. If any of the arguments to `UpdateXML()` are NULL, the function returns NULL.

```sql
mysql> SELECT
    -> UpdateXML('<a><b>ccc</b><d></d></a>', '/a', '<e>fff</e>') AS val1,
    -> UpdateXML('<a><b>ccc</b><d></d></a>', '/b', '<e>fff</e>') AS val2,
    -> UpdateXML('<a><b>ccc</b><d></d></a>', '//b', '<e>fff</e>') AS val3,
    -> UpdateXML('<a><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val4,
    -> UpdateXML('<a><d></d><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val5
    -> \G
```

```
largest: 1. row ****************************
val1: <e>fff</e>
```
XML Functions

Note

A discussion in depth of XPath syntax and usage are beyond the scope of this manual. Please see the XML Path Language (XPath) 1.0 specification for definitive information. A useful resource for those new to XPath or who are wishing a refresher in the basics is the Zvon.org XPath Tutorial, which is available in several languages.

Descriptions and examples of some basic XPath expressions follow:

• /tag

Matches <tag/> if and only if <tag/> is the root element.

Example: /a has a match in <a><b/></a> because it matches the outermost (root) tag. It does not match the inner a element in <b><a/></b> because in this instance it is the child of another element.

• /tag1/tag2

Matches <tag2/> if and only if it is a child of <tag1/>, and <tag1/> is the root element.

Example: /a/b matches the b element in the XML fragment <a><b/></a> because it is a child of the root element a. It does not have a match in <b><a/></b> because in this case, b is the root element (and hence the child of no other element). Nor does the XPath expression have a match in <a><c><b/></c></a>; here, b is a descendant of a, but not actually a child of a.

This construct is extendable to three or more elements. For example, the XPath expression /a/b/c matches the c element in the fragment <a><b><c/></b></a>.

• //tag

Matches any instance of <tag>.

Example: //a matches the a element in any of the following: <a><b><c/></b></a>; <a><b/></a>; <a><b><c/></b></a>.

// can be combined with /. For example, //a/b matches the b element in either of the fragments <a><b/></a> or <c><a><b/></a></c>.

Note

//tag is the equivalent of /descendant-or-self::*//tag. A common error is to confuse this with /descendant-or-self::*tag, although the latter expression can actually lead to very different results, as can be seen here:
The * operator acts as a "wildcard" that matches any element. For example, the expression `/b` matches the `b` element in either of the XML fragments `<a><b/></a>` or `<c><b/></c>`. However, the expression does not produce a match in the fragment `<b><a/></b>` because `b` must be a child of some other element. The wildcard may be used in any position: The expression `/b/*/` matches any child of a `b` element that is itself not the root element.

You can match any of several locators using the `|` (UNION) operator. For example, the expression `//b|//c` matches all `b` and `c` elements in the XML target.

It is also possible to match an element based on the value of one or more of its attributes. This done using the syntax `tag[@attribute="value"]`. For example, the expression `//b[@id="idB"]` matches the second `b` element in the fragment `<a><b id="idA"/></a><c><b id="idB"/></c>`.
a>. To match against any element having attribute="value", use the XPath expression // *[attribute="value"].

To filter multiple attribute values, simply use multiple attribute-comparison clauses in succession. For example, the expression //b[@c="x"][@d="y"] matches the element <b c="x" d="y"/>
 occurring anywhere in a given XML fragment.

To find elements for which the same attribute matches any of several values, you can use multiple locators joined by the | operator. For example, to match all b elements whose c attributes have either of the values 23 or 17, use the expression //b[@c="23"] | //b[@c="17"]. You can also use the logical or operator for this purpose: //b[@c="23" or @c="17"].

Note
The difference between or and | is that or joins conditions, while | joins result sets.

XPath Limitations. The XPath syntax supported by these functions is currently subject to the following limitations:

• Nodeset-to-nodeset comparison (such as '/a/b[@c=@@d]' ) is not supported.

• All of the standard XPath comparison operators are supported. (Bug #22823)

• Relative locator expressions are resolved in the context of the root node. For example, consider the following query and result:

    mysql> SELECT ExtractValue(
               -> '<a><b c="1">X</b><b c="2">Y</b></a>',
               -> 'a/b' 
               -> ) AS result;

+--------+
<table>
<thead>
<tr>
<th>result</th>
</tr>
</thead>
<tbody>
<tr>
<td>X Y</td>
</tr>
</tbody>
</table>
+---------+
1 row in set (0.03 sec)

In this case, the locator a/b resolves to /a/b.

Relative locators are also supported within predicates. In the following example, d[../@c="1"] is resolved as /a/b[@c="1"]/d:

    mysql> SELECT ExtractValue(
               -> '<a>
               -> '<b c="1"><d>X</d></b>
               -> '<b c="2"><d>X</d></b>
               -> '</a>',
               -> 'a/b/d[../@c="1"]'
               -> ) AS result;

+--------+
<table>
<thead>
<tr>
<th>result</th>
</tr>
</thead>
<tbody>
<tr>
<td>X</td>
</tr>
</tbody>
</table>
+---------+
1 row in set (0.00 sec)

• Locators prefixed with expressions that evaluate as scalar values—including variable references, literals, numbers, and scalar function calls—are not permitted, and their use results in an error.

• The :: operator is not supported in combination with node types such as the following:
XML Functions

- `axis::comment()`
- `axis::text()`
- `axis::processing-instructions()`
- `axis::node()`

However, name tests (such as `axis::name` and `axis::*`) are supported, as shown in these examples:

```sql
mysql> SELECT ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::b');
+-------------------------------------------------------+
| ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::b') |
+-------------------------------------------------------+
| x                                                     |
+-------------------------------------------------------+
1 row in set (0.02 sec)

mysql> SELECT ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::*');
+-------------------------------------------------------+
| ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::*') |
+-------------------------------------------------------+
| x y                                                   |
+-------------------------------------------------------+
1 row in set (0.01 sec)
```

- “Up-and-down” navigation is not supported in cases where the path would lead “above” the root element. That is, you cannot use expressions which match on descendants of ancestors of a given element, where one or more of the ancestors of the current element is also an ancestor of the root element (see Bug #16321).

- The following XPath functions are not supported, or have known issues as indicated:
  - `id()`
  - `lang()`
  - `local-name()`
  - `name()`
  - `namespace-uri()`
  - `normalize-space()`
  - `starts-with()`
  - `string()`
  - `substring-after()`
  - `substring-before()`
  - `translate()`

- The following axes are not supported:
  - `following-sibling`
  - `following`
XML Functions

- preceding-sibling
- preceding

XPath expressions passed as arguments to `ExtractValue()` and `UpdateXML()` may contain the colon character (:) in element selectors, which enables their use with markup employing XML namespaces notation. For example:

```sql
mysql> SET @xml = '<a>111<b:c>222<d>333</d><e:f>444</e:f></b:c></a>;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//e:f');</sql>
+-----------------------------+
| ExtractValue(@xml, '//e:f') |
+-----------------------------+ 444
+-----------------------------+
1 row in set (0.00 sec)

mysql> SELECT UpdateXML(@xml, '//b:c', '<g:h>555</g:h>');
+--------------------------------------------+
| UpdateXML(@xml, '//b:c', '<g:h>555</g:h>') |
+--------------------------------------------+ <a>111<g:h>555</g:h></a>
+--------------------------------------------+
1 row in set (0.00 sec)
```

This is similar in some respects to what is permitted by Apache Xalan and some other parsers, and is much simpler than requiring namespace declarations or the use of the `namespace-uri()` and `local-name()` functions.

**Error handling.** For both `ExtractValue()` and `UpdateXML()`, the XPath locator used must be valid and the XML to be searched must consist of elements which are properly nested and closed. If the locator is invalid, an error is generated:

```sql
mysql> SELECT ExtractValue('a>c</a><b/>', '/&a');
ERROR 1105 (HY000): XPATH syntax error: '&a'
```

If `xml_frag` does not consist of elements which are properly nested and closed, `NULL` is returned and a warning is generated, as shown in this example:

```sql
mysql> SELECT ExtractValue('a>c</a><b/', '//a');
+-------------------------------------+
| ExtractValue('a>c</a><b/', '//a')   |
| NULL                               |
+-------------------------------------+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS
```

---

2389
Important

The replacement XML used as the third argument to `UpdateXML()` is not checked to determine whether it consists solely of elements which are properly nested and closed.

**XPath Injection.**  
*Code injection* occurs when malicious code is introduced into the system to gain unauthorized access to privileges and data. It is based on exploiting assumptions made by developers about the type and content of data input from users. XPath is no exception in this regard.

A common scenario in which this can happen is the case of application which handles authorization by matching the combination of a login name and password with those found in an XML file, using an XPath expression like this one:

```
//user[login/text()='neapolitan' and password/text()='1c3cr34m']/attribute::id
```

This is the XPath equivalent of an SQL statement like this one:

```
SELECT id FROM users WHERE login='neapolitan' AND password='1c3cr34m';
```

A PHP application employing XPath might handle the login process like this:

```php
<?php

$file     =   "users.xml";
$login    =   $POST["login"];  
$password =   $POST["password"];  

$xpath = "//user[login/text()=$login and password/text()=$password]/attribute::id";

if( file_exists($file) )
{
    $xml = simplexml_load_file($file);  
    if($result = $xml->xpath($xpath))
        echo "You are now logged in as user $result[0].";  
    else  
        echo "Invalid login name or password.";  
}
else  
    exit("Failed to open $file.";)
?>
```

No checks are performed on the input. This means that a malevolent user can “short-circuit” the test by entering `' or 1=1` for both the login name and password, resulting in `$xpath` being evaluated as shown here:

```
//user[login/text()='' or 1=1 and password/text()='' or 1=1]/attribute::id
```

Since the expression inside the square brackets always evaluates as `true`, it is effectively the same as this one, which matches the `id` attribute of every `user` element in the XML document:

```
//user/attribute::id
```

One way in which this particular attack can be circumvented is simply by quoting the variable names to be interpolated in the definition of `$xpath`, forcing the values passed from a Web form to be converted to strings:

```php
$xpath = "//user[login/text()='$login' and password/text()='$password']/attribute::id";
```
This is the same strategy that is often recommended for preventing SQL injection attacks. In general, the practices you should follow for preventing XPath injection attacks are the same as for preventing SQL injection:

• Never accepted untested data from users in your application.
• Check all user-submitted data for type; reject or convert data that is of the wrong type
• Test numeric data for out of range values; truncate, round, or reject values that are out of range. Test strings for illegal characters and either strip them out or reject input containing them.
• Do not output explicit error messages that might provide an unauthorized user with clues that could be used to compromise the system; log these to a file or database table instead.

Just as SQL injection attacks can be used to obtain information about database schemas, so can XPath injection be used to traverse XML files to uncover their structure, as discussed in Amit Klein's paper Blind XPath Injection (PDF file, 46KB).

It is also important to check the output being sent back to the client. Consider what can happen when we use the MySQL `ExtractValue()` function:

```sql
mysql> SELECT ExtractValue(
    -> LOAD_FILE('users.xml'),
    -> '//user[login/text()='' or 1=1 and password/text()='' or 1=1]/attribute::id'
    -> ) AS id;
+-------------------------------+
| id                            |
+-------------------------------+
| 00327 13579 02403 42354 28570 |
+-------------------------------+
1 row in set (0.01 sec)
```

Because `ExtractValue()` returns multiple matches as a single space-delimited string, this injection attack provides every valid ID contained within `users.xml` to the user as a single row of output. As an extra safeguard, you should also test output before returning it to the user. Here is a simple example:

```sql
mysql> SELECT @id = ExtractValue(
    -> LOAD_FILE('users.xml'),
    -> '//user[login/text()='' or 1=1 and password/text()='' or 1=1]/attribute::id'
    -> );
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT IF(
    -> INSTR(@id, ' ') = 0,
    -> @id,
    -> 'Unable to retrieve user ID')
    -> AS singleID;
+----------------------------+
| singleID                   |
| Unable to retrieve user ID |
+----------------------------+
1 row in set (0.00 sec)
```

In general, the guidelines for returning data to users securely are the same as for accepting user input. These can be summed up as:

• Always test outgoing data for type and permissible values.
• Never permit unauthorized users to view error messages that might provide information about the application that could be used to exploit it.

### 12.12 Bit Functions and Operators
Bit Operations

### Table 12.17 Bit Functions and Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

</tr>
</tbody>
</table>

Bit functions and operators comprise `BIT_COUNT()`, `BIT_AND()`, `BIT_OR()`, `BIT_XOR()`, `&`, `|`, `^`, `~`, `<<`, and `>>`. (The `BIT_AND()`, `BIT_OR()`, and `BIT_XOR()` aggregate functions are described in Section 12.19.1, “Aggregate Function Descriptions”.)

Bit functions and operators permit binary string type arguments (`BINARY`, `VARBINARY`, and the `BLOB` types) and return a value of like type. Nonbinary string arguments are converted to `BIGINT`.

- Bit Operations
- Binary String Bit-Operation Examples
- Bitwise AND, OR, and XOR Operations
- Bitwise Complement and Shift Operations
- `BIT_COUNT()` Operations
- `BIT_AND()`, `BIT_OR()`, and `BIT_XOR()` Operations
- Special Handling of Hexadecimal Literals, Bit Literals, and NULL Literals

### Bit Operations

MySQL 8.2 handles binary string arguments directly (without conversion) and produces binary string results. Arguments that are not integers or binary strings are converted to integers.

Arguments that count as binary strings include column values, routine parameters, local variables, and user-defined variables that have a binary string type: `BINARY`, `VARBINARY`, or one of the `BLOB` types.

You can specify arguments to bit operations using hexadecimal literals or bit literals with the intent that they represent numbers; MySQL evaluates bit operations in numeric context when all bit arguments are hexadecimal or bit literals. For evaluation as binary strings instead, use the `_binary` introducer for at least one of the literal values.

- These bit operations evaluate the hexadecimal literals and bit literals as integers:

  ```sql
  mysql> SELECT X'40' | X'01', b'11110001' & b'01001111';
  +----------------+-----------------------------------------------+
  | X'40' | X'01' | b'11110001' & b'01001111' |
  +----------------+-----------------------------------------------+
  | 65 | 65 |
  +----------------+-----------------------------------------------+
  ```

- These bit operations evaluate the hexadecimal literals and bit literals as binary strings, due to the `_binary` introducer:

  ```sql
  mysql> SELECT _binary X'40' | X'01', _binary b'11110001' & _binary b'01001111';
  ```
Although the bit operations in both statements produce a result with a numeric value of 65, the second statement operates in binary-string context, for which 65 is ASCII A.

In numeric evaluation context, permitted values of hexadecimal literal and bit literal arguments have a maximum of 64 bits, as do results. By contrast, in binary-string evaluation context, permitted arguments (and results) can exceed 64 bits:

```
mysql> SELECT _binary X'4040404040404040' | X'0102030405060708';
+---------------------------------------------------+
| _binary X'4040404040404040' | X'0102030405060708' |
| ABCDEFGH                                          |
+---------------------------------------------------+
```

There are several ways to refer to a hexadecimal literal or bit literal in a bit operation to cause binary-string evaluation:

- `_binary literal`
- `BINARY literal`
- `CAST(literal AS BINARY)`

Another way to produce binary-string evaluation of hexadecimal literals or bit literals is to assign them to user-defined variables, which results in variables that have a binary string type:

```
mysql> SET @v1 = X'40', @v2 = X'01', @v3 = b'11110001', @v4 = b'01001111';
mysql> SELECT @v1 | @v2, @v3 & @v4;
+-----------+-----------+
| @v1       | @v2       |
| A         | A         |
+-----------+-----------+
```

In binary-string context, bitwise operation arguments must have the same length or an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs:

```
mysql> SELECT _binary X'40' | X'0001';
ERROR 3513 (HY000): Binary operands of bitwise operators must be of equal length
```

To satisfy the equal-length requirement, pad the shorter value with leading zero digits or, if the longer value begins with leading zero digits and a shorter result value is acceptable, strip them:

```
mysql> SELECT _binary X'0040' | X'0001';
+---------------------------+
| _binary X'0040' | X'0001' |
| A                        |
+---------------------------+
mysql> SELECT _binary X'40' | X'01';
+-----------------------+
| _binary X'40' | X'01' |
| A              |
+-----------------------+
```

Padding or stripping can also be accomplished using functions such as `LPAD()`, `RPAD()`, `SUBSTR()`, or `CAST()`. In such cases, the expression arguments are no longer all literals and `_binary` becomes unnecessary. Examples:
Binary String Bit-Operation Examples

The following example illustrates use of bit operations to extract parts of a UUID value, in this case, the
timestamp and IEEE 802 node number. This technique requires bitmasks for each extracted part.

Convert the text UUID to the corresponding 16-byte binary value so that it can be manipulated using bit
operations in binary-string context:

```
mysql> SET @uuid = UUID_TO_BIN('6ccd780c-baba-1026-9564-5b8c656024db');
mysql> SELECT HEX(@uuid);
```

```
<table>
<thead>
<tr>
<th>HEX(@uuid)</th>
</tr>
</thead>
<tbody>
<tr>
<td>6CCD780CBABA102695645B8C656024DB</td>
</tr>
</tbody>
</table>
```

Construct bitmasks for the timestamp and node number parts of the value. The timestamp comprises the
first three parts (64 bits, bits 0 to 63) and the node number is the last part (48 bits, bits 80 to 127):

```
mysql> SET @ts_mask = CAST(X'FFFFFFFFFFFFFFFF' AS BINARY(16));
mysql> SET @node_mask = CAST(X'FFFFFFFFFFFF' AS BINARY(16)) >> 80;
```

```
<table>
<thead>
<tr>
<th>HEX(@ts_mask)</th>
</tr>
</thead>
<tbody>
<tr>
<td>FFFFFFFFFFFFFFFF0000000000000000</td>
</tr>
</tbody>
</table>
```

```
<table>
<thead>
<tr>
<th>HEX(@node_mask)</th>
</tr>
</thead>
<tbody>
<tr>
<td>00000000000000000000000000000000FFFFFFFFFFF</td>
</tr>
</tbody>
</table>
```

The `CAST(... AS BINARY(16))` function is used here because the masks must be the same length as
the UUID value against which they are applied. The same result can be produced using other functions to
pad the masks to the required length:

```
SET @ts_mask= RPAD(X'FFFFFFFFFFFFFFFFF', 16, X'00');
SET @node_mask = LPAD(X'FFFFFFFFFFFF', 16, X'00') ;
```

Use the masks to extract the timestamp and node number parts:

```
mysql> SELECT HEX(@uuid & @ts_mask) AS 'timestamp part';
```

```
<table>
<thead>
<tr>
<th>timestamp part</th>
</tr>
</thead>
<tbody>
<tr>
<td>6CCD780CBABA102695645B8C656024DB</td>
</tr>
</tbody>
</table>
```
The preceding example uses these bit operations: right shift (\(>>\)) and bitwise AND (\(\&\)).

**Note**

`UUID_TO_BIN()` takes a flag that causes some bit rearrangement in the resulting binary UUID value. If you use that flag, modify the extraction masks accordingly.

The next example uses bit operations to extract the network and host parts of an IPv6 address. Suppose that the network part has a length of 80 bits. Then the host part has a length of 128 − 80 = 48 bits. To extract the network and host parts of the address, convert it to a binary string, then use bit operations in binary-string context.

Convert the text IPv6 address to the corresponding binary string:

```sql
mysql> SET @ip = INET6_ATON('fe80::219:d1ff:fe91:1a72');
```

Define the network length in bits:

```sql
mysql> SET @net_len = 80;
```

Construct network and host masks by shifting the all-ones address left or right. To do this, begin with the address ::, which is shorthand for all zeros, as you can see by converting it to a binary string like this:

```sql
mysql> SELECT HEX(INET6_ATON('::')) AS 'all zeros';
```

```
+----------------------------------+
| all zeros                        |
+----------------------------------+
| 00000000000000000000000000000000 |
+----------------------------------+
```

To produce the complementary value (all ones), use the ~ operator to invert the bits:

```sql
mysql> SELECT HEX(~INET6_ATON('::')) AS 'all ones';
```

```
+----------------------------------+
| all ones                         |
+----------------------------------+
| FFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFF |
+----------------------------------+
```

Shift the all-ones value left or right to produce the network and host masks:

```sql
mysql> SET @net_mask = ~INET6_ATON('::') << (128 - @net_len);
mysql> SET @host_mask = ~INET6_ATON('::') >> @net_len;
```

Display the masks to verify that they cover the correct parts of the address:

```sql
mysql> SELECT INET6_NTOA(@net_mask) AS 'network mask';
```

```
+----------------------------+
| network mask               |
+----------------------------+
| ffff:ffff:ffff:ffff::     |
+----------------------------+
```

```sql
mysql> SELECT INET6_NTOA(@host_mask) AS 'host mask';
```

```
+------------------------+
| host mask              |
+------------------------+
| ::ffff:255.255.255.255 |
+------------------------+
```
Bitwise AND, OR, and XOR Operations

Extract and display the network and host parts of the address:

```
mysql> SET @net_part = @ip & @net_mask;
mysql> SET @host_part = @ip & @host_mask;
mysql> SELECT INET6_NTOA(@net_part) AS 'network part';
+-----------------+
| network part    |
| fe80::219:0:0:0 |
+-----------------+
mysql> SELECT INET6_NTOA(@host_part) AS 'host part';
+------------------+
| host part        |
| ::d1ff:fe91:1a72 |
+------------------+
```

The preceding example uses these bit operations: Complement (~), left shift (<<), and bitwise AND (&).

The remaining discussion provides details on argument handling for each group of bit operations, and more information about literal-value handling in bit operations.

Bitwise AND, OR, and XOR Operations

For &, |, and ^ bit operations, the result type depends on whether the arguments are evaluated as binary strings or numbers:

- **Binary-string evaluation** occurs when the arguments have a binary string type, and at least one of them is not a hexadecimal literal, bit literal, or NULL literal. Numeric evaluation occurs otherwise, with argument conversion to unsigned 64-bit integers as necessary.

- **Binary-string evaluation** produces a binary string of the same length as the arguments. If the arguments have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

Examples of numeric evaluation:

```
mysql> SELECT 64 | 1, X'40' | X'01';
+--------+---------------+
| 64 | 1 | X'40' | X'01' |
+--------+---------------+
|     65 |            65 |
+--------+---------------+
```

Examples of binary-string evaluation:

```
mysql> SELECT _binary X'40' | X'01';
+-----------------------+
| _binary X'40' | X'01' |
| A               |
+-----------------------+
mysql> SET @var1 = X'40', @var2 = X'01';
mysql> SELECT @var1 | @var2;
+---------------+
| @var1 | @var2 |
| A             |
+---------------+
```

Bitwise Complement and Shift Operations

For ~, <<, and >> bit operations, the result type depends on whether the bit argument is evaluated as a binary string or number:
BIT_COUNT() Operations

- Binary-string evaluation occurs when the bit argument has a binary string type, and is not a hexadecimal literal, bit literal, or NULL literal. Numeric evaluation occurs otherwise, with argument conversion to an unsigned 64-bit integer as necessary.

- Binary-string evaluation produces a binary string of the same length as the bit argument. Numeric evaluation produces an unsigned 64-bit integer.

For shift operations, bits shifted off the end of the value are lost without warning, regardless of the argument type. In particular, if the shift count is greater or equal to the number of bits in the bit argument, all bits in the result are 0.

Examples of numeric evaluation:

```
mysql> SELECT ~0, 64 << 2, X'40' << 2;
+----------------------+---------+------------+
| ~0                   | 64 << 2 | X'40' << 2 |
+----------------------+---------+------------+
| 18446744073709551615 |     256 |        256 |
+----------------------+---------+------------+
```

Examples of binary-string evaluation:

```
mysql> SELECT HEX(_binary X'1111000022220000' >> 16);
+----------------------------------------+
| HEX(_binary X'1111000022220000' >> 16) |
+----------------------------------------+
| 0000111100002222                       |
+----------------------------------------+

mysql> SELECT HEX(_binary X'1111000022220000' << 16);
+----------------------------------------+
| HEX(_binary X'1111000022220000' << 16) |
+----------------------------------------+
| 0000222200000000                       |
+----------------------------------------+
```

BIT_COUNT() Operations

The BIT_COUNT() function always returns an unsigned 64-bit integer, or NULL if the argument is NULL.

```
mysql> SELECT BIT_COUNT(127);
+----------------+
| BIT_COUNT(127) |
+----------------+
|              7 |
+----------------+

mysql> SELECT BIT_COUNT(b'010101'), BIT_COUNT(_binary b'010101');
+----------------+------------------+
| BIT_COUNT(b'010101') | BIT_COUNT(_binary b'010101') |
+----------------+------------------+
|              3 |                  3 |
+----------------+------------------+
```

BIT_AND(), BIT_OR(), and BIT_XOR() Operations

For the BIT_AND(), BIT_OR(), and BIT_XOR() bit functions, the result type depends on whether the function argument values are evaluated as binary strings or numbers:
Special Handling of Hexadecimal Literals, Bit Literals, and NULL Literals

- Binary-string evaluation occurs when the argument values have a binary string type, and the argument is not a hexadecimal literal, bit literal, or NULL literal. Numeric evaluation occurs otherwise, with argument value conversion to unsigned 64-bit integers as necessary.

- Binary-string evaluation produces a binary string of the same length as the argument values. If argument values have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. If the argument size exceeds 511 bytes, an `ER_INVALID_BITWISE_AGGREGATE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

NULL values do not affect the result unless all values are NULL. In that case, the result is a neutral value having the same length as the length of the argument values (all bits 1 for `BIT_AND()`, all bits 0 for `BIT_OR()`, and `BIT_XOR()`).

Example:

```sql
mysql> CREATE TABLE t (group_id INT, a VARBINARY(6));
mysql> INSERT INTO t VALUES (1, NULL);
mysql> INSERT INTO t VALUES (1, NULL);
mysql> INSERT INTO t VALUES (2, NULL);
mysql> INSERT INTO t VALUES (2, X'1234');
mysql> INSERT INTO t VALUES (2, X'FF34');
mysql> SELECT HEX(BIT_AND(a)), HEX(BIT_OR(a)), HEX(BIT_XOR(a))
    FROM t GROUP BY group_id;
+-----------------+----------------+-----------------+
<table>
<thead>
<tr>
<th>HEX(BIT_AND(a))</th>
<th>HEX(BIT_OR(a))</th>
<th>HEX(BIT_XOR(a))</th>
</tr>
</thead>
<tbody>
<tr>
<td>FFFFFFFF</td>
<td>000000000000</td>
<td>000000000000</td>
</tr>
<tr>
<td>1234</td>
<td>FF34</td>
<td>ED00</td>
</tr>
</tbody>
</table>
+-----------------+----------------+-----------------+
```

Special Handling of Hexadecimal Literals, Bit Literals, and NULL Literals

MySQL 8.2 evaluates bit operations in numeric context when all bit arguments are hexadecimal literals, bit literals, or NULL literals. That is, bit operations on binary-string bit arguments do not use binary-string evaluation if all bit arguments are unadorned hexadecimal literals, bit literals, or NULL literals. (This does not apply to such literals if they are written with a `_binary` introducer, `BINARY` operator, or other way of specifying them explicitly as binary strings.)

Examples:

- These bit operations evaluate the literals in numeric context and produce a BIGINT result:
  ```sql
  b'0001' | b'0010'
  X'0008' << 8
  ```

- These bit operations evaluate NULL in numeric context and produce a BIGINT result that has a NULL value:
  ```sql
  NULL & NULL
  NULL >> 4
  ```

You can cause those operations to evaluate the arguments in binary-string context by indicating explicitly that at least one argument is a binary string:

```sql
_Binary b'0001' | b'0010'
_Binary X'0008' << 8
BINARY NULL & NULL
BINARY NULL >> 4
```

The result of the last two expressions is NULL, just as without the `BINARY` operator, but the data type of the result is a binary string type rather than an integer type.
### 12.13 Encryption and Compression Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

</table>

Many encryption and compression functions return strings for which the result might contain arbitrary byte values. If you want to store these results, use a column with a `VARBINARY` or `BLOB` binary string data type. This avoids potential problems with trailing space removal or character set conversion that would change data values, such as may occur if you use a nonbinary string data type (`CHAR`, `VARCHAR`, `TEXT`).

Some encryption functions return strings of ASCII characters: `MD5()`, `SHA()`, `SHA1()`, `SHA2()`, `STATEMENT_DIGEST()`, `STATEMENT_DIGEST_TEXT()`. Their return value is a string that has a character set and collation determined by the `character_set_connection` and `collation_connection` system variables. This is a nonbinary string unless the character set is `binary`.

If an application stores values from a function such as `MD5()` or `SHA1()` that returns a string of hex digits, more efficient storage and comparisons can be obtained by converting the hex representation to binary using `UNHEX()` and storing the result in a `BINARY(N)` column. Each pair of hexadecimal digits requires one byte in binary form, so the value of `N` depends on the length of the hex string. `N` is 16 for an `MD5()` value and 20 for a `SHA1()` value. For `SHA2()`, `N` ranges from 28 to 32 depending on the argument specifying the desired bit length of the result.

The size penalty for storing the hex string in a `CHAR` column is at least two times, up to eight times if the value is stored in a column that uses the `utf8mb4` character set (where each character uses 4 bytes). Storing the string also results in slower comparisons because of the larger values and the need to take character set collation rules into account.

Suppose that an application stores `MD5()` string values in a `CHAR(32)` column:

```sql
CREATE TABLE md5_tbl (md5_val CHAR(32), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(MD5('abcdef'), ...);
```

To convert hex strings to more compact form, modify the application to use `UNHEX()` and `BINARY(16)` instead as follows:

```sql
CREATE TABLE md5_tbl (md5_val BINARY(16), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(UNHEX(MD5('abcdef')), ...);
```
Applications should be prepared to handle the very rare case that a hashing function produces the same value for two different input values. One way to make collisions detectable is to make the hash column a primary key.

**Note**
Exploits for the MD5 and SHA-1 algorithms have become known. You may wish to consider using another one-way encryption function described in this section instead, such as SHA2().

**Caution**
Passwords or other sensitive values supplied as arguments to encryption functions are sent as cleartext to the MySQL server unless an SSL connection is used. Also, such values appear in any MySQL logs to which they are written. To avoid these types of exposure, applications can encrypt sensitive values on the client side before sending them to the server. The same considerations apply to encryption keys. To avoid exposing these, applications can use stored procedures to encrypt and decrypt values on the server side.

- `AES_DECRYPT(crypt_str, key_str[, init_vector][, kdf_name][, salt][, info | iterations])`

  This function decrypts data using the official AES (Advanced Encryption Standard) algorithm. For more information, see the description of `AES_ENCRYPT()`.

  Statements that use `AES_DECRYPT()` are unsafe for statement-based replication.

- `AES_ENCRYPT(str, key_str[, init_vector][, kdf_name][, salt][, info | iterations])`

  `AES_ENCRYPT()` and `AES_DECRYPT()` implement encryption and decryption of data using the official AES (Advanced Encryption Standard) algorithm, previously known as “Rijndael.” The AES standard permits various key lengths. By default these functions implement AES with a 128-bit key length. Key lengths of 192 or 256 bits can be used, as described later. The key length is a trade off between performance and security.

  `AES_ENCRYPT()` encrypts the string `str` using the key string `key_str`, and returns a binary string containing the encrypted output. `AES_DECRYPT()` decrypts the encrypted string `crypt_str` using the key string `key_str`, and returns the original (binary) string in hexadecimal format. (To obtain the string as plaintext, cast the result to `CHAR`. Alternatively, start the `mysql` client with `--skip-binary-as-hex` to cause all binary values to be displayed as text.) If either function argument is `NULL`, the function returns `NULL`. If `AES_DECRYPT()` detects invalid data or incorrect padding, it returns `NULL`. However, it is possible for `AES_DECRYPT()` to return a non-`NULL` value (possibly garbage) if the input data or the key is invalid.

  These functions support the use of a key derivation function (KDF) to create a cryptographically strong secret key from the information passed in `key_str`. The derived key is used to encrypt and decrypt the data, and it remains in the MySQL Server instance and is not accessible to users. Using a KDF is highly recommended, as it provides better security than specifying your own premade key or deriving it by a simpler method as you use the function. The functions support HKDF (available from OpenSSL 1.1.0), for which you can specify an optional salt and context-specific information to include in the keying material, and PBKDF2 (available from OpenSSL 1.0.2), for which you can specify an optional salt and set the number of iterations used to produce the key.

  `AES_ENCRYPT()` and `AES_DECRYPT()` permit control of the block encryption mode. The `block_encryption_mode` system variable controls the mode for block-based encryption algorithms.
Its default value is `aes-128-ecb`, which signifies encryption using a key length of 128 bits and ECB mode. For a description of the permitted values of this variable, see Section 5.1.8, “Server System Variables”. The optional `init_vector` argument is used to provide an initialization vector for block encryption modes that require it.

Statements that use `AES_ENCRYPT()` or `AES_DECRYPT()` are unsafe for statement-based replication.

If `AES_ENCRYPT()` is invoked from within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

The arguments for the `AES_ENCRYPT()` and `AES_DECRYPT()` functions are as follows:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>str</code></td>
<td>The string for <code>AES_ENCRYPT()</code> to encrypt using the key string <code>key_str</code>, or the key derived from it by the specified KDF. The string can be any length. Padding is automatically added to <code>str</code> so it is a multiple of a block as required by block-based algorithms such as AES. This padding is automatically removed by the <code>AES_DECRYPT()</code> function.</td>
</tr>
<tr>
<td><code>crypt_str</code></td>
<td>The encrypted string for <code>AES_DECRYPT()</code> to decrypt using the key string <code>key_str</code>, or the key derived from it by the specified KDF. The string can be any length. The length of <code>crypt_str</code> can be calculated from the length of the original string using this formula:</td>
</tr>
<tr>
<td></td>
<td>16 * (trunc(<code>string_length</code> / 16) + 1)</td>
</tr>
<tr>
<td><code>key_str</code></td>
<td>The encryption key, or the input keying material that is used as the basis for deriving a key using a key derivation function (KDF). For the same instance of data, use the same value of <code>key_str</code> for encryption with <code>AES_ENCRYPT()</code> and decryption with <code>AES_DECRYPT()</code>. If you are using a KDF, <code>key_str</code> can be any arbitrary information such as a password or passphrase. In the further arguments for the function, you specify the KDF name, then add further options to increase the security as appropriate for the KDF. When you use a KDF, the function creates a cryptographically strong secret key from the information passed in <code>key_str</code> and any salt or additional information that you provide in the other arguments. The derived key is used to encrypt and decrypt the data, and it remains in the MySQL Server instance and is not accessible to users. Using a KDF is highly recommended, as it provides better security than specifying your own premade key or deriving it by a simpler method as you use the function.</td>
</tr>
<tr>
<td></td>
<td>If you are not using a KDF, for a key length of 128 bits, the most secure way to pass a key to the <code>key_str</code> argument is to create a truly random 128-bit value and pass it as a binary value. For example:</td>
</tr>
</tbody>
</table>

```sql
INSERT INTO t
VALUES (1, AES_ENCRYPT('text', UNHEX('F3229A0B371ED2D9441B830D21A390C3')))
```

A passphrase can be used to generate an AES key by hashing the passphrase. For example:

```sql
INSERT INTO t
VALUES (1, AES_ENCRYPT('text', hash('password')))
```
Encryption and Compression Functions

VALUES (1, AES_ENCRYPT('text', UNHEX(SHA2('My secret passphrase',512))));

If you exceed the maximum key length of 128 bits, a warning is returned. If you are not using a KDF, do not pass a password or passphrase directly to `key_str`, hash it first. Previous versions of this documentation suggested the former approach, but it is no longer recommended as the examples shown here are more secure.

`init_vector`

An initialization vector, for block encryption modes that require it. The `block_encryption_mode` system variable controls the mode. For the same instance of data, use the same value of `init_vector` for encryption with `AES_ENCRYPT()` and decryption with `AES_DECRYPT()`.

**Note**

If you are using a KDF, you must specify an initialization vector or a null string for this argument, in order to access the later arguments to define the KDF.

For modes that require an initialization vector, it must be 16 bytes or longer (bytes in excess of 16 are ignored). An error occurs if `init_vector` is missing. For modes that do not require an initialization vector, it is ignored and a warning is generated if `init_vector` is specified, unless you are using a KDF.

The default value for the `block_encryption_mode` system variable is `aes-128-ecb`, or ECB mode, which does not require an initialization vector. The alternative permitted block encryption modes CBC, CFB1, CFB8, CFB128, and OFB all require an initialization vector.

A random string of bytes to use for the initialization vector can be produced by calling `RANDOM_BYTES(16)`.

`kdf_name`

The name of the key derivation function (KDF) to create a key from the input keying material passed in `key_str`, and other arguments as appropriate for the KDF. Optional.

For the same instance of data, use the same value of `kdf_name` for encryption with `AES_ENCRYPT()` and decryption with `AES_DECRYPT()`. When you specify `kdf_name`, you must specify `init_vector`, using either a valid initialization vector, or a null string if the encryption mode does not require an initialization vector.

The following values are supported:

- **hkdf**  
  HKDF, which is available from OpenSSL 1.1.0. HKDF extracts a pseudorandom key from the keying material then expands it into additional keys. With HKDF, you can specify an optional salt (`salt`) and context-specific
Encryption and Compression Functions

information such as application details \textit{(info)} to include in the keying material.

\texttt{pbkdf2\_hmac}

PBKDF2, which is available from OpenSSL 1.0.2. PBKDF2 applies a pseudorandom function to the keying material, and repeats this process a large number of times to produce the key. With PBKDF2, you can specify an optional salt \texttt{(salt)} to include in the keying material, and set the number of iterations used to produce the key \texttt{(iterations)}.

In this example, HKDF is specified as the key derivation function, and a salt and context information are provided. The argument for the initialization vector is included but is the empty string:

\begin{verbatim}
SELECT AES_ENCRYPT('mytext','mykeystring', '', 'hkdf', 'salt', 'info');
\end{verbatim}

In this example, PBKDF2 is specified as the key derivation function, a salt is provided, and the number of iterations is doubled from the recommended minimum:

\begin{verbatim}
SELECT AES_ENCRYPT('mytext','mykeystring', '', 'pbkdf2\_hmac','salt', '2000');
\end{verbatim}

\texttt{salt}

A salt to be passed to the key derivation function \texttt{(KDF)}. Optional. Both HKDF and PBKDF2 can use salts, and their use is recommended to help prevent attacks based on dictionaries of common passwords or rainbow tables.

A salt consists of random data, which for security must be different for each encryption operation. A random string of bytes to use for the salt can be produced by calling \texttt{RANDOM\_BYTES()}. This example produces a 64-bit salt:

\begin{verbatim}
SET @salt = RANDOM\_BYTES(8);
\end{verbatim}

For the same instance of data, use the same value of \texttt{salt} for encryption with \texttt{AES\_ENCRYPT()} and decryption with \texttt{AES\_DECRYPT()}. The salt can safely be stored along with the encrypted data.

\texttt{info}

Context-specific information for HKDF to include in the keying material, such as information about the application. Optional; available when you specify \texttt{hkdf} as the KDF name. HKDF adds this information to the keying material specified in \texttt{key\_str} and the salt specified in \texttt{salt} to produce the key.

For the same instance of data, use the same value of \texttt{info} for encryption with \texttt{AES\_ENCRYPT()} and decryption with \texttt{AES\_DECRYPT()}. 2403
Encryption and Compression Functions

**iterations**

The iteration count for PBKDF2 to use when producing the key. Optional; available when you specify `pbkdf2_hmac` as the KDF name. A higher count gives greater resistance to brute-force attacks because it has a greater computational cost for the attacker, but the same is necessarily true for the key derivation process. The default if you do not specify this argument is 1000, which is the minimum recommended by the OpenSSL standard.

For the same instance of data, use the same value of `iterations` for encryption with `AES_ENCRYPT()` and decryption with `AES_DECRYPT()`.

```sql
mysql> SET block_encryption_mode = 'aes-256-cbc';
mysql> SET @key_str = SHA2('My secret passphrase',512);
mysql> SET @init_vector = RANDOM_BYTES(16);
mysql> SET @crypt_str = AES_ENCRYPT('text',@key_str,@init_vector);
mysql> SELECT CAST(AES_DECRYPT(@crypt_str,@key_str,@init_vector) AS CHAR);
+-------------------------------------------------------------+
| CAST(AES_DECRYPT(@crypt_str,@key_str,@init_vector) AS CHAR) |
+-------------------------------------------------------------+
| text                                                        |
+-------------------------------------------------------------+
```

**COMPRESS(string_to_compress)**

Compresses a string and returns the result as a binary string. This function requires MySQL to have been compiled with a compression library such as zlib. Otherwise, the return value is always NULL. The return value is also NULL if `string_to_compress` is NULL. The compressed string can be uncompressed with `UNCOMPRESS()`.

```sql
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',1000)));  
    -> 21
mysql> SELECT LENGTH(COMPRESS(''));  
    -> 0
mysql> SELECT LENGTH(COMPRESS('a'));  
    -> 13
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',16)));  
    -> 15
```

The compressed string contents are stored the following way:

- Empty strings are stored as empty strings.
- Nonempty strings are stored as a 4-byte length of the uncompressed string (low byte first), followed by the compressed string. If the string ends with space, an extra . character is added to avoid problems with endspace trimming should the result be stored in a `CHAR` or `VARCHAR` column. (However, use of nonbinary string data types such as `CHAR` or `VARCHAR` to store compressed strings is not recommended anyway because character set conversion may occur. Use a `VARBINARY` or `BLOB` binary string column instead.)

If `COMPRESS()` is invoked from within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex` option. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

2404
Encryption and Compression Functions

- **MD5**(str)

  Calculates an MD5 128-bit checksum for the string. The value is returned as a string of 32 hexadecimal digits, or NULL if the argument was NULL. The return value can, for example, be used as a hash key. See the notes at the beginning of this section about storing hash values efficiently.

  The return value is a string in the connection character set.

  If FIPS mode is enabled, **MD5()** returns NULL. See Section 6.8, “FIPS Support”.

  ```
  mysql> SELECT MD5('testing');
  -> 'ae2b1fca515949e5d54fb22b8ed95575'
  ```

  This is the “RSA Data Security, Inc. MD5 Message-Digest Algorithm.”

  See the note regarding the MD5 algorithm at the beginning this section.

- **RANDOM_BYTES**(len)

  This function returns a binary string of len random bytes generated using the random number generator of the SSL library. Permitted values of len range from 1 to 1024. For values outside that range, an error occurs. Returns NULL if len is NULL.

  **RANDOM_BYTES()** can be used to provide the initialization vector for the AES_DECRYPT() and AES_ENCRYPT() functions. For use in that context, len must be at least 16. Larger values are permitted, but bytes in excess of 16 are ignored.

  **RANDOM_BYTES()** generates a random value, which makes its result nondeterministic. Consequently, statements that use this function are unsafe for statement-based replication.

  If **RANDOM_BYTES()** is invoked from within the mysql client, binary strings display using hexadecimal notation, depending on the value of the --binary-as-hex. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

- **SHA1**(str), **SHA**(str)

  Calculates an SHA-1 160-bit checksum for the string, as described in RFC 3174 (Secure Hash Algorithm). The value is returned as a string of 40 hexadecimal digits, or NULL if the argument is NULL. One of the possible uses for this function is as a hash key. See the notes at the beginning of this section about storing hash values efficiently. **SHA()** is synonymous with **SHA1()**.

  The return value is a string in the connection character set.

  ```
  mysql> SELECT SHA1('abc');
  -> 'a9993e364706816aba3e25717850c26c9cd0d89d'
  ```

  **SHA1()** can be considered a cryptographically more secure equivalent of **MD5()**. However, see the note regarding the MD5 and SHA-1 algorithms at the beginning this section.

- **SHA2**(str, hash_length)

  Calculates the SHA-2 family of hash functions (SHA-224, SHA-256, SHA-384, and SHA-512). The first argument is the plaintext string to be hashed. The second argument indicates the desired bit length of the result, which must have a value of 224, 256, 384, 512, or 0 (which is equivalent to 256). If either argument is NULL or the hash length is not one of the permitted values, the return value is NULL.
Encryption and Compression Functions

Otherwise, the function result is a hash value containing the desired number of bits. See the notes at the beginning of this section about storing hash values efficiently.

The return value is a string in the connection character set.

```sql
mysql> SELECT SHA2('abc', 224);
-> '23097d223405d8228642a477bda255b32aadbe4bda0b37e36c9da7'
```

This function works only if MySQL has been configured with SSL support. See Section 6.3, “Using Encrypted Connections”.

SHA2() can be considered cryptographically more secure than MD5() or SHA1().

- **STATEMENT_DIGEST(statement)**

Given an SQL statement as a string, returns the statement digest hash value as a string in the connection character set, or NULL if the argument is NULL. The related STATEMENT_DIGEST_TEXT() function returns the normalized statement digest. For information about statement digesting, see Section 27.10, “Performance Schema Statement Digests and Sampling”.

Both functions use the MySQL parser to parse the statement. If parsing fails, an error occurs. The error message includes the parse error only if the statement is provided as a literal string.

The `max_digest_length` system variable determines the maximum number of bytes available to these functions for computing normalized statement digests.

```sql
mysql> SET @stmt = 'SELECT * FROM mytable WHERE cola = 10 AND colb = 20';
mysql> SELECT STATEMENT_DIGEST(@stmt);
+------------------------------------------------------------------+
| STATEMENT_DIGEST(@stmt)                                          |
+------------------------------------------------------------------+
| 3bb95eeade896657c4526e74ff2a2862039d0a0fe8a9e7155b5fe492c7d8377 |
+------------------------------------------------------------------+
mysql> SELECT STATEMENT_DIGEST_TEXT(@stmt);
+----------------------------------------------------------+
| STATEMENT_DIGEST_TEXT(@stmt)                             |
+----------------------------------------------------------+
| SELECT * FROM `mytable` WHERE `cola` = ? AND `colb` = ?  |
+----------------------------------------------------------+
```

- **STATEMENT_DIGEST_TEXT(statement)**

Given an SQL statement as a string, returns the normalized statement digest as a string in the connection character set, or NULL if the argument is NULL. For additional discussion and examples, see the description of the related STATEMENT_DIGEST() function.

- **UNCOMPRESS(string_to_uncompress)**

Uncompresses a string compressed by the COMPRESS() function. If the argument is not a compressed value, the result is NULL; if `string_to_uncompress` is NULL, the result is also NULL. This function requires MySQL to have been compiled with a compression library such as zlib. Otherwise, the return value is always NULL.

```sql
mysql> SELECT UNCOMPRESS(COMPRESS('any string'));
-> 'any string'
mysql> SELECT UNCOMPRESS('any string');
-> NULL
```
• **UNCOMPRESSED_LENGTH(compressed_string)**

Returns the length that the compressed string had before being compressed. Returns NULL if compressed_string is NULL.

```sql
mysql> SELECT UNCOMPRESSED_LENGTH(COMPRESS(REPEAT('a',30)));
-> 30
```

• **VALIDATE_PASSWORD_STRENGTH(str)**

Given an argument representing a plaintext password, this function returns an integer to indicate how strong the password is, or NULL if the argument is NULL. The return value ranges from 0 (weak) to 100 (strong).

Password assessment by VALIDATE_PASSWORD_STRENGTH() is done by the validate_password component. If that component is not installed, the function always returns 0. For information about installing validate_password, see Section 6.4.3, "The Password Validation Component". To examine or configure the parameters that affect password testing, check or set the system variables implemented by validate_password. See Section 6.4.3.2, "Password Validation Options and Variables".

The password is subjected to increasingly strict tests and the return value reflects which tests were satisfied, as shown in the following table. In addition, if the validate_password.check_user_name system variable is enabled and the password matches the user name, VALIDATE_PASSWORD_STRENGTH() returns 0 regardless of how other validate_password system variables are set.

### 12.14 Locking Functions

This section describes functions used to manipulate user-level locks.

**Table 12.19 Locking Functions**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET_LOCK()</td>
<td>Get a named lock</td>
</tr>
<tr>
<td>IS_FREE_LOCK()</td>
<td>Whether the named lock is free</td>
</tr>
<tr>
<td>IS_USED_LOCK()</td>
<td>Whether the named lock is in use; return connection identifier if true</td>
</tr>
<tr>
<td>RELEASE_ALL_LOCKS()</td>
<td>Release all current named locks</td>
</tr>
<tr>
<td>RELEASE_LOCK()</td>
<td>Release the named lock</td>
</tr>
</tbody>
</table>

• **GET_LOCK(str,timeout)**

Tries to obtain a lock with a name given by the string str, using a timeout of timeout seconds. A negative timeout value means infinite timeout. The lock is exclusive. While held by one session, other sessions cannot obtain a lock of the same name.
Locking Functions

Returns 1 if the lock was obtained successfully, 0 if the attempt timed out (for example, because another client has previously locked the name), or NULL if an error occurred (such as running out of memory or the thread was killed with `mysqladmin kill`).

A lock obtained with `GET_LOCK()` is released explicitly by executing `RELEASE_LOCK()` or implicitly when your session terminates (either normally or abnormally). Locks obtained with `GET_LOCK()` are not released when transactions commit or roll back.

`GET_LOCK()` is implemented using the metadata locking (MDL) subsystem. Multiple simultaneous locks can be acquired and `GET_LOCK()` does not release any existing locks. For example, suppose that you execute these statements:

```sql
SELECT GET_LOCK('lock1',10);
SELECT GET_LOCK('lock2',10);
SELECT RELEASE_LOCK('lock2');
SELECT RELEASE_LOCK('lock1');
```

The second `GET_LOCK()` acquires a second lock and both `RELEASE_LOCK()` calls return 1 (success).

It is even possible for a given session to acquire multiple locks for the same name. Other sessions cannot acquire a lock with that name until the acquiring session releases all its locks for the name.

Uniquely named locks acquired with `GET_LOCK()` appear in the Performance Schema `metadata_locks` table. The `OBJECT_TYPE` column says `USER_LEVEL_LOCK` and the `OBJECT_NAME` column indicates the lock name. In the case that multiple locks are acquired for the same name, only the first lock for the name registers a row in the `metadata_locks` table. Subsequent locks for the name increment a counter in the lock but do not acquire additional metadata locks. The `metadata_locks` row for the lock is deleted when the last lock instance on the name is released.

The capability of acquiring multiple locks means there is the possibility of deadlock among clients. When this happens, the server chooses a caller and terminates its lock-acquisition request with an `ER_USER_LOCK_DEADLOCK` error. This error does not cause transactions to roll back.

MySQL enforces a maximum length on lock names of 64 characters.

`GET_LOCK()` can be used to implement application locks or to simulate record locks. Names are locked on a server-wide basis. If a name has been locked within one session, `GET_LOCK()` blocks any request by another session for a lock with the same name. This enables clients that agree on a given lock name to use the name to perform cooperative advisory locking. But be aware that it also enables a client that is not among the set of cooperating clients to lock a name, either inadvertently or deliberately, and thus prevent any of the cooperating clients from locking that name. One way to reduce the likelihood of this is
to use lock names that are database-specific or application-specific. For example, use lock names of the form `db_name.str` or `app_name.str`.

If multiple clients are waiting for a lock, the order in which they acquire it is undefined. Applications should not assume that clients acquire the lock in the same order that they issued the lock requests.

`GET_LOCK()` is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

Since `GET_LOCK()` establishes a lock only on a single `mysqld`, it is not suitable for use with NDB Cluster, which has no way of enforcing an SQL lock across multiple MySQL servers. See Section 23.2.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”, for more information.

**Caution**

With the capability of acquiring multiple named locks, it is possible for a single statement to acquire a large number of locks. For example:

```
INSERT INTO ... SELECT GET_LOCK(t1.col_name) FROM t1;
```

These types of statements may have certain adverse effects. For example, if the statement fails part way through and rolls back, locks acquired up to the point of failure still exist. If the intent is for there to be a correspondence between rows inserted and locks acquired, that intent is not satisfied. Also, if it is important that locks are granted in a certain order, be aware that result set order may differ depending on which execution plan the optimizer chooses. For these reasons, it may be best to limit applications to a single lock-acquisition call per statement.

A different locking interface is available as either a plugin service or a set of loadable functions. This interface provides lock namespaces and distinct read and write locks, unlike the interface provided by `GET_LOCK()` and related functions. For details, see Section 5.6.9.1, “The Locking Service”.

- **IS_FREE_LOCK(str)**

  Checks whether the lock named `str` is free to use (that is, not locked). Returns `1` if the lock is free (no one is using the lock), `0` if the lock is in use, and `NULL` if an error occurs (such as an incorrect argument).

  This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- **IS_USED_LOCK(str)**

  Checks whether the lock named `str` is in use (that is, locked). If so, it returns the connection identifier of the client session that holds the lock. Otherwise, it returns `NULL`.

  This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- **RELEASE_ALL_LOCKS()**

  Releases all named locks held by the current session and returns the number of locks released (0 if there were none)

  This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.
• **RELEASE_LOCK**(str)

Releases the lock named by the string `str` that was obtained with `GET_LOCK()`. Returns 1 if the lock was released, 0 if the lock was not established by this thread (in which case the lock is not released), and NULL if the named lock did not exist. The lock does not exist if it was never obtained by a call to `GET_LOCK()` or if it has previously been released.

The **DO** statement is convenient to use with `RELEASE_LOCK()`. See Section 13.2.3, “DO Statement”.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

# 12.15 Information Functions

Table 12.20 Information Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BENCHMARK()</td>
<td>Repeatedly execute an expression</td>

<tr>
<td>SESSION_USER()</td>
<td>Synonym for USER()</td>
</tr>
<tr>
<td>SYSTEM_USER()</td>
<td>Synonym for USER()</td>
</tr>
<tr>
<td>USER()</td>
<td>The user name and host name provided by the client</td>
</tr>
<tr>
<td>VERSION()</td>
<td>Return a string that indicates the MySQL server version</td>
</tr>
</tbody>
</table>

• **BENCHMARK**(count, expr)
Information Functions

The `BENCHMARK()` function executes the expression `expr` repeatedly `count` times. It may be used to time how quickly MySQL processes the expression. The result value is 0, or NULL for inappropriate arguments such as a NULL or negative repeat count.

The intended use is from within the `mysql` client, which reports query execution times:

```
mysql> SELECT BENCHMARK(1000000, AES_ENCRYPT('hello', 'goodbye'));
+---------------------------------------------------+
| BENCHMARK(1000000, AES_ENCRYPT('hello', 'goodbye')) |
| 0                                                  |
+---------------------------------------------------+
1 row in set (4.74 sec)
```

The time reported is elapsed time on the client end, not CPU time on the server end. It is advisable to execute `BENCHMARK()` several times, and to interpret the result with regard to how heavily loaded the server machine is.

`BENCHMARK()` is intended for measuring the runtime performance of scalar expressions, which has some significant implications for the way that you use it and interpret the results:

- Only scalar expressions can be used. Although the expression can be a subquery, it must return a single column and at most a single row. For example, `BENCHMARK(10, (SELECT * FROM t))` fails if the table `t` has more than one column or more than one row.

- Executing a `SELECT expr` statement `N` times differs from executing `SELECT BENCHMARK(N, expr)` in terms of the amount of overhead involved. The two have very different execution profiles and you should not expect them to take the same amount of time. The former involves the parser, optimizer, table locking, and runtime evaluation `N` times each. The latter involves only runtime evaluation `N` times, and all the other components just once. Memory structures already allocated are reused, and runtime optimizations such as local caching of results already evaluated for aggregate functions can alter the results. Use of `BENCHMARK()` thus measures performance of the runtime component by giving more weight to that component and removing the "noise" introduced by the network, parser, optimizer, and so forth.

  - `CHARSET(str)`

Returns the character set of the string argument, or NULL if the argument is NULL.

```
mysql> SELECT CHARSET('abc');
-> 'utf8mb3'
mysql> SELECT CHARSET(CONVERT('abc' USING latin1));
-> 'latin1'
mysql> SELECT CHARSET(USER());
-> 'utf8mb3'
```

  - `COERCIBILITY(str)`

Returns the collation coercibility value of the string argument.

```
mysql> SELECT COERCIBILITY('abc' COLLATE utf8mb4_swedish_ci);
-> 0
mysql> SELECT COERCIBILITY(USER());
-> 3
mysql> SELECT COERCIBILITY('abc');
-> 4
mysql> SELECT COERCIBILITY(1000);
```
The return values have the meanings shown in the following table. Lower values have higher precedence.

<table>
<thead>
<tr>
<th>Coercibility</th>
<th>Meaning</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Explicit collation</td>
<td>Value with COLLATE clause</td>
</tr>
<tr>
<td>1</td>
<td>No collation</td>
<td>Concatenation of strings with different collations</td>
</tr>
<tr>
<td>2</td>
<td>Implicit collation</td>
<td>Column value, stored routine parameter or local variable</td>
</tr>
<tr>
<td>3</td>
<td>System constant</td>
<td>USER() return value</td>
</tr>
<tr>
<td>4</td>
<td>Coercible</td>
<td>Literal string</td>
</tr>
<tr>
<td>5</td>
<td>Numeric</td>
<td>Numeric or temporal value</td>
</tr>
<tr>
<td>6</td>
<td>Ignorable</td>
<td>NULL or an expression derived from NULL</td>
</tr>
</tbody>
</table>

For more information, see Section 10.8.4, “Collation Coercibility in Expressions”.

- **COLLATION**(str)**

  Returns the collation of the string argument.

  ```
  mysql> SELECT COLLATION('abc');
  -> 'utf8mb4_0900_ai_ci'
  mysql> SELECT COLLATION(_utf8mb4'abc');
  -> 'utf8mb4_0900_ai_ci'
  mysql> SELECT COLLATION(_latin1'abc');
  -> 'latin1_swedish_ci'
  ```

- **CONNECTION_ID()**

  Returns the connection ID (thread ID) for the connection. Every connection has an ID that is unique among the set of currently connected clients.

  The value returned by CONNECTION_ID() is the same type of value as displayed in the ID column of the Information Schema PROCESSLIST table, the Id column of SHOW PROCESSLIST output, and the PROCESSLIST_ID column of the Performance Schema threads table.

  ```
  mysql> SELECT CONNECTION_ID();
  -> 23786
  ```

  **Warning**

  Changing the session value of the pseudo_thread_id system variable changes the value returned by the CONNECTION_ID() function.

- **CURRENT_ROLE()**

  Returns a utf8mb3 string containing the current active roles for the current session, separated by commas, or NONE if there are none. The value reflects the setting of the sql_quote_show_create system variable.

  Suppose that an account is granted roles as follows:

  ```
  GRANT 'r1', 'r2' TO 'u1'@'localhost';
  ```
SET DEFAULT ROLE ALL TO 'u1'@'localhost';

In sessions for **u1**, the initial `CURRENT_ROLE()` value names the default account roles. Using `SET ROLE` changes that:

```sql
mysql> SELECT CURRENT_ROLE();
+-------------------+
| CURRENT_ROLE()    |
+-------------------+
| `r1`@`%`, `r2`@`%` |
+-------------------+

mysql> SET ROLE 'r1'; SELECT CURRENT_ROLE();
+----------------+
| CURRENT_ROLE() |
+----------------+
| `r1`@`%`       |
+----------------+
```

**CURRENT_USER, CURRENT_USER()**

Returns the user name and host name combination for the MySQL account that the server used to authenticate the current client. This account determines your access privileges. The return value is a string in the `utf8mb3` character set.

The value of `CURRENT_USER()` can differ from the value of `USER()`.

```sql
mysql> SELECT USER();
-> 'davida@localhost'
mysql> SELECT * FROM mysql.user;
ERROR 1044: Access denied for user ''@'localhost' to database 'mysql'
mysql> SELECT CURRENT_USER();
-> '@localhost'
```

The example illustrates that although the client specified a user name of **davida** (as indicated by the value of the `USER()` function), the server authenticated the client using an anonymous user account (as
Information Functions

seen by the empty user name part of the \texttt{CURRENT_USER()} value). One way this might occur is that there is no account listed in the grant tables for \texttt{davida}.

Within a stored program or view, \texttt{CURRENT_USER()} returns the account for the user who defined the object (as given by its \texttt{DEFINER} value) unless defined with the \texttt{SQL SECURITY INVOKER} characteristic. In the latter case, \texttt{CURRENT_USER()} returns the object's invoker.

Triggers and events have no option to define the \texttt{SQL SECURITY} characteristic, so for these objects, \texttt{CURRENT_USER()} returns the account for the user who defined the object. To return the invoker, use \texttt{USER()} or \texttt{SESSION_USER()}.

The following statements support use of the \texttt{CURRENT_USER()} function to take the place of the name of (and, possibly, a host for) an affected user or a definer; in such cases, \texttt{CURRENT_USER()} is expanded where and as needed:

- \texttt{DROP USER}
- \texttt{RENAME USER}
- \texttt{GRANT}
- \texttt{REVOKE}
- \texttt{CREATE FUNCTION}
- \texttt{CREATE PROCEDURE}
- \texttt{CREATE TRIGGER}
- \texttt{CREATE EVENT}
- \texttt{CREATE VIEW}
- \texttt{ALTER EVENT}
- \texttt{ALTER VIEW}
- \texttt{SET PASSWORD}

For information about the implications that this expansion of \texttt{CURRENT_USER()} has for replication, see \texttt{Section 17.5.1.8, “Replication of CURRENT_USER().”}.

This function can be used for the default value of a \texttt{VARCHAR} or \texttt{TEXT} column, as shown in the following \texttt{CREATE TABLE} statement:

```
CREATE TABLE t (c VARCHAR(288) DEFAULT (CURRENT_USER()));
```

- \texttt{DATABASE()}

Returns the default (current) database name as a string in the \texttt{utf8mb3} character set. If there is no default database, \texttt{DATABASE()} returns \texttt{NULL}. Within a stored routine, the default database is the database that the routine is associated with, which is not necessarily the same as the database that is the default in the calling context.

```
mysql> SELECT DATABASE();
-> 'test'
```

If there is no default database, \texttt{DATABASE()} returns \texttt{NULL}.
Information Functions

• **FOUND_ROWS()**

**Note**

The `SQL_CALC_FOUND_ROWS` query modifier and accompanying `FOUND_ROWS()` function are deprecated; expect them to be removed in a future version of MySQL. Execute the query with `LIMIT`, and then a second query with `COUNT(*)` and without `LIMIT` to determine whether there are additional rows. For example, instead of these queries:

```sql
SELECT SQL_CALC_FOUND_ROWS * FROM tbl_name WHERE id > 100 LIMIT 10;
SELECT FOUND_ROWS();
```

Use these queries instead:

```sql
SELECT * FROM tbl_name WHERE id > 100 LIMIT 10;
SELECT COUNT(*) FROM tbl_name WHERE id > 100;
```

`COUNT(*)` is subject to certain optimizations. `SQL_CALC_FOUND_ROWS` causes some optimizations to be disabled.

A `SELECT` statement may include a `LIMIT` clause to restrict the number of rows the server returns to the client. In some cases, it is desirable to know how many rows the statement would have returned without the `LIMIT`, but without running the statement again. To obtain this row count, include an `SQL_CALC_FOUND_ROWS` option in the `SELECT` statement, and then invoke `FOUND_ROWS()` afterward:

```sql
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM tbl_name WHERE id > 100 LIMIT 10;
mysql> SELECT FOUND_ROWS();
```

The second `SELECT` returns a number indicating how many rows the first `SELECT` would have returned had it been written without the `LIMIT` clause.

In the absence of the `SQL_CALC_FOUND_ROWS` option in the most recent successful `SELECT` statement, `FOUND_ROWS()` returns the number of rows in the result set returned by that statement. If the statement includes a `LIMIT` clause, `FOUND_ROWS()` returns the number of rows up to the limit. For example, `FOUND_ROWS()` returns 10 or 60, respectively, if the statement includes `LIMIT 10` or `LIMIT 50, 10`.

The row count available through `FOUND_ROWS()` is transient and not intended to be available past the statement following the `SELECT SQL_CALC_FOUND_ROWS` statement. If you need to refer to the value later, save it:

```sql
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM ... ;
mysql> SET @rows = FOUND_ROWS();
```

If you are using `SELECT SQL_CALC_FOUND_ROWS`, MySQL must calculate how many rows are in the full result set. However, this is faster than running the query again without `LIMIT`, because the result set need not be sent to the client.

`SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` can be useful in situations when you want to restrict the number of rows that a query returns, but also determine the number of rows in the full result set without running the query again. An example is a Web script that presents a paged display containing links to
the pages that show other sections of a search result. Using `FOUND_ROWS()` enables you to determine how many other pages are needed for the rest of the result.

The use of `SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` is more complex for `UNION` statements than for simple `SELECT` statements, because `LIMIT` may occur at multiple places in a `UNION`. It may be applied to individual `SELECT` statements in the `UNION`, or global to the `UNION` result as a whole.

The intent of `SQL_CALC_FOUND_ROWS` for `UNION` is that it should return the row count that would be returned without a global `LIMIT`. The conditions for use of `SQL_CALC_FOUND_ROWS` with `UNION` are:

- The `SQL_CALC_FOUND_ROWS` keyword must appear in the first `SELECT` of the `UNION`.
- The value of `FOUND_ROWS()` is exact only if `UNION ALL` is used. If `UNION` without `ALL` is used, duplicate removal occurs and the value of `FOUND_ROWS()` is only approximate.
- If no `LIMIT` is present in the `UNION`, `SQL_CALC_FOUND_ROWS` is ignored and returns the number of rows in the temporary table that is created to process the `UNION`.

Beyond the cases described here, the behavior of `FOUND_ROWS()` is undefined (for example, its value following a `SELECT` statement that fails with an error).

- **Important**

  `FOUND_ROWS()` is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

- **ICU_VERSION()**

  The version of the International Components for Unicode (ICU) library used to support regular expression operations (see Section 12.8.2, “Regular Expressions”). This function is primarily intended for use in test cases.

- **LAST_INSERT_ID(), LAST_INSERT_ID(expr)**

  With no argument, `LAST_INSERT_ID()` returns a `BIGINT UNSIGNED` (64-bit) value representing the first automatically generated value successfully inserted for an `AUTO_INCREMENT` column as a result of the most recently executed `INSERT` statement. The value of `LAST_INSERT_ID()` remains unchanged if no rows are successfully inserted.

  With an argument, `LAST_INSERT_ID(expr)` returns an unsigned integer, or `NULL` if the argument is `NULL`.

  For example, after inserting a row that generates an `AUTO_INCREMENT` value, you can get the value like this:

  ```
  mysql> SELECT LAST_INSERT_ID();
  -> 195
  ```

  The currently executing statement does not affect the value of `LAST_INSERT_ID()`. Suppose that you generate an `AUTO_INCREMENT` value with one statement, and then refer to `LAST_INSERT_ID()` in a multiple-row `INSERT` statement that inserts rows into a table with its own `AUTO_INCREMENT` column. The value of `LAST_INSERT_ID()` remains stable in the second statement: its value for the second and later rows is not affected by the earlier row insertions. (You should be aware that, if you mix references to `LAST_INSERT_ID()` and `LAST_INSERT_ID(expr)`, the effect is undefined.)

  If the previous statement returned an error, the value of `LAST_INSERT_ID()` is undefined. For transactional tables, if the statement is rolled back due to an error, the value of `LAST_INSERT_ID()` is
left undefined. For manual `ROLLBACK`, the value of `LAST_INSERT_ID()` is not restored to that before the transaction; it remains as it was at the point of the `ROLLBACK`.

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects. The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

• If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value is seen by statements that follow the procedure call.

• For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so statements coming after it do not see a changed value.

The ID that was generated is maintained in the server on a `per-connection basis`. This means that the value returned by the function to a given client is the first `AUTO_INCREMENT` value generated for most recent statement affecting an `AUTO_INCREMENT` column by that client. This value cannot be affected by other clients, even if they generate `AUTO_INCREMENT` values of their own. This behavior ensures that each client can retrieve its own ID without concern for the activity of other clients, and without the need for locks or transactions.

The value of `LAST_INSERT_ID()` is not changed if you set the `AUTO_INCREMENT` column of a row to a non-“magic” value (that is, a value that is not `NULL` and not `0`).

---

**Important**

If you insert multiple rows using a single `INSERT` statement, `LAST_INSERT_ID()` returns the value generated for the *first* inserted row *only*. The reason for this is to make it possible to reproduce easily the same `INSERT` statement against some other server.

For example:

```sql
mysql> USE test;

mysql> CREATE TABLE t (  
      id INT AUTO_INCREMENT NOT NULL PRIMARY KEY,  
      name VARCHAR(10) NOT NULL  
    );

mysql> INSERT INTO t VALUES (NULL, 'Bob');

mysql> SELECT * FROM t;
+----+------+
| id | name |
+----+------+
|  1 | Bob  |
+----+------+

mysql> SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
|  1               |
+------------------+

mysql> INSERT INTO t VALUES  
   (NULL, 'Mary'), (NULL, 'Jane'), (NULL, 'Lisa');

mysql> SELECT * FROM t;
+----+------+
| id | name |
+----+------+
|    |      |
+----+------+
```

---
Although the second `INSERT` statement inserted three new rows into `t`, the ID generated for the first of these rows was `2`, and it is this value that is returned by `LAST_INSERT_ID()` for the following `SELECT` statement.

If you use `INSERT IGNORE` and the row is ignored, the `LAST_INSERT_ID()` remains unchanged from the current value (or 0 is returned if the connection has not yet performed a successful `INSERT`) and, for non-transactional tables, the `AUTO_INCREMENT` counter is not incremented. For InnoDB tables, the `AUTO_INCREMENT` counter is incremented if `innodb_autoinc_lock_mode` is set to `1` or `2`, as demonstrated in the following example:
The attempted insertion of duplicate rows fail but errors are ignored.

```sql
mysql> INSERT IGNORE INTO t (val) VALUES (1),(2);
Query OK, 0 rows affected (0.00 sec)
Records: 2  Duplicates: 2  Warnings: 0
```

With `innodb_autoinc_lock_mode=1`, the AUTO_INCREMENT counter is incremented for the ignored rows.

```sql
mysql> SHOW CREATE TABLE t
```

```
*************************** 1. row ***************************
Table: t
CREATE TABLE `t` (  `id` int(11) NOT NULL AUTO_INCREMENT,  `val` int(11) DEFAULT NULL,  PRIMARY KEY (`id`),  UNIQUE KEY `i1` (`val`) ) ENGINE=InnoDB AUTO_INCREMENT=5 DEFAULT CHARSET=latin1
```

The LAST_INSERT_ID is unchanged because the previous insert was unsuccessful.

```sql
mysql> SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
|                1 |
```

For more information, see Section 15.6.1.6, “AUTO_INCREMENT Handling in InnoDB”.

If `expr` is given as an argument to `LAST_INSERT_ID()`, the value of the argument is returned by the function and is remembered as the next value to be returned by `LAST_INSERT_ID()`. This can be used to simulate sequences:

1. Create a table to hold the sequence counter and initialize it:

   ```sql
   mysql> CREATE TABLE sequence (id INT NOT NULL);
   mysql> INSERT INTO sequence VALUES (0);
   ```

2. Use the table to generate sequence numbers like this:

   ```sql
   mysql> UPDATE sequence SET id=LAST_INSERT_ID(id+1);
   mysql> SELECT LAST_INSERT_ID();
   ```

   The `UPDATE` statement increments the sequence counter and causes the next call to `LAST_INSERT_ID()` to return the updated value. The `SELECT` statement retrieves that value. The `mysql_insert_id()` C API function can also be used to get the value. See `mysql_insert_id()`.

You can generate sequences without calling `LAST_INSERT_ID()`; however, the utility of using the function this way is that the ID value is maintained in the server as the last automatically generated value. It is multi-user safe because multiple clients can issue the `UPDATE` statement and get their own sequence value with the `SELECT` statement (or `mysql_insert_id()`), without affecting or being affected by other clients that generate their own sequence values.

Note that `mysql_insert_id()` is only updated after `INSERT` and `UPDATE` statements, so you cannot use the C API function to retrieve the value for `LAST_INSERT_ID(expr)` after executing other SQL statements like `SELECT` or `SET`.

```sql
| 1 |
```

---

2419
• **ROLES_GRAPHML()**

Returns a `utf8mb3` string containing a GraphML document representing memory role subgraphs. The `ROLE_ADMIN` privilege (or the deprecated `SUPER` privilege) is required to see content in the `<graphml>` element. Otherwise, the result shows only an empty element:

```sql
mysql> SELECT ROLES_GRAPHML();
+---------------------------------------------------+
| ROLES_GRAPHML()                                   |
+---------------------------------------------------+
| <?xml version="1.0" encoding="UTF-8"?><graphml /> |
+---------------------------------------------------+
```

• **ROW_COUNT()**

`ROW_COUNT()` returns a value as follows:

- **DDL statements**: 0. This applies to statements such as `CREATE TABLE` or `DROP TABLE`.
- **DML statements other than SELECT**: The number of affected rows. This applies to statements such as `UPDATE`, `INSERT`, or `DELETE` (as before), but now also to statements such as `ALTER TABLE` and `LOAD DATA`.
- **SELECT**: -1 if the statement returns a result set, or the number of rows “affected” if it does not. For example, for `SELECT * FROM t1`, `ROW_COUNT()` returns -1. For `SELECT * FROM t1 INTO OUTFILE 'file_name'`, `ROW_COUNT()` returns the number of rows written to the file.
- **SIGNAL** statements: 0.

For UPDATE statements, the affected-rows value by default is the number of rows actually changed. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to `mysqld`, the affected-rows value is the number of rows “found”; that is, matched by the WHERE clause.

For REPLACE statements, the affected-rows value is 2 if the new row replaced an old row, because in this case, one row was inserted after the duplicate was deleted.

For INSERT ... ON DUPLICATE KEY UPDATE statements, the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

The `ROW_COUNT()` value is similar to the value from the `mysql_affected_rows()` C API function and the row count that the mysql client displays following statement execution.

```sql
mysql> INSERT INTO t VALUES(1),(2),(3);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT ROW_COUNT();
+-------------+
| ROW_COUNT() |
+-------------+
|           3 |
+-------------+
1 row in set (0.00 sec)

mysql> DELETE FROM t WHERE i IN(1,2);
Query OK, 2 rows affected (0.00 sec)

mysql> SELECT ROW_COUNT();
+-------------+
| ROW_COUNT() |
+-------------+
|           1 |
+-------------+
```
Information Functions

<table>
<thead>
<tr>
<th>Row_COUNT()</th>
</tr>
</thead>
<tbody>
<tr>
<td>---------------------</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>1 row in set (0.00 sec)</td>
</tr>
</tbody>
</table>

**Important**

ROW_COUNT() is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

- **SCHEMA()**

  This function is a synonym for DATABASE().

- **SESSION_USER()**

  SESSION_USER() is a synonym for USER().

  Like USER(), this function can be used for the default value of a VARCHAR or TEXT column, as shown in the following CREATE TABLE statement:

  ```
  CREATE TABLE t (c VARCHAR(288) DEFAULT (SESSION_USER()));
  ```

- **SYSTEM_USER()**

  SYSTEM_USER() is a synonym for USER().

  Note

  The SYSTEM_USER() function is distinct from the SYSTEM_USER privilege. The former returns the current MySQL account name. The latter distinguishes the system user and regular user account categories (see Section 6.2.11, “Account Categories”).

  Like USER(), this function can be used for the default value of a VARCHAR or TEXT column, as shown in the following CREATE TABLE statement:

  ```
  CREATE TABLE t (c VARCHAR(288) DEFAULT (SYSTEM_USER()));
  ```

- **USER()**

  Returns the current MySQL user name and host name as a string in the utf8mb3 character set.

  ```
  mysql> SELECT USER();
  -> 'davida@localhost'
  ```

  The value indicates the user name you specified when connecting to the server, and the client host from which you connected. The value can be different from that of CURRENT_USER().

  This function can be used for the default value of a VARCHAR or TEXT column, as shown in the following CREATE TABLE statement:

  ```
  CREATE TABLE t (c VARCHAR(288) DEFAULT (USER()));
  ```

- **VERSION()**

  Returns a string that indicates the MySQL server version. The string uses the utf8mb3 character set. The value might have a suffix in addition to the version number. See the description of the version system variable in Section 5.1.8, “Server System Variables”.

2421
Spatial Analysis Functions

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

```sql
mysql> SELECT VERSION();
-> '8.2.0-standard'
```

12.16 Spatial Analysis Functions

MySQL provides functions to perform various operations on spatial data. These functions can be grouped into several major categories according to the type of operation they perform:

- Functions that create geometries in various formats (WKT, WKB, internal)
- Functions that convert geometries between formats
- Functions that access qualitative or quantitative properties of a geometry
- Functions that describe relations between two geometries
- Functions that create new geometries from existing ones

For general background about MySQL support for using spatial data, see Section 11.4, “Spatial Data Types”.

12.16.1 Spatial Function Reference

The following table lists each spatial function and provides a short description of each one.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GeomCollection()</td>
<td>Construct geometry collection from geometries</td>
</tr>
<tr>
<td>GeometryCollection()</td>
<td>Construct geometry collection from geometries</td>
</tr>
<tr>
<td>LineString()</td>
<td>Construct LineString from Point values</td>
</tr>
<tr>
<td>MBRContains()</td>
<td>Whether MBR of one geometry contains MBR of another</td>
</tr>

12.16.2 Argument Handling by Spatial Functions

Spatial values, or geometries, have the properties described in Section 11.4.2.2, “Geometry Class”. The following discussion lists general spatial function argument-handling characteristics. Specific functions or groups of functions may have additional or different argument-handling characteristics, as discussed in the sections where those function descriptions occur. Where that is true, those descriptions take precedence over the general discussion here.

Spatial functions are defined only for valid geometry values. See Section 11.4.4, “Geometry Well-Formedness and Validity”.

Each geometry value is associated with a spatial reference system (SRS), which is a coordinate-based system for geographic locations. See Section 11.4.5, “Spatial Reference System Support”.

The spatial reference identifier (SRID) of a geometry identifies the SRS in which the geometry is defined. In MySQL, the SRID value is an integer associated with the geometry value. The maximum usable SRID value is $2^{32} - 1$. If a larger value is given, only the lower 32 bits are used.

SRID 0 represents an infinite flat Cartesian plane with no units assigned to its axes. To ensure SRID 0 behavior, create geometry values using SRID 0. SRID 0 is the default for new geometry values if no SRID is specified.

For computations on multiple geometry values, all values must be in the same SRS or an error occurs. Thus, spatial functions that take multiple geometry arguments require those arguments to be in the same SRS. If a spatial function returns ER_GIS_DIFFERENT_SRIDS, it means that the geometry arguments were not all in the same SRS. You must modify them to have the same SRS.

A geometry returned by a spatial function is in the SRS of the geometry arguments because geometry values produced by any spatial function inherit the SRID of the geometry arguments.

The Open Geospatial Consortium guidelines require that input polygons already be closed, so unclosed polygons are rejected as invalid rather than being closed.

In MySQL, the only valid empty geometry is represented in the form of an empty geometry collection. Empty geometry collection handling is as follows: An empty WKT input geometry collection may be

12.16.3 Functions That Create Geometry Values from WKT Values

These functions take as arguments a Well-Known Text (WKT) representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry. For a description of WKT format, see Well-Known Text (WKT) Format.

Functions in this section detect arguments in either Cartesian or geographic spatial reference systems (SRSs), and return results appropriate to the SRS.

\texttt{ST\_GeomFromText()} accepts a WKT value of any geometry type as its first argument. Other functions provide type-specific construction functions for construction of geometry values of each geometry type.

Functions such as \texttt{ST\_MPointFromText()} and \texttt{ST\_GeomFromText()} that accept WKT-format representations of \texttt{MultiPoint} values permit individual points within values to be surrounded by parentheses. For example, both of the following function calls are valid:

\begin{verbatim}
ST\_MPointFromText('MULTIPOINT (1 1, 2 2, 3 3)')
ST\_MPointFromText('MULTIPOINT ((1 1), (2 2), (3 3))')
\end{verbatim}

Functions such as \texttt{ST\_GeomFromText()} that accept WKT geometry collection arguments understand both OpenGIS 'GEOMETRYCOLLECTION EMPTY' standard syntax and MySQL 'GEOMETRYCOLLECTION()' nonstandard syntax. Functions such as \texttt{ST\_AsWKT()} that produce WKT values produce 'GEOMETRYCOLLECTION EMPTY' standard syntax:

\begin{verbatim}
mysql> SET @s1 = ST\_GeomFromText('GEOMETRYCOLLECTION()');
mysql> SET @s2 = ST\_GeomFromText('GEOMETRYCOLLECTION EMPTY');
mysql> SELECT ST\_AsWKT(@s1), ST\_AsWKT(@s2);
+--------------------------+--------------------------+
| ST\_AsWKT(@s1)            | ST\_AsWKT(@s2)            |
|--------------------------+--------------------------|
| GEOMETRYCOLLECTION EMPTY | GEOMETRYCOLLECTION EMPTY |
+--------------------------+--------------------------+
\end{verbatim}

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any geometry argument is \texttt{NULL} or is not a syntactically well-formed geometry, or if the SRID argument is \texttt{NULL}, the return value is \texttt{NULL}.

- By default, geographic coordinates (latitude, longitude) are interpreted as in the order specified by the spatial reference system of geometry arguments. An optional \texttt{options} argument may be given to override the default axis order. \texttt{options} consists of a list of comma-separated \texttt{key=value}. The only permitted \texttt{key} value is \texttt{axis-order}, with permitted values of \texttt{lat-long}, \texttt{long-lat} and \texttt{srid-defined} (the default).

  If the \texttt{options} argument is \texttt{NULL}, the return value is \texttt{NULL}. If the \texttt{options} argument is invalid, an error occurs to indicate why.

- If an SRID argument refers to an undefined spatial reference system (SRS), an \texttt{ER\_SRS\_NOT\_FOUND} error occurs.

- For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:
Functions That Create Geometry Values from WKT Values

- If a longitude value is not in the range (-180, 180], an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
- If a latitude value is not in the range [-90, 90], an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

These functions are available for creating geometries from WKT values:

- `ST_GeomCollFromText(wkt [, srid [, options]]),`  
  `ST_GeometryCollectionFromText(wkt [, srid [, options]]),`  
  `ST_GeomCollFromTxt(wkt [, srid [, options]])`

  Constructs a `GeometryCollection` value using its WKT representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

```sql
mysql> SET @g = "MULTILINESTRING((10 10, 11 11), (9 9, 10 10))";
mysql> SELECT ST_AsText(ST_GeomCollFromText(@g));
+--------------------------------------------+
<table>
<thead>
<tr>
<th>ST_AsText(ST_GeomCollFromText(@g))</th>
</tr>
</thead>
<tbody>
<tr>
<td>MULTILINESTRING((10 10,11 11),(9 9,10 10))</td>
</tr>
</tbody>
</table>
+--------------------------------------------+
```

- `ST_GeomFromText(wkt [, srid [, options]]),`  
  `ST_GeometryFromText(wkt [, srid [, options]]),`  
  `ST_GeomFromTxt(wkt [, srid [, options]])`

  Constructs a geometry value of any type using its WKT representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

- `ST_LineFromText(wkt [, srid [, options]]),`  
  `ST_LineStringFromText(wkt [, srid [, options]])`

  Constructs a `LineString` value using its WKT representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

- `ST_MLineFromText(wkt [, srid [, options]]),`  
  `ST_MultiLineStringFromText(wkt [, srid [, options]])`

  Constructs a `MultiLineString` value using its WKT representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

- `ST_MPointFromText(wkt [, srid [, options]]),`  
  `ST_MultiPointFromText(wkt [, srid [, options]])`

  Constructs a `MultiPoint` value using its WKT representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

- `ST_MPolyFromText(wkt [, srid [, options]]),`  
  `ST_MultiPolygonFromText(wkt [, srid [, options]])`

  Constructs a `MultiPolygon` value using its WKT representation and SRID.

  These functions handle their arguments as described in the introduction to this section.
Functions That Create Geometry Values from WKB Values

- `ST_PointFromText(wkt [, srid [, options]])`
  Constructs a **Point** value using its WKT representation and SRID.
  `ST_PointFromText()` handles its arguments as described in the introduction to this section.

- `ST_PolyFromText(wkt [, srid [, options]])`, `ST_PolygonFromText(wkt [, srid [, options]])`
  Constructs a **Polygon** value using its WKT representation and SRID.
  These functions handle their arguments as described in the introduction to this section.

### 12.16.4 Functions That Create Geometry Values from WKB Values

These functions take as arguments a **BLOB** containing a Well-Known Binary (WKB) representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry. For a description of WKB format, see **Well-Known Binary (WKB) Format**.

Functions in this section detect arguments in either Cartesian or geographic spatial reference systems (SRSs), and return results appropriate to the SRS.

- `ST_GeomFromWKB()` accepts a WKB value of any geometry type as its first argument. Other functions provide type-specific construction functions for construction of geometry values of each geometry type.

Prior to MySQL 8.2, these functions also accepted geometry objects as returned by the functions in Section 12.16.5, "MySQL-Specific Functions That Create Geometry Values". Geometry arguments are no longer permitted and produce an error. To migrate calls from using geometry arguments to using WKB arguments, follow these guidelines:

- Rewrite constructs such as `ST_GeomFromWKB(Point(0, 0))` as `Point(0, 0)`.
- Rewrite constructs such as `ST_GeomFromWKB(Point(0, 0), 4326)` as `ST_SRID(Point(0, 0), 4326)` or `ST_GeomFromWKB(ST_AsWKB(Point(0, 0)), 4326)`.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If the WKB or SRID argument is `NULL`, the return value is `NULL`.

- By default, geographic coordinates (latitude, longitude) are interpreted as in the order specified by the spatial reference system of geometry arguments. An optional `options` argument may be given to override the default axis order. `options` consists of a list of comma-separated `key=value`. The only permitted `key` value is `axis-order`, with permitted values of `lat-long`, `long-lat` and `srid-defined` (the default).

  If the `options` argument is `NULL`, the return value is `NULL`. If the `options` argument is invalid, an error occurs to indicate why.

- If an SRID argument refers to an undefined spatial reference system (SRS), an **ER_SRS_NOT_FOUND** error occurs.

- For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range `(-180, 180]`, an **ER_LONGITUDE_OUT_OF_RANGE** error occurs.
  - If a latitude value is not in the range `[-90, 90]`, an **ER_LATITUDE_OUT_OF_RANGE** error occurs.
Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

These functions are available for creating geometries from WKB values:

- `ST_GeomCollFromWKB(wkb [, srid [, options]])`, `ST_GeometryCollectionFromWKB(wkb [, srid [, options]])`

  Constructs a `GeometryCollection` value using its WKB representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

- `ST_GeomFromWKB(wkb [, srid [, options]])`, `ST_GeometryFromWKB(wkb [, srid [, options]])`

  Constructs a geometry value of any type using its WKB representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

- `ST_LineFromWKB(wkb [, srid [, options]])`, `ST_LineStringFromWKB(wkb [, srid [, options]])`

  Constructs a `LineString` value using its WKB representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

- `ST_MLineFromWKB(wkb [, srid [, options]])`, `ST_MultiLineStringFromWKB(wkb [, srid [, options]])`

  Constructs a `MultiLineString` value using its WKB representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

- `ST_MPointFromWKB(wkb [, srid [, options]])`, `ST_MultiPointFromWKB(wkb [, srid [, options]])`

  Constructs a `MultiPoint` value using its WKB representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

- `ST_MPolyFromWKB(wkb [, srid [, options]])`, `ST_MultiPolygonFromWKB(wkb [, srid [, options]])`

  Constructs a `MultiPolygon` value using its WKB representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

- `ST_PointFromWKB(wkb [, srid [, options]])`

  Constructs a `Point` value using its WKB representation and SRID.

  `ST_PointFromWKB()` handles its arguments as described in the introduction to this section.

- `ST_PolyFromWKB(wkb [, srid [, options]])`, `ST_PolygonFromWKB(wkb [, srid [, options]])`

  Constructs a `Polygon` value using its WKB representation and SRID.
MySQL-Specific Functions That Create Geometry Values

These functions handle their arguments as described in the introduction to this section.

12.16.5 MySQL-Specific Functions That Create Geometry Values

MySQL provides a set of useful nonstandard functions for creating geometry values. The functions described in this section are MySQL extensions to the OpenGIS specification.

These functions produce geometry objects from either WKB values or geometry objects as arguments. If any argument is not a proper WKB or geometry representation of the proper object type, the return value is NULL.

For example, you can insert the geometry return value from `Point()` directly into a `POINT` column:

```
INSERT INTO t1 (pt_col) VALUES(Point(1,2));
```

- **GeomCollection(g [, g] ...)**
  Constructs a GeomCollection value from the geometry arguments.
  
  `GeomCollection()` returns all the proper geometries contained in the arguments even if a nonsupported geometry is present.
  
  `GeomCollection()` with no arguments is permitted as a way to create an empty geometry.
  
  Also, functions such as `ST_GeomFromText()` that accept WKT geometry collection arguments understand both OpenGIS 'GEOMETRYCOLLECTION EMPTY' standard syntax and MySQL 'GEOMETRYCOLLECTION()' nonstandard syntax.

  `GeomCollection()` and `GeometryCollection()` are synonymous, with `GeomCollection()` the preferred function.

- **GeometryCollection(g [, g] ...)**
  Constructs a GeomCollection value from the geometry arguments.
  
  `GeometryCollection()` returns all the proper geometries contained in the arguments even if a nonsupported geometry is present.
  
  `GeometryCollection()` with no arguments is permitted as a way to create an empty geometry.
  
  Also, functions such as `ST_GeomFromText()` that accept WKT geometry collection arguments understand both OpenGIS 'GEOMETRYCOLLECTION EMPTY' standard syntax and MySQL 'GEOMETRYCOLLECTION()' nonstandard syntax.

  `GeomCollection()` and `GeometryCollection()` are synonymous, with `GeomCollection()` the preferred function.

- **LineString(pt [, pt] ...)**
  Constructs a LineString value from a number of Point or WKB Point arguments. If the number of arguments is less than two, the return value is NULL.

- **MultiLineString(ls [, ls] ...)**
  Constructs a MultiLineString value using LineString or WKB LineString arguments.

- **MultiPoint(pt [, pt2] ...)**
  Constructs a MultiPoint value using Point or WKB Point arguments.
• **MultiPolygon(poly [, poly] ...)***

Constructs a `MultiPolygon` value from a set of `Polygon` or WKB `Polygon` arguments.

• **Point(x, y)***

Constructs a `Point` using its coordinates.

• **Polygon(ls [, ls] ...)***

Constructs a `Polygon` value from a number of `LineString` or WKB `LineString` arguments. If any argument does not represent a `LinearRing` (that is, not a closed and simple `LineString`), the return value is **NULL**.

### 12.16.6 Geometry Format Conversion Functions

MySQL supports the functions listed in this section for converting geometry values from internal geometry format to WKT or WKB format, or for swapping the order of X and Y coordinates.

There are also functions to convert a string from WKT or WKB format to internal geometry format. See Section 12.16.3, “Functions That Create Geometry Values from WKT Values”, and Section 12.16.4, “Functions That Create Geometry Values from WKB Values”.

Functions such as `ST_GeomFromText()` that accept WKT geometry collection arguments understand both OpenGIS "GEOMETRYCOLLECTION EMPTY" standard syntax and MySQL 'GEOMETRYCOLLECTION()' nonstandard syntax. Another way to produce an empty geometry collection is by calling `GeometryCollection()` with no arguments. Functions such as `ST_AsWKT()` that produce WKT values produce 'GEOMETRYCOLLECTION EMPTY' standard syntax:

```sql
mysql> SET @s1 = ST_GeomFromText('GEOMETRYCOLLECTION()');
mysql> SET @s2 = ST_GeomFromText('GEOMETRYCOLLECTION EMPTY');
mysql> SELECT ST_AsWKT(@s1), ST_AsWKT(@s2);
+--------------------------+--------------------------+
| ST_AsWKT(@s1)            | ST_AsWKT(@s2)            |
| GEOMETRYCOLLECTION EMPTY | GEOMETRYCOLLECTION EMPTY |
+--------------------------+--------------------------+
mysql> SELECT ST_AsWKT(GeomCollection());
+--------------------------+--------------------------+
| ST_AsWKT(GeomCollection()) |
| GEOMETRYCOLLECTION EMPTY  |
+--------------------------+--------------------------+
```

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is **NULL**, the return value is **NULL**.

- If any geometry argument is not a syntactically well-formed geometry, an **ER_GIS_INVALID_DATA** error occurs.

- If any geometry argument is in an undefined spatial reference system, the axes are output in the order they appear in the geometry and an **ER_WARN_SRS_NOT_FOUND_AXIS_ORDER** warning occurs.

- By default, geographic coordinates (latitude, longitude) are interpreted as in the order specified by the spatial reference system of geometry arguments. An optional `options` argument may be given to override the default axis order. `options` consists of a list of comma-separated `key=value`. The only permitted `key` value is `axis-order`, with permitted values of `lat-long`, `long-lat` and `srid-defined` (the default).
If the `options` argument is `NULL`, the return value is `NULL`. If the `options` argument is invalid, an error occurs to indicate why.

• Otherwise, the return value is non-`NULL`.

These functions are available for format conversions or coordinate swapping:

• `ST_AsBinary(g [, options]), ST_AsWKB(g [, options])`

Converts a value in internal geometry format to its WKB representation and returns the binary result.

The function return value has geographic coordinates (latitude, longitude) in the order specified by the spatial reference system that applies to the geometry argument. An optional `options` argument may be given to override the default axis order.

`ST_AsBinary()` and `ST_AsWKB()` handle their arguments as described in the introduction to this section.

```
mysql> SET @g = ST_LineFromText('LINESTRING(0 5,5 10,10 15)', 4326);
mysql> SELECT ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g)));
+-----------------------------------------+
| ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g))) |
+-----------------------------------------+
| LINESTRING(5 0,10 5,15 10)              |
+-----------------------------------------+
mysql> SELECT ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=long-lat')));
+----------------------------------------------------------------+
| ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=long-lat'))) |
+----------------------------------------------------------------+
| LINESTRING(0 5,5 10,10 15)                                     |
+----------------------------------------------------------------+
mysql> SELECT ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=lat-long')));
+----------------------------------------------------------------+
| ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=lat-long'))) |
+----------------------------------------------------------------+
| LINESTRING(5 0,10 5,15 10)                                     |
+----------------------------------------------------------------+
```

• `ST_AsText(g [, options]), ST_AsWKT(g [, options])`

Converts a value in internal geometry format to its WKT representation and returns the string result.

The function return value has geographic coordinates (latitude, longitude) in the order specified by the spatial reference system that applies to the geometry argument. An optional `options` argument may be given to override the default axis order.

`ST_AsText()` and `ST_AsWKT()` handle their arguments as described in the introduction to this section.

```
mysql> SET @g = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_GeomFromText(@g));
+--------------------------------+
| ST_AsText(ST_GeomFromText(@g)) |
+--------------------------------+
| LINESTRING(1 1,2 2,3 3)        |
+--------------------------------+
mysql> SELECT ST_AsText(ST_GeomFromText(@g, 'axis-order=long-lat'));
+----------------------------------------------------------------+
| ST_AsText(ST_GeomFromText(@g, 'axis-order=long-lat')) |
+----------------------------------------------------------------+
| LINESTRING(1 1,2 2,3 3)        |
+----------------------------------------------------------------+
mysql> SELECT ST_AsText(ST_GeomFromText(@g, 'axis-order=lat-long'));
+----------------------------------------------------------------+
| ST_AsText(ST_GeomFromText(@g, 'axis-order=lat-long')) |
+----------------------------------------------------------------+
| LINESTRING(1 1,2 2,3 3)        |
+----------------------------------------------------------------+
```

Output for `MultiPoint` values includes parentheses around each point. For example:

```
mysql> SELECT ST_AsText(ST_GeomFromText(@mp));
+---------------------------------+
| ST_AsText(ST_GeomFromText(@mp)) |
+---------------------------------+
```

2432
Geometry Property Functions

- **ST_SwapXY(g)**

  Accepts an argument in internal geometry format, swaps the X and Y values of each coordinate pair within the geometry, and returns the result.

  `ST_SwapXY()` handles its arguments as described in the introduction to this section.

  ```
  mysql> SET @g = ST_LineFromText('LINESTRING(0 5,5 10,10 15)');
  mysql> SELECT ST_AsText(@g);
  +----------------------------+
  | ST_AsText(@g)              |
  +----------------------------+
  | LINESTRING(0 5,5 10,10 15) |
  +----------------------------+
  mysql> SELECT ST_AsText(ST_SwapXY(@g));
  +----------------------------+
  | ST_AsText(ST_SwapXY(@g))   |
  +----------------------------+
  | LINESTRING(5 0,10 5,15 10) |
  +----------------------------+
  ```

**12.16.7 Geometry Property Functions**

Each function that belongs to this group takes a geometry value as its argument and returns some quantitative or qualitative property of the geometry. Some functions restrict their argument type. Such functions return `NULL` if the argument is of an incorrect geometry type. For example, the `ST_Area()` polygon function returns `NULL` if the object type is neither `Polygon` nor `MultiPolygon`.

**12.16.7.1 General Geometry Property Functions**

The functions listed in this section do not restrict their argument and accept a geometry value of any type. Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is `NULL`, the return value is `NULL`.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- If any SRID argument is not within the range of a 32-bit unsigned integer, an `ER_DATA_OUT_OF_RANGE` error occurs.
- If any SRID argument refers to an undefined SRS, an `ER_SRS_NOT_FOUND` error occurs.
- Otherwise, the return value is non-`NULL`.

These functions are available for obtaining geometry properties:

- **ST_Dimension(g)**

  Returns the inherent dimension of the geometry value `g`. The dimension can be −1, 0, 1, or 2. The meaning of these values is given in Section 11.4.2.2, “Geometry Class”.

  `ST_Dimension()` handles its arguments as described in the introduction to this section.
Geometry Property Functions

- **ST_Dimension($g$)**

  Returns the minimum bounding rectangle (MBR) for the geometry value $g$. The result is returned as a `Polygon` value that is defined by the corner points of the bounding box:

  \[
  \text{POLYGON}((\text{MINX} \ \text{MINY}, \ \text{MAXX} \ \text{MINY}, \ \text{MAXX} \ \text{MAXY}, \ \text{MINX} \ \text{MAXY}, \ \text{MINX} \ \text{MINY}))
  \]

  If the argument is a point or a vertical or horizontal line segment, `ST_Envelope()` returns the point or the line segment as its MBR rather than returning an invalid polygon:

  ```sql
  SELECT ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,1 2)')));
  ```

  ```text
  ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,1 2)'))) = LINESTRING(1 1,1 2)
  ```

  `ST_Envelope()` handles its arguments as described in the introduction to this section, with this exception:

  - If the geometry has an SRID value for a geographic spatial reference system (SRS), an `ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS` error occurs.

- **ST_GeometryType($g$)**

  Returns a binary string indicating the name of the geometry type of which the geometry instance $g$ is a member. The name corresponds to one of the instantiable `Geometry` subclasses.

  ```sql
  SELECT ST_GeometryType(ST_GeomFromText('POINT(1 1)'));
  ```

  ```text
  ST_GeometryType(ST_GeomFromText('POINT(1 1)')) = POINT
  ```

- **ST_IsEmpty($g$)**

  This function is a placeholder that returns 1 for an empty geometry collection value or 0 otherwise.

  The only valid empty geometry is represented in the form of an empty geometry collection value. MySQL does not support GIS `EMPTY` values such as `POINT EMPTY`.

  `ST_IsEmpty()` handles its arguments as described in the introduction to this section.

- **ST_IsSimple($g$)**
Geometry Property Functions

Returns 1 if the geometry value \( g \) is simple according to the ISO SQL/MM Part 3: Spatial standard. \texttt{ST_IsSimple()} returns 0 if the argument is not simple.

The descriptions of the instantiable geometric classes given under Section 11.4.2, “The OpenGIS Geometry Model” include the specific conditions that cause class instances to be classified as not simple.

\texttt{ST_IsSimple()} handles its arguments as described in the introduction to this section, with this exception:

\begin{itemize}
  \item If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
    \begin{itemize}
      \item If a longitude value is not in the range \((-180, 180]\), an \texttt{ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE} error occurs.
      \item If a latitude value is not in the range \([-90, 90]\), an \texttt{ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE} error occurs.
    \end{itemize}
  \end{itemize}

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

\begin{itemize}
  \item \texttt{ST_SRID(g [, srid])}
  \end{itemize}

With a single argument representing a valid geometry object \( g \), \texttt{ST_SRID()} returns an integer indicating the ID of the spatial reference system (SRS) associated with \( g \).

With the optional second argument representing a valid SRID value, \texttt{ST_SRID()} returns an object with the same type as its first argument with an SRID value equal to the second argument. This only sets the SRID value of the object; it does not perform any transformation of coordinate values.

\texttt{ST_SRID()} handles its arguments as described in the introduction to this section, with this exception:

\begin{itemize}
  \item For the single-argument syntax, \texttt{ST_SRID()} returns the geometry SRID even if it refers to an undefined SRS. An \texttt{ER_SRS_NOT_FOUND} error does not occur.
\end{itemize}

\texttt{ST_SRID(g, target_srid)} and \texttt{ST_Transform(g, target_srid)} differ as follows:

\begin{itemize}
  \item \texttt{ST_SRID()} changes the geometry SRID value without transforming its coordinates.
  \item \texttt{ST_Transform()} transforms the geometry coordinates in addition to changing its SRID value.
\end{itemize}

\begin{verbatim}
mysql> SET @g = ST_GeomFromText('LineString(1 1,2 2)', 0);
mysql> SELECT ST_SRID(@g);
+-------------+
<table>
<thead>
<tr>
<th>ST_SRID(@g)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
+-------------+
mysql> SET @g = ST_SRID(@g, 4326);
mysql> SELECT ST_SRID(@g);
+-------------+
<table>
<thead>
<tr>
<th>ST_SRID(@g)</th>
</tr>
</thead>
<tbody>
<tr>
<td>4326</td>
</tr>
</tbody>
</table>
+-------------+
It is possible to create a geometry in a particular SRID by passing to \texttt{ST_SRID()} the result of one of the MySQL-specific functions for creating spatial values, along with an SRID value. For example:

\begin{verbatim}
SET @g1 = ST_SRID(Point(1, 1), 4326);
\end{verbatim}
\end{verbatim}
Geometry Property Functions

However, that method creates the geometry in SRID 0, then casts it to SRID 4326 (WGS 84). A preferable alternative is to create the geometry with the correct spatial reference system to begin with. For example:

```
SET @g1 = ST_PointFromText('POINT(1 1)', 4326);
SET @g1 = ST_GeomFromText('POINT(1 1)', 4326);
```

The two-argument form of `ST_SRID()` is useful for tasks such as correcting or changing the SRS of geometries that have an incorrect SRID.

12.16.7.2 Point Property Functions

A `Point` consists of X and Y coordinates, which may be obtained using the `ST_X()` and `ST_Y()` functions, respectively. These functions also permit an optional second argument that specifies an X or Y coordinate value, in which case the function result is the `Point` object from the first argument with the appropriate coordinate modified to be equal to the second argument.

For `Point` objects that have a geographic spatial reference system (SRS), the longitude and latitude may be obtained using the `ST_Longitude()` and `ST_Latitude()` functions, respectively. These functions also permit an optional second argument that specifies a longitude or latitude value, in which case the function result is the `Point` object from the first argument with the longitude or latitude modified to be equal to the second argument.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is `NULL`, the return value is `NULL`.
- If any geometry argument is a valid geometry but not a `Point` object, an `ER_UNEXPECTED_GEOMETRY_TYPE` error occurs.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- If an X or Y coordinate argument is provided and the value is `-inf`, `+inf`, or `NaN`, an `ER_DATA_OUT_OF_RANGE` error occurs.
- If a longitude or latitude value is out of range, an error occurs:
  - If a longitude value is not in the range `(-180, 180]`, an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
  - If a latitude value is not in the range `[-90, 90]`, an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

- Otherwise, the return value is non-`NULL`.

These functions are available for obtaining point properties:

- `ST_Latitude(p [, new_latitude_val])`

  With a single argument representing a valid `Point` object `p` that has a geographic spatial reference system (SRS), `ST_Latitude()` returns the latitude value of `p` as a double-precision number.

  With the optional second argument representing a valid latitude value, `ST_Latitude()` returns a `Point` object like the first argument with its latitude equal to the second argument.
**ST_Latitude()** handles its arguments as described in the introduction to this section, with the addition that if the **Point** object is valid but does not have a geographic SRS, an **ER_SRS_NOT_GEOGRAPHIC** error occurs.

```sql
mysql> SET @pt = ST_GeomFromText('POINT(45 90)', 4326);
mysql> SELECT ST_Latitude(@pt);
+------------------+
| ST_Latitude(@pt) |
+------------------+
| 45               |
```

```sql
mysql> SELECT ST_AsText(ST_Latitude(@pt, 10));
+---------------------------------+
| ST_AsText(ST_Latitude(@pt, 10)) |
+---------------------------------+
| POINT(45 10)                    |
```

**• **ST_Longitude(p [, new_longitude_val])**

With a single argument representing a valid **Point** object **p** that has a geographic spatial reference system (SRS), **ST_Longitude()** returns the longitude value of **p** as a double-precision number.

With the optional second argument representing a valid longitude value, **ST_Longitude()** returns a **Point** object like the first argument with its longitude equal to the second argument.

**ST_Longitude()** handles its arguments as described in the introduction to this section, with the addition that if the **Point** object is valid but does not have a geographic SRS, an **ER_SRS_NOT_GEOGRAPHIC** error occurs.

```sql
mysql> SET @pt = ST_GeomFromText('POINT(45 90)', 4326);
mysql> SELECT ST_Longitude(@pt);
+-------------------+
| ST_Longitude(@pt) |
+-------------------+
| 90                |
```

```sql
mysql> SELECT ST_AsText(ST_Longitude(@pt, 10));
+----------------------------------+
| ST_AsText(ST_Longitude(@pt, 10)) |
+----------------------------------+
| POINT(45 10)                     |
```

**• **ST_X(p [, new_x_val])**

With a single argument representing a valid **Point** object **p**, **ST_X()** returns the X-coordinate value of **p** as a double-precision number. The X coordinate is considered to refer to the axis that appears first in the **Point** spatial reference system (SRS) definition.

With the optional second argument, **ST_X()** returns a **Point** object like the first argument with its X coordinate equal to the second argument. If the **Point** object has a geographic SRS, the second argument must be in the proper range for longitude or latitude values.

**ST_X()** handles its arguments as described in the introduction to this section.

```sql
mysql> SELECT ST_X(Point(56.7, 53.34));
+--------------------------+
| ST_X(Point(56.7, 53.34)) |
+--------------------------+
| 56.7                     |
```
12.16.7.3 LineString and MultiLineString Property Functions

A LineString consists of Point values. You can extract particular points of a LineString, count the number of points that it contains, or obtain its length.

Some functions in this section also work for MultiLineString values.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is NULL or any geometry argument is an empty geometry, the return value is NULL.
- If any geometry argument is not a syntactically well-formed geometry, an ER_GIS_INVALID_DATA error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an ER_SRS_NOT_FOUND error occurs.
- Otherwise, the return value is non-NULL.

These functions are available for obtaining linestring properties:

- **ST_EndPoint(ls)**

Returns the Point that is the endpoint of the LineString value ls.

ST_EndPoint() handles its arguments as described in the introduction to this section.
Geometry Property Functions

<table>
<thead>
<tr>
<th>ST_EndPoint(ST_GeomFromText(@ls))</th>
<th>POINT(3 3)</th>
</tr>
</thead>
</table>

- **ST_IsClosed(ls)**

  For a LineString value `ls`, `ST_IsClosed()` returns 1 if `ls` is closed (that is, its `ST_StartPoint()` and `ST_EndPoint()` values are the same).

  For a MultiLineString value `ls`, `ST_IsClosed()` returns 1 if `ls` is closed (that is, the `ST_StartPoint()` and `ST_EndPoint()` values are the same for each LineString in `ls`).

  `ST_IsClosed()` returns 0 if `ls` is not closed, and NULL if `ls` is NULL.

  `ST_IsClosed()` handles its arguments as described in the introduction to this section, with this exception:

  - If the geometry has an SRID value for a geographic spatial reference system (SRS), an ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS error occurs.

```sql
mysql> SET @ls1 = 'LineString(1 1,2 2,3 3,2 2)';
mysql> SET @ls2 = 'LineString(1 1,2 2,3 3,1 1)';

mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls1));
+------------------+
<table>
<thead>
<tr>
<th>ST_IsClosed(@ls1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
+------------------+

mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls2));
+------------------+
<table>
<thead>
<tr>
<th>ST_IsClosed(@ls2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
+------------------+

mysql> SET @ls3 = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';

mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls3));
+------------------+
<table>
<thead>
<tr>
<th>ST_IsClosed(@ls3)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
+------------------+
```
ST_Length(\textit{ls} [, \textit{unit}])

Returns a double-precision number indicating the length of the \textit{LineString} or \textit{MultiLineString} value \textit{ls} in its associated spatial reference system. The length of a \textit{MultiLineString} value is equal to the sum of the lengths of its elements.

\textbf{ST_Length()} computes a result as follows:

- If the geometry is a valid \textit{LineString} in a Cartesian SRS, the return value is the Cartesian length of the geometry.
- If the geometry is a valid \textit{MultiLineString} in a Cartesian SRS, the return value is the sum of the Cartesian lengths of its elements.
- If the geometry is a valid \textit{LineString} in a geographic SRS, the return value is the geodetic length of the geometry in that SRS, in meters.
- If the geometry is a valid \textit{MultiLineString} in a geographic SRS, the return value is the sum of the geodetic lengths of its elements in that SRS, in meters.

\textbf{ST_Length()} handles its arguments as described in the introduction to this section, with these exceptions:

- If the geometry is not a \textit{LineString} or \textit{MultiLineString}, the return value is \texttt{NULL}.
- If the geometry is geometrically invalid, either the result is an undefined length (that is, it can be any number), or an error occurs.
- If the length computation result is \texttt{+inf}, an \texttt{ER\_DATA\_OUT\_OF\_RANGE} error occurs.
- If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range \((-180, 180]\), an \texttt{ER\_GEOMETRY\_PARAM\_LONGITUDE\_OUT\_OF\_RANGE} error occurs.
  - If a latitude value is not in the range \([-90, 90]\), an \texttt{ER\_GEOMETRY\_PARAM\_LATITUDE\_OUT\_OF\_RANGE} error occurs.

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

\textbf{ST_Length()} permits an optional \textit{unit} argument that specifies the linear unit for the returned length value. These rules apply:

- If a unit is specified but not supported by MySQL, an \texttt{ER\_UNIT\_NOT\_FOUND} error occurs.
- If a supported linear unit is specified and the SRID is 0, an \texttt{ER\_GEOMETRY\_IN\_UNKNOWN\_LENGTH\_UNIT} error occurs.
- If a supported linear unit is specified and the SRID is not 0, the result is in that unit.
- If a unit is not specified, the result is in the unit of the SRS of the geometries, whether Cartesian or geographic. Currently, all MySQL SRSs are expressed in meters.

A unit is supported if it is found in the \texttt{INFORMATION\_SCHEMA ST\_UNITS\_OF\_MEASURE} table. See Section 26.3.37, "The \texttt{INFORMATION\_SCHEMA ST\_UNITS\_OF\_MEASURE} Table".

\begin{verbatim}
mysql> SET @ls = ST_GeomFromText('LineString(1 1, 2 2, 3 3)');
\end{verbatim}
Geometry Property Functions

mysql> SELECT ST_Length(@ls);
+-------------------+
| ST_Length(@ls)    |
+-------------------+
| 2.8284271247461903 |
+-------------------+

mysql> SET @mls = ST_GeomFromText('MultiLineString((1 1,2 2,3 3),(4 4,5 5))');
m.mysql> SELECT ST_Length(@mls);
+-------------------+
| ST_Length(@mls)    |
+-------------------+
| 4.242640687119286 |
+-------------------+

mysql> SET @ls = ST_GeomFromText('LineString(1 1,2 2,3 3)', 4326);
m.mysql> SELECT ST_Length(@ls);
+-------------------+
| ST_Length(@ls)    |
+-------------------+
| 313701.9623204328 |
+-------------------+

mysql> SELECT ST_Length(@ls, 'metre');
+-------------------------+
| ST_Length(@ls, 'metre') |
+-------------------------+
| 313701.9623204328       |
+-------------------------+

mysql> SELECT ST_Length(@ls, 'foot');
+------------------------+
| ST_Length(@ls, 'foot') |
+------------------------+
| 1029205.9131247795     |
+------------------------+

• ST_NumPoints(ls)

Returns the number of Point objects in the LineString value ls.

ST_NumPoints() handles its arguments as described in the introduction to this section.

mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_NumPoints(ST_GeomFromText(@ls));
+------------------------------------+
| ST_NumPoints(ST_GeomFromText(@ls)) |
+------------------------------------+
|                                  3 |
+------------------------------------+

• ST_PointN(ls, N)

Returns the N-th Point in the Linestring value ls. Points are numbered beginning with 1.

ST_PointN() handles its arguments as described in the introduction to this section.

mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_PointN(ST_GeomFromText(@ls),2));
+----------------------------------------------+
| ST_AsText(ST_PointN(ST_GeomFromText(@ls),2)) |
+----------------------------------------------+
| POINT(2 2)                                   |
+----------------------------------------------+
Geometry Property Functions

- **ST_StartPoint(ls)**

  Returns the **Point** that is the start point of the **LineString** value `ls`.

  `ST_StartPoint()` handles its arguments as described in the introduction to this section.

  ```sql
  mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
  mysql> SELECT ST_AsText(ST_StartPoint(ST_GeomFromText(@ls)));
  +------------------------------------------------+
  | ST_AsText(ST_StartPoint(ST_GeomFromText(@ls))) |
  +------------------------------------------------+
  | POINT(1 1)                                     |
  +------------------------------------------------+
  
```

12.16.7.4 Polygon and MultiPolygon Property Functions

Functions in this section return properties of **Polygon** or **MultiPolygon** values.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is **NULL** or any geometry argument is an empty geometry, the return value is **NULL**.
- If any geometry argument is not a syntactically well-formed geometry, an **ER_GIS_INVALID_DATA** error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an **ER_SRS_NOT_FOUND** error occurs.
- For functions that take multiple geometry arguments, if those arguments are not in the same SRS, an **ER_GIS_DIFFERENT_SRIDS** error occurs.
- Otherwise, the return value is non-**NULL**.

These functions are available for obtaining polygon properties:

- **ST_Area({poly|mpoly})**

  Returns a double-precision number indicating the area of the **Polygon** or **MultiPolygon** argument, as measured in its spatial reference system.

  `ST_Area()` handles its arguments as described in the introduction to this section, with these exceptions:

  - If the geometry is geometrically invalid, either the result is an undefined area (that is, it can be any number), or an error occurs.
  - If the geometry is valid but is not a **Polygon** or **MultiPolygon** object, an **ER_UNEXPECTED_GEOMETRY_TYPE** error occurs.
  - If the geometry is a valid **Polygon** in a Cartesian SRS, the result is the Cartesian area of the polygon.
  - If the geometry is a valid **MultiPolygon** in a Cartesian SRS, the result is the sum of the Cartesian area of the polygons.
  - If the geometry is a valid **Polygon** in a geographic SRS, the result is the geodetic area of the polygon in that SRS, in square meters.
  - If the geometry is a valid **MultiPolygon** in a geographic SRS, the result is the sum of geodetic area of the polygons in that SRS, in square meters.
  - If an area computation results in `+inf`, an **ER_DATA_OUT_OF_RANGE** error occurs.
Geometry Property Functions

- If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range \((-180, 180]\), an \texttt{ER\_GEOMETRY\_PARAM\_LONGITUDE\_OUT\_OF\_RANGE} error occurs.
  - If a latitude value is not in the range \([-90, 90]\), an \texttt{ER\_GEOMETRY\_PARAM\_LATITUDE\_OUT\_OF\_RANGE} error occurs.

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

```sql
mysql> SET @poly = 'Polygon((0 0,1 1,1 2,2 1,1 1))';
mysql> SELECT ST_Area(ST_GeomFromText(@poly));
+---------------------------------+
| ST_Area(ST_GeomFromText(@poly)) |
+---------------------------------+
|                               4 |
+---------------------------------+
mysql> SET @mpoly = 'MultiPolygon(((0 0,1 1,1 2,2 1,1 1)))';
mysql> SELECT ST_Area(ST_GeomFromText(@mpoly));
+----------------------------------+
| ST_Area(ST_GeomFromText(@mpoly)) |
+----------------------------------+
|                                8 |
+----------------------------------+
```

- \texttt{ST\_Centroid\((\texttt{poly}|\texttt{mpoly})\)}

  Returns the mathematical centroid for the \texttt{Polygon} or \texttt{MultiPolygon} argument as a \texttt{Point}. The result is not guaranteed to be on the \texttt{MultiPolygon}.

  This function processes geometry collections by computing the centroid point for components of highest dimension in the collection. Such components are extracted and made into a single \texttt{MultiPolygon}, \texttt{MultiLineString}, or \texttt{MultiPoint} for centroid computation.

  \texttt{ST\_Centroid()} handles its arguments as described in the introduction to this section, with these exceptions:
  - The return value is \texttt{NULL} for the additional condition that the argument is an empty geometry collection.
  - If the geometry has an SRID value for a geographic spatial reference system (SRS), an \texttt{ER\_NOT\_IMPLEMENTED\_FOR\_GEOGRAPHIC\_SRS} error occurs.

```sql
mysql> SET @poly = ST_GeomFromText('POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7,5 5))');
mysql> SELECT ST_GeometryType(@poly),ST_AsText(ST_Centroid(@poly));
+------------------------+--------------------------------------------+
| ST_GeometryType(@poly) | ST_AsText(ST_Centroid(@poly))              |
+------------------------+--------------------------------------------+
| POLYGON                | POINT(4.958333333333333 4.958333333333333) |
+------------------------+--------------------------------------------+
```
Geometry Property Functions

- **ST_ExteriorRing(poly)**

  Returns the exterior ring of the Polygon value \( poly \) as a LineString.

  **ST_ExteriorRing()** handles its arguments as described in the introduction to this section.

  ```
  mysql> SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
  mysql> SELECT ST_AsText(ST_ExteriorRing(ST_GeomFromText(@poly)));
  +------------------------------------------------------------------+
  | ST_AsText(ST_ExteriorRing(ST_GeomFromText(@poly)))               |
  +------------------------------------------------------------------+
  | LINESTRING(0 0,0 3,3 3,3 0,0)                                    |
  +------------------------------------------------------------------+
  ```

- **ST_InteriorRingN(poly, N)**

  Returns the \( N \)-th interior ring for the Polygon value \( poly \) as a LineString. Rings are numbered beginning with 1.

  **ST_InteriorRingN()** handles its arguments as described in the introduction to this section.

  ```
  mysql> SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
  mysql> SELECT ST_AsText(ST_InteriorRingN(ST_GeomFromText(@poly),1));
  +------------------------------------------------------------------+
  | ST_AsText(ST_InteriorRingN(ST_GeomFromText(@poly),1))             |
  +------------------------------------------------------------------+
  | LINESTRING(1 1,1 2,2 2,2 1,1)                                    |
  +------------------------------------------------------------------+
  ```

- **ST_NumInteriorRing(poly), ST_NumInteriorRings(poly)**

  Returns the number of interior rings in the Polygon value \( poly \).

  **ST_NumInteriorRing()** and **ST_NumInteriorRings()** handle their arguments as described in the introduction to this section.

  ```
  mysql> SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
  mysql> SELECT ST_NumInteriorRings(ST_GeomFromText(@poly));
  +--------------------------------------------------+
  | ST_NumInteriorRings(ST_GeomFromText(@poly))      |
  +--------------------------------------------------+
  | 1                                               |
  +--------------------------------------------------+
  ```

12.16.7.5 GeometryCollection Property Functions

These functions return properties of GeometryCollection values.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is **NULL** or any geometry argument is an empty geometry, the return value is **NULL**.
- If any geometry argument is not a syntactically well-formed geometry, an **ER_GIS_INVALID_DATA** error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an **ER_SRS_NOT_FOUND** error occurs.
- Otherwise, the return value is non-**NULL**.
These functions are available for obtaining geometry collection properties:

- **ST_GeometryN(gc, N)**
  
  Returns the $N$-th geometry in the **GeometryCollection** value `gc`. Geometries are numbered beginning with 1.

  `ST_GeometryN()` handles its arguments as described in the introduction to this section.

  ```sql
  mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
  mysql> SELECT ST_AsText(ST_GeometryN(ST_GeomFromText(@gc),1));
  +-------------------------------------------------+
  | ST_AsText(ST_GeometryN(ST_GeomFromText(@gc),1)) |
  +-------------------------------------------------+
  | POINT(1 1)                                      |
  +-------------------------------------------------+
  ```

- **ST_NumGeometries(gc)**
  
  Returns the number of geometries in the **GeometryCollection** value `gc`.

  `ST_NumGeometries()` handles its arguments as described in the introduction to this section.

  ```sql
  mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
  mysql> SELECT ST_NumGeometries(ST_GeomFromText(@gc));
  +----------------------------------------+
  | ST_NumGeometries(ST_GeomFromText(@gc)) |
  +----------------------------------------+
  |                                      2 |
  +----------------------------------------+
  ```

### 12.16.8 Spatial Operator Functions

OpenGIS proposes a number of functions that can produce geometries. They are designed to implement spatial operators. These functions support all argument type combinations except those that are inapplicable according to the Open Geospatial Consortium specification.

MySQL also implements certain functions that are extensions to OpenGIS, as noted in the function descriptions. In addition, Section 12.16.7, “Geometry Property Functions”, discusses several functions that construct new geometries from existing ones. See that section for descriptions of these functions:

- **ST_Envelope(g)**
- **ST_StartPoint(ls)**
- **ST_EndPoint(ls)**
- **ST_PointN(ls, N)**
- **ST_ExteriorRing(poly)**
- **ST_InteriorRingN(poly, N)**
- **ST_GeometryN(gc, N)**

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is `NULL`, the return value is `NULL`.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
Spatial Operator Functions

- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an ER_SRS_NOT_FOUND error occurs.

- For functions that take multiple geometry arguments, if those arguments are not in the same SRS, an ER_GIS_DIFFERENT_SRIDS error occurs.

- If any geometry argument has an SRID value for a geographic SRS and the function does not handle geographic geometries, an ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS error occurs.

- For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range \((-180, 180]\), an ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE error occurs.
  - If a latitude value is not in the range \([-90, 90]\), an ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

- Otherwise, the return value is non-NUL.

These spatial operator functions are available:

- \texttt{ST_Buffer(g, d [, strategy1 [, strategy2 [, strategy3]]])]}

Returns a geometry that represents all points whose distance from the geometry value \(g\) is less than or equal to a distance of \(d\). The result is in the same SRS as the geometry argument.

If the geometry argument is empty, \texttt{ST_Buffer()} returns an empty geometry.

If the distance is 0, \texttt{ST_Buffer()} returns the geometry argument unchanged:

```
mysql> SET @pt = ST_GeomFromText('POINT(0 0)');
mysql> SELECT ST_AsText(ST_Buffer(@pt, 0));
```

If the geometry argument is in a Cartesian SRS:

- \texttt{ST_Buffer()} supports negative distances for \texttt{Polygon} and \texttt{MultiPolygon} values, and for geometry collections containing \texttt{Polygon} or \texttt{MultiPolygon} values.

- If the result is reduced so much that it disappears, the result is an empty geometry.

- An ER_WRONG_ARGUMENTS error occurs for \texttt{ST_Buffer()} with a negative distance for \texttt{Point}, \texttt{MultiPoint}, \texttt{LineString}, and \texttt{MultiLineString} values, and for geometry collections not containing any \texttt{Polygon} or \texttt{MultiPolygon} values.

Point geometries in a geographic SRS are permitted, subject to the following conditions:

- If the distance is not negative and no strategies are specified, the function returns the geographic buffer of the \texttt{Point} in its SRS. The distance argument must be in the SRS distance unit (currently always meters).
• If the distance is negative or any strategy (except NULL) is specified, an ER_WRONG_ARGUMENTS error occurs.

For non-Point geometries, an ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS error occurs.

ST_Buffer() permits up to three optional strategy arguments following the distance argument. Strategies influence buffer computation. These arguments are byte string values produced by the ST_Buffer_Strategy() function, to be used for point, join, and end strategies:

• Point strategies apply to Point and MultiPoint geometries. If no point strategy is specified, the default is ST_Buffer_Strategy('point_circle', 32).

• Join strategies apply to LineString, MultiLineString, Polygon, and MultiPolygon geometries. If no join strategy is specified, the default is ST_Buffer_Strategy('join_round', 32).

• End strategies apply to LineString and MultiLineString geometries. If no end strategy is specified, the default is ST_Buffer_Strategy('end_round', 32).

Up to one strategy of each type may be specified, and they may be given in any order.

If the buffer strategies are invalid, an ER_WRONG_ARGUMENTS error occurs. Strategies are invalid under any of these circumstances:

• Multiple strategies of a given type (point, join, or end) are specified.

• A value that is not a strategy (such as an arbitrary binary string or a number) is passed as a strategy.

• A Point strategy is passed and the geometry contains no Point or MultiPoint values.

• An end or join strategy is passed and the geometry contains no LineString, Polygon, MultiLineString or MultiPolygon values.
Spatial Operator Functions

- **ST_Buffer_Strategy(strategy [, points_per_circle])**

  This function returns a strategy byte string for use with `ST_Buffer()` to influence buffer computation. Information about strategies is available at [Boost.org](https://www.boost.org).

  The first argument must be a string indicating a strategy option:
  - For point strategies, permitted values are 'point_circle' and 'point_square'.
  - For join strategies, permitted values are 'join_round' and 'join_miter'.
  - For end strategies, permitted values are 'end_round' and 'end_flat'.

  If the first argument is 'point_circle', 'join_round', 'join_miter', or 'end_round', the `points_per_circle` argument must be given as a positive numeric value. The maximum `points_per_circle` value is the value of the `max_points_in_geometry` system variable.

  For examples, see the description of `ST_Buffer()`.

  `ST_Buffer_Strategy()` handles its arguments as described in the introduction to this section, with these exceptions:
  - If any argument is invalid, an `ER_WRONG_ARGUMENTS` error occurs.
  - If the first argument is 'point_square' or 'end_flat', the `points_per_circle` argument must not be given or an `ER_WRONG_ARGUMENTS` error occurs.

- **ST_ConvexHull(g)**

  Returns a geometry that represents the convex hull of the geometry value `g`.

  This function computes a geometry's convex hull by first checking whether its vertex points are colinear. The function returns a linear hull if so, a polygon hull otherwise. This function processes geometry collections by extracting all vertex points of all components of the collection, creating a `MultiPoint` value from them, and computing its convex hull.

  `ST_ConvexHull()` handles its arguments as described in the introduction to this section, with this exception:
  - The return value is `NULL` for the additional condition that the argument is an empty geometry collection.

```sql
mysql> SET @g = 'MULTIPOINT(5 0,25 0,15 10,15 25)';
mysql> SELECT ST_AsText(ST_ConvexHull(ST_GeomFromText(@g)));
+-----------------------------------------------+
| ST_AsText(ST_ConvexHull(ST_GeomFromText(@g))) |
+-----------------------------------------------+
| POLYGON((5 0,25 0,15 25,5 0))                 |
+-----------------------------------------------+
```
Spatial Operator Functions

- **ST_Difference**(g1, g2)

  Returns a geometry that represents the point set difference of the geometry values g1 and g2. The result is in the same SRS as the geometry arguments.

  **ST_Difference()** permits arguments in either a Cartesian or a geographic SRS, and handles its arguments as described in the introduction to this section.

  ```
  mysql> SET @g1 = Point(1,1), @g2 = Point(2,2);
  mysql> SELECT ST_AsText(ST_Difference(@g1, @g2));
  +------------------------------------+
  | ST_AsText(ST_Difference(@g1, @g2)) |
  +------------------------------------+
  | POINT(1 1)                         |
  +------------------------------------+
  ```

- **ST_Intersection**(g1, g2)

  Returns a geometry that represents the point set intersection of the geometry values g1 and g2. The result is in the same SRS as the geometry arguments.

  **ST_Intersection()** permits arguments in either a Cartesian or a geographic SRS, and handles its arguments as described in the introduction to this section.

  ```
  mysql> SET @g1 = ST_GeomFromText('LineString(1 1, 3 3)');
  mysql> SET @g2 = ST_GeomFromText('LineString(1 3, 3 1)');
  mysql> SELECT ST_AsText(ST_Intersection(@g1, @g2));
  +--------------------------------------+
  | ST_AsText(ST_Intersection(@g1, @g2)) |
  +--------------------------------------+
  | POINT(2 2)                           |
  +--------------------------------------+
  ```

- **ST_LineInterpolatePoint**(ls, fractional_distance)

  This function takes a LineString geometry and a fractional distance in the range [0.0, 1.0] and returns the Point along the LineString at the given fraction of the distance from its start point to its endpoint. It can be used to answer questions such as which Point lies halfway along the road described by the geometry argument.

  The function is implemented for LineString geometries in all spatial reference systems, both Cartesian and geographic.

  If the fractional_distance argument is 1.0, the result may not be exactly the last point of the LineString argument but a point close to it due to numerical inaccuracies in approximate-value computations.

  A related function, **ST_LineInterpolatePoints()**, takes similar arguments but returns a MultiPoint consisting of Point values along the LineString at each fraction of the distance from
its start point to its endpoint. For examples of both functions, see the `ST_LineInterpolatePoints()` description.

`ST_LineInterpolatePoint()` handles its arguments as described in the introduction to this section, with these exceptions:

- If the geometry argument is not a `LineString`, an `ER_UNEXPECTED_GEOMETRY_TYPE` error occurs.
- If the fractional distance argument is outside the range [0.0, 1.0], an `ER_DATA_OUT_OF_RANGE` error occurs.

`ST_LineInterpolatePoint()` is a MySQL extension to OpenGIS.

- `ST_LineInterpolatePoints(ls, fractional_distance)`

This function takes a `LineString` geometry and a fractional distance in the range (0.0, 1.0] and returns the `MultiPoint` consisting of the `LineString` start point, plus `Point` values along the `LineString` at each fraction of the distance from its start point to its endpoint. It can be used to answer questions such as which `Point` values lie every 10% of the way along the road described by the geometry argument.

The function is implemented for `LineString` geometries in all spatial reference systems, both Cartesian and geographic.

If the `fractional_distance` argument divides 1.0 with zero remainder the result may not contain the last point of the `LineString` argument but a point close to it due to numerical inaccuracies in approximate-value computations.

A related function, `ST_LineInterpolatePoint()`, takes similar arguments but returns the `Point` along the `LineString` at the given fraction of the distance from its start point to its endpoint.

`ST_LineInterpolatePoints()` handles its arguments as described in the introduction to this section, with these exceptions:

- If the geometry argument is not a `LineString`, an `ER_UNEXPECTED_GEOMETRY_TYPE` error occurs.
- If the fractional distance argument is outside the range [0.0, 1.0], an `ER_DATA_OUT_OF_RANGE` error occurs.

```
mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0,0 5,5 5)');
mysql> SELECT ST_AsText(ST_LineInterpolatePoint(@ls1, .5));
+----------------------------------------------+
| ST_AsText(ST_LineInterpolatePoint(@ls1, .5)) |
+----------------------------------------------+
| POINT(0 5)                                  |
+----------------------------------------------+
mysql> SELECT ST_AsText(ST_LineInterpolatePoint(@ls1, .75));
+-----------------------------------------------+
| ST_AsText(ST_LineInterpolatePoint(@ls1, .75)) |
+-----------------------------------------------+
| POINT(2.5 5)                                  |
+-----------------------------------------------+
mysql> SELECT ST_AsText(ST_LineInterpolatePoint(@ls1, 1));
+---------------------------------------------+
| ST_AsText(ST_LineInterpolatePoint(@ls1, 1)) |
+---------------------------------------------+
| POINT(5 5)                                  |
+---------------------------------------------+
mysql> SELECT ST_AsText(ST_LineInterpolatePoints(@ls1, .25));
```
Spatial Operator Functions

| ST_AsText(ST_LineInterpolatePoints(@ls1, .25)) | +------------------------------------------------+ | MULTIPOINT((0 2.5),(0 5),(2.5 5),(5 5)) |

ST_LineInterpolatePoints() is a MySQL extension to OpenGIS.

- **ST_PointAtDistance(ls, distance)**

  This function takes a LineString geometry and a distance in the range \([0.0, \text{ST_Length}(ls)]\) measured in the unit of the spatial reference system (SRS) of the LineString, and returns the Point along the LineString at that distance from its start point. It can be used to answer questions such as which Point value is 400 meters from the start of the road described by the geometry argument.

  The function is implemented for LineString geometries in all spatial reference systems, both Cartesian and geographic.

  ST_PointAtDistance() handles its arguments as described in the introduction to this section, with these exceptions:

  - If the geometry argument is not a LineString, an ER_UNEXPECTED_GEOMETRY_TYPE error occurs.
  - If the fractional distance argument is outside the range \([0.0, \text{ST_Length}(ls)]\), an ER_DATA_OUT_OF_RANGE error occurs.

ST_PointAtDistance() is a MySQL extension to OpenGIS.

- **ST_SymDifference(g1, g2)**

  Returns a geometry that represents the point set symmetric difference of the geometry values \(g1\) and \(g2\), which is defined as:

  \[ g1 \text{ symdifference } g2 := (g1 \text{ union } g2) \text{ difference } (g1 \text{ intersection } g2) \]

  Or, in function call notation:

  \[ \text{ST_SymDifference}(g1, g2) = \text{ST_Difference}(\text{ST_Union}(g1, g2), \text{ST_Intersection}(g1, g2)) \]

  The result is in the same SRS as the geometry arguments.

ST_SymDifference() permits arguments in either a Cartesian or a geographic SRS, and handles its arguments as described in the introduction to this section.

mysql> SET @g1 = ST_GeomFromText('MULTIPOINT(5 0,15 10,15 25)');
mysql> SET @g2 = ST_GeomFromText('MULTIPOINT(1 1,15 10,15 25)');
mysql> SELECT ST_AsText(ST_SymDifference(@g1, @g2));
+---------------------------------------+
| ST_AsText(ST_SymDifference(@g1, @g2)) |
+---------------------------------------+
| MULTIPOINT((1 1),(5 0))               |
+---------------------------------------+
• **ST_Transform(g, target_srid)**

Transforms a geometry from one spatial reference system (SRS) to another. The return value is a geometry of the same type as the input geometry with all coordinates transformed to the target SRID, `target_srid`. MySQL supports all SRSs defined by EPSG except for those listed here:

- EPSG 1042 Krovak Modified
- EPSG 1043 Krovak Modified (North Orientated)
- EPSG 9816 Tunisia Mining Grid
- EPSG 9826 Lambert Conic Conformal (West Orientated)

**ST_Transform()** handles its arguments as described in the introduction to this section, with these exceptions:

- Geometry arguments that have an SRID value for a geographic SRS do not produce an error.
- If the geometry or target SRID argument has an SRID value that refers to an undefined spatial reference system (SRS), an **ER_SRS_NOT_FOUND** error occurs.
- If the geometry is in an SRS that **ST_Transform()** cannot transform from, an **ER_TRANSFORM_SOURCE_SRS_NOT_SUPPORTED** error occurs.
- If the target SRID is in an SRS that **ST_Transform()** cannot transform to, an **ER_TRANSFORM_TARGET_SRS_NOT_SUPPORTED** error occurs.
- If the geometry is in an SRS that is not WGS 84 and has no TOWGS84 clause, an **ER_TRANSFORM_SOURCE_SRS_MISSING_TOWGS84** error occurs.
- If the target SRID is in an SRS that is not WGS 84 and has no TOWGS84 clause, an **ER_TRANSFORM_TARGET_SRS_MISSING_TOWGS84** error occurs.

**ST_SRID(g, target_srid)** and **ST_Transform(g, target_srid)** differ as follows:

- **ST_SRID()** changes the geometry SRID value without transforming its coordinates.
- **ST_Transform()** transforms the geometry coordinates in addition to changing its SRID value.

```sql
mysql> SET @p = ST_GeomFromText('POINT(52.381389 13.064444)', 4326);
mysql> SELECT ST_AsText(@p);
+----------------------------+
| ST_AsText(@p)              |
+----------------------------+
| POINT(52.381389 13.064444) |
+----------------------------+
mysql> SET @p = ST_Transform(@p, 4230);
mysql> SELECT ST_AsText(@p);
+---------------------------------------------+
| ST_AsText(@p)                               |
| POINT(52.38208611407426 13.065520672345304) |
+---------------------------------------------+
```

2452
Functions That Test Spatial Relations Between Geometry Objects

- **ST_Union**\((g1, g2)\)

  Returns a geometry that represents the point set union of the geometry values \(g1\) and \(g2\). The result is in the same SRS as the geometry arguments.

  **ST_Union()** permits arguments in either a Cartesian or a geographic SRS, and handles its arguments as described in the introduction to this section.

```sql
mysql> SET @g1 = ST_GeomFromText('LineString(1 1, 3 3)');
mysql> SET @g2 = ST_GeomFromText('LineString(1 3, 3 1)');
mysql> SELECT ST_AsText(ST_Union(@g1, @g2));
+--------------------------------------+
| ST_AsText(ST_Union(@g1, @g2))        |
+--------------------------------------+
| MULTILINESTRING((1 1,3 3),(1 3,3 1)) |
+--------------------------------------+
```

12.16.9 Functions That Test Spatial Relations Between Geometry Objects

The functions described in this section take two geometries as arguments and return a qualitative or quantitative relation between them.

MySQL implements two sets of functions using function names defined by the OpenGIS specification. One set tests the relationship between two geometry values using precise object shapes, the other set uses object minimum bounding rectangles (MBRs).

### 12.16.9.1 Spatial Relation Functions That Use Object Shapes

The OpenGIS specification defines the following functions to test the relationship between two geometry values \(g1\) and \(g2\), using precise object shapes. The return values 1 and 0 indicate true and false, respectively, except that distance functions return distance values.

Functions in this section detect arguments in either Cartesian or geographic spatial reference systems (SRSs), and return results appropriate to the SRS.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is NULL or any geometry argument is an empty geometry, the return value is NULL.

- If any geometry argument is not a syntactically well-formed geometry, an ER_GIS_INVALID_DATA error occurs.

- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an ER_SRS_NOT_FOUND error occurs.

- For functions that take multiple geometry arguments, if those arguments are not in the same SRS, an ER_GIS_DIFFERENT_SRIDS error occurs.

- If any geometry argument is geometrically invalid, either the result is true or false (it is undefined which), or an error occurs.

- For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range \((-180, 180]\), an ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE error occurs.
  - If a latitude value is not in the range \([-90, 90]\), an ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE error occurs.
Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

- Otherwise, the return value is non-NULL.

Some functions in this section permit a unit argument that specifies the length unit for the return value. Unless otherwise specified, functions handle their unit argument as follows:

- A unit is supported if it is found in the INFORMATION_SCHEMA ST_UNITS_OF_MEASURE table. See Section 26.3.37, “The INFORMATION_SCHEMA ST_UNITS_OF_MEASURE Table”.
- If a unit is specified but not supported by MySQL, an ER_UNIT_NOT_FOUND error occurs.
- If a supported linear unit is specified and the SRID is 0, an ER_GEOMETRY_IN_UNKNOWN_LENGTH_UNIT error occurs.
- If a supported linear unit is specified and the SRID is not 0, the result is in that unit.
- If a unit is not specified, the result is in the unit of the SRS of the geometries, whether Cartesian or geographic. Currently, all MySQL SRSs are expressed in meters.

These object-shape functions are available for testing geometry relationships:

- **ST_Contains(g1, g2)**
  Returns 1 or 0 to indicate whether \( g_1 \) completely contains \( g_2 \). This tests the opposite relationship as ST_Within().
  **ST_Contains()** handles its arguments as described in the introduction to this section.

- **ST_Crosses(g1, g2)**
  Two geometries spatially cross if their spatial relation has the following properties:
  - Unless \( g_1 \) and \( g_2 \) are both of dimension 1: \( g_1 \) crosses \( g_2 \) if the interior of \( g_2 \) has points in common with the interior of \( g_1 \), but \( g_2 \) does not cover the entire interior of \( g_1 \).
  - If both \( g_1 \) and \( g_2 \) are of dimension 1: If the lines cross each other in a finite number of points (that is, no common line segments, only single points in common).
  This function returns 1 or 0 to indicate whether \( g_1 \) spatially crosses \( g_2 \).
  **ST_Crosses()** handles its arguments as described in the introduction to this section except that the return value is NULL for these additional conditions:
  - \( g_1 \) is of dimension 2 (Polygon or MultiPolygon).
  - \( g_2 \) is of dimension 1 (Point or MultiPoint).

- **ST_Disjoint(g1, g2)**
  Returns 1 or 0 to indicate whether \( g_1 \) is spatially disjoint from (does not intersect) \( g_2 \).
  **ST_Disjoint()** handles its arguments as described in the introduction to this section.

- **ST_Distance(g1, g2 [, unit])**
  Returns the distance between \( g_1 \) and \( g_2 \), measured in the length unit of the spatial reference system (SRS) of the geometry arguments, or in the unit of the optional unit argument if that is specified.
Functions That Test Spatial Relations Between Geometry Objects

This function processes geometry collections by returning the shortest distance among all combinations of the components of the two geometry arguments.

**ST_Distance()** handles its geometry arguments as described in the introduction to this section, with these exceptions:

- **ST_Distance()** detects arguments in a geographic (ellipsoidal) spatial reference system and returns the geodetic distance on the ellipsoid. **ST_Distance()** supports distance calculations for geographic SRS arguments of all geometry types.

- If any argument is geometrically invalid, either the result is an undefined distance (that is, it can be any number), or an error occurs.

- If an intermediate or final result produces NaN or a negative number, an **ER_GIS_INVALID_DATA** error occurs.

**ST_Distance()** permits specifying the linear unit for the returned distance value with an optional *unit* argument which **ST_Distance()** handles as described in the introduction to this section.

```sql
mysql> SET @g1 = ST_GeomFromText('POINT(1 1)');
mysql> SET @g2 = ST_GeomFromText('POINT(2 2)');
mysql> SELECT ST_Distance(@g1, @g2);
+-----------------------+
| ST_Distance(@g1, @g2) |
| 1.4142135623730951    |
+-----------------------+

mysql> SET @g1 = ST_GeomFromText('POINT(1 1)', 4326); 
mysql> SET @g2 = ST_GeomFromText('POINT(2 2)', 4326); 
mysql> SELECT ST_Distance(@g1, @g2);
+-----------------------+
| ST_Distance(@g1, @g2) |
| 156874.3859490455     |
+-----------------------+

mysql> SELECT ST_Distance(@g1, @g2, 'metre');
+-----------------------------------+
| ST_Distance(@g1, @g2, 'metre')    |
| 156874.3859490455                 |
+-----------------------------------+

mysql> SELECT ST_Distance(@g1, @g2, 'foot');
+-------------------------------+
| ST_Distance(@g1, @g2, 'foot')  |
| 514679.7439273146             |
+-------------------------------+
```

For the special case of distance calculations on a sphere, see the **ST_Distance_Sphere()** function.

- **ST_Equals**(g1, g2)

Returns 1 or 0 to indicate whether *g1* is spatially equal to *g2*.

**ST_Equals()** handles its arguments as described in the introduction to this section, except that it does not return NULL for empty geometry arguments.

```sql
mysql> SET @g1 = Point(1,1), @g2 = Point(2,2);
mysql> SELECT ST_Equals(@g1, @g1), ST_Equals(@g1, @g2);
+---------------------+---------------------+
| ST_Equals(@g1, @g1) | ST_Equals(@g1, @g2) |
| 1                   | 0                   |
+---------------------+---------------------+
```
Functions That Test Spatial Relations Between Geometry Objects

- **ST_FrechetDistance(g1, g2 [, unit])**

  Returns the discrete Fréchet distance between two geometries, reflecting how similar the geometries are. The result is a double-precision number measured in the length unit of the spatial reference system (SRS) of the geometry arguments, or in the length unit of the unit argument if that argument is given.

  This function implements the discrete Fréchet distance, which means it is restricted to distances between the points of the geometries. For example, given two LineString arguments, only the points explicitly mentioned in the geometries are considered. Points on the line segments between these points are not considered.

  **ST_FrechetDistance()** handles its geometry arguments as described in the introduction to this section, with these exceptions:

  - The geometries may have a Cartesian or geographic SRS, but only LineString values are supported. If the arguments are in the same Cartesian or geographic SRS, but either is not a LineString, an ER_NOT_IMPLEMENTED_FOR_CARTESIAN_SRS or ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS error occurs, depending on the SRS type.

  **ST_FrechetDistance()** handles its optional unit argument as described in the introduction to this section.

    mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0,0 5,5 5)');
    mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 1,0 6,3 3,5 6)');
    mysql> SELECT ST_FrechetDistance(@ls1, @ls2);
    +--------------------------------+
    | ST_FrechetDistance(@ls1, @ls2) |
    +--------------------------------+
    | 2.8284271247461903             |
    +--------------------------------+
    mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0,0 5,5 5)', 4326);
    mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 1,0 6,3 3,5 6)', 4326);
    mysql> SELECT ST_FrechetDistance(@ls1, @ls2);
    +--------------------------------+
    | ST_FrechetDistance(@ls1, @ls2) |
    +--------------------------------+
    | 313421.1999416798              |
    +--------------------------------+
    mysql> SELECT ST_FrechetDistance(@ls1, @ls2, 'foot');
    +----------------------------------------+
    | ST_FrechetDistance(@ls1, @ls2, 'foot') |
    +----------------------------------------+
    | 1028284.7767115477                 |
    +----------------------------------------+

- **ST_HausdorffDistance(g1, g2 [, unit])**

  Returns the discrete Hausdorff distance between two geometries, reflecting how similar the geometries are. The result is a double-precision number measured in the length unit of the spatial reference system (SRS) of the geometry arguments, or in the length unit of the unit argument if that argument is given.

  This function implements the discrete Hausdorff distance, which means it is restricted to distances between the points of the geometries. For example, given two LineString arguments, only the points explicitly mentioned in the geometries are considered. Points on the line segments between these points are not considered.
Functions That Test Spatial Relations Between Geometry Objects

`ST_HausdorffDistance()` handles its geometry arguments as described in the introduction to this section, with these exceptions:

- If the geometry arguments are in the same Cartesian or geographic SRS, but are not in a supported combination, an `ER_NOT_IMPLEMENTED_FOR_CARTESIAN_SRS` or `ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS` error occurs, depending on the SRS type. These combinations are supported:
  - `LineString` and `LineString`
  - `Point` and `MultiPoint`
  - `LineString` and `MultiLineString`
  - `MultiPoint` and `MultiPoint`
  - `MultiLineString` and `MultiLineString`

`ST_HausdorffDistance()` handles its optional `unit` argument as described in the introduction to this section.

```sql
mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0,0 5,5 5)');
mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 1,0 6,3 3,5 6)');
mysql> SELECT ST_HausdorffDistance(@ls1, @ls2);
+----------------------------------+
| ST_HausdorffDistance(@ls1, @ls2) |
+----------------------------------+
|                                1 |
+----------------------------------+

mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0,0 5,5 5)', 4326);
mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 1,0 6,3 3,5 6)', 4326);
mysql> SELECT ST_HausdorffDistance(@ls1, @ls2);
+----------------------------------+
| ST_HausdorffDistance(@ls1, @ls2) |
+----------------------------------+
|               111319.49079326246 |
+----------------------------------+

mysql> SELECT ST_HausdorffDistance(@ls1, @ls2, 'foot');
+------------------------------------------+
| ST_HausdorffDistance(@ls1, @ls2, 'foot') |
+------------------------------------------+
|                        365221.4264870815 |
+------------------------------------------+
```

- `ST_Intersects(g1, g2)`

  Returns 1 or 0 to indicate whether `g1` spatially intersects `g2`.

- `ST_Overlaps(g1, g2)`

  Two geometries spatially overlap if they intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

  This function returns 1 or 0 to indicate whether `g1` spatially overlaps `g2`.

- `ST_Overlaps()` handles its arguments as described in the introduction to this section except that the return value is `NULL` for the additional condition that the dimensions of the two geometries are not equal.
Functions That Test Spatial Relations Between Geometry Objects

- **ST_Touches\((g_1, g_2)\)**
  
  Two geometries *spatially touch* if their interiors do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

  This function returns 1 or 0 to indicate whether \(g_1\) spatially touches \(g_2\).

  **ST_Touches()** handles its arguments as described in the introduction to this section except that the return value is NULL for the additional condition that both geometries are of dimension 0 (Point or MultiPoint).

- **ST_Within\((g_1, g_2)\)**
  
  Returns 1 or 0 to indicate whether \(g_1\) is spatially within \(g_2\). This tests the opposite relationship as ST_Contains().

  **ST_Within()** handles its arguments as described in the introduction to this section.

12.16.9.2 Spatial Relation Functions That Use Minimum Bounding Rectangles

MySQL provides several MySQL-specific functions that test the relationship between minimum bounding rectangles (MBRs) of two geometries \(g_1\) and \(g_2\). The return values 1 and 0 indicate true and false, respectively.

The bounding box of a point is interpreted as a point that is both boundary and interior.

The bounding box of a straight horizontal or vertical line is interpreted as a line where the interior of the line is also boundary. The endpoints are boundary points.

If any of the parameters are geometry collections, the interior, boundary, and exterior of those parameters are those of the union of all elements in the collection.

Functions in this section detect arguments in either Cartesian or geographic spatial reference systems (SRSs), and return results appropriate to the SRS.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is NULL or an empty geometry, the return value is NULL.

- If any geometry argument is not a syntactically well-formed geometry, an ER_GIS_INVALID_DATA error occurs.

- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an ER_SRS_NOT_FOUND error occurs.

- For functions that take multiple geometry arguments, if those arguments are not in the same SRS, an ER_GIS_DIFFERENT_SRIDS error occurs.

- If any argument is geometrically invalid, either the result is true or false (it is undefined which), or an error occurs.

- For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:

  - If a longitude value is not in the range \((-180, 180]\), an ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE error occurs.

  - If a latitude value is not in the range \([-90, 90]\), an ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE error occurs.
Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

- Otherwise, the return value is non-NULL.

These MBR functions are available for testing geometry relationships:

1. **MBRContains** (**g1**, **g2**)

   Returns 1 or 0 to indicate whether the minimum bounding rectangle of **g1** contains the minimum bounding rectangle of **g2**. This tests the opposite relationship as **MBRWithin**().

   MBRContains() handles its arguments as described in the introduction to this section.

   ```
   mysql> SET @g1 = ST_GeomFromText('Polygon((0 0 3 3, 3 0, 0 0))');
   mysql> SET @g2 = ST_GeomFromText('Point(1 1)');
   mysql> SELECT MBRContains(@g1, @g2), MBRWithin(@g2, @g1);
   +----------------------+--------------------+
   | MBRContains(@g1, @g2) | MBRWithin(@g2, @g1) |
   +----------------------+--------------------+
   |                    1 |                  1 |
   +----------------------+--------------------+
   ```

2. **MBRCoveredBy** (**g1**, **g2**)

   Returns 1 or 0 to indicate whether the minimum bounding rectangle of **g1** is covered by the minimum bounding rectangle of **g2**. This tests the opposite relationship as **MBRCovers()**.

   MBRCoveredBy() handles its arguments as described in the introduction to this section.

   ```
   mysql> SET @g1 = ST_GeomFromText('Polygon((0 0 3 3, 3 0, 0 0))');
   mysql> SET @g2 = ST_GeomFromText('Point(1 1)');
   mysql> SELECT MBRCovers(@g1, @g2), MBRCoveredBy(@g1, @g2);
   +--------------------+-----------------------+
   | MBRCovers(@g1, @g2) | MBRCoveredBy(@g1, @g2) |
   +--------------------+-----------------------+
   |                  1 |                     0 |
   +--------------------+-----------------------+
   ```

3. **MBRCovers** (**g1**, **g2**)

   Returns 1 or 0 to indicate whether the minimum bounding rectangle of **g1** covers the minimum bounding rectangle of **g2**. This tests the opposite relationship as **MBRCoveredBy**(). See the description of MBRCoveredBy() for examples.

   MBRCovers() handles its arguments as described in the introduction to this section.

4. **MBRDisjoint** (**g1**, **g2**)

   Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries **g1** and **g2** are disjoint (do not intersect).

   MBRDisjoint() handles its arguments as described in the introduction to this section.

5. **MBREquals** (**g1**, **g2**)

   ```
   2459
   ```
Spatial Geohash Functions

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries $g_1$ and $g_2$ are the same.

$\text{MBREquals()}$ handles its arguments as described in the introduction to this section, except that it does not return NULL for empty geometry arguments.

- $\text{MBRIntersects}(g_1, g_2)$

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries $g_1$ and $g_2$ intersect.

$\text{MBRIntersects()}$ handles its arguments as described in the introduction to this section.

- $\text{MBROverlaps}(g_1, g_2)$

Two geometries spatially overlap if they intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

This function returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries $g_1$ and $g_2$ overlap.

$\text{MBROverlaps()}$ handles its arguments as described in the introduction to this section.

- $\text{MBRTouches}(g_1, g_2)$

Two geometries spatially touch if their interiors do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

This function returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries $g_1$ and $g_2$ touch.

$\text{MBRTouches()}$ handles its arguments as described in the introduction to this section.

- $\text{MBRWithin}(g_1, g_2)$

Returns 1 or 0 to indicate whether the minimum bounding rectangle of $g_1$ is within the minimum bounding rectangle of $g_2$. This tests the opposite relationship as $\text{MBRContains()}$.

$\text{MBRWithin()}$ handles its arguments as described in the introduction to this section.

```
mysql> SET @g1 = ST_GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = ST_GeomFromText('Polygon((0 0,0 5,5 5,5 0,0 0))');
mysql> SELECT MBRWithin(@g1,@g2), MBRWithin(@g2,@g1);
+--------------------+--------------------+
| MBRWithin(@g1,@g2) | MBRWithin(@g2,@g1) |
+--------------------+--------------------+
|                  1 |                  0 |
+--------------------+--------------------+
```

12.16.10 Spatial Geohash Functions

Geohash is a system for encoding latitude and longitude coordinates of arbitrary precision into a text string. Geohash values are strings that contain only characters chosen from "0123456789bcdefghjkmnpqrstuvwxyz".

The functions in this section enable manipulation of geohash values, which provides applications the capabilities of importing and exporting geohash data, and of indexing and searching geohash values.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:
Spatial Geohash Functions

- If any argument is **NULL**, the return value is **NULL**.
- If any argument is invalid, an error occurs.
- If any argument has a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range \((-180, 180]\), an **ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE** error occurs.
  - If a latitude value is not in the range \([-90, 90]\), an **ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE** error occurs.

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

- If any point argument does not have SRID 0 or 4326, an **ER_SRS_NOT_FOUND** error occurs. **point** argument SRID validity is not checked.
- If any SRID argument refers to an undefined spatial reference system (SRS), an **ER_SRS_NOT_FOUND** error occurs.
- If any SRID argument is not within the range of a 32-bit unsigned integer, an **ER_DATA_OUT_OF_RANGE** error occurs.
- Otherwise, the return value is non-**NULL**.

These geohash functions are available:

- **ST_GeoHash(longitude, latitude, max_length), ST_GeoHash(point, max_length)**

  Returns a geohash string in the connection character set and collation.

  For the first syntax, the *longitude* must be a number in the range \([-180, 180]\), and the *latitude* must be a number in the range \([-90, 90]\). For the second syntax, a **POINT** value is required, where the X and Y coordinates are in the valid ranges for longitude and latitude, respectively.

  The resulting string is no longer than *max_length* characters, which has an upper limit of 100. The string might be shorter than *max_length* characters because the algorithm that creates the geohash value continues until it has created a string that is either an exact representation of the location or *max_length* characters, whichever comes first.

  **ST_GeoHash()** handles its arguments as described in the introduction to this section.

  ```
  mysql> SELECT ST_GeoHash(180,0,10), ST_GeoHash(-180,-90,15);
  +----------------------+-------------------------+
  | ST_GeoHash(180,0,10) | ST_GeoHash(-180,-90,15) |
  +----------------------+-------------------------+
  | xbpbpbpbpb           | 000000000000000         |
  +----------------------+-------------------------+
  ```

- **ST_LatFromGeoHash(geohash_str)**

  Returns the latitude from a geohash string value, as a double-precision number in the range \([-90, 90]\).

  The **ST_LatFromGeoHash()** decoding function reads no more than 433 characters from the *geohash_str* argument. That represents the upper limit on information in the internal representation of coordinate values. Characters past the 433rd are ignored, even if they are otherwise illegal and produce an error.

  **ST_LatFromGeoHash()** handles its arguments as described in the introduction to this section.
Spatial GeoJSON Functions

- **ST_LongFromGeoHash(geohash_str)**

  Returns the longitude from a geohash string value, as a double-precision number in the range \([-180, 180]\).

  The remarks in the description of **ST_LatFromGeoHash()** regarding the maximum number of characters processed from the `geohash_str` argument also apply to **ST_LongFromGeoHash()**.

  **ST_LongFromGeoHash()** handles its arguments as described in the introduction to this section.

- **ST_PointFromGeoHash(geohash_str, srid)**

  Returns a `POINT` value containing the decoded geohash value, given a geohash string value.

  The X and Y coordinates of the point are the longitude in the range \([-180, 180]\) and the latitude in the range \([-90, 90]\), respectively.

  The `srid` argument is an 32-bit unsigned integer.

  The remarks in the description of **ST_LatFromGeoHash()** regarding the maximum number of characters processed from the `geohash_str` argument also apply to **ST_PointFromGeoHash()**.

  **ST_PointFromGeoHash()** handles its arguments as described in the introduction to this section.

12.16.11 Spatial GeoJSON Functions

This section describes functions for converting between GeoJSON documents and spatial values. GeoJSON is an open standard for encoding geometric/geographical features. For more information, see [http://geojson.org](http://geojson.org). The functions discussed here follow GeoJSON specification revision 1.0.

GeoJSON supports the same geometric/geographic data types that MySQL supports. Feature and FeatureCollection objects are not supported, except that geometry objects are extracted from them. CRS support is limited to values that identify an SRID.

MySQL also supports a native `JSON` data type and a set of SQL functions to enable operations on JSON values. For more information, see Section 11.5, “The JSON Data Type”, and Section 12.17, “JSON Functions”.

2462
Spatial GeoJSON Functions

• ST_AsGeoJSON(g [, max_dec_digits [, options]])
Generates a GeoJSON object from the geometry g. The object string has the connection character set
and collation.
If any argument is NULL, the return value is NULL. If any non-NULL argument is invalid, an error occurs.
max_dec_digits, if specified, limits the number of decimal digits for coordinates and causes rounding
32
of output. If not specified, this argument defaults to its maximum value of 2 − 1. The minimum is 0.
options, if specified, is a bitmask. The following table shows the permitted flag values. If the geometry
argument has an SRID of 0, no CRS object is produced even for those flag values that request one.
Flag Value

Meaning

0

No options. This is the default if options is not
specified.

1

Add a bounding box to the output.

2

Add a short-format CRS URN to the output. The
default format is a short format (EPSG:srid).

4

Add a long-format CRS URN
(urn:ogc:def:crs:EPSG::srid). This flag
overrides flag 2. For example, option values of 5
and 7 mean the same (add a bounding box and a
long-format CRS URN).

mysql> SELECT ST_AsGeoJSON(ST_GeomFromText('POINT(11.11111 12.22222)'),2);
+-------------------------------------------------------------+
| ST_AsGeoJSON(ST_GeomFromText('POINT(11.11111 12.22222)'),2) |
+-------------------------------------------------------------+
| {"type": "Point", "coordinates": [11.11, 12.22]}
|
+-------------------------------------------------------------+

• ST_GeomFromGeoJSON(str [, options [, srid]])
Parses a string str representing a GeoJSON object and returns a geometry.
If any argument is NULL, the return value is NULL. If any non-NULL argument is invalid, an error occurs.
options, if given, describes how to handle GeoJSON documents that contain geometries with
coordinate dimensions higher than 2. The following table shows the permitted options values.

Option Value

Meaning

1

Reject the document and produce an error. This is
the default if options is not specified.

2463


Spatial GeoJSON Functions

<table>
<thead>
<tr>
<th>Option Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>2, 3, 4</td>
<td>Accept the document and strip off the coordinates for higher coordinate dimensions.</td>
</tr>
</tbody>
</table>

`options` values of 2, 3, and 4 currently produce the same effect. If geometries with coordinate dimensions higher than 2 are supported in the future, you can expect these values to produce different effects.

The `srid` argument, if given, must be a 32-bit unsigned integer. If not given, the geometry return value has an SRID of 4326.

If `srid` refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.

For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:

- If a longitude value is not in the range \((-180, 180]\), an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
- If a latitude value is not in the range \([-90, 90]\), an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

GeoJSON geometry, feature, and feature collection objects may have a `crs` property. The parsing function parses named CRS URNs in the `urn:ogc:def:crs:EPSG::srid` and `EPSG:srid` namespaces, but not CRSSs given as link objects. Also, `urn:ogc:def:crs:OGC:1.3:CRS84` is recognized as SRID 4326. If an object has a CRS that is not understood, an error occurs, with the exception that if the optional `srid` argument is given, any CRS is ignored even if it is invalid.

If a `crs` member that specifies an SRID different from the top-level object SRID is found at a lower level of the GeoJSON document, an `ER_INVALID_GEOJSON_CRS_NOT_TOP_LEVEL` error occurs.

As specified in the GeoJSON specification, parsing is case-sensitive for the `type` member of the GeoJSON input (Point, LineString, and so forth). The specification is silent regarding case sensitivity for other parsing, which in MySQL is not case-sensitive.

This example shows the parsing result for a simple GeoJSON object. Observe that the order of coordinates depends on the SRID used.

```sql
mysql> SET @json = '{ "type": "Point", "coordinates": [102.0, 0.0]}';
mysql> SELECT ST_AsText(ST_GeomFromGeoJSON(@json));
| ST_AsText(ST_GeomFromGeoJSON(@json)) |
+--------------------------------------+
| POINT(0 102)                         |
+--------------------------------------+
mysql> SELECT ST_SRID(ST_GeomFromGeoJSON(@json));
| ST_SRID(ST_GeomFromGeoJSON(@json))   |
+-------------------------------------+
| 4326                                |
+-------------------------------------+
mysql> SELECT ST_AsText(ST_SRID(ST_GeomFromGeoJSON(@json),0));
| ST_AsText(ST_SRID(ST_GeomFromGeoJSON(@json),0)) |
+-------------------------------------------------+
| POINT(102 0)                                  |
+-------------------------------------------------+
```
12.16.12 Spatial Aggregate Functions

MySQL supports aggregate functions that perform a calculation on a set of values. For general information about these functions, see Section 12.19.1, “Aggregate Function Descriptions”. This section describes the ST_Collect() spatial aggregate function.

ST_Collect() can be used as a window function, as signified in its syntax description by [over_clause], representing an optional OVER clause. over_clause is described in Section 12.20.2, “Window Function Concepts and Syntax”, which also includes other information about window function usage.

- ST_Collect([DISTINCT] g) [over_clause]

Aggregates geometry values and returns a single geometry collection value. With the DISTINCT option, returns the aggregation of the distinct geometry arguments.

As with other aggregate functions, GROUP BY may be used to group arguments into subsets. ST_Collect() returns an aggregate value for each subset.

This function executes as a window function if over_clause is present. over_clause is as described in Section 12.20.2, “Window Function Concepts and Syntax”. In contrast to most aggregate functions that support windowing, ST_Collect() permits use of over_clause together with DISTINCT.

ST_Collect() handles its arguments as follows:

- NULL arguments are ignored.
- If all arguments are NULL or the aggregate result is empty, the return value is NULL.
- If any geometry argument is not a syntactically well-formed geometry, an ER_GIS_INVALID_DATA error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an ER_SRS_NOT_FOUND error occurs.
- If there are multiple geometry arguments and those arguments are in the same SRS, the return value is in that SRS. If those arguments are not in the same SRS, an ER_GIS_DIFFERENT_SRIDS_AGGREGATION error occurs.
- The result is the narrowest MultiXxx or GeometryCollection value possible, with the result type determined from the non-NULL geometry arguments as follows:
  - If all arguments are Point values, the result is a MultiPoint value.
  - If all arguments are LineString values, the result is a MultiLineString value.
  - If all arguments are Polygon values, the result is a MultiPolygon value.
  - Otherwise, the arguments are a mix of geometry types and the result is a GeometryCollection value.

This example data set shows hypothetical products by year and location of manufacture:

```
CREATE TABLE product (  
    year INTEGER,  
    product VARCHAR(256),  
    location Geometry  
);```
Spatial Aggregate Functions

**Sample Queries Using `ST_Collect()`**

```sql
mysql> SELECT ST_AsText(ST_Collect(location)) AS result
FROM product;
```
```
+------------------------------------------------------------------+
| result                                                           |
+------------------------------------------------------------------+
| MULTIPOINT((60 -24),(28 -77),(28 -77),(38 60),(60 -24),(28 -77)) |
+------------------------------------------------------------------+
```

```sql
mysql> SELECT ST_AsText(ST_Collect(DISTINCT location)) AS result
FROM product;
```
```
+---------------------------------------+
| result                                |
+---------------------------------------+
| MULTIPOINT((60 -24),(28 -77),(38 60)) |
+---------------------------------------+
```

```sql
mysql> SELECT year, ST_AsText(ST_Collect(location)) AS result
FROM product GROUP BY year;
```
```
+------+------------------------------------------------+
| year | result                                         |

+-------------------------------+
```
12.16.13 Spatial Convenience Functions

The functions in this section provide convenience operations on geometry values.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

• If any argument is NULL, the return value is NULL.
• If any geometry argument is not a syntactically well-formed geometry, an ER_GIS_INVALID_DATA error occurs.
• If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an ER_SRS_NOT_FOUND error occurs.
• For functions that take multiple geometry arguments, if those arguments are not in the same SRS, an ER_GIS_DIFFERENT_SRIDS error occurs.
• Otherwise, the return value is non-NULL.

These convenience functions are available:

• \texttt{ST\_Distance\_Sphere(}g1\texttt{, g2 [, radius]})

  Returns the minimum spherical distance between Point or MultiPoint arguments on a sphere, in meters. (For general-purpose distance calculations, see the \texttt{ST\_Distance()} function.) The optional \texttt{radius} argument should be given in meters.

  If both geometry parameters are valid Cartesian Point or MultiPoint values in SRID 0, the return value is shortest distance between the two geometries on a sphere with the provided radius. If omitted, the default radius is 6,370,986 meters, Point X and Y coordinates are interpreted as longitude and latitude, respectively, in degrees.

  If both geometry parameters are valid Point or MultiPoint values in a geographic spatial reference system (SRS), the return value is the shortest distance between the two geometries on a sphere with the provided radius. If omitted, the default radius is equal to the mean radius, defined as \((2a+b)/3\), where \(a\) is the semi-major axis and \(b\) is the semi-minor axis of the SRS.

  \texttt{ST\_Distance\_Sphere()} handles its arguments as described in the introduction to this section, with these exceptions:

  • Supported geometry argument combinations are Point and Point, or Point and MultiPoint (in any argument order). If at least one of the geometries is neither Point nor MultiPoint, and its SRID is 0, an ER_NOT_IMPLEMENTED_FOR_CARTESIAN_SRS error occurs. If at least one of the geometries is neither Point nor MultiPoint, and its SRID refers to a geographic SRS, an ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS error occurs. If any geometry refers to a projected SRS, an ER_NOT_IMPLEMENTED_FOR_PROJECTED_SRS error occurs.

  • If any argument has a longitude or latitude that is out of range, an error occurs:

  • If a longitude value is not in the range \((-180, 180]\), an \texttt{ER\_GEOMETRY\_PARAM\_LONGITUDE\_OUT\_OF\_RANGE} error occurs.

  • If a latitude value is not in the range \([-90, 90]\), an \texttt{ER\_GEOMETRY\_PARAM\_LATITUDE\_OUT\_OF\_RANGE} error occurs.
Spatial Convenience Functions

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

• If the `radius` argument is present but not positive, an `ER_NONPOSITIVE_RADIUS` error occurs.

• If the distance exceeds the range of a double-precision number, an `ER_STD_OVERFLOW_ERROR` error occurs.

```sql
mysql> SET @pt1 = ST_GeomFromText('POINT(0 0)');
mysql> SET @pt2 = ST_GeomFromText('POINT(180 0)');
mysql> SELECT ST_Distance_Sphere(@pt1, @pt2);
```

```
+--------------------------------+    
| ST_Distance_Sphere(@pt1, @pt2) |    
+--------------------------------+    
|             20015042.813723423 |    
```

• `ST_IsValid(g)`

Returns 1 if the argument is geometrically valid, 0 if the argument is not geometrically valid. Geometry validity is defined by the OGC specification.

The only valid empty geometry is represented in the form of an empty geometry collection value. `ST_IsValid()` returns 1 in this case. MySQL does not support GIS `EMPTY` values such as `POINT EMPTY`.

`ST_IsValid()` handles its arguments as described in the introduction to this section, with this exception:

• If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
  
  • If a longitude value is not in the range `(-180, 180]`, an `ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE` error occurs.
  
  • If a latitude value is not in the range `[-90, 90]`, an `ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

```sql
mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0, -0.00 0, 0.0 0)');
mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 0, 1 1)');
mysql> SELECT ST_IsValid(@ls1);
```

```
+------------------+    
| ST_IsValid(@ls1) |    
+------------------+    
|                0 |    
```

```sql
mysql> SELECT ST_IsValid(@ls2);
```

```
+------------------+    
| ST_IsValid(@ls2) |    
+------------------+    
|                1 |    
```
• **ST_MakeEnvelope**\( (pt_1, pt_2) \)

Returns the rectangle that forms the envelope around two points, as a *Point*, *LineString*, or *Polygon*.

Calculations are done using the Cartesian coordinate system rather than on a sphere, spheroid, or on earth.

Given two points \( pt_1 \) and \( pt_2 \), **ST_MakeEnvelope()** creates the result geometry on an abstract plane like this:

- If \( pt_1 \) and \( pt_2 \) are equal, the result is the point \( pt_1 \).
- Otherwise, if \( (pt_1, pt_2) \) is a vertical or horizontal line segment, the result is the line segment \( (pt_1, pt_2) \).
- Otherwise, the result is a polygon using \( pt_1 \) and \( pt_2 \) as diagonal points.

The result geometry has an SRID of 0.

**ST_MakeEnvelope()** handles its arguments as described in the introduction to this section, with these exceptions:

- If the arguments are not *Point* values, an **ER_WRONG_ARGUMENTS** error occurs.
- An **ER_GIS_INVALID_DATA** error occurs for the additional condition that any coordinate value of the two points is infinite or NaN.
- If any geometry has an SRID value for a geographic spatial reference system (SRS), an **ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS** error occurs.

```sql
mysql> SET @pt1 = ST_GeomFromText('POINT(0 0)');
mysql> SET @pt2 = ST_GeomFromText('POINT(1 1)');
mysql> SELECT ST_AsText(ST_MakeEnvelope(@pt1, @pt2));
+----------------------------------------+
<table>
<thead>
<tr>
<th>ST_AsText(ST_MakeEnvelope(@pt1, @pt2))</th>
</tr>
</thead>
<tbody>
<tr>
<td>POLYGON((0 0,1 0,1 1,0 1,0 0))</td>
</tr>
</tbody>
</table>
```
- **ST_Simplify**(g, *max_distance*)

Simplifies a geometry using the Douglas-Peucker algorithm and returns a simplified value of the same type.

The geometry may be any geometry type, although the Douglas-Peucker algorithm may not actually process every type. A geometry collection is processed by giving its components one by one to the simplification algorithm, and the returned geometries are put into a geometry collection as result.

The *max_distance* argument is the distance (in units of the input coordinates) of a vertex to other segments to be removed. Vertices within this distance of the simplified linestring are removed.

According to Boost.Geometry, geometries might become invalid as a result of the simplification process, and the process might create self-intersections. To check the validity of the result, pass it to **ST_IsValid()**.

**ST_Simplify()** handles its arguments as described in the introduction to this section, with this exception:

- If the *max_distance* argument is not positive, or is NaN, an **ER_WRONG_ARGUMENTS** error occurs.

```sql
mysql> SET @g = ST_GeomFromText('LINESTRING(0 0,0 1,1 1,1 2,2 2,2 3,3 3)');
mysql> SELECT ST_AsText(ST_Simplify(@g, 0.5));
+---------------------------------+
| ST_AsText(ST_Simplify(@g, 0.5)) |
+---------------------------------+
| LINESTRING(0 0,0 1,1 1,2 3,3 3)  |
+---------------------------------+
mysql> SELECT ST_AsText(ST_Simplify(@g, 1.0));
+---------------------------------+
| ST_AsText(ST_Simplify(@g, 1.0))  |
+---------------------------------+
| LINESTRING(0 0,3 3)             |
+---------------------------------+
```
• **ST.Validate**

Validates a geometry according to the OGC specification. A geometry can be syntactically well-formed (WKB value plus SRID) but geometrically invalid. For example, this polygon is geometrically invalid:

```
POLYGON((0 0, 0 0, 0 0, 0 0, 0 0))
```

**ST.Validate** returns the geometry if it is syntactically well-formed and is geometrically valid, **NULL** if the argument is not syntactically well-formed or is not geometrically valid or is **NULL**.

**ST.Validate** can be used to filter out invalid geometry data, although at a cost. For applications that require more precise results not tainted by invalid data, this penalty may be worthwhile.

If the geometry argument is valid, it is returned as is, except that if an input **Polygon** or **MultiPolygon** has clockwise rings, those rings are reversed before checking for validity. If the geometry is valid, the value with the reversed rings is returned.

The only valid empty geometry is represented in the form of an empty geometry collection value. **ST.Validate** returns it directly without further checks in this case.

**ST.Validate** handles its arguments as described in the introduction to this section, with the exceptions listed here:

- If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range (-180, 180], an **ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE** error occurs.
  - If a latitude value is not in the range [-90, 90], an **ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE** error occurs.

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

```sql
mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0)');
mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 0, 1 1)');
mysql> SELECT ST_AsText(ST_Validate(@ls1));
+-----------------------------+
| ST_AsText(ST_Validate(@ls1)) |
| NULL                        |
+-----------------------------+
mysql> SELECT ST_AsText(ST_Validate(@ls2));
+-----------------------------+
| ST_AsText(ST_Validate(@ls2)) |
| LINESTRING(0 0, 1 1)        |
+-----------------------------+
```

### 12.17 JSON Functions

The functions described in this section perform operations on JSON values. For discussion of the **JSON** data type and additional examples showing how to use these functions, see Section 11.5, "The JSON Data Type".

For functions that take a JSON argument, an error occurs if the argument is not a valid JSON value. Arguments parsed as JSON are indicated by **json_doc**; arguments indicated by **val** are not parsed.

Functions that return JSON values always perform normalization of these values (see Normalization, Merging, and Autowrapping of JSON Values), and thus orders them. **The precise outcome of the sort is subject to change at any time; do not rely on it to be consistent between releases.**
A set of spatial functions for operating on GeoJSON values is also available. See Section 12.16.11, “Spatial GeoJSON Functions”.

### 12.17.1 JSON Function Reference

Table 12.22 JSON Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Deprecated</th>
</tr>
</thead>
<tbody>
<tr>
<td>-&gt;</td>
<td>Return value from JSON column after evaluating path; equivalent to JSON_EXTRACT().</td>
<td></td>
</tr>
<tr>
<td>-&gt;&gt;&gt;</td>
<td>Return value from JSON column after evaluating path and unquoting the result; equivalent to JSON_UNQUOTE(JSON_EXTRACT()).</td>
<td></td>
</tr>
<tr>
<td>JSON_ARRAY()</td>
<td>Create JSON array</td>
<td></td>
</tr>
<tr>
<td>JSON_ARRAY_APPEND()</td>
<td>Append data to JSON document</td>
<td></td>
</tr>
<tr>
<td>JSON_ARRAY_INSERT()</td>
<td>Insert into JSON array</td>
<td></td>
</tr>
<tr>
<td>JSON_CONTAINS()</td>
<td>Whether JSON document contains specific object at path</td>
<td></td>
</tr>
<tr>
<td>JSON_CONTAINS_PATH()</td>
<td>Whether JSON document contains any data at path</td>
<td></td>
</tr>
<tr>
<td>JSON_DEPTH()</td>
<td>Maximum depth of JSON document</td>

<tr>
<td>JSON_VALUE()</td>
<td>Extract value from JSON document at location pointed to by path provided; return this value as VARCHAR(512) or specified type</td>
<td></td>
</tr>
<tr>
<td>MEMBER_OF()</td>
<td>Returns true (1) if first operand matches any element of JSON array passed as second operand, otherwise returns false (0)</td>
<td></td>
</tr>
</tbody>
</table>

MySQL supports two aggregate JSON functions `JSON_ARRAYAGG()` and `JSON_OBJECTAGG()`. See Section 12.19, “Aggregate Functions”, for descriptions of these.

MySQL also supports “pretty-printing” of JSON values in an easy-to-read format, using the `JSONPRETTY()` function. You can see how much storage space a given JSON value takes up, and how much space remains for additional storage, using `JSON_STORAGE_SIZE()` and `JSON_STORAGE_FREE()`, respectively. For complete descriptions of these functions, see Section 12.17.8, “JSON Utility Functions”.

### 12.17.2 Functions That Create JSON Values

The functions listed in this section compose JSON values from component elements.
Functions That Search JSON Values

• JSON_ARRAY([val[, val] ...])
Evaluates a (possibly empty) list of values and returns a JSON array containing those values.
mysql> SELECT JSON_ARRAY(1, "abc", NULL, TRUE, CURTIME());
+---------------------------------------------+
| JSON_ARRAY(1, "abc", NULL, TRUE, CURTIME()) |
+---------------------------------------------+
| [1, "abc", null, true, "11:30:24.000000"]
|
+---------------------------------------------+

• JSON_OBJECT([key, val[, key, val] ...])
Evaluates a (possibly empty) list of key-value pairs and returns a JSON object containing those pairs. An
error occurs if any key name is NULL or the number of arguments is odd.
mysql> SELECT JSON_OBJECT('id', 87, 'name', 'carrot');
+-----------------------------------------+
| JSON_OBJECT('id', 87, 'name', 'carrot') |
+-----------------------------------------+
| {"id": 87, "name": "carrot"}
|
+-----------------------------------------+

• JSON_QUOTE(string)
Quotes a string as a JSON value by wrapping it with double quote characters and escaping interior
quote and other characters, then returning the result as a utf8mb4 string. Returns NULL if the argument
is NULL.
This function is typically used to produce a valid JSON string literal for inclusion within a JSON
document.
Certain special characters are escaped with backslashes per the escape sequences shown in
Table 12.23, “JSON_UNQUOTE() Special Character Escape Sequences”.
mysql> SELECT JSON_QUOTE('null'), JSON_QUOTE('"null"');
+--------------------+----------------------+
| JSON_QUOTE('null') | JSON_QUOTE('"null"') |
+--------------------+----------------------+
| "null"
| "\"null\""
|
+--------------------+----------------------+
mysql> SELECT JSON_QUOTE('[1, 2, 3]');
+-------------------------+
| JSON_QUOTE('[1, 2, 3]') |
+-------------------------+
| "[1, 2, 3]"
|
+-------------------------+

You can also obtain JSON values by casting values of other types to the JSON type using CAST(value
AS JSON); see Converting between JSON and non-JSON values, for more information.
Two aggregate functions generating JSON values are available. JSON_ARRAYAGG() returns a result set
as a single JSON array, and JSON_OBJECTAGG() returns a result set as a single JSON object. For more
information, see Section 12.19, “Aggregate Functions”.

12.17.3 Functions That Search JSON Values
The functions in this section perform search or comparison operations on JSON values to extract data
from them, report whether data exists at a location within them, or report the path to data within them. The
MEMBER OF() operator is also documented herein.
• JSON_CONTAINS(target, candidate[, path])

2474


Functions That Search JSON Values

Indicates by returning 1 or 0 whether a given `candidate` JSON document is contained within a `target` JSON document, or—if a `path` argument was supplied—whether the candidate is found at a specific path within the target. Returns `NULL` if any argument is `NULL`, or if the path argument does not identify a section of the target document. An error occurs if `target` or `candidate` is not a valid JSON document, or if the `path` argument is not a valid path expression or contains a `*` or `**` wildcard.

To check only whether any data exists at the path, use `JSON_CONTAINS_PATH()` instead.

The following rules define containment:

- A candidate scalar is contained in a target scalar if and only if they are comparable and are equal. Two scalar values are comparable if they have the same `JSON_TYPE()` types, with the exception that values of types `INTEGER` and `DECIMAL` are also comparable to each other.

- A candidate array is contained in a target array if and only if every element in the candidate is contained in some element of the target.

- A candidate nonarray is contained in a target array if and only if the candidate is contained in some element of the target.

- A candidate object is contained in a target object if and only if for each key in the candidate there is a key with the same name in the target and the value associated with the candidate key is contained in the value associated with the target key.

Otherwise, the candidate value is not contained in the target document.

Queries using `JSON_CONTAINS()` on InnoDB tables can be optimized using multi-valued indexes; see `Multi-Valued Indexes`, for more information.
Functions That Search JSON Values

- **JSON_CONTAINS_PATH**(json_doc, one_or_all, path[, path] ...)

  Returns 0 or 1 to indicate whether a JSON document contains data at a given path or paths. Returns NULL if any argument is NULL. An error occurs if the json_doc argument is not a valid JSON document, any path argument is not a valid path expression, or one_or_all is not 'one' or 'all'.

  To check for a specific value at a path, use **JSON_CONTAINS()** instead.

  The return value is 0 if no specified path exists within the document. Otherwise, the return value depends on the one_or_all argument:

  - 'one': 1 if at least one path exists within the document, 0 otherwise.
  - 'all': 1 if all paths exist within the document, 0 otherwise.

- **JSON_EXTRACT**(json_doc, path[, path] ...)

  Returns data from a JSON document, selected from the parts of the document matched by the path arguments. Returns NULL if any argument is NULL or no paths locate a value in the document. An error occurs if the json_doc argument is not a valid JSON document or any path argument is not a valid path expression.

  The return value consists of all values matched by the path arguments. If it is possible that those arguments could return multiple values, the matched values are autowrapped as an array, in the order corresponding to the paths that produced them. Otherwise, the return value is the single matched value.
MySQL supports the `->` operator as shorthand for this function as used with 2 arguments where the left hand side is a JSON column identifier (not an expression) and the right hand side is the JSON path to be matched within the column.

- **column->path**

The `->` operator serves as an alias for the `JSON_EXTRACT()` function when used with two arguments, a column identifier on the left and a JSON path (a string literal) on the right that is evaluated against the JSON document (the column value). You can use such expressions in place of column references wherever they occur in SQL statements.

The two `SELECT` statements shown here produce the same output:

```sql
mysql> SELECT c, JSON_EXTRACT(c, "$\text{.id}\"), g
FROM jemp
WHERE JSON_EXTRACT(c, "$\text{.id}\") > 1
ORDER BY JSON_EXTRACT(c, "\$.name\")
;
```

```
<table>
<thead>
<tr>
<th>c</th>
<th>c-&gt;&quot;$.id&quot;</th>
<th>g</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;id&quot;: &quot;3&quot;, &quot;name&quot;: &quot;Barney&quot;}</td>
<td>&quot;3&quot;</td>
<td>3</td>
</tr>
<tr>
<td>{&quot;id&quot;: &quot;4&quot;, &quot;name&quot;: &quot;Betty&quot;}</td>
<td>&quot;4&quot;</td>
<td>4</td>
</tr>
<tr>
<td>{&quot;id&quot;: &quot;2&quot;, &quot;name&quot;: &quot;Wilma&quot;}</td>
<td>&quot;2&quot;</td>
<td>2</td>
</tr>
</tbody>
</table>
```

3 rows in set (0.00 sec)

```sql
mysql> SELECT c, c->"$.id", g
FROM jemp
WHERE c->"$.id" > 1
ORDER BY c->"$.name"
;
```

```
<table>
<thead>
<tr>
<th>c</th>
<th>c-&gt;&quot;$.id&quot;</th>
<th>g</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;id&quot;: &quot;3&quot;, &quot;name&quot;: &quot;Barney&quot;}</td>
<td>&quot;3&quot;</td>
<td>3</td>
</tr>
<tr>
<td>{&quot;id&quot;: &quot;4&quot;, &quot;name&quot;: &quot;Betty&quot;}</td>
<td>&quot;4&quot;</td>
<td>4</td>
</tr>
<tr>
<td>{&quot;id&quot;: &quot;2&quot;, &quot;name&quot;: &quot;Wilma&quot;}</td>
<td>&quot;2&quot;</td>
<td>2</td>
</tr>
</tbody>
</table>
```

3 rows in set (0.00 sec)

This functionality is not limited to `SELECT`, as shown here:

```sql
mysql> ALTER TABLE jemp ADD COLUMN n INT;
Query OK, 0 rows affected (0.68 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> UPDATE jemp SET n=1 WHERE c->"$.id" = "4"
;
Query OK, 1 row affected (0.04 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT c, c->"$.id", g, n
FROM jemp
WHERE JSON_EXTRACT(c, "$\text{.id}\") > 1
ORDER BY c->"$.name"
;
```

```
<table>
<thead>
<tr>
<th>c</th>
<th>c-&gt;&quot;$.id&quot;</th>
<th>g</th>
<th>n</th>
</tr>
</thead>
</table>
```
Functions That Search JSON Values

```sql
mysql> DELETE FROM jemp WHERE c->"$.id" = "4";
Query OK, 1 row affected (0.04 sec)

mysql> SELECT c, c->"$.id", g, n
    > FROM jemp
    > WHERE JSON_EXTRACT(c, "$.id") > 1
    > ORDER BY c->"$.name";
```

(See Indexing a Generated Column to Provide a JSON Column Index, for the statements used to create and populate the table just shown.)

This also works with JSON array values, as shown here:

```sql
mysql> CREATE TABLE tj10 (a JSON, b INT);
Query OK, 0 rows affected (0.26 sec)

mysql> INSERT INTO tj10
    > VALUES ("[3,10,5,17,44]", 33), ("[3,10,5,17,[22,44,66]]", 0);
Query OK, 1 row affected (0.04 sec)

mysql> SELECT a->"$[4]" FROM tj10;
```

```
<table>
<thead>
<tr>
<th>a-&gt;&quot;$[4]&quot;</th>
</tr>
</thead>
<tbody>
<tr>
<td>44</td>
</tr>
<tr>
<td>[22, 44, 66]</td>
</tr>
</tbody>
</table>
```

2 rows in set (0.00 sec)

```sql
mysql> SELECT * FROM tj10 WHERE a->"$[0]" = 3;
```

```
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>[3, 10, 5, 17, 44]</td>
<td>33</td>
</tr>
<tr>
<td>[3, 10, 5, 17, [22, 44, 66]]</td>
<td>0</td>
</tr>
</tbody>
</table>
```

2 rows in set (0.00 sec)

Nested arrays are supported. An expression using `->` evaluates as `NULL` if no matching key is found in the target JSON document, as shown here:

```sql
mysql> SELECT * FROM tj10 WHERE a->"$[4][1]" IS NOT NULL;
```

```
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>[3, 10, 5, 17, [22, 44, 66]]</td>
<td>0</td>
</tr>
</tbody>
</table>
```

mysql> SELECT a->"$[4][1]" FROM tj10;
```

```
<table>
<thead>
<tr>
<th>a-&gt;&quot;$[4][1]&quot;</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
</tr>
</tbody>
</table>
```

2478
Functions That Search JSON Values

<table>
<thead>
<tr>
<th>44</th>
</tr>
</thead>
<tbody>
<tr>
<td>2 rows in set (0.00 sec)</td>
</tr>
</tbody>
</table>

This is the same behavior as seen in such cases when using `JSON_EXTRACT()`:

```sql
mysql> SELECT JSON_EXTRACT(a, "[$[4][1]]") FROM tj10;
+-----------------------------+
| JSON_EXTRACT(a, "$[4][1]" ) |
| NULL                        |
| 44                          |
+-----------------------------+
2 rows in set (0.00 sec)
```

- `column->>path`

This is an improved, unquoting extraction operator. Whereas the `->` operator simply extracts a value, the `->>` operator in addition unquotes the extracted result. In other words, given a JSON column value `column` and a path expression `path` (a string literal), the following three expressions return the same value:

- `JSON_UNQUOTE(JSON_EXTRACT(column, path))`
- `JSON_UNQUOTE(column -> path)`
- `column->>path`  

The `->>` operator can be used wherever `JSON_UNQUOTE(JSON_EXTRACT())` would be allowed. This includes (but is not limited to) `SELECT` lists, `WHERE` and `HAVING` clauses, and `ORDER BY` and `GROUP BY` clauses.

The next few statements demonstrate some `->>` operator equivalences with other expressions in the `mysql` client:

```sql
mysql> SELECT * FROM jemp WHERE g > 2;
+-------------------+------+
| c                 | g    |
+-------------------+------+
| {"id": "3", "name": "Barney"} | 3    |
| {"id": "4", "name": "Betty"}  | 4    |
+-------------------+------+
2 rows in set (0.01 sec)

mysql> SELECT c->'$.name' AS name
-> FROM jemp WHERE g > 2;
+--------+
| name   |
| "Barney" |
| "Betty"  |
+--------+
2 rows in set (0.00 sec)

mysql> SELECT JSON_UNQUOTE(c->'$.name') AS name
-> FROM jemp WHERE g > 2;
+--------+
| name   |
| Barney |
| Betty  |
+--------+
2 rows in set (0.00 sec)
```
Functions That Search JSON Values

```sql
mysql> SELECT c->>'$.name' AS name
    > FROM jemp WHERE g > 2;
```

```
+---------+
| name    |
+---------+
| Barney  |
| Betty   |
+---------+
2 rows in set (0.00 sec)
```

See Indexing a Generated Column to Provide a JSON Column Index, for the SQL statements used to create and populate the `jemp` table in the set of examples just shown.

This operator can also be used with JSON arrays, as shown here:

```sql
mysql> CREATE TABLE tj10 (a JSON, b INT);
Query OK, 0 rows affected (0.26 sec)
mysql> INSERT INTO tj10 VALUES
    > ('[3,10,5,"x",44]', 33),
    > ('[3,10,5,17,[22,"y",66]]', 0);
Query OK, 2 rows affected (0.04 sec)
Records: 2  Duplicates: 0  Warnings: 0
mysql> SELECT a->"$[3]", a->"$[4][1]" FROM tj10;
```

```
+-----------+--------------+
| a->"$[3]" | a->"$[4][1]" |
+-----------+--------------+
| "x"       | NULL         |
| 17        | "y"          |
+-----------+--------------+
2 rows in set (0.00 sec)
```

```sql
mysql> SELECT a->>>"$[3]", a->>>"$[4][1]" FROM tj10;
```

```
+------------+---------------+
| a->"$[3]"  | a->>>"$[4][1]" |
+------------+---------------+
| x          | NULL          |
| 17         | y             |
+------------+---------------+
2 rows in set (0.00 sec)
```

As with `->`, the `->>>` operator is always expanded in the output of `EXPLAIN`, as the following example demonstrates:

```sql
mysql> EXPLAIN SELECT c->>'$.name' AS name
    > FROM jemp WHERE g > 2\G
```

```
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: jemp

Level: Note
```

2480
Functions That Search JSON Values

Code: 1003
Message: /* select#1 */ select
json_unquote(json_extract(`jtest`.`jemp`.`c`,'$.name')) AS `name` from
`jtest`.`jemp` where (`jtest`.`jemp`.`g` > 2)
1 row in set (0.00 sec)

This is similar to how MySQL expands the -> operator in the same circumstances.
• JSON_KEYS(json_doc[, path])
Returns the keys from the top-level value of a JSON object as a JSON array, or, if a path argument is
given, the top-level keys from the selected path. Returns NULL if any argument is NULL, the json_doc
argument is not an object, or path, if given, does not locate an object. An error occurs if the json_doc
argument is not a valid JSON document or the path argument is not a valid path expression or contains
a * or ** wildcard.
The result array is empty if the selected object is empty. If the top-level value has nested subobjects, the
return value does not include keys from those subobjects.
mysql> SELECT JSON_KEYS('{"a": 1, "b": {"c": 30}}');
+---------------------------------------+
| JSON_KEYS('{"a": 1, "b": {"c": 30}}') |
+---------------------------------------+
| ["a", "b"]
|
+---------------------------------------+
mysql> SELECT JSON_KEYS('{"a": 1, "b": {"c": 30}}', '$.b');
+----------------------------------------------+
| JSON_KEYS('{"a": 1, "b": {"c": 30}}', '$.b') |
+----------------------------------------------+
| ["c"]
|
+----------------------------------------------+

• JSON_OVERLAPS(json_doc1, json_doc2)
Compares two JSON documents. Returns true (1) if the two document have any key-value pairs or array
elements in common. If both arguments are scalars, the function performs a simple equality test. If either
argument is NULL, the function returns NULL.
This function serves as counterpart to JSON_CONTAINS(), which requires all elements of the array
searched for to be present in the array searched in. Thus, JSON_CONTAINS() performs an AND
operation on search keys, while JSON_OVERLAPS() performs an OR operation.
Queries on JSON columns of InnoDB tables using JSON_OVERLAPS() in the WHERE clause can be
optimized using multi-valued indexes. Multi-Valued Indexes, provides detailed information and examples.
When comparing two arrays, JSON_OVERLAPS() returns true if they share one or more array elements
in common, and false if they do not:
mysql> SELECT JSON_OVERLAPS("[1,3,5,7]", "[2,5,7]");
+---------------------------------------+
| JSON_OVERLAPS("[1,3,5,7]", "[2,5,7]") |
+---------------------------------------+
|
1 |
+---------------------------------------+
1 row in set (0.00 sec)
mysql> SELECT JSON_OVERLAPS("[1,3,5,7]", "[2,6,7]");
+---------------------------------------+
| JSON_OVERLAPS("[1,3,5,7]", "[2,6,7]") |
+---------------------------------------+
|
1 |
+---------------------------------------+

2481


Functions That Search JSON Values

mysql> SELECT JSON_OVERLAPS('"[1,3,5,7]"', '"[2,6,8]"');
+-----------------------------------------------------------------------+
| JSON_OVERLAPS('"[1,3,5,7]"', '"[2,6,8]"') |
| 0 |
+-----------------------------------------------------------------------+
1 row in set (0.00 sec)

Partial matches are treated as no match, as shown here:

mysql> SELECT JSON_OVERLAPS('"[[1,2],[3,4],5]"', '"[1,[[2,3],[4,5]]]"');
+-----------------------------------------------------------------------+
| JSON_OVERLAPS('"[[1,2],[3,4],5]"', '"[1,[[2,3],[4,5]]]"') |
| 0 |
+-----------------------------------------------------------------------+
1 row in set (0.00 sec)

When comparing objects, the result is true if they have at least one key-value pair in common.

mysql> SELECT JSON_OVERLAPS('"{"a":1,"b":10,"d":10}"', '"{"c":1,"e":10,"f":1,"d":10}"');
+-----------------------------------------------------------------------+
| JSON_OVERLAPS('"{"a":1,"b":10,"d":10}"', '"{"c":1,"e":10,"f":1,"d":10}"') |
| 1 |
+-----------------------------------------------------------------------+
1 row in set (0.00 sec)

mysql> SELECT JSON_OVERLAPS('"{"a":1,"b":10,"d":10}"', '"{"a":5,"e":10,"f":1,"d":20}"');
+-----------------------------------------------------------------------+
| JSON_OVERLAPS('"{"a":1,"b":10,"d":10}"', '"{"a":5,"e":10,"f":1,"d":20}"') |
| 0 |
+-----------------------------------------------------------------------+
1 row in set (0.00 sec)

If two scalars are used as the arguments to the function, `JSON_OVERLAPS()` performs a simple test for equality:

mysql> SELECT JSON_OVERLAPS('"5"', '"5"');
+-------------------------+
| JSON_OVERLAPS('"5"', '"5"') |
| 1 |
+-------------------------+
1 row in set (0.00 sec)

mysql> SELECT JSON_OVERLAPS('"5"', '"6"');
+-------------------------+
| JSON_OVERLAPS('"5"', '"6"') |
| 0 |
+-------------------------+
1 row in set (0.00 sec)

When comparing a scalar with an array, `JSON_OVERLAPS()` attempts to treat the scalar as an array element. In this example, the second argument 6 is interpreted as [6], as shown here:

mysql> SELECT JSON_OVERLAPS('"[4,5,6,7]"', '"6"');
+-------------------------+
| JSON_OVERLAPS('"[4,5,6,7]"', '"6"') |
| 1 |
+-------------------------+
1 row in set (0.00 sec)
The function does not perform type conversions:

```mysql
mysql> SELECT JSON_OVERLAPS('[4,5,"6",7]', '6');
+-----------------------------------+
<table>
<thead>
<tr>
<th>JSON_OVERLAPS('[4,5,&quot;6&quot;,7]', '6')</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
+-----------------------------------+
1 row in set (0.00 sec)
mysql>
mysql> SELECT JSON_OVERLAPS('[4,5,6,7]', '"6"');
+-----------------------------------+
<table>
<thead>
<tr>
<th>JSON_OVERLAPS('[4,5,6,7]', '&quot;6&quot;')</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
+-----------------------------------+
1 row in set (0.00 sec)
```

- **JSON_SEARCH(json_doc, one_or_all, search_str[, escape_char[, path] ...])**

Returns the path to the given string within a JSON document. Returns NULL if any of the `json_doc`, `search_str`, or `path` arguments are NULL; no path exists within the document; or `search_str` is not found. An error occurs if the `json_doc` argument is not a valid JSON document, any `path` argument is not a valid path expression, `one_or_all` is not 'one' or 'all', or `escape_char` is not a constant expression.

The `one_or_all` argument affects the search as follows:

- 'one': The search terminates after the first match and returns one path string. It is undefined which match is considered first.

- 'all': The search returns all matching path strings such that no duplicate paths are included. If there are multiple strings, they are autowrapped as an array. The order of the array elements is undefined.

Within the `search_str` search string argument, the % and _ characters work as for the LIKE operator: % matches any number of characters (including zero characters), and _ matches exactly one character.

To specify a literal % or _ character in the search string, precede it by the escape character. The default is \ if the `escape_char` argument is missing or NULL. Otherwise, `escape_char` must be a constant that is empty or one character.

For more information about matching and escape character behavior, see the description of LIKE in Section 12.8.1, "String Comparison Functions and Operators". For escape character handling, a difference from the LIKE behavior is that the escape character for JSON_SEARCH() must evaluate to a constant at compile time, not just at execution time. For example, if JSON_SEARCH() is used in a prepared statement and the escape_char argument is supplied using a ? parameter, the parameter value might be constant at execution time, but is not at compile time.
Functions That Search JSON Values

```
+-----------------------------------------------+
| JSON_SEARCH(@j, 'all', 'abc')                |
| ["$[0]", "$[2].x"]                        |
+-----------------------------------------------+
mysql> SELECT JSON_SEARCH(@j, 'all', 'ghi');
| JSON_SEARCH(@j, 'all', 'ghi')                |
| NULL                                         |
+-----------------------------------------------+
mysql> SELECT JSON_SEARCH(@j, 'all', '10');
| JSON_SEARCH(@j, 'all', '10')                 |
| "$[1][0].k"                                 |
+-----------------------------------------------+
mysql> SELECT JSON_SEARCH(@j, 'all', '10', NULL, '$');
| JSON_SEARCH(@j, 'all', '10', NULL, '$')      |
| "$[1][0].k"                                 |
+-----------------------------------------------+
mysql> SELECT JSON_SEARCH(@j, 'all', '10', NULL, '$[*]');
| JSON_SEARCH(@j, 'all', '10', NULL, '$[*]')   |
| "$[1][0].k"                                 |
+-----------------------------------------------+
mysql> SELECT JSON_SEARCH(@j, 'all', '10', NULL, '$**.k');
| JSON_SEARCH(@j, 'all', '10', NULL, '$**.k')  |
| "$[1][0].k"                                 |
+-----------------------------------------------+
mysql> SELECT JSON_SEARCH(@j, 'all', '10', NULL, '$[1]');
| JSON_SEARCH(@j, 'all', '10', NULL, '$[1]')   |
| "$[1][0].k"                                 |
+-----------------------------------------------+
mysql> SELECT JSON_SEARCH(@j, 'all', '10', NULL, '$[1][0]');
| JSON_SEARCH(@j, 'all', '10', NULL, '$[1][0]')|
| "$[1][0].k"                                 |
+-----------------------------------------------+
```
## Functions That Search JSON Values

For more information about the JSON path syntax supported by MySQL, including rules governing the wildcard operators `*` and `**`, see JSON Path Syntax.

- **JSON_VALUE(json_doc, path)**

Extracts a value from a JSON document at the path given in the specified document, and returns the extracted value, optionally converting it to a desired type. The complete syntax is shown here:

```
JSON_VALUE(json_doc, path [RETURNING type] [on_empty] [on_error])
```

**on_empty:**
- `NULL | ERROR | DEFAULT value` ON EMPTY

**on_error:**
- `NULL | ERROR | DEFAULT value` ON ERROR
Functions That Search JSON Values

`json_doc` is a valid JSON document. If this is `NULL`, the function returns `NULL`.

`path` is a JSON path pointing to a location in the document. This must be a string literal value.

`type` is one of the following data types:

- FLOAT
- DOUBLE
- DECIMAL
- SIGNED
- UNSIGNED
- DATE
- TIME
- DATETIME
- YEAR

YEAR values of one or two digits are not supported.

- CHAR
- JSON

The types just listed are the same as the (non-array) types supported by the `CAST()` function.

If not specified by a `RETURNING` clause, the `JSON_VALUE()` function's return type is `VARCHAR(512)`. When no character set is specified for the return type, `JSON_VALUE()` uses `utf8mb4` with the binary
Functions That Search JSON Values

collation, which is case-sensitive; if utf8mb4 is specified as the character set for the result, the server
uses the default collation for this character set, which is not case-sensitive.
When the data at the specified path consists of or resolves to a JSON null literal, the function returns
SQL NULL.
on_empty, if specified, determines how JSON_VALUE() behaves when no data is found at the path
given; this clause takes one of the following values:
• NULL ON EMPTY: The function returns NULL; this is the default ON EMPTY behavior.
• DEFAULT value ON EMPTY: the provided value is returned. The value's type must match that of
the return type.
• ERROR ON EMPTY: The function throws an error.
If used, on_error takes one of the following values with the corresponding outcome when an error
occurs, as listed here:
• NULL ON ERROR: JSON_VALUE() returns NULL; this is the default behavior if no ON ERROR clause is
used.
• DEFAULT value ON ERROR: This is the value returned; its value must match that of the return type.
• ERROR ON ERROR: An error is thrown.
ON EMPTY, if used, must precede any ON ERROR clause. Specifying them in the wrong order results in a
syntax error.
Error handling.

In general, errors are handled by JSON_VALUE() as follows:

• All JSON input (document and path) is checked for validity. If any of it is not valid, an SQL error is
thrown without triggering the ON ERROR clause.
• ON ERROR is triggered whenever any of the following events occur:
• Attempting to extract an object or an array, such as that resulting from a path that resolves to
multiple locations within the JSON document
• Conversion errors, such as attempting to convert 'asdf' to an UNSIGNED value
• Truncation of values
• A conversion error always triggers a warning even if NULL ON ERROR or DEFAULT ... ON ERROR
is specified.
• The ON EMPTY clause is triggered when the source JSON document (expr) contains no data at the
specified location (path).
Examples.

Two simple examples are shown here:

mysql> SELECT JSON_VALUE('{"fname": "Joe", "lname": "Palmer"}', '$.fname');
+--------------------------------------------------------------+
| JSON_VALUE('{"fname": "Joe", "lname": "Palmer"}', '$.fname') |
+--------------------------------------------------------------+
| Joe
|
+--------------------------------------------------------------+
mysql> SELECT JSON_VALUE('{"item": "shoes", "price": "49.95"}', '$.price'

2487


Functions That Search JSON Values

The statement `SELECT JSON_VALUE(json_doc, path RETURNING type)` is equivalent to the following statement:

```sql
SELECT CAST(
    JSON_UNQUOTE( JSON_EXTRACT(json_doc, path) )
AS type
);
```

`JSON_VALUE()` simplifies creating indexes on JSON columns by making it unnecessary in many cases to create a generated column and then an index on the generated column. You can do this when creating a table `t1` that has a `JSON` column by creating an index on an expression that uses `JSON_VALUE()` operating on that column (with a path that matches a value in that column), as shown here:

```sql
CREATE TABLE t1(
    j JSON,
    INDEX i1 ( (JSON_VALUE(j, '$.id' RETURNING UNSIGNED)) )
);
```

The following `EXPLAIN` output shows that a query against `t1` employing the index expression in the `WHERE` clause uses the index thus created:

```sql
mysql> EXPLAIN SELECT * FROM t1
    > WHERE JSON_VALUE(j, '$.id' RETURNING UNSIGNED) = 123
```

This achieves much the same effect as creating a table `t2` with an index on a generated column (see Indexing a Generated Column to Provide a JSON Column Index), like this one:

```sql
CREATE TABLE t2 (
    j JSON,
    g INT GENERATED ALWAYS AS (j->"$.id"),
    INDEX i1 (g)
);
```

The `EXPLAIN` output for a query against this table, referencing the generated column, shows that the index is used in the same way as for the previous query against table `t1`:

```sql
mysql> EXPLAIN SELECT * FROM t2 WHERE g = 123
```
For information about using indexes on generated columns for indirect indexing of JSON columns, see Indexing a Generated Column to Provide a JSON Column Index.

- **value MEMBER OF(json_array)**

Returns true (1) if value is an element of json_array, otherwise returns false (0). value must be a scalar or a JSON document; if it is a scalar, the operator attempts to treat it as an element of a JSON array. If value or json_array is NULL, the function returns NULL.

Queries using MEMBER OF() on JSON columns of InnoDB tables in the WHERE clause can be optimized using multi-valued indexes. See Multi-Valued Indexes, for detailed information and examples.

Simple scalars are treated as array values, as shown here:

```sql
mysql> SELECT 17 MEMBER OF('[23, "abc", 17, "ab", 10]');
+-------------------------------------------+
| 17 MEMBER OF('[23, "abc", 17, "ab", 10]') |
|                                         1 |
+-------------------------------------------+
1 row in set (0.00 sec)

mysql> SELECT 'ab' MEMBER OF('[23, "abc", 17, "ab", 10]');
+---------------------------------------------+
| 'ab' MEMBER OF('[23, "abc", 17, "ab", 10]') |
|                                           1 |
+---------------------------------------------+
1 row in set (0.00 sec)
```

Partial matches of array element values do not match:

```sql
mysql> SELECT 7 MEMBER OF('[23, "abc", 17, "ab", 10]');
+------------------------------------------+
| 7 MEMBER OF('[23, "abc", 17, "ab", 10]') |
|                                        0 |
+------------------------------------------+
1 row in set (0.00 sec)

mysql> SELECT 'a' MEMBER OF('[23, "abc", 17, "ab", 10]');
+--------------------------------------------+
| 'a' MEMBER OF('[23, "abc", 17, "ab", 10]') |
|                                          0 |
+--------------------------------------------+
1 row in set (0.00 sec)
```

Conversions to and from string types are not performed:

```sql
mysql> SELECT
    
    -> 17 MEMBER OF('[23, "abc", "17", "ab", 10]'),
    
    -> "17" MEMBER OF('[23, "abc", 17, "ab", 10]')

*************************** 1. row ***************************
| 17 MEMBER OF('[23, "abc", "17", "ab", 10]'): 0 |
|                                                                                               |
|                                                                                               |
|                                                                                               |
|                                                                                               |
|                                                                                               |
|                                                                                               |
|                                                                                               |

2489
Functions That Modify JSON Values

"17" MEMBER OF('[23, "abc", 17, "ab", 10]'): 0
1 row in set (0.00 sec)

To use this operator with a value which itself an array, it is necessary to cast it explicitly as a JSON
array. You can do this with CAST(... AS JSON):
mysql> SELECT CAST('[4,5]' AS JSON) MEMBER OF('[[3,4],[4,5]]');
+--------------------------------------------------+
| CAST('[4,5]' AS JSON) MEMBER OF('[[3,4],[4,5]]') |
+--------------------------------------------------+
|
1 |
+--------------------------------------------------+
1 row in set (0.00 sec)

It is also possible to perform the necessary cast using the JSON_ARRAY() function, like this:
mysql> SELECT JSON_ARRAY(4,5) MEMBER OF('[[3,4],[4,5]]');
+--------------------------------------------+
| JSON_ARRAY(4,5) MEMBER OF('[[3,4],[4,5]]') |
+--------------------------------------------+
|
1 |
+--------------------------------------------+
1 row in set (0.00 sec)

Any JSON objects used as values to be tested or which appear in the target array must be coerced to
the correct type using CAST(... AS JSON) or JSON_OBJECT(). In addition, a target array containing
JSON objects must itself be cast using JSON_ARRAY. This is demonstrated in the following sequence of
statements:
mysql> SET @a = CAST('{"a":1}' AS JSON);
Query OK, 0 rows affected (0.00 sec)
mysql> SET @b = JSON_OBJECT("b", 2);
Query OK, 0 rows affected (0.00 sec)
mysql> SET @c = JSON_ARRAY(17, @b, "abc", @a, 23);
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @a MEMBER OF(@c), @b MEMBER OF(@c);
+------------------+------------------+
| @a MEMBER OF(@c) | @b MEMBER OF(@c) |
+------------------+------------------+
|
1 |
1 |
+------------------+------------------+
1 row in set (0.00 sec)

12.17.4 Functions That Modify JSON Values
The functions in this section modify JSON values and return the result.
• JSON_ARRAY_APPEND(json_doc, path, val[, path, val] ...)
Appends values to the end of the indicated arrays within a JSON document and returns the result.
Returns NULL if any argument is NULL. An error occurs if the json_doc argument is not a valid JSON
document or any path argument is not a valid path expression or contains a * or ** wildcard.
The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes
the new value against which the next pair is evaluated.
If a path selects a scalar or object value, that value is autowrapped within an array and the new value
is added to that array. Pairs for which the path does not identify any value in the JSON document are
ignored.

2490


### Functions That Modify JSON Values

- **JSON_ARRAY_APPEND(json_doc, path, val, path, val) ...

  Updates a JSON document, inserting into an array within the document and returning the modified document. Returns **NULL** if any argument is **NULL**. An error occurs if the **json_doc** argument is not a valid JSON document or any **path** argument is not a valid path expression or contains a * or ** wildcard or does not end with an array element identifier.

  The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

  Pairs for which the path does not identify any array in the JSON document are ignored. If a path identifies an array element, the corresponding value is inserted at that element position, shifting any following values to the right. If a path identifies an array position past the end of an array, the value is inserted at the end of the array.
Functions That Modify JSON Values

Earlier modifications affect the positions of the following elements in the array, so subsequent paths in the same `JSON_ARRAY_INSERT()` call should take this into account. In the final example, the second path inserts nothing because the path no longer matches anything after the first insert.

- **JSON_INSERT(json_doc, path, val[, path, val] ...)**

  Inserts data into a JSON document and returns the result. Returns `NULL` if any argument is `NULL`. An error occurs if the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression or contains a `*` or `**` wildcard.

  The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

  A path-value pair for an existing path in the document is ignored and does not overwrite the existing document value. A path-value pair for a nonexisting path in the document adds the value to the document if the path identifies one of these types of values:

  - A member not present in an existing object. The member is added to the object and associated with the new value.
  - A position past the end of an existing array. The array is extended with the new value. If the existing value is not an array, it is autowrapped as an array, then extended with the new value.

  Otherwise, a path-value pair for a nonexisting path in the document is ignored and has no effect.

  For a comparison of `JSON_INSERT()`, `JSON_REPLACE()`, and `JSON_SET()`, see the discussion of `JSON_SET()`.
The third and final value listed in the result is a quoted string and not an array like the second one (which is not quoted in the output); no casting of values to the JSON type is performed. To insert the array as an array, you must perform such casts explicitly, as shown here:

```sql
mysql> SELECT JSON_INSERT(@j, '$.a', 10, '$.c', CAST('[true, false]' AS JSON));
+------------------------------------------------------------------+
| JSON_INSERT(@j, '$.a', 10, '$.c', CAST('[true, false]' AS JSON)) |
+------------------------------------------------------------------+
| {"a": 1, "b": [2, 3], "c": [true, false]}                        |
+------------------------------------------------------------------+
1 row in set (0.00 sec)
```

- **JSON_MERGE(json_doc, json_doc[, json_doc] ...)**
  
  Deprecated synonym for **JSON_MERGE_PRESERVE()**.

- **JSON_MERGE_PATCH(json_doc, json_doc[, json_doc] ...)**
  
  Performs an **RFC 7396** compliant merge of two or more JSON documents and returns the merged result, without preserving members having duplicate keys. Raises an error if at least one of the documents passed as arguments to this function is not valid.

  **Note**
  
  For an explanation and example of the differences between this function and **JSON_MERGE_PRESERVE()**, see **JSON_MERGE_PATCH() compared with JSON_MERGE_PRESERVE()**.

  **JSON_MERGE_PATCH()** performs a merge as follows:

  1. If the first argument is not an object, the result of the merge is the same as if an empty object had been merged with the second argument.

  2. If the second argument is not an object, the result of the merge is the second argument.

  3. If both arguments are objects, the result of the merge is an object with the following members:

     - All members of the first object which do not have a corresponding member with the same key in the second object.

     - All members of the second object which do not have a corresponding key in the first object, and whose value is not the JSON **null** literal.

     - All members with a key that exists in both the first and the second object, and whose value in the second object is not the JSON **null** literal. The values of these members are the results of recursively merging the value in the first object with the value in the second object.

  For additional information, see **Normalization, Merging, and Autowrapping of JSON Values**.

```sql
mysql> SELECT JSON_MERGE_PATCH('[1, 2]', '[true, false]');
+-------------------------------------------------------------+
| JSON_MERGE_PATCH('[1, 2]', '[true, false]') |
+-------------------------------------------------------------+
| [true, false] |
+-------------------------------------------------------------+

mysql> SELECT JSON_MERGE_PATCH('{}name": "x"', '{}"id": 47}');
+---------------------------------------------+
| JSON_MERGE_PATCH('{}name": "x"', '{}"id": 47}'); |
+---------------------------------------------+
| {} |
+---------------------------------------------+
```
Functions That Modify JSON Values

| JSON_MERGE_PATCH('{"name": "x"}', '{"id": 47}') |
+-------------------------------------------------+
| {"id": 47, "name": "x"}
|
+-------------------------------------------------+
mysql> SELECT JSON_MERGE_PATCH('1', 'true');
+-------------------------------+
| JSON_MERGE_PATCH('1', 'true') |
+-------------------------------+
| true
|
+-------------------------------+
mysql> SELECT JSON_MERGE_PATCH('[1, 2]', '{"id": 47}');
+------------------------------------------+
| JSON_MERGE_PATCH('[1, 2]', '{"id": 47}') |
+------------------------------------------+
| {"id": 47}
|
+------------------------------------------+
mysql> SELECT JSON_MERGE_PATCH('{ "a": 1, "b":2 }',
>
'{ "a": 3, "c":4 }');
+-----------------------------------------------------------+
| JSON_MERGE_PATCH('{ "a": 1, "b":2 }','{ "a": 3, "c":4 }') |
+-----------------------------------------------------------+
| {"a": 3, "b": 2, "c": 4}
|
+-----------------------------------------------------------+
mysql> SELECT JSON_MERGE_PATCH('{ "a": 1, "b":2 }','{ "a": 3, "c":4 }',
>
'{ "a": 5, "d":6 }');
+-------------------------------------------------------------------------------+
| JSON_MERGE_PATCH('{ "a": 1, "b":2 }','{ "a": 3, "c":4 }','{ "a": 5, "d":6 }') |
+-------------------------------------------------------------------------------+
| {"a": 5, "b": 2, "c": 4, "d": 6}
|
+-------------------------------------------------------------------------------+

You can use this function to remove a member by specifying null as the value of the same member in
the second argument, as shown here:
mysql> SELECT JSON_MERGE_PATCH('{"a":1, "b":2}', '{"b":null}');
+--------------------------------------------------+
| JSON_MERGE_PATCH('{"a":1, "b":2}', '{"b":null}') |
+--------------------------------------------------+
| {"a": 1}
|
+--------------------------------------------------+

This example shows that the function operates in a recursive fashion; that is, values of members are not
limited to scalars, but rather can themselves be JSON documents:
mysql> SELECT JSON_MERGE_PATCH('{"a":{"x":1}}', '{"a":{"y":2}}');
+----------------------------------------------------+
| JSON_MERGE_PATCH('{"a":{"x":1}}', '{"a":{"y":2}}') |
+----------------------------------------------------+
| {"a": {"x": 1, "y": 2}}
|
+----------------------------------------------------+

JSON_MERGE_PATCH() compared with JSON_MERGE_PRESERVE().
The behavior of
JSON_MERGE_PATCH() is the same as that of JSON_MERGE_PRESERVE(), with the following two
exceptions:
• JSON_MERGE_PATCH() removes any member in the first object with a matching key in the second
object, provided that the value associated with the key in the second object is not JSON null.

2494


Functions That Modify JSON Values

- If the second object has a member with a key matching a member in the first object, 
  \texttt{JSON\_MERGE\_PATCH()} \textit{replaces} the value in the first object with the value in the second object, 
  whereas \texttt{JSON\_MERGE\_PRESERVE()} \textit{appends} the second value to the first value.

This example compares the results of merging the same 3 JSON objects, each having a matching key
"a", with each of these two functions:

\begin{verbatim}
mysql> \texttt{SET @x = '{ "a": 1, "b": 2 }',}
   \texttt{  @y = '{ "a": 3, "c": 4 }',}
   \texttt{  @z = '{ "a": 5, "d": 6 }';}
mysql> \texttt{SELECT JSON\_MERGE\_PATCH(@x, @y, @z) AS Patch,}
   \texttt{}\texttt{  JSON\_MERGE\_PRESERVE(@x, @y, @z) AS Preserve;}
\end{verbatim}

\begin{verbatim}
+-----------------------------+-----------------------------+
| Patch: {"a": 5, "b": 2, "c": 4, "d": 6} |
| Preserve: {"a": [1, 3, 5], "b": 2, "c": 4, "d": 6} |
\end{verbatim}

- \texttt{JSON\_MERGE\_PRESERVE(json\_doc, json\_doc[, json\_doc] ...)}

Merges two or more JSON documents and returns the merged result. Returns \texttt{NULL} if any argument is \texttt{NULL}. An error occurs if any argument is not a valid JSON document.

Merging takes place according to the following rules. For additional information, see \texttt{Normalization, Merging, and Autowrapping of JSON Values}.

- Adjacent arrays are merged to a single array.
- Adjacent objects are merged to a single object.
- A scalar value is autowrapped as an array and merged as an array.
- An adjacent array and object are merged by autowrapping the object as an array and merging the two arrays.

\begin{verbatim}
mysql> \texttt{SELECT JSON\_MERGE\_PRESERVE('[1, 2]', '[true, false]');}
+----------------------------------+
| JSON\_MERGE\_PRESERVE('[1, 2]', '[true, false]') |
| [1, 2, true, false] |
+----------------------------------+
mysql> \texttt{SELECT JSON\_MERGE\_PRESERVE('{"name": "x"}', '{"id": 47}');}
+----------------------------------+
| JSON\_MERGE\_PRESERVE('{"name": "x"}', '{"id": 47}') |
| {"id": 47, "name": "x"} |
+----------------------------------+
mysql> \texttt{SELECT JSON\_MERGE\_PRESERVE('1', 'true');}
+----------------------------------+
| JSON\_MERGE\_PRESERVE('1', 'true') |
| [1, true] |
+----------------------------------+
mysql> \texttt{SELECT JSON\_MERGE\_PRESERVE('[1, 2]', '{"id": 47}');}
+----------------------------------+
| JSON\_MERGE\_PRESERVE('[1, 2]', '{"id": 47}') |
| [1, 2, {"id": 47}] |
+----------------------------------+
\end{verbatim}
Functions That Modify JSON Values

SELECT JSON_MERGE_PRESERVE('{ "a": 1, "b": 2 }','{ "a": 3, "c": 4 }');
|
| JSON_MERGE_PRESERVE('{ "a": 1, "b": 2 }','{ "a": 3, "c": 4 }')
| [{"a": [1, 3], "b": 2, "c": 4}]

SELECT JSON_MERGE_PRESERVE('{ "a": 1, "b": 2 }','{ "a": 3, "c": 4 }','{ "a": 5, "d": 6 }');
|
| JSON_MERGE_PRESERVE('{ "a": 1, "b": 2 }','{ "a": 3, "c": 4 }','{ "a": 5, "d": 6 }')
| [{"a": [1, 3, 5], "b": 2, "c": 4, "d": 6}]

This function is similar to but differs from JSON_MERGE_PATCH() in significant respects; see JSON_MERGE_PATCH() compared with JSON_MERGE_PRESERVE(), for more information.

• JSON_REMOVE(json_doc, path[, path] ...)

Removes data from a JSON document and returns the result. Returns NULL if any argument is NULL. An error occurs if the json_doc argument is not a valid JSON document or any path argument is not a valid path expression or is $ or contains a * or ** wildcard.

The path arguments are evaluated left to right. The document produced by evaluating one path becomes the new value against which the next path is evaluated.

It is not an error if the element to be removed does not exist in the document; in that case, the path does not affect the document.

SELECT JSON_REPLACE(@j, '$[1]');
|
| JSON_REPLACE(@j, '$[1]')
| ["a", ["b", "c"], "d"]

SELECT JSON_REPLACE(@j, '[$1]', 10, '[$c]', [true, false]);

• JSON_REPLACE(json_doc, path, val[, path, val] ...)

Replaces existing values in a JSON document and returns the result. Returns NULL if any argument is NULL. An error occurs if the json_doc argument is not a valid JSON document or any path argument is not a valid path expression or contains a * or ** wildcard.

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

A path-value pair for an existing path in the document overwrites the existing document value with the new value. A path-value pair for a nonexisting path in the document is ignored and has no effect.

The optimizer can perform a partial, in-place update of a JSON column instead of removing the old document and writing the new document in its entirety to the column. This optimization can be performed for an update statement that uses the JSON_REPLACE() function and meets the conditions outlined in Partial Updates of JSON Values.

For a comparison of JSON_INSERT(), JSON_REPLACE(), and JSON_SET(), see the discussion of JSON_SET().

SELECT JSON_REPLACE(@j, '.$a', 10, '.$c', [true, false]);
Functions That Modify JSON Values

+-----------------------------------------------------+
| JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]') |
+-----------------------------------------------------+
| {"a": 10, "b": [2, 3]}                              |
+-----------------------------------------------------+

• **JSON_SET**(json_doc, path, val[, path, val] ...)

Inserts or updates data in a JSON document and returns the result. Returns NULL if json_doc or path is NULL, or if path, when given, does not locate an object. Otherwise, an error occurs if the json_doc argument is not a valid JSON document or any path argument is not a valid path expression or contains a * or ** wildcard.

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

A path-value pair for an existing path in the document overwrites the existing document value with the new value. A path-value pair for a nonexisting path in the document adds the value to the document if the path identifies one of these types of values:

• A member not present in an existing object. The member is added to the object and associated with the new value.

• A position past the end of an existing array. The array is extended with the new value. If the existing value is not an array, it is auto-wrapped as an array, then extended with the new value.

Otherwise, a path-value pair for a nonexisting path in the document is ignored and has no effect.

The optimizer can perform a partial, in-place update of a JSON column instead of removing the old document and writing the new document in its entirety to the column. This optimization can be performed for an update statement that uses the JSON_SET() function and meets the conditions outlined in Partial Updates of JSON Values.

The JSON_SET(), JSON_INSERT(), and JSON_REPLACE() functions are related:

• **JSON_SET()** replaces existing values and adds nonexisting values.

• **JSON_INSERT()** inserts values without replacing existing values.

• **JSON_REPLACE()** replaces only existing values.

The following examples illustrate these differences, using one path that does exist in the document ($a$) and another that does not exist ($c$):

```sql
mysql> SET @j = '{ "a": 1, "b": [2, 3]}';
mysql> SELECT JSON_SET(@j, '$.a', 10, '$.c', '[true, false]');
+-----------------------------------------------+
| JSON_SET(@j, '$.a', 10, '$.c', '[true, false]') |
| {"a": 10, "b": [2, 3], "c": [true, false]}    |
+-----------------------------------------------+
mysql> SELECT JSON_INSERT(@j, '$.a', 10, '$.c', '[true, false]');
+-----------------------------------------------+
| JSON_INSERT(@j, '$.a', 10, '$.c', '[true, false]') |
| {"a": 1, "b": [2, 3], "c": [true, false]}        |
+-----------------------------------------------+
mysql> SELECT JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]');
+-----------------------------------------------+
| JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]') |
```
Functions That Modify JSON Values

- **JSON_UNQUOTE(json_val)**

  Unquotes JSON value and returns the result as a utf8mb4 string. Returns NULL if the argument is NULL. An error occurs if the value starts and ends with double quotes but is not a valid JSON string literal.

  Within a string, certain sequences have special meaning unless the **NO_BACKSLASH_ESCAPES** SQL mode is enabled. Each of these sequences begins with a backslash (\), known as the *escape character*. MySQL recognizes the escape sequences shown in **Table 12.23, “JSON_UNQUOTE() Special Character Escape Sequences”**. For all other escape sequences, backslash is ignored. That is, the escaped character is interpreted as if it was not escaped. For example, \x is just x. These sequences are case-sensitive. For example, \b is interpreted as a backspace, but \B is interpreted as B.

  **Table 12.23 JSON_UNQUOTE() Special Character Escape Sequences**

<table>
<thead>
<tr>
<th>Escape Sequence</th>
<th>Character Represented by Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;   &quot;</td>
<td>A double quote (&quot;) character</td>
</tr>
<tr>
<td>\b</td>
<td>A backspace character</td>
</tr>
<tr>
<td>\f</td>
<td>A formfeed character</td>
</tr>
<tr>
<td>\n</td>
<td>A newline (linefeed) character</td>
</tr>
<tr>
<td>\r</td>
<td>A carriage return character</td>
</tr>
<tr>
<td>\t</td>
<td>A tab character</td>
</tr>
<tr>
<td>\   \</td>
<td>A backslash () character</td>
</tr>
<tr>
<td>\uXXXX</td>
<td>UTF-8 bytes for Unicode value XXXX</td>
</tr>
</tbody>
</table>

  Two simple examples of the use of this function are shown here:

  mysql> SET @j = '\"abc\"';
  mysql> SELECT @j, JSON_UNQUOTE(@j);
  +-------+------------------+
  | @j    | JSON_UNQUOTE(@j) |
  +-------+------------------+
  | "abc" | abc              |
  +-------+------------------+
  mysql> SET @j = '\[1, 2, 3\]';
  mysql> SELECT @j, JSON_UNQUOTE(@j);
  +-----------+------------------+
  | @j        | JSON_UNQUOTE(@j) |
  +-----------+------------------+
  | \[1, 2, 3\] | [1, 2, 3]        |
  +-----------+------------------+

  The following set of examples shows how JSON_UNQUOTE handles escapes with **NO_BACKSLASH_ESCAPES** disabled and enabled:

  mysql> SELECT @@sql_mode;
  +------------+
  | @@sql_mode |
  +------------+
  mysql> SELECT JSON_UNQUOTE('"\\\t\\u0032"');
12.17.5 Functions That Return JSON Value Attributes

The functions in this section return attributes of JSON values.

- **JSON_DEPTH(json_doc)**

Returns the maximum depth of a JSON document. Returns NULL if the argument is NULL. An error occurs if the argument is not a valid JSON document.

An empty array, empty object, or scalar value has depth 1. A nonempty array containing only elements of depth 1 or nonempty object containing only member values of depth 1 has depth 2. Otherwise, a JSON document has depth greater than 2.

- **JSON_LENGTH(json_doc[, path])**

Returns the length of a JSON document, or, if a path argument is given, the length of the value within the document identified by the path. Returns NULL if any argument is NULL or the path argument does not identify a value in the document. An error occurs if the json_doc argument is not a valid JSON document or the path argument is not a valid path expression.

The length of a document is determined as follows:

- The length of a scalar is 1.
Functions That Return JSON Value Attributes

- The length of an array is the number of array elements.
- The length of an object is the number of object members.
- The length does not count the length of nested arrays or objects.

```
mysql> SELECT JSON_LENGTH('[1, 2, {"a": 3}]');
+---------------------------------+
| JSON_LENGTH('[1, 2, {"a": 3}]') |
| 3                               |
+---------------------------------+

mysql> SELECT JSON_LENGTH('{"a": 1, "b": {"c": 30}}');
+---------------------------------+
| JSON_LENGTH('{"a": 1, "b": {"c": 30}}') |
| 2                               |
+---------------------------------+

mysql> SELECT JSON_LENGTH('{"a": 1, "b": {"c": 30}}', '$.b');
+---------------------------------+
| JSON_LENGTH('{"a": 1, "b": {"c": 30}}', '$.b') |
| 1                               |
+---------------------------------+
```

- `JSON_TYPE(json_val)`

Returns a `utf8mb4` string indicating the type of a JSON value. This can be an object, an array, or a scalar type, as shown here:

```
mysql> SET @j = '{"a": [10, true]}';

mysql> SELECT JSON_TYPE(@j);
+---------------+
| JSON_TYPE(@j) |
| OBJECT        |
+---------------+

mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a'));
+------------------------------------+
| JSON_TYPE(JSON_EXTRACT(@j, '$.a')) |
| ARRAY                              |
+------------------------------------+

mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a[0]'));
+---------------------------------------+
| JSON_TYPE(JSON_EXTRACT(@j, '$.a[0]')) |
| INTEGER                               |
+---------------------------------------+

mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a[1]'));
+---------------------------------------+
| JSON_TYPE(JSON_EXTRACT(@j, '$.a[1]')) |
| BOOLEAN                               |
+---------------------------------------+
```

`JSON_TYPE()` returns `NULL` if the argument is `NULL`:

```
mysql> SELECT JSON_TYPE(NULL);
+-----------------+
| JSON_TYPE(NULL) |
| NULL            |
+-----------------+
```
Functions That Return JSON Value Attributes

+-----------------+

An error occurs if the argument is not a valid JSON value:

mysql> SELECT JSON_TYPE(1);
ERROR 3146 (22032): Invalid data type for JSON data in argument 1
to function json_type; a JSON string or JSON type is required.

For a non-NULL, non-error result, the following list describes the possible JSON_TYPE() return values:

• Purely JSON types:
  • OBJECT: JSON objects
  • ARRAY: JSON arrays
  • BOOLEAN: The JSON true and false literals
  • NULL: The JSON null literal

• Numeric types:
  • INTEGER: MySQL TINYINT, SMALLINT, MEDIUMINT and INT and BIGINT scalars
  • DOUBLE: MySQL DOUBLE FLOAT scalars
  • DECIMAL: MySQL DECIMAL and NUMERIC scalars

• Temporal types:
  • DATETIME: MySQL DATETIME and TIMESTAMP scalars
  • DATE: MySQL DATE scalars
  • TIME: MySQL TIME scalars

• String types:
  • STRING: MySQL utf8mb3 character type scalars: CHAR, VARCHAR, TEXT, ENUM, and SET

• Binary types:
  • BLOB: MySQL binary type scalars including BINARY, VARBINARY, BLOB, and BIT

• All other types:
  • OPAQUE (raw bits)

• JSON_VALID(val)

Returns 0 or 1 to indicate whether a value is valid JSON. Returns NULL if the argument is NULL.

mysql> SELECT JSON_VALID(’{"a": 1}’);
+------------------------+
<table>
<thead>
<tr>
<th>JSON_VALID(’{&quot;a&quot;: 1}’)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
+------------------------+

mysql> SELECT JSON_VALID(’hello’), JSON_VALID(’"hello”’);
+---------------------+-----------------------+
<table>
<thead>
<tr>
<th>JSON_VALID(’hello’)</th>
<th>JSON_VALID(’&quot;hello”’)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
12.17.6 JSON Table Functions

This section contains information about JSON functions that convert JSON data to tabular data. MySQL 8.2 supports one such function, JSON_TABLE().

JSON_TABLE(expr, path COLUMNS (column_list) [AS] alias)

Extracts data from a JSON document and returns it as a relational table having the specified columns. The complete syntax for this function is shown here:

```sql
JSON_TABLE(
    expr,
    path COLUMNS (column_list)
) [AS] alias
```

column_list:
- `column[, column][, ...]`

column:
- `name` FOR ORDINALITY
  - `name type PATH string path [on_empty] [on_error]`
  - `name type EXISTS PATH string path`
  - `NESTED [PATH] path COLUMNS (column_list)``

`on_empty`:
- `{NULL | DEFAULT json_string | ERROR} ON EMPTY`

`on_error`:
- `{NULL | DEFAULT json_string | ERROR} ON ERROR`

**expr:** This is an expression that returns JSON data. This can be a constant (`"a":1`), a column (t1.json_data, given table t1 specified prior to JSON_TABLE() in the FROM clause), or a function call (JSON_EXTRACT(t1.json_data, '$.post.comments')).

**path:** A JSON path expression, which is applied to the data source. We refer to the JSON value matching the path as the *row source*; this is used to generate a row of relational data. The COLUMNS clause evaluates the row source, finds specific JSON values within the row source, and returns those JSON values as SQL values in individual columns of a row of relational data.

The alias is required. The usual rules for table aliases apply (see Section 9.2, “Schema Object Names”).

This function compares column names in case-insensitive fashion.

JSON_TABLE() supports four types of columns, described in the following list:

1. `name` FOR ORDINALITY: This type enumerates rows in the COLUMNS clause; the column named `name` is a counter whose type is UNSIGNED INT, and whose initial value is 1. This is equivalent to specifying a column as AUTO_INCREMENT in a CREATE TABLE statement, and can be used to distinguish parent rows with the same value for multiple rows generated by a NESTED [PATH] clause.

2. `name type PATH string_path [on_empty] [on_error]`: Columns of this type are used to extract values specified by string_path. type is a MySQL scalar data type (that is, it cannot be an object or array). JSON_TABLE() extracts data as JSON then coerces it to the column type, using the regular automatic type conversion applying to JSON data in MySQL. A missing value triggers the on_empty clause. Saving an object or array triggers the optional on_error clause; this also occurs when an error takes place during coercion from the value saved as JSON to the table column, such as trying to save the string 'asd' to an integer column.
3. **name type EXISTS PATH path**: This column returns 1 if any data is present at the location specified by `path`, and 0 otherwise. `type` can be any valid MySQL data type, but should normally be specified as some variety of INT.

4. **NESTED [PATH] path COLUMNS (column_list)**: This flattens nested objects or arrays in JSON data into a single row along with the JSON values from the parent object or array. Using multiple `PATH` options allows projection of JSON values from multiple levels of nesting into a single row.

   The `path` is relative to the parent path row path of `JSON_TABLE()`, or the path of the parent `NESTED [PATH]` clause in the event of nested paths.

   `on empty`, if specified, determines what `JSON_TABLE()` does in the event that data is missing (depending on type). This clause is also triggered on a column in a `NESTED PATH` clause when the latter has no match and a NULL complemented row is produced for it. `on empty` takes one of the following values:

   - **NULL ON EMPTY**: The column is set to NULL; this is the default behavior.
   - **DEFAULT json_string ON EMPTY**: the provided `json_string` is parsed as JSON, as long as it is valid, and stored instead of the missing value. Column type rules also apply to the default value.
   - **ERROR ON EMPTY**: An error is thrown.

   If used, `on_error` takes one of the following values with the corresponding result as shown here:

   - **NULL ON ERROR**: The column is set to NULL; this is the default behavior.
   - **DEFAULT json_string ON ERROR**: The `json_string` is parsed as JSON (provided that it is valid) and stored instead of the object or array.
   - **ERROR ON ERROR**: An error is thrown.

   Specifying `ON ERROR` before `ON EMPTY` is nonstandard and deprecated in MySQL; trying to do so causes the server to issue a warning. Expect support for the nonstandard syntax to be removed in a future version of MySQL.

   When a value saved to a column is truncated, such as saving 3.14159 in a `DECIMAL(10,1)` column, a warning is issued independently of any `ON ERROR` option. When multiple values are truncated in a single statement, the warning is issued only once.

   When the expression and path passed to this function resolve to JSON null, `JSON_TABLE()` returns SQL NULL, in accordance with the SQL standard, as shown here:

   ```sql
   mysql> SELECT * -> FROM -> JSON_TABLE( -> '[ {"c1": null } ]', -> '{$[*]}' COLUMNS( c1 INT PATH '.c1' ERROR ON ERROR ) -> ) as jt;
   +------+
   | c1   |
   +------+
   | NULL |
   +------+
   1 row in set (0.00 sec)
   ```

   The following query demonstrates the use of `ON EMPTY` and `ON ERROR`. The row corresponding to `{"b":1}` is empty for the path `".a"`, and attempting to save `[1,2]` as a scalar produces an error; these rows are highlighted in the output shown.
MySQL> SELECT *
-> FROM
-> JSON_TABLE(
-> '[["a":"3"],{"a":2},{"b":1},{"a":0},{"a":[1,2]]}',
-> "$[*]"
-> COLUMNS(
-> rowid FOR ORDINALITY,
-> ac VARCHAR(100) PATH ".a" DEFAULT '111' ON EMPTY DEFAULT '999' ON ERROR,
-> aj JSON PATH ".a" DEFAULT '{"x": 333}' ON EMPTY,
-> bx INT EXISTS PATH ".b"
-> )
-> ) AS tt;

+-------+------+------------+------+
| rowid | ac   | aj         | bx   |
+-------+------+------------+------+
|     1 | 3    | "3"        |    0 |
|     2 | 2    | 2          |    0 |
|     3 | 111  | {"x": 333} |    1 |
|     4 | 0    | 0          |    0 |
|     5 | 999  | [1, 2]     |    0 |
+-------+------+------------+------+
5 rows in set (0.00 sec)

Column names are subject to the usual rules and limitations governing table column names. See Section 9.2, "Schema Object Names".

All JSON and JSON path expressions are checked for validity; an invalid expression of either type causes an error.

Each match for the path preceding the COLUMNS keyword maps to an individual row in the result table. For example, the following query gives the result shown here:

MySQL> SELECT *
-> FROM
-> JSON_TABLE(
-> '[["x":2,"y":"8"],{"x":"3","y":"7"},{"x":4,"y":6}]',
-> "$[*]" COLUMNS(
-> xval VARCHAR(100) PATH ".x",
-> yval VARCHAR(100) PATH ".y"
-> )
-> ) AS jt1;

+------+------+
| xval | yval |
+------+------+
| 2    | 8    |
| 3    | 7    |
| 4    | 6    |
+------+------+

The expression "$[*]" matches each element of the array. You can filter the rows in the result by modifying the path. For example, using "$[1]" limits extraction to the second element of the JSON array used as the source, as shown here:

MySQL> SELECT *
-> FROM
-> JSON_TABLE(
-> '[["x":2,"y":"8"],{"x":3,"y":7},{"x":4,"y":6}]',
-> "$[1]" COLUMNS(
-> xval VARCHAR(100) PATH ".x",
-> yval VARCHAR(100) PATH ".y"
-> )
-> ) AS jt1;
Within a column definition, "$" passes the entire match to the column; "$\cdot x$" and "$\cdot y$" pass only the values corresponding to the keys $x$ and $y$, respectively, within that match. For more information, see JSON Path Syntax.

**NESTED PATH** (or simply **NESTED; PATH** is optional) produces a set of records for each match in the **COLUMNS** clause to which it belongs. If there is no match, all columns of the nested path are set to **NULL**. This implements an outer join between the topmost clause and **NESTED [PATH]**. An inner join can be emulated by applying a suitable condition in the **WHERE** clause, as shown here:

```sql
mysql> SELECT *
            -> FROM
            -> JSON_TABLE(
            -> '[[""a": 1, "b": [11,111]],{""a": 2, "b": [22,222]}],""a":3])',
            -> '$[*]' COLUMNS(
            -> a INT PATH '$.a',
            -> NESTED PATH '$.b[*]' COLUMNS (b INT PATH '$')
            )
            AS jt
            WHERE b IS NOT NULL;

+------+------+------+
| a    | b    |      |
+------+------+------+
| 1    | 11   |      |
| 1    | 111  |      |
| 2    | 22   |      |
| 2    | 222  |      |
+------+------+------+
```

Sibling nested paths—that is, two or more instances of **NESTED [PATH]** in the same **COLUMNS** clause—are processed one after another, one at a time. While one nested path is producing records, columns of any sibling nested path expressions are set to **NULL**. This means that the total number of records for a single match within a single containing **COLUMNS** clause is the sum and not the product of all records produced by **NESTED [PATH]** modifiers, as shown here:

```sql
mysql> SELECT *
            -> FROM
            -> JSON_TABLE(
            -> '[[""a": 1, "b": [11,111]],{""a": 2, "b": [22,222]}],""a":3])',
            -> '$[*]' COLUMNS(
            -> a INT PATH '$.a',
            -> NESTED PATH '$.b[*]' COLUMNS (b1 INT PATH '$'),
            -> NESTED PATH '$.b[*]' COLUMNS (b2 INT PATH '$')
            )
            AS jt;

+------+------+------+
| a    | b1   | b2   |
+------+------+------+
| 1    | 11   | NULL |
| 1    | 111  | NULL |
| 1    | NULL | 11   |
| 1    | NULL | 111  |
| 2    | 22   | NULL |
| 2    | 222  | NULL |
| 2    | NULL | 22   |
| 2    | NULL | 222  |
+------+------+------+
```
A **FOR ORDINALITY** column enumerates records produced by the **COLUMNS** clause, and can be used to distinguish parent records of a nested path, especially if values in parent records are the same, as can be seen here:

```sql
mysql> SELECT *
    -> FROM
    -> JSON_TABLE(
    -> '(["a": "a_val",
    ->  "b": {"c": "c_val", "l": [1,2]}],
    ->  "a": "a_val",
    ->  "b": {"c": "c_val","l": [11]}, {"c": "c_val", "l": [22]}),
    ->  \$[*]\) COLUMNS(
    ->  top_ord FOR ORDINALITY,
    ->  apath VARCHAR(10) PATH ".a",
    ->  NESTED PATH ".b[*]" COLUMNS (
    ->    bpath VARCHAR(10) PATH ".c",
    ->    ord FOR ORDINALITY,
    ->    NESTED PATH ".l[*]" COLUMNS (lpath varchar(10) PATH ".")
    -> )
    -> ) as jt;
+---------+---------+---------+------+-------+
| top_ord | apath   | bpath   | ord  | lpath |
+---------+---------+---------+------+-------+
|       1 |  a_val  |  c_val  |    1 | 1     |
|       1 |  a_val  |  c_val  |    1 | 2     |
|       2 |  a_val  |  c_val  |    1 | 11    |
|       2 |  a_val  |  c_val  |    2 | 22    |
+---------+---------+---------+------+-------+
```

The source document contains an array of two elements; each of these elements produces two rows. The values of `apath` and `bpath` are the same over the entire result set; this means that they cannot be used to determine whether `lpath` values came from the same or different parents. The value of the `ord` column remains the same as the set of records having `top_ord` equal to 1, so these two values are from a single object. The remaining two values are from different objects, since they have different values in the `ord` column.

Normally, you cannot join a derived table which depends on columns of preceding tables in the same **FROM** clause. MySQL, per the SQL standard, makes an exception for table functions; these are considered lateral derived tables. This is implicit, and for this reason is not allowed before **JSON_TABLE()**, also according to the standard.

Suppose you have a table `t1` created and populated using the statements shown here:

```sql
CREATE TABLE t1 (c1 INT, c2 CHAR(1), c3 JSON);

INSERT INTO t1 () VALUES
    ROW(1, 'a', JSON_OBJECT('a', 23, 'b', 27, 'c', 1)),
    ROW(1, 'y', JSON_OBJECT('a', 44, 'b', 22, 'c', 11)),
    ROW(2, 'x', JSON_OBJECT('b', 1, 'c', 15)),
    ROW(3, 'w', JSON_OBJECT('a', 5, 'b', 6, 'c', 7)),
    ROW(5, 'v', JSON_OBJECT('a', 123, 'c', 1111))
;
```

You can then execute joins, such as this one, in which **JSON_TABLE()** acts as a derived table while at the same time it refers to a column in a previously referenced table:

```sql
SELECT c1, c2, JSON_EXTRACT(c3, '$.*')
FROM t1 AS m
JOIN
    JSON_TABLE(
        m.c3,
        '$.*'
    )
```
MySQL supports validation of JSON documents against JSON schemas conforming to Draft 4 of the JSON Schema specification. This can be done using either of the functions detailed in this section, both of which take two arguments, a JSON schema, and a JSON document which is validated against the schema. JSON_SCHEMA_VALID() returns true if the document validates against the schema, and false if it does not; JSON_SCHEMA_VALIDATION_REPORT() provides a report in JSON format on the validation.

Both functions handle null or invalid input as follows:

- If at least one of the arguments is NULL, the function returns NULL.
- If at least one of the arguments is not valid JSON, the function raises an error (ER_INVALID_TYPE_FOR_JSON)
- In addition, if the schema is not a valid JSON object, the function returns ER_INVALID_JSON_TYPE.

MySQL supports the required attribute in JSON schemas to enforce the inclusion of required properties (see the examples in the function descriptions).

MySQL supports the id, $schema, description, and type attributes in JSON schemas but does not require any of these.

MySQL does not support external resources in JSON schemas; using the $ref keyword causes JSON_SCHEMA_VALID() to fail with ER_NOT_SUPPORTED_YET.

Note
MySQL supports regular expression patterns in JSON schema, which supports but silently ignores invalid patterns (see the description of JSON_SCHEMA_VALID() for an example).

These functions are described in detail in the following list:

- JSON_SCHEMA_VALID(schema, document)

  Validates a JSON document against a JSON schema. Both schema and document are required. The schema must be a valid JSON object; the document must be a valid JSON document. Provided that these conditions are met: If the document validates against the schema, the function returns true (1); otherwise, it returns false (0).

  In this example, we set a user variable @schema to the value of a JSON schema for geographical coordinates, and another one @document to the value of a JSON document containing one such coordinate. We then verify that @document validates according to @schema by using them as the arguments to JSON_SCHEMA_VALID():

  mysql> SET @schema = '{
      ' >    "id": "http://json-schema.org/geo",
      ' >    "$schema": "http://json-schema.org/draft-04/schema#",
      ' >    "description": "A geographical coordinate",
      ' >    "type": "object",
      '
  '}'}
Since `@schema` contains the `required` attribute, we can set `@document` to a value that is otherwise valid but does not contain the required properties, then test it against `@schema`, like this:

```sql
mysql> SET @document = '{}';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT JSON_SCHEMA_VALID(@schema, @document);
+---------------------------------------+
| JSON_SCHEMA_VALID(@schema, @document) |
+---------------------------------------+
|                                     0 |
+---------------------------------------+
1 row in set (0.00 sec)
```

If we now set the value of `@schema` to the same JSON schema but without the `required` attribute, `@document` validates because it is a valid JSON object, even though it contains no properties, as shown here:

```sql
mysql> SET @schema = '{
    "id": "http://json-schema.org/geo",
    "$schema": "http://json-schema.org/draft-04/schema#",
    "description": "A geographical coordinate",
    "type": "object",
    "properties": {
        "latitude": {
            "type": "number",
            "minimum": -90,
            "maximum": 90
        },
        "longitude": {
            "type": "number",
            "minimum": -180,
            "maximum": 180
        }
    }
};
mysql> SELECT JSON_SCHEMA_VALID(@schema, @document);
+---------------------------------------+
| JSON_SCHEMA_VALID(@schema, @document) |
+---------------------------------------+
|                                     1 |
+---------------------------------------+
1 row in set (0.00 sec)
```
JSON_SCHEMA_VALID() and CHECK constraints. JSON_SCHEMA_VALID() can also be used to enforce CHECK constraints.

Consider the table geo created as shown here, with a JSON column coordinate representing a point of latitude and longitude on a map, governed by the JSON schema used as an argument in a JSON_SCHEMA_VALID() call which is passed as the expression for a CHECK constraint on this table:

```sql
CREATE TABLE geo ( coordinate JSON,
  CHECK(
    coordinate JSON_SCHEMA_VALID(
      '{
        "type": "object",
        "properties":{
          "latitude": {"type": "number", "minimum": -90, "maximum": 90},
          "longitude": {"type": "number", "minimum": -180, "maximum": 180}
        },
        "required": ["latitude", "longitude"]
      }
    )
  )
);```

Note

Because a MySQL CHECK constraint cannot contain references to variables, you must pass the JSON schema to JSON_SCHEMA_VALID() inline when using it to specify such a constraint for a table.

We assign JSON values representing coordinates to three variables, as shown here:

```sql
SET @point1 = '{"latitude":59, "longitude":18}';
SET @point2 = '{"latitude":91, "longitude":0}';
SET @point3 = '{"longitude":120}';
```

The first of these values is valid, as can be seen in the following INSERT statement:

```sql
INSERT INTO geo VALUES(@point1);
```

The second JSON value is invalid and so fails the constraint, as shown here:

```sql
INSERT INTO geo VALUES(@point2);
```
JSON Schema Validation Functions

ERROR 3819 (HY000): Check constraint 'geo_chk_1' is violated.

You can obtain precise information about the nature of the failure—in this case, that the latitude value
exceeds the maximum defined in the schema—by issuing a SHOW WARNINGS statement:
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Error
Code: 3934
Message: The JSON document location '#/latitude' failed requirement 'maximum' at
JSON Schema location '#/properties/latitude'.
*************************** 2. row ***************************
Level: Error
Code: 3819
Message: Check constraint 'geo_chk_1' is violated.
2 rows in set (0.00 sec)

The third coordinate value defined above is also invalid, since it is missing the required latitude
property. As before, you can see this by attempting to insert the value into the geo table, then issuing
SHOW WARNINGS afterwards:
mysql> INSERT INTO geo VALUES(@point3);
ERROR 3819 (HY000): Check constraint 'geo_chk_1' is violated.
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Error
Code: 3934
Message: The JSON document location '#' failed requirement 'required' at JSON
Schema location '#'.
*************************** 2. row ***************************
Level: Error
Code: 3819
Message: Check constraint 'geo_chk_1' is violated.
2 rows in set (0.00 sec)

See Section 13.1.20.6, “CHECK Constraints”, for more information.
JSON Schema has support for specifying regular expression patterns for strings, but the implementation
used by MySQL silently ignores invalid patterns. This means that JSON_SCHEMA_VALID() can return
true even when a regular expression pattern is invalid, as shown here:
mysql> SELECT JSON_SCHEMA_VALID('{"type":"string","pattern":"("}', '"abc"');
+---------------------------------------------------------------+
| JSON_SCHEMA_VALID('{"type":"string","pattern":"("}', '"abc"') |
+---------------------------------------------------------------+
|
1 |
+---------------------------------------------------------------+
1 row in set (0.04 sec)

• JSON_SCHEMA_VALIDATION_REPORT(schema,document)
Validates a JSON document against a JSON schema. Both schema and document are required. As
with JSON_VALID_SCHEMA(), the schema must be a valid JSON object, and the document must be a
valid JSON document. Provided that these conditions are met, the function returns a report, as a JSON
document, on the outcome of the validation. If the JSON document is considered valid according to the
JSON Schema, the function returns a JSON object with one property valid having the value "true". If
the JSON document fails validation, the function returns a JSON object which includes the properties
listed here:
• valid: Always "false" for a failed schema validation
• reason: A human-readable string containing the reason for the failure
2510


• **schema-location**: A JSON pointer URI fragment identifier indicating where in the JSON schema the validation failed (see Note following this list)

• **document-location**: A JSON pointer URI fragment identifier indicating where in the JSON document the validation failed (see Note following this list)

• **schema-failed-keyword**: A string containing the name of the keyword or property in the JSON schema that was violated

**Note**

JSON pointer URI fragment identifiers are defined in [RFC 6901 - JavaScript Object Notation (JSON) Pointer](https://tools.ietf.org/html/rfc6901). (These are not the same as the JSON path notation used by `JSON_EXTRACT()` and other MySQL JSON functions.) In this notation, # represents the entire document, and #/myprop represents the portion of the document included in the top-level property named myprop. See the specification just cited and the examples shown later in this section for more information.

In this example, we set a user variable `@schema` to the value of a JSON schema for geographical coordinates, and another one `@document` to the value of a JSON document containing one such coordinate. We then verify that `@document` validates according to `@schema` by using them as the arguments to `JSON_SCHEMA_VALIDATION_REPORT()`:

```sql
mysql> SET @schema = '{
  'id': "http://json-schema.org/geo",
  'schema': "http://json-schema.org/draft-04/schema#",
  'description': "A geographical coordinate",
  'type': "object",
  'properties': {
    'latitude': {
      'type': "number",
      'minimum': -90,
      'maximum': 90
    },
    'longitude': {
      'type': "number",
      'minimum': -180,
      'maximum': 180
    }
  },
  'required': ['latitude', 'longitude']
}';
Query OK, 0 rows affected (0.01 sec)

mysql> SET @document = '{
  'latitude': 63.444697,
  'longitude': 10.445118
}';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT JSON_SCHEMA_VALIDATION_REPORT(@schema, @document);
+-------------------------------------------+
| JSON_SCHEMA_VALIDATION_REPORT(@schema, @document) |
| {"valid": true}                                 |
+-------------------------------------------+
```
Now we set @document such that it specifies an illegal value for one of its properties, like this:

```
mysql> SET @document = '{
  > "latitude": 63.444697,
  > "longitude": 310.445118
  > }';
```

Validation of @document now fails when tested with JSON_SCHEMA_VALIDATION_REPORT(). The output from the function call contains detailed information about the failure (with the function wrapped by JSONPRETTY() to provide better formatting), as shown here:

```
mysql> SELECT JSON_PRETTY(JSON_SCHEMA_VALIDATION_REPORT(@schema, @document))
*************************** 1. row ***************************
JSON_PRETTY(JSON_SCHEMA_VALIDATION_REPORT(@schema, @document)): {
  "valid": false,
  "reason": "The JSON document location '#/longitude' failed requirement 'maximum' at JSON Schema location '#/properties/longitude",
  "schema-location": "#/longitude",
  "document-location": "#/longitude",
  "schema-failed-keyword": "maximum"
}
1 row in set (0.00 sec)
```

Since @schema contains the required attribute, we can set @document to a value that is otherwise valid but does not contain the required properties, then test it against @schema. The output of JSON_SCHEMA_VALIDATION_REPORT() shows that validation fails due to lack of a required element, like this:

```
mysql> SET @document = '{}';
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SELECT JSON_PRETTY(JSON_SCHEMA_VALIDATION_REPORT(@schema, @document))
*************************** 1. row ***************************
JSON_PRETTY(JSON_SCHEMA_VALIDATION_REPORT(@schema, @document)): {
  "valid": false,
  "reason": "The JSON document location '#' failed requirement 'required' at JSON Schema location '#'",
  "schema-location": "#",
  "document-location": "#",
  "schema-failed-keyword": "required"
}
1 row in set (0.00 sec)
```

If we now set the value of @schema to the same JSON schema but without the required attribute, @document validates because it is a valid JSON object, even though it contains no properties, as shown here:

```
mysql> SET @schema = '{
  "id": "http://json-schema.org/geo",
  "$schema": "http://json-schema.org/draft-04/schema#",
  "description": "A geographical coordinate",
  "type": "object",
  "properties": {
    "latitude": {
      "type": "number",
      "minimum": -90,
      "maximum": 90
    },
    "longitude": {
      "type": "number",
      "minimum": -180,
      "maximum": 180
    }
  }
}
```
12.17.8 JSON Utility Functions

This section documents utility functions that act on JSON values, or strings that can be parsed as JSON values. JSON_PRETTY() prints out a JSON value in a format that is easy to read. JSON_STORAGE_SIZE() and JSON_STORAGE_FREE() show, respectively, the amount of storage space used by a given JSON value and the amount of space remaining in a JSON column following a partial update.

• JSON_PRETTY(json_val)

Provides pretty-printing of JSON values similar to that implemented in PHP and by other languages and database systems. The value supplied must be a JSON value or a valid string representation of a JSON value. Extraneous whitespaces and newlines present in this value have no effect on the output. For a NULL value, the function returns NULL. If the value is not a JSON document, or if it cannot be parsed as one, the function fails with an error.

Formatting of the output from this function adheres to the following rules:

• Each array element or object member appears on a separate line, indented by one additional level as compared to its parent.

• Each level of indentation adds two leading spaces.

• A comma separating individual array elements or object members is printed before the newline that separates the two elements or members.

• The key and the value of an object member are separated by a colon followed by a space (': ').

• An empty object or array is printed on a single line. No space is printed between the opening and closing brace.

• Special characters in string scalars and key names are escaped employing the same rules used by the JSON_QUOTE() function.
• **JSON_STORAGE_FREE(json_val)**

For a JSON column value, this function shows how much storage space was freed in its binary representation after it was updated in place using `JSON_SET()`, `JSON_REPLACE()`, or `JSON_REMOVE()`. The argument can also be a valid JSON document or a string which can be parsed as one—either as a literal value or as the value of a user variable—in which case the function returns 0. It returns a positive, nonzero value if the argument is a JSON column value which has been updated as described previously, such that its binary representation takes up less space than it did prior to the update. For a JSON column which has been updated such that its binary representation is the same as or larger than before, or if the update was not able to take advantage of a partial update, it returns 0; it returns `NULL` if the argument is `NULL`.

If `json_val` is not `NULL`, and neither is a valid JSON document nor can be successfully parsed as one, an error results.

In this example, we create a table containing a JSON column, then insert a row containing a JSON object:

```sql
mysql> CREATE TABLE jtable (jcol JSON);
Query OK, 0 rows affected (0.38 sec)

mysql> INSERT INTO jtable VALUES
  ->  ("{"a": 10, "b": "wxyz", "c": "[true, false]"})
Query OK, 1 row affected (0.04 sec)
```
Now we update the column value using `JSON_SET()` such that a partial update can be performed; in this case, we replace the value pointed to by the `c` key (the array `[true, false]`) with one that takes up less space (the integer 1):

```
mysql> UPDATE jtable
    -> SET jcol = JSON_SET(jcol, "$.a", 10, "$.b", "wx", "$.c", 1);
Query OK, 1 row affected (0.03 sec)
Rows matched: 1  Changed: 1  Warnings: 0
```

The effects of successive partial updates on this free space are cumulative, as shown in this example using `JSON_SET()` to reduce the space taken up by the value having key `b` (and making no other changes):

```
mysql> UPDATE jtable
    -> SET jcol = JSON_SET(jcol, "$.a", 10, "$.b", "wx", "$.c", 1);
Query OK, 1 row affected (0.03 sec)
Rows matched: 1  Changed: 1  Warnings: 0
```

Updating the column without using `JSON_SET()`, `JSON_REPLACE()`, or `JSON_REMOVE()` means that the optimizer cannot perform the update in place; in this case, `JSON_STORAGE_FREE()` returns 0, as shown here:

```
mysql> UPDATE jtable SET jcol = '{"a": 10, "b": 1}';
Query OK, 1 row affected (0.05 sec)
Rows matched: 1  Changed: 1  Warnings: 0
```

```sql
SELECT * FROM jtable;
+----------------------------------+
| jcol |
+----------------------------------+
| {"a": 10, "b": "wx", "c": 1} |
+----------------------------------+
1 row in set (0.00 sec)
```
Partial updates of JSON documents can be performed only on column values. For a user variable that stores a JSON value, the value is always completely replaced, even when the update is performed using JSON_SET():

```sql
mysql> SET @j = '{"a": 10, "b": "wxzy", "c": "[true, false]"}';
Query OK, 0 rows affected (0.00 sec)
mysql> SET @j = JSON_SET(@j, '".a"', 10, '".b"', 'wxzy', '".c"', '1');
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @j, JSON_STORAGE_FREE(@j) AS Free;
+---------------------------------+------+
<table>
<thead>
<tr>
<th>@j</th>
<th>Free</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;a&quot;: 10, &quot;b&quot;: &quot;wxzy&quot;, &quot;c&quot;: &quot;1&quot;}</td>
<td>0</td>
</tr>
</tbody>
</table>
+---------------------------------+------+
1 row in set (0.00 sec)
```

For a JSON literal, this function always returns 0:

```sql
mysql> SELECT JSON_STORAGE_FREE('{"a": 10, "b": "wxzy", "c": "1"}') AS Free;
+------+
| Free  |
| 0     |
+------+
1 row in set (0.00 sec)
```

- **JSON_STORAGE_SIZE(json_val)**

This function returns the number of bytes used to store the binary representation of a JSON document. When the argument is a JSON column, this is the space used to store the JSON document as it was inserted into the column, prior to any partial updates that may have been performed on it afterwards. **json_val** must be a valid JSON document or a string which can be parsed as one. In the case where it is string, the function returns the amount of storage space in the JSON binary representation that is created by parsing the string as JSON and converting it to binary. It returns **NULL** if the argument is NULL.

An error results when **json_val** is not NULL, and is not—or cannot be successfully parsed as—a JSON document.

To illustrate this function's behavior when used with a JSON column as its argument, we create a table named `jtable` containing a JSON column `jcol`, insert a JSON value into the table, then obtain the storage space used by this column with **JSON_STORAGE_SIZE()**, as shown here:

```sql
mysql> CREATE TABLE jtable (jcol JSON);
Query OK, 0 rows affected (0.42 sec)
mysql> INSERT INTO jtable VALUES
-> ("{"a": 1000, "b": "wxzy", "c": "[1, 3, 5, 7]"}");
Query OK, 1 row affected (0.04 sec)
mysql> SELECT
-> jcol,
-> JSON_STORAGE_SIZE(jcol) AS Size,
-> JSON_STORAGE_FREE(jcol) AS Free
-> FROM jtable;
+-----------------+-----+-----+
| jcol            | Size| Free|
| {"a": 1000, "b": "wxzy", "c": "[1, 3, 5, 7]"} | 47  | 0   |
+-----------------+-----+-----+
```
According to the output of `JSON_STORAGE_SIZE()`, the JSON document inserted into the column takes up 47 bytes. We also checked the amount of space freed by any previous partial updates of the column using `JSON_STORAGE_FREE()`; since no updates have yet been performed, this is 0, as expected.

Next we perform an `UPDATE` on the table that should result in a partial update of the document stored in `jcol`, and then test the result as shown here:

```
mysql> UPDATE jtable SET jcol = JSON_SET(jcol, ".b", "a");
Query OK, 1 row affected (0.04 sec)
Rows matched: 1  Changed: 1  Warnings: 0
```

```
mysql> SELECT jcol, JSON_STORAGE_SIZE(jcol) AS Size, JSON_STORAGE_FREE(jcol) AS Free
FROM jtable;
```

<table>
<thead>
<tr>
<th>jcol</th>
<th>Size</th>
<th>Free</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;a&quot;: 1000, &quot;b&quot;: &quot;a&quot;, &quot;c&quot;: &quot;:[1, 3, 5, ?]&quot;}</td>
<td>47</td>
<td>3</td>
</tr>
</tbody>
</table>

1 row in set (0.00 sec)

The value returned by `JSON_STORAGE_FREE()` in the previous query indicates that a partial update of the JSON document was performed, and that this freed 3 bytes of space used to store it. The result returned by `JSON_STORAGE_SIZE()` is unchanged by the partial update.

Partial updates are supported for updates using `JSON_SET()`, `JSON_REPLACE()`, or `JSON_REMOVE()`. The direct assignment of a value to a JSON column cannot be partially updated; following such an update, `JSON_STORAGE_SIZE()` always shows the storage used for the newly-set value:

```
mysql> UPDATE jtable
```

```
mysql> SET jcol = '{"a": 4.55, "b": "wxyz", "c": ":[true, false]"}';
Query OK, 1 row affected (0.04 sec)
Rows matched: 1  Changed: 1  Warnings: 0
```

```
mysql> SELECT jcol, JSON_STORAGE_SIZE(jcol) AS Size
FROM jtable;
```

<table>
<thead>
<tr>
<th>jcol</th>
<th>Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;a&quot;: 4.55, &quot;b&quot;: &quot;wxyz&quot;, &quot;c&quot;: &quot;:[true, false]&quot;}</td>
<td>56</td>
</tr>
</tbody>
</table>

1 row in set (0.00 sec)

A JSON user variable cannot be partially updated. This means that this function always shows the space currently used to store a JSON document in a user variable:

```
mysql> SET @j = '[100, "sakila", [1, 3, 5], 425.05]';
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SELECT @j, JSON_STORAGE_SIZE(@j) AS Size;
```

<table>
<thead>
<tr>
<th>@j</th>
<th>Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>[100, &quot;sakila&quot;, [1, 3, 5], 425.05]</td>
<td>45</td>
</tr>
</tbody>
</table>
12.18 Replication Functions

The functions described in the following sections are used with MySQL Replication.

### Table 12.24 Replication Functions

<table>

<td>Changes the mode of a group running in multi-primary mode to single-primary mode</td>
<td></td>
</tr>
</tbody>
</table>

### 12.18.1.1 Function which Configures Group Replication Primary

The following function enables you to set a member of a single-primary replication group to take over as the primary. The current primary becomes a read-only secondary, and the specified group member becomes the read-write primary. The function can be used on any member of a replication group running in single-primary mode. This function replaces the usual primary election process; see Section 18.5.1.1, “Changing the Primary”, for more information.

If a standard source to replica replication channel is running on the existing primary member in addition to the Group Replication channels, you must stop that replication channel before you can change the primary member. You can identify the current primary using the `MEMBER_ROLE` column in the Performance Schema table `replication_group_members`, or the `group_replication_primary_member` status variable.

Any uncommitted transactions that the group is waiting on must be committed, rolled back, or terminated before the operation can complete. You can specify a timeout for transactions that are running when you use the function. For the timeout to work, all members of the group must be MySQL version 8.0.29 or newer.

When the timeout expires, for any transactions that did not yet reach their commit phase, the client session is disconnected so that the transaction does not proceed. Transactions that reached their commit phase are allowed to complete. When you set a timeout, it also prevents new transactions starting on the primary from that point on. Explicitly defined transactions (with a `START TRANSACTION` or `BEGIN` statement) are subject to the timeout, disconnection, and incoming transaction blocking even if they do not modify any data. To allow inspection of the primary while the function is operating, single statements that do not modify data, as listed in Permitted Queries Under Consistency Rules, are permitted to proceed.

- `group_replication_set_as_primary()`

  Appoints a specific member of the group as the new primary, overriding any election process.

  **Syntax:**

  ```sql
  STRING group_replication_set_as_primary(member_uuid[, timeout])
  ```

  **Arguments:**

  - `member_uuid`: A string containing the UUID of the member of the group that you want to become the new primary.
• timeout: An integer specifying a timeout in seconds for transactions that are running on the existing primary when you use the function. You can set a timeout from 0 seconds (immediately) up to 3600 seconds (60 minutes). When you set a timeout, new transactions cannot start on the primary from that point on. There is no default setting for the timeout, so if you do not set it, there is no upper limit to the wait time, and new transactions can start during that time.

Return value:
A string containing the result of the operation, for example whether it was successful or not.

Example:
```
SELECT group_replication_set_as_primary('00371d66-3c45-11ea-804b-080027337932', 300);
```

This function waits for all ongoing transactions and DML operations to finish before electing the new primary. In MySQL 8.2, it also waits for the completion of any ongoing DDL statements such as `ALTER TABLE`. Operations that are considered DDL statements for this purpose are listed here:

- ALTER TABLE
- ANALYZE TABLE
- CACHE INDEX
- CHECK TABLE
- CREATE INDEX
- CREATE TABLE
- DROP INDEX
- LOAD INDEX
- OPTIMIZE TABLE
- REPAIR TABLE
- TRUNCATE TABLE
- DROP TABLE

This also includes any open cursors (see Section 13.6.6, “Cursors”).

For more information, see Section 18.5.1.1, “Changing the Primary”.

12.18.1.2 Functions which Configure the Group Replication Mode

The following functions enable you to control the mode which a replication group is running in, either single-primary or multi-primary mode.

• group_replication_switch_to_multi_primary_mode()

Changes a group running in single-primary mode to multi-primary mode. Must be issued on a member of a replication group running in single-primary mode.

Syntax:
STRING group_replication_switch_to_multi_primary_mode()

This function has no parameters.

Return value:

A string containing the result of the operation, for example whether it was successful or not.

Example:

```
SELECT group_replication_switch_to_multi_primary_mode()
```

All members which belong to the group become primaries.

For more information, see Section 18.5.1.2, “Changing the Group Mode”

• group_replication_switch_to_single_primary_mode()

Changes a group running in multi-primary mode to single-primary mode, without the need to stop Group Replication. Must be issued on a member of a replication group running in multi-primary mode. When you change to single-primary mode, strict consistency checks are also disabled on all group members, as required in single-primary mode (group_replication_enforce_update_everywhere Checks=OFF).

Syntax:

```
STRING group_replication_switch_to_single_primary_mode([str])
```

Arguments:

• str: A string containing the UUID of a member of the group which should become the new single primary. Other members of the group become secondaries.

Return value:

A string containing the result of the operation, for example whether it was successful or not.

Example:

```
SELECT group_replication_switch_to_single_primary_mode(member_uuid);
```

For more information, see Section 18.5.1.2, “Changing the Group Mode”

12.18.1.3 Functions to Inspect and Configure the Maximum Consensus Instances of a Group

The following functions enable you to inspect and configure the maximum number of consensus instances that a group can execute in parallel.

• group_replication_get_write_concurrency()

Check the maximum number of consensus instances that a group can execute in parallel.

Syntax:

```
INT group_replication_get_write_concurrency()
```

This function has no parameters.
Group Replication Functions

Return value:

The maximum number of consensus instances currently set for the group.

Example:

```sql
SELECT group_replication_get_write_concurrency()
```

For more information, see Section 18.5.1.3, “Using Group Replication Group Write Consensus”.

- `group_replication_set_write_concurrency()`

  Configures the maximum number of consensus instances that a group can execute in parallel. The `GROUP_REPLICATION_ADMIN` privilege is required to use this function.

  Syntax:

  ```sql
  STRING group_replication_set_write_concurrency(instances)
  ```

  Arguments:

  - `members`: Sets the maximum number of consensus instances that a group can execute in parallel. Default value is 10, valid values are integers in the range of 10 to 200.

  Return value:

  Any resulting error as a string.

Example:

```sql
SELECT group_replication_set_write_concurrency(instances);
```

For more information, see Section 18.5.1.3, “Using Group Replication Group Write Consensus”.

### 12.18.1.4 Functions to Inspect and Set the Group Replication Communication Protocol Version

The following functions enable you to inspect and configure the Group Replication communication protocol version that is used by a replication group.

- **Section 18.7.4, “Message Compression”**
- **Section 18.7.5, “Message Fragmentation”**
- **Section 18.7.3, “Single Consensus Leader”**
- **`group_replication_get_communication_protocol()`**

  Inspect the Group Replication communication protocol version that is currently in use for a group.

  Syntax:

  ```sql
  STRING group_replication_get_communication_protocol()
  ```

  This function has no parameters.

  Return value:
The oldest MySQL Server version that can join this group and use the group's communication protocol. Note that the `group_replication_get_communication_protocol()` function returns the minimum MySQL version that the group supports, which might differ from the version number that was passed to `group_replication_set_communication_protocol()`, and from the MySQL Server version that is installed on the member where you use the function.

If the protocol cannot be inspected because this server instance does not belong to a replication group, an error is returned as a string.

Example:

```
SELECT group_replication_get_communication_protocol();
```

<table>
<thead>
<tr>
<th>group_replication_get_communication_protocol()</th>
</tr>
</thead>
<tbody>
<tr>
<td>8.2.0</td>
</tr>
</tbody>
</table>

For more information, see Section 18.5.1.4, “Setting a Group's Communication Protocol Version”.

• `group_replication_set_communication_protocol()`

Downgrade the Group Replication communication protocol version of a group so that members at earlier releases can join, or upgrade the Group Replication communication protocol version of a group after upgrading MySQL Server on all members. The `GROUP_REPLICATION_ADMIN` privilege is required to use this function, and all existing group members must be online when you issue the statement, with no loss of majority.

**Note**

For MySQL InnoDB cluster, the communication protocol version is managed automatically whenever the cluster topology is changed using AdminAPI operations. You do not have to use these functions yourself for an InnoDB cluster.

Syntax:

```
STRING group_replication_set_communication_protocol(version)
```

Arguments:

• `version`: For a downgrade, specify the MySQL Server version of the prospective group member that has the oldest installed server version. In this case, the command makes the group fall back to a communication protocol compatible with that server version if possible. The minimum server version that you can specify is MySQL 5.7.14. For an upgrade, specify the new MySQL Server version to which the existing group members have been upgraded.

Return value:

A string containing the result of the operation, for example whether it was successful or not.

Example:

```
SELECT group_replication_set_communication_protocol("5.7.25");
```

For more information, see Section 18.5.1.4, “Setting a Group's Communication Protocol Version”.
12.18.1.5 Functions to Set and Reset Group Replication Member Actions

The following functions can be used to enable and disable actions for members of a group to take in specified situations, and to reset the configuration to the default setting for all member actions. They can only be used by administrators with the GROUP_REPLICATION_ADMIN privilege or the deprecated SUPER privilege.

You configure member actions on the group’s primary using the `group_replication_enable_member_action` and `group_replication_disable_member_action` functions. The member actions configuration, consisting of all the member actions and whether they are enabled or disabled, is then propagated to other group members and joining members using Group Replication’s group messages. This means that the group members will all act in the same way when they are in the specified situation, and you only need to use the function on the primary.

The functions can also be used on a server that is not part of a group, as long as the Group Replication plugin is installed. In that case, the member actions configuration is not propagated to any other servers.

The `group_replication_reset_member_actions` function can only be used on a server that is not part of a group. It resets the member actions configuration to the default settings, and resets its version number. The server must be writeable (with the `read_only` system variable set to `OFF`) and have the Group Replication plugin installed.

The available member actions are as follows:

- **mysql_disable_super_read_only_if_primary**
  - This member action is taken after a member is elected as the group’s primary, which is the event `AFTER_PRIMARY_ELECTION`. The member action is enabled by default. You can disable it using the `group_replication_disable_member_action()` function, and re-enable it using `group_replication_enable_member_action()`.
  - When this member action is enabled and taken, super read-only mode is disabled on the primary, so that the primary becomes read-write and accepts updates from a replication source server and from clients. This is the normal situation.
  - When this member action is disabled and not taken, the primary remains in super read-only mode after election. In this state, it does not accept updates from any clients, even users who have the `CONNECTION_ADMIN` or `SUPER` privilege. It does continue to accept updates performed by replication threads. This setup means that when a group’s purpose is to provide a secondary backup to another group for disaster tolerance, you can ensure that the secondary group remains synchronized with the first.

- **mysql_start_failover_channels_if_primary**
  - This member action is taken after a member is elected as the group’s primary, which is the event `AFTER_PRIMARY_ELECTION`. The member action is enabled by default. You can disable it using the `group_replication_disable_member_action()` function, and re-enable it using `group_replication_enable_member_action()`.
  - When this member action is enabled, asynchronous connection failover for replicas is active for a replication channel on a Group Replication primary when you set `SOURCE_CONNECTION_AUTO_FAILOVER=1` in
the `CHANGE REPLICATION SOURCE TO` statement for the channel. When the feature is active and correctly configured, if the primary that is replicating goes offline or into an error state, the new primary starts replication on the same channel when it is elected. This is the normal situation. For instructions to configure the feature, see Section 17.4.9.2, “Asynchronous Connection Failover for Replicas”.

When this member action is disabled, asynchronous connection failover does not take place for the replicas. If the primary goes offline or into an error state, replication stops for the channel. Note that if there is more than one channel with `SOURCE_CONNECTION_AUTO_FAILOVER=1`, the member action covers all the channels, so they cannot be individually enabled and disabled by this method. Set `SOURCE_CONNECTION_AUTO_FAILOVER=0` to disable an individual channel.

For more information on member actions and how to view the member actions configuration, see Section 18.5.1.5, “Configuring Member Actions”.

- **group_replication_disable_member_action()**

  Disable a member action so that the member does not take it in the specified situation. If the server where you use the function is part of a group, it must be the current primary in a group in single-primary mode, and it must be part of the majority. The changed setting is propagated to other group members and joining members, so they will all act in the same way when they are in the specified situation, and you only need to use the function on the primary.

  Syntax:

  ```
  STRING group_replication_disable_member_action(name, event)
  ```

  Arguments:

  - **name**: The name of the member action to disable.
  - **event**: The event that triggers the member action.

  Return value:

  A string containing the result of the operation, for example whether it was successful or not.

  Example:

  ```
  SELECT group_replication_disable_member_action("mysql_disable_super_read_only_if_primary", "AFTER_PRIMARY_ELECTION");
  ```

  For more information, see Section 18.5.1.5, “Configuring Member Actions”.

- **group_replication_enable_member_action()**

  Enable a member action for the member to take in the specified situation. If the server where you use the function is part of a group, it must be the current primary in a group in single-primary mode, and it must be part of the majority. The changed setting is propagated to other group members and joining members, so they will all act in the same way when they are in the specified situation, and you only need to use the function on the primary.

  Syntax:

  ```
  STRING group_replication_enable_member_action(name, event)
  ```

  Arguments:

  - **name**: The name of the member action to enable.
  - **event**: The event that triggers the member action.

  Return value:

  A string containing the result of the operation, for example whether it was successful or not.
Arguments:

- **name**: The name of the member action to enable.
- **event**: The event that triggers the member action.

Return value:

A string containing the result of the operation, for example whether it was successful or not.

Example:

```
SELECT group_replication_enable_member_action("mysql_disable_super_read_only_if_primary", "AFTER_PRIMARY_ELECTION");
```

For more information, see Section 18.5.1.5, “Configuring Member Actions”.

- **group_replication_reset_member_actions()**

Reset the member actions configuration to the default settings, and reset its version number to 1.

The `group_replication_reset_member_actions()` function can only be used on a server that is not currently part of a group. The server must be writeable (with the `read_only` system variable set to `OFF`) and have the Group Replication plugin installed. You can use this function to remove the member actions configuration that a server used when it was part of a group, if you intend to use it as a standalone server with no member actions or different member actions.

Syntax:

```
STRING group_replication_reset_member_actions()
```

Arguments:

None.

Return value:

A string containing the result of the operation, for example whether it was successful or not.

Example:

```
SELECT group_replication_reset_member_actions();
```

For more information, see Section 18.5.1.5, “Configuring Member Actions”.

### 12.18.2 Functions Used with Global Transaction Identifiers (GTIDs)

The functions described in this section are used with GTID-based replication. It is important to keep in mind that all of these functions take string representations of GTID sets as arguments. As such, the GTID sets must always be quoted when used with them. See GTID Sets for more information.

The union of two GTID sets is simply their representations as strings, joined together with an interposed comma. In other words, you can define a very simple function for obtaining the union of two GTID sets, similar to that created here:

```
CREATE FUNCTION GTID_UNION(g1 TEXT, g2 TEXT)
    RETURNS TEXT DETERMINISTIC
    RETURN CONCAT(g1,',',g2);
```
Functions Used with Global Transaction Identifiers (GTIDs)

For more information about GTIDs and how these GTID functions are used in practice, see Section 17.1.3, “Replication with Global Transaction Identifiers”.

Table 12.26 GTID Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WAIT_FOR_EXECUTED_GTID_SET()</td>
<td>Wait until the given GTIDs have executed on the replica.</td>
</tr>
</tbody>
</table>

- **GTID_SUBSET(set1, set2)**

  Given two sets of global transaction identifiers `set1` and `set2`, returns true if all GTIDs in `set1` are also in `set2`. Returns **NULL** if `set1` or `set2` is **NULL**. Returns false otherwise.

  The GTID sets used with this function are represented as strings, as shown in the following examples:

  ```
  mysql> SELECT GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23-25',
                           '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57')
  *************************** 1. row ***************************
  GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23-25',
              '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57'): 1
  1 row in set (0.00 sec)
  mysql> SELECT GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25',
                           '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57')
  *************************** 1. row ***************************
  GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25',
              '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57'): 0
  1 row in set (0.00 sec)
  ```

- **GTID_SUBTRACT(set1, set2)**

  Given two sets of global transaction identifiers `set1` and `set2`, returns only those GTIDs from `set1` that are not in `set2`. Returns **NULL** if `set1` or `set2` is **NULL**.

  All GTID sets used with this function are represented as strings and must be quoted, as shown in these examples:

  ```
  mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
                              '3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25')
  *************************** 1. row ***************************
  GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
  1 row in set (0.00 sec)
  mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
                              '3E11FA47-71CA-11E1-9E33-C80AA9429562:23-24')
  *************************** 1. row ***************************
  GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
  1 row in set (0.00 sec)
  ```
Subtracting a GTID set from itself produces an empty set, as shown here:

```sql
mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
                      '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57');
```

• `WAIT_FOR_EXECUTED_GTID_SET(gtid_set[, timeout])`

Wait until the server has applied all of the transactions whose global transaction identifiers are contained in `gtid_set`; that is, until the condition GTID_SUBSET(`gtid_subset`, @@GLOBAL.gtid_executed) holds. See Section 17.1.3.1, “GTID Format and Storage” for a definition of GTID sets.

If a timeout is specified, and `timeout` seconds elapse before all of the transactions in the GTID set have been applied, the function stops waiting. `timeout` is optional, and the default timeout is 0 seconds, in which case the function always waits until all of the transactions in the GTID set have been applied. `timeout` must be greater than or equal to 0; when running in strict SQL mode, a negative `timeout` value is immediately rejected with an error (ER_WRONG_ARGUMENTS); otherwise the function returns NULL, and raises a warning.

`WAIT_FOR_EXECUTED_GTID_SET()` monitors all the GTIDs that are applied on the server, including transactions that arrive from all replication channels and user clients. It does not take into account whether replication channels have been started or stopped.

For more information, see Section 17.1.3, “Replication with Global Transaction Identifiers”.

GTID sets used with this function are represented as strings and so must be quoted as shown in the following example:

```sql
mysql> SELECT WAIT_FOR_EXECUTED_GTID_SET('3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5');
```

For a syntax description for GTID sets, see Section 17.1.3.1, “GTID Format and Storage”.

For `WAIT_FOR_EXECUTED_GTID_SET()`, the return value is the state of the query, where 0 represents success, and 1 represents timeout. Any other failures generate an error.

`gtid_mode` cannot be changed to OFF while any client is using this function to wait for GTIDs to be applied.

### 12.18.3 Asynchronous Replication Channel Failover Functions

The following functions enable you to add or remove replication source servers to or from the source list for a replication channel, as well as clear the source list for a given server.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>asynchronous_connection_failover_add_managed()</code></td>
<td>Add group member source server configuration information to a replication channel source list</td>
</tr>
<tr>
<td><code>asynchronous_connection_failover_add_source()</code></td>
<td>Add source server configuration information to a replication channel source list</td>
</tr>
</tbody>
</table>
Asynchronous Replication Channel Failover Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>asynchronous_connection_failover_delete</td>
<td>Remove a managed group from a replication channel source list</td>
</tr>
<tr>
<td>asynchronous_connection_failover_delete</td>
<td>Remove a source server from a replication channel source list</td>
</tr>
<tr>
<td>asynchronous_connection_failover_reset</td>
<td>Remove all settings relating to group replication asynchronous failover</td>
</tr>
</tbody>
</table>

The asynchronous connection failover mechanism automatically establishes an asynchronous (source to replica) replication connection to a new source from the appropriate list after the existing connection from the replica to its source fails. The connection is also changed if the currently connected source does not have the highest weighted priority in the group. For Group Replication source servers that are defined as part of a managed group, the connection is also failed over to another group member if the currently connected source leaves the group or is no longer in the majority. For more information on the mechanism, see Section 17.4.9, “Switching Sources and Replicas with Asynchronous Connection Failover”.

Source lists are stored in the `mysql.replication_asynchronous_connection_failover` and `mysql.replication_asynchronous_connection_failover_managed` tables, and can be viewed in the Performance Schema `replication_asynchronous_connection_failover` table.

If the replication channel is on a Group Replication primary for a group where failover between replicas is active, the source list is broadcast to all the group members when they join or when it is updated by any method. Failover between replicas is controlled by the `mysql_start_failover_channels_if_primary` member action, which is enabled by default, and can be disabled using the `group_replication_disable_member_action` function.

- **asynchronous_connection_failover_add_managed()**

  Add configuration information for a replication source server that is part of a managed group (a Group Replication group member) to the source list for a replication channel. You only need to add one group member. The replica automatically adds the rest from the current group membership, then keeps the source list updated in line with membership change.

  **Syntax:**

  ```
  asynchronous_connection_failover_add_managed(channel, managed_type, managed_name, host, port, network_namespace)
  ```

  **Arguments:**

  - **channel**: The replication channel for which this replication source server is part of the source list.
  - **managed_type**: The type of managed service that the asynchronous connection failover mechanism must provide for this server. The only value currently accepted is `GroupReplication`.
  - **managed_name**: The identifier for the managed group that the server is a part of. For the `GroupReplication` managed service, the identifier is the value of the `group_replication_group_name` system variable.
  - **host**: The host name for this replication source server.
  - **port**: The port number for this replication source server.
  - **network_namespace**: The network namespace for this replication source server. Specify an empty string, as this parameter is reserved for future use.
Asynchronous Replication Channel Failover Functions

• **primary_weight**: The priority of this replication source server in the replication channel's source list when it is acting as the primary for the managed group. The weight is from 1 to 100, with 100 being the highest. For the primary, 80 is a suitable weight. The asynchronous connection failover mechanism activates if the currently connected source is not the highest weighted in the group. Assuming that you set up the managed group to give a higher weight to a primary and a lower weight to a secondary, when the primary changes, its weight increases, and the replica changes over the connection to it.

• **secondary_weight**: The priority of this replication source server in the replication channel's source list when it is acting as a secondary in the managed group. The weight is from 1 to 100, with 100 being the highest. For a secondary, 60 is a suitable weight.

Return value:

A string containing the result of the operation, for example whether it was successful or not.

Example:

```sql
SELECT asynchronous_connection_failover_add_managed('channel2', 'GroupReplication', 'aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa', '127.0.0.1', 3310, '', 80, 60);
```

```plaintext
+----------------------------------------------------------------------------------------------------------------------------------------------------+
| asynchronous_connection_failover_add_managed('channel2', 'GroupReplication', 'aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa', '127.0.0.1', 3310, '', 80, 60) |
+----------------------------------------------------------------------------------------------------------------------------------------------------+
| Source managed configuration details successfully inserted.                                                                                  |
+----------------------------------------------------------------------------------------------------------------------------------------------------+
```

For more information, see Section 17.4.9, “Switching Sources and Replicas with Asynchronous Connection Failover”.

• **asynchronous_connection_failover_add_source()**

Add configuration information for a replication source server to the source list for a replication channel.

Syntax:

```sql
asynchronous_connection_failover_add_source(channel, host, port, network_namespace, weight)
```

Arguments:

• **channel**: The replication channel for which this replication source server is part of the source list.

• **host**: The host name for this replication source server.

• **port**: The port number for this replication source server.

• **network_namespace**: The network namespace for this replication source server. Specify an empty string, as this parameter is reserved for future use.

• **weight**: The priority of this replication source server in the replication channel's source list. The priority is from 1 to 100, with 100 being the highest, and 50 being the default. When the asynchronous connection failover mechanism activates, the source with the highest priority setting among the alternative sources listed in the source list for the channel is chosen for the first connection attempt. If this attempt does not work, the replica tries with all the listed sources in descending order of priority, then starts again from the highest priority source. If multiple sources have the same priority, the replica
orders them randomly. The asynchronous connection failover mechanism activates if the source currently connected is not the highest weighted in the group.

Return value:

A string containing the result of the operation, for example whether it was successful or not.

Example:

```
SELECT asynchronous_connection_failover_add_source('channel2', '127.0.0.1', 3310, '', 80);
```

For more information, see Section 17.4.9, “Switching Sources and Replicas with Asynchronous Connection Failover”.

- **asynchronous_connection_failover_delete_managed()**

Remove an entire managed group from the source list for a replication channel. When you use this function, all the replication source servers defined in the managed group are removed from the channel’s source list.

Syntax:

```
asynchronous_connection_failover_delete_managed(channel, managed_name)
```

Arguments:

- **channel**: The replication channel for which this replication source server was part of the source list.

- **managed_name**: The identifier for the managed group that the server is a part of.
  For the GroupReplication managed service, the identifier is the value of the `group_replication_group_name` system variable.

Return value:

A string containing the result of the operation, for example whether it was successful or not.

Example:

```
SELECT asynchronous_connection_failover_delete_managed('channel2', 'aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa');
```

For more information, see Section 17.4.9, “Switching Sources and Replicas with Asynchronous Connection Failover”.

2532
• **asynchronous_connection_failover_delete_source()**

Remove configuration information for a replication source server from the source list for a replication channel.

Syntax:

```sql
asynchronous_connection_failover_delete_source(channel, host, port, network_namespace)
```

Arguments:

- **channel**: The replication channel for which this replication source server was part of the source list.
- **host**: The host name for this replication source server.
- **port**: The port number for this replication source server.
- **network_namespace**: The network namespace for this replication source server. Specify an empty string, as this parameter is reserved for future use.

Return value:

A string containing the result of the operation, for example whether it was successful or not.

Example:

```sql
SELECT asynchronous_connection_failover_delete_source('channel2', '127.0.0.1', 3310, ' ');
```

```
| asynchronous_connection_failover_delete_source('channel2', '127.0.0.1', 3310, ' ') |
| Source configuration details successfully deleted. |
```

For more information, see Section 17.4.9, “Switching Sources and Replicas with Asynchronous Connection Failover”. 

• **asynchronous_connection_failover_reset()**

Remove all settings relating to the asynchronous connection failover mechanism. The function clears the Performance Schema tables `replication_asynchronous_connection_failover` and `replication_asynchronous_connection_failover Managed`.

`asynchronous_connection_failover_reset()` can be used only on a server that is not currently part of a group, and that does not have any replication channels running. You can use this function to clean up a server that is no longer being used in a managed group.

**Syntax:**

```sql
STRING asynchronous_connection_failover_reset()
```

**Arguments:**

None.

**Return value:**

A string containing the result of the operation, for example whether it was successful or not.

**Example:**

```sql
mysql> SELECT asynchronous_connection_failover_reset();
+-------------------------------------------------------------------------+
| asynchronous_connection_failover_reset()                                |
| The UDF asynchronous_connection_failover_reset() executed successfully.  |
+-------------------------------------------------------------------------+
1 row in set (0.00 sec)
```

For more information, see Section 17.4.9, “Switching Sources and Replicas with Asynchronous Connection Failover”.

### 12.18.4 Position-Based Synchronization Functions

The functions listed in this section are used for controlling position-based synchronization of source and replica servers in MySQL Replication.

**Table 12.28 Positional Synchronization Functions**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Deprecated</th>
</tr>
</thead>
<tbody>
<tr>
<td>MASTER_POS_WAIT()</td>
<td>Block until the replica has read and applied all updates up to the specified position</td>
<td>Yes</td>
</tr>
<tr>
<td>SOURCE_POS_WAIT()</td>
<td>Block until the replica has read and applied all updates up to the specified position</td>
<td></td>
</tr>
</tbody>
</table>

• **MASTER_POS_WAIT(log_name, log_pos[, timeout][, channel])**

Depreciated alias for `SOURCE_POS_WAIT()`.

• **SOURCE_POS_WAIT(log_name, log_pos[, timeout][, channel])**

This function is for control of source-replica synchronization. It blocks until the replica has read and applied all updates up to the specified position in the source's binary log.
The return value is the number of log events the replica had to wait for to advance to the specified position. The function returns NULL if the replication SQL thread is not started, the replica's source information is not initialized, the arguments are incorrect, or an error occurs. It returns -1 if the timeout has been exceeded. If the replication SQL thread stops while SOURCE_POS_WAIT() is waiting, the function returns NULL. If the replica is past the specified position, the function returns immediately.

If the binary log file position has been marked as invalid, the function waits until a valid file position is known. The binary log file position can be marked as invalid when the CHANGE REPLICATION SOURCE TO option GTID_ONLY is set for the replication channel, and the server is restarted or replication is stopped. The file position becomes valid after a transaction is successfully applied past the given file position. If the applier does not reach the stated position, the function waits until the timeout. Use a SHOW REPLICA STATUS statement to check if the binary log file position has been marked as invalid.

On a multithreaded replica, the function waits until expiry of the limit set by the replica_checkpoint_group or replica_checkpoint_period system variable, when the checkpoint operation is called to update the status of the replica. Depending on the setting for the system variables, the function might therefore return some time after the specified position was reached.

If binary log transaction compression is in use and the transaction payload at the specified position is compressed (as a Transaction_payload_event), the function waits until the whole transaction has been read and applied, and the positions have updated.

If a timeout value is specified, SOURCE_POS_WAIT() stops waiting when timeout seconds have elapsed. timeout must be greater than or equal to 0. (When the server is running in strict SQL mode, a negative timeout value is immediately rejected with ER_WRONG_ARGUMENTS; otherwise the function returns NULL, and raises a warning.)

The optional channel value enables you to name which replication channel the function applies to. See Section 17.2.2, “Replication Channels” for more information.

This function is unsafe for statement-based replication. A warning is logged if you use this function when binlog_format is set to STATEMENT.

### 12.19 Aggregate Functions

Aggregate functions operate on sets of values. They are often used with a GROUP BY clause to group values into subsets. This section describes most aggregate functions. For information about aggregate functions that operate on geometry values, see Section 12.16.12, “Spatial Aggregate Functions”.

#### 12.19.1 Aggregate Function Descriptions

This section describes aggregate functions that operate on sets of values. They are often used with a GROUP BY clause to group values into subsets.

**Table 12.29 Aggregate Functions**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AVG()</td>
<td>Return the average value of the argument</td>
</tr>
<tr>
<td>BIT_AND()</td>
<td>Return bitwise AND</td>
</tr>
<tr>
<td>BIT_OR()</td>
<td>Return bitwise OR</td>
</tr>
<tr>
<td>BIT_XOR()</td>
<td>Return bitwise XOR</td>
</tr>
</tbody>
</table>
## Aggregate Function Descriptions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COUNT()</td>
<td>Return a count of the number of rows returned</td>
</tr>
<tr>
<td>COUNT(DISTINCT)</td>
<td>Return the count of a number of different values</td>
</tr>
<tr>
<td>GROUP_CONCAT()</td>
<td>Return a concatenated string</td>
</tr>
<tr>
<td>JSON_ARRAYAGG()</td>
<td>Return result set as a single JSON array</td>
</tr>
<tr>
<td>JSON_OBJECTAGG()</td>
<td>Return result set as a single JSON object</td>
</tr>
<tr>
<td>MAX()</td>
<td>Return the maximum value</td>
</tr>
<tr>
<td>MIN()</td>
<td>Return the minimum value</td>
</tr>
<tr>
<td>STD()</td>
<td>Return the population standard deviation</td>
</tr>
<tr>
<td>STDDEV()</td>
<td>Return the population standard deviation</td>
</tr>
<tr>
<td>STDDEV_POP()</td>
<td>Return the population standard deviation</td>
</tr>
<tr>
<td>STDDEV_SAMP()</td>
<td>Return the sample standard deviation</td>
</tr>
<tr>
<td>SUM()</td>
<td>Return the sum</td>
</tr>
<tr>
<td>VAR_POP()</td>
<td>Return the population standard variance</td>
</tr>
<tr>
<td>VAR_SAMP()</td>
<td>Return the sample variance</td>
</tr>
<tr>
<td>VARIANCE()</td>
<td>Return the population standard variance</td>
</tr>
</tbody>
</table>

Unless otherwise stated, aggregate functions ignore NULL values.

If you use an aggregate function in a statement containing no GROUP BY clause, it is equivalent to grouping on all rows. For more information, see Section 12.19.3, “MySQL Handling of GROUP BY”.

Most aggregate functions can be used as window functions. Those that can be used this way are signified in their syntax description by [over_clause], representing an optional OVER clause. over_clause is described in Section 12.20.2, “Window Function Concepts and Syntax”, which also includes other information about window function usage.

For numeric arguments, the variance and standard deviation functions return a DOUBLE value. The SUM() and AVG() functions return a DECIMAL value for exact-value arguments (integer or DECIMAL), and a DOUBLE value for approximate-value arguments (FLOAT or DOUBLE).

The SUM() and AVG() aggregate functions do not work with temporal values. (They convert the values to numbers, losing everything after the first nonnumeric character.) To work around this problem, convert to numeric units, perform the aggregate operation, and convert back to a temporal value. Examples:

```sql
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

Functions such as SUM() or AVG() that expect a numeric argument cast the argument to a number if necessary. For SET or ENUM values, the cast operation causes the underlying numeric value to be used.

The BIT_AND(), BIT_OR(), and BIT_XOR() aggregate functions perform bit operations.

MySQL bit functions and operators permit binary string type arguments (BINARY, VARBINARY, and the BLOB types) and return a value of like type, which enables them to take arguments and produce return values larger than 64 bits. For discussion about argument evaluation and result types for bit operations, see the introductory discussion in Section 12.12, “Bit Functions and Operators”.

- `AVG([DISTINCT] expr) [over_clause]`
Returns the average value of \( expr \). The `DISTINCT` option can be used to return the average of the distinct values of \( expr \).

If there are no matching rows, `AVG()` returns `NULL`. The function also returns `NULL` if \( expr \) is `NULL`.

This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.20.2, “Window Function Concepts and Syntax”; it cannot be used with `DISTINCT`.

```
mysql> SELECT student_name, AVG(test_score)
    FROM student
    GROUP BY student_name;
```

• `BIT_AND(expr) [over_clause]`

Returns the bitwise `AND` of all bits in \( expr \).

The result type depends on whether the function argument values are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the argument values have a binary string type, and the argument is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument value conversion to unsigned 64-bit integers as necessary.

- Binary-string evaluation produces a binary string of the same length as the argument values. If argument values have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. If the argument size exceeds 511 bytes, an `ER_INVALID_BITWISE_AGGREGATE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

If there are no matching rows, `BIT_AND()` returns a neutral value (all bits set to 1) having the same length as the argument values.

`NULL` values do not affect the result unless all values are `NULL`. In that case, the result is a neutral value having the same length as the argument values.

For more information discussion about argument evaluation and result types, see the introductory discussion in Section 12.12, “Bit Functions and Operators”.

If `BIT_AND()` is invoked from within the `mysql` client, binary string results display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.20.2, “Window Function Concepts and Syntax”.

• `BIT_OR(expr) [over_clause]`

Returns the bitwise `OR` of all bits in \( expr \).

The result type depends on whether the function argument values are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the argument values have a binary string type, and the argument is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument value conversion to unsigned 64-bit integers as necessary.

- Binary-string evaluation produces a binary string of the same length as the argument values. If argument values have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs.
If the argument size exceeds 511 bytes, an `ER_INVALID_BITWISE_AGGREGATE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

If there are no matching rows, `BIT_OR()` returns a neutral value (all bits set to 0) having the same length as the argument values.

`NULL` values do not affect the result unless all values are `NULL`. In that case, the result is a neutral value having the same length as the argument values.

For more information discussion about argument evaluation and result types, see the introductory discussion in Section 12.12, “Bit Functions and Operators”.

If `BIT_OR()` is invoked from within the `mysql` client, binary string results display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.20.2, “Window Function Concepts and Syntax”.

- `BIT_XOR(expr) [over_clause]`

Returns the bitwise XOR of all bits in `expr`.

The result type depends on whether the function argument values are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the argument values have a binary string type, and the argument is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument value conversion to unsigned 64-bit integers as necessary.

- Binary-string evaluation produces a binary string of the same length as the argument values. If argument values have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. If the argument size exceeds 511 bytes, an `ER_INVALID_BITWISE_AGGREGATE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

If there are no matching rows, `BIT_XOR()` returns a neutral value (all bits set to 0) having the same length as the argument values.

`NULL` values do not affect the result unless all values are `NULL`. In that case, the result is a neutral value having the same length as the argument values.

For more information discussion about argument evaluation and result types, see the introductory discussion in Section 12.12, “Bit Functions and Operators”.

If `BIT_XOR()` is invoked from within the `mysql` client, binary string results display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.20.2, “Window Function Concepts and Syntax”.

- `COUNT(expr) [over_clause]`

Returns a count of the number of non-`NULL` values of `expr` in the rows retrieved by a `SELECT` statement. The result is a `BIGINT` value.

If there are no matching rows, `COUNT()` returns 0. `COUNT(NULL)` returns 0.
Aggregate Function Descriptions

This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.20.2, “Window Function Concepts and Syntax”.

```
mysql> SELECT student.student_name,COUNT(*)
    FROM student,course
    WHERE student.student_id=course.student_id
    GROUP BY student_name;
```

`COUNT(*)` is somewhat different in that it returns a count of the number of rows retrieved, whether or not they contain `NULL` values.

For transactional storage engines such as **InnoDB**, storing an exact row count is problematic. Multiple transactions may be occurring at the same time, each of which may affect the count.

**InnoDB** does not keep an internal count of rows in a table because concurrent transactions might “see” different numbers of rows at the same time. Consequently, `SELECT COUNT(*)` statements only count rows visible to the current transaction.

```
SELECT COUNT(*) FROM tbl_name
```

query performance for **InnoDB** tables is optimized for single-threaded workloads if there are no extra clauses such as `WHERE` or `GROUP BY`.

**InnoDB** processes `SELECT COUNT(*)` statements by traversing the smallest available secondary index unless an index or optimizer hint directs the optimizer to use a different index. If a secondary index is not present, **InnoDB** processes `SELECT COUNT(*)` statements by scanning the clustered index.

Processing of `SELECT COUNT(*)` statements takes some time if index records are not entirely in the buffer pool. For a faster count, create a counter table and let your application update it according to the inserts and deletes it does. However, this method may not scale well in situations where thousands of concurrent transactions are initiating updates to the same counter table. If an approximate row count is sufficient, use `SHOW TABLE STATUS`.

**InnoDB** handles `SELECT COUNT(*)` and `SELECT COUNT(1)` operations in the same way. There is no performance difference.

For **MyISAM** tables, `COUNT(*)` is optimized to return very quickly if the `SELECT` retrieves from one table, no other columns are retrieved, and there is no `WHERE` clause. For example:

```
mysql> SELECT COUNT(*) FROM student;
```

This optimization only applies to **MyISAM** tables, because an exact row count is stored for this storage engine and can be accessed very quickly. `COUNT(1)` is only subject to the same optimization if the first column is defined as `NOT NULL`.

- `COUNT(DISTINCT expr,[expr...])`

Returns a count of the number of rows with different non-`NULL` `expr` values.

If there are no matching rows, `COUNT(DISTINCT)` returns 0.

```
mysql> SELECT COUNT(DISTINCT results) FROM student;
```

In MySQL, you can obtain the number of distinct expression combinations that do not contain `NULL` by giving a list of expressions. In standard SQL, you would have to do a concatenation of all expressions inside `COUNT(DISTINCT ...)`.
**GROUP_CONCAT(expr)**

This function returns a string result with the concatenated non-**NULL** values from a group. It returns **NULL** if there are no non-**NULL** values. The full syntax is as follows:

```
GROUP_CONCAT([DISTINCT] expr [, expr ...]
  [ORDER BY {unsigned_integer | col_name | expr}
    [ASC | DESC] [, col_name ...]]
  [SEPARATOR str_val])
```

```
mysql> SELECT student_name,
      GROUP_CONCAT(test_score)
FROM student
GROUP BY student_name;
```

Or:

```
mysql> SELECT student_name,
      GROUP_CONCAT(DISTINCT test_score
                   ORDER BY test_score DESC SEPARATOR ' ')
FROM student
GROUP BY student_name;
```

In MySQL, you can get the concatenated values of expression combinations. To eliminate duplicate values, use the **DISTINCT** clause. To sort values in the result, use the **ORDER BY** clause. To sort in reverse order, add the **DESC** (descending) keyword to the name of the column you are sorting by in the **ORDER BY** clause. The default is ascending order; this may be specified explicitly using the **ASC** keyword. The default separator between values in a group is comma (,). To specify a separator explicitly, use **SEPARATOR** followed by the string literal value that should be inserted between group values. To eliminate the separator altogether, specify **SEPARATOR ''**.

The result is truncated to the maximum length that is given by the **group_concat_max_len** system variable, which has a default value of 1024. The value can be set higher, although the effective maximum length of the return value is constrained by the value of **max_allowed_packet**. The syntax to change the value of **group_concat_max_len** at runtime is as follows, where *val* is an unsigned integer:

```
SET [GLOBAL | SESSION] group_concat_max_len = val;
```

The return value is a nonbinary or binary string, depending on whether the arguments are nonbinary or binary strings. The result type is **TEXT** or **BLOB** unless **group_concat_max_len** is less than or equal to 512, in which case the result type is **VARCHAR** or **VARBINARY**.

If **GROUP_CONCAT()** is invoked from within the **mysql** client, binary string results display using hexadecimal notation, depending on the value of the **--binary-as-hex**. For more information about that option, see Section 4.5.1, "mysql — The MySQL Command-Line Client".

See also **CONCAT()** and **CONCAT_WS()**: Section 12.8, “String Functions and Operators”.

**JSON_ARRAYAGG(col_or_expr) [over_clause]**

Aggregates a result set as a single **JSON** array whose elements consist of the rows. The order of elements in this array is undefined. The function acts on a column or an expression that evaluates to a
Aggregate Function Descriptions

single value. Returns NULL if the result contains no rows, or in the event of an error. If `col_or_expr` is NULL, the function returns an array of JSON [null] elements.

This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.20.2, “Window Function Concepts and Syntax”.

mysql> SELECT o_id, attribute, value FROM t3;
+-----+--------+-------+
| o_id| attribute | value |
|-----|----------+-------|
| 2   | color    | red   |
| 2   | fabric   | silk  |
| 3   | color    | green |
| 3   | shape    | square|
+-----+--------+-------+
4 rows in set (0.00 sec)

mysql> SELECT o_id, JSON_ARRAYAGG(attribute) AS attributes FROM t3 GROUP BY o_id;
+-----+---------------------+
<table>
<thead>
<tr>
<th>o_id</th>
<th>attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>[&quot;color&quot;, &quot;fabric&quot;]</td>
</tr>
<tr>
<td>3</td>
<td>[&quot;color&quot;, &quot;shape&quot;]</td>
</tr>
</tbody>
</table>
+-----+---------------------+
2 rows in set (0.00 sec)

• `JSON_OBJECTAGG(key, value) [over_clause]`

Takes two column names or expressions as arguments, the first of these being used as a key and the second as a value, and returns a JSON object containing key-value pairs. Returns NULL if the result contains no rows, or in the event of an error. An error occurs if any key name is NULL or the number of arguments is not equal to 2.

This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.20.2, “Window Function Concepts and Syntax”.

mysql> SELECT o_id, attribute, value FROM t3;
+-----+--------+-------+
| o_id| attribute | value |
|-----|----------+-------|
| 2   | color    | red   |
| 2   | fabric   | silk  |
| 3   | color    | green |
| 3   | shape    | square|
+-----+--------+-------+
4 rows in set (0.00 sec)

mysql> SELECT o_id, JSON_OBJECTAGG(attribute, value) AS attributes FROM t3 GROUP BY o_id;
+-----+---------------------------------------+
<table>
<thead>
<tr>
<th>o_id</th>
<th>JSON_OBJECTAGG(attribute, value)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>{&quot;color&quot;: &quot;red&quot;, &quot;fabric&quot;: &quot;silk&quot;}</td>
</tr>
<tr>
<td>3</td>
<td>{&quot;color&quot;: &quot;green&quot;, &quot;shape&quot;: &quot;square&quot;}</td>
</tr>
</tbody>
</table>
+-----+---------------------------------------+
2 rows in set (0.00 sec)

Duplicate key handling. When the result of this function is normalized, values having duplicate keys are discarded. In keeping with the MySQL `JSON` data type specification that does not permit duplicate keys, only the last value encountered is used with that key in the returned object (“last duplicate key
This means that the result of using this function on columns from a `SELECT` can depend on the order in which the rows are returned, which is not guaranteed.

When used as a window function, if there are duplicate keys within a frame, only the last value for the key is present in the result. The value for the key from the last row in the frame is deterministic if the `ORDER BY` specification guarantees that the values have a specific order. If not, the resulting value of the key is nondeterministic.

Consider the following:

```sql
mysql> CREATE TABLE t(c VARCHAR(10), i INT);
Query OK, 0 rows affected (0.33 sec)

mysql> INSERT INTO t VALUES ('key', 3), ('key', 4), ('key', 5);
Query OK, 3 rows affected (0.10 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT c, i FROM t;
+------+------+
| c    | i    |
+------+------+
| key  | 3    |
| key  | 4    |
| key  | 5    |
+------+------+
3 rows in set (0.00 sec)

mysql> SELECT JSON_OBJECTAGG(c, i) FROM t;
+----------------------+
| JSON_OBJECTAGG(c, i) |
+----------------------+
| {"key": 5}          |
+----------------------+
1 row in set (0.00 sec)

mysql> DELETE FROM t;
Query OK, 3 rows affected (0.08 sec)

mysql> INSERT INTO t VALUES ('key', 3), ('key', 5), ('key', 4);
Query OK, 3 rows affected (0.06 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT c, i FROM t;
+------+------+
| c    | i    |
+------+------+
| key  | 3    |
| key  | 5    |
| key  | 4    |
+------+------+
3 rows in set (0.00 sec)

mysql> SELECT JSON_OBJECTAGG(c, i) FROM t;
+----------------------+
| JSON_OBJECTAGG(c, i) |
+----------------------+
| {"key": 4}          |
+----------------------+
1 row in set (0.00 sec)
```

The key chosen from the last query is nondeterministic. If the query does not use `GROUP BY` (which usually imposes its own ordering regardless) and you prefer a particular key ordering, you can invoke `JSON_OBJECTAGG()` as a window function by including an `OVER` clause with an `ORDER BY` specification.
to impose a particular order on frame rows. The following examples show what happens with and without ORDER BY for a few different frame specifications.

Without ORDER BY, the frame is the entire partition:

```
mysql> SELECT JSON_OBJECTAGG(c, i) OVER () AS json_object FROM t;
+-------------+
<table>
<thead>
<tr>
<th>json_object</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;key&quot;: 4}</td>
</tr>
<tr>
<td>{&quot;key&quot;: 4}</td>
</tr>
<tr>
<td>{&quot;key&quot;: 4}</td>
</tr>
</tbody>
</table>
+-------------+
```

With ORDER BY, where the frame is the default of RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW (in both ascending and descending order):

```
mysql> SELECT JSON_OBJECTAGG(c, i) OVER (ORDER BY i) AS json_object FROM t;
+-------------+
<table>
<thead>
<tr>
<th>json_object</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;key&quot;: 3}</td>
</tr>
<tr>
<td>{&quot;key&quot;: 4}</td>
</tr>
<tr>
<td>{&quot;key&quot;: 5}</td>
</tr>
</tbody>
</table>
+-------------+
```

```
mysql> SELECT JSON_OBJECTAGG(c, i) OVER (ORDER BY i DESC) AS json_object FROM t;
+-------------+
<table>
<thead>
<tr>
<th>json_object</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;key&quot;: 5}</td>
</tr>
<tr>
<td>{&quot;key&quot;: 4}</td>
</tr>
<tr>
<td>{&quot;key&quot;: 3}</td>
</tr>
</tbody>
</table>
+-------------+
```

With ORDER BY and an explicit frame of the entire partition:

```
mysql> SELECT JSON_OBJECTAGG(c, i) OVER (ORDER BY i
                   ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING) AS json_object FROM t;
+-------------+
<table>
<thead>
<tr>
<th>json_object</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;key&quot;: 5}</td>
</tr>
<tr>
<td>{&quot;key&quot;: 5}</td>
</tr>
<tr>
<td>{&quot;key&quot;: 5}</td>
</tr>
</tbody>
</table>
+-------------+
```

To return a particular key value (such as the smallest or largest), include a LIMIT clause in the appropriate query. For example:

```
mysql> SELECT JSON_OBJECTAGG(c, i) OVER (ORDER BY i) AS json_object FROM t LIMIT 1;
+-------------+
<table>
<thead>
<tr>
<th>json_object</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;key&quot;: 3}</td>
</tr>
</tbody>
</table>
+-------------+
```

```
mysql> SELECT JSON_OBJECTAGG(c, i) OVER (ORDER BY i DESC) AS json_object FROM t LIMIT 1;
+-------------+
<table>
<thead>
<tr>
<th>json_object</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;key&quot;: 5}</td>
</tr>
</tbody>
</table>
+-------------+
```
See Normalization, Merging, and Autowrapping of JSON Values, for additional information and examples.

**MAX([[DISTINCT] expr] [over_clause])**

Returns the maximum value of `expr`. `MAX()` may take a string argument; in such cases, it returns the maximum string value. See Section 8.3.1, “How MySQL Uses Indexes”. The `DISTINCT` keyword can be used to find the maximum of the distinct values of `expr`, however, this produces the same result as omitting `DISTINCT`.

If there are no matching rows, or if `expr` is `NULL`, `MAX()` returns `NULL`.

This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.20.2, “Window Function Concepts and Syntax”; it cannot be used with `DISTINCT`.

```sql
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
    FROM student
    GROUP BY student_name;
```

For `MAX()`, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string's relative position in the set. This differs from how `ORDER BY` compares them.

**MIN([[DISTINCT] expr] [over_clause])**

Returns the minimum value of `expr`. `MIN()` may take a string argument; in such cases, it returns the minimum string value. See Section 8.3.1, “How MySQL Uses Indexes”. The `DISTINCT` keyword can be used to find the minimum of the distinct values of `expr`, however, this produces the same result as omitting `DISTINCT`.

If there are no matching rows, or if `expr` is `NULL`, `MIN()` returns `NULL`.

This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.20.2, “Window Function Concepts and Syntax”; it cannot be used with `DISTINCT`.

```sql
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
    FROM student
    GROUP BY student_name;
```

For `MIN()`, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string's relative position in the set. This differs from how `ORDER BY` compares them.

**STD(expr) [over_clause]**

Returns the population standard deviation of `expr`. `STD()` is a synonym for the standard SQL function `STDDEV_POP()`, provided as a MySQL extension.

If there are no matching rows, or if `expr` is `NULL`, `STD()` returns `NULL`.

This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.20.2, “Window Function Concepts and Syntax”.
• **STDDEV**(expr) [over_clause]

Returns the population standard deviation of expr. **STDDEV()** is a synonym for the standard SQL function **STDDEV_POP()**, provided for compatibility with Oracle.

If there are no matching rows, or if expr is NULL, **STDDEV()** returns NULL.

This function executes as a window function if over_clause is present. over_clause is as described in Section 12.20.2, “Window Function Concepts and Syntax”.

• **STDDEV_POP**(expr) [over_clause]

Returns the population standard deviation of expr (the square root of **VAR_POP()**). You can also use **STD()** or **STDDEV()**, which are equivalent but not standard SQL.

If there are no matching rows, or if expr is NULL, **STDDEV_POP()** returns NULL.

This function executes as a window function if over_clause is present. over_clause is as described in Section 12.20.2, “Window Function Concepts and Syntax”.

• **STDDEV_SAMP**(expr) [over_clause]

Returns the sample standard deviation of expr (the square root of **VAR_SAMP()**).

If there are no matching rows, or if expr is NULL, **STDDEV_SAMP()** returns NULL.

This function executes as a window function if over_clause is present. over_clause is as described in Section 12.20.2, “Window Function Concepts and Syntax”.

• **SUM([DISTINCT] expr) [over_clause]**

Returns the sum of expr. If the return set has no rows, **SUM()** returns NULL. The **DISTINCT** keyword can be used to sum only the distinct values of expr.

If there are no matching rows, or if expr is NULL, **SUM()** returns NULL.

This function executes as a window function if over_clause is present. over_clause is as described in Section 12.20.2, “Window Function Concepts and Syntax”; it cannot be used with **DISTINCT**.

• **VAR_POP**(expr) [over_clause]

Returns the population standard variance of expr. It considers rows as the whole population, not as a sample, so it has the number of rows as the denominator. You can also use **VARIANCE()**, which is equivalent but is not standard SQL.

If there are no matching rows, or if expr is NULL, **VAR_POP()** returns NULL.

This function executes as a window function if over_clause is present. over_clause is as described in Section 12.20.2, “Window Function Concepts and Syntax”.

• **VAR_SAMP**(expr) [over_clause]

Returns the sample variance of expr. That is, the denominator is the number of rows minus one.

If there are no matching rows, or if expr is NULL, **VAR_SAMP()** returns NULL.

This function executes as a window function if over_clause is present. over_clause is as described in Section 12.20.2, “Window Function Concepts and Syntax”. 

2545
• \( \text{VARIANCE}(\text{expr}) \ [\text{over\_clause}] \)

Returns the population standard variance of \( \text{expr} \). \( \text{VARIANCE()} \) is a synonym for the standard SQL function \( \text{VAR\_POP()} \), provided as a MySQL extension.

If there are no matching rows, or if \( \text{expr} \) is \text{NULL}, \( \text{VARIANCE()} \) returns \text{NULL}.

This function executes as a window function if \( \text{over\_clause} \) is present. \( \text{over\_clause} \) is as described in Section 12.20.2, “Window Function Concepts and Syntax”.

### 12.19.2 GROUP BY Modifiers

The \text{GROUP BY} clause permits a \text{WITH ROLLUP} modifier that causes summary output to include extra rows that represent higher-level (that is, super-aggregate) summary operations. \text{ROLLUP} thus enables you to answer questions at multiple levels of analysis with a single query. For example, \text{ROLLUP} can be used to provide support for OLAP (Online Analytical Processing) operations.

Suppose that a \text{sales} table has \text{year}, \text{country}, \text{product}, and \text{profit} columns for recording sales profitability:

```sql
CREATE TABLE sales
(
    year INT,
    country VARCHAR(20),
    product VARCHAR(32),
    profit INT
);
```

To summarize table contents per year, use a simple \text{GROUP BY} like this:

```sql
mysql> SELECT year, SUM(profit) AS profit
    FROM sales
    GROUP BY year;
```

<table>
<thead>
<tr>
<th>year</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>3010</td>
</tr>
</tbody>
</table>

The output shows the total (aggregate) profit for each year. To also determine the total profit summed over all years, you must add up the individual values yourself or run an additional query. Or you can use \text{ROLLUP}, which provides both levels of analysis with a single query. Adding a \text{WITH ROLLUP} modifier to the \text{GROUP BY} clause causes the query to produce another (super-aggregate) row that shows the grand total over all year values:

```sql
mysql> SELECT year, SUM(profit) AS profit
    FROM sales
    GROUP BY year WITH ROLLUP;
```

<table>
<thead>
<tr>
<th>year</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>3010</td>
</tr>
<tr>
<td>NULL</td>
<td>7535</td>
</tr>
</tbody>
</table>

The \text{NULL} value in the \text{year} column identifies the grand total super-aggregate line.

\text{ROLLUP} has a more complex effect when there are multiple \text{GROUP BY} columns. In this case, each time there is a change in value in any but the last grouping column, the query produces an extra super-aggregate summary row.
For example, without ROLLUP, a summary of the sales table based on year, country, and product might look like this, where the output indicates summary values only at the year/country/product level of analysis:

```
mysql> SELECT year, country, product, SUM(profit) AS profit
FROM sales
GROUP BY year, country, product;
```

```
+-----+---------+------------+--------+
| year | country | product    | profit |
|-----+---------+------------+--------+
| 2000 | Finland | Computer   |   1500 |
| 2000 | Finland | Phone      |    100 |
| 2000 | India   | Calculator |    150 |
| 2000 | India   | Computer   |  1200 |
| 2000 | USA     | Calculator |     75 |
| 2000 | USA     | Computer   |  1500 |
| 2001 | Finland | Phone      |     10 |
| 2001 | USA     | Calculator |     50 |
| 2001 | USA     | Computer   |  2700 |
| 2001 | USA     | TV         |    250 |
|-----+---------+------------+--------+
```

With ROLLUP added, the query produces several extra rows:

```
mysql> SELECT year, country, product, SUM(profit) AS profit
FROM sales
GROUP BY year, country, product WITH ROLLUP;
```

```
+-----+---------+------------+--------+
| year | country | product    | profit |
|-----+---------+------------+--------+
| 2000 | Finland | Computer   |   1500 |
| 2000 | Finland | Phone      |    100 |
| 2000 | Finland | NULL       |  1600 |
| 2000 | India   | Calculator |    150 |
| 2000 | India   | Computer   |  1200 |
| 2000 | India   | NULL       |  1350 |
| 2000 | USA     | Calculator |     75 |
| 2000 | USA     | Computer   |  1500 |
| 2000 | USA     | NULL       |  1575 |
| 2001 | Finland | Phone      |     10 |
| 2001 | Finland | NULL       |     10 |
| 2001 | USA     | Calculator |     50 |
| 2001 | USA     | Computer   |  2700 |
| 2001 | USA     | TV         |    250 |
| 2001 | USA     | NULL       |  3000 |
| 2001 | NULL    | NULL       |  3010 |
| NULL | NULL    | NULL       |  7535 |
|-----+---------+------------+--------+
```

Now the output includes summary information at four levels of analysis, not just one:

- Following each set of product rows for a given year and country, an extra super-aggregate summary row appears showing the total for all products. These rows have the product column set to NULL.
- Following each set of rows for a given year, an extra super-aggregate summary row appears showing the total for all countries and products. These rows have the country and products columns set to NULL.
- Finally, following all other rows, an extra super-aggregate summary row appears showing the grand total for all years, countries, and products. This row has the year, country, and products columns set to NULL.

The NULL indicators in each super-aggregate row are produced when the row is sent to the client. The server looks at the columns named in the GROUP BY clause following the leftmost one that has changed.
value. For any column in the result set with a name that matches any of those names, its value is set to `NULL`. (If you specify grouping columns by column position, the server identifies which columns to set to `NULL` by position.)

Because the `NULL` values in the super-aggregate rows are placed into the result set at such a late stage in query processing, you can test them as `NULL` values only in the select list or `HAVING` clause. You cannot test them as `NULL` values in join conditions or the `WHERE` clause to determine which rows to select. For example, you cannot add `WHERE product IS NULL` to the query to eliminate from the output all but the super-aggregate rows.

The `NULL` values do appear as `NULL` on the client side and can be tested as such using any MySQL client programming interface. However, at this point, you cannot distinguish whether a `NULL` represents a regular grouped value or a super-aggregate value. To test the distinction, use the `GROUPING()` function, described later.

For `GROUP BY ... WITH ROLLUP` queries, to test whether `NULL` values in the result represent super-aggregate values, the `GROUPING()` function is available for use in the select list, `HAVING` clause, and `ORDER BY` clause. For example, `GROUPING(year)` returns 1 when `NULL` in the `year` column occurs in a super-aggregate row, and 0 otherwise. Similarly, `GROUPING(country)` and `GROUPING(product)` return 1 for super-aggregate `NULL` values in the `country` and `product` columns, respectively:

```sql
mysql> SELECT
    -> year, country, product, SUM(profit) AS profit,
    -> GROUPING(year) AS grp_year,
    -> GROUPING(country) AS grp_country,
    -> GROUPING(product) AS grp_product
    -> FROM sales
    -> GROUP BY year, country, product WITH ROLLUP;
```

```
+------+---------+------------+--------+----------+-------------+-------------+
| year | country | product    | profit | grp_year | grp_country | grp_product |
+------+---------+------------+--------+----------+-------------+-------------+
| 2000 | Finland | Computer   |   1500 |        0 |           0 |           0 |
| 2000 | Finland | Phone      |    100 |        0 |           0 |           0 |
| 2000 | Finland | NULL       |   1600 |        0 |           0 |           1 |
| 2000 | India   | Calculator |   150  |        0 |           0 |           0 |
| 2000 | India   | Computer   |  1200  |        0 |           0 |           0 |
| 2000 | India   | NULL       |   1350 |        0 |           0 |           1 |
| 2000 | USA     | Calculator |    75  |        0 |           0 |           0 |
| 2000 | USA     | Computer   |  1500  |        0 |           0 |           0 |
| 2000 | USA     | NULL       |  1575  |        0 |           0 |           1 |
| 2000 | NULL    | NULL       |   4525 |        0 |           1 |           1 |
| 2001 | Finland | Phone      |    10  |        0 |           0 |           0 |
| 2001 | Finland | NULL       |    10  |        0 |           0 |           1 |
| 2001 | USA     | Calculator |    50  |        0 |           0 |           0 |
| 2001 | USA     | Computer   |  2700  |        0 |           0 |           0 |
| 2001 | USA     | TV         |   250  |        0 |           0 |           0 |
| 2001 | USA     | NULL       |  3000  |        0 |           0 |           1 |
| 2001 | NULL    | NULL       |  3010  |        0 |           1 |           1 |
| NULL | NULL    | NULL       |  7535  |        1 |           1 |           1 |
+------+---------+------------+--------+----------+-------------+-------------+
```

Instead of displaying the `GROUPING()` results directly, you can use `GROUPING()` to substitute labels for super-aggregate `NULL` values:

```sql
mysql> SELECT
    -> IF(GROUPING(year), 'All years', year) AS year,
    -> IF(GROUPING(country), 'All countries', country) AS country,
    -> IF(GROUPING(product), 'All products', product) AS product,
    -> SUM(profit) AS profit
    -> FROM sales
    -> GROUP BY year, country, product WITH ROLLUP;
```

```
+-----------+---------------+--------------+--------+
<table>
<thead>
<tr>

</tr>
</tbody>
</table>
+-----------+---------------+--------------+--------+
```
With multiple expression arguments, `GROUPING()` returns a result representing a bitmask that combines the results for each expression, with the lowest-order bit corresponding to the result for the rightmost expression. For example, `GROUPING(year, country, product)` is evaluated like this:

```
result for GROUPING(product)
+ result for GROUPING(country) << 1
+ result for GROUPING(year) << 2
```

The result of such a `GROUPING()` is nonzero if any of the expressions represents a super-aggregate `NULL`, so you can return only the super-aggregate rows and filter out the regular grouped rows like this:

```
mysql> SELECT year, country, product, SUM(profit) AS profit
    FROM sales
    GROUP BY year, country, product WITH ROLLUP
    HAVING GROUPING(year, country, product) <> 0;
```

The `sales` table contains no `NULL` values, so all `NULL` values in a `ROLLUP` result represent super-aggregate values. When the data set contains `NULL` values, `ROLLUP` summaries may contain `NULL` values not only in super-aggregate rows, but also in regular grouped rows. `GROUPING()` enables these to be distinguished. Suppose that table `t1` contains a simple data set with two grouping factors for a set of quantity values, where `NULL` indicates something like “other” or “unknown”:

```
mysql> SELECT * FROM t1;
```

The `sales` table contains no `NULL` values, so all `NULL` values in a `ROLLUP` result represent super-aggregate values. When the data set contains `NULL` values, `ROLLUP` summaries may contain `NULL` values not only in super-aggregate rows, but also in regular grouped rows. `GROUPING()` enables these to be distinguished. Suppose that table `t1` contains a simple data set with two grouping factors for a set of quantity values, where `NULL` indicates something like “other” or “unknown”:

```
mysql> SELECT * FROM t1;
```
A simple **ROLLUP** operation produces these results, in which it is not so easy to distinguish **NULL** values in super-aggregate rows from **NULL** values in regular grouped rows:

```sql
mysql> SELECT name, size, SUM(quantity) AS quantity
    FROM t1
    GROUP BY name, size WITH ROLLUP;
```

<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
<th>quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>ball</td>
<td>NULL</td>
<td>5</td>
</tr>
<tr>
<td>ball</td>
<td>large</td>
<td>20</td>
</tr>
<tr>
<td>ball</td>
<td>small</td>
<td>10</td>
</tr>
<tr>
<td>ball</td>
<td>NULL</td>
<td>35</td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>3</td>
</tr>
<tr>
<td>hoop</td>
<td>large</td>
<td>5</td>
</tr>
<tr>
<td>hoop</td>
<td>small</td>
<td>15</td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>23</td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
<td>58</td>
</tr>
</tbody>
</table>

Using **GROUPING()** to substitute labels for the super-aggregate **NULL** values makes the result easier to interpret:

```sql
mysql> SELECT
    IF(GROUPING(name) = 1, 'All items', name) AS name,
    IF(GROUPING(size) = 1, 'All sizes', size) AS size,
    SUM(quantity) AS quantity
    FROM t1
    GROUP BY name, size WITH ROLLUP;
```

<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
<th>quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>ball</td>
<td>NULL</td>
<td>5</td>
</tr>
<tr>
<td>ball</td>
<td>All sizes</td>
<td>35</td>
</tr>
<tr>
<td>ball</td>
<td>large</td>
<td>20</td>
</tr>
<tr>
<td>ball</td>
<td>All sizes</td>
<td>10</td>
</tr>
<tr>
<td>ball</td>
<td>small</td>
<td>35</td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>3</td>
</tr>
<tr>
<td>hoop</td>
<td>large</td>
<td>5</td>
</tr>
<tr>
<td>hoop</td>
<td>small</td>
<td>15</td>
</tr>
<tr>
<td>hoop</td>
<td>All sizes</td>
<td>23</td>
</tr>
<tr>
<td>All items</td>
<td>All sizes</td>
<td>58</td>
</tr>
</tbody>
</table>

**Other Considerations When using ROLLUP**

The following discussion lists some behaviors specific to the MySQL implementation of **ROLLUP**.

**ORDER BY** and **ROLLUP** can be used together, which enables the use of **ORDER BY** and **GROUPING()** to achieve a specific sort order of grouped results. For example:

```sql
mysql> SELECT year, SUM(profit) AS profit
    FROM sales
    GROUP BY year WITH ROLLUP
    ORDER BY GROUPING(year) DESC;
```

<table>
<thead>
<tr>
<th>year</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>7535</td>
</tr>
<tr>
<td>2000</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>3010</td>
</tr>
</tbody>
</table>
In both cases, the super-aggregate summary rows sort with the rows from which they are calculated, and their placement depends on sort order (at the end for ascending sort, at the beginning for descending sort).

`LIMIT` can be used to restrict the number of rows returned to the client. `LIMIT` is applied after `ROLLUP`, so the limit applies against the extra rows added by `ROLLUP`. For example:

```sql
mysql> SELECT year, country, product, SUM(profit) AS profit
    FROM sales
    GROUP BY year, country, product WITH ROLLUP
    LIMIT 5;
```

<table>
<thead>
<tr>
<th>year</th>
<th>country</th>
<th>product</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>Finland</td>
<td>Computer</td>
<td>1500</td>
</tr>
<tr>
<td>2000</td>
<td>Finland</td>
<td>Phone</td>
<td>100</td>
</tr>
<tr>
<td>2000</td>
<td>Finland</td>
<td>NULL</td>
<td>1600</td>
</tr>
<tr>
<td>2000</td>
<td>India</td>
<td>Calculator</td>
<td>150</td>
</tr>
<tr>
<td>2000</td>
<td>India</td>
<td>Computer</td>
<td>1200</td>
</tr>
</tbody>
</table>

Using `LIMIT` with `ROLLUP` may produce results that are more difficult to interpret, because there is less context for understanding the super-aggregate rows.

A MySQL extension permits a column that does not appear in the `GROUP BY` list to be named in the `select` list. (For information about nonaggregated columns and `GROUP BY`, see Section 12.19.3, "MySQL Handling of GROUP BY".) In this case, the server is free to choose any value from this nonaggregated column in summary rows, and this includes the extra rows added by `WITH ROLLUP`. For example, in the following query, `country` is a nonaggregated column that does not appear in the `GROUP BY` list and values chosen for this column are nondeterministic:

```sql
mysql> SELECT year, country, SUM(profit) AS profit
    FROM sales
    GROUP BY year WITH ROLLUP;
```

<table>
<thead>
<tr>
<th>year</th>
<th>country</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>India</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>3010</td>
</tr>
<tr>
<td>NULL</td>
<td>USA</td>
<td>7535</td>
</tr>
</tbody>
</table>

This behavior is permitted when the `ONLY_FULL_GROUP_BY` SQL mode is not enabled. If that mode is enabled, the server rejects the query as illegal because `country` is not listed in the `GROUP BY` clause. With `ONLY_FULL_GROUP_BY` enabled, you can still execute the query by using the `ANY_VALUE()` function for nondeterministic-value columns:

```sql
mysql> SELECT year, ANY_VALUE(country) AS country, SUM(profit) AS profit
    FROM sales
    GROUP BY year WITH ROLLUP;
```

<table>
<thead>
<tr>
<th>year</th>
<th>country</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>India</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>3010</td>
</tr>
<tr>
<td>NULL</td>
<td>USA</td>
<td>7535</td>
</tr>
</tbody>
</table>

A rollup column cannot be used as an argument to `MATCH()` (and is rejected with an error) except when called in a `WHERE` clause. See Section 12.9, "Full-Text Search Functions", for more information.

12.19.3 MySQL Handling of GROUP BY
SQL-92 and earlier does not permit queries for which the select list, \texttt{HAVING} condition, or \texttt{ORDER BY} list refer to nonaggregated columns that are not named in the \texttt{GROUP BY} clause. For example, this query is illegal in standard SQL-92 because the nonaggregated \texttt{name} column in the select list does not appear in the \texttt{GROUP BY}:

\begin{verbatim}
SELECT o.custid, c.name, MAX(o.payment)
FROM orders AS o, customers AS c
WHERE o.custid = c.custid
GROUP BY o.custid;
\end{verbatim}

For the query to be legal in SQL-92, the \texttt{name} column must be omitted from the select list or named in the \texttt{GROUP BY} clause.

SQL:1999 and later permits such nonaggregates per optional feature T301 if they are functionally dependent on \texttt{GROUP BY} columns: If such a relationship exists between \texttt{name} and \texttt{custid}, the query is legal. This would be the case, for example, were \texttt{custid} a primary key of \texttt{customers}.

MySQL implements detection of functional dependence. If the \texttt{ONLY_FULL_GROUP_BY} SQL mode is enabled (which it is by default), MySQL rejects queries for which the select list, \texttt{HAVING} condition, or \texttt{ORDER BY} list refer to nonaggregated columns that are neither named in the \texttt{GROUP BY} clause nor are functionally dependent on them.

MySQL also permits a nonaggregate column not named in a \texttt{GROUP BY} clause when SQL \texttt{ONLY_FULL_GROUP_BY} mode is enabled, provided that this column is limited to a single value, as shown in the following example:

\begin{verbatim}
mysql> CREATE TABLE mytable (
    -> id INT UNSIGNED NOT NULL PRIMARY KEY,
    -> a VARCHAR(10),
    -> b INT
    ->);
mysql> INSERT INTO mytable
    -> VALUES (1, 'abc', 1000),
    -> (2, 'abc', 2000),
    -> (3, 'def', 4000);
mysql> SET SESSION sql_mode = sys.list_add(@@session.sql_mode, 'ONLY_FULL_GROUP_BY');
mysql> SELECT a, SUM(b) FROM mytable WHERE a = 'abc';
+---------+--------+
| a       | SUM(b) |
+---------+--------+
| abc     | 3000   |
+---------+--------+
\end{verbatim}

It is also possible to have more than one nonaggregate column in the \texttt{SELECT} list when employing \texttt{ONLY_FULL_GROUP_BY}. In this case, every such column must be limited to a single value in the \texttt{WHERE} clause, and all such limiting conditions must be joined by logical \texttt{AND}, as shown here:

\begin{verbatim}
mysql> DROP TABLE IF EXISTS mytable;
mysql> CREATE TABLE mytable (
    -> id INT UNSIGNED NOT NULL PRIMARY KEY,
    -> a VARCHAR(10),
    -> b VARCHAR(10),
    -> c INT
    ->);
mysql> INSERT INTO mytable
    -> VALUES (1, 'abc', 'qrs', 1000),
    -> (2, 'abc', 'tuv', 2000),
    -> (3, 'def', 'qrs', 4000),
\end{verbatim}
MySQL Handling of GROUP BY

If **ONLY_FULL_GROUP_BY** is disabled, a MySQL extension to the standard SQL use of **GROUP BY** permits the select list, **HAVING** condition, or **ORDER BY** list to refer to nonaggregated columns even if the columns are not functionally dependent on **GROUP BY** columns. This causes MySQL to accept the preceding query. In this case, the server is free to choose any value from each group, so unless they are the same, the values chosen are nondeterministic, which is probably not what you want. Furthermore, the selection of values from each group cannot be influenced by adding an **ORDER BY** clause. Result set sorting occurs after values have been chosen, and **ORDER BY** does not affect which value within each group the server chooses. Disabling **ONLY_FULL_GROUP_BY** is useful primarily when you know that, due to some property of the data, all values in each nonaggregated column not named in the **GROUP BY** clause are the same for each group.

You can achieve the same effect without disabling **ONLY_FULL_GROUP_BY** by using **ANY_VALUE()** to refer to the nonaggregated column.

The following discussion demonstrates functional dependence, the error message MySQL produces when functional dependence is absent, and ways of causing MySQL to accept a query in the absence of functional dependence.

This query might be invalid with **ONLY_FULL_GROUP_BY** enabled because the nonaggregated **address** column in the select list is not named in the **GROUP BY** clause:

```
SELECT name, address, MAX(age) FROM t GROUP BY name;
```

The query is valid if **name** is a primary key of **t** or is a unique **NOT NULL** column. In such cases, MySQL recognizes that the selected column is functionally dependent on a grouping column. For example, if **name** is a primary key, its value determines the value of **address** because each group has only one value of the primary key and thus only one row. As a result, there is no randomness in the choice of **address** value in a group and no need to reject the query.

The query is invalid if **name** is not a primary key of **t** or a unique **NOT NULL** column. In this case, no functional dependency can be inferred and an error occurs:

```
mysql> SELECT name, address, MAX(age) FROM t GROUP BY name;
ERROR 1055 (42000): Expression #2 of SELECT list is not in GROUP BY clause and contains nonaggregated column 'mydb.t.address' which is not functionally dependent on columns in GROUP BY clause; this is incompatible with sql_mode=only_full_group_by
```

If you know that, **for a given data set**, each **name** value in fact uniquely determines the **address** value, **address** is effectively functionally dependent on **name**. To tell MySQL to accept the query, you can use the **ANY_VALUE()** function:
MySQL Handling of GROUP BY

```sql
SELECT name, ANY_VALUE(address), MAX(age) FROM t GROUP BY name;
```

Alternatively, disable `ONLY_FULL_GROUP_BY`.

The preceding example is quite simple, however. In particular, it is unlikely you would group on a single primary key column because every group would contain only one row. For additional examples demonstrating functional dependence in more complex queries, see Section 12.19.4, “Detection of Functional Dependence”.

If a query has aggregate functions and no `GROUP BY` clause, it cannot have nonaggregated columns in the select list, `HAVING` condition, or `ORDER BY` list with `ONLY_FULL_GROUP_BY` enabled:

```sql
mysql> SELECT name, MAX(age) FROM t;
ERROR 1140 (42000): In aggregated query without GROUP BY, expression #1 of SELECT list contains nonaggregated column 'mydb.t.name'; this is incompatible with sql_mode=only_full_group_by
```

Without `GROUP BY`, there is a single group and it is nondeterministic which `name` value to choose for the group. Here, too, `ANY_VALUE()` can be used, if it is immaterial which `name` value MySQL chooses:

```sql
SELECT ANY_VALUE(name), MAX(age) FROM t;
```

`ONLY_FULL_GROUP_BY` also affects handling of queries that use `DISTINCT` and `ORDER BY`. Consider the case of a table `t` with three columns `c1`, `c2`, and `c3` that contains these rows:

<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
<th>c3</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>A</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>B</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>C</td>
</tr>
</tbody>
</table>

Suppose that we execute the following query, expecting the results to be ordered by `c3`:

```sql
SELECT DISTINCT c1, c2 FROM t ORDER BY c3;
```

To order the result, duplicates must be eliminated first. But to do so, should we keep the first row or the third? This arbitrary choice influences the retained value of `c3`, which in turn influences ordering and makes it arbitrary as well. To prevent this problem, a query that has `DISTINCT` and `ORDER BY` is rejected as invalid if any `ORDER BY` expression does not satisfy at least one of these conditions:

- The expression is equal to one in the select list
- All columns referenced by the expression and belonging to the query's selected tables are elements of the select list

Another MySQL extension to standard SQL permits references in the `HAVING` clause to aliased expressions in the select list. For example, the following query returns `name` values that occur only once in table `orders`:

```sql
SELECT name, COUNT(name) FROM orders GROUP BY name HAVING COUNT(name) = 1;
```

The MySQL extension permits the use of an alias in the `HAVING` clause for the aggregated column:

```sql
SELECT name, COUNT(name) AS c FROM orders GROUP BY name HAVING c = 1;
```
Standard SQL permits only column expressions in `GROUP BY` clauses, so a statement such as this is invalid because `FLOOR(value/100)` is a noncolumn expression:

```sql
SELECT id, FLOOR(value/100)
FROM tbl_name
GROUP BY id, FLOOR(value/100);
```

MySQL extends standard SQL to permit noncolumn expressions in `GROUP BY` clauses and considers the preceding statement valid.

Standard SQL also does not permit aliases in `GROUP BY` clauses. MySQL extends standard SQL to permit aliases, so another way to write the query is as follows:

```sql
SELECT id, FLOOR(value/100) AS val
FROM tbl_name
GROUP BY id, val;
```

The alias `val` is considered a column expression in the `GROUP BY` clause.

In the presence of a noncolumn expression in the `GROUP BY` clause, MySQL recognizes equality between that expression and expressions in the select list. This means that with `ONLY_FULL_GROUP_BY` SQL mode enabled, the query containing `GROUP BY id, FLOOR(value/100)` is valid because that same `FLOOR()` expression occurs in the select list. However, MySQL does not try to recognize functional dependence on `GROUP BY` noncolumn expressions, so the following query is invalid with `ONLY_FULL_GROUP_BY` enabled, even though the third selected expression is a simple formula of the `id` column and the `FLOOR()` expression in the `GROUP BY` clause:

```sql
SELECT id, FLOOR(value/100), id+FLOOR(value/100)
FROM tbl_name
GROUP BY id, FLOOR(value/100);
```

A workaround is to use a derived table:

```sql
SELECT id, F, id+F
FROM
(SELECT id, FLOOR(value/100) AS F
FROM tbl_name
GROUP BY id, FLOOR(value/100)) AS dt;
```

### 12.19.4 Detection of Functional Dependence

The following discussion provides several examples of the ways in which MySQL detects functional dependencies. The examples use this notation:

\[
\{X\} \rightarrow \{Y\}
\]

Understand this as "\(X\) uniquely determines \(Y\)," which also means that \(Y\) is functionally dependent on \(X\).

The examples use the `world` database, which can be downloaded from [https://dev.mysql.com/doc/index-other.html](https://dev.mysql.com/doc/index-other.html). You can find details on how to install the database on the same page.

- Functional Dependencies Derived from Keys
- Functional Dependencies Derived from Multiple-Column Keys and from Equalities
- Functional Dependency Special Cases
- Functional Dependencies and Views
Combinations of Functional Dependencies

Functional Dependencies Derived from Keys

The following query selects, for each country, a count of spoken languages:

```sql
SELECT co.Name, COUNT(*)
FROM countrylanguage cl, country co
GROUP BY co.Code;
```

`co.Code` is a primary key of `co`, so all columns of `co` are functionally dependent on it, as expressed using this notation:

```
{co.Code} -> {co.*}
```

Thus, `co.Name` is functionally dependent on `GROUP BY` columns and the query is valid.

A UNIQUE index over a NOT NULL column could be used instead of a primary key and the same functional dependence would apply. (This is not true for a UNIQUE index that permits NULL values because it permits multiple NULL values and in that case uniqueness is lost.)

Functional Dependencies Derived from Multiple-Column Keys and from Equalities

This query selects, for each country, a list of all spoken languages and how many people speak them:

```sql
SELECT co.Name, cl.Language,
cl.Percentage * co.Population / 100.0 AS SpokenBy
FROM countrylanguage cl, country co
GROUP BY cl.CountryCode, cl.Language;
```

The pair `(cl.CountryCode, cl.Language)` is a two-column composite primary key of `cl`, so that column pair uniquely determines all columns of `cl`:

```
{cl.CountryCode, cl.Language} -> {cl.*}
```

Moreover, because of the equality in the WHERE clause:

```
{cl.CountryCode} -> {co.Code}
```

And, because `co.Code` is primary key of `co`:

```
{co.Code} -> {co.*}
```

"Uniquely determines" relationships are transitive, therefore:

```
{cl.CountryCode, cl.Language} -> {cl.*,co.*}
```

As a result, the query is valid.

As with the previous example, a UNIQUE key over NOT NULL columns could be used instead of a primary key.

An INNER JOIN condition can be used instead of WHERE. The same functional dependencies apply:

```sql
SELECT co.Name, cl.Language,
cl.Percentage * co.Population/100.0 AS SpokenBy
FROM countrylanguage cl INNER JOIN country co
GROUP BY cl.CountryCode, cl.Language;
```
Functional Dependency Special Cases

Whereas an equality test in a `WHERE` condition or `INNER JOIN` condition is symmetric, an equality test in an outer join condition is not, because tables play different roles.

Assume that referential integrity has been accidentally broken and there exists a row of `countrylanguage` without a corresponding row in `country`. Consider the same query as in the previous example, but with a `LEFT JOIN`:

```sql
SELECT co.Name, cl.Language, cl.Percentage * co.Population/100.0 AS SpokenBy
FROM countrylanguage cl LEFT JOIN country co
GROUP BY cl.CountryCode, cl.Language;
```

For a given value of `cl.CountryCode`, the value of `co.Code` in the join result is either found in a matching row (determined by `cl.CountryCode`) or is `NULL`-complemented if there is no match (also determined by `cl.CountryCode`). In each case, this relationship applies:

\[ \{cl.CountryCode\} \rightarrow \{co.Code\} \]

`cl.CountryCode` is itself functionally dependent on `\{cl.CountryCode, cl.Language\}` which is a primary key.

If in the join result `co.Code` is `NULL`-complemented, `co.Name` is as well. If `co.Code` is not `NULL`-complemented, then because `co.Code` is a primary key, it determines `co.Name`. Therefore, in all cases:

\[ \{co.Code\} \rightarrow \{co.Name\} \]

Which yields:

\[ \{cl.CountryCode, cl.Language\} \rightarrow \{*, co.\} \]

As a result, the query is valid.

However, suppose that the tables are swapped, as in this query:

```sql
SELECT co.Name, cl.Language, cl.Percentage * co.Population/100.0 AS SpokenBy
FROM country co LEFT JOIN countrylanguage cl
GROUP BY cl.CountryCode, cl.Language;
```

Now this relationship does *not* apply:

\[ \{cl.CountryCode, cl.Language\} \rightarrow \{*, co.\} \]

Indeed, all `NULL`-complemented rows made for `cl` is put into a single group (they have both `GROUP BY` columns equal to `NULL`), and inside this group the value of `co.Name` can vary. The query is invalid and MySQL rejects it.

Functional dependence in outer joins is thus linked to whether determinant columns belong to the left or right side of the `LEFT JOIN`. Determination of functional dependence becomes more complex if there are nested outer joins or the join condition does not consist entirely of equality comparisons.

Functional Dependencies and Views

Suppose that a view on countries produces their code, their name in uppercase, and how many different official languages they have:

```sql
CREATE VIEW country2 AS
```
SELECT co.Code, UPPER(co.Name) AS UpperName,
COUNT(cl.Language) AS OfficialLanguages
FROM country AS co JOIN countrylanguage AS cl
WHERE cl.isOfficial = 'T'
GROUP BY co.Code;

This definition is valid because:

\[ \{\text{co.Code}\} \rightarrow \{\text{co.*}\} \]

In the view result, the first selected column is \text{co.Code}, which is also the group column and thus
determines all other selected expressions:

\[ \{\text{country2.Code}\} \rightarrow \{\text{country2.*}\} \]

MySQL understands this and uses this information, as described following.

This query displays countries, how many different official languages they have, and how many cities they
have, by joining the view with the \text{city} table:

```
SELECT co2.Code, co2.UpperName, co2.OfficialLanguages,
COUNT(*) AS Cities
FROM country2 AS co2 JOIN city ci
GROUP BY co2.Code;
```

This query is valid because, as seen previously:

\[ \{\text{co2.Code}\} \rightarrow \{\text{co2.*}\} \]

MySQL is able to discover a functional dependency in the result of a view and use that to validate a
query which uses the view. The same would be true if \text{country2} were a derived table (or common table
expression), as in:

```
SELECT co2.Code, co2.UpperName, co2.OfficialLanguages,
COUNT(*) AS Cities
FROM

( SELECT co.Code, UPPER(co.Name) AS UpperName,
COUNT(cl.Language) AS OfficialLanguages
FROM country AS co JOIN countrylanguage AS cl
WHERE cl.isOfficial = 'T'
GROUP BY co.Code
) AS co2
GROUP BY co2.Code;
```

### Combinations of Functional Dependencies

MySQL is able to combine all of the preceding types of functional dependencies (key based, equality
based, view based) to validate more complex queries.

#### 12.20 Window Functions

MySQL supports window functions that, for each row from a query, perform a calculation using rows
related to that row. The following sections discuss how to use window functions, including descriptions
of the \text{OVER} and \text{WINDOW} clauses. The first section provides descriptions of the nonaggregate window
functions. For descriptions of the aggregate window functions, see Section 12.19.1, “Aggregate Function
Descriptions”.

2558
12.20.1 Window Function Descriptions

This section describes nonaggregate window functions that, for each row from a query, perform a calculation using rows related to that row. Most aggregate functions also can be used as window functions; see Section 12.19.1, “Aggregate Function Descriptions”.

For window function usage information and examples, and definitions of terms such as the OVER clause, window, partition, frame, and peer, see Section 12.20.2, “Window Function Concepts and Syntax”.

Table 12.30 Window Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUME_DIST()</td>
<td>Cumulative distribution value</td>
</tr>
<tr>
<td>DENSE_RANK()</td>
<td>Rank of current row within its partition, without gaps</td>
</tr>
<tr>
<td>FIRST_VALUE()</td>
<td>Value of argument from first row of window frame</td>
</tr>
<tr>
<td>LAG()</td>
<td>Value of argument from row lagging current row within partition</td>
</tr>
<tr>
<td>LAST_VALUE()</td>
<td>Value of argument from last row of window frame</td>
</tr>
<tr>
<td>LEAD()</td>
<td>Value of argument from row leading current row within partition</td>
</tr>
<tr>
<td>NTH_VALUE()</td>
<td>Value of argument from N-th row of window frame</td>
</tr>
<tr>
<td>NTILE()</td>
<td>Bucket number of current row within its partition.</td>
</tr>
<tr>
<td>PERCENT_RANK()</td>
<td>Percentage rank value</td>
</tr>
<tr>
<td>RANK()</td>
<td>Rank of current row within its partition, with gaps</td>
</tr>
<tr>
<td>ROW_NUMBER()</td>
<td>Number of current row within its partition</td>
</tr>
</tbody>
</table>

In the following function descriptions, over_clause represents the OVER clause, described in Section 12.20.2, “Window Function Concepts and Syntax”. Some window functions permit a null_treatment clause that specifies how to handle NULL values when calculating results. This clause is optional. It is part of the SQL standard, but the MySQL implementation permits only RESPECT NULLS (which is also the default). This means that NULL values are considered when calculating results. IGNORE NULLS is parsed, but produces an error.

- **CUME_DIST() over_clause**

Returns the cumulative distribution of a value within a group of values; that is, the percentage of partition values less than or equal to the value in the current row. This represents the number of rows preceding or peer with the current row in the window ordering of the window partition divided by the total number of rows in the window partition. Return values range from 0 to 1.

This function should be used with ORDER BY to sort partition rows into the desired order. Without ORDER BY, all rows are peers and have value \( \frac{N}{N} = 1 \), where \( N \) is the partition size.

over_clause is as described in Section 12.20.2, “Window Function Concepts and Syntax”.

The following query shows, for the set of values in the val column, the CUME_DIST() value for each row, as well as the percentage rank value returned by the similar PERCENT_RANK() function. For reference, the query also displays row numbers using ROW_NUMBER():
Window Function Descriptions

mysql> SELECT val, ROW_NUMBER() OVER w AS 'row_number', CUME_DIST() OVER w AS 'cume_dist', PERCENT_RANK() OVER w AS 'percent_rank' FROM numbers WINDOW w AS (ORDER BY val);

+-----+------------+--------------------+--------------+
| val | row_number | cume_dist          | percent_rank |
+-----+------------+--------------------+--------------+
| 1   |          1 | 0.2222222222222222 |            0 |
| 1   |          2 | 0.2222222222222222 |            0 |
| 2   |          3 | 0.3333333333333333 | 0.25        |
| 3   |          4 | 0.6666666666666666 | 0.375       |
| 3   |          5 | 0.6666666666666666 | 0.375       |
| 3   |          6 | 0.6666666666666666 | 0.375       |
| 4   |          7 | 0.8888888888888888 | 0.75        |
| 4   |          8 | 0.8888888888888888 | 0.75        |
| 5   |          9 |                  1 |            1 |
+-----+------------+--------------------+--------------+

• DENSE_RANK() over_clause

Returns the rank of the current row within its partition, without gaps. Peers are considered ties and receive the same rank. This function assigns consecutive ranks to peer groups; the result is that groups of size greater than one do not produce noncontiguous rank numbers. For an example, see the RANK() function description.

This function should be used with ORDER BY to sort partition rows into the desired order. Without ORDER BY, all rows are peers.

over_clause is as described in Section 12.20.2, “Window Function Concepts and Syntax”.

• FIRST_VALUE(expr) [null_treatment] over_clause

Returns the value of expr from the first row of the window frame.

over_clause is as described in Section 12.20.2, “Window Function Concepts and Syntax”. null_treatment is as described in the section introduction.

The following query demonstrates FIRST_VALUE(), LAST_VALUE(), and two instances of NTH_VALUE():

mysql> SELECT time, subject, val, FIRST_VALUE(val) OVER w AS 'first', LAST_VALUE(val) OVER w AS 'last', NTH_VALUE(val, 2) OVER w AS 'second', NTH_VALUE(val, 4) OVER w AS 'fourth' FROM observations WINDOW w AS (PARTITION BY subject ORDER BY time ROWS UNBOUNDED PRECEDING);

+----------+---------+------+-------+------+--------+--------+
| time     | subject | val  | first | last | second | fourth |
+----------+---------+------+-------+------+--------+--------+
| 07:00:00 | st113   | 10   | 10    | 10   | NULL   | NULL   |
| 07:15:00 | st113   | 9    | 10    | 9    | NULL   | NULL   |
| 07:30:00 | st113   | 25   | 10    | 25   | 9      | NULL   |
| 07:45:00 | st113   | 20   | 10    | 20   | 9      | 20     |
| 07:00:00 | xh458   | 0    | 0     | 0    | NULL   | NULL   |
| 07:15:00 | xh458   | 10   | 0     | 10   | 10     | NULL   |
| 07:30:00 | xh458   | 5    | 0     | 5    | 10     | NULL   |
| 07:45:00 | xh458   | 30   | 0     | 30   | 10     | 30     |
Window Function Descriptions

Each function uses the rows in the current frame, which, per the window definition shown, extends from the first partition row to the current row. For the `NTH_VALUE()` calls, the current frame does not always include the requested row; in such cases, the return value is `NULL`.

- **LAG(expr [, N[, default]]) [null_treatment] over_clause**

  Returns the value of `expr` from the row that lags (precedes) the current row by `N` rows within its partition. If there is no such row, the return value is `default`. For example, if `N` is 3, the return value is `default` for the first three rows. If `N` or `default` are missing, the defaults are 1 and `NULL`, respectively.

  - `N` must be a literal nonnegative integer. If `N` is 0, `expr` is evaluated for the current row.
  - `N` cannot be `NULL`, and must be an integer in the range 0 to $2^{63}$, inclusive, in any of the following forms:
    - an unsigned integer constant literal
    - a positional parameter marker (`?`)
    - a user-defined variable
    - a local variable in a stored routine

  `over_clause` is as described in Section 12.20.2, “Window Function Concepts and Syntax”. `null_treatment` is as described in the section introduction.

  **LAG()** (and the similar **LEAD()** function) are often used to compute differences between rows. The following query shows a set of time-ordered observations and, for each one, the **LAG()** and **LEAD()** values from the adjoining rows, as well as the differences between the current and adjoining rows:

```sql
mysql> SELECT
t, val,
LAG(val) OVER w AS 'lag',
LEAD(val) OVER w AS 'lead',
val - LAG(val) OVER w AS 'lag diff',
val - LEAD(val) OVER w AS 'lead diff'
FROM series
WINDOW w AS (ORDER BY t);
```

<table>
<thead>
<tr>
<th>t</th>
<th>val</th>
<th>lag</th>
<th>lead</th>
<th>lag diff</th>
<th>lead diff</th>
</tr>
</thead>
<tbody>
<tr>
<td>12:00:00</td>
<td>100</td>
<td>NULL</td>
<td>125</td>
<td>NULL</td>
<td>-25</td>
</tr>
<tr>
<td>13:00:00</td>
<td>125</td>
<td>100</td>
<td>132</td>
<td>25</td>
<td>-7</td>
</tr>
<tr>
<td>14:00:00</td>
<td>132</td>
<td>125</td>
<td>145</td>
<td>7</td>
<td>-13</td>
</tr>
<tr>
<td>15:00:00</td>
<td>145</td>
<td>132</td>
<td>140</td>
<td>13</td>
<td>5</td>
</tr>
<tr>
<td>16:00:00</td>
<td>140</td>
<td>145</td>
<td>150</td>
<td>-5</td>
<td>-10</td>
</tr>
<tr>
<td>17:00:00</td>
<td>150</td>
<td>140</td>
<td>200</td>
<td>10</td>
<td>-50</td>
</tr>
<tr>
<td>18:00:00</td>
<td>200</td>
<td>150</td>
<td>NULL</td>
<td>50</td>
<td>NULL</td>
</tr>
</tbody>
</table>
In the example, the `LAG()` and `LEAD()` calls use the default `N` and `default` values of 1 and `NULL`, respectively.

The first row shows what happens when there is no previous row for `LAG()`: The function returns the `default` value (in this case, `NULL`). The last row shows the same thing when there is no next row for `LEAD()`.

`LAG()` and `LEAD()` also serve to compute sums rather than differences. Consider this data set, which contains the first few numbers of the Fibonacci series:

```sql
SELECT n FROM fib ORDER BY n;
```

```plaintext
+------+
| n    |
+------+
|    1 |
|    1 |
|    2 |
|    3 |
|    5 |
|    8 |
```

The following query shows the `LAG()` and `LEAD()` values for the rows adjacent to the current row. It also uses those functions to add to the current row value the values from the preceding and following rows. The effect is to generate the next number in the Fibonacci series, and the next number after that:

```sql
SELECT
    n,
    LAG(n, 1, 0) OVER w AS 'lag',
    LEAD(n, 1, 0) OVER w AS 'lead',
    n + LAG(n, 1, 0) OVER w AS 'next_n',
    n + LEAD(n, 1, 0) OVER w AS 'next_next_n'
FROM fib
WINDOW w AS (ORDER BY n);
```

```plaintext
+------+------+------+--------+-------------+
| n    | lag  | lead | next_n | next_next_n |
+------+------+------+--------+-------------+
|    1 |    0 |    1 |      1 |           2 |
|    1 |    1 |    2 |      2 |           3 |
|    2 |    1 |    3 |      3 |           5 |
|    3 |    2 |    5 |      5 |           8 |
|    5 |    3 |    8 |      8 |          13 |
|    8 |    5 |    0 |     13 |           8 |
```

One way to generate the initial set of Fibonacci numbers is to use a recursive common table expression. For an example, see Fibonacci Series Generation.

You cannot use a negative value for the rows argument of this function.

- `LAST_VALUE(expr) [null_treatment] over_clause`

  Returns the value of `expr` from the last row of the window frame.

  `over_clause` is as described in Section 12.20.2, “Window Function Concepts and Syntax”.
  `null_treatment` is as described in the section introduction.

  For an example, see the `FIRST_VALUE()` function description.
Window Function Descriptions

- **LEAD(expr [, N[, default]])[null_treatment] over_clause**

  Returns the value of `expr` from the row that leads (follows) the current row by `N` rows within its partition. If there is no such row, the return value is `default`. For example, if `N` is 3, the return value is `default` for the last three rows. If `N` or `default` are missing, the defaults are 1 and `NULL`, respectively.

  `N` must be a literal nonnegative integer. If `N` is 0, `expr` is evaluated for the current row.

  `N` cannot be `NULL`, and must be an integer in the range 0 to $2^{63}$, inclusive, in any of the following forms:
  - an unsigned integer constant literal
  - a positional parameter marker (?)
  - a user-defined variable
  - a local variable in a stored routine

  `over_clause` is as described in Section 12.20.2, “Window Function Concepts and Syntax”. `null_treatment` is as described in the section introduction.

  For an example, see the `LAG()` function description.

  Use of a negative value for the rows argument of this function is not permitted.

- **NTH_VALUE(expr, N) [from_first_last][null_treatment] over_clause**

  Returns the value of `expr` from the `N`-th row of the window frame. If there is no such row, the return value is `NULL`.

  `N` must be a literal positive integer.

  `from_first_last` is part of the SQL standard, but the MySQL implementation permits only `FROM FIRST` (which is also the default). This means that calculations begin at the first row of the window. `FROM LAST` is parsed, but produces an error. To obtain the same effect as `FROM LAST` (begin calculations at the last row of the window), use `ORDER BY` to sort in reverse order.

  `over_clause` is as described in Section 12.20.2, “Window Function Concepts and Syntax”. `null_treatment` is as described in the section introduction.

  For an example, see the `FIRST_VALUE()` function description.

  You cannot use `NULL` for the row argument of this function.
• **NTILE(N) over_clause**

  Divides a partition into \( N \) groups (buckets), assigns each row in the partition its bucket number, and returns the bucket number of the current row within its partition. For example, if \( N \) is 4, `NTILE()` divides rows into four buckets. If \( N \) is 100, `NTILE()` divides rows into 100 buckets.

  \( N \) must be a literal positive integer. Bucket number return values range from 1 to \( N \).

  \( N \) cannot be `NULL`, and must be an integer in the range \( 0 \) to \( 2^{63} \), inclusive, in any of the following forms:
  
  - an unsigned integer constant literal
  - a positional parameter marker (\( ? \))
  - a user-defined variable
  - a local variable in a stored routine

  This function should be used with `ORDER BY` to sort partition rows into the desired order.

  `over_clause` is as described in Section 12.20.2, “Window Function Concepts and Syntax”.

  The following query shows, for the set of values in the `val` column, the percentile values resulting from dividing the rows into two or four groups. For reference, the query also displays row numbers using `ROW_NUMBER()`:

  ```sql
  mysql> SELECT
  > val,
  > ROW_NUMBER() OVER w AS 'row_number',
  > NTILE(2) OVER w AS 'ntile2',
  > NTILE(4) OVER w AS 'ntile4'
  > FROM numbers
  > WINDOW w AS (ORDER BY val);
  +---------+-----------+-------+-------+
  | val     | row_number| ntile2| ntile4|
  |---------+-----------+-------+-------|
  |        1|           1|      1|      1|
  |        1|           2|      1|      1|
  |        2|           3|      1|      1|
  |        3|           4|      1|      2|
  |        3|           5|      1|      2|
  |        3|           6|      2|      3|
  |        4|           7|      2|      3|
  |        4|           8|      2|      4|
  |        5|           9|      2|      4|
  +---------+-----------+-------+-------+
  
  The construct `NTILE(NULL)` is not permitted.
Window Function Descriptions

• **PERCENT_RANK() over_clause**

Returns the percentage of partition values less than the value in the current row, excluding the highest value. Return values range from 0 to 1 and represent the row relative rank, calculated as the result of this formula, where \( rank \) is the row rank and \( rows \) is the number of partition rows:

\[
\frac{(rank - 1)}{(rows - 1)}
\]

This function should be used with `ORDER BY` to sort partition rows into the desired order. Without `ORDER BY`, all rows are peers.

`over_clause` is as described in Section 12.20.2, “Window Function Concepts and Syntax”.

For an example, see the **CUME_DIST()** function description.

• **RANK() over_clause**

Returns the rank of the current row within its partition, with gaps. Peers are considered ties and receive the same rank. This function does not assign consecutive ranks to peer groups if groups of size greater than one exist; the result is noncontiguous rank numbers.

This function should be used with `ORDER BY` to sort partition rows into the desired order. Without `ORDER BY`, all rows are peers.

`over_clause` is as described in Section 12.20.2, “Window Function Concepts and Syntax”.

The following query shows the difference between **RANK()**, which produces ranks with gaps, and **DENSE_RANK()**, which produces ranks without gaps. The query shows rank values for each member of a set of values in the `val` column, which contains some duplicates. **RANK()** assigns peers (the duplicates) the same rank value, and the next greater value has a rank higher by the number of peers minus one. **DENSE_RANK()** also assigns peers the same rank value, but the next higher value has a rank one greater. For reference, the query also displays row numbers using **ROW_NUMBER()**:

```sql
mysql> SELECT val, ROW_NUMBER() OVER w AS 'row_number', RANK() OVER w AS 'rank', DENSE_RANK() OVER w AS 'dense_rank'
FROM numbers WINDOW w AS (ORDER BY val);
```

<table>
<thead>
<tr>
<th>val</th>
<th>row_number</th>
<th>rank</th>
<th>dense_rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>4</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>5</td>
<td>4</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>6</td>
<td>4</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td>7</td>
<td>7</td>
<td>4</td>
</tr>
<tr>
<td>4</td>
<td>8</td>
<td>7</td>
<td>4</td>
</tr>
<tr>
<td>5</td>
<td>9</td>
<td>9</td>
<td>5</td>
</tr>
</tbody>
</table>
```
• **ROW_NUMBER() over_clause**

Returns the number of the current row within its partition. Rows numbers range from 1 to the number of partition rows.

**ORDER BY** affects the order in which rows are numbered. Without **ORDER BY**, row numbering is nondeterministic.

**ROW_NUMBER()** assigns peers different row numbers. To assign peers the same value, use **RANK()** or **DENSE_RANK()**. For an example, see the **RANK()** function description.

**over_clause** is as described in Section 12.20.2, “Window Function Concepts and Syntax”.

### 12.20.2 Window Function Concepts and Syntax

This section describes how to use window functions. Examples use the same sales information data set as found in the discussion of the **GROUPING()** function in Section 12.19.2, “GROUP BY Modifiers”:

```sql
mysql> SELECT * FROM sales ORDER BY country, year, product;
+------+---------+------------+--------+
| year | country | product    | profit |
+------+---------+------------+--------+
| 2000 | Finland | Computer   |   1500 |
| 2000 | Finland | Phone      |    100 |
| 2001 | Finland | Phone      |     10 |
| 2000 | India   | Calculator |     75 |
| 2000 | India   | Computer   |   1200 |
| 2000 | USA     | Calculator |     75 |
| 2000 | USA     | Computer   |   1500 |
| 2001 | USA     | Calculator |     50 |
| 2001 | USA     | Computer   |   1500 |
| 2001 | USA     | Computer   |   1200 |
| 2001 | USA     | TV         |    150 |
| 2001 | USA     | TV         |    100 |
+------+---------+------------+--------+
```

A window function performs an aggregate-like operation on a set of query rows. However, whereas an aggregate operation groups query rows into a single result row, a window function produces a result for each query row:

- The row for which function evaluation occurs is called the current row.
- The query rows related to the current row over which function evaluation occurs comprise the window for the current row.

For example, using the sales information table, these two queries perform aggregate operations that produce a single global sum for all rows taken as a group, and sums grouped per country:

```sql
mysql> SELECT SUM(profit) AS total_profit
           FROM sales;
+--------------+
| total_profit |
+--------------+
|         7535  |
+--------------+
mysql> SELECT country, SUM(profit) AS country_profit
           FROM sales
           GROUP BY country
           ORDER BY country;
+---------+----------------+
| country | country_profit |
+---------+----------------+
```

2566
By contrast, window operations do not collapse groups of query rows to a single output row. Instead, they produce a result for each row. Like the preceding queries, the following query uses `SUM()`, but this time as a window function:

```sql
mysql> SELECT
    -> year, country, product, profit,
    -> SUM(profit) OVER() AS total_profit,
    -> SUM(profit) OVER(PARTITION BY country) AS country_profit
FROM sales
ORDER BY country, year, product, profit;
```

<table>
<thead>

</table>

Each window operation in the query is signified by inclusion of an `OVER` clause that specifies how to partition query rows into groups for processing by the window function:

- The first `OVER` clause is empty, which treats the entire set of query rows as a single partition. The window function thus produces a global sum, but does so for each row.
- The second `OVER` clause partitions rows by country, producing a sum per partition (per country). The function produces this sum for each partition row.

Window functions are permitted only in the select list and `ORDER BY` clause. Query result rows are determined from the `FROM` clause, after `WHERE`, `GROUP BY`, and `HAVING` processing, and windowing execution occurs before `ORDER BY`, `LIMIT`, and `SELECT DISTINCT`.

The `OVER` clause is permitted for many aggregate functions, which therefore can be used as window or nonwindow functions, depending on whether the `OVER` clause is present or absent:

- `AVG()`
- `BIT_AND()`
- `BIT_OR()`
- `BIT_XOR()`
- `COUNT()`
- `JSON_ARRAYAGG()`
- `JSON_OBJECTAGG()`
- `MAX()`
- `MIN()`
- `STDDEV_POP()`, `STDDEV()`, `STD()`
- `STDDEV_SAMP()`
- `SUM()`
- `VAR_POP()`, `VARIANCE()`
- `VAR_SAMP()`
Window Function Concepts and Syntax

For details about each aggregate function, see Section 12.19.1, “Aggregate Function Descriptions”.

MySQL also supports nonaggregate functions that are used only as window functions. For these, the \texttt{OVER} clause is mandatory:

\begin{verbatim}
CUME_DIST()
DENSE_RANK()
FIRST_VALUE()
LAG()
LAST_VALUE()
LEAD()
NTH_VALUE()
NTILE()
PERCENT_RANK()
RANK()
ROW_NUMBER()
\end{verbatim}

For details about each nonaggregate function, see Section 12.20.1, “Window Function Descriptions”.

As an example of one of those nonaggregate window functions, this query uses \texttt{ROW_NUMBER()}, which produces the row number of each row within its partition. In this case, rows are numbered per country. By default, partition rows are unordered and row numbering is nondeterministic. To sort partition rows, include an \texttt{ORDER BY} clause within the window definition. The query uses unordered and ordered partitions (the \texttt{row_num1} and \texttt{row_num2} columns) to illustrate the difference between omitting and including \texttt{ORDER BY}:

\begin{verbatim}
mysql> SELECT
    ...|
    year, country, product, profit,
    ...
    ROW_NUMBER() OVER(PARTITION BY country) AS row_num1,
    ...
    ROW_NUMBER() OVER(PARTITION BY country ORDER BY year, product) AS row_num2
FROM sales;
\end{verbatim}

<table>
<thead>
<tr>
<th>year</th>

</tbody>
</table>

As mentioned previously, to use a window function (or treat an aggregate function as a window function), include an \texttt{OVER} clause following the function call. The \texttt{OVER} clause has two forms:

\begin{verbatim}
over_clause:
{OVER (window_spec) | OVER window_name}
\end{verbatim}

Both forms define how the window function should process query rows. They differ in whether the window is defined directly in the \texttt{OVER} clause, or supplied by a reference to a named window defined elsewhere in the query:

- In the first case, the window specification appears directly in the \texttt{OVER} clause, between the parentheses.
- In the second case, \texttt{window_name} is the name for a window specification defined by a \texttt{WINDOW} clause elsewhere in the query. For details, see Section 12.20.4, “Named Windows”.

For \texttt{OVER (window_spec)} syntax, the window specification has several parts, all optional:
Window Function Frame Specification

\[
\text{window_spec:} \\
[\text{window_name}] \ [\text{partition_clause}] \ [\text{order_clause}] \ [\text{frame_clause}]
\]

If \text{OVER(\)} is empty, the window consists of all query rows and the window function computes a result using all rows. Otherwise, the clauses present within the parentheses determine which query rows are used to compute the function result and how they are partitioned and ordered:

- \text{window_name}: The name of a window defined by a \text{WINDOW} clause elsewhere in the query. If \text{window_name} appears by itself within the \text{OVER} clause, it completely defines the window. If partitioning, ordering, or framing clauses are also given, they modify interpretation of the named window. For details, see Section 12.20.4, “Named Windows”.

- \text{partition_clause}: A \text{PARTITION BY} clause indicates how to divide the query rows into groups. The window function result for a given row is based on the rows of the partition that contains the row. If \text{PARTITION BY} is omitted, there is a single partition consisting of all query rows.

\begin{itemize}
  \item \text{Note}
  \end{itemize}

Partitioning for window functions differs from table partitioning. For information about table partitioning, see Chapter 24, 
Partitioning.

\text{partition_clause} has this syntax:

\[
\text{partition_clause:} \\
\text{PARTITION BY expr [, expr] ...}
\]

Standard SQL requires \text{PARTITION BY} to be followed by column names only. A MySQL extension is to permit expressions, not just column names. For example, if a table contains a \text{TIMESTAMP} column named \text{ts}, standard SQL permits \text{PARTITION BY ts} but not \text{PARTITION BY HOUR(ts)}, whereas MySQL permits both.

- \text{order_clause}: An \text{ORDER BY} clause indicates how to sort rows in each partition. Partition rows that are equal according to the \text{ORDER BY} clause are considered peers. If \text{ORDER BY} is omitted, partition rows are unordered, with no processing order implied, and all partition rows are peers.

\text{order_clause} has this syntax:

\[
\text{order_clause:} \\
\text{ORDER BY expr [ASC|DESC] [, expr [ASC|DESC]] ...}
\]

Each \text{ORDER BY} expression optionally can be followed by \text{ASC} or \text{DESC} to indicate sort direction. The default is \text{ASC} if no direction is specified. \text{NULL} values sort first for ascending sorts, last for descending sorts.

An \text{ORDER BY} in a window definition applies within individual partitions. To sort the result set as a whole, include an \text{ORDER BY} at the query top level.

- \text{frame_clause}: A frame is a subset of the current partition and the frame clause specifies how to define the subset. The frame clause has many subclauses of its own. For details, see Section 12.20.3, “Window Function Frame Specification”.

12.20.3 Window Function Frame Specification

The definition of a window used with a window function can include a frame clause. A frame is a subset of the current partition and the frame clause specifies how to define the subset.

Frames are determined with respect to the current row, which enables a frame to move within a partition depending on the location of the current row within its partition. Examples:
Window Function Frame Specification

- By defining a frame to be all rows from the partition start to the current row, you can compute running totals for each row.

- By defining a frame as extending $N$ rows on either side of the current row, you can compute rolling averages.

The following query demonstrates the use of moving frames to compute running totals within each group of time-ordered level values, as well as rolling averages computed from the current row and the rows that immediately precede and follow it:

```sql
mysql> SELECT
time, subject, val,
SUM(val) OVER (PARTITION BY subject ORDER BY time
ROWS UNBOUNDED PRECEDING)
AS running_total,
AVG(val) OVER (PARTITION BY subject ORDER BY time
ROWS BETWEEN 1 PRECEDING AND 1 FOLLOWING)
AS running_average
FROM observations;
```

<table>
<thead>
<tr>
<th>time</th>
<th>subject</th>
<th>val</th>
<th>running_total</th>
<th>running_average</th>
</tr>
</thead>
<tbody>
<tr>
<td>07:00:00</td>
<td>st113</td>
<td>10</td>
<td>10</td>
<td>9.5000</td>
</tr>
<tr>
<td>07:15:00</td>
<td>st113</td>
<td>9</td>
<td>19</td>
<td>14.6667</td>
</tr>
<tr>
<td>07:30:00</td>
<td>st113</td>
<td>25</td>
<td>44</td>
<td>18.0000</td>
</tr>
<tr>
<td>07:45:00</td>
<td>st113</td>
<td>20</td>
<td>64</td>
<td>22.5000</td>
</tr>
<tr>
<td>07:00:00</td>
<td>xh458</td>
<td>0</td>
<td>0</td>
<td>5.0000</td>
</tr>
<tr>
<td>07:15:00</td>
<td>xh458</td>
<td>10</td>
<td>10</td>
<td>5.0000</td>
</tr>
<tr>
<td>07:30:00</td>
<td>xh458</td>
<td>5</td>
<td>15</td>
<td>15.0000</td>
</tr>
<tr>
<td>07:45:00</td>
<td>xh458</td>
<td>30</td>
<td>45</td>
<td>20.0000</td>
</tr>
<tr>
<td>08:00:00</td>
<td>xh458</td>
<td>25</td>
<td>70</td>
<td>27.5000</td>
</tr>
</tbody>
</table>

For the running_average column, there is no frame row preceding the first one or following the last. In these cases, AVG() computes the average of the rows that are available.

Aggregate functions used as window functions operate on rows in the current row frame, as do these nonaggregate window functions:

- FIRST_VALUE()
- LAST_VALUE()
- NTH_VALUE()

Standard SQL specifies that window functions that operate on the entire partition should have no frame clause. MySQL permits a frame clause for such functions but ignores it. These functions use the entire partition even if a frame is specified:

- CUME_DIST()
- DENSE_RANK()
- LAG()
- LEAD()
- NTILE()
- PERCENT_RANK()
- RANK()
- ROW_NUMBER()

The frame clause, if given, has this syntax:

```
frame_clause:
  frame_units frame_extent

frame_units:
```
{ROWS | RANGE}

In the absence of a frame clause, the default frame depends on whether an ORDER BY clause is present, as described later in this section.

The `frame_units` value indicates the type of relationship between the current row and frame rows:

- **ROWS**: The frame is defined by beginning and ending row positions. Offsets are differences in row numbers from the current row number.
- **RANGE**: The frame is defined by rows within a value range. Offsets are differences in row values from the current row value.

The `frame_extent` value indicates the start and end points of the frame. You can specify just the start of the frame (in which case the current row is implicitly the end) or use BETWEEN to specify both frame endpoints:

```
frame_extent:  
  {frame_start | frame_between}

frame_between:  
  BETWEEN frame_start AND frame_end

frame_start, frame_end: {  
  CURRENT ROW  
  | UNBOUNDED PRECEDING  
  | UNBOUNDED FOLLOWING  
  | expr PRECEDING  
  | expr FOLLOWING  
}
```

With BETWEEN syntax, `frame_start` must not occur later than `frame_end`.

The permitted `frame_start` and `frame_end` values have these meanings:

- **CURRENT ROW**: For ROWS, the bound is the current row. For RANGE, the bound is the peers of the current row.
- **UNBOUNDED PRECEDING**: The bound is the first partition row.
- **UNBOUNDED FOLLOWING**: The bound is the last partition row.
- **expr PRECEDING**: For ROWS, the bound is `expr` rows before the current row. For RANGE, the bound is the rows with values equal to the current row value minus `expr`; if the current row value is NULL, the bound is the peers of the row.

For `expr PRECEDING` (and `expr FOLLOWING`), `expr` can be a ? parameter marker (for use in a prepared statement), a nonnegative numeric literal, or a temporal interval of the form INTERVAL `val unit`. For INTERVAL expressions, `val` specifies nonnegative interval value, and `unit` is a keyword indicating the units in which the value should be interpreted. (For details about the permitted `units` specifiers, see the description of the DATE_ADD() function in Section 12.7, "Date and Time Functions".)

RANGE on a numeric or temporal `expr` requires ORDER BY on a numeric or temporal expression, respectively.

Examples of valid `expr PRECEDING` and `expr FOLLOWING` indicators:

```
10 PRECEDING
INTERVAL 5 DAY PRECEDING
5 FOLLOWING
INTERVAL '2:30' MINUTE_SECOND FOLLOWING
```
Window Function Frame Specification

- **expr FOLLOWING**: For **ROWS**, the bound is **expr** rows after the current row. For **RANGE**, the bound is the rows with values equal to the current row value plus **expr**; if the current row value is **NULL**, the bound is the peers of the row.

For permitted values of **expr**, see the description of **expr PRECEDING**.

The following query demonstrates **FIRST_VALUE()**, **LAST_VALUE()**, and two instances of **NTH_VALUE()**:

```sql
mysql> SELECT time, subject, val,
  FIRST_VALUE(val) OVER w AS 'first',
  LAST_VALUE(val) OVER w AS 'last',
  NTH_VALUE(val, 2) OVER w AS 'second',
  NTH_VALUE(val, 4) OVER w AS 'fourth'
FROM observations
WINDOW w AS (PARTITION BY subject ORDER BY time
  ROWS UNBOUNDED PRECEDING);
```

<table>

<td>10</td>
<td>30</td>
<td>NULL</td>
</tr>
</tbody>
</table>

Each function uses the rows in the current frame, which, per the window definition shown, extends from the first partition row to the current row. For the **NTH_VALUE()** calls, the current frame does not always include the requested row; in such cases, the return value is **NULL**.

In the absence of a frame clause, the default frame depends on whether an **ORDER BY** clause is present:

- With **ORDER BY**: The default frame includes rows from the partition start through the current row, including all peers of the current row (rows equal to the current row according to the **ORDER BY** clause). The default is equivalent to this frame specification:
  
  **RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW**

- Without **ORDER BY**: The default frame includes all partition rows (because, without **ORDER BY**, all partition rows are peers). The default is equivalent to this frame specification:
  
  **RANGE BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING**

Because the default frame differs depending on presence or absence of **ORDER BY**, adding **ORDER BY** to a query to get deterministic results may change the results. (For example, the values produced by **SUM()** might change.) To obtain the same results but ordered per **ORDER BY**, provide an explicit frame specification to be used regardless of whether **ORDER BY** is present.

The meaning of a frame specification can be nonobvious when the current row value is **NULL**. Assuming that to be the case, these examples illustrate how various frame specifications apply:

- **ORDER BY X ASC RANGE BETWEEN 10 FOLLOWING AND 15 FOLLOWING**
  The frame starts at **NULL** and stops at **NULL**, thus includes only rows with value **NULL**.

- **ORDER BY X ASC RANGE BETWEEN 10 FOLLOWING AND UNBOUNDED FOLLOWING**
12.20.4 Named Windows

Windows can be defined and given names by which to refer to them in OVER clauses. To do this, use a WINDOW clause. If present in a query, the WINDOW clause falls between the positions of the HAVING and ORDER BY clauses, and has this syntax:

```
WINDOW window_name AS (window_spec)
[, window_name AS (window_spec)] ...
```

For each window definition, window_name is the window name, and window_spec is the same type of window specification as given between the parentheses of an OVER clause, as described in Section 12.20.2, "Window Function Concepts and Syntax":

```
window_spec:
  [window_name] [partition_clause] [order_clause] [frame_clause]
```

A WINDOW clause is useful for queries in which multiple OVER clauses would otherwise define the same window. Instead, you can define the window once, give it a name, and refer to the name in the OVER clauses. Consider this query, which defines the same window multiple times:

```
SELECT val,
  ROW_NUMBER() OVER (ORDER BY val) AS 'row_number',
  RANK() OVER (ORDER BY val) AS 'rank',
  DENSE_RANK() OVER (ORDER BY val) AS 'dense_rank'
FROM numbers;
```

The query can be written more simply by using WINDOW to define the window once and referring to the window by name in the OVER clauses:

```
SELECT val,
  ROW_NUMBER() OVER w AS 'row_number',
  RANK() OVER w AS 'rank',
```
DENSE_RANK() OVER w AS 'dense_rank'
FROM numbers
WINDOW w AS (ORDER BY val);

A named window also makes it easier to experiment with the window definition to see the effect on query results. You need only modify the window definition in the WINDOW clause, rather than multiple OVER clause definitions.

If an OVER clause uses OVER (window_name ...) rather than OVER window_name, the named window can be modified by the addition of other clauses. For example, this query defines a window that includes partitioning, and uses ORDER BY in the OVER clauses to modify the window in different ways:

```sql
SELECT
  DISTINCT year, country,
  FIRST_VALUE(year) OVER (w ORDER BY year ASC) AS first,
  FIRST_VALUE(year) OVER (w ORDER BY year DESC) AS last
FROM sales
WINDOW w AS (PARTITION BY country);
```

An OVER clause can only add properties to a named window, not modify them. If the named window definition includes a partitioning, ordering, or framing property, the OVER clause that refers to the window name cannot also include the same kind of property or an error occurs:

- This construct is permitted because the window definition and the referring OVER clause do not contain the same kind of properties:
  ```sql
  OVER (w ORDER BY country)
  ... WINDOW w AS (PARTITION BY country)
  ```

- This construct is not permitted because the OVER clause specifies PARTITION BY for a named window that already has PARTITION BY:
  ```sql
  OVER (w PARTITION BY year)
  ... WINDOW w AS (PARTITION BY country)
  ```

The definition of a named window can itself begin with a window_name. In such cases, forward and backward references are permitted, but not cycles:

- This is permitted; it contains forward and backward references but no cycles:
  ```sql
  WINDOW w1 AS (w2), w2 AS (), w3 AS {w1}
  ```

- This is not permitted because it contains a cycle:
  ```sql
  WINDOW w1 AS (w2), w2 AS {w3}, w3 AS {w1}
  ```

### 12.20.5 Window Function Restrictions

The SQL standard imposes a constraint on window functions that they cannot be used in UPDATE or DELETE statements to update rows. Using such functions in a subquery of these statements (to select rows) is permitted.

MySQL does not support these window function features:

- DISTINCT syntax for aggregate window functions.
- Nested window functions.
- Dynamic frame endpoints that depend on the value of the current row.

The parser recognizes these window constructs which nevertheless are not supported:
Performance Schema Functions

- The `GROUPS` frame units specifier is parsed, but produces an error. Only `ROWS` and `RANGE` are supported.

- The `EXCLUDE` clause for frame specification is parsed, but produces an error.

- `IGNORE NULLS` is parsed, but produces an error. Only `RESPECT NULLS` is supported.

- `FROM LAST` is parsed, but produces an error. Only `FROM FIRST` is supported.

A maximum of 127 windows is supported for a given `SELECT`. Note that a single query may use multiple `SELECT` clauses, and each of these clauses supports up to 127 windows. The number of distinct windows is defined as the sum of the named windows and any implicit windows specified as part of any window function's `OVER` clause. You should also be aware that queries using very large numbers of windows may require increasing the default thread stack size (`thread_stack` system variable).

### 12.21 Performance Schema Functions

MySQL includes built-in SQL functions that format or retrieve Performance Schema data, and that may be used as equivalents for the corresponding `sys` schema stored functions. The built-in functions can be invoked in any schema and require no qualifier, unlike the `sys` functions, which require either a `sys` schema qualifier or that `sys` be the current schema.

#### Table 12.31 Performance Schema Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>FORMAT_BYTES()</code></td>
<td>Convert byte count to value with units</td>
</tr>
<tr>
<td><code>FORMAT_PICO_TIME()</code></td>
<td>Convert time in picoseconds to value with units</td>
</tr>
<tr>
<td><code>PS_CURRENT_THREAD_ID()</code></td>
<td>Performance Schema thread ID for current thread</td>
</tr>
<tr>
<td><code>PS_THREAD_ID()</code></td>
<td>Performance Schema thread ID for given thread</td>
</tr>
</tbody>
</table>

The built-in functions supersede the corresponding `sys` functions, which are deprecated; expect them to be removed in a future version of MySQL. Applications that use the `sys` functions should be adjusted to use the built-in functions instead, keeping in mind some minor differences between the `sys` functions and the built-in functions. For details about these differences, see the function descriptions in this section.

- **`FORMAT_BYTES(count)`**

  Given a numeric byte count, converts it to human-readable format and returns a string consisting of a value and a units indicator. The string contains the number of bytes rounded to 2 decimal places and a minimum of 3 significant digits. Numbers less than 1024 bytes are represented as whole numbers and are not rounded. Returns `NULL` if `count` is `NULL`.

  The units indicator depends on the size of the byte-count argument as shown in the following table.

<table>
<thead>
<tr>
<th>Argument Value</th>

</tr>
</thead>
<tbody>
<tr>
<td>512 bytes</td>
<td>16.00 EiB</td>
</tr>
</tbody>
</table>

FORMAT_BYTES() may be used instead of the sys schema format_bytes() function, keeping in mind this difference:

- FORMAT_BYTES() uses the EiB units indicator. sys.format_bytes() does not.

- FORMAT_PICO_TIME(time_val)

Given a numeric Performance Schema latency or wait time in picoseconds, converts it to human-readable format and returns a string consisting of a value and a units indicator. The string contains the decimal time rounded to 2 decimal places and a minimum of 3 significant digits. Times under 1 nanosecond are represented as whole numbers and are not rounded.

If time_val is NULL, this function returns NULL.

The units indicator depends on the size of the time-value argument as shown in the following table.

<table>
<thead>
<tr>
<th>Argument Value</th>
<th>Result Units</th>
<th>Result Units Indicator</th>
</tr>
</thead>
<tbody>
<tr>
<td>Up to $10^3$ - 1</td>
<td>picoseconds</td>
<td>ps</td>
</tr>
<tr>
<td>Up to $10^6$ - 1</td>
<td>nanoseconds</td>
<td>ns</td>
</tr>
<tr>
<td>Up to $10^9$ - 1</td>
<td>microseconds</td>
<td>us</td>
</tr>
<tr>
<td>Up to $10^{12}$ - 1</td>
<td>milliseconds</td>
<td>ms</td>
</tr>
<tr>
<td>Up to $60 \times 10^{12}$ - 1</td>
<td>seconds</td>
<td>s</td>
</tr>
<tr>
<td>Up to $3.6 \times 10^{15}$ - 1</td>
<td>minutes</td>
<td>min</td>
</tr>
<tr>
<td>Up to $8.64 \times 10^{16}$ - 1</td>
<td>hours</td>
<td>h</td>
</tr>
<tr>
<td>$8.64 \times 10^{16}$ and up</td>
<td>days</td>
<td>d</td>
</tr>
</tbody>
</table>

mysql> SELECT FORMAT_PICO_TIME(3501), FORMAT_PICO_TIME(188732396662000);
<table>
<thead>
<tr>
<th>FORMAT_PICO_TIME(3501)</th>
<th>FORMAT_PICO_TIME(188732396662000)</th>
</tr>
</thead>
<tbody>
<tr>
<td>3.50 ns</td>
<td>3.15 min</td>
</tr>
</tbody>
</table>

FORMAT_PICO_TIME() may be used instead of the sys schema format_time() function, keeping in mind these differences:

- To indicate minutes, sys.format_time() uses the m units indicator, whereas FORMAT_PICO_TIME() uses min.

- sys.format_time() uses the w (weeks) units indicator. FORMAT_PICO_TIME() does not.
• **PS_CURRENT_THREAD_ID()**

Returns a **BIGINT UNSIGNED** value representing the Performance Schema thread ID assigned to the current connection.

The thread ID return value is a value of the type given in the **THREAD_ID** column of Performance Schema tables.

Performance Schema configuration affects **PS_CURRENT_THREAD_ID()** the same way as for **PS_THREAD_ID()**. For details, see the description of that function.

```sql
mysql> SELECT PS_CURRENT_THREAD_ID();
+------------------------+
| PS_CURRENT_THREAD_ID() |
+------------------------+
|                     52 |
+------------------------+
```

**PS_CURRENT_THREAD_ID()** may be used as a shortcut for invoking the `sys` schema `ps_thread_id()` function with an argument of NULL or `CONNECTION_ID()`.

• **PS_THREAD_ID(connection_id)**

Given a connection ID, returns a **BIGINT UNSIGNED** value representing the Performance Schema thread ID assigned to the connection ID, or **NULL** if no thread ID exists for the connection ID. The latter can occur for threads that are not instrumented, or if `connection_id` is **NULL**.

The connection ID argument is a value of the type given in the **PROCESSLIST_ID** column of the Performance Schema **threads** table or the **Id** column of **SHOW PROCESSLIST** output.

The thread ID return value is a value of the type given in the **THREAD_ID** column of Performance Schema tables.

Performance Schema configuration affects **PS_THREAD_ID()** operation as follows. (These remarks also apply to **PS_CURRENT_THREAD_ID()**.)

• Disabling the **thread_instrumentation** consumer disables statistics from being collected and aggregated at the thread level, but has no effect on **PS_THREAD_ID()**.

• If `performance_schema_max_thread_instances` is not 0, the Performance Schema allocates memory for thread statistics and assigns an internal ID to each thread for which instance memory is available. If there are threads for which instance memory is not available, **PS_THREAD_ID()** returns **NULL**; in this case, **Performance_schema_thread_instances_lost** is nonzero.

• If `performance_schema_max_thread_instances` is 0, the Performance Schema allocates no thread memory and **PS_THREAD_ID()** returns **NULL**.

• If the Performance Schema itself is disabled, **PS_THREAD_ID()** produces an error.

```sql
mysql> SELECT PS_THREAD_ID(6);
+-----------------+
| PS_THREAD_ID(6) |
+-----------------+
|              45 |
```
**Internal Functions**

`PS_THREAD_ID()` may be used instead of the `sys` schema `ps_thread_id()` function, keeping in mind this difference:

- With an argument of `NULL`, `sys.ps_thread_id()` returns the thread ID for the current connection, whereas `PS_THREAD_ID()` returns `NULL`. To obtain the current connection thread ID, use `PS_CURRENT_THREAD_ID()` instead.

- **ANY_VALUE(arg)**

  This function is useful for GROUP BY queries when the ONLY_FULL_GROUP_BY SQL mode is enabled, for cases when MySQL rejects a query that you know is valid for reasons that MySQL cannot determine. The function return value and type are the same as the return value and type of its argument, but the function result is not checked for the ONLY_FULL_GROUP_BY SQL mode.

For example, if `name` is a nonindexed column, the following query fails with ONLY_FULL_GROUP_BY enabled:

```sql
mysql> SELECT name, address, MAX(age) FROM t GROUP BY name;
ERROR 1055 (42000): Expression #2 of SELECT list is not in GROUP BY clause and contains nonaggregated column 'mydb.t.address' which is not functionally dependent on columns in GROUP BY clause; this is incompatible with sql_mode=only_full_group_by
```

The failure occurs because `address` is a nonaggregated column that is neither named among GROUP BY columns nor functionally dependent on them. As a result, the `address` value for rows within each `name` group is nondeterministic. There are multiple ways to cause MySQL to accept the query:

- Alter the table to make `name` a primary key or a unique NOT NULL column. This enables MySQL to determine that `address` is functionally dependent on `name`; that is, `address` is uniquely determined by `name`. (This technique is inapplicable if NULL must be permitted as a valid `name` value.)

- Use **ANY_VALUE()** to refer to `address`:

  ```sql
  SELECT name, ANY_VALUE(address), MAX(age) FROM t GROUP BY name;
  ```

  In this case, MySQL ignores the nondeterminism of `address` values within each `name` group and accepts the query. This may be useful if you simply do not care which value of a nonaggregated column is chosen for each group. **ANY_VALUE()** is not an aggregate function, unlike functions such as `SUM()` or `COUNT()`. It simply acts to suppress the test for nondeterminism.
Miscellaneous Functions

• Disable `ONLY_FULL_GROUP_BY`. This is equivalent to using `ANY_VALUE()` with `ONLY_FULL_GROUP_BY` enabled, as described in the previous item.

`ANY_VALUE()` is also useful if functional dependence exists between columns but MySQL cannot determine it. The following query is valid because `age` is functionally dependent on the grouping column `age-1`, but MySQL cannot tell that and rejects the query with `ONLY_FULL_GROUP_BY` enabled:

```sql
SELECT age FROM t GROUP BY age-1;
```

To cause MySQL to accept the query, use `ANY_VALUE()`:

```sql
SELECT ANY_VALUE(age) FROM t GROUP BY age-1;
```

`ANY_VALUE()` can be used for queries that refer to aggregate functions in the absence of a `GROUP BY` clause:

```sql
mysql> SELECT name, MAX(age) FROM t;
ERROR 1140 (42000): In aggregated query without GROUP BY, expression #1 of SELECT list contains nonaggregated column 'mydb.t.name'; this is incompatible with sql_mode=only_full_group_by
```

Without `GROUP BY`, there is a single group and it is nondeterministic which `name` value to choose for the group. `ANY_VALUE()` tells MySQL to accept the query:

```sql
SELECT ANY_VALUE(name), MAX(age) FROM t;
```

It may be that, due to some property of a given data set, you know that a selected nonaggregated column is effectively functionally dependent on a `GROUP BY` column. For example, an application may enforce uniqueness of one column with respect to another. In this case, using `ANY_VALUE()` for the effectively functionally dependent column may make sense.

For additional discussion, see Section 12.19.3, “MySQL Handling of GROUP BY”.

• `BIN_TO_UUID(binary_uuid), BIN_TO_UUID(binary_uuid, swap_flag)`

`BIN_TO_UUID()` is the inverse of `UUID_TO_BIN()`. It converts a binary UUID to a string UUID and returns the result. The binary value should be a UUID as a `VARBINARY(16)` value. The return value is a string of five hexadecimal numbers separated by dashes. (For details about this format, see the `UUID()` function description.) If the UUID argument is `NULL`, the return value is `NULL`. If any argument is invalid, an error occurs.

`BIN_TO_UUID()` takes one or two arguments:

- The one-argument form takes a binary UUID value. The UUID value is assumed not to have its time-low and time-high parts swapped. The string result is in the same order as the binary argument.

- The two-argument form takes a binary UUID value and a swap-flag value:

  - If `swap_flag` is 0, the two-argument form is equivalent to the one-argument form. The string result is in the same order as the binary argument.

  - If `swap_flag` is 1, the UUID value is assumed to have its time-low and time-high parts swapped. These parts are swapped back to their original position in the result value.

For usage examples and information about time-part swapping, see the `UUID_TO_BIN()` function description.
• **DEFAULT**(col_name)**

Returns the default value for a table column. An error results if the column has no default value.

The use of `DEFAULT(col_name)` to specify the default value for a named column is permitted only for columns that have a literal default value, not for columns that have an expression default value.

```sql
mysql> UPDATE t SET i = DEFAULT(i)+1 WHERE id < 100;
```

• **FORMAT**(X, D)**

Formats the number X to a format like '#,###,###.##', rounded to D decimal places, and returns the result as a string. For details, see Section 12.8, “String Functions and Operators”.

• **GROUPING**(expr [,...])

For `GROUP BY` queries that include a `WITH ROLLUP` modifier, the `ROLLUP` operation produces super-aggregate output rows where `null` represents the set of all values. The `GROUPING()` function enables you to distinguish `null` values for super-aggregate rows from `null` values in regular grouped rows.

`GROUPING()` is permitted in the select list, `HAVING` clause, and `ORDER BY` clause.

Each argument to `GROUPING()` must be an expression that exactly matches an expression in the `GROUP BY` clause. The expression cannot be a positional specifier. For each expression, `GROUPING()` produces 1 if the expression value in the current row is a `null` representing a super-aggregate value. Otherwise, `GROUPING()` produces 0, indicating that the expression value is a `null` for a regular result row or is not `null`.

Suppose that table `t1` contains these rows, where `null` indicates something like “other” or “unknown”:

```sql
mysql> SELECT * FROM t1;
+-----+-----+---------+
<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
<th>quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>ball</td>
<td>small</td>
<td>10</td>
</tr>
<tr>
<td>ball</td>
<td>large</td>
<td>20</td>
</tr>
<tr>
<td>ball</td>
<td>null</td>
<td>5</td>
</tr>
<tr>
<td>hoop</td>
<td>small</td>
<td>15</td>
</tr>
<tr>
<td>hoop</td>
<td>large</td>
<td>5</td>
</tr>
<tr>
<td>hoop</td>
<td>null</td>
<td>3</td>
</tr>
</tbody>
</table>
+-----+-----+---------+
```

A summary of the table without `WITH ROLLUP` looks like this:

```sql
mysql> SELECT name, size, SUM(quantity) AS quantity FROM t1 GROUP BY name, size;
+-----+-----+---------+
<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
<th>quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>ball</td>
<td>small</td>
<td>10</td>
</tr>
<tr>
<td>ball</td>
<td>large</td>
<td>20</td>
</tr>
<tr>
<td>ball</td>
<td>null</td>
<td>5</td>
</tr>
<tr>
<td>hoop</td>
<td>small</td>
<td>15</td>
</tr>
<tr>
<td>hoop</td>
<td>large</td>
<td>5</td>
</tr>
<tr>
<td>hoop</td>
<td>null</td>
<td>3</td>
</tr>
</tbody>
</table>
+-----+-----+---------+
```
The result contains NULL values, but those do not represent super-aggregate rows because the query does not include WITH ROLLUP.

Adding WITH ROLLUP produces super-aggregate summary rows containing additional NULL values. However, without comparing this result to the previous one, it is not easy to see which NULL values occur in super-aggregate rows and which occur in regular grouped rows:

```sql
SELECT name, size, SUM(quantity) AS quantity
FROM t1
GROUP BY name, size WITH ROLLUP;
```

```
+------+-------+----------+
| name | size  | quantity |
+------+-------+----------+
| ball | NULL  |        5 |
| ball | large |       20 |
| ball | small |       10 |
| ball | NULL  |       35 |
| hoop | NULL  |        3 |
| hoop | large |       5 |
| hoop | small |       15 |
| hoop | NULL  |       23 |
| NULL | NULL  |       58 |
+------+-------+----------+
```

To distinguish NULL values in super-aggregate rows from those in regular grouped rows, use GROUPING(), which returns 1 only for super-aggregate NULL values:

```sql
SELECT
    name, size, SUM(quantity) AS quantity,
    GROUPING(name) AS grp_name,
    GROUPING(size) AS grp_size
FROM t1
GROUP BY name, size WITH ROLLUP;
```

```
+-----------+-----------+----------+----------+----------+
| name      | size      | quantity | grp_name | grp_size |
+-----------+-----------+----------+----------+----------+
| ball      | NULL      |        5 |        0 |        0 |
| ball      | large     |       20 |        0 |        0 |
| ball      | small     |       10 |        0 |        0 |
| ball      | NULL      |       35 |        0 |        1 |
| hoop      | NULL      |        3 |        0 |        0 |
| hoop      | large     |        5 |        0 |        0 |
| hoop      | small     |       15 |        0 |        0 |
| hoop      | NULL      |       23 |        0 |        1 |
| NULL      | NULL      |       58 |        1 |        1 |
+-----------+-----------+----------+----------+----------+
```

Common uses for GROUPING():

- Substitute a label for super-aggregate NULL values:

```sql
SELECT
    IF(GROUPING(name) = 1, 'All items', name) AS name,
    IF(GROUPING(size) = 1, 'All sizes', size) AS size,
    SUM(quantity) AS quantity
FROM t1
GROUP BY name, size WITH ROLLUP;
```

```
+-----------+-----------+----------+
| name      | size      | quantity |
+-----------+-----------+----------+
| ball      | NULL      |        5 |
| ball      | large     |       20 |
```

**Miscellaneous Functions**

| ball  | small | 10 |
| ball  | All sizes | 35 |
| hoop  | NULL   | 3  |
| hoop  | large  | 5  |
| hoop  | small  | 15 |
| hoop  | All sizes | 23 |
| All items | All sizes | 58 |

- Return only super-aggregate lines by filtering out the regular grouped lines:

```sql
mysql> SELECT name, size, SUM(quantity) AS quantity
           FROM t1
           GROUP BY name, size WITH ROLLUP
           HAVING GROUPING(name) = 1 OR GROUPING(size) = 1;
```

<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
<th>quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>ball</td>
<td>NULL</td>
<td>35</td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>23</td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
<td>58</td>
</tr>
</tbody>
</table>

`GROUPING()` permits multiple expression arguments. In this case, the `GROUPING()` return value represents a bitmask combined from the results for each expression, where the lowest-order bit corresponds to the result for the rightmost expression. For example, with three expression arguments, `GROUPING(expr1, expr2, expr3)` is evaluated like this:

- result for `GROUPING(expr3)`
- result for `GROUPING(expr2) << 1`
- result for `GROUPING(expr1) << 2`

The following query shows how `GROUPING()` results for single arguments combine for a multiple-argument call to produce a bitmask value:

```sql
mysql> SELECT name, size, SUM(quantity) AS quantity,
                      GROUPING(name) AS grp_name,
                      GROUPING(size) AS grp_size,
                      GROUPING(name, size) AS grp_all
                      FROM t1
                      GROUP BY name, size WITH ROLLUP;
```

<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
<th>quantity</th>
<th>grp_name</th>
<th>grp_size</th>
<th>grp_all</th>
</tr>
</thead>
<tbody>
<tr>
<td>ball</td>
<td>NULL</td>
<td>5</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>ball</td>
<td>large</td>
<td>20</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>ball</td>
<td>small</td>
<td>10</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>ball</td>
<td>NULL</td>
<td>35</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>3</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>hoop</td>
<td>large</td>
<td>5</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>hoop</td>
<td>small</td>
<td>15</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>23</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
<td>58</td>
<td>1</td>
<td>1</td>
<td>3</td>
</tr>
</tbody>
</table>

With multiple expression arguments, the `GROUPING()` return value is nonzero if any expression represents a super-aggregate value. Multiple-argument `GROUPING()` syntax thus provides a simpler way to write the earlier query that returned only super-aggregate rows, by using a single multiple-argument `GROUPING()` call rather than multiple single-argument calls:

```sql
mysql> SELECT name, size, SUM(quantity) AS quantity
                      FROM t1
                      GROUP BY name, size WITH ROLLUP
```
Use of `GROUPING()` is subject to these limitations:

- Do not use subquery `GROUP BY` expressions as `GROUPING()` arguments because matching might fail. For example, matching fails for this query:

  ```sql
  mysql> SELECT GROUPING((SELECT MAX(name) FROM t1))
  FROM t1
  GROUP BY (SELECT MAX(name) FROM t1) WITH ROLLUP;
  ERROR 3580 (HY000): Argument #1 of GROUPING function is not in GROUP BY
  ```

- `GROUP BY` literal expressions should not be used within a `HAVING` clause as `GROUPING()` arguments. Due to differences between when the optimizer evaluates `GROUP BY` and `HAVING`, matching may succeed but `GROUPING()` evaluation does not produce the expected result. Consider this query:

  ```sql
  SELECT a AS f1, 'w' AS f2
  FROM t
  GROUP BY f1, f2 WITH ROLLUP
  HAVING GROUPING(f2) = 1;
  ```

  `GROUPING()` is evaluated earlier for the literal constant expression than for the `HAVING` clause as a whole and returns 0. To check whether a query such as this is affected, use `EXPLAIN` and look for `Impossible having` in the `Extra` column.

  For more information about `WITH ROLLUP` and `GROUPING()`, see Section 12.19.2, “GROUP BY Modifiers”.

- `INET_ATON(expr)`

  Given the dotted-quad representation of an IPv4 network address as a string, returns an integer that represents the numeric value of the address in network byte order (big endian). `INET_ATON()` returns `NULL` if it does not understand its argument, or if `expr` is `NULL`.

  ```sql
  mysql> SELECT INET_ATON('10.0.5.9');
  -> 167773449
  ```

  For this example, the return value is calculated as $10 \times 256^3 + 0 \times 256^2 + 5 \times 256 + 9$.

  `INET_ATON()` may or may not return a non-`NULL` result for short-form IP addresses (such as `'127.1'` as a representation of `'127.0.0.1'`). Because of this, `INET_ATON()` a should not be used for such addresses.

  **Note**

  To store values generated by `INET_ATON()`, use an `INT UNSIGNED` column rather than `INT`, which is signed. If you use a signed column, values corresponding to IP addresses for which the first octet is greater than 127 cannot be stored correctly. See Section 11.1.7, “Out-of-Range and Overflow Handling”. 

  2585
• **INET_NTOA**\((\text{expr})\)

Given a numeric IPv4 network address in network byte order, returns the dotted-quad string representation of the address as a string in the connection character set. **INET_NTOA** returns NULL if it does not understand its argument.

```sql
mysql> SELECT INET_NTOA(167773449);
-> '10.0.5.9'
```

• **INET6_ATON**\((\text{expr})\)

Given an IPv6 or IPv4 network address as a string, returns a binary string that represents the numeric value of the address in network byte order (big endian). Because numeric-format IPv6 addresses require more bytes than the largest integer type, the representation returned by this function has the **VARBINARY** data type: **VARBINARY**\((16)\) for IPv6 addresses and **VARBINARY**\((4)\) for IPv4 addresses. If the argument is not a valid address, or if it is NULL, **INET6_ATON** returns NULL.

The following examples use **HEX**\()\) to display the **INET6_ATON**\()\) result in printable form:

```sql
mysql> SELECT HEX(INET6_ATON('fdfe::5a55:caff:fefa:9089'));
-> 'FDFE0000000000005A55CAFFFEFA9089'
mysql> SELECT HEX(INET6_ATON('10.0.5.9'));
-> '0A000509'
```

**INET6_ATON**\()\) observes several constraints on valid arguments. These are given in the following list along with examples.

- A trailing zone ID is not permitted, as in `fe80::3%1` or `fe80::3%eth0`.
- A trailing network mask is not permitted, as in `2001:45f:3:ba::/64` or `198.51.100.0/24`.
- For values representing IPv4 addresses, only classless addresses are supported. Classful addresses such as `198.51.1` are rejected. A trailing port number is not permitted, as in `198.51.100.2:8080`. Hexadecimal numbers in address components are not permitted, as in `198.0xa0.1.2`. Octal numbers are not supported: `198.51.10.1` is treated as `198.51.10.1`, not `198.51.8.1`. These IPv4 constraints also apply to IPv6 addresses that have IPv4 address parts, such as IPv4-compatible or IPv4-mapped addresses.

To convert an IPv4 address `expr` represented in numeric form as an **INT** value to an IPv6 address represented in numeric form as a **VARBINARY** value, use this expression:

```sql
INET6_ATON(INET_NTOA(expr))
```

For example:

```sql
mysql> SELECT HEX(INET6_ATON(INET_NTOA(167773449)));
-> '0A000509'
```

**INET6_ATON**\()\) is invoked from within the **mysql** client, binary strings display using hexadecimal notation, depending on the value of the **--binary-as-hex** option. For more information about that option, see Section 4.5.1, “**mysql** — The MySQL Command-Line Client”.

• **INET6_NTOA**\((\text{expr})\)

Given an IPv6 or IPv4 network address represented in numeric form as a binary string, returns the string representation of the address as a string in the connection character set. If the argument is not a valid address, or if it is NULL, **INET6_NTOA** returns NULL.

**INET6_NTOA** has these properties:
• It does not use operating system functions to perform conversions, thus the output string is platform independent.

• The return string has a maximum length of 39 (4 x 8 + 7). Given this statement:

```sql
CREATE TABLE t AS SELECT INET6_NTOA(expr) AS c1;
```

The resulting table would have this definition:

```sql
CREATE TABLE t (c1 VARCHAR(39) CHARACTER SET utf8mb3 DEFAULT NULL);
```

• The return string uses lowercase letters for IPv6 addresses.

```sql
mysql> SELECT INET6_NTOA(INET6_ATON('fdfe::5a55:caff:fefa:9089'));
-> 'fdfe::5a55:caff:fefa:9089'
mysql> SELECT INET6_NTOA(INET6_ATON('10.0.5.9'));
-> '10.0.5.9'
mysql> SELECT INET6_NTOA(INET6_ATON('::10.0.5.9'));
-> 'fdfe::5a55:caff:fefa:9089'
mysql> SELECT INET6_NTOA(INET6_ATON('::ffff:10.0.5.9'));
-> 'fdfe::5a55:caff:fefa:9089'
```

If `INET6_NTOA()` is invoked from within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

• **IS_IPV4(expr)**

Returns 1 if the argument is a valid IPv4 address specified as a string, 0 otherwise. Returns `NULL` if `expr` is `NULL`.

```sql
mysql> SELECT IS_IPV4('10.0.5.9'), IS_IPV4('10.0.5.256');
-> 1, 0
```

For a given argument, if `IS_IPV4()` returns 1, `INET_ATON()` (and `INET6_ATON()`) returns non-`NULL`. The converse statement is not true: In some cases, `INET_ATON()` returns non-`NULL` when `IS_IPV4()` returns 0.

As implied by the preceding remarks, `IS_IPV4()` is more strict than `INET_ATON()` about what constitutes a valid IPv4 address, so it may be useful for applications that need to perform strong checks against invalid values. Alternatively, use `INET6_ATON()` to convert IPv4 addresses to internal form and check for a `NULL` result (which indicates an invalid address). `INET6_ATON()` is equally strong as `IS_IPV4()` about checking IPv4 addresses.

• **IS_IPV4_COMPAT(expr)**

This function takes an IPv6 address represented in numeric form as a binary string, as returned by `INET6_ATON()`. It returns 1 if the argument is a valid IPv4-compatible IPv6 address, 0 otherwise (unless `expr` is `NULL`, in which case the function returns `NULL`). IPv4-compatible addresses have the form `::ipv4_address`.

```sql
mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::10.0.5.9'));
-> 1
mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::ffff:10.0.5.9'));
```
The IPv4 part of an IPv4-compatible address can also be represented using hexadecimal notation. For example, 198.51.100.1 has this raw hexadecimal value:

mysql> SELECT HEX(INET6_ATON('198.51.100.1'));
-> 'C6336401'

Expressed in IPv4-compatible form, ::198.51.100.1 is equivalent to ::c0a8:0001 or (without leading zeros) ::c0a8:1

mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::198.51.100.1')),
      -> IS_IPV4_COMPAT(INET6_ATON('::c0a8:0001')),
      -> IS_IPV4_COMPAT(INET6_ATON('::c0a8:1'));
-> 1, 1, 1

• IS_IPV4_MAPPED(expr)

This function takes an IPv6 address represented in numeric form as a binary string, as returned by INET6_ATON(). It returns 1 if the argument is a valid IPv4-mapped IPv6 address, 0 otherwise, unless expr is NULL, in which case the function returns NULL. IPv4-mapped addresses have the form ::ffff:ipv4_address.

mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::10.0.5.9'));
-> 0
mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::ffff:10.0.5.9'));
-> 1

As with IS_IPV4_COMPAT() the IPv4 part of an IPv4-mapped address can also be represented using hexadecimal notation:

mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::ffff:198.51.100.1')),
      -> IS_IPV4_MAPPED(INET6_ATON('::ffff:c0a8:0001')),
      -> IS_IPV4_MAPPED(INET6_ATON('::ffff:c0a8:1'));
-> 1, 1, 1

• IS_IPV6(expr)

Returns 1 if the argument is a valid IPv6 address specified as a string, 0 otherwise, unless expr is NULL, in which case the function returns NULL. This function does not consider IPv4 addresses to be valid IPv6 addresses.

mysql> SELECT IS_IPV6('10.0.5.9'), IS_IPV6('::1');
-> 0, 1

For a given argument, if IS_IPV6() returns 1, INET6_ATON() returns non-NULL.

• IS_UUID(string_uuid)

Returns 1 if the argument is a valid string-format UUID, 0 if the argument is not a valid UUID, and NULL if the argument is NULL.

“Valid” means that the value is in a format that can be parsed. That is, it has the correct length and contains only the permitted characters (hexadecimal digits in any lettercase and, optionally, dashes and curly braces). This format is most common:

aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee

These other formats are also permitted:
For the meanings of fields within the value, see the UUID() function description.

mysql> SELECT IS_UUID('6ccd780c-baba-1026-9564-5b8c656024db');
+-----------------+
| IS_UUID('6ccd780c-baba-1026-9564-5b8c656024db') |
| 1               |
+-----------------+
mysql> SELECT IS_UUID('6CCD780C-BABA-1026-9564-5B8C656024DB');
+-----------------+
| IS_UUID('6CCD780C-BABA-1026-9564-5B8C656024DB') |
| 1               |
+-----------------+
mysql> SELECT IS_UUID('6ccd780cbaba102695645b8c656024db');
+-----------------+
| IS_UUID('6ccd780cbaba102695645b8c656024db') |
| 1               |
+-----------------+
mysql> SELECT IS_UUID('{6ccd780c-baba-1026-9564-5b8c656024db}');
+-----------------+
| IS_UUID('{6ccd780c-baba-1026-9564-5b8c656024db}') |
| 1               |
+-----------------+
mysql> SELECT IS_UUID('6ccd780c-baba-1026-9564-5b8c6560');
+-----------------+
| IS_UUID('6ccd780c-baba-1026-9564-5b8c6560') |
| 0               |
+-----------------+
mysql> SELECT IS_UUID(RAND());
+-----------------+
| IS_UUID(RAND()) |
| 0               |
+-----------------+

• NAME_CONST(name, value)

  Returns the given value. When used to produce a result set column, NAMECONST() causes the column to have the given name. The arguments should be constants.

mysql> SELECT NAME_CONST('myname', 14);
+--------+
| myname |
| 14     |
+--------+

This function is for internal use only. The server uses it when writing statements from stored programs that contain references to local program variables, as described in Section 25.7, “Stored Program Binary Logging”. You might see this function in the output from mysqlbinlog.

For your applications, you can obtain exactly the same result as in the example just shown by using simple aliasing, like this:

mysql> SELECT 14 AS myname;
+--------+
| myname |
| 14     |
+--------+
See Section 13.2.13, “SELECT Statement”, for more information about column aliases.

- **SLEEP(duration)**

Sleeps (pauses) for the number of seconds given by the `duration` argument, then returns 0. The duration may have a fractional part. If the argument is `NULL` or negative, `SLEEP()` produces a warning, or an error in strict SQL mode.

When sleep returns normally (without interruption), it returns 0:

```sql
mysql> SELECT SLEEP(1000);
+-------------+
<table>
<thead>
<tr>
<th>SLEEP(1000)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
+-------------+
```

When `SLEEP()` is the only thing invoked by a query that is interrupted, it returns 1 and the query itself returns no error. This is true whether the query is killed or times out:

- This statement is interrupted using `KILL QUERY` from another session:

```sql
mysql> SELECT SLEEP(1000);
+-------------+
<table>
<thead>
<tr>
<th>SLEEP(1000)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
+-------------+
```

- This statement is interrupted by timing out:

```sql
mysql> SELECT /*+ MAX_EXECUTION_TIME(1) */ SLEEP(1000);
+-------------+
<table>
<thead>
<tr>
<th>SLEEP(1000)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
+-------------+
```

When `SLEEP()` is only part of a query that is interrupted, the query returns an error:

- This statement is interrupted using `KILL QUERY` from another session:

```sql
mysql> SELECT 1 FROM t1 WHERE SLEEP(1000);
ERROR 1317 (70100): Query execution was interrupted
```

- This statement is interrupted by timing out:

```sql
mysql> SELECT /*+ MAX_EXECUTION_TIME(1000) */ 1 FROM t1 WHERE SLEEP(1000);
ERROR 3024 (HY000): Query execution was interrupted, maximum statement execution time exceeded
```

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`. 
• **UUID()**

Returns a Universal Unique Identifier (UUID) generated according to RFC 4122, “A Universally Unique IDentifier (UUID) URN Namespace” (http://www.ietf.org/rfc/rfc4122.txt).

A UUID is designed as a number that is globally unique in space and time. Two calls to UUID() are expected to generate two different values, even if these calls are performed on two separate devices not connected to each other.

**Warning**

Although UUID() values are intended to be unique, they are not necessarily unguessable or unpredictable. If unpredictability is required, UUID values should be generated some other way.

UUID() returns a value that conforms to UUID version 1 as described in RFC 4122. The value is a 128-bit number represented as a utf8mb3 string of five hexadecimal numbers in aaaaaaaaaa-bbbb-cccc-dddd-eeeeeeeeee format:

- The first three numbers are generated from the low, middle, and high parts of a timestamp. The high part also includes the UUID version number.
- The fourth number preserves temporal uniqueness in case the timestamp value loses monotonicity (for example, due to daylight saving time).
- The fifth number is an IEEE 802 node number that provides spatial uniqueness. A random number is substituted if the latter is not available (for example, because the host device has no Ethernet card, or it is unknown how to find the hardware address of an interface on the host operating system). In this case, spatial uniqueness cannot be guaranteed. Nevertheless, a collision should have very low probability.

The MAC address of an interface is taken into account only on FreeBSD, Linux, and Windows. On other operating systems, MySQL uses a randomly generated 48-bit number.

```
mysql> SELECT UUID();
-> '6ccd780c-baba-1026-9564-5b8c656024db'
```

To convert between string and binary UUID values, use the UUID_TO_BIN() and BIN_TO_UUID() functions. To check whether a string is a valid UUID value, use the IS_UUID() function.

This function is unsafe for statement-based replication. A warning is logged if you use this function when binlog_format is set to STATEMENT.

• **UUID_SHORT()**

Returns a “short” universal identifier as a 64-bit unsigned integer. Values returned by UUID_SHORT() differ from the string-format 128-bit identifiers returned by the UUID() function and have different
uniqueness properties. The value of `UUID_SHORT()` is guaranteed to be unique if the following conditions hold:

- The `server_id` value of the current server is between 0 and 255 and is unique among your set of source and replica servers
- You do not set back the system time for your server host between `mysqld` restarts
- You invoke `UUID_SHORT()` on average fewer than 16 million times per second between `mysqld` restarts

The `UUID_SHORT()` return value is constructed this way:

```sql
(server_id & 255) << 56
+ (server_startup_time_in_seconds << 24)
+ incremented_variable++;
```

```sql
mysql> SELECT UUID_SHORT();
-> 92395783831158784
```

**Note**

`UUID_SHORT()` does not work with statement-based replication.

- `UUID_TO_BIN(string_uuid), UUID_TO_BIN(string_uuid, swap_flag)`

Converts a string UUID to a binary UUID and returns the result. (The `IS_UUID()` function description lists the permitted string UUID formats.) The return binary UUID is a `VARBINARY(16)` value. If the UUID argument is `NULL`, the return value is `NULL`. If any argument is invalid, an error occurs.

`UUID_TO_BIN()` takes one or two arguments:

- The one-argument form takes a string UUID value. The binary result is in the same order as the string argument.

- The two-argument form takes a string UUID value and a flag value:
  - If `swap_flag` is 0, the two-argument form is equivalent to the one-argument form. The binary result is in the same order as the string argument.
  - If `swap_flag` is 1, the format of the return value differs: The time-low and time-high parts (the first and third groups of hexadecimal digits, respectively) are swapped. This moves the more rapidly varying part to the right and can improve indexing efficiency if the result is stored in an indexed column.

Time-part swapping assumes the use of UUID version 1 values, such as are generated by the `UUID()` function. For UUID values produced by other means that do not follow version 1 format, time-part swapping provides no benefit. For details about version 1 format, see the `UUID()` function description.

Suppose that you have the following string UUID value:

```sql
mysql> SET @uuid = '6ccd780c-baba-1026-9564-5b8c656024db';
```

To convert the string UUID to binary with or without time-part swapping, use `UUID_TO_BIN()`:

```sql
mysql> SELECT HEX(UUID_TO_BIN(@uuid));
```

<table>
<thead>
<tr>
<th>HEX(UUID_TO_BIN(@uuid))</th>
</tr>
</thead>
<tbody>
<tr>
<td>2592</td>
</tr>
</tbody>
</table>
To convert a binary UUID returned by `UUID_TO_BIN()` to a string UUID, use `BIN_TO_UUID()`. If you produce a binary UUID by calling `UUID_TO_BIN()` with a second argument of 1 to swap time parts, you should also pass a second argument of 1 to `BIN_TO_UUID()` to unswap the time parts when converting the binary UUID back to a string UUID:

```sql
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid));
+--------------------------------------+
| BIN_TO_UUID(UUID_TO_BIN(@uuid))      |
| 6ccd780c-baba-1026-9564-5b8c656024db |
+--------------------------------------+
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid, 0));
+--------------------------------------+
| BIN_TO_UUID(UUID_TO_BIN(@uuid, 0))   |
| 6ccd780c-baba-1026-9564-5b8c656024db |
+--------------------------------------+
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid, 1));
+--------------------------------------+
| BIN_TO_UUID(UUID_TO_BIN(@uuid, 1))   |
| 1026baba6ccd780c95645b8c656024db     |
+--------------------------------------+
```

If the use of time-part swapping is not the same for the conversion in both directions, the original UUID is not recovered properly:

```sql
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid, 0), 1);
+--------------------------------------+
| BIN_TO_UUID(UUID_TO_BIN(@uuid, 0), 1) |
| baba1026-780c-6ccd-9564-5b8c656024db |
+--------------------------------------+
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid, 1), 0);
+--------------------------------------+
| BIN_TO_UUID(UUID_TO_BIN(@uuid, 1), 0) |
| 1026baba-6ccd-780c-9564-5b8c656024db |
+--------------------------------------+
```

If `UUID_TO_BIN()` is invoked from within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client".
• **VALUES(col_name)**

In an `INSERT ... ON DUPLICATE KEY UPDATE` statement, you can use the `VALUES(col_name)` function in the `UPDATE` clause to refer to column values from the `INSERT` portion of the statement. In other words, `VALUES(col_name)` in the `UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in the `ON DUPLICATE KEY UPDATE` clause of `INSERT` statements and returns `NULL` otherwise. See Section 13.2.7.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”.

```sql
mysql> INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
    
    -> ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

**Important**

This usage is deprecated, and subject to removal in a future release of MySQL. Use a row alias, or row and column aliases, instead. For more information and examples, see Section 13.2.7.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”.

### 12.24 Precision Math

MySQL provides support for precision math: numeric value handling that results in extremely accurate results and a high degree control over invalid values. Precision math is based on these two features:

- SQL modes that control how strict the server is about accepting or rejecting invalid data.
- The MySQL library for fixed-point arithmetic.

These features have several implications for numeric operations and provide a high degree of compliance with standard SQL:

- **Precise calculations**: For exact-value numbers, calculations do not introduce floating-point errors. Instead, exact precision is used. For example, MySQL treats a number such as `.0001` as an exact value rather than as an approximation, and summing it 10,000 times produces a result of exactly `1`, not a value that is merely “close” to `1`.

- **Well-defined rounding behavior**: For exact-value numbers, the result of `ROUND()` depends on its argument, not on environmental factors such as how the underlying C library works.

- **Platform independence**: Operations on exact numeric values are the same across different platforms such as Windows and Unix.

- **Control over handling of invalid values**: Overflow and division by zero are detectable and can be treated as errors. For example, you can treat a value that is too large for a column as an error rather than having the value truncated to lie within the range of the column’s data type. Similarly, you can treat division by zero as an error rather than as an operation that produces a result of `NULL`. The choice of which approach to take is determined by the setting of the server SQL mode.

The following discussion covers several aspects of how precision math works, including possible incompatibilities with older applications. At the end, some examples are given that demonstrate how MySQL handles numeric operations precisely. For information about controlling the SQL mode, see Section 5.1.11, “Server SQL Modes”.

### 12.24.1 Types of Numeric Values
DECIMAL Data Type Characteristics

The scope of precision math for exact-value operations includes the exact-value data types (integer and DECIMAL types) and exact-value numeric literals. Approximate-value data types and numeric literals are handled as floating-point numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: 1, .2, 3.4, −5, −6.78, +9.10.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: 1.2E3, 1.2E−3, −1.2E3, −1.2E−3.

Two numbers that look similar may be treated differently. For example, 2.34 is an exact-value (fixed-point) number, whereas 2.34E0 is an approximate-value (floating-point) number.

The DECIMAL data type is a fixed-point type and calculations are exact. In MySQL, the DECIMAL type has several synonyms: NUMERIC, DEC, FIXED. The integer types also are exact-value types.

The FLOAT and DOUBLE data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with FLOAT or DOUBLE are DOUBLE PRECISION and REAL.

### 12.24.2 DECIMAL Data Type Characteristics

This section discusses the characteristics of the DECIMAL data type (and its synonyms), with particular regard to the following topics:

- Maximum number of digits
- Storage format
- Storage requirements
- The nonstandard MySQL extension to the upper range of DECIMAL columns

The declaration syntax for a DECIMAL column is \texttt{DECIMAL(M, D)}. The ranges of values for the arguments are as follows:

- \( M \) is the maximum number of digits (the precision). It has a range of 1 to 65.
- \( D \) is the number of digits to the right of the decimal point (the scale). It has a range of 0 to 30 and must be no larger than \( M \).

If \( D \) is omitted, the default is 0. If \( M \) is omitted, the default is 10.

The maximum value of 65 for \( M \) means that calculations on DECIMAL values are accurate up to 65 digits. This limit of 65 digits of precision also applies to exact-value numeric literals, so the maximum range of such literals differs from before. (There is also a limit on how long the text of DECIMAL literals can be; see Section 12.24.3, “Expression Handling”.)

Values for DECIMAL columns are stored using a binary format that packs nine decimal digits into 4 bytes. The storage requirements for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires 4 bytes, and any remaining digits left over require some fraction of 4 bytes. The storage required for remaining digits is given by the following table.

<table>
<thead>
<tr>
<th>Leftover Digits</th>
<th>Number of Bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1–2</td>
<td>1</td>
</tr>
<tr>
<td>3–4</td>
<td>2</td>
</tr>
</tbody>
</table>
For example, a `DECIMAL(18,9)` column has nine digits on either side of the decimal point, so the integer part and the fractional part each require 4 bytes. A `DECIMAL(20,6)` column has fourteen integer digits and six fractional digits. The integer digits require four bytes for nine of the digits and 3 bytes for the remaining five digits. The six fractional digits require 3 bytes.

`DECIMAL` columns do not store a leading `+` character or `–` character or leading 0 digits. If you insert `+0003.1` into a `DECIMAL(5,1)` column, it is stored as 3.1. For negative numbers, a literal `–` character is not stored.

`DECIMAL` columns do not permit values larger than the range implied by the column definition. For example, a `DECIMAL(3,0)` column supports a range of −999 to 999. A `DECIMAL(M,D)` column permits up to $M-D$ digits to the left of the decimal point.

The SQL standard requires that the precision of `NUMERIC(M,D)` be exactly $M$ digits. For `DECIMAL(M,D)`, the standard requires a precision of at least $M$ digits but permits more. In MySQL, `DECIMAL(M,D)` and `NUMERIC(M,D)` are the same, and both have a precision of exactly $M$ digits.

For a full explanation of the internal format of `DECIMAL` values, see the file `strings/decimal.c` in a MySQL source distribution. The format is explained (with an example) in the `decimal2bin()` function.

### 12.24.3 Expression Handling

With precision math, exact-value numbers are used as given whenever possible. For example, numbers in comparisons are used exactly as given without a change in value. In strict SQL mode, for `INSERT` into a column with an exact data type (`DECIMAL` or integer), a number is inserted with its exact value if it is within the column range. When retrieved, the value should be the same as what was inserted. (If strict SQL mode is not enabled, truncation for `INSERT` is permissible.)

Handling of a numeric expression depends on what kind of values the expression contains:

- If any approximate values are present, the expression is approximate and is evaluated using floating-point arithmetic.

- If no approximate values are present, the expression contains only exact values. If any exact value contains a fractional part (a value following the decimal point), the expression is evaluated using `DECIMAL` exact arithmetic and has a precision of 65 digits. The term “exact” is subject to the limits of what can be represented in binary. For example, `1.0/3.0` can be approximated in decimal notation as `.333...`, but not written as an exact number, so `(1.0/3.0)*3.0` does not evaluate to exactly 1.0.

- Otherwise, the expression contains only integer values. The expression is exact and is evaluated using integer arithmetic and has a precision the same as `BIGINT` (64 bits).

If a numeric expression contains any strings, they are converted to double-precision floating-point values and the expression is approximate.

Inserts into numeric columns are affected by the SQL mode, which is controlled by the `sql_mode` system variable. (See Section 5.1.11, “Server SQL Modes”.) The following discussion mentions strict mode (selected by the `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` mode values) and `ERROR FOR DIVISION BY ZERO`. To turn on all restrictions, you can simply use `TRADITIONAL` mode, which includes both strict mode values and `ERROR FOR DIVISION BY ZERO`:

```sql
SET sql_mode='TRADITIONAL';
```
If a number is inserted into an exact type column (DECIMAL or integer), it is inserted with its exact value if it is within the column range and precision.

If the value has too many digits in the fractional part, rounding occurs and a note is generated. Rounding is done as described in Section 12.24.4, “Rounding Behavior”. Truncation due to rounding of the fractional part is not an error, even in strict mode.

If the value has too many digits in the integer part, it is too large (out of range) and is handled as follows:

- If strict mode is not enabled, the value is truncated to the nearest legal value and a warning is generated.
- If strict mode is enabled, an overflow error occurs.

Underflow is not detected, so underflow handling is undefined.

For inserts of strings into numeric columns, conversion from string to number is handled as follows if the string has nonnumeric contents:

- A string that does not begin with a number cannot be used as a number and produces an error in strict mode, or a warning otherwise. This includes the empty string.

- A string that begins with a number can be converted, but the trailing nonnumeric portion is truncated. If the truncated portion contains anything other than spaces, this produces an error in strict mode, or a warning otherwise.

By default, division by zero produces a result of NULL and no warning. By setting the SQL mode appropriately, division by zero can be restricted.

With the ERROR_FOR_DIVISION_BY_ZERO SQL mode enabled, MySQL handles division by zero differently:

- If strict mode is not enabled, a warning occurs.
- If strict mode is enabled, inserts and updates involving division by zero are prohibited, and an error occurs.

In other words, inserts and updates involving expressions that perform division by zero can be treated as errors, but this requires ERROR_FOR_DIVISION_BY_ZERO in addition to strict mode.

Suppose that we have this statement:

```
INSERT INTO t SET i = 1/0;
```

This is what happens for combinations of strict and ERROR_FOR_DIVISION_BY_ZERO modes.

<table>
<thead>
<tr>
<th>sql_mode Value</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>'' (Default)</td>
<td>No warning, no error; i is set to NULL.</td>
</tr>
<tr>
<td>strict</td>
<td>No warning, no error; i is set to NULL.</td>
</tr>
<tr>
<td>ERROR_FOR_DIVISION_BY_ZERO</td>
<td>Warning, no error; i is set to NULL.</td>
</tr>
<tr>
<td>strict,ERROR_FOR_DIVISION_BY_ZERO</td>
<td>Error condition; no row is inserted.</td>
</tr>
</tbody>
</table>

12.24.4 Rounding Behavior

This section discusses precision math rounding for the ROUND() function and for inserts into columns with exact-value types (DECIMAL and integer).
The `ROUND()` function rounds differently depending on whether its argument is exact or approximate:

- For exact-value numbers, `ROUND()` uses the “round half up” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative. (In other words, it is rounded toward zero.)

- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with a fractional part exactly half way between two integers is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```sql
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+------------+--------------+
| ROUND(2.5) | ROUND(25E-1) |
+------------+--------------+
| 3          |            2 |
+------------+--------------+
```

For inserts into a `DECIMAL` or integer column, the target is an exact data type, so rounding uses “round half away from zero,” regardless of whether the value to be inserted is exact or approximate:

```sql
mysql> CREATE TABLE t (d DECIMAL(10,0));
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t VALUES(2.5),(2.5E0);
Query OK, 2 rows affected, 2 warnings (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 2

mysql> SHOW WARNINGS;
+-------+------+----------------------------------------+
<table>
<thead>
<tr>
<th>Level</th>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Note</td>
<td>1265</td>
<td>Data truncated for column 'd' at row 1</td>
</tr>
<tr>
<td>Note</td>
<td>1265</td>
<td>Data truncated for column 'd' at row 2</td>
</tr>
</tbody>
</table>
+-------+------+----------------------------------------+
2 rows in set (0.00 sec)

mysql> SELECT d FROM t;
+------+
| d    |
+------+
| 3    |
| 3    |
+------+
2 rows in set (0.00 sec)
```

The `SHOW WARNINGS` statement displays the notes that are generated by truncation due to rounding of the fractional part. Such truncation is not an error, even in strict SQL mode (see Section 12.24.3, “Expression Handling”).

### 12.24.5 Precision Math Examples

This section provides some examples that show precision math query results in MySQL. These examples demonstrate the principles described in Section 12.24.3, “Expression Handling”, and Section 12.24.4, “Rounding Behavior”.

**Example 1.** Numbers are used with their exact value as given when possible:

```sql
mysql> SELECT (.1 + .2) = .3;  
+----------------+
| (.1 + .2) = .3  |
+----------------+
```
Precision Math Examples

For floating-point values, results are inexact:

```sql
mysql> SELECT (.1E0 + .2E0) = .3E0;
+----------------------+
| (.1E0 + .2E0) = .3E0 |
|                    0  |
+----------------------+
```

Another way to see the difference in exact and approximate value handling is to add a small number to a sum many times. Consider the following stored procedure, which adds .0001 to a variable 1,000 times.

```sql
CREATE PROCEDURE p ()
BEGIN
DECLARE i INT DEFAULT 0;
DECLARE d DECIMAL(10,4) DEFAULT 0;
DECLARE f FLOAT DEFAULT 0;
WHILE i < 10000 DO
  SET d = d + .0001;
  SET f = f + .0001E0;
  SET i = i + 1;
END WHILE;
SELECT d, f;
END;
```

The sum for both d and f logically should be 1, but that is true only for the decimal calculation. The floating-point calculation introduces small errors:

<table>
<thead>
<tr>
<th>d</th>
<th>f</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.0000</td>
<td>0.99999999999991</td>
</tr>
</tbody>
</table>

Example 2. Multiplication is performed with the scale required by standard SQL. That is, for two numbers X1 and X2 that have scale S1 and S2, the scale of the result is S1 + S2:

```sql
mysql> SELECT .01 * .01;
+-----------+
| .01 * .01 |
| 0.0001    |
+-----------+
```

Example 3. Rounding behavior for exact-value numbers is well-defined:

Rounding behavior (for example, with the ROUND() function) is independent of the implementation of the underlying C library, which means that results are consistent from platform to platform.

- Rounding for exact-value columns (DECIMAL and integer) and exact-valued numbers uses the “round half away from zero” rule. A value with a fractional part of .5 or greater is rounded away from zero to the nearest integer, as shown here:

```sql
mysql> SELECT ROUND(2.5), ROUND(-2.5);
+------------+-------------+
| ROUND(2.5) | ROUND(-2.5) |
| 3          | -3          |
+------------+-------------+
```
• Rounding for floating-point values uses the C library, which on many systems uses the “round to nearest even” rule. A value with a fractional part exactly half way between two integers is rounded to the nearest even integer:

```
mysql> SELECT ROUND(2.5E0), ROUND(-2.5E0);
+--------------+---------------+
<table>
<thead>
<tr>
<th>ROUND(2.5E0)</th>
<th>ROUND(-2.5E0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>-2</td>
</tr>
</tbody>
</table>
+--------------+---------------+
```

**Example 4.** In strict mode, inserting a value that is out of range for a column causes an error, rather than truncation to a legal value.

When MySQL is not running in strict mode, truncation to a legal value occurs:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET i = 128;
Query OK, 1 row affected, 1 warning (0.00 sec)

mysql> SELECT i FROM t;
+------+
| i    |
+------+
| 127  |
+------+
1 row in set (0.00 sec)
```

However, an error occurs if strict mode is in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 128;
ERROR 1264 (22003): Out of range value adjusted for column 'i' at row 1

mysql> SELECT i FROM t;
Empty set (0.00 sec)
```

**Example 5:** In strict mode and with `ERROR_FOR_DIVISION_BY_ZERO` set, division by zero causes an error, not a result of `NULL`.

In nonstrict mode, division by zero has a result of `NULL`:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT i FROM t;
+------+
| i    |
+------+
```

2600
However, division by zero is an error if the proper SQL modes are in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
ERROR 1365 (22012): Division by 0

mysql> SELECT i FROM t;
Empty set (0.01 sec)
```

**Example 6.** Exact-value literals are evaluated as exact values.

Approximate-value literals are evaluated using floating point, but exact-value literals are handled as DECIMAL:

```
mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
Query OK, 1 row affected (0.01 sec)
Records: 1  Duplicates: 0  Warnings: 0

mysql> DESCRIBE t;
+-------+-----------------------+------+-----+---------+-------+
| Field | Type                  | Null | Key | Default | Extra |
+-------+-----------------------+------+-----+---------+-------+
| a     | decimal(2,1) unsigned | NO   |     | 0.0     |       |
| b     | double                | NO   |     | 0       |       |
+-------+-----------------------+------+-----+---------+-------+
2 rows in set (0.01 sec)
```

**Example 7.** If the argument to an aggregate function is an exact numeric type, the result is also an exact numeric type, with a scale at least that of the argument.

Consider these statements:

```
mysql> CREATE TABLE t (i INT, d DECIMAL, f FLOAT);
mysql> INSERT INTO t VALUES(1,1,1);
mysql> CREATE TABLE y SELECT AVG(i), AVG(d), AVG(f) FROM t;
```

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type:

```
mysql> DESCRIBE y;
+------|----------------+-------+-------+-------+
| Field| Type           | Null  | Key   | Default|
+------|----------------+-------+-------+-------+
| AVG(i)| decimal(14,4) | YES   | NULL  | NULL   |
| AVG(d)| decimal(14,4) | YES   | NULL  | NULL   |
| AVG(f)| double        | YES   | NULL  | NULL   |
+------|----------------+-------+-------+-------+
```

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type.

This chapter describes the syntax for the SQL statements supported by MySQL.
13.1 Data Definition Statements

13.1.1 Atomic Data Definition Statement Support

MySQL 8.2 supports atomic Data Definition Language (DDL) statements. This feature is referred to as
atomic DDL. An atomic DDL statement combines the data dictionary updates, storage engine operations,
and binary log writes associated with a DDL operation into a single, atomic operation. The operation is
either committed, with applicable changes persisted to the data dictionary, storage engine, and binary log,
or is rolled back, even if the server halts during the operation.

Note

Atomic DDL is not transactional DDL. DDL statements, atomic or otherwise,
implicitly end any transaction that is active in the current session, as if you had done
a COMMIT before executing the statement. This means that DDL statements cannot
be performed within another transaction, within transaction control statements such
as START TRANSACTION ... COMMIT, or combined with other statements within
the same transaction.

Atomic DDL is made possible by the MySQL data dictionary, which provides centralized, transactional
metadata storage.

The atomic DDL feature is described under the following topics in this section:

- Supported DDL Statements
- Atomic DDL Characteristics
- Storage Engine Support
- Viewing DDL Logs

Supported DDL Statements

The atomic DDL feature supports both table and non-table DDL statements. Table-related DDL operations
require storage engine support, whereas non-table DDL operations do not. Currently, only the InnoDB
storage engine supports atomic DDL.

- Supported table DDL statements include CREATE, ALTER, and DROP statements for databases,
tables, and indexes, and the TRUNCATE TABLE statement.

- Supported non-table DDL statements include:
  - CREATE and DROP statements, and, if applicable, ALTER statements for stored programs, triggers,
    views, and loadable functions.
  - Account management statements: CREATE, ALTER, DROP, and, if applicable, RENAME statements for
    users and roles, as well as GRANT and REVOKE statements.

The following statements are not supported by the atomic DDL feature:

- Table-related DDL statements that involve a storage engine other than InnoDB.
- INSTALL PLUGIN and UNINSTALL PLUGIN statements.
- INSTALL COMPONENT and UNINSTALL COMPONENT statements.
- CREATE SERVER, ALTER SERVER, and DROP SERVER statements.
Atomic DDL Characteristics

The characteristics of atomic DDL statements include the following:

- Metadata updates, binary log writes, and storage engine operations, where applicable, are combined into a single atomic operation.
- There are no intermediate commits at the SQL layer during the DDL operation.
- Where applicable:
  - The state of data dictionary, routine, event, and loadable function caches is consistent with the status of the DDL operation, meaning that caches are updated to reflect whether or not the DDL operation was completed successfully or rolled back.
  - The storage engine methods involved in a DDL operation do not perform intermediate commits, and the storage engine registers itself as part of the DDL operation.
  - The storage engine supports redo and rollback of DDL operations, which is performed in the Post-DDL phase of the DDL operation.
  - The visible behaviour of DDL operations is atomic, which changes the behavior of some DDL statements. See Changes in DDL Statement Behavior.

Storage Engine Support

Currently, only the InnoDB storage engine supports atomic DDL. Storage engines that do not support atomic DDL are exempted from DDL atomicity. DDL operations involving exempted storage engines remain capable of introducing inconsistencies that can occur when operations are interrupted or only partially completed.

To support redo and rollback of DDL operations, InnoDB writes DDL logs to the mysql.innodb_ddl_log table, which is a hidden data dictionary table that resides in the mysql.ibd data dictionary tablespace.

To view DDL logs that are written to the mysql.innodb_ddl_log table during a DDL operation, enable the innodb_print_ddl_logs configuration option. For more information, see Viewing DDL Logs.

Note

The redo logs for changes to the mysql.innodb_ddl_log table are flushed to disk immediately regardless of the innodb_flush_log_at_trx_commit setting. Flushing the redo logs immediately avoids situations where data files are modified by DDL operations but the redo logs for changes to the mysql.innodb_ddl_log table resulting from those operations are not persisted to disk. Such a situation could cause errors during rollback or recovery.

The InnoDB storage engine executes DDL operations in phases. DDL operations such as ALTER TABLE may perform the Prepare and Perform phases multiple times prior to the Commit phase.

1. **Prepare**: Create the required objects and write the DDL logs to the mysql.innodb_ddl_log table. The DDL logs define how to roll forward and roll back the DDL operation.
2. **Perform**: Perform the DDL operation. For example, perform a create routine for a CREATE TABLE operation.
3. **Commit**: Update the data dictionary and commit the data dictionary transaction.
Atomic Data Definition Statement Support

4. **Post-DDL**: Replay and remove DDL logs from the `mysql.innodb_ddl_log` table. To ensure that rollback can be performed safely without introducing inconsistencies, file operations such as renaming or removing data files are performed in this final phase. This phase also removes dynamic metadata from the `mysql.innodb_dynamic_metadata` data dictionary table for DROP TABLE, TRUNCATE TABLE, and other DDL operations that rebuild the table.

DDL logs are replayed and removed from the `mysql.innodb_ddl_log` table during the Post-DDL phase, regardless of whether the DDL operation is committed or rolled back. DDL logs should only remain in the `mysql.innodb_ddl_log` table if the server is halted during a DDL operation. In this case, the DDL logs are replayed and removed after recovery.

In a recovery situation, a DDL operation may be committed or rolled back when the server is restarted. If the data dictionary transaction that was performed during the Commit phase of a DDL operation is present in the redo log and binary log, the operation is considered successful and is rolled forward. Otherwise, the incomplete data dictionary transaction is rolled back when InnoDB replays data dictionary redo logs, and the DDL operation is rolled back.

### Viewing DDL Logs

To view DDL logs that are written to the `mysql.innodb_ddl_log` data dictionary table during atomic DDL operations that involve the InnoDB storage engine, enable `innodb_print_ddl_logs` to have MySQL write the DDL logs to `stderr`. Depending on the host operating system and MySQL configuration, `stderr` may be the error log, terminal, or console window. See Section 5.4.2.2, "Default Error Log Destination Configuration".

InnoDB writes DDL logs to the `mysql.innodb_ddl_log` table to support redo and rollback of DDL operations. The `mysql.innodb_ddl_log` table is a hidden data dictionary table that resides in the `mysql.ibd` data dictionary tablespace. Like other hidden data dictionary tables, the `mysql.innodb_ddl_log` table cannot be accessed directly in non-debug versions of MySQL. (See Section 14.1, "Data Dictionary Schema"). The structure of the `mysql.innodb_ddl_log` table corresponds to this definition:

```sql
CREATE TABLE mysql.innodb_ddl_log (  
    id BIGINT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,  
    thread_id BIGINT UNSIGNED NOT NULL,  
    type INT UNSIGNED NOT NULL,  
    space_id INT UNSIGNED,  
    page_no INT UNSIGNED,  
    index_id BIGINT UNSIGNED,  
    table_id BIGINT UNSIGNED,  
    old_file_path VARCHAR(512) COLLATE utf8mb4_bin,  
    new_file_path VARCHAR(512) COLLATE utf8mb4_bin,  
    KEY(thread_id)  
);```

- **id**: A unique identifier for a DDL log record.
- **thread_id**: Each DDL log record is assigned a `thread_id`, which is used to replay and remove DDL logs that belong to a particular DDL operation. DDL operations that involve multiple data file operations generate multiple DDL log records.
- **type**: The DDL operation type. Types include FREE (drop an index tree), DELETE (delete a file), RENAME (rename a file), or DROP (drop metadata from the `mysql.innodb_dynamic_metadata` data dictionary table).
- **space_id**: The tablespace ID.
- **page_no**: A page that contains allocation information; an index tree root page, for example.
- **index_id**: The index ID.
ALTER DATABASE Statement

- **table_id**: The table ID.
- **old_file_path**: The old tablespace file path. Used by DDL operations that create or drop tablespace files; also used by DDL operations that rename a tablespace.
- **new_file_path**: The new tablespace file path. Used by DDL operations that rename tablespace files.

This example demonstrates enabling `innodb_print_ddl_logs` to view DDL logs written to `stderr` for a `CREATE TABLE` operation.

```sql
mysql> SET GLOBAL innodb_print_ddl_logs=1;
mysql> CREATE TABLE t1 (c1 INT) ENGINE = InnoDB;

[Note] [000000] InnoDB: DDL log insert : [DDL record: DELETE SPACE, id=18, thread_id=7, space_id=5, old_file_path=./test/t1.ibd]
[Note] [000000] InnoDB: DDL log delete : by id 18
[Note] [000000] InnoDB: DDL log insert : [DDL record: REMOVE CACHE, id=19, thread_id=7, table_id=1058, new_file_path=test/t1]
[Note] [000000] InnoDB: DDL log delete : by id 19
[Note] [000000] InnoDB: DDL log insert : [DDL record: FREE, id=20, thread_id=7, space_id=5, index_id=132, page_no=4]
[Note] [000000] InnoDB: DDL log delete : by id 20
[Note] [000000] InnoDB: DDL log post ddl : begin for thread id : 7
[Note] [000000] InnoDB: DDL log post ddl : end for thread id : 7
```

13.1.2 ALTER DATABASE Statement

```sql
ALTER {DATABASE | SCHEMA} [db_name]
alter_option ...
```

```sql
alter_option: {
    [DEFAULT] CHARACTER SET [=] charset_name
    [DEFAULT] COLLATE [=] collation_name
    [DEFAULT] ENCRYPTION [=] {'Y' | 'N'}
    READ ONLY [=] {DEFAULT | 0 | 1}
}
```

**ALTER DATABASE** enables you to change the overall characteristics of a database. These characteristics are stored in the data dictionary. This statement requires the ALTER privilege on the database. **ALTER SCHEMA** is a synonym for **ALTER DATABASE**.

If the database name is omitted, the statement applies to the default database. In that case, an error occurs if there is no default database.

For any `alter_option` omitted from the statement, the database retains its current option value, with the exception that changing the character set may change the collation and vice versa.

- Character Set and Collation Options
- Encryption Option
- Read Only Option

**Character Set and Collation Options**

The `CHARACTER SET` option changes the default database character set. The `COLLATE` option changes the default database collation. For information about character set and collation names, see Chapter 10, **Character Sets, Collations, Unicode**.

To see the available character sets and collations, use the `SHOW CHARACTER SET` and `SHOW COLLATION` statements, respectively. See **Section 13.7.7.4, “SHOW CHARACTER SET Statement”**, and **Section 13.7.7.5, “SHOW COLLATION Statement”**.
A stored routine that uses the database defaults when the routine is created includes those defaults as part of its definition. (In a stored routine, variables with character data types use the database defaults if the character set or collation are not specified explicitly. See Section 13.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”.) If you change the default character set or collation for a database, any stored routines that are to use the new defaults must be dropped and recreated.

Encryption Option

The ENCRYPTION option, defines the default database encryption, which is inherited by tables created in the database. The permitted values are 'Y' (encryption enabled) and 'N' (encryption disabled).

The mysql system schema cannot be set to default encryption. The existing tables within it are part of the general mysql tablespace, which may be encrypted. The information_schema contains only views. It is not possible to create any tables within it. There is nothing on the disk to encrypt. All tables in the performance_schema use the PERFORMANCE_SCHEMA engine, which is purely in-memory. It is not possible to create any other tables in it. There is nothing on the disk to encrypt.

Only newly created tables inherit the default database encryption. For existing tables associated with the database, their encryption remains unchanged. If the table_encryption_privilege_check system variable is enabled, the TABLE_ENCRYPTION_ADMIN privilege is required to specify a default encryption setting that differs from the value of the default_table_encryption system variable. For more information, see Defining an Encryption Default for Schemas and General Tablespaces.

Read Only Option

The READ ONLY option controls whether to permit modification of the database and objects within it. The permitted values are DEFAULT or 0 (not read only) and 1 (read only). This option is useful for database migration because a database for which READ ONLY is enabled can be migrated to another MySQL instance without concern that the database might be changed during the operation.

With NDB Cluster, making a database read only on one mysql server is synchronized to other mysql servers in the same cluster, so that the database becomes read only on all mysql servers.

The READ ONLY option, if enabled, is displayed in the INFORMATION_SCHEMA SCHEMATA_EXTENSIONS table. See Section 26.3.32, “The INFORMATION_SCHEMA SCHEMATA_EXTENSIONS Table”.

The READ ONLY option cannot be enabled for these system schemas: mysql, information_schema, performance_schema.

In ALTER DATABASE statements, the READ ONLY option interacts with other instances of itself and with other options as follows:

- An error occurs if multiple instances of READ ONLY conflict (for example, READ ONLY = 1 READ ONLY = 0).

- An ALTER DATABASE statement that contains only (nonconflicting) READ ONLY options is permitted even for a read-only database.

- A mix of (nonconflicting) READ ONLY options with other options is permitted if the read-only state of the database either before or after the statement permits modifications. If the read-only state both before and after prohibits changes, an error occurs.

This statement succeeds whether or not the database is read only:

```
ALTER DATABASE mydb READ ONLY = 0 DEFAULT COLLATE utf8mb4_bin;
```

This statement succeeds if the database is not read only, but fails if it is already read only:

```
ALTER DATABASE mydb READ ONLY = 1 DEFAULT COLLATE utf8mb4_bin;
```
Enabling `READ ONLY` affects all users of the database, with these exceptions that are not subject to read-only checks:

- Statements executed by the server as part of server initialization, restart, upgrade, or replication.
- Statements in a file named at server startup by the `init_file` system variable.
- `TEMPORARY` tables; it is possible to create, alter, drop, and write to `TEMPORARY` tables in a read-only database.
- NDB Cluster non-SQL inserts and updates.

Other than for the excepted operations just listed, enabling `READ ONLY` prohibits write operations to the database and its objects, including their definitions, data, and metadata. The following list details affected SQL statements and operations:

- The database itself:
  - `CREATE DATABASE`
  - `ALTER DATABASE` (except to change the `READ ONLY` option)
  - `DROP DATABASE`
- Views:
  - `CREATE VIEW`
  - `ALTER VIEW`
  - `DROP VIEW`
- Selecting from views that invoke functions with side effects.
- Updating updatable views.
- Statements that create or drop objects in a writable database are rejected if they affect metadata of a view in a read-only database (for example, by making the view valid or invalid).
- Stored routines:
  - `CREATE PROCEDURE`
  - `DROP PROCEDURE`
  - `CALL` (of procedures with side effects)
  - `CREATE FUNCTION`
  - `DROP FUNCTION`
  - `SELECT` (of functions with side effects)
- For procedures and functions, read-only checks follow prelocking behavior. For `CALL` statements, read-only checks are done on a per-statement basis, so if some conditionally executed statement writing to a read-only database does not actually execute, the call still succeeds. On the other hand, for a function called within a `SELECT`, execution of the function body happens in prelocked mode. As long as a some statement within the function writes to a read-only database, execution of the function fails with an error regardless of whether the statement actually executes.
• Triggers:
  • CREATE TRIGGER
  • DROP TRIGGER
  • Trigger invocation.

• Events:
  • CREATE EVENT
  • ALTER EVENT
  • DROP EVENT

• Event execution:
  • Executing an event in the database fails because that would change the last-execution timestamp, which is event metadata stored in the data dictionary. Failure of event execution also has the effect of causing the event scheduler to stop.

  • If an event writes to an object in a read-only database, execution of the event fails with an error, but the event scheduler is not stopped.
ALTER DATABASE Statement

- Tables:
  - CREATE TABLE
  - ALTER TABLE
  - CREATE INDEX
  - DROP INDEX
  - RENAME TABLE
  - TRUNCATE TABLE
  - DROP TABLE
  - DELETE
  - INSERT
  - IMPORT TABLE
  - LOAD DATA
  - LOAD XML
  - REPLACE
  - UPDATE

- For cascading foreign keys where the child table is in a read-only database, updates and deletes on the parent are rejected even if the child table is not directly affected.

- For a `MERGE` table such as `CREATE TABLE s1.t(i int) ENGINE MERGE UNION (s2.t, s3.t), INSERT_METHOD=...`, the following behavior applies:
  - Inserting into the `MERGE` table (`INSERT INTO s1.t`) fails if at least one of `s1, s2, s3` is read only, regardless of insert method. The insert is refused even if it would actually end up in a writable table.
  - Dropping the `MERGE` table (`DROP TABLE s1.t`) succeeds as long as `s1` is not read only. It is permitted to drop a `MERGE` table that refers to a read-only database.

An `ALTER DATABASE` statement blocks until all concurrent transactions that have already accessed an object in the database being altered have committed. Conversely, a write transaction accessing an object in a database being altered in a concurrent `ALTER DATABASE` blocks until the `ALTER DATABASE` has committed.

If the Clone plugin is used to clone a local or remote data directory, the databases in the clone retain the read-only state they had in the source data directory. The read-only state does not affect the cloning process itself. If it is not desirable to have the same database read-only state in the clone, the option must be changed explicitly for the clone after the cloning process has finished, using `ALTER DATABASE` operations on the clone.

When cloning from a donor to a recipient, if the recipient has a user database that is read only, cloning fails with an error message. Cloning may be retried after making the database writable.
**ALTER EVENT Statement**

**READ ONLY** is permitted for **ALTER DATABASE**, but not for **CREATE DATABASE**. However, for a read-only database, the statement produced by **SHOW CREATE DATABASE** does include **READ ONLY=1** within a comment to indicate its read-only status:

```sql
mySQL> ALTER DATABASE mydb READ ONLY = 1;
mySQL> SHOW CREATE DATABASE mydb\G
*************************** 1. row ***************************
Database: mydb
Create Database: CREATE DATABASE `mydb`  
/*!40100 DEFAULT CHARACTER SET utf8mb4
 COLLATE utf8mb4_0900_ai_ci */
/*!80016 DEFAULT ENCRYPTION='N' */
/* READ ONLY = 1 */
```

If the server executes a **CREATE DATABASE** statement containing such a comment, the server ignores the comment and the **READ ONLY** option is not processed. This has implications for **mysqldump** and **mysqlpump**, which use **SHOW CREATE DATABASE** to produce **CREATE DATABASE** statements in dump output:

- In a dump file, the **CREATE DATABASE** statement for a read-only database contains the commented **READ ONLY** option.

- The dump file can be restored as usual, but because the server ignores the commented **READ ONLY** option, the restored database is *not* read only. If the database is to be read only after being restored, you must execute **ALTER DATABASE** manually to make it so.

Suppose that **mydb** is read only and you dump it as follows:

```bash
$> mysqldump --databases mydb > mydb.sql
```

A restore operation later must be followed by **ALTER DATABASE** if **mydb** should still be read only:

```bash
$> mysql
mysql> SOURCE mydb.sql;
mysql> ALTER DATABASE mydb READ ONLY = 1;
```

MySQL Enterprise Backup is not subject to this issue. It backs up and restores a read-only database like any other, but enables the **READ ONLY** option at restore time if it was enabled at backup time.

**ALTER DATABASE** is written to the binary log, so a change to the **READ ONLY** option on a replication source server also affects replicas. To prevent this from happening, binary logging must be disabled prior to execution of the **ALTER DATABASE** statement. For example, to prepare for migrating a database without affecting replicas, perform these operations:

1. Within a single session, disable binary logging and enable **READ ONLY** for the database:
   ```sql
   mysql> SET sql_log_bin = OFF;
   mysql> ALTER DATABASE mydb READ ONLY = 1;
   ```

2. Dump the database, for example, with **mysqldump** or **mysqlpump**:
   ```bash
   $> mysqldump --databases mydb > mydb.sql
   ```

3. Within a single session, disable binary logging and disable **READ ONLY** for the database:
   ```sql
   mysql> SET sql_log_bin = OFF;
   mysql> ALTER DATABASE mydb READ ONLY = 0;
   ```

**13.1.3 ALTER EVENT Statement**
ALTER EVENT Statement

The `ALTER EVENT` statement changes one or more of the characteristics of an existing event without the need to drop and recreate it. The syntax for each of the `DEFINER`, `ON SCHEDULE`, `ON COMPLETION`, `COMMENT`, `ENABLE/DISABLE`, and `DO` clauses is exactly the same as when used with `CREATE EVENT`. (See Section 13.1.13, "CREATE EVENT Statement").

Any user can alter an event defined on a database for which that user has the `EVENT` privilege. When a user executes a successful `ALTER EVENT` statement, that user becomes the definer for the affected event.

The `ALTER EVENT` works only with an existing event:

```sql
mysql> ALTER EVENT no_such_event
    > ON SCHEDULE
    > EVERY '2:3' DAY_HOUR;
ERROR 1517 (HY000): Unknown event 'no_such_event'
```

In each of the following examples, assume that the event named `myevent` is defined as shown here:

```sql
CREATE EVENT myevent
  ON SCHEDULE
    EVERY 6 HOUR
  COMMENT 'A sample comment.'
  DO
    UPDATE myschema.mytable SET mycol = mycol + 1;
```

The following statement changes the schedule for `myevent` from once every six hours starting immediately to once every twelve hours, starting four hours from the time the statement is run:

```sql
ALTER EVENT myevent
  ON SCHEDULE
    EVERY 12 HOUR
    STARTS CURRENT_TIMESTAMP + INTERVAL 4 HOUR;
```

It is possible to change multiple characteristics of an event in a single statement. This example changes the SQL statement executed by `myevent` to one that deletes all records from `mytable`; it also changes the schedule for the event such that it executes once, one day after this `ALTER EVENT` statement is run.

```sql
ALTER EVENT myevent
  ON SCHEDULE
    AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
  DO
    TRUNCATE TABLE myschema.mytable;
```

Specify the options in an `ALTER EVENT` statement only for those characteristics that you want to change; omitted options keep their existing values. This includes any default values for `CREATE EVENT` such as `ENABLE`.

To disable `myevent`, use this `ALTER EVENT` statement:

```sql
ALTER EVENT myevent
  DISABLE;
```

The `ON SCHEDULE` clause may use expressions involving built-in MySQL functions and user variables to obtain any of the `timestamp` or `interval` values which it contains. You cannot use stored routines or
loadable functions in such expressions, and you cannot use any table references; however, you can use `SELECT FROM DUAL`. This is true for both `ALTER EVENT` and `CREATE EVENT` statements. References to stored routines, loadable functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Although an `ALTER EVENT` statement that contains another `ALTER EVENT` statement in its `DO` clause appears to succeed, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

To rename an event, use the `ALTER EVENT` statement's `RENAME TO` clause. This statement renames the event `myevent` to `yourevent`:

```
ALTER EVENT myevent
    RENAME TO yourevent;
```

You can also move an event to a different database using `ALTER EVENT ... RENAME TO ...` and `db_name.event_name` notation, as shown here:

```
ALTER EVENT olddb.myevent
    RENAME TO newdb.myevent;
```

To execute the previous statement, the user executing it must have the `EVENT` privilege on both the `olddb` and `newdb` databases.

**Note**

There is no `RENAME EVENT` statement.

The value `DISABLE ON REPLICA` is used on a replica instead of `ENABLE` or `DISABLE` to indicate an event that was created on the replication source server and replicated to the replica, but that is not executed on the replica. Normally, `DISABLE ON REPLICA` is set automatically as required; however, there are some circumstances under which you may want or need to change it manually. See Section 17.5.1.16, “Replication of Invoked Features”, for more information.

`DISABLE ON REPLICA` replaces `DISABLE ON SLAVE`, which is deprecated as of MySQL 8.2.0.

### 13.1.4 ALTER FUNCTION Statement

```
ALTER FUNCTION  func_name  [characteristic  ...]
characteristic:  {
    COMMENT 'string'
    | LANGUAGE  SQL
    | { CONTAINS  SQL  |  NO  SQL  |  READS  SQL  DATA  |  MODIFIES  SQL  DATA }
    | SQL  SECURITY  {  DEFINER  |  INVOKER  }
}
```

This statement can be used to change the characteristics of a stored function. More than one change may be specified in an `ALTER FUNCTION` statement. However, you cannot change the parameters or body of a stored function using this statement; to make such changes, you must drop and re-create the function using `DROP FUNCTION` and `CREATE FUNCTION`.

You must have the `ALTER ROUTINE` privilege for the function. (That privilege is granted automatically to the function creator.) If binary logging is enabled, the `ALTER FUNCTION` statement might also require the `SUPER` privilege, as described in Section 25.7, “Stored Program Binary Logging”.

### 13.1.5 ALTER INSTANCE Statement

```
ALTER INSTANCE  instance_action
```
**ALTER INSTANCE** defines actions applicable to a MySQL server instance. The statement supports these actions:

- **ALTER INSTANCE {ENABLE | DISABLE} INNODB REDO_LOG**
  
  This action enables or disables InnoDB redo logging. Redo logging is enabled by default. This feature is intended only for loading data into a new MySQL instance. The statement is not written to the binary log.

  **Warning**
  
  Do not disable redo logging on a production system. While it is permitted to shut down and restart the server while redo logging is disabled, an unexpected server stoppage while redo logging is disabled can cause data loss and instance corruption.

  An **ALTER INSTANCE [ENABLE|DISABLE] INNODB REDO_LOG** operation requires an exclusive backup lock, which prevents other **ALTER INSTANCE** operations from executing concurrently. Other **ALTER INSTANCE** operations must wait for the lock to be released before executing.

  For more information, see Disabling Redo Logging.

- **ALTER INSTANCE ROTATE INNODB MASTER KEY**
  
  This action rotates the master encryption key used for InnoDB tablespace encryption. Key rotation requires the **ENCRYPTION_KEY_ADMIN** or **SUPER** privilege. To perform this action, a keyring plugin must be installed and configured. For instructions, see Section 6.4.4, “The MySQL Keyring”.

  **ALTER INSTANCE ROTATE INNODB MASTER KEY** supports concurrent DML. However, it cannot be run concurrently with **CREATE TABLE ... ENCRYPTION** or **ALTER TABLE ... ENCRYPTION** operations, and locks are taken to prevent conflicts that could arise from concurrent execution of these statements. If one of the conflicting statements is running, it must complete before another can proceed.

  **ALTER INSTANCE ROTATE INNODB MASTER KEY** statements are written to the binary log so that they can be executed on replicated servers.

  For additional **ALTER INSTANCE ROTATE INNODB MASTER KEY** usage information, see Section 15.13, “InnoDB Data-at-Rest Encryption”.

- **ALTER INSTANCE ROTATE BINLOG MASTER KEY**
  
  This action rotates the binary log master key used for binary log encryption. Key rotation for the binary log master key requires the **BINLOG_ENCRYPTION_ADMIN** or **SUPER** privilege. The statement cannot be used if the **binlog_encryption** system variable is set to **OFF**. To perform this action, a keyring plugin must be installed and configured. For instructions, see Section 6.4.4, “The MySQL Keyring”.

  **ALTER INSTANCE ROTATE BINLOG MASTER KEY** actions are not written to the binary log and are not executed on replicas. Binary log master key rotation can therefore be carried out in replication environments including a mix of MySQL versions. To schedule regular rotation of the binary log master key...
key on all applicable source and replica servers, you can enable the MySQL Event Scheduler on each server and issue the `ALTER INSTANCE ROTATE BINLOG MASTER KEY` statement using a `CREATE EVENT` statement. If you rotate the binary log master key because you suspect that the current or any of the previous binary log master keys might have been compromised, issue the statement on every applicable source and replica server, which enables you to verify immediate compliance.

For additional `ALTER INSTANCE ROTATE BINLOG MASTER KEY` usage information, including what to do if the process does not complete correctly or is interrupted by an unexpected server halt, see Section 17.3.2, “Encrypting Binary Log Files and Relay Log Files”.

• **ALTER INSTANCE RELOAD TLS**

This action reconfigures a TLS context from the current values of the system variables that define the context. It also updates the status variables that reflect the active context values. This action requires the `CONNECTION_ADMIN` privilege. For additional information about reconfiguring the TLS context, including which system and status variables are context-related, see Server-Side Runtime Configuration and Monitoring for Encrypted Connections.

By default, the statement reloads the TLS context for the main connection interface. If the `FOR CHANNEL` clause is given, the statement reloads the TLS context for the named channel: `mysql_main` for the main connection interface, `mysql_admin` for the administrative connection interface. For information about the different interfaces, see Section 5.1.12.1, “Connection Interfaces”. The updated TLS context properties are exposed in the Performance Schema `tls_channel_status` table. See Section 27.12.22.9, “The tls_channel_status Table”.

Updating the TLS context for the main interface may also affect the administrative interface because unless some nondefault TLS value is configured for that interface, it uses the same TLS context as the main interface.

**Note**

When you reload the TLS context, OpenSSL reloads the file containing the CRL (certificate revocation list) as part of the process. If the CRL file is large, the server allocates a large chunk of memory (ten times the file size), which is doubled while the new instance is being loaded and the old one has not yet been released. The process resident memory is not immediately reduced after a large allocation is freed, so if you issue the `ALTER INSTANCE RELOAD TLS` statement repeatedly with a large CRL file, the process resident memory usage may grow as a result of this.

By default, the `RELOAD TLS` action rolls back with an error and has no effect if the configuration values do not permit creation of the new TLS context. The previous context values continue to be used for new connections. If the optional `NO ROLLBACK ON ERROR` clause is given and the new context cannot be created, rollback does not occur. Instead, a warning is generated and encryption is disabled for new connections on the interface to which the statement applies.

`ALTER INSTANCE RELOAD TLS` statements are not written to the binary log (and thus are not replicated). TLS configuration is local and depends on local files not necessarily present on all servers involved.

• **ALTER INSTANCE RELOAD KEYRING**

If a keyring component is installed, this action tells the component to re-read its configuration file and reinitialize any keyring in-memory data. If you modify the component configuration at runtime, the new configuration does not take effect until you perform this action. Keyring reloading requires the `ENCRYPTION_KEY_ADMIN` privilege.
This action enables reconfiguring only the currently installed keyring component. It does not enable changing which component is installed. For example, if you change the configuration for the installed keyring component, `ALTER INSTANCE RELOAD KEYRING` causes the new configuration to take effect. On the other hand, if you change the keyring component named in the server manifest file, `ALTER INSTANCE RELOAD KEYRING` has no effect and the current component remains installed.

`ALTER INSTANCE RELOAD KEYRING` statements are not written to the binary log (and thus are not replicated).

### 13.1.6 ALTER LOGFILE GROUP Statement

This statement adds an UNDO file named `file_name` to an existing log file group `logfile_group`. An `ALTER LOGFILE GROUP` statement has one and only one `ADD UNDOFILE` clause. No `DROP UNDOFILE` clause is currently supported.

```sql
ALTER LOGFILE GROUP logfile_group
    ADD UNDOFILE 'file_name'
    [INITIAL_SIZE [-] size]
    [WAIT]
    ENGINE [-] engine_name
```

This statement adds an UNDO file named `file_name` to an existing log file group `logfile_group`. An `ALTER LOGFILE GROUP` statement has one and only one `ADD UNDOFILE` clause. No `DROP UNDOFILE` clause is currently supported.

#### Note

All NDB Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and an undo log file with the same name, or an undo log file and a data file with the same name.

The optional `INITIAL_SIZE` parameter sets the UNDO file's initial size in bytes; if not specified, the initial size defaults to 134217728 (128 MB). You may optionally follow `size` with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters `M` (megabytes) or `G` (gigabytes). (Bug #13116514, Bug #16104705, Bug #62858)

On 32-bit systems, the maximum supported value for `INITIAL_SIZE` is 4294967296 (4 GB). (Bug #29186)

The minimum allowed value for `INITIAL_SIZE` is 1048576 (1 MB). (Bug #29574)

#### Note

`WAIT` is parsed but otherwise ignored. This keyword currently has no effect, and is intended for future expansion.

The `ENGINE` parameter (required) determines the storage engine which is used by this log file group, with `engine_name` being the name of the storage engine. Currently, the only accepted values for `engine_name` are “NDBCLUSTER” and “NDB”. The two values are equivalent.

Here is an example, which assumes that the log file group `lg_3` has already been created using `CREATE LOGFILE GROUP` (see Section 13.1.16, “CREATE LOGFILE GROUP Statement”):

```sql
ALTER LOGFILE GROUP lg_3
    ADD UNDOFILE 'undo_10.dat'
    INITIAL_SIZE=32M
    ENGINE=NDBCLUSTER;
```

When `ALTER LOGFILE GROUP` is used with `ENGINE = NDBCLUSTER` (alternatively, `ENGINE = NDB`), an UNDO log file is created on each NDB Cluster data node. You can verify that the UNDO files were created and obtain information about them by querying the InformationSchema `FILES` table. For example:
ALTER PROCEDURE Statement

```
mysql> SELECT FILE_NAME, LOGFILE_GROUP_NUMBER, EXTRA
    -> FROM INFORMATION_SCHEMA.FILES
    -> WHERE LOGFILE_GROUP_NAME = 'lg_3';
                      +-------------+----------------------+----------------+
                      | FILE_NAME   | LOGFILE_GROUP_NUMBER | EXTRA          |
                      +-------------+----------------------+----------------+
                      | newdata.dat |                    0 | CLUSTER_NODE=3 |
                      | newdata.dat |                    0 | CLUSTER_NODE=4 |
                      | undo_10.dat |                   11 | CLUSTER_NODE=3 |
                      | undo_10.dat |                   11 | CLUSTER_NODE=4 |
                      +-------------+----------------------+----------------+
4 rows in set (0.01 sec)
```

(See Section 26.3.15, “The INFORMATION_SCHEMA FILES Table”.)

Memory used for UNDO_BUFFER_SIZE comes from the global pool whose size is determined by the value of the SharedGlobalMemory data node configuration parameter. This includes any default value implied for this option by the setting of the InitialLogFileGroup data node configuration parameter.

ALTER LOGFILE GROUP is useful only with Disk Data storage for NDB Cluster. For more information, see Section 23.6.11, “NDB Cluster Disk Data Tables”.

### 13.1.7 ALTER PROCEDURE Statement

```
ALTER PROCEDURE proc_name [characteristic ...]

characteristic: {
    COMMENT 'string'
    | LANGUAGE SQL
    | ( CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA )
    | SQL SECURITY { DEFINER | INVOKER }
}
```

This statement can be used to change the characteristics of a stored procedure. More than one change may be specified in an ALTER PROCEDURE statement. However, you cannot change the parameters or body of a stored procedure using this statement; to make such changes, you must drop and re-create the procedure using DROP PROCEDURE and CREATE PROCEDURE.

You must have the ALTER ROUTINE privilege for the procedure. By default, that privilege is granted automatically to the procedure creator. This behavior can be changed by disabling the automatic_sp_privileges system variable. See Section 25.2.2, “Stored Routines and MySQL Privileges”.

### 13.1.8 ALTER SERVER Statement

```
ALTER SERVER server_name OPTIONS (option [, option] ...)
```

Alters the server information for server_name, adjusting any of the options permitted in the CREATE SERVER statement. The corresponding fields in the mysql.servers table are updated accordingly. This statement requires the SUPER privilege.

For example, to update the USER option:

```
ALTER SERVER s OPTIONS (USER 'sally');
```

ALTER_SERVER causes an implicit commit. See Section 13.3.3, “Statements That Cause an Implicit Commit”. 

2619
ALTER TABLE Statement

ALTER SERVER

is not written to the binary log, regardless of the logging format that is in use.

13.1.9 ALTER TABLE Statement

ALTER TABLE tbl_name

[alter_option [, alter_option] ...]

[partition_options]

alter_option: {

table_options

| ADD [COLUMN] col_name column_definition
| [FIRST | AFTER col_name]
| ADD [COLUMN] (col_name column_definition, ...)
| ADD [INDEX | KEY] [index_name]
| (index_type) (key_part, ...) [index_option] ...
| ADD [FULLTEXT | SPATIAL] [INDEX | KEY] [index_name]
| (key_part, ...) [index_option] ...
| ADD [CONSTRAINT [symbol]] PRIMARY KEY
| [index_type] (key_part, ...)
| [index_option] ...
| ADD [CONSTRAINT [symbol]] UNIQUE [INDEX | KEY]
| [index_name] [index_type] (key_part, ...)
| [index_option] ...
| ADD [CONSTRAINT [symbol]] FOREIGN KEY
| [index_name] (col_name, ...)
| reference_definition
| ADD [CONSTRAINT [symbol]] CHECK (expr) [(NOT) ENFORCED]
| DROP [CHECK | CONSTRAINT] symbol
| ALTER [CHECK | CONSTRAINT] symbol [NOT] ENFORCED
| ALGORITHM [=} {DEFAULT | INSTANT | INPLACE | COPY}
| ALTER [COLUMN] col_name {
| SET DEFAULT {literal | (expr)}
| SET {VISIBLE | INVISIBLE}
| DROP DEFAULT
| ALTER INDEX index_name {VISIBLE | INVISIBLE}
| CHANGE [COLUMN] old_col_name new_col_name column_definition
| [FIRST | AFTER col_name]
| [DEFAULT] CHARACTER SET [=} charset_name [COLLATE [=} collation_name]
| CONVERT TO CHARACTER SET charset_name [COLLATE collation_name]
| {DISABLE | ENABLE} KEYS
| {DISCARD | IMPORT} TABLESPACE
| DROP [COLUMN] col_name
| DROP [INDEX | KEY] index_name
| DROP PRIMARY KEY
| DROP FOREIGN KEY fk_symbol
| FORCE
| LOCK [=} {DEFAULT | NONE | SHARED | EXCLUSIVE}
| MODIFY [COLUMN] col_name column_definition
| [FIRST | AFTER col_name]
| ORDER BY col_name [, col_name] ...
| RENAME COLUMN old_col_name TO new_col_name
| RENAME (INDEX | KEY) old_index_name TO new_index_name
| RENAME [TO | AS] new_tbl_name
| [WITHOUT | WITH] VALIDATION
|

partition_options:

partition_option [partition_option] ...

partition_option: {

ADD PARTITION (partition_definition)
| DROP PARTITION partition_names
| DROP PARTITION (partition_names | ALL) TABLESPACE
| IMPORT PARTITION (partition_names | ALL) TABLESPACE
| TRUNCATE PARTITION {partition_names | ALL}

2620
ALTER TABLE Statement

ALTER TABLE Statement

COALESCE PARTITION number
REORGANIZE PARTITION partition_names INTO (partition_definitions)
EXCHANGE PARTITION partition_name WITH TABLE tbl_name [(WITH | WITHOUT) VALIDATION]
ANALYZE PARTITION {partition_names | ALL}
CHECK PARTITION {partition_names | ALL}

ALTER TABLE Statement changes the structure of a table. For example, you can add or delete columns, create or destroy indexes, change the type of existing columns, or rename columns or the table itself. You can also change characteristics such as the storage engine used for the table or the table comment.

- To use ALTER TABLE, you need ALTER, CREATE, and INSERT privileges for the table. Renaming a table requires ALTER and DROP on the old table, ALTER, CREATE, and INSERT on the new table.
ALTER TABLE Statement

- Following the table name, specify the alterations to be made. If none are given, `ALTER TABLE` does nothing.

- The syntax for many of the permissible alterations is similar to clauses of the `CREATE TABLE` statement. `column_definition` clauses use the same syntax for `ADD` and `CHANGE` as for `CREATE TABLE`. For more information, see Section 13.1.20, “CREATE TABLE Statement”.

- The word `COLUMN` is optional and can be omitted, except for `RENAME COLUMN` (to distinguish a column-renaming operation from the `RENAME` table-renaming operation).

- Multiple `ADD`, `ALTER`, `DROP`, and `CHANGE` clauses are permitted in a single `ALTER TABLE` statement, separated by commas. This is a MySQL extension to standard SQL, which permits only one of each clause per `ALTER TABLE` statement. For example, to drop multiple columns in a single statement, do this:

  ```sql
  ALTER TABLE t2 DROP COLUMN c, DROP COLUMN d;
  ```

- If a storage engine does not support an attempted `ALTER TABLE` operation, a warning may result. Such warnings can be displayed with `SHOW WARNINGS`. See Section 13.7.7.44, “SHOW WARNINGS Statement”. For information on troubleshooting `ALTER TABLE`, see Section B.3.6.1, “Problems with ALTER TABLE”.

- For information about generated columns, see Section 13.1.9.2, “ALTER TABLE and Generated Columns”.

- For usage examples, see Section 13.1.9.3, “ALTER TABLE Examples”.

- InnoDB supports addition of multi-valued indexes on JSON columns using a `key_part` specification can take the form `(CAST json_path AS type ARRAY)`. See Multi-Valued Indexes, for detailed information regarding multi-valued index creation and usage of, as well as restrictions and limitations on multi-valued indexes.

- With the `mysql_info()` C API function, you can find out how many rows were copied by `ALTER TABLE`. See `mysql_info()`.

There are several additional aspects to the `ALTER TABLE` statement, described under the following topics in this section:

- Table Options
- Performance and Space Requirements
- Concurrency Control
- Adding and Dropping Columns
- Renaming, Redefining, and Reordering Columns
- Primary Keys and Indexes
- Foreign Keys and Other Constraints
- Changing the Character Set
- Importing InnoDB Tables
- Row Order for MyISAM Tables
- Partitioning Options
ALTER TABLE Statement

Table Options

table_options signifies table options of the kind that can be used in the CREATE TABLE statement, such as ENGINE, AUTO_INCREMENT, AVG_ROW_LENGTH, MAX_ROWS, ROW_FORMAT, or TABLESPACE.

For descriptions of all table options, see Section 13.1.20, “CREATE TABLE Statement”. However, ALTER TABLE ignores DATA DIRECTORY and INDEX DIRECTORY when given as table options. ALTER TABLE permits them only as partitioning options, and requires that you have the FILE privilege.

Use of table options with ALTER TABLE provides a convenient way of altering single table characteristics. For example:

- If t1 is currently not an InnoDB table, this statement changes its storage engine to InnoDB:

  ```sql
  ALTER TABLE t1 ENGINE = InnoDB;
  ```

  - See Section 15.6.1.5, “Converting Tables from MyISAM to InnoDB” for considerations when switching tables to the InnoDB storage engine.

  - When you specify an ENGINE clause, ALTER TABLE rebuilds the table. This is true even if the table already has the specified storage engine.

  - Running ALTER TABLE tbl_name ENGINE=INNODB on an existing InnoDB table performs a "null" ALTER TABLE operation, which can be used to defragment an InnoDB table, as described in Section 15.11.4, “Defragmenting a Table”. Running ALTER TABLE tbl_name FORCE on an InnoDB table performs the same function.

  - ALTER TABLE tbl_name ENGINE=INNODB and ALTER TABLE tbl_name FORCE use online DDL. For more information, see Section 15.12, “InnoDB and Online DDL”.

  - The outcome of attempting to change the storage engine of a table is affected by whether the desired storage engine is available and the setting of the NO_ENGINE_SUBSTITUTION SQL mode, as described in Section 5.1.11, “Server SQL Modes”.

  - To prevent inadvertent loss of data, ALTER TABLE cannot be used to change the storage engine of a table to MERGE or BLACKHOLE.

  - To change the InnoDB table to use compressed row-storage format:

    ```sql
    ALTER TABLE t1 ROW_FORMAT = COMPRESSED;
    ```

  - The ENCRYPTION clause enables or disables page-level data encryption for an InnoDB table. A keyring plugin must be installed and configured to enable encryption.

    If the table_encryption_privilege_check variable is enabled, the TABLE_ENCRYPTION_ADMIN privilege is required to use an ENCRYPTION clause with a setting that differs from the default schema encryption setting.

    ENCRYPTION is also supported for tables residing in general tablespaces.

    For tables that reside in general tablespaces, table and tablespace encryption must match.

    Altering table encryption by moving a table to a different tablespace or changing the storage engine is not permitted without explicitly specifying an ENCRYPTION clause.

    Specifying an ENCRYPTION clause with a value other than 'N' or '' is not permitted if the table uses a storage engine that does not support encryption. Attempting to create a table without an ENCRYPTION
clause in an encryption-enabled schema using a storage engine that does not support encryption is also not permitted.

For more information, see Section 15.13, “InnoDB Data-at-Rest Encryption”.

- To reset the current auto-increment value:

  ```sql
  ALTER TABLE t1 AUTO_INCREMENT = 13;
  ```

  You cannot reset the counter to a value less than or equal to the value that is currently in use. For both InnoDB and MyISAM, if the value is less than or equal to the maximum value currently in the AUTO_INCREMENT column, the value is reset to the current maximum AUTO_INCREMENT column value plus one.

- To change the default table character set:

  ```sql
  ALTER TABLE t1 CHARACTER SET = utf8mb4;
  ```

  See also Changing the Character Set.

- To add (or change) a table comment:

  ```sql
  ALTER TABLE t1 COMMENT = 'New table comment';
  ```

- Use `ALTER TABLE` with the TABLESPACE option to move InnoDB tables between existing general tablespaces, file-per-table tablespaces, and the system tablespace. See Moving Tables Between Tablespaces Using ALTER TABLE.

- **ALTER TABLE ... TABLESPACE** operations always cause a full table rebuild, even if the TABLESPACE attribute has not changed from its previous value.

- **ALTER TABLE ... TABLESPACE** syntax does not support moving a table from a temporary tablespace to a persistent tablespace.

- The DATA DIRECTORY clause, which is supported with `CREATE TABLE ... TABLESPACE`, is not supported with **ALTER TABLE ... TABLESPACE**, and is ignored if specified.

- For more information about the capabilities and limitations of the TABLESPACE option, see CREATE TABLE.

- MySQL NDB Cluster 8.2 supports setting NDB_TABLE options for controlling a table’s partition balance (fragment count type), read-from-any-replica capability, full replication, or any combination of these, as part of the table comment for an ALTER TABLE statement in the same manner as for CREATE TABLE, as shown in this example:

  ```sql
  ALTER TABLE t1 COMMENT = "NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RA_BY_NODE";
  ```

  It is also possible to set NDB_COMMENT options for columns of NDB tables as part of an ALTER TABLE statement, like this one:

  ```sql
  ALTER TABLE t1
  CHANGE COLUMN c1 c1 BLOB
  COMMENT = 'NDB_COLUMN=BLOB_INLINE_SIZE=4096,MAX_BLOB_PART_SIZE';
  ```

  Bear in mind that **ALTER TABLE ... COMMENT ...** discards any existing comment for the table. See Setting NDB_TABLE options, for additional information and examples.

- ENGINE_ATTRIBUTE and SECONDARYENGINE_ATTRIBUTE options are used to specify table, column, and index attributes for primary and secondary storage engines. The options are reserved for future use.
ALTER TABLE Statement

Index attributes cannot be altered. An index must be dropped and added back with the desired change, which can be performed in a single ALTER TABLE statement.

To verify that the table options were changed as intended, use SHOW CREATE TABLE, or query the Information Schema TABLES table.

Performance and Space Requirements

ALTER TABLE operations are processed using one of the following algorithms:

- **COPY**: Operations are performed on a copy of the original table, and table data is copied from the original table to the new table row by row. Concurrent DML is not permitted.

- **INPLACE**: Operations avoid copying table data but may rebuild the table in place. An exclusive metadata lock on the table may be taken briefly during preparation and execution phases of the operation. Typically, concurrent DML is supported.

- **INSTANT**: Operations only modify metadata in the data dictionary. An exclusive metadata lock on the table may be taken briefly during the execution phase of the operation. Table data is unaffected, making operations instantaneous. Concurrent DML is permitted.

For tables using the NDB storage engine, these algorithms work as follows:

- **COPY**: NDB creates a copy of the table and alters it; the NDB Cluster handler then copies the data between the old and new versions of the table. Subsequently, NDB deletes the old table and renames the new one.

  This is sometimes also referred to as a “copying” or “offline” ALTER TABLE.

- **INPLACE**: The data nodes make the required changes; the NDB Cluster handler does not copy data or otherwise take part.

  This is sometimes also referred to as a “non-copying” or “online” ALTER TABLE.

- **INSTANT**: Not supported by NDB.

See Section 23.6.12, “Online Operations with ALTER TABLE in NDB Cluster”, for more information.

The ALGORITHM clause is optional. If the ALGORITHM clause is omitted, MySQL uses ALGORITHM=INSTANT for storage engines and ALTER TABLE clauses that support it. Otherwise, ALGORITHM=INPLACE is used. If ALGORITHM=INPLACE is not supported, ALGORITHM=COPY is used.

**Note**

After adding a column to a partitioned table using ALGORITHM=INSTANT, it is no longer possible to perform ALTER TABLE ... EXCHANGE PARTITION on the table.

Specifying an ALGORITHM clause requires the operation to use the specified algorithm for clauses and storage engines that support it, or fail with an error otherwise. Specifying ALGORITHM=DEFAULT is the same as omitting the ALGORITHM clause.

ALTER TABLE operations that use the COPY algorithm wait for other operations that are modifying the table to complete. After alterations are applied to the table copy, data is copied over, the original table is deleted, and the table copy is renamed to the name of the original table. While the ALTER TABLE operation executes, the original table is readable by other sessions (with the exception noted shortly). Updates and writes to the table started after the ALTER TABLE operation begins are stalled until the new table is ready, then are automatically redirected to the new table. The temporary copy of the table is
ALTER TABLE Statement

created in the database directory of the original table unless it is a RENAME TO operation that moves the table to a database that resides in a different directory.

The exception referred to earlier is that ALTER TABLE blocks reads (not just writes) at the point where it is ready to clear outdated table structures from the table and table definition caches. At this point, it must acquire an exclusive lock. To do so, it waits for current readers to finish, and blocks new reads and writes.

An ALTER TABLE operation that uses the COPY algorithm prevents concurrent DML operations. Concurrent queries are still allowed. That is, a table-copying operation always includes at least the concurrency restrictions of LOCK=SHARED (allow queries but not DML). You can further restrict concurrency for operations that support the LOCK clause by specifying LOCK=EXCLUSIVE, which prevents DML and queries. For more information, see Concurrency Control.

To force use of the COPY algorithm for an ALTER TABLE operation that would otherwise not use it, specify ALGORITHM=COPY or enable the old_alter_table system variable. If there is a conflict between the old_alter_table setting and an ALGORITHM clause with a value other than DEFAULT, the ALGORITHM clause takes precedence.

For InnoDB tables, an ALTER TABLE operation that uses the COPY algorithm on a table that resides in a shared tablespace can increase the amount of space used by the tablespace. Such operations require as much additional space as the data in the table plus indexes. For a table residing in a shared tablespace, the additional space used during the operation is not released back to the operating system as it is for a table that resides in a file-per-table tablespace.

For information about space requirements for online DDL operations, see Section 15.12.3, “Online DDL Space Requirements”.

ALTER TABLE operations that support the INPLACE algorithm include:

- ALTER TABLE operations supported by the InnoDB online DDL feature. See Section 15.12.1, “Online DDL Operations”.

- Renaming a table. MySQL renames files that correspond to the table tbl_name without making a copy. (You can also use the RENAME TABLE statement to rename tables. See Section 13.1.36, “RENAME TABLE Statement”.) Privileges granted specifically for the renamed table are not migrated to the new name. They must be changed manually.

- Operations that modify table metadata only. These operations are immediate because the server does not touch table contents. Metadata-only operations include:
  - Renaming a column. In NDB Cluster, this operation can also be performed online.
  - Changing the default value of a column (except for NDB tables).
  - Modifying the definition of an ENUM or SET column by adding new enumeration or set members to the end of the list of valid member values, as long as the storage size of the data type does not change. For example, adding a member to a SET column that has 8 members changes the required storage per value from 1 byte to 2 bytes; this requires a table copy. Adding members in the middle of the list causes renumbering of existing members, which requires a table copy.
  - Changing the definition of a spatial column to remove the SRID attribute. (Adding or changing an SRID attribute requires a rebuild, and cannot be done in place, because the server must verify that all values have the specified SRID value.)
  - Changing a column character set, when these conditions apply:
    - The column data type is CHAR, VARCHAR, a TEXT type, or ENUM.
• The character set change is from \texttt{utf8mb3} to \texttt{utf8mb4}, or any character set to \texttt{binary}.

• There is no index on the column.

• Changing a generated column, when these conditions apply:
  • For \texttt{InnoDB} tables, statements that modify generated stored columns but do not change their type, expression, or nullability.
  • For non-\texttt{InnoDB} tables, statements that modify generated stored or virtual columns but do not change their type, expression, or nullability.

  An example of such a change is a change to the column comment.

• Renaming an index.

• Adding or dropping a secondary index, for \texttt{InnoDB} and \texttt{NDB} tables. See Section 15.12.1, “Online DDL Operations”.

• For \texttt{NDB} tables, operations that add and drop indexes on variable-width columns. These operations occur online, without table copying and without blocking concurrent DML actions for most of their duration. See Section 23.6.12, “Online Operations with ALTER TABLE in NDB Cluster”.

• Modifying index visibility with an \texttt{ALTER INDEX} operation.

• Column modifications of tables containing generated columns that depend on columns with a \texttt{DEFAULT} value if the modified columns are not involved in the generated column expressions. For example, changing the \texttt{NULL} property of a separate column can be done in place without a table rebuild.

\texttt{ALTER TABLE} operations that support the \texttt{INSTANT} algorithm include:

• Adding a column. This feature is referred to as “Instant \texttt{ADD COLUMN}”. Limitations apply. See Section 15.12.1, “Online DDL Operations”.

• Dropping a column. This feature is referred to as “Instant \texttt{DROP COLUMN}”. Limitations apply. See Section 15.12.1, “Online DDL Operations”.

• Adding or dropping a virtual column.

• Adding or dropping a column default value.

• Modifying the definition of an \texttt{ENUM} or \texttt{SET} column. The same restrictions apply as described above for \texttt{ALGORITHM=INSTANT}.

• Changing the index type.

• Renaming a table. The same restrictions apply as described above for \texttt{ALGORITHM=INSTANT}.

For more information about operations that support \texttt{ALGORITHM=INSTANT}, see Section 15.12.1, “Online DDL Operations”.

\texttt{ALTER TABLE} upgrades MySQL 5.5 temporal columns to 5.6 format for \texttt{ADD COLUMN}, \texttt{CHANGE COLUMN}, \texttt{MODIFY COLUMN}, \texttt{ADD INDEX}, and \texttt{FORCE} operations. This conversion cannot be done using the \texttt{INPLACE} algorithm because the table must be rebuilt, so specifying \texttt{ALGORITHM=INPLACE} in these cases results in an error. Specify \texttt{ALGORITHM=COPY} if necessary.

If an \texttt{ALTER TABLE} operation on a multicolumn index used to partition a table by \texttt{KEY} changes the order of the columns, it can only be performed using \texttt{ALGORITHM=COPY}.
ALTER TABLE Statement

The `WITHOUT VALIDATION` and `WITH VALIDATION` clauses affect whether `ALTER TABLE` performs an in-place operation for virtual generated column modifications. See Section 13.1.9.2, "ALTER TABLE and Generated Columns".

NDB Cluster 8.2 supports online operations using the same `ALGORITHM=INPLACE` syntax used with the standard MySQL Server. NDB does not allow changing a tablespace online. See Section 23.6.12, "Online Operations with ALTER TABLE in NDB Cluster", for more information.

When performing a copying `ALTER TABLE`, NDB checks to ensure that no concurrent writes have been made to the affected table. If it finds that any have been made, NDB rejects the `ALTER TABLE` statement and raises `ER_TABLE_DEF_CHANGED`.

`ALTER TABLE` with `DISCARD ... PARTITION ... TABLESPACE` or `IMPORT ... PARTITION ... TABLESPACE` does not create any temporary tables or temporary partition files.

`ALTER TABLE` with `ADD PARTITION, DROP PARTITION, COALESCE PARTITION, REBUILD PARTITION, or REORGANIZE PARTITION` does not create temporary tables (except when used with NDB tables); however, these operations can and do create temporary partition files.

`ADD` or `DROP` operations for `RANGE` or `LIST` partitions are immediate operations or nearly so. `ADD` or `COALESCE` operations for `HASH` or `KEY` partitions copy data between all partitions, unless `LINEAR HASH` or `LINEAR KEY` was used; this is effectively the same as creating a new table, although the `ADD` or `COALESCE` operation is performed partition by partition. `REORGANIZE` operations copy only changed partitions and do not touch unchanged ones.

For `MyISAM` tables, you can speed up index re-creation (the slowest part of the alteration process) by setting the `myisam_sort_buffer_size` system variable to a high value.

Concurrency Control

For `ALTER TABLE` operations that support it, you can use the `LOCK` clause to control the level of concurrent reads and writes on a table while it is being altered. Specifying a non-default value for this clause enables you to require a certain amount of concurrent access or exclusivity during the alter operation, and halts the operation if the requested degree of locking is not available.

Only `LOCK = DEFAULT` is permitted for operations that use `ALGORITHM=INSTANT`. The other `LOCK` clause parameters are not applicable.

The parameters for the `LOCK` clause are:

- `LOCK = DEFAULT`
  Maximum level of concurrency for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation: Permit concurrent reads and writes if supported. If not, permit concurrent reads if supported. If not, enforce exclusive access.

- `LOCK = NONE`
  If supported, permit concurrent reads and writes. Otherwise, an error occurs.

- `LOCK = SHARED`
  If supported, permit concurrent reads but block writes. Writes are blocked even if concurrent writes are supported by the storage engine for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation. If concurrent reads are not supported, an error occurs.

- `LOCK = EXCLUSIVE`

ENFORCE EXCLUSIVE ACCESS. THIS IS DONE EVEN IF CONCURRENT READS/WRITES ARE SUPPORTED BY THE STORAGE ENGINE FOR THE GIVEN ALGORITHM CLAUSE (IF ANY) AND ALTER TABLE OPERATION.

**Adding and Dropping Columns**

Use ADD to add new columns to a table, and DROP to remove existing columns. DROP col_name is a MySQL extension to standard SQL.

To add a column at a specific position within a table row, use FIRST or AFTER col_name. The default is to add the column last.

If a table contains only one column, the column cannot be dropped. If what you intend is to remove the table, use the DROP TABLE statement instead.

If columns are dropped from a table, the columns are also removed from any index of which they are a part. If all columns that make up an index are dropped, the index is dropped as well. If you use CHANGE or MODIFY to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.

For **ALTER TABLE ... ADD**, if the column has an expression default value that uses a nondeterministic function, the statement may produce a warning or error. For further information, see Section 11.6, “Data Type Default Values”, and Section 17.1.3.7, “Restrictions on Replication with GTIDs”.

**Renaming, Redefining, and Reordering Columns**

The CHANGE, MODIFY, RENAME COLUMN, and ALTER clauses enable the names and definitions of existing columns to be altered. They have these comparative characteristics:

- **CHANGE**:
  - Can rename a column and change its definition, or both.
  - Has more capability than MODIFY or RENAME COLUMN, but at the expense of convenience for some operations. CHANGE requires naming the column twice if not renaming it, and requires respecifying the column definition if only renaming it.
  - With FIRST or AFTER, can reorder columns.

- **MODIFY**:
  - Can change a column definition but not its name.
  - More convenient than CHANGE to change a column definition without renaming it.
  - With FIRST or AFTER, can reorder columns.

- **RENAME COLUMN**:
  - Can change a column name but not its definition.
  - More convenient than CHANGE to rename a column without changing its definition.

- **ALTER**: Used only to change a column default value.

CHANGE is a MySQL extension to standard SQL. MODIFY and RENAME COLUMN are MySQL extensions for Oracle compatibility.
ALTER TABLE Statement

To alter a column to change both its name and definition, use `CHANGE`, specifying the old and new names and the new definition. For example, to rename an `INT NOT NULL` column from `a` to `b` and change its definition to use the `BIGINT` data type while retaining the `NOT NULL` attribute, do this:

```sql
ALTER TABLE t1 CHANGE a b BIGINT NOT NULL;
```

To change a column definition but not its name, use `CHANGE` or `MODIFY`. With `CHANGE`, the syntax requires two column names, so you must specify the same name twice to leave the name unchanged. For example, to change the definition of column `b`, do this:

```sql
ALTER TABLE t1 CHANGE b b INT NOT NULL;
```

`MODIFY` is more convenient to change the definition without changing the name because it requires the column name only once:

```sql
ALTER TABLE t1 MODIFY b INT NOT NULL;
```

To change a column name but not its definition, use `CHANGE` or `RENAME COLUMN`. With `CHANGE`, the syntax requires a column definition, so to leave the definition unchanged, you must respecify the definition the column currently has. For example, to rename an `INT NOT NULL` column from `b` to `a`, do this:

```sql
ALTER TABLE t1 CHANGE b a INT NOT NULL;
```

`RENAME COLUMN` is more convenient to change the name without changing the definition because it requires only the old and new names:

```sql
ALTER TABLE t1 RENAME COLUMN b TO a;
```

In general, you cannot rename a column to a name that already exists in the table. However, this is sometimes not the case, such as when you swap names or move them through a cycle. If a table has columns named `a`, `b`, and `c`, these are valid operations:

```sql
-- swap a and b
ALTER TABLE t1 RENAME COLUMN a TO b,
    RENAME COLUMN b TO a;
-- "rotate" a, b, c through a cycle
ALTER TABLE t1 RENAME COLUMN a TO b,
    RENAME COLUMN b TO c,
    RENAME COLUMN c TO a;
```

For column definition changes using `CHANGE` or `MODIFY`, the definition must include the data type and all attributes that should apply to the new column, other than index attributes such as `PRIMARY KEY` or `UNIQUE`. Attributes present in the original definition but not specified for the new definition are not carried forward. Suppose that a column `col1` is defined as `INT UNSIGNED DEFAULT 1 COMMENT 'my column'` and you modify the column as follows, intending to change only `INT` to `BIGINT`:

```sql
ALTER TABLE t1 MODIFY col1 BIGINT;
```

That statement changes the data type from `INT` to `BIGINT`, but it also drops the `UNSIGNED`, `DEFAULT`, and `COMMENT` attributes. To retain them, the statement must include them explicitly:

```sql
ALTER TABLE t1 MODIFY col1 BIGINT UNSIGNED DEFAULT 1 COMMENT 'my column';
```

For data type changes using `CHANGE` or `MODIFY`, MySQL tries to convert existing column values to the new type as well as possible.

**Warning**

This conversion may result in alteration of data. For example, if you shorten a string column, values may be truncated. To prevent the operation from succeeding if conversions to the new data type would result in loss of data, enable strict SQL mode before using `ALTER TABLE` (see Section 5.1.11, “Server SQL Modes”).
If you use `CHANGE` or `MODIFY` to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.

For columns renamed by `CHANGE` or `RENAME COLUMN`, MySQL automatically renames these references to the renamed column:

- Indexes that refer to the old column, including invisible indexes and disabled `MyISAM` indexes.
- Foreign keys that refer to the old column.

For columns renamed by `CHANGE` or `RENAME COLUMN`, MySQL does not automatically rename these references to the renamed column:

- Generated column and partition expressions that refer to the renamed column. You must use `CHANGE` to redefine such expressions in the same `ALTER TABLE` statement as the one that renames the column.
- Views and stored programs that refer to the renamed column. You must manually alter the definition of these objects to refer to the new column name.

To reorder columns within a table, use `FIRST` and `AFTER` in `CHANGE` or `MODIFY` operations.

`ALTER ... SET DEFAULT` or `ALTER ... DROP DEFAULT` specify a new default value for a column or remove the old default value, respectively. If the old default is removed and the column can be `NULL`, the new default is `NULL`. If the column cannot be `NULL`, MySQL assigns a default value as described in Section 11.6, “Data Type Default Values”.

`ALTER ... SET VISIBLE` and `ALTER ... SET INVISIBLE` enable column visibility to be changed. See Section 13.1.20.10, “Invisible Columns”.

### Primary Keys and Indexes

`DROP PRIMARY KEY` drops the primary key. If there is no primary key, an error occurs. For information about the performance characteristics of primary keys, especially for InnoDB tables, see Section 8.3.2, “Primary Key Optimization”.

If the `sql_require_primary_key` system variable is enabled, attempting to drop a primary key produces an error.

If you add a `UNIQUE INDEX` or `PRIMARY KEY` to a table, MySQL stores it before any nonunique index to permit detection of duplicate keys as early as possible.

`DROP INDEX` removes an index. This is a MySQL extension to standard SQL. See Section 13.1.27, “DROP INDEX Statement”. To determine index names, use `SHOW INDEX FROM tbl_name`.

Some storage engines permit you to specify an index type when creating an index. The syntax for the `index_type` specifier is `USING type_name`. For details about `USING`, see Section 13.1.15, “CREATE INDEX Statement”. The preferred position is after the column list. Expect support for use of the option before the column list to be removed in a future MySQL release.

`index_option` values specify additional options for an index. `USING` is one such option. For details about permissible `index_option` values, see Section 13.1.15, “CREATE INDEX Statement”.

`RENAME INDEX old_index_name TO new_index_name` renames an index. This is a MySQL extension to standard SQL. The content of the table remains unchanged. `old_index_name` must be the name of an existing index in the table that is not dropped by the same `ALTER TABLE` statement. `new_index_name` is the new index name, which cannot duplicate the name of an index in the resulting table after changes have been applied. Neither index name can be `PRIMARY`. 

2631
If you use `ALTER TABLE` on a `MyISAM` table, all nonunique indexes are created in a separate batch (as for `REPAIR TABLE`). This should make `ALTER TABLE` much faster when you have many indexes.

For `MyISAM` tables, key updating can be controlled explicitly. Use `ALTER TABLE ... DISABLE KEYS` to tell MySQL to stop updating nonunique indexes. Then use `ALTER TABLE ... ENABLE KEYS` to re-create missing indexes. `MyISAM` does this with a special algorithm that is much faster than inserting keys one by one, so disabling keys before performing bulk insert operations should give a considerable speedup. Using `ALTER TABLE ... DISABLE KEYS` requires the `INDEX` privilege in addition to the privileges mentioned earlier.

While the nonunique indexes are disabled, they are ignored for statements such as `SELECT` and `EXPLAIN` that otherwise would use them.

After an `ALTER TABLE` statement, it may be necessary to run `ANALYZE TABLE` to update index cardinality information. See Section 13.7.7.23, “SHOW INDEX Statement”.

The `ALTER INDEX` operation permits an index to be made visible or invisible. An invisible index is not used by the optimizer. Modification of index visibility applies to indexes other than primary keys (either explicit or implicit). This feature is storage engine neutral (supported for any engine). For more information, see Section 8.3.12, “Invisible Indexes”.

### Foreign Keys and Other Constraints

The `FOREIGN KEY` and `REFERENCES` clauses are supported by the InnoDB and NDB storage engines, which implement `ADD [CONSTRAINT [symbol]] FOREIGN KEY [index_name] (....) REFERENCES ... (....)`. See Section 13.1.20.5, “FOREIGN KEY Constraints”. For other storage engines, the clauses are parsed but ignored.

For `ALTER TABLE`, unlike `CREATE TABLE`, `ADD FOREIGN KEY` ignores `index_name` if given and uses an automatically generated foreign key name. As a workaround, include the `CONSTRAINT` clause to specify the foreign key name:

```sql
ADD CONSTRAINT name FOREIGN KEY (....) ...
```

### Important

MySQL silently ignores inline `REFERENCES` specifications, where the references are defined as part of the column specification. MySQL accepts only `REFERENCES` clauses defined as part of a separate `FOREIGN KEY` specification.

### Note

Partitioned InnoDB tables do not support foreign keys. This restriction does not apply to NDB tables, including those explicitly partitioned by `[LINEAR] KEY`. For more information, see Section 24.6.2, “Partitioning Limitations Relating to Storage Engines”.

MySQL Server and NDB Cluster both support the use of `ALTER TABLE` to drop foreign keys:

```sql
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

Adding and dropping a foreign key in the same `ALTER TABLE` statement is supported for `ALTER TABLE ... ALGORITHM=INPLACE` but not for `ALTER TABLE ... ALGORITHM=COPY`.

The server prohibits changes to foreign key columns that have the potential to cause loss of referential integrity. A workaround is to use `ALTER TABLE ... DROP FOREIGN KEY` before changing the column definition and `ALTER TABLE ... ADD FOREIGN KEY` afterward. Examples of prohibited changes include:
ALTER TABLE Statement

• Changes to the data type of foreign key columns that may be unsafe. For example, changing VARCHAR(20) to VARCHAR(30) is permitted, but changing it to VARCHAR(1024) is not because that alters the number of length bytes required to store individual values.

• Changing a NULL column to NOT NULL in non-strict mode is prohibited to prevent converting NULL values to default non-NULL values, for which there are no corresponding values in the referenced table. The operation is permitted in strict mode, but an error is returned if any such conversion is required.

```
ALTER TABLE tbl_name RENAME new_tbl_name changes internally generated foreign key constraint names and user-defined foreign key constraint names that begin with the string "tbl_name_ibfk_" to reflect the new table name. InnoDB interprets foreign key constraint names that begin with the string “tbl_name_ibfk_” as internally generated names.
```

```
ALTER TABLE permits CHECK constraints for existing tables to be added, dropped, or altered:
```

• Add a new CHECK constraint:

```
ALTER TABLE tbl_name
ADD [CONSTRAINT [symbol]] CHECK (expr) [[NOT] ENFORCED];
```

The meaning of constraint syntax elements is the same as for CREATE TABLE. See Section 13.1.20.6, “CHECK Constraints”.

• Drop an existing CHECK constraint named symbol:

```
ALTER TABLE tbl_name
DROP CHECK symbol;
```

• Alter whether an existing CHECK constraint named symbol is enforced:

```
ALTER TABLE tbl_name
ALTER CHECK symbol [NOT] ENFORCED;
```

The DROP CHECK and ALTER CHECK clauses are MySQL extensions to standard SQL.

ALTER TABLE permits more general (and SQL standard) syntax for dropping and altering existing constraints of any type, where the constraint type is determined from the constraint name:

• Drop an existing constraint named symbol:

```
ALTER TABLE tbl_name
DROP CONSTRAINT symbol;
```

If the sql_require_primary_key system variable is enabled, attempting to drop a primary key produces an error.

• Alter whether an existing constraint named symbol is enforced:

```
ALTER TABLE tbl_name
ALTER CONSTRAINT symbol [NOT] ENFORCED;
```

Only CHECK constraints can be altered to be unenforced. All other constraint types are always enforced.

The SQL standard specifies that all types of constraints (primary key, unique index, foreign key, check) belong to the same namespace. In MySQL, each constraint type has its own namespace per schema. Consequently, names for each type of constraint must be unique per schema, but constraints of different types can have the same name. When multiple constraints have the same name, DROP CONSTRAINT and ADD CONSTRAINT are ambiguous and an error occurs. In such cases, constraint-specific syntax must be used to modify the constraint. For example, use DROP PRIMARY KEY or DROP FOREIGN KEY to drop a primary key or foreign key.
ALTER TABLE Statement

If a table alteration causes a violation of an enforced CHECK constraint, an error occurs and the table is not modified. Examples of operations for which an error occurs:

- Attempts to add the AUTO_INCREMENT attribute to a column that is used in a CHECK constraint.
- Attempts to add an enforced CHECK constraint or enforce a nonenforced CHECK constraint for which existing rows violate the constraint condition.
- Attempts to modify, rename, or drop a column that is used in a CHECK constraint, unless that constraint is also dropped in the same statement. Exception: If a CHECK constraint refers only to a single column, dropping the column automatically drops the constraint.

`ALTER TABLE tbl_name RENAME new_tbl_name` changes internally generated and user-defined CHECK constraint names that begin with the string “tbl_name_chk_” to reflect the new table name. MySQL interprets CHECK constraint names that begin with the string “tbl_name_chk_” as internally generated names.

Changing the Character Set

To change the table default character set and all character columns (CHAR, VARCHAR, TEXT) to a new character set, use a statement like this:

```
ALTER TABLE tbl_name CONVERT TO CHARACTER SET charset_name;
```

The statement also changes the collation of all character columns. If you specify no COLLATE clause to indicate which collation to use, the statement uses default collation for the character set. If this collation is inappropriate for the intended table use (for example, if it would change from a case-sensitive collation to a case-insensitive collation), specify a collation explicitly.

For a column that has a data type of VARCHAR or one of the TEXT types, `CONVERT TO CHARACTER SET` changes the data type as necessary to ensure that the new column is long enough to store as many characters as the original column. For example, a TEXT column has two length bytes, which store the byte-length of values in the column, up to a maximum of 65,535. For a latin1 TEXT column, each character requires a single byte, so the column can store up to 65,535 characters. If the column is converted to utf8mb4, each character might require up to 4 bytes, for a maximum possible length of $4 \times 65,535 = 262,140$ bytes. That length does not fit in a TEXT column’s length bytes, so MySQL converts the data type to MEDIUMTEXT, which is the smallest string type for which the length bytes can record a value of 262,140. Similarly, a VARCHAR column might be converted to MEDIUMTEXT.

To avoid data type changes of the type just described, do not use `CONVERT TO CHARACTER SET`. Instead, use `MODIFY` to change individual columns. For example:

```
ALTER TABLE t MODIFY latin1_text_col TEXT CHARACTER SET utf8mb4;
ALTER TABLE t MODIFY latin1_varchar_col VARCHAR(5) CHARACTER SET utf8mb4;
```

If you specify `CONVERT TO CHARACTER SET binary`, the CHAR, VARCHAR, and TEXT columns are converted to their corresponding binary string types (BINARY, VARBINARY, BLOB). This means that the columns no longer have a character set and a subsequent `CONVERT TO` operation does not apply to them.

If `charset_name` is `DEFAULT` in a `CONVERT TO CHARACTER SET` operation, the character set named by the `character_set_database` system variable is used.

Warning

The `CONVERT TO` operation converts column values between the original and named character sets. This is not what you want if you have a column in one character set (like latin1) but the stored values actually use some other,
incompatible character set (like utf8mb4). In this case, you have to do the following for each such column:

```sql
ALTER TABLE t1 CHANGE c1 c1 BLOB;
ALTER TABLE t1 CHANGE c1 c1 TEXT CHARACTER SET utf8mb4;
```

The reason this works is that there is no conversion when you convert to or from BLOB columns.

To change only the default character set for a table, use this statement:

```sql
ALTER TABLE tbl_name DEFAULT CHARACTER SET charset_name;
```

The word DEFAULT is optional. The default character set is the character set that is used if you do not specify the character set for columns that you add to a table later (for example, with ALTER TABLE ... ADD column).

When the foreign_key_checks system variable is enabled, which is the default setting, character set conversion is not permitted on tables that include a character string column used in a foreign key constraint. The workaround is to disable foreign_key_checks before performing the character set conversion. You must perform the conversion on both tables involved in the foreign key constraint before re-enabling foreign_key_checks. If you re-enable foreign_key_checks after converting only one of the tables, an ON DELETE CASCADE or ON UPDATE CASCADE operation could corrupt data in the referencing table due to implicit conversion that occurs during these operations (Bug #45290, Bug #74816).

**Importing InnoDB Tables**

An InnoDB table created in its own file-per-table tablespace can be imported from a backup or from another MySQL server instance using DISCARD TABLESPACE and IMPORT TABLESPACE clauses. See Section 15.6.1.3, “Importing InnoDB Tables”.

**Row Order for MyISAM Tables**

ORDER BY enables you to create the new table with the rows in a specific order. This option is useful primarily when you know that you query the rows in a certain order most of the time. By using this option after major changes to the table, you might be able to get higher performance. In some cases, it might make sorting easier for MySQL if the table is in order by the column that you want to order it by later.

**Note**
The table does not remain in the specified order after inserts and deletes.

ORDER BY syntax permits one or more column names to be specified for sorting, each of which optionally can be followed by ASC or DESC to indicate ascending or descending sort order, respectively. The default is ascending order. Only column names are permitted as sort criteria; arbitrary expressions are not permitted. This clause should be given last after any other clauses.

ORDER BY does not make sense for InnoDB tables because InnoDB always orders table rows according to the clustered index.

When used on a partitioned table, ALTER TABLE ... ORDER BY orders rows within each partition only.

**Partitioning Options**

partition_options signifies options that can be used with partitioned tables for repartitioning, to add, drop, discard, import, merge, and split partitions, and to perform partitioning maintenance.
It is possible for an `ALTER TABLE` statement to contain a `PARTITION BY` or `REMOVE PARTITIONING` clause in an addition to other alter specifications, but the `PARTITION BY` or `REMOVE PARTITIONING` clause must be specified last after any other specifications. The `ADD PARTITION`, `DROP PARTITION`, `DISCARD PARTITION`, `IMPORT PARTITION`, `COALESCE PARTITION`, `REORGANIZE PARTITION`, `EXCHANGE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, and `REPAIR PARTITION` options cannot be combined with other alter specifications in a single `ALTER TABLE`, since the options just listed act on individual partitions.

For more information about partition options, see Section 13.1.20, “CREATE TABLE Statement”, and Section 13.1.9.1, “ALTER TABLE Partition Operations”. For information about and examples of `ALTER TABLE ... EXCHANGE PARTITION` statements, see Section 24.3.3, “Exchanging Partitions and Subpartitions with Tables”.

### 13.1.9.1 ALTER TABLE Partition Operations

Partitioning-related clauses for `ALTER TABLE` can be used with partitioned tables for repartitioning, to add, drop, discard, import, merge, and split partitions, and to perform partitioning maintenance.

- Simply using a `partition_options` clause with `ALTER TABLE` on a partitioned table repartitions the table according to the partitioning scheme defined by the `partition_options`. This clause always begins with `PARTITION BY`, and follows the same syntax and other rules as apply to the `partition_options` clause for `CREATE TABLE` (for more detailed information, see Section 13.1.20, “CREATE TABLE Statement”), and can also be used to partition an existing table that is not already partitioned. For example, consider a (nonpartitioned) table defined as shown here:

  ```sql
  CREATE TABLE t1 (    id INT,    year_col INT );
  ```

  This table can be partitioned by `HASH`, using the `id` column as the partitioning key, into 8 partitions by means of this statement:

  ```sql
  ALTER TABLE t1    PARTITION BY HASH(id)    PARTITIONS 8;
  ```

  MySQL supports an `ALGORITHM` option with `[SUB]PARTITION BY [LINEAR] KEY. ALGORITHM=1 causes the server to use the same key-hashing functions as MySQL 5.1 when computing the placement of rows in partitions; `ALGORITHM=2` means that the server employs the key-hashing functions implemented and used by default for new `KEY` partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a MySQL 5.1 server.) Not specifying the option has the same effect as using `ALGORITHM=2`. This option is intended for use chiefly when upgrading or downgrading `[LINEAR] KEY partitioned tables between MySQL 5.1 and later MySQL versions, or for creating tables partitioned by `KEY` or `LINEAR KEY` on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server.

  The table that results from using an `ALTER TABLE ... PARTITION BY` statement must follow the same rules as one created using `CREATE TABLE ... PARTITION BY`. This includes the rules governing the relationship between any unique keys (including any primary key) that the table might have, and the column or columns used in the partitioning expression, as discussed in Section 24.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”. The `CREATE TABLE ... PARTITION BY` rules for specifying the number of partitions also apply to `ALTER TABLE ... PARTITION BY`.

  The `partition_definition` clause for `ALTER TABLE ADD PARTITION` supports the same options as the clause of the same name for the `CREATE TABLE` statement. (See Section 13.1.20, “CREATE
ALTER TABLE Statement

TABLE Statement*, for the syntax and description.) Suppose that you have the partitioned table created as shown here:

```sql
CREATE TABLE t1 (
  id INT,
  year_col INT
)
PARTITION BY RANGE (year_col) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1995),
  PARTITION p2 VALUES LESS THAN (1999)
);
```

You can add a new partition `p3` to this table for storing values less than 2002 as follows:

```sql
ALTER TABLE t1 ADD PARTITION (PARTITION p3 VALUES LESS THAN (2002));
```

DROP PARTITION can be used to drop one or more RANGE or LIST partitions. This statement cannot be used with HASH or KEY partitions; instead, use COALESCE PARTITION (see later in this section). Any data that was stored in the dropped partitions named in the partition_names list is discarded. For example, given the table `t1` defined previously, you can drop the partitions named `p0` and `p1` as shown here:

```sql
ALTER TABLE t1 DROP PARTITION p0, p1;
```

Note

DROP PARTITION does not work with tables that use the NDB storage engine. See Section 24.3.1, “Management of RANGE and LIST Partitions”, and Section 23.2.7, “Known Limitations of NDB Cluster”.

ADD PARTITION and DROP PARTITION do not currently support IF [NOT] EXISTS.

The DISCARD PARTITION ... TABLESPACE and IMPORT PARTITION ... TABLESPACE options extend the Transportable Tablespace feature to individual InnoDB table partitions. Each InnoDB table partition has its own tablespace file (.ibd file). The Transportable Tablespace feature makes it easy to copy the tablespaces from a running MySQL server instance to another running instance, or to perform a restore on the same instance. Both options take a comma-separated list of one or more partition names. For example:

```sql
ALTER TABLE t1 DISCARD PARTITION p2, p3 TABLESPACE;
ALTER TABLE t1 IMPORT PARTITION p2, p3 TABLESPACE;
```

When running DISCARD PARTITION ... TABLESPACE and IMPORT PARTITION ... TABLESPACE on subpartitioned tables, both partition and subpartition names are allowed. When a partition name is specified, subpartitions of that partition are included.

The Transportable Tablespace feature also supports copying or restoring partitioned InnoDB tables. For more information, see Section 15.6.1.3, “Importing InnoDB Tables”.

Renames of partitioned tables are supported. You can rename individual partitions indirectly using ALTER TABLE ... REORGANIZE PARTITION; however, this operation copies the partition's data.

To delete rows from selected partitions, use the TRUNCATE PARTITION option. This option takes a list of one or more comma-separated partition names. Consider the table `t1` created by this statement:

```sql
CREATE TABLE t1 (
  id INT,
);
To delete all rows from partition \texttt{p0}, use the following statement:

\begin{verbatim}
ALTER TABLE t1 TRUNCATE PARTITION p0;
\end{verbatim}

The statement just shown has the same effect as the following \texttt{DELETE} statement:

\begin{verbatim}
DELETE FROM t1 WHERE year_col < 1991;
\end{verbatim}

When truncating multiple partitions, the partitions do not have to be contiguous: This can greatly simplify delete operations on partitioned tables that would otherwise require very complex \texttt{WHERE} conditions if done with \texttt{DELETE} statements. For example, this statement deletes all rows from partitions \texttt{p1} and \texttt{p3}:

\begin{verbatim}
ALTER TABLE t1 TRUNCATE PARTITION p1, p3;
\end{verbatim}

An equivalent \texttt{DELETE} statement is shown here:

\begin{verbatim}
DELETE FROM t1 WHERE \\
( year_col >= 1991 AND year_col < 1995 ) \\
OR \\
( year_col >= 2003 AND year_col < 2007 );
\end{verbatim}

If you use the \texttt{ALL} keyword in place of the list of partition names, the statement acts on all table partitions.

\texttt{TRUNCATE PARTITION} merely deletes rows; it does not alter the definition of the table itself, or of any of its partitions.

To verify that the rows were dropped, check the \texttt{INFORMATION_SCHEMA.PARTITIONS} table, using a query such as this one:

\begin{verbatim}
SELECT PARTITION_NAME, TABLE_ROWS \\
FROM INFORMATION_SCHEMA.PARTITIONS \\
WHERE TABLE_NAME = 't1';
\end{verbatim}

\texttt{COALESCE PARTITION} can be used with a table that is partitioned by \texttt{HASH} or \texttt{KEY} to reduce the number of partitions by \texttt{number}. Suppose that you have created table \texttt{t2} as follows:

\begin{verbatim}
CREATE TABLE t2 ( \\
  name VARCHAR (30), \\
  started DATE \\
) \\
PARTITION BY HASH( YEAR(started) )
\end{verbatim}
To reduce the number of partitions used by `t2` from 6 to 4, use the following statement:

```
ALTER TABLE t2 COALESCE PARTITION 2;
```

The data contained in the last `number` partitions is merged into the remaining partitions. In this case, partitions 4 and 5 are merged into the first 4 partitions (the partitions numbered 0, 1, 2, and 3).

To change some but not all the partitions used by a partitioned table, you can use `REORGANIZE PARTITION`. This statement can be used in several ways:

- To merge a set of partitions into a single partition. This is done by naming several partitions in the `partition_names` list and supplying a single definition for `partition_definition`.
- To split an existing partition into several partitions. Accomplish this by naming a single partition for `partition_names` and providing multiple `partition_definitions`.
- To change the ranges for a subset of partitions defined using `VALUES LESS THAN` or the value lists for a subset of partitions defined using `VALUES IN`.

**Note**

For partitions that have not been explicitly named, MySQL automatically provides the default names `p0`, `p1`, `p2`, and so on. The same is true with regard to subpartitions.

For more detailed information about and examples of `ALTER TABLE ... REORGANIZE PARTITION` statements, see Section 24.3.1, “Management of RANGE and LIST Partitions”.

- To exchange a table partition or subpartition with a table, use the `ALTER TABLE ... EXCHANGE PARTITION` statement—that is, to move any existing rows in the partition or subpartition to the nonpartitioned table, and any existing rows in the nonpartitioned table to the table partition or subpartition.

Once one or more columns have been added to a partitioned table using `ALGORITHM=INSTANT`, it is no longer possible to exchange partitions with that table.

For usage information and examples, see Section 24.3.3, “Exchanging Partitions and Subpartitions with Tables”.

- Several options provide partition maintenance and repair functionality analogous to that implemented for nonpartitioned tables by statements such as `CHECK TABLE` and `REPAIR TABLE` (which are also supported for partitioned tables; for more information, see Section 13.7.3, “Table Maintenance Statements”). These include `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, and `REPAIR PARTITION`. Each of these options takes a `partition_names` clause consisting of one or more names of partitions, separated by commas. The partitions must already exist in the target table. You can also use the `ALL` keyword in place of `partition_names`, in which case the statement acts on all table partitions. For more information and examples, see Section 24.3.4, “Maintenance of Partitions”.

  *InnoDB* does not currently support per-partition optimization; `ALTER TABLE ... OPTIMIZE PARTITION` causes the entire table to rebuilt and analyzed, and an appropriate warning to be issued.
(Bug #11751825, Bug #42822) To work around this problem, use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead.

The `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, and `REPAIR PARTITION` options are not supported for tables which are not partitioned.

- `REMOVE PARTITIONING` enables you to remove a table's partitioning without otherwise affecting the table or its data. This option can be combined with other `ALTER TABLE` options such as those used to add, drop, or rename columns or indexes.

- Using the `ENGINE` option with `ALTER TABLE` changes the storage engine used by the table without affecting the partitioning. The target storage engine must provide its own partitioning handler. Only the InnoDB and NDB storage engines have native partitioning handlers; NDB is not currently supported in MySQL 8.2.

It is possible for an `ALTER TABLE` statement to contain a `PARTITION BY` or `REMOVE PARTITIONING` clause in an addition to other alter specifications, but the `PARTITION BY` or `REMOVE PARTITIONING` clause must be specified last after any other specifications.

The `ADD PARTITION`, `DROP PARTITION`, `COALESCE PARTITION`, `REORGANIZE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, and `REPAIR PARTITION` options cannot be combined with other alter specifications in a single `ALTER TABLE`, since the options just listed act on individual partitions. For more information, see Section 13.1.9.1, “ALTER TABLE Partition Operations”.

Only a single instance of any one of the following options can be used in a given `ALTER TABLE` statement: `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `TRUNCATE PARTITION`, `EXCHANGE PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, `REMOVE PARTITIONING`.

For example, the following two statements are invalid:

```sql
ALTER TABLE t1 ANALYZE PARTITION p1, ANALYZE PARTITION p2;
ALTER TABLE t1 ANALYZE PARTITION p1, CHECK PARTITION p2;
```

In the first case, you can analyze partitions `p1` and `p2` of table `t1` concurrently using a single statement with a single `ANALYZE PARTITION` option that lists both of the partitions to be analyzed, like this:

```sql
ALTER TABLE t1 ANALYZE PARTITION p1, p2;
```

In the second case, it is not possible to perform `ANALYZE` and `CHECK` operations on different partitions of the same table concurrently. Instead, you must issue two separate statements, like this:

```sql
ALTER TABLE t1 ANALYZE PARTITION p1;
ALTER TABLE t1 CHECK PARTITION p2;
```

`REBUILD` operations are currently unsupported for subpartitions. The `REBUILD` keyword is expressly disallowed with subpartitions, and causes `ALTER TABLE` to fail with an error if so used.

`CHECK PARTITION` and `REPAIR PARTITION` operations fail when the partition to be checked or repaired contains any duplicate key errors.

For more information about these statements, see Section 24.3.4, “Maintenance of Partitions”.

### 13.1.9.2 ALTER TABLE and Generated Columns

`ALTER TABLE` operations permitted for generated columns are `ADD`, `MODIFY`, and `CHANGE`.

- Generated columns can be added.
create table t1 (c1 int);
alter table t1 add column c2 int generated always as (c1 + 1) stored;

- The data type and expression of generated columns can be modified.

create table t1 (c1 int, c2 int generated always as (c1 + 1) stored);
alter table t1 modify column c2 tinyint generated always as (c1 + 5) stored;

- Generated columns can be renamed or dropped, if no other column refers to them.

create table t1 (c1 int, c2 int generated always as (c1 + 1) virtual);
alter table t1 change c2 c3 int generated always as (c1 + 1) stored;
alter table t1 drop column c3;

- Virtual generated columns cannot be altered to stored generated columns, or vice versa. To work around this, drop the column, then add it with the new definition.

create table t1 (c1 int, c2 int generated always as (c1 + 1) virtual);
alter table t1 drop column c2;
alter table t1 add column c2 int generated always as (c1 + 1) stored;

- Nongenerated columns can be altered to stored but not virtual generated columns.

create table t1 (c1 int, c2 int);
alter table t1 modify column c2 int generated always as (c1 + 1) stored;

- Stored but not virtual generated columns can be altered to nongenerated columns. The stored generated values become the values of the nongenerated column.

create table t1 (c1 int, c2 int generated always as (c1 + 1) stored);
alter table t1 modify column c2 int;

- \texttt{ADD COLUMN} is not an in-place operation for stored columns (done without using a temporary table) because the expression must be evaluated by the server. For stored columns, indexing changes are done in place, and expression changes are not done in place. Changes to column comments are done in place.

- For non-partitioned tables, \texttt{ADD COLUMN} and \texttt{DROP COLUMN} are in-place operations for virtual columns. However, adding or dropping a virtual column cannot be performed in place in combination with other \texttt{ALTER TABLE} operations.

  For partitioned tables, \texttt{ADD COLUMN} and \texttt{DROP COLUMN} are not in-place operations for virtual columns.

- InnoDB supports secondary indexes on virtual generated columns. Adding or dropping a secondary index on a virtual generated column is an in-place operation. For more information, see Section 13.1.20.9, “Secondary Indexes and Generated Columns”.

- When a \texttt{VIRTUAL} generated column is added to a table or modified, it is not ensured that data being calculated by the generated column expression is not out of range for the column. This can lead to inconsistent data being returned and unexpectedly failed statements. To permit control over whether validation occurs for such columns, \texttt{ALTER TABLE} supports \texttt{WITHOUT VALIDATION} and \texttt{WITH VALIDATION} clauses:

  - With \texttt{WITHOUT VALIDATION} (the default if neither clause is specified), an in-place operation is performed (if possible), data integrity is not checked, and the statement finishes more quickly. However, later reads from the table might report warnings or errors for the column if values are out of range.

  - With \texttt{WITH VALIDATION}, \texttt{ALTER TABLE} copies the table. If an out-of-range or any other error occurs, the statement fails. Because a table copy is performed, the statement takes longer.
**ALTER TABLE Statement**

*WITHOUT VALIDATION* and *WITH VALIDATION* are permitted only with *ADD COLUMN*, *CHANGE COLUMN*, and *MODIFY COLUMN* operations. Otherwise, an *ER_WRONG_USAGE* error occurs.

- If expression evaluation causes truncation or provides incorrect input to a function, the `ALTER TABLE` statement terminates with an error and the DDL operation is rejected.

- An `ALTER TABLE` statement that changes the default value of a column `col_name` may also change the value of a generated column expression that refers to the column using `col_name`, which may change the value of a generated column expression that refers to the column using `DEFAULT(col_name)`. For this reason, `ALTER TABLE` operations that change the definition of a column cause a table rebuild if any generated column expression uses `DEFAULT()`.

13.1.9.3 ALTER TABLE Examples

Begin with a table `t1` created as shown here:
```
CREATE TABLE t1 (a INTEGER, b CHAR(10));
```
To rename the table from `t1` to `t2`:
```
ALTER TABLE t1 RENAME t2;
```
To change column `a` from `INTEGER` to `TINYINT NOT NULL` (leaving the name the same), and to change column `b` from `CHAR(10)` to `CHAR(20)` as well as renaming it from `b` to `c`:
```
ALTER TABLE t2 MODIFY a TINYINT NOT NULL, CHANGE b c CHAR(20);
```
To add a new `TIMESTAMP` column named `d`:
```
ALTER TABLE t2 ADD d TIMESTAMP;
```
To add an index on column `d` and a `UNIQUE` index on column `a`:
```
ALTER TABLE t2 ADD INDEX (d), ADD UNIQUE (a);
```
To remove column `c`:
```
ALTER TABLE t2 DROP COLUMN c;
```
To add a new `AUTO_INCREMENT` integer column named `c`:
```
ALTER TABLE t2 ADD c INT UNSIGNED NOT NULL AUTO_INCREMENT,
    ADD PRIMARY KEY (c);
```
We indexed `c` (as a `PRIMARY KEY`) because `AUTO_INCREMENT` columns must be indexed, and we declare `c` as `NOT NULL` because primary key columns cannot be `NULL`.

For NDB tables, it is also possible to change the storage type used for a table or column. For example, consider an NDB table created as shown here:
```
mysql> CREATE TABLE t1 (c1 INT) TABLESPACE ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.27 sec)
```
To convert this table to disk-based storage, you can use the following `ALTER TABLE` statement:
```
mysql> ALTER TABLE t1 TABLESPACE ts_1 STORAGE DISK;
Query OK, 0 rows affected (2.99 sec)
Records: 0  Duplicates: 0  Warnings: 0
```
ALTER TABLE Statement

```
mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
Table: t1
Create Table: CREATE TABLE `t1` (
   `c1` int(11) DEFAULT NULL
) /*!50100 TABLESPACE ts_1 STORAGE DISK */
ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.01 sec)
```

It is not necessary that the tablespace was referenced when the table was originally created; however, the tablespace must be referenced by the `ALTER TABLE`:

```
mysql> CREATE TABLE t2 (c1 INT) ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.00 sec)
```

```
mysql> ALTER TABLE t2 STORAGE DISK;
ERROR 1005 (HY000): Can't create table 'c.#sql-1750_3' (errno: 140)
```

```
mysql> ALTER TABLE t2 TABLESPACE ts_1 STORAGE DISK;
Query OK, 0 rows affected (3.42 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

```
mysql> SHOW CREATE TABLE t2\G
*************************** 1. row ***************************
Table: t1
Create Table: CREATE TABLE `t2` (
   `c1` int(11) DEFAULT NULL
) /*!50100 TABLESPACE ts_1 STORAGE DISK */
ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.01 sec)
```

To change the storage type of an individual column, you can use `ALTER TABLE ... MODIFY [COLUMN]`. For example, suppose you create an NDB Cluster Disk Data table with two columns, using this `CREATE TABLE` statement:

```
mysql> CREATE TABLE t3 (c1 INT, c2 INT)
      ->   TABLESPACE ts_1 STORAGE DISK ENGINE NDB;
Query OK, 0 rows affected (1.34 sec)
```

To change column `c2` from disk-based to in-memory storage, include a STORAGE MEMORY clause in the column definition used by the `ALTER TABLE` statement, as shown here:

```
mysql> ALTER TABLE t3 MODIFY c2 INT STORAGE MEMORY;
Query OK, 0 rows affected (3.14 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

You can make an in-memory column into a disk-based column by using `STORAGE DISK` in a similar fashion.

Column `c1` uses disk-based storage, since this is the default for the table (determined by the table-level `STORAGE DISK` clause in the `CREATE TABLE` statement). However, column `c2` uses in-memory storage, as can be seen here in the output of `SHOW CREATE TABLE`:

```
mysql> SHOW CREATE TABLE t3\G
*************************** 1. row ***************************
Table: t3
Create Table: CREATE TABLE `t3` (
   `c1` int(11) DEFAULT NULL,
   `c2` int(11) /*!50120 STORAGE MEMORY */ DEFAULT NULL
) /*!50100 TABLESPACE ts_1 STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.02 sec)
```

When you add an `AUTO_INCREMENT` column, column values are filled in with sequence numbers automatically. For MyISAM tables, you can set the first sequence number by executing `SET INSERT_ID=value` before `ALTER TABLE` or by using the `AUTO_INCREMENT=value` table option.
With MyISAM tables, if you do not change the AUTO_INCREMENT column, the sequence number is not affected. If you drop an AUTO_INCREMENT column and then add another AUTO_INCREMENT column, the numbers are resequenced beginning with 1.

When replication is used, adding an AUTO_INCREMENT column to a table might not produce the same ordering of the rows on the replica and the source. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the source and replica, the rows must be ordered before assigning an AUTO_INCREMENT number. Assuming that you want to add an AUTO_INCREMENT column to the table t1, the following statements produce a new table t2 identical to t1 but with an AUTO_INCREMENT column:

```
CREATE TABLE t2 (id INT AUTO_INCREMENT PRIMARY KEY)
SELECT * FROM t1 ORDER BY col1, col2;
```

This assumes that the table t1 has columns col1 and col2.

This set of statements also produces a new table t2 identical to t1, with the addition of an AUTO_INCREMENT column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

**Important**

To guarantee the same ordering on both source and replica, all columns of t1 must be referenced in the ORDER BY clause.

Regardless of the method used to create and populate the copy having the AUTO_INCREMENT column, the final step is to drop the original table and then rename the copy:

```
DROP TABLE t1;
ALTER TABLE t2 RENAME t1;
```

**13.1.10 ALTER TABLESPACE Statement**

With MyISAM tables, if you do not change the AUTO_INCREMENT column, the sequence number is not affected. If you drop an AUTO_INCREMENT column and then add another AUTO_INCREMENT column, the numbers are resequenced beginning with 1.

When replication is used, adding an AUTO_INCREMENT column to a table might not produce the same ordering of the rows on the replica and the source. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the source and replica, the rows must be ordered before assigning an AUTO_INCREMENT number. Assuming that you want to add an AUTO_INCREMENT column to the table t1, the following statements produce a new table t2 identical to t1 but with an AUTO_INCREMENT column:

```
CREATE TABLE t2 (id INT AUTO_INCREMENT PRIMARY KEY)
SELECT * FROM t1 ORDER BY col1, col2;
```

This assumes that the table t1 has columns col1 and col2.

This set of statements also produces a new table t2 identical to t1, with the addition of an AUTO_INCREMENT column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

**Important**

To guarantee the same ordering on both source and replica, all columns of t1 must be referenced in the ORDER BY clause.

Regardless of the method used to create and populate the copy having the AUTO_INCREMENT column, the final step is to drop the original table and then rename the copy:

```
DROP TABLE t1;
ALTER TABLE t2 RENAME t1;
```

**13.1.10 ALTER TABLESPACE Statement**

ALTER [UNDO] TABLESPACE tablespace_name
    NDB only:
    {ADD | DROP} DATAFILE 'file_name'
    [INITIAL_SIZE [=] size]
    [WAIT]
    InnoDB and NDB:
    [RENAME TO tablespace_name]
    InnoDB only:
    [AUTOEXTEND_SIZE [=] 'value']
    [SET {ACTIVE | INACTIVE}]
    [ENCRYPTION [=] {'Y' | 'N'}]
    InnoDB and NDB:
    [ENGINE [=] engine_name]
    Reserved for future use:
    [ENGINE_ATTRIBUTE [=] 'string']

This statement is used with NDB and InnoDB tablespaces. It can be used to add a new data file to, or to drop a data file from an NDB tablespace. It can also be used to rename an NDB Cluster Disk Data tablespace, rename an InnoDB general tablespace, encrypt an InnoDB general tablespace, or mark an InnoDB undo tablespace as active or inactive.

The UNDO keyword is used with the SET {ACTIVE | INACTIVE} clause to mark an InnoDB undo tablespace as active or inactive. For more information, see Section 15.6.3.4, “Undo Tablespaces”.  

2644
The **ADD DATAFILE** variant enables you to specify an initial size for an **NDB** Disk Data tablespace using an **INITIAL_SIZE** clause, where **size** is measured in bytes; the default value is 134217728 (128 MB). You may optionally follow **size** with a one-letter abbreviation for an order of magnitude, similar to those used in **my.cnf**. Generally, this is one of the letters **M** (megabytes) or **G** (gigabytes).

On 32-bit systems, the maximum supported value for **INITIAL_SIZE** is 4294967296 (4 GB). (Bug #29186)

**INITIAL_SIZE** is rounded, explicitly, as for **CREATE TABLESPACE**.

Once a data file has been created, its size cannot be changed; however, you can add more data files to an NDB tablespace using additional **ALTER TABLESPACE ... ADD DATAFILE** statements.

When **ALTER TABLESPACE ... ADD DATAFILE** is used with **ENGINE = NDB**, a data file is created on each Cluster data node, but only one row is generated in the Information Schema **FILES** table. See the description of this table, as well as Section 23.6.11.1, “NDB Cluster Disk Data Objects”, for more information. **ADD DATAFILE** is not supported with **InnoDB** tablespaces.

Using **DROP DATAFILE** with **ALTER TABLESPACE** drops the data file ‘**file_name**’ from an NDB tablespace. You cannot drop a data file from a tablespace which is in use by any table; in other words, the data file must be empty (no extents used). See Section 23.6.11.1, “NDB Cluster Disk Data Objects”. In addition, any data file to be dropped must previously have been added to the tablespace with **CREATE TABLESPACE** or **ALTER TABLESPACE**. **DROP DATAFILE** is not supported with **InnoDB** tablespaces.

**WAIT** is parsed but otherwise ignored. It is intended for future expansion.

The **ENGINE** clause, which specifies the storage engine used by the tablespace, is deprecated; expect it to be removed in a future release. The tablespace storage engine is known by the data dictionary, making the **ENGINE** clause obsolete. If the storage engine is specified, it must match the tablespace storage engine defined in the data dictionary. The only values for **engine_name** compatible with **NDB** tablespaces are **NDB** and **NDBCLUSTER**.

**RENAME TO** operations are implicitly performed in **autocommit** mode, regardless of the **autocommit** setting.

A **RENAME TO** operation cannot be performed while **LOCK TABLES** or **FLUSH TABLES WITH READ LOCK** is in effect for tables that reside in the tablespace.

Exclusive **metadata locks** are taken on tables that reside in a general tablespace while the tablespace is renamed, which prevents concurrent DDL. Concurrent DML is supported.

The **CREATE TABLESPACE** privilege is required to rename an **InnoDB** general tablespace.

The **AUTOEXTEND_SIZE** option defines the amount by which **InnoDB** extends the size of a tablespace when it becomes full. The setting must be a multiple of 4MB. The default setting is 0, which causes the tablespace to be extended according to the implicit default behavior. For more information, see Section 15.6.3.9, “Tablespace AUTOEXTEND_SIZE Configuration”.

The **ENCRYPTION** clause enables or disables page-level data encryption for an **InnoDB** general tablespace or the **mysql** system tablespace.

A keyring plugin must be installed and configured before encryption can be enabled.

If the **table_encryption_privilege_check** variable is enabled, the **TABLE_ENCRYPTION_ADMIN** privilege is required to alter a general tablespace with an **ENCRYPTION** clause setting that differs from the **default_table_encryption** setting.
Enabling encryption for a general tablespace fails if any table in the tablespace belongs to a schema defined with `DEFAULT ENCRYPTION='N'`. Similarly, disabling encryption fails if any table in the general tablespace belongs to a schema defined with `DEFAULT ENCRYPTION='Y'`.

If an `ALTER TABLESPACE` statement executed on a general tablespace does not include an `ENCRYPTION` clause, the tablespace retains its current encryption status, regardless of the `default_table_encryption` setting.

When a general tablespace or the `mysql` system tablespace is encrypted, all tables residing in the tablespace are encrypted. Likewise, a table created in an encrypted tablespace is encrypted.

The `INPLACE` algorithm is used when altering the `ENCRYPTION` attribute of a general tablespace or the `mysql` system tablespace. The `INPLACE` algorithm permits concurrent DML on tables that reside in the tablespace. Concurrent DDL is blocked.

For more information, see Section 15.13, “InnoDB Data-at-Rest Encryption”.

The `ENGINE_ATTRIBUTE` option is used to specify tablespace attributes for primary storage engines. The option is reserved for future use.

Permitted values are a string literal containing a valid `JSON` document or an empty string (`""`). Invalid `JSON` is rejected.

```
ALTER TABLESPACE ts1 ENGINE_ATTRIBUTE='{"key":"value"}';
```

`ENGINE_ATTRIBUTE` values can be repeated without error. In this case, the last specified value is used.

`ENGINE_ATTRIBUTE` values are not checked by the server, nor are they cleared when the table's storage engine is changed.

It is not permitted to alter an individual element of a JSON attribute value. You can only add or replace an attribute.

### 13.1.11 ALTER VIEW Statement

```
ALTER
  [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]  
  [DEFINER = user]  
  [SQL SECURITY { DEFINER | INVOKER }]
VIEW view_name [(column_list)]
AS select_statement
  [WITH [CASCADED | LOCAL] CHECK OPTION]
```

This statement changes the definition of a view, which must exist. The syntax is similar to that for `CREATE VIEW` (see Section 13.1.23, “CREATE VIEW Statement”). This statement requires the `CREATE VIEW` and `DROP` privileges for the view, and some privilege for each column referred to in the `SELECT` statement. `ALTER VIEW` is permitted only to the definer or users with the `SET_USER_ID` privilege (or the deprecated `SUPER` privilege).

### 13.1.12 CREATE DATABASE Statement

```
CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
  [create_option] ... 
```

`create_option`: [DEFAULT]  
  | CHARACTER SET [=] charset_name  
  | COLLATE [=] collation_name  
  | ENCRYPTION [=] {'Y' | 'N'}

2646
CREATE DATABASE creates a database with the given name. To use this statement, you need the CREATE privilege for the database. CREATE SCHEMA is a synonym for CREATE DATABASE.

An error occurs if the database exists and you did not specify IF NOT EXISTS.

CREATE DATABASE is not permitted within a session that has an active LOCK TABLES statement.

Each create_option specifies a database characteristic. Database characteristics are stored in the data dictionary.

- The CHARACTER SET option specifies the default database character set. The COLLATE option specifies the default database collation. For information about character set and collation names, see Chapter 10, Character Sets, Collations, Unicode.

To see the available character sets and collations, use the the SHOW CHARACTER SET and SHOW COLLATION statements, respectively. See Section 13.7.7.4, “SHOW CHARACTER SET Statement”, and Section 13.7.7.5, “SHOW COLLATION Statement”.

- The ENCRYPTION option defines the default database encryption, which is inherited by tables created in the database. The permitted values are 'Y' (encryption enabled) and 'N' (encryption disabled). If the ENCRYPTION option is not specified, the value of the default_table_encryption system variable defines the default database encryption. If the table_encryption_privilege_check system variable is enabled, the TABLE_ENCRYPTION_ADMIN privilege is required to specify a default encryption setting that differs from the default_table_encryption setting. For more information, see Defining an Encryption Default for Schemas and General Tablespaces.

A database in MySQL is implemented as a directory containing files that correspond to tables in the database. Because there are no tables in a database when it is initially created, the CREATE DATABASE statement creates only a directory under the MySQL data directory. Rules for permissible database names are given in Section 9.2, “Schema Object Names”. If a database name contains special characters, the name for the database directory contains encoded versions of those characters as described in Section 9.2.4, “Mapping of Identifiers to File Names”.

Creating a database directory by manually creating a directory under the data directory (for example, with mkdir) is unsupported in MySQL 8.2.

When you create a database, let the server manage the directory and the files in it. Manipulating database directories and files directly can cause inconsistencies and unexpected results.

MySQL has no limit on the number of databases. The underlying file system may have a limit on the number of directories.

You can also use the mysqladmin program to create databases. See Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”.

### 13.1.13 CREATE EVENT Statement

```
CREATE [DEFINER = user] EVENT event_name ON SCHEDULE schedule
[ON COMPLETION [NOT] PRESERVE]
[ENABLE | DISABLE | DISABLE ON {REPLICA | SLAVE}]
[COMMENT ‘string’]
DO event_body;
```

schedule: {

CREATE EVENT Statement

This statement creates and schedules a new event. The event does not run unless the Event Scheduler is enabled. For information about checking Event Scheduler status and enabling it if necessary, see Section 25.4.2, “Event Scheduler Configuration”.

CREATE EVENT requires the EVENT privilege for the schema in which the event is to be created. If the DEFINER clause is present, the privileges required depend on the user value, as discussed in Section 25.6, “Stored Object Access Control”.

The minimum requirements for a valid CREATE EVENT statement are as follows:

- The keywords CREATE EVENT plus an event name, which uniquely identifies the event in a database schema.
- An ON SCHEDULE clause, which determines when and how often the event executes.
- A DO clause, which contains the SQL statement to be executed by an event.

This is an example of a minimal CREATE EVENT statement:

```sql
CREATE EVENT myevent
    ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
    DO
        UPDATE myschema.mytable SET mycol = mycol + 1;
```

The previous statement creates an event named myevent. This event executes once—one hour following its creation—by running an SQL statement that increments the value of the myschema.mytable table's mycol column by 1.

The event_name must be a valid MySQL identifier with a maximum length of 64 characters. Event names are not case-sensitive, so you cannot have two events named myevent and MyEvent in the same schema. In general, the rules governing event names are the same as those for names of stored routines. See Section 9.2, “Schema Object Names”.

An event is associated with a schema. If no schema is indicated as part of event_name, the default (current) schema is assumed. To create an event in a specific schema, qualify the event name with a schema using schema_name.event_name syntax.

The DEFINER clause specifies the MySQL account to be used when checking access privileges at event execution time. If the DEFINER clause is present, the user value should be a MySQL account specified as 'user_name'@'host_name', CURRENT_USER, or CURRENT_USER(). The permitted user values depend on the privileges you hold, as discussed in Section 25.6, “Stored Object Access Control”. Also see that section for additional information about event security.

If the DEFINER clause is omitted, the default definer is the user who executes the CREATE EVENT statement. This is the same as specifying DEFINER = CURRENT_USER explicitly.

Within an event body, the CURRENT_USER function returns the account used to check privileges at event execution time, which is the DEFINER user. For information about user auditing within events, see Section 6.2.23, “SQL-Based Account Activity Auditing”.

| interval: |
| quantity {YEAR | QUARTER | MONTH | DAY | HOUR | MINUTE | WEEK | SECOND | YEAR_MONTH | DAY_HOUR | DAY_MINUTE | DAY_SECOND | HOUR_MINUTE | HOUR_SECOND | MINUTE_SECOND} |
**CREATE EVENT Statement**

**IF NOT EXISTS** has the same meaning for **CREATE EVENT** as for **CREATE TABLE**: If an event named *event_name* already exists in the same schema, no action is taken, and no error results. (However, a warning is generated in such cases.)

The **ON SCHEDULE** clause determines when, how often, and for how long the *event_body* defined for the event repeats. This clause takes one of two forms:

- **AT timestamp** is used for a one-time event. It specifies that the event executes one time only at the date and time given by *timestamp*, which must include both the date and time, or must be an expression that resolves to a datetime value. You may use a value of either the **DATETIME** or **TIMESTAMP** type for this purpose. If the date is in the past, a warning occurs, as shown here:

  ```
  mysql> SELECT NOW();
  +---------------------+
  | NOW()               |
  +---------------------+
  | 2006-02-10 23:59:01 |
  +---------------------+
  1 row in set (0.04 sec)
  mysql>
  ```

  ```
  CREATE EVENT e_totals
  -> ON SCHEDULE AT '2006-02-10 23:59:00'
  -> DO INSERT INTO test.totals VALUES (NOW());
  Query OK, 0 rows affected, 1 warning (0.00 sec)
  mysql>
  SHOW WARNINGS\G
  *************************** 1. row ***************************
  Level: Note
  Code: 1588
  Message: Event execution time is in the past and ON COMPLETION NOT PRESERVE is set. The event was dropped immediately after creation.
  ```

**CREATE EVENT** statements which are themselves invalid—for whatever reason—fail with an error.

You may use **CURRENT_TIMESTAMP** to specify the current date and time. In such a case, the event acts as soon as it is created.

To create an event which occurs at some point in the future relative to the current date and time—such as that expressed by the phrase “three weeks from now”—you can use the optional clause **+ INTERVAL interval**. The *interval* portion consists of two parts, a quantity and a unit of time, and follows the syntax rules described in **Temporal Intervals**, except that you cannot use any units keywords that involving microseconds when defining an event. With some interval types, complex time units may be used. For example, “two minutes and ten seconds” can be expressed as **+ INTERVAL '2:10' MINUTE_SECOND**.

You can also combine intervals. For example, **AT CURRENT_TIMESTAMP + INTERVAL 3 WEEK + INTERVAL 2 DAY** is equivalent to “three weeks and two days from now”. Each portion of such a clause must begin with **+ INTERVAL**.

- To repeat actions at a regular interval, use an **EVERY** clause. The **EVERY** keyword is followed by an *interval* as described in the previous discussion of the **AT** keyword. (**+ INTERVAL** is **not** used with **EVERY**.) For example, **EVERY 6 WEEK** means “every six weeks”.

  Although **+ INTERVAL** clauses are not permitted in an **EVERY** clause, you can use the same complex time units permitted in a **+ INTERVAL**.

  An **EVERY** clause may contain an optional **STARTS** clause. **STARTS** is followed by a **timestamp** value that indicates when the action should begin repeating, and may also use **+ INTERVAL interval** to specify an amount of time “from now”. For example, **EVERY 3 MONTH STARTS CURRENT_TIMESTAMP**
CREATE EVENT Statement

+ INTERVAL 1 WEEK means “every three months, beginning one week from now”. Similarly, you can express “every two weeks, beginning six hours and fifteen minutes from now” as EVERY 2 WEEK STARTS CURRENT_TIMESTAMP + INTERVAL '6:15' HOUR_MINUTE. Not specifying STARTS is the same as using STARTS CURRENT_TIMESTAMP—that is, the action specified for the event begins repeating immediately upon creation of the event.

An EVERY clause may contain an optional ENDS clause. The ENDS keyword is followed by a timestamp value that tells MySQL when the event should stop repeating. You may also use + INTERVAL interval with ENDS; for instance, EVERY 12 HOUR STARTS CURRENT_TIMESTAMP + INTERVAL 30 MINUTE ENDS CURRENT_TIMESTAMP + INTERVAL 4 WEEK is equivalent to “every twelve hours, beginning thirty minutes from now, and ending four weeks from now”. Not using ENDS means that the event continues executing indefinitely.

ENDS supports the same syntax for complex time units as STARTS does.

You may use STARTS, ENDS, both, or neither in an EVERY clause.

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the GET_LOCK() function, or row or table locking.

The ON SCHEDULE clause may use expressions involving built-in MySQL functions and user variables to obtain any of the timestamp or interval values which it contains. You may not use stored functions or loadable functions in such expressions, nor may you use SELECT FROM DUAL. This is true for both CREATE EVENT and ALTER EVENT statements. References to stored functions, loadable functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Times in the ON SCHEDULE clause are interpreted using the current session time_zone value. This becomes the event time zone; that is, the time zone that is used for event scheduling and is in effect within the event as it executes. These times are converted to UTC and stored along with the event time zone internally. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. For additional information about representation of event times, see Section 25.4.4, “Event Metadata”. See also Section 13.7.7.19, “SHOW EVENTS Statement”, and Section 26.3.14, “The INFORMATION_SCHEMA EVENTS Table”.

Normally, once an event has expired, it is immediately dropped. You can override this behavior by specifying ON COMPLETION PRESERVE. Using ON COMPLETION NOT PRESERVE merely makes the default nonpersistent behavior explicit.

You can create an event but prevent it from being active using the DISABLE keyword. Alternatively, you can use ENABLE to make explicit the default status, which is active. This is most useful in conjunction with ALTER EVENT (see Section 13.1.3, “ALTER EVENT Statement”).

A third value may also appear in place of ENABLE or DISABLE; DISABLE ON REPLICA is set for the status of an event on a replica to indicate that the event was created on the replication source server and replicated to the replica, but is not executed on the replica. See Section 17.5.1.16, “Replication of Invoked Features”.

DISABLE ON REPLICA replaces DISABLE ON SLAVE, which is deprecated as of MySQL 8.2.0.

You may supply a comment for an event using a COMMENT clause. comment may be any string of up to 64 characters that you wish to use for describing the event. The comment text, being a string literal, must be surrounded by quotation marks.

The DO clause specifies an action carried by the event, and consists of an SQL statement. Nearly any valid MySQL statement that can be used in a stored routine can also be used as the action statement for
a scheduled event. (See Section 25.8, “Restrictions on Stored Programs”.) For example, the following event `e_hourly` deletes all rows from the `sessions` table once per hour, where this table is part of the `site_activity` schema:

```
CREATE EVENT e_hourly
ON SCHEDULE
EVERY 1 HOUR
COMMENT 'Clears out sessions table each hour.'
DO
DELETE FROM site_activity.sessions;
```

MySQL stores the `sql_mode` system variable setting in effect when an event is created or altered, and always executes the event with this setting in force, regardless of the current server SQL mode when the event begins executing.

A `CREATE EVENT` statement that contains an `ALTER EVENT` statement in its `DO` clause appears to succeed; however, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

**Note**

Statements such as `SELECT` or `SHOW` that merely return a result set have no effect when used in an event; the output from these is not sent to the MySQL Monitor, nor is it stored anywhere. However, you can use statements such as `SELECT ... INTO` and `INSERT INTO ... SELECT` that store a result. (See the next example in this section for an instance of the latter.)

The schema to which an event belongs is the default schema for table references in the `DO` clause. Any references to tables in other schemas must be qualified with the proper schema name.

As with stored routines, you can use compound-statement syntax in the `DO` clause by using the `BEGIN` and `END` keywords, as shown here:

```
delimiter |
CREATE EVENT e_daily
ON SCHEDULE
EVERY 1 DAY
COMMENT 'Saves total number of sessions then clears the table each day'
DO
BEGIN
    INSERT INTO site_activity.totals (time, total)
    SELECT CURRENT_TIMESTAMP, COUNT(*)
    FROM site_activity.sessions;
    DELETE FROM site_activity.sessions;
END |
delimiter ;
```

This example uses the `delimiter` command to change the statement delimiter. See Section 25.1, “Defining Stored Programs”.

More complex compound statements, such as those used in stored routines, are possible in an event. This example uses local variables, an error handler, and a flow control construct:

```
delimiter |
CREATE EVENT e
ON SCHEDULE
EVERY 5 SECOND
DO
BEGIN
```
CREATE FUNCTION Statement

```
DECLARE v INTEGER;
DECLARE CONTINUE HANDLER FOR SQLEXCEPTION BEGIN END;
SET v = 0;
WHILE v < 5 DO
    INSERT INTO t1 VALUES (0);
    UPDATE t2 SET s1 = s1 + 1;
    SET v = v + 1;
END WHILE;
END |
delimiter ;
```

There is no way to pass parameters directly to or from events; however, it is possible to invoke a stored routine with parameters within an event:

```
CREATE EVENT e_call_myproc
    ON SCHEDULE
        AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
    DO CALL myproc(5, 27);
```

If an event’s definer has privileges sufficient to set global system variables (see Section 5.1.9.1, “System Variable Privileges”), the event can read and write global variables. As granting such privileges entails a potential for abuse, extreme care must be taken in doing so.

Generally, any statements that are valid in stored routines may be used for action statements executed by events. For more information about statements permissible within stored routines, see Section 25.2.1, “Stored Routine Syntax”. It is not possible to create an event as part of a stored routine or to create an event by another event.

13.1.14 CREATE FUNCTION Statement

The `CREATE FUNCTION` statement is used to create stored functions and loadable functions:

- For information about creating stored functions, see Section 13.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”.
- For information about creating loadable functions, see Section 13.7.4.1, “CREATE FUNCTION Statement for Loadable Functions”.

13.1.15 CREATE INDEX Statement

```
CREATE [UNIQUE | FULLTEXT | SPATIAL] INDEX index_name
    [index_type]
    ON tbl_name (key_part,...)
    [index_option]
    [algorithm_option | lock_option] ...

key_part: {col_name [{length}] | (expr)} [ASC | DESC]

index_option: |
    KEY_BLOCK_SIZE [=] value
    index_type
    WITH PARSER parser_name
    COMMENT 'string'
    {VISIBLE | INVISIBLE}
    ENGINE_ATTRIBUTE [=] 'string'
    | SECONDARY_ENGINE_ATTRIBUTE [=] 'string'

index_type:
    USING {BTREE | HASH}
```
CREATE INDEX Statement

algorithm_option:
   ALGORITHM [=] {DEFAULT | INPLACE | COPY}

lock_option:
   LOCK [=] {DEFAULT | NONE | SHARED | EXCLUSIVE}

Normally, you create all indexes on a table at the time the table itself is created with CREATE TABLE. See Section 13.1.20, “CREATE TABLE Statement”. This guideline is especially important for InnoDB tables, where the primary key determines the physical layout of rows in the data file. CREATE INDEX enables you to add indexes to existing tables.

CREATE INDEX is mapped to an ALTER TABLE statement to create indexes. See Section 13.1.9, “ALTER TABLE Statement”. CREATE INDEX cannot be used to create a PRIMARY KEY; use ALTER TABLE instead. For more information about indexes, see Section 8.3.1, “How MySQL Uses Indexes”.

InnoDB supports secondary indexes on virtual columns. For more information, see Section 13.1.20.9, “Secondary Indexes and Generated Columns”.

When the innodb_stats_persistent setting is enabled, run the ANALYZE TABLE statement for an InnoDB table after creating an index on that table.

The expr for a key_part specification can also take the form (CAST json_expression AS type ARRAY) to create a multi-valued index on a JSON column. See Multi-Valued Indexes.

An index specification of the form (key_part1, key_part2, ...) creates an index with multiple key parts. Index key values are formed by concatenating the values of the given key parts. For example (col1, col2, col3) specifies a multiple-column index with index keys consisting of values from col1, col2, and col3.

A key_part specification can end with ASC or DESC to specify whether index values are stored in ascending or descending order. The default is ascending if no order specifier is given.

ASC and DESC are not supported for HASH indexes, multi-valued indexes or SPATIAL indexes.

The following sections describe different aspects of the CREATE INDEX statement:

• Column Prefix Key Parts
• Functional Key Parts
• Unique Indexes
• Full-Text Indexes
• Multi-Valued Indexes
• Spatial Indexes
• Index Options
• Table Copying and Locking Options

Column Prefix Key Parts

For string columns, indexes can be created that use only the leading part of column values, using col_name(length) syntax to specify an index prefix length:

• Prefixes can be specified for CHAR, VARCHAR, BINARY, and VARBINARY key parts.
CREATE INDEX Statement

• Prefixes must be specified for BLOB and TEXT key parts. Additionally, BLOB and TEXT columns can be indexed only for InnoDB, MyISAM, and BLACKHOLE tables.

• Prefix limits are measured in bytes. However, prefix lengths for index specifications in CREATE TABLE, ALTER TABLE, and CREATE INDEX statements are interpreted as number of characters for nonbinary string types (CHAR, VARCHAR, TEXT) and number of bytes for binary string types (BINARY, VARBINARY, BLOB). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

Prefix support and lengths of prefixes (where supported) are storage engine dependent. For example, a prefix can be up to 767 bytes long for InnoDB tables that use the REDUNDANT or COMPACT row format. The prefix length limit is 3072 bytes for InnoDB tables that use the DYNAMIC or COMPRESSED row format. For MyISAM tables, the prefix length limit is 1000 bytes. The NDB storage engine does not support prefixes (see Section 23.2.7.6, “Unsupported or Missing Features in NDB Cluster”).

If a specified index prefix exceeds the maximum column data type size, CREATE INDEX handles the index as follows:

• For a nonunique index, either an error occurs (if strict SQL mode is enabled), or the index length is reduced to lie within the maximum column data type size and a warning is produced (if strict SQL mode is not enabled).

• For a unique index, an error occurs regardless of SQL mode because reducing the index length might enable insertion of nonunique entries that do not meet the specified uniqueness requirement.

The statement shown here creates an index using the first 10 characters of the name column (assuming that name has a nonbinary string type):

```
CREATE INDEX part_of_name ON customer (name(10));
```

If names in the column usually differ in the first 10 characters, lookups performed using this index should not be much slower than using an index created from the entire name column. Also, using column prefixes for indexes can make the index file much smaller, which could save a lot of disk space and might also speed up INSERT operations.

Functional Key Parts

A “normal” index indexes column values or prefixes of column values. For example, in the following table, the index entry for a given t1 row includes the full col1 value and a prefix of the col2 value consisting of its first 10 characters:

```
CREATE TABLE t1 (  
    col1 VARCHAR(10),  
    col2 VARCHAR(20),  
    INDEX (col1, col2(10))  
);  
```

Functional key parts that index expression values can also be used in place of column or column prefix values. Use of functional key parts enables indexing of values not stored directly in the table. Examples:

```
CREATE TABLE t1 (col1 INT, col2 INT, INDEX func_index ((ABS(col1))));
CREATE INDEX idx1 ON t1 ((col1 + col2));
CREATE INDEX idx2 ON t1 ((col1 + col2), (col1 - col2), col1);
ALTER TABLE t1 ADD INDEX ((col1 * 40) DESC);
```

An index with multiple key parts can mix nonfunctional and functional key parts.

ASC and DESC are supported for functional key parts.
CREATE INDEX Statement

Functional key parts must adhere to the following rules. An error occurs if a key part definition contains disallowed constructs.

- In index definitions, enclose expressions within parentheses to distinguish them from columns or column prefixes. For example, this is permitted; the expressions are enclosed within parentheses:

  ```sql
  INDEX ((col1 + col2), (col3 - col4))
  ```

  This produces an error; the expressions are not enclosed within parentheses:

  ```sql
  INDEX (col1 + col2, col3 - col4)
  ```

- A functional key part cannot consist solely of a column name. For example, this is not permitted:

  ```sql
  INDEX ((col1), (col2))
  ```

  Instead, write the key parts as nonfunctional key parts, without parentheses:

  ```sql
  INDEX (col1, col2)
  ```

- A functional key part expression cannot refer to column prefixes. For a workaround, see the discussion of `SUBSTRING()` and `CAST()` later in this section.

- Functional key parts are not permitted in foreign key specifications.

For `CREATE TABLE ... LIKE`, the destination table preserves functional key parts from the original table.

Functional indexes are implemented as hidden virtual generated columns, which has these implications:

- Each functional key part counts against the limit on total number of table columns; see Section 8.4.7, “Limits on Table Column Count and Row Size”.

- Functional key parts inherit all restrictions that apply to generated columns. Examples:
  - Only functions permitted for generated columns are permitted for functional key parts.
  - Subqueries, parameters, variables, stored functions, and loadable functions are not permitted.

For more information about applicable restrictions, see Section 13.1.20.8, “CREATE TABLE and Generated Columns”, and Section 13.1.9.2, “ALTER TABLE and Generated Columns”.

- The virtual generated column itself requires no storage. The index itself takes up storage space as any other index.

`UNIQUE` is supported for indexes that include functional key parts. However, primary keys cannot include functional key parts. A primary key requires the generated column to be stored, but functional key parts are implemented as virtual generated columns, not stored generated columns.

`SPATIAL` and `FULLTEXT` indexes cannot have functional key parts.

If a table contains no primary key, InnoDB automatically promotes the first `UNIQUE NOT NULL` index to the primary key. This is not supported for `UNIQUE NOT NULL` indexes that have functional key parts.

Nonfunctional indexes raise a warning if there are duplicate indexes. Indexes that contain functional key parts do not have this feature.

To remove a column that is referenced by a functional key part, the index must be removed first. Otherwise, an error occurs.
Although nonfunctional key parts support a prefix length specification, this is not possible for functional key parts. The solution is to use `SUBSTRING()` (or `CAST()`, as described later in this section). For a functional key part containing the `SUBSTRING()` function to be used in a query, the `WHERE` clause must contain `SUBSTRING()` with the same arguments. In the following example, only the second `SELECT` is able to use the index because that is the only query in which the arguments to `SUBSTRING()` match the index specification:

```sql
CREATE TABLE tbl (
  col1 LONGTEXT,
  INDEX idx1 ((SUBSTRING(col1, 1, 10)))
);
SELECT * FROM tbl WHERE SUBSTRING(col1, 1, 9) = '123456789';
SELECT * FROM tbl WHERE SUBSTRING(col1, 1, 10) = '1234567890';
```

Functional key parts enable indexing of values that cannot be indexed otherwise, such as `JSON` values. However, this must be done correctly to achieve the desired effect. For example, this syntax does not work:

```sql
CREATE TABLE employees (
  data JSON,
  INDEX ((data->>'$.name'))
);
```

The syntax fails because:

- The `->>` operator translates into `JSON_UNQUOTE(JSON_EXTRACT(...))`.
- `JSON_UNQUOTE()` returns a value with a data type of `LONGTEXT`, and the hidden generated column thus is assigned the same data type.
- MySQL cannot index `LONGTEXT` columns specified without a prefix length on the key part, and prefix lengths are not permitted in functional key parts.

To index the `JSON` column, you could try using the `CAST()` function as follows:

```sql
CREATE TABLE employees (
  data JSON,
  INDEX ((CAST(data->>'$.name' AS CHAR(30))))
);
```

The hidden generated column is assigned the `VARCHAR(30)` data type, which can be indexed. But this approach produces a new issue when trying to use the index:

- `CAST()` returns a string with the collation `utf8mb4_0900_ai_ci` (the server default collation).
- `JSON_UNQUOTE()` returns a string with the collation `utf8mb4_bin` (hard coded).

As a result, there is a collation mismatch between the indexed expression in the preceding table definition and the `WHERE` clause expression in the following query:

```sql
SELECT * FROM employees WHERE data->>'$.name' = 'James';
```

The index is not used because the expressions in the query and the index differ. To support this kind of scenario for functional key parts, the optimizer automatically strips `CAST()` when looking for an index to use, but only if the collation of the indexed expression matches that of the query expression. For an index with a functional key part to be used, either of the following two solutions work (although they differ somewhat in effect):

- Solution 1. Assign the indexed expression the same collation as `JSON_UNQUOTE()`:
CREATE INDEX Statement

```
data JSON,
INDEX idx ((CAST(data->>"$.name" AS CHAR(30)) COLLATE utf8mb4_bin))
);
```

```
INSERT INTO employees VALUES
('{ "name": "james", "salary": 9000 }'),
('{ "name": "James", "salary": 10000 }'),
('{ "name": "Mary", "salary": 12000 }'),
('{ "name": "Peter", "salary": 8000 }');
```

```
SELECT * FROM employees WHERE data->>'$.name' = 'James';
```

The `->>` operator is the same as `JSON_UNQUOTE(JSON_EXTRACT(...))`, and `JSON_UNQUOTE()` returns a string with collation `utf8mb4_bin`. The comparison is thus case-sensitive, and only one row matches:

```
+------------------------------------+
| data                               |
+------------------------------------+
| {"name": "James", "salary": 10000} |
+------------------------------------+
```

• Solution 2. Specify the full expression in the query:

```
CREATE TABLE employees (  
data JSON,
INDEX idx ((CAST(data->>'$.name' AS CHAR(30))))  
);
```

```
INSERT INTO employees VALUES
('{ "name": "james", "salary": 9000 }'),
('{ "name": "James", "salary": 10000 }'),
('{ "name": "Mary", "salary": 12000 }'),
('{ "name": "Peter", "salary": 8000 }');
```

```
SELECT * FROM employees WHERE CAST(data->>'$.name' AS CHAR(30)) = 'James';
```

CAST() returns a string with collation `utf8mb4_0900_ai_ci`, so the comparison case-insensitive and two rows match:

```
+------------------------------------+
| data                               |
+------------------------------------+
| {"name": "james", "salary": 9000} |
| {"name": "James", "salary": 10000} |
+------------------------------------+
```

Be aware that although the optimizer supports automatically stripping CAST() with indexed generated columns, the following approach does not work because it produces a different result with and without an index (Bug#27337092):

```
mysql> CREATE TABLE employees (  
data JSON,  
    generated_col VARCHAR(30) AS (CAST(data->>'$.name' AS CHAR(30)))  
);  
Query OK, 0 rows affected, 1 warning (0.03 sec)
```

```
mysql> INSERT INTO employees (data)  
VALUES ('{"name": "james"}'), ('{"name": "James"}');  
Query OK, 2 rows affected, 1 warning (0.01 sec)  
Records: 2  Duplicates: 0  Warnings: 1
```

```
mysql> SELECT * FROM employees WHERE data->>'$.name' = 'James';  
+-------------------+---------------+  
<table>
<thead>
<tr>
<th>data</th>
<th>generated_col</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;name&quot;: &quot;James&quot;}</td>
<td>James</td>
</tr>
</tbody>
</table>
+-------------------+---------------+  
1 row in set (0.00 sec)
```
CREATE INDEX Statement

```
mysql> ALTER TABLE employees ADD INDEX idx (generated_col);
Query OK, 0 rows affected, 1 warning (0.03 sec)
Records: 0  Duplicates: 0  Warnings: 1

mysql> SELECT * FROM employees WHERE data->>'$.name' = 'James';
+-------------------+---------------+
| data              | generated_col |
| "name": "james"  | james         |
| "name": "James"  | James         |
+-------------------+---------------+
2 rows in set (0.01 sec)
```

Unique Indexes

A **UNIQUE** index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. If you specify a prefix value for a column in a **UNIQUE** index, the column values must be unique within the prefix length. A **UNIQUE** index permits multiple **NULL** values for columns that can contain **NULL**.

If a table has a **PRIMARY KEY** or **UNIQUE NOT NULL** index that consists of a single column that has an integer type, you can use **_rowid** to refer to the indexed column in **SELECT** statements, as follows:

- **_rowid** refers to the **PRIMARY KEY** column if there is a **PRIMARY KEY** consisting of a single integer column. If there is a **PRIMARY KEY** but it does not consist of a single integer column, **_rowid** cannot be used.
- Otherwise, **_rowid** refers to the column in the first **UNIQUE NOT NULL** index if that index consists of a single integer column. If the first **UNIQUE NOT NULL** index does not consist of a single integer column, **_rowid** cannot be used.

Full-Text Indexes

**FULLTEXT** indexes are supported only for **InnoDB** and **MyISAM** tables and can include only **CHAR**, **VARCHAR**, and **TEXT** columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See Section 12.9, “Full-Text Search Functions”, for details of operation.

Multi-Valued Indexes

**InnoDB** supports multi-valued indexes. A multi-valued index is a secondary index defined on a column that stores an array of values. A “normal” index has one index record for each data record (1:1). A multi-valued index can have multiple index records for a single data record (N:1). Multi-valued indexes are intended for indexing **JSON** arrays. For example, a multi-valued index defined on the array of zip codes in the following **JSON** document creates an index record for each zip code, with each index record referencing the same data record.

```
{
    "user":"Bob",
    "user_id":31,
    "zipcode":[94477,94536]
}
```

Creating multi-valued Indexes

You can create a multi-valued index in a **CREATE TABLE**, **ALTER TABLE**, or **CREATE INDEX** statement. This requires using **CAST(... AS ... ARRAY)** in the index definition, which casts same-typed scalar values in a **JSON** array to an SQL data type array. A virtual column is then generated transparently with the values in the SQL data type array; finally, a functional index (also referred to as a virtual index) is created.
CREATE INDEX Statement

on the virtual column. It is the functional index defined on the virtual column of values from the SQL data
type array that forms the multi-valued index.

The examples in the following list show the three different ways in which a multi-valued index zips can
be created on an array $.zipcode on a JSON column custinfo in a table named customers. In each
case, the JSON array is cast to an SQL data type array of UNSIGNED integer values.

- **CREATE TABLE only:**

```sql
CREATE TABLE customers {
    id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    modified DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    custinfo JSON,
    INDEX zips( (CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY)) )
};
```

- **CREATE TABLE plus ALTER TABLE:**

```sql
CREATE TABLE customers {
    id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    modified DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    custinfo JSON
};
ALTER TABLE customers ADD INDEX zips( (CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY)) );
```

- **CREATE TABLE plus CREATE INDEX:**

```sql
CREATE TABLE customers {
    id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    modified DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    custinfo JSON
};
CREATE INDEX zips ON customers ( (CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY)) );
```

A multi-valued index can also be defined as part of a composite index. This example shows a composite
index that includes two single-valued parts (for the id and modified columns), and one multi-valued part
(for the custinfo column):

```sql
CREATE TABLE customers {
    id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    modified DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    custinfo JSON
};
ALTER TABLE customers ADD INDEX comp(id, modified,
    (CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY)) );
```

Only one multi-valued key part can be used in a composite index. The multi-valued key part may be
used in any order relative to the other parts of the key. In other words, the ALTER TABLE statement just
shown could have used `comp(id, (CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY),
modified))` (or any other ordering) and still have been valid.

**Using multi-valued Indexes**

The optimizer uses a multi-valued index to fetch records when the following functions are specified in a
WHERE clause:

- **MEMBER OF()**
- **JSON_CONTAINS()**
CREATE INDEX Statement

• JSON_OVERLAPS()
We can demonstrate this by creating and populating the customers table using the following CREATE
TABLE and INSERT statements:
mysql> CREATE TABLE customers (
->
id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->
modified DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
->
custinfo JSON
->
);
Query OK, 0 rows affected (0.51 sec)
mysql> INSERT INTO customers VALUES
->
(NULL, NOW(), '{"user":"Jack","user_id":37,"zipcode":[94582,94536]}'),
->
(NULL, NOW(), '{"user":"Jill","user_id":22,"zipcode":[94568,94507,94582]}'),
->
(NULL, NOW(), '{"user":"Bob","user_id":31,"zipcode":[94477,94507]}'),
->
(NULL, NOW(), '{"user":"Mary","user_id":72,"zipcode":[94536]}'),
->
(NULL, NOW(), '{"user":"Ted","user_id":56,"zipcode":[94507,94582]}');
Query OK, 5 rows affected (0.07 sec)
Records: 5 Duplicates: 0 Warnings: 0

First we execute three queries on the customers table, one each using MEMBER OF(),
JSON_CONTAINS(), and JSON_OVERLAPS(), with the result from each query shown here:
mysql> SELECT * FROM customers
->
WHERE 94507 MEMBER OF(custinfo->'$.zipcode');
+----+---------------------+-------------------------------------------------------------------+
| id | modified
| custinfo
|
+----+---------------------+-------------------------------------------------------------------+
| 2 | 2019-06-29 22:23:12 | {"user": "Jill", "user_id": 22, "zipcode": [94568, 94507, 94582]} |
| 3 | 2019-06-29 22:23:12 | {"user": "Bob", "user_id": 31, "zipcode": [94477, 94507]}
|
|
+----+---------------------+-------------------------------------------------------------------+
3 rows in set (0.00 sec)
mysql> SELECT * FROM customers
->
WHERE JSON_CONTAINS(custinfo->'$.zipcode', CAST('[94507,94582]' AS JSON));
+----+---------------------+-------------------------------------------------------------------+
| id | modified
| custinfo
|
+----+---------------------+-------------------------------------------------------------------+
| 2 | 2019-06-29 22:23:12 | {"user": "Jill", "user_id": 22, "zipcode": [94568, 94507, 94582]} |
|
+----+---------------------+-------------------------------------------------------------------+
2 rows in set (0.00 sec)
mysql> SELECT * FROM customers
->
WHERE JSON_OVERLAPS(custinfo->'$.zipcode', CAST('[94507,94582]' AS JSON));
+----+---------------------+-------------------------------------------------------------------+
| id | modified
| custinfo
|
+----+---------------------+-------------------------------------------------------------------+
| 1 | 2019-06-29 22:23:12 | {"user": "Jack", "user_id": 37, "zipcode": [94582, 94536]}
|
| 2 | 2019-06-29 22:23:12 | {"user": "Jill", "user_id": 22, "zipcode": [94568, 94507, 94582]} |
| 3 | 2019-06-29 22:23:12 | {"user": "Bob", "user_id": 31, "zipcode": [94477, 94507]}
|
|
+----+---------------------+-------------------------------------------------------------------+
4 rows in set (0.00 sec)

Next, we run EXPLAIN on each of the previous three queries:

mysql> EXPLAIN SELECT * FROM customers
->
WHERE 94507 MEMBER OF(custinfo->'$.zipcode');
+----+-------------+-----------+------------+------+---------------+------+---------+------+------+----------+
| id | select_type | table
| partitions | type | possible_keys | key | key_len | ref | rows | filtered |
+----+-------------+-----------+------------+------+---------------+------+---------+------+------+----------+
| 1 | SIMPLE
| customers | NULL
| ALL | NULL
| NULL | NULL
| NULL |
5 |
100.00 |
+----+-------------+-----------+------------+------+---------------+------+---------+------+------+----------+

2660


CREATE INDEX Statement

None of the three queries just shown are able to use any keys. To solve this problem, we can add a multi-valued index on the \texttt{zipcode} array in the JSON column (\texttt{custinfo}), like this:

```
mysql> \texttt{ALTER TABLE customers}
-> ADD INDEX \texttt{zips( (CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY)) )};
```

When we run the previous \texttt{EXPLAIN} statements again, we can now observe that the queries can (and do) use the index \texttt{zips} that was just created:

```
mysql> \texttt{EXPLAIN SELECT * FROM customers}
-> WHERE 94507 MEMBER OF(custinfo->'$.zipcode');
```

```
<table>
<thead>
<tr>
<th>id</th>
<th>select_type</th>
<th>table</th>
<th>partitions</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>
<th>rows</th>
<th>filtered</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SIMPLE</td>
<td>customers</td>
<td>NULL</td>
<td>ref</td>
<td>zips</td>
<td>zips</td>
<td>9</td>
<td>const</td>
<td>1</td>
<td>100.00</td>
<td>Using where</td>
</tr>
</tbody>
</table>
```

```
mysql> \texttt{EXPLAIN SELECT * FROM customers}
-> WHERE JSON_CONTAINS(custinfo->'$.zipcode', CAST('[94507,94582]' AS JSON));
```

```
<table>
<thead>
<tr>
<th>id</th>
<th>select_type</th>
<th>table</th>
<th>partitions</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>
<th>rows</th>
<th>filtered</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SIMPLE</td>
<td>customers</td>
<td>NULL</td>
<td>range</td>
<td>zips</td>
<td>zips</td>
<td>9</td>
<td>NULL</td>
<td>6</td>
<td>100.00</td>
<td>Using where</td>
</tr>
</tbody>
</table>
```

```
mysql> \texttt{EXPLAIN SELECT * FROM customers}
-> WHERE JSON_OVERLAPS(custinfo->'$.zipcode', CAST('[94507,94582]' AS JSON));
```

```
<table>
<thead>
<tr>
<th>id</th>
<th>select_type</th>
<th>table</th>
<th>partitions</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>

<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SIMPLE</td>
<td>customers</td>
<td>NULL</td>
<td>range</td>
<td>zips</td>
<td>zips</td>
<td>9</td>
<td>NULL</td>
<td>6</td>
<td>100.00</td>
<td>Using where</td>
</tr>
</tbody>
</table>
```

A multi-valued index can be defined as a unique key. If defined as a unique key, attempting to insert a value already present in the multi-valued index returns a duplicate key error. If duplicate values are already present, attempting to add a unique multi-valued index fails, as shown here:

```
mysql> \texttt{ALTER TABLE customers DROP INDEX zips;}
```

Query OK, 0 rows affected (0.55 sec)
Records: 0 Duplicates: 0 Warnings: 0
CREATE INDEX Statement

mysql> ALTER TABLE customers
    -> ADD UNIQUE INDEX zips((CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY)));
ERROR 1062 (23000): Duplicate entry '94507' for key 'customers.zips'
mysql> ALTER TABLE customers
    -> ADD INDEX zips((CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY)));
Query OK, 0 rows affected (0.36 sec)
Records: 0  Duplicates: 0  Warnings: 0

Characteristics of Multi-Valued Indexes

Multi-valued indexes have the additional characteristics listed here:

- DML operations that affect multi-valued indexes are handled in the same way as DML operations that
  affect a normal index, with the only difference being that there may be more than one insert or update for
  a single clustered index record.

- Nullability and multi-valued indexes:
  - If a multi-valued key part has an empty array, no entries are added to the index, and the data record is
    not accessible by an index scan.
  - If multi-valued key part generation returns a **NULL** value, a single entry containing **NULL** is added to
    the multi-valued index. If the key part is defined as **NOT NULL**, an error is reported.
  - If the typed array column is set to **NULL**, the storage engine stores a single record containing **NULL**
    that points to the data record.
  - **JSON** null values are not permitted in indexed arrays. If any returned value is **NULL**, it is treated as a
    **JSON** null and an **Invalid JSON value** error is reported.

- Because multi-valued indexes are virtual indexes on virtual columns, they must adhere to the same rules
  as secondary indexes on virtual generated columns.

- Index records are not added for empty arrays.

Limitations and Restrictions on Multi-valued Indexes

Multi-valued indexes are subject to the limitations and restrictions listed here:

- Only one multi-valued key part is permitted per multi-valued index. However, the **CAST(... AS ... ARRAY)**
  expression can refer to multiple arrays within a **JSON** document, as shown here:

```
CAST(data->'$.arr[*][*]' AS UNSIGNED ARRAY)
```

In this case, all values matching the **JSON** expression are stored in the index as a single flat array.

- An index with a multi-valued key part does not support ordering and therefore cannot be used as a
  primary key. For the same reason, a multi-valued index cannot be defined using the **ASC** or **DESC**
  keyword.

- A multi-valued index cannot be a covering index.

- The maximum number of values per record for a multi-valued index is determined by the amount of data
  than can be stored on a single undo log page, which is 65221 bytes (64K minus 315 bytes for overhead),
  which means that the maximum total length of key values is also 65221 bytes. The maximum number
  of keys depends on various factors, which prevents defining a specific limit. Tests have shown a multi-
  valued index to permit as many as 1604 integer keys per record, for example. When the limit is reached,
  an error similar to the following is reported: **ERROR 3905 (HY000): Exceeded max number of values
  per record for multi-valued index 'idx' by 1 value(s).**
• The only type of expression that is permitted in a multi-valued key part is a JSON expression. The expression need not reference an existing element in a JSON document inserted into the indexed column, but must itself be syntactically valid.

• Because index records for the same clustered index record are dispersed throughout a multi-valued index, a multi-valued index does not support range scans or index-only scans.

• Multi-valued indexes are not permitted in foreign key specifications.

• Index prefixes cannot be defined for multi-valued indexes.

• Multi-valued indexes cannot be defined on data cast as BINARY (see the description of the CAST() function).

• Online creation of a multi-value index is not supported, which means the operation uses ALGORITHM=COPY. See Performance and Space Requirements.

• Character sets and collations other than the following two combinations of character set and collation are not supported for multi-valued indexes:

  1. The binary character set with the default binary collation
  2. The utf8mb4 character set with the default utf8mb4_0900_as_cs collation.

• As with other indexes on columns of InnoDB tables, a multi-valued index cannot be created with USING HASH; attempting to do so results in a warning: This storage engine does not support the HASH index algorithm, storage engine default was used instead. (USING BTREE is supported as usual.)

Spatial Indexes

The MyISAM, InnoDB, NDB, and ARCHIVE storage engines support spatial columns such as POINT and GEOMETRY. (Section 11.4, “Spatial Data Types”, describes the spatial data types.) However, support for spatial column indexing varies among engines. Spatial and nonspatial indexes on spatial columns are available according to the following rules.

Spatial indexes on spatial columns have these characteristics:

• Available only for InnoDB and MyISAM tables. Specifying SPATIAL INDEX for other storage engines results in an error.

• An index on a spatial column must be a SPATIAL index. The SPATIAL keyword is thus optional but implicit for creating an index on a spatial column.

• Available for single spatial columns only. A spatial index cannot be created over multiple spatial columns.

• Indexed columns must be NOT NULL.

• Column prefix lengths are prohibited. The full width of each column is indexed.

• Not permitted for a primary key or unique index.

Nonspatial indexes on spatial columns (created with INDEX, UNIQUE, or PRIMARY KEY) have these characteristics:

• Permitted for any storage engine that supports spatial columns except ARCHIVE.

• Columns can be NULL unless the index is a primary key.
CREATE INDEX Statement

- The index type for a non-SPATIAL index depends on the storage engine. Currently, B-tree is used.
- Permitted for a column that can have NULL values only for InnoDB, MyISAM, and MEMORY tables.

**Index Options**

Following the key part list, index options can be given. An index_option value can be any of the following:

- **KEY_BLOCK_SIZE [=] value**

  For MyISAM tables, KEY_BLOCK_SIZE optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A KEY_BLOCK_SIZE value specified for an individual index definition overrides a table-level KEY_BLOCK_SIZE value.

  KEY_BLOCK_SIZE is not supported at the index level for InnoDB tables. See Section 13.1.20, “CREATE TABLE Statement”.

- **index_type**

  Some storage engines permit you to specify an index type when creating an index. For example:

  ```sql
  CREATE TABLE lookup (id INT) ENGINE = MEMORY;
  CREATE INDEX id_index ON lookup (id) USING BTREE;
  ```

  Table 13.1, “Index Types Per Storage Engine” shows the permissible index type values supported by different storage engines. Where multiple index types are listed, the first one is the default when no index type specifier is given. Storage engines not listed in the table do not support an index_type clause in index definitions.

  **Table 13.1 Index Types Per Storage Engine**

<table>
<thead>
<tr>
<th>Storage Engine</th>
<th>Permissible Index Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>InnoDB</td>
<td>BTREE</td>
</tr>
<tr>
<td>MyISAM</td>
<td>BTREE</td>
</tr>
<tr>
<td>MEMORY/HEAP</td>
<td>HASH, BTREE</td>
</tr>
<tr>
<td>NDB</td>
<td>HASH, BTREE (see note in text)</td>
</tr>
</tbody>
</table>

The index_type clause cannot be used for FULLTEXT INDEX specifications. Full-text index implementation is storage-engine dependent. Spatial indexes are implemented as R-tree indexes.

If you specify an index type that is not valid for a given storage engine, but another index type is available that the engine can use without affecting query results, the engine uses the available type. The parser recognizes RTREE as a type name. This is permitted only for SPATIAL indexes.

**BTREE** indexes are implemented by the NDB storage engine as T-tree indexes.

---

**Note**

For indexes on NDB table columns, the USING option can be specified only for a unique index or primary key. USING HASH prevents the creation of an ordered index; otherwise, creating a unique index or primary key on an NDB table automatically results in the creation of both an ordered index and a hash index, each of which indexes the same set of columns.
CREATE INDEX Statement

For unique indexes that include one or more NULL columns of an NDB table, the hash index can be used only to look up literal values, which means that IS [NOT] NULL conditions require a full scan of the table. One workaround is to make sure that a unique index using one or more NULL columns on such a table is always created in such a way that it includes the ordered index; that is, avoid employing USING HASH when creating the index.

If you specify an index type that is not valid for a given storage engine, but another index type is available that the engine can use without affecting query results, the engine uses the available type. The parser recognizes RTREE as a type name, but currently this cannot be specified for any storage engine.

Note

Use of the index_type option before the ON tbl_name clause is deprecated; expect support for use of the option in this position to be removed in a future MySQL release. If an index_type option is given in both the earlier and later positions, the final option applies.

TYPE type_name is recognized as a synonym for USING type_name. However, USING is the preferred form.

The following tables show index characteristics for the storage engines that support the index_type option.

<table>

</tr>
</tbody>
</table>

Table note:

1. **USING HASH** prevents creation of an implicit ordered index.

- **WITH PARSER parser_name**

This option can be used only with **FULLTEXT** indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. **InnoDB** and **MyISAM** support full-text parser plugins. If you have a **MyISAM** table with an associated full-text parser plugin, you can convert the table to **InnoDB** using **ALTER TABLE**. See **Full-Text Parser Plugins** and **Writing Full-Text Parser Plugins** for more information.
CREATE LOGFILE GROUP Statement

- **COMMENT 'string'**

  Index definitions can include an optional comment of up to 1024 characters.

  The `MERGE_THRESHOLD` for index pages can be configured for individual indexes using the `index_option COMMENT` clause of the `CREATE INDEX` statement. For example:

  ```
  CREATE TABLE t1 (id INT);
  CREATE INDEX id_index ON t1 (id) COMMENT 'MERGE_THRESHOLD=40';
  ```

  If the page-full percentage for an index page falls below the `MERGE_THRESHOLD` value when a row is deleted or when a row is shortened by an update operation, InnoDB attempts to merge the index page with a neighboring index page. The default `MERGE_THRESHOLD` value is 50, which is the previously hardcoded value.

  `MERGE_THRESHOLD` can also be defined at the index level and table level using `CREATE TABLE` and `ALTER TABLE` statements. For more information, see Section 15.8.11, “Configuring the Merge Threshold for Index Pages”.

- **VISIBLE, INVISIBLE**

  Specify index visibility. Indexes are visible by default. An invisible index is not used by the optimizer. Specification of index visibility applies to indexes other than primary keys (either explicit or implicit). For more information, see Section 8.3.12, “Invisible Indexes”.

  - The `ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` are used to specify index attributes for primary and secondary storage engines. The options are reserved for future use.

    Permitted values are a string literal containing a valid JSON document or an empty string (""). Invalid JSON is rejected.

    ```
    CREATE INDEX i1 ON t1 (c1) ENGINE_ATTRIBUTE='{"key":"value"}';
    ```

    `ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` values can be repeated without error. In this case, the last specified value is used.

    `ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` values are not checked by the server, nor are they cleared when the table's storage engine is changed.

Table Copying and Locking Options

- `ALGORITHM` and `LOCK` clauses may be given to influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the same meaning as for the `ALTER TABLE` statement. For more information, see Section 13.1.9, “ALTER TABLE Statement”

  NDB Cluster supports online operations using the same `ALGORITHM=INPLACE` syntax used with the standard MySQL Server. See Section 23.6.12, “Online Operations with ALTER TABLE in NDB Cluster”, for more information.

13.1.16 CREATE LOGFILE GROUP Statement

  ```
  CREATE LOGFILE GROUP logfile_group
  ADD UNDOFILE 'undo_file'
  [INITIAL_SIZE [=] initial_size]
  [UNDO_BUFFER_SIZE [=] undo_buffer_size]
  [REDO_BUFFER_SIZE [=] redo_buffer_size]
  [NODEGROUP [=] nodegroup_id]
  ```
CREATE LOGFILE GROUP Statement

This statement creates a new log file group named `logfile_group` having a single UNDO file named `undo_file`. A CREATE LOGFILE GROUP statement has one and only one ADD UNDOFILE clause. For rules covering the naming of log file groups, see Section 9.2, “Schema Object Names”.

Note

All NDB Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group with the same name, or a tablespace and a data file with the same name.

There can be only one log file group per NDB Cluster instance at any given time.

The optional INITIAL_SIZE parameter sets the UNDO file’s initial size; if not specified, it defaults to 128M (128 megabytes). The optional UNDO_BUFFER_SIZE parameter sets the size used by the UNDO buffer for the log file group; The default value for UNDO_BUFFER_SIZE is 8M (eight megabytes); this value cannot exceed the amount of system memory available. Both of these parameters are specified in bytes. You may optionally follow either or both of these with a one-letter abbreviation for an order of magnitude, similar to those used in my.cnf. Generally, this is one of the letters M (for megabytes) or G (for gigabytes).

Memory used for UNDO_BUFFER_SIZE comes from the global pool whose size is determined by the value of the SharedGlobalMemory data node configuration parameter. This includes any default value implied for this option by the setting of the InitialLogFileGroup data node configuration parameter.

The maximum permitted for UNDO_BUFFER_SIZE is 629145600 (600 MB).

On 32-bit systems, the maximum supported value for INITIAL_SIZE is 4294967296 (4 GB). (Bug #29186)

The minimum allowed value for INITIAL_SIZE is 1048576 (1 MB).

The ENGINE option determines the storage engine to be used by this log file group, with engine_name being the name of the storage engine. In MySQL 8.2, this must be NDB (or NDBCLUSTER). If ENGINE is not set, MySQL tries to use the engine specified by the default_storage_engine server system variable (formerly storage_engine). In any case, if the engine is not specified as NDB or NDBCLUSTER, the CREATE LOGFILE GROUP statement appears to succeed but actually fails to create the log file group, as shown here:

```sql
mysql> CREATE LOGFILE GROUP lg1
   ->    ADD UNDOFILE 'undo.dat' INITIAL_SIZE = 10M;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-------+------+------------------------------------------------------------------------------------------------+
| Level | Code | Message                                                                                        |
+-------+------+------------------------------------------------------------------------------------------------+---+-----+--------------------------------------------------------------------------------+---+-----+-----------------------------------------------------------------------------------+---+-----+-----------------------------------------------------------------------------------+---+-----+-----------------------------------------------------------------------------------+
| Error | 1478 | Table storage engine 'InnoDB' does not support the create option 'TABLESPACE or LOGFILE GROUP' |
+-------+------+------------------------------------------------------------------------------------------------+---+-----+--------------------------------------------------------------------------------+---+-----+-----------------------------------------------------------------------------------+---+-----+-----------------------------------------------------------------------------------+---+-----+-----------------------------------------------------------------------------------+
1 row in set (0.00 sec)

mysql> DROP LOGFILE GROUP lg1 ENGINE = NDB;
ERROR 1529 (HY000): Failed to drop LOGFILE GROUP

mysql> CREATE LOGFILE GROUP lg1
   ->    ADD UNDOFILE 'undo.dat' INITIAL_SIZE = 10M
```
CREATE LOGFILE GROUP statement does not actually return an error when a non-NDB storage engine is named, but rather appears to succeed, is a known issue which we hope to address in a future release of NDB Cluster.

`REDO_BUFFER_SIZE`, `NODEGROUP`, `WAIT`, and `COMMENT` are parsed but ignored, and so have no effect in MySQL 8.2. These options are intended for future expansion.

When used with `ENGINE [=] NDB`, a log file group and associated `UNDO` log file are created on each Cluster data node. You can verify that the `UNDO` files were created and obtain information about them by querying the Information Schema `FILES` table. For example:

```sql
mysql> SELECT LOGFILE_GROUP_NAME, LOGFILE_GROUP_NUMBER, EXTRA
    -> FROM INFORMATION_SCHEMA.FILES
    -> WHERE FILE_NAME = 'undo_10.dat';
```

<table>
<thead>
<tr>
<th>LOGFILE_GROUP_NAME</th>
<th>LOGFILE_GROUP_NUMBER</th>
<th>EXTRA</th>
</tr>
</thead>
<tbody>
<tr>
<td>lg_3</td>
<td>11</td>
<td>CLUSTER_NODE=3</td>
</tr>
<tr>
<td>lg_3</td>
<td>11</td>
<td>CLUSTER_NODE=4</td>
</tr>
</tbody>
</table>

2 rows in set (0.06 sec)

CREATE LOGFILE GROUP is useful only with Disk Data storage for NDB Cluster. See Section 23.6.11, “NDB Cluster Disk Data Tables”.

13.1.17 CREATE PROCEDURE and CREATE FUNCTION Statements

```sql
CREATE [DEFINER = user]
PROCEDURE [IF NOT EXISTS] sp_name ( [proc_parameter[, ...]] )
[characteristic ...] routine_body

CREATE [DEFINER = user]
FUNCTION [IF NOT EXISTS] sp_name ( [func_parameter[, ...]] )
RETURNS type
[characteristic ...] routine_body
```

`proc_parameter`: [ IN | OUT | INOUT ] param_name type

`func_parameter`: param_name type

`type`: Any valid MySQL data type

`characteristic`: {
  COMMENT 'string'
  | LANGUAGE SQL
  | [NOT] DETERMINISTIC
  | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
}

`routine_body`: Valid SQL routine statement

These statements are used to create a stored routine (a stored procedure or function). That is, the specified routine becomes known to the server. By default, a stored routine is associated with the
CREATE PROCEDURE and CREATE FUNCTION Statements

By default, MySQL automatically grants the ALTER ROUTINE and EXECUTE privileges to the routine creator. This behavior can be changed by disabling the automatic_sp_privileges system variable. See Section 25.2.2, “Stored Routines and MySQL Privileges”.

The DEFINER and SQL SECURITY clauses specify the security context to be used when checking access privileges at routine execution time, as described later in this section.

If the routine name is the same as the name of a built-in SQL function, a syntax error occurs unless you use a space between the name and the following parenthesis when defining the routine or invoking it later. For this reason, avoid using the names of existing SQL functions for your own stored routines.

The IGNORE_SPACE SQL mode applies to built-in functions, not to stored routines. It is always permissible to have spaces after a stored routine name, regardless of whether IGNORE_SPACE is enabled.

IF NOT EXISTS prevents an error from occurring if there already exists a routine with the same name. This option is supported with both CREATE FUNCTION and CREATE PROCEDURE.

If a built-in function with the same name already exists, attempting to create a stored function with CREATE FUNCTION ... IF NOT EXISTS succeeds with a warning indicating that it has the same name as a native function; this is no different than when performing the same CREATE FUNCTION statement without specifying IF NOT EXISTS.

If a loadable function with the same name already exists, attempting to create a stored function using IF NOT EXISTS succeeds with a warning. This is the same as without specifying IF NOT EXISTS.

See Function Name Resolution, for more information.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of () should be used. Parameter names are not case-sensitive.

Each parameter is an IN parameter by default. To specify otherwise for a parameter, use the keyword OUT or INOUT before the parameter name.

Note

Specifying a parameter as IN, OUT, or INOUT is valid only for a PROCEDURE. For a FUNCTION, parameters are always regarded as IN parameters.

An IN parameter passes a value into a procedure. The procedure might modify the value, but the modification is not visible to the caller when the procedure returns. An OUT parameter passes a value from
the procedure back to the caller. Its initial value is NULL within the procedure, and its value is visible to the caller when the procedure returns. An INOUT parameter is initialized by the caller, can be modified by the procedure, and any change made by the procedure is visible to the caller when the procedure returns.

For each OUT or INOUT parameter, pass a user-defined variable in the CALL statement that invokes the procedure so that you can obtain its value when the procedure returns. If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an OUT or INOUT parameter. If you are calling the procedure from within a trigger, you can also pass NEW.col_name as an OUT or INOUT parameter.

For information about the effect of unhandled conditions on procedure parameters, see Section 13.6.7.8, “Condition Handling and OUT or INOUT Parameters”.

Routine parameters cannot be referenced in statements prepared within the routine; see Section 25.8, “Restrictions on Stored Programs”.

The following example shows a simple stored procedure that, given a country code, counts the number of cities for that country that appear in the city table of the world database. The country code is passed using an IN parameter, and the city count is returned using an OUT parameter:

```sql
mysql> delimiter //
mysql> CREATE PROCEDURE citycount (IN country CHAR(3), OUT cities INT)
   -> BEGIN
   -> SELECT COUNT(*) INTO cities FROM world.city
   -> WHERE CountryCode = country;
   -> END//
Query OK, 0 rows affected (0.01 sec)
mysql> delimiter ;
mysql> CALL citycount('JPN', @cities); -- cities in Japan
Query OK, 1 row affected (0.00 sec)
mysql> SELECT @cities;
+---------+
| @cities |
+---------+
|     248 |
1 row in set (0.00 sec)
mysql> CALL citycount('FRA', @cities); -- cities in France
Query OK, 1 row affected (0.00 sec)
mysql> SELECT @cities;
+---------+
| @cities |
+---------+
|      40 |
1 row in set (0.00 sec)
```

The example uses the mysql client delimiter command to change the statement delimiter from ; to // while the procedure is being defined. This enables the ; delimiter used in the procedure body to be passed through to the server rather than being interpreted by mysql itself. See Section 25.1, “Defining Stored Programs”.

The RETURNS clause may be specified only for a FUNCTION, for which it is mandatory. It indicates the return type of the function, and the function body must contain a RETURN value statement. If the RETURN statement returns a value of a different type, the value is coerced to the proper type. For example, if a
function specifies an `ENUM` or `SET` value in the `RETURNS` clause, but the `RETURN` statement returns an integer, the value returned from the function is the string for the corresponding `ENUM` member of set of `SET` members.

The following example function takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal ; statement delimiters:

```sql
mysql> CREATE FUNCTION hello (s CHAR(20))
    -> RETURNS CHAR(50) DETERMINISTIC
    -> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+----------------+
<table>
<thead>
<tr>
<th>hello('world')</th>
</tr>
</thead>
</table>
+----------------+
1 row in set (0.00 sec)
```

Parameter types and function return types can be declared to use any valid data type. The `COLLATE` attribute can be used if preceded by a `CHARACTER SET` specification.

The `routine_body` consists of a valid SQL routine statement. This can be a simple statement such as `SELECT` or `INSERT`, or a compound statement written using `BEGIN` and `END`. Compound statements can contain declarations, loops, and other control structure statements. The syntax for these statements is described in Section 13.6, "Compound Statement Syntax". In practice, stored functions tend to use compound statements, unless the body consists of a single `RETURN` statement.

MySQL permits routines to contain DDL statements, such as `CREATE` and `DROP`. MySQL also permits stored procedures (but not stored functions) to contain SQL transaction statements such as `COMMIT`. Stored functions may not contain statements that perform explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to permit them.

Statements that return a result set can be used within a stored procedure but not within a stored function. This prohibition includes `SELECT` statements that do not have an `INTO var_list` clause and other statements such as `SHOW`, `EXPLAIN`, and `CHECK TABLE`. For statements that can be determined at function definition time to return a result set, a `Not allowed to return a result set from a function` error occurs (`ER_SP_NO_RETSET`). For statements that can be determined only at runtime to return a result set, a `PROCEDURE %s can't return a result set in the given context` error occurs (`ER_SP_BADSELECT`).

`USE` statements within stored routines are not permitted. When a routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). The causes the routine to have the given default database while it executes. References to objects in databases other than the routine default database should be qualified with the appropriate database name.

For additional information about statements that are not permitted in stored routines, see Section 25.8, “Restrictions on Stored Programs”.

For information about invoking stored procedures from within programs written in a language that has a MySQL interface, see Section 13.2.1, “CALL Statement”.

MySQL stores the `sql_mode` system variable setting in effect when a routine is created or altered, and always executes the routine with this setting in force, regardless of the current server SQL mode when the routine begins executing.
CREATE PROCEDURE and CREATE FUNCTION Statements

The switch from the SQL mode of the invoker to that of the routine occurs after evaluation of arguments and assignment of the resulting values to routine parameters. If you define a routine in strict SQL mode but invoke it in nonstrict mode, assignment of arguments to routine parameters does not take place in strict mode. If you require that expressions passed to a routine be assigned in strict SQL mode, you should invoke the routine with strict mode in effect.

The **COMMENT** characteristic is a MySQL extension, and may be used to describe the stored routine. This information is displayed by the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements.

The **LANGUAGE** characteristic indicates the language in which the routine is written. The server ignores this characteristic; only SQL routines are supported.

A routine is considered “deterministic” if it always produces the same result for the same input parameters, and “not deterministic” otherwise. If neither **DETERMINISTIC** nor **NOT DETERMINISTIC** is given in the routine definition, the default is **NOT DETERMINISTIC**. To declare that a function is deterministic, you must specify **DETERMINISTIC** explicitly.

Assessment of the nature of a routine is based on the “honesty” of the creator: MySQL does not check that a routine declared **DETERMINISTIC** is free of statements that produce nondeterministic results. However, misdeclaring a routine might affect results or affect performance. Declaring a nondeterministic routine as **DETERMINISTIC** might lead to unexpected results by causing the optimizer to make incorrect execution plan choices. Declaring a deterministic routine as **NONDETERMINISTIC** might diminish performance by causing available optimizations not to be used.

If binary logging is enabled, the **DETERMINISTIC** characteristic affects which routine definitions MySQL accepts. See Section 25.7, “Stored Program Binary Logging”.

A routine that contains the **NOW()** function (or its synonyms) or **RAND()** is nondeterministic, but it might still be replication-safe. For **NOW()**, the binary log includes the timestamp and replicates correctly. **RAND()** also replicates correctly as long as it is called only a single time during the execution of a routine. (You can consider the routine execution timestamp and random number seed as implicit inputs that are identical on the source and replica.)

Several characteristics provide information about the nature of data use by the routine. In MySQL, these characteristics are advisory only. The server does not use them to constrain what kinds of statements a routine is permitted to execute.

- **CONTAINS SQL** indicates that the routine does not contain statements that read or write data. This is the default if none of these characteristics is given explicitly. Examples of such statements are `SET @x = 1` or `DO RELEASE_LOCK('abc')`, which execute but neither read nor write data.

- **NO SQL** indicates that the routine contains no SQL statements.

- **READS SQL DATA** indicates that the routine contains statements that read data (for example, **SELECT**), but not statements that write data.

- **MODIFIES SQL DATA** indicates that the routine contains statements that may write data (for example, **INSERT** or **DELETE**).

The **SQL SECURITY** characteristic can be **DEFINER** or **INVOKER** to specify the security context; that is, whether the routine executes using the privileges of the account named in the routine **DEFINER** clause or the user who invokes it. This account must have permission to access the database with which the routine is associated. The default value is **DEFINER**. The user who invokes the routine must have the **EXECUTE** privilege for it, as must the **DEFINER** account if the routine executes in definer security context.

The **DEFINER** clause specifies the MySQL account to be used when checking access privileges at routine execution time for routines that have the **SQL SECURITY DEFINER** characteristic.
CREATE PROCEDURE and CREATE FUNCTION Statements

If the `DEFINER` clause is present, the `user` value should be a MySQL account specified as 'user_name'@'host_name', `CURRENT_USER`, or `CURRENT_USER()`. The permitted `user` values depend on the privileges you hold, as discussed in Section 25.6, “Stored Object Access Control”. Also see that section for additional information about stored routine security.

If the `DEFINER` clause is omitted, the default definer is the user who executes the `CREATE PROCEDURE` or `CREATE FUNCTION` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

Within the body of a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, the `CURRENT_USER` function returns the routine's `DEFINER` value. For information about user auditing within stored routines, see Section 6.2.23, “SQL-Based Account Activity Auditing”.

Consider the following procedure, which displays a count of the number of MySQL accounts listed in the `mysql.user` system table:

```sql
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
BEGIN
  SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure is assigned a `DEFINER` account of 'admin'@'localhost' no matter which user defines it. It executes with the privileges of that account no matter which user invokes it (because the default security characteristic is `DEFINER`). The procedure succeeds or fails depending on whether invoker has the `EXECUTE` privilege for it and 'admin'@'localhost' has the `SELECT` privilege for the `mysql.user` table.

Now suppose that the procedure is defined with the `SQL SECURITY INVOKER` characteristic:

```sql
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
SQL SECURITY INVOKER
BEGIN
  SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure still has a `DEFINER` of 'admin'@'localhost', but in this case, it executes with the privileges of the invoking user. Thus, the procedure succeeds or fails depending on whether the invoker has the `EXECUTE` privilege for it and the `SELECT` privilege for the `mysql.user` table.

By default, when a routine with the `SQL SECURITY DEFINER` characteristic is executed, MySQL Server does not set any active roles for the MySQL account named in the `DEFINER` clause, only the default roles. The exception is if the `activate_all_roles_on_login` system variable is enabled, in which case MySQL Server sets all roles granted to the `DEFINER` user, including mandatory roles. Any privileges granted through roles are therefore not checked by default when the `CREATE PROCEDURE` or `CREATE FUNCTION` statement is issued. For stored programs, if execution should occur with roles different from the default, the program body can execute `SET ROLE` to activate the required roles. This must be done with caution since the privileges assigned to roles can be changed.

The server handles the data type of a routine parameter, local routine variable created with `DECLARE`, or function return value as follows:

- Assignments are checked for data type mismatches and overflow. Conversion and overflow problems result in warnings, or errors in strict SQL mode.
- Only scalar values can be assigned. For example, a statement such as `SET x = (SELECT 1, 2)` is invalid.
- For character data types, if `CHARACTER SET` is included in the declaration, the specified character set and its default collation is used. If the `COLLATE` attribute is also present, that collation is used rather than the default collation.
If CHARACTER SET and COLLATE are not present, the database character set and collation in effect at routine creation time are used. To avoid having the server use the database character set and collation, provide an explicit CHARACTER SET and a COLLATE attribute for character data parameters.

If you alter the database default character set or collation, stored routines that are to use the new database defaults must be dropped and recreated.

The database character set and collation are given by the value of the character_set database and collation database system variables. For more information, see Section 10.3.3, “Database Character Set and Collation”.

13.1.18 CREATE SERVER Statement

CREATE SERVER server_name
FOREIGN DATA WRAPPER wrapper_name
OPTIONS (option [, option] ...)

This statement creates the definition of a server for use with the FEDERATED storage engine. The CREATE SERVER statement creates a new row in the servers table in the mysql database. This statement requires the SUPER privilege.

The server_name should be a unique reference to the server. Server definitions are global within the scope of the server, it is not possible to qualify the server definition to a specific database. server_name has a maximum length of 64 characters (names longer than 64 characters are silently truncated), and is case-insensitive. You may specify the name as a quoted string.

The wrapper_name is an identifier and may be quoted with single quotation marks.

For each option you must specify either a character literal or numeric literal. Character literals are UTF-8, support a maximum length of 64 characters and default to a blank (empty) string. String literals are silently truncated to 64 characters. Numeric literals must be a number between 0 and 9999, default value is 0.

Note

The OWNER option is currently not applied, and has no effect on the ownership or operation of the server connection that is created.

The CREATE SERVER statement creates an entry in the mysql.servers table that can later be used with the CREATE TABLE statement when creating a FEDERATED table. The options that you specify are used to populate the columns in the mysql.servers table. The table columns are Server_name, Host, Db, Username, Password, Port and Socket.

For example:

CREATE SERVER s
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'Remote', HOST '198.51.100.106', DATABASE 'test');

Be sure to specify all options necessary to establish a connection to the server. The user name, host name, and database name are mandatory. Other options might be required as well, such as password.
CREATE SPATIAL REFERENCE SYSTEM Statement

The data stored in the table can be used when creating a connection to a **FEDERATED** table:

```sql
CREATE TABLE t (s1 INT) ENGINE=FEDERATED CONNECTION='s';
```

For more information, see Section 16.8, “The FEDERATED Storage Engine”.

**CREATE SERVER** causes an implicit commit. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

**CREATE SERVER** is not written to the binary log, regardless of the logging format that is in use.

### 13.1.19 CREATE SPATIAL REFERENCE SYSTEM Statement

```sql
CREATE OR REPLACE SPATIAL REFERENCE SYSTEM
  srid srs_attribute ...

CREATE SPATIAL REFERENCE SYSTEM
  [IF NOT EXISTS]
  srid srs_attribute ...

srs_attribute: {
  NAME 'srs_name'
  | DEFINITION 'definition'
  | ORGANIZATION 'org_name' IDENTIFIED BY org_id
  | DESCRIPTION 'description'
}

srid, org_id: 32-bit unsigned integer
```

This statement creates a **spatial reference system** (SRS) definition and stores it in the data dictionary. It requires the **SUPER** privilege. The resulting data dictionary entry can be inspected using the `INFORMATION_SCHEMA.ST_SPATIAL_REFERENCE_SYSTEMS` table.

SRID values must be unique, so if neither **OR REPLACE** nor **IF NOT EXISTS** is specified, an error occurs if an SRS definition with the given `srid` value already exists.

With **CREATE OR REPLACE** syntax, any existing SRS definition with the same SRID value is replaced, unless the SRID value is used by some column in an existing table. In that case, an error occurs. For example:

```sql
mysql> CREATE OR REPLACE SPATIAL REFERENCE SYSTEM 4326 ...;
ERROR 3716 (SR005): Can't modify SRID 4326. There is at least one column depending on it.
```

To identify which column or columns use the SRID, use this query, replacing 4326 with the SRID of the definition you are trying to create:

```sql
SELECT * FROM INFORMATION_SCHEMA.ST_GEOMETRY_COLUMNS WHERE SRS_ID=4326;
```

With **CREATE ... IF NOT EXISTS** syntax, any existing SRS definition with the same SRID value causes the new definition to be ignored and a warning occurs.

SRID values must be in the range of 32-bit unsigned integers, with these restrictions:

- **SRID 0** is a valid SRID but cannot be used with **CREATE SPATIAL REFERENCE SYSTEM**.
- If the value is in a reserved SRID range, a warning occurs. Reserved ranges are [0, 32767] (reserved by EPSG), [60,000,000, 69,999,999] (reserved by EPSG), and [2,000,000,000, 2,147,483,647] (reserved by MySQL). EPSG stands for the **European Petroleum Survey Group**.
- Users should not create SRSs with SRIDs in the reserved ranges. Doing so runs the risk of the SRIDs conflicting with future SRS definitions distributed with MySQL, with the result that the new system-provided SRSs are not installed for MySQL upgrades or that the user-defined SRSs are overwritten.
CREATE SPATIAL REFERENCE SYSTEM Statement

Attributes for the statement must satisfy these conditions:

- Attributes can be given in any order, but no attribute can be given more than once.
- The **NAME** and **DEFINITION** attributes are mandatory.
- The **NAME srs_name** attribute value must be unique. The combination of the **ORGANIZATION org_name** and **org_id** attribute values must be unique.
- The **NAME srs_name** attribute value and **ORGANIZATION org_name** attribute value cannot be empty or begin or end with whitespace.
- String values in attribute specifications cannot contain control characters, including newline.
- The following table shows the maximum lengths for string attribute values.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Maximum Length (characters)</th>
</tr>
</thead>
<tbody>
<tr>
<td>NAME</td>
<td>80</td>
</tr>
<tr>
<td>DEFINITION</td>
<td>4096</td>
</tr>
<tr>
<td>ORGANIZATION</td>
<td>256</td>
</tr>
<tr>
<td>DESCRIPTION</td>
<td>2048</td>
</tr>
</tbody>
</table>

Here is an example **CREATE SPATIAL REFERENCE SYSTEM** statement. The **DEFINITION** value is reformatted across multiple lines for readability. (For the statement to be legal, the value actually must be given on a single line.)

```
CREATE SPATIAL REFERENCE SYSTEM 4120
NAME 'Greek'
ORGANIZATION 'EPSG' IDENTIFIED BY 4120
DEFINITION
    'GEOGCS["Greek",DATUM["Greek",SPHEROID["Bessel 1841",
6377397.155,299.1528128,AUTHORITY["EPSG","7004"],
6371229.314,298.25716667,AUTHORITY["EPSG","6120"],
AUTHORITY["EPSG","8901"],UNIT["degree",0.017453292519943278,
AUTHORITY["EPSG","9122"],AXIS["Lat",NORTH],AXIS["Lon",EAST],
AUTHORITY["EPSG","4120"]];
```

The grammar for SRS definitions is based on the grammar defined in *OpenGIS Implementation Specification: Coordinate Transformation Services*, Revision 1.00, OGC 01-009, January 12, 2001, Section 7.2. This specification is available at [http://www.opengeospatial.org/standards/ct](http://www.opengeospatial.org/standards/ct).

MySQL incorporates these changes to the specification:

- Only the `<horz cs>` production rule is implemented (that is, geographic and projected SRSs).
- There is an optional, nonstandard `<authority>` clause for `<parameter>`. This makes it possible to recognize projection parameters by authority instead of name.
- The specification does not make **AXIS** clauses mandatory in **GEOGCS** spatial reference system definitions. However, if there are no **AXIS** clauses, MySQL cannot determine whether a definition has axes in latitude-longitude order or longitude-latitude order. MySQL enforces the nonstandard requirement that each **GEOGCS** definition must include two **AXIS** clauses. One must be **NORTH** or **SOUTH**, and the other **EAST** or **WEST**. The **AXIS** clause order determines whether the definition has axes in latitude-longitude order or longitude-latitude order.
- SRS definitions may not contain newlines.
If an SRS definition specifies an authority code for the projection (which is recommended), an error occurs if the definition is missing mandatory parameters. In this case, the error message indicates what the problem is. The projection methods and mandatory parameters that MySQL supports are shown in Table 13.7, “Supported Spatial Reference System Projection Methods” and Table 13.8, “Spatial Reference System Projection Parameters”.

The following table shows the projection methods that MySQL supports. MySQL permits unknown projection methods but cannot check the definition for mandatory parameters and cannot convert spatial data to or from an unknown projection. For detailed explanations of how each projection works, including formulas, see EPSG Guidance Note 7-2.

The following table shows the projection parameters that MySQL recognizes. Recognition occurs primarily by authority code. If there is no authority code, MySQL falls back to case-insensitive string matching on the parameter name. For details about each parameter, look it up by code in the EPSG Online Registry.

CREATE TABLE creates a table with the given name. You must have the CREATE privilege for the table.

By default, tables are created in the default database, using the InnoDB storage engine. An error occurs if the table exists, if there is no default database, or if the database does not exist.

MySQL has no limit on the number of tables. The underlying file system may have a limit on the number of files that represent tables. Individual storage engines may impose engine-specific constraints. InnoDB permits up to 4 billion tables.

For information about the physical representation of a table, see Section 13.1.20.1, “Files Created by CREATE TABLE”.

There are several aspects to the CREATE TABLE statement, described under the following topics in this section:

- Table Name
- Temporary Tables
- Table Cloning and Copying
- Column Data Types and Attributes
- Indexes, Foreign Keys, and CHECK Constraints
- Table Options
- Table Partitioning

Table Name

- tbl_name
CREATE TABLE Statement

The table name can be specified as `db_name.tbl_name` to create the table in a specific database. This works regardless of whether there is a default database, assuming that the database exists. If you use quoted identifiers, quote the database and table names separately. For example, write `mydb`.`mytbl`, not `mydb.mytbl`.

Rules for permissible table names are given in Section 9.2, “Schema Object Names”.

- **IF NOT EXISTS**

  Prevents an error from occurring if the table exists. However, there is no verification that the existing table has a structure identical to that indicated by the `CREATE TABLE` statement.

Temporary Tables

You can use the `TEMPORARY` keyword when creating a table. A `TEMPORARY` table is visible only within the current session, and is dropped automatically when the session is closed. For more information, see Section 13.1.20.2, “CREATE TEMPORARY TABLE Statement”.

Table Cloning and Copying

- **LIKE**

  Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

  ```sql
  CREATE TABLE new_tbl LIKE orig_tbl;
  ```

  For more information, see Section 13.1.20.3, “CREATE TABLE ... LIKE Statement”.

- **[AS] query_expression**

  To create one table from another, add a `SELECT` statement at the end of the `CREATE TABLE` statement:

  ```sql
  CREATE TABLE new_tbl AS SELECT * FROM orig_tbl;
  ```

  For more information, see Section 13.1.20.4, “CREATE TABLE ... SELECT Statement”.

- **IGNORE | REPLACE**

  The `IGNORE` and `REPLACE` options indicate how to handle rows that duplicate unique key values when copying a table using a `SELECT` statement.

  For more information, see Section 13.1.20.4, “CREATE TABLE ... SELECT Statement”.

Column Data Types and Attributes

There is a hard limit of 4096 columns per table, but the effective maximum may be less for a given table and depends on the factors discussed in Section 8.4.7, “Limits on Table Column Count and Row Size”.

- **data_type**

  `data_type` represents the data type in a column definition. For a full description of the syntax available for specifying column data types, as well as information about the properties of each type, see Chapter 11, Data Types.

  - Some attributes do not apply to all data types. `AUTO_INCREMENT` applies only to integer and floating-point types.
• Character data types (CHAR, VARCHAR, the TEXT types, ENUM, SET, and any synonyms) can include CHARACTER SET to specify the character set for the column. CHARSET is a synonym for CHARACTER SET. A collation for the character set can be specified with the COLLATE attribute, along with any other attributes. For details, see Chapter 10, Character Sets, Collations, Unicode. Example:

```sql
CREATE TABLE t (c CHAR(20) CHARACTER SET utf8mb4 COLLATE utf8mb4_bin);
```

MySQL 8.2 interprets length specifications in character column definitions in characters. Lengths for BINARY and VARBINARY are in bytes.

• For CHAR, VARCHAR, BINARY, and VARBINARY columns, indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length. BLOB and TEXT columns also can be indexed, but a prefix length must be given. Prefix lengths are given in characters for nonbinary string types and in bytes for binary string types. That is, index entries consist of the first `length` characters of each column value for CHAR, VARCHAR, and TEXT columns, and the first `length` bytes of each column value for BINARY, VARBINARY, and BLOB columns. Indexing only a prefix of column values like this can make the index file much smaller. For additional information about index prefixes, see Section 13.1.15, “CREATE INDEX Statement”.

Only the InnoDB and MyISAM storage engines support indexing on BLOB and TEXT columns. For example:

```sql
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

If a specified index prefix exceeds the maximum column data type size, CREATE TABLE handles the index as follows:

• For a nonunique index, either an error occurs (if strict SQL mode is enabled), or the index length is reduced to lie within the maximum column data type size and a warning is produced (if strict SQL mode is not enabled).

• For a unique index, an error occurs regardless of SQL mode because reducing the index length might enable insertion of nonunique entries that do not meet the specified uniqueness requirement.

• JSON columns cannot be indexed. You can work around this restriction by creating an index on a generated column that extracts a scalar value from the JSON column. See Indexing a Generated Column to Provide a JSON Column Index, for a detailed example.

• NOT NULL | NULL

If neither NULL nor NOT NULL is specified, the column is treated as though NULL had been specified.

In MySQL 8.2, only the InnoDB, MyISAM, and MEMORY storage engines support indexes on columns that can have NULL values. In other cases, you must declare indexed columns as NOT NULL or an error results.

• DEFAULT

Specifies a default value for a column. For more information about default value handling, including the case that a column definition includes no explicit DEFAULT value, see Section 11.6, “Data Type Default Values”.

If the NO_ZERO_DATE or NO_ZERO_IN_DATE SQL mode is enabled and a date-valued default is not correct according to that mode, CREATE TABLE produces a warning if strict SQL mode is not enabled and an error if strict mode is enabled. For example, with NO_ZERO_IN_DATE enabled, `c1 DATE DEFAULT '2010-00-00'` produces a warning.
CREATE TABLE Statement

• **VISIBLE, INVISIBLE**

Specify column visibility. The default is **VISIBLE** if neither keyword is present. A table must have at least one visible column. Attempting to make all columns invisible produces an error. For more information, see Section 13.1.20.10, “Invisible Columns”.

• **AUTO_INCREMENT**

An integer or floating-point column can have the additional attribute **AUTO_INCREMENT**. When you insert a value of **NULL** (recommended) or **0** into an indexed **AUTO_INCREMENT** column, the column is set to the next sequence value. Typically this is `value+1`, where `value` is the largest value for the column currently in the table. **AUTO_INCREMENT** sequences begin with **1**.

To retrieve an **AUTO_INCREMENT** value after inserting a row, use the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function. See Section 12.15, “Information Functions”, and `mysql_insert_id()`.

If the **NO_AUTO_VALUE_ON_ZERO** SQL mode is enabled, you can store **0** in **AUTO_INCREMENT** columns as **0** without generating a new sequence value. See Section 5.1.11, “Server SQL Modes”.

There can be only one **AUTO_INCREMENT** column per table, it must be indexed, and it cannot have a **DEFAULT** value. An **AUTO_INCREMENT** column works properly only if it contains only positive values. Inserting a negative number is regarded as inserting a very large positive number. This is done to avoid precision problems when numbers “wrap” over from positive to negative and also to ensure that you do not accidentally get an **AUTO_INCREMENT** column that contains **0**.

For **MyISAM** tables, you can specify an **AUTO_INCREMENT** secondary column in a multiple-column key. See Section 3.6.9, “Using AUTO_INCREMENT”.

To make MySQL compatible with some ODBC applications, you can find the **AUTO_INCREMENT** value for the last inserted row with the following query:

```sql
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

This method requires that `sql_auto_is_null` variable is not set to 0. See Section 5.1.8, “Server System Variables”.

For information about **InnoDB** and **AUTO_INCREMENT**, see Section 15.6.1.6, “AUTO_INCREMENT Handling in InnoDB”. For information about **AUTO_INCREMENT** and MySQL Replication, see Section 17.5.1.1, “Replication and AUTO_INCREMENT”.

• **COMMENT**

A comment for a column can be specified with the **COMMENT** option, up to 1024 characters long. The comment is displayed by the `SHOW CREATE TABLE` and `SHOW FULL COLUMNS` statements. It is also shown in the **COLUMN_COMMENT** column of the Information Schema **COLUMNS** table.

• **COLUMN_FORMAT**

In NDB Cluster, it is also possible to specify a data storage format for individual columns of **NDB** tables using **COLUMN_FORMAT**. Permissible column formats are **FIXED**, **DYNAMIC**, and **DEFAULT**. **FIXED** is used to specify fixed-width storage, **DYNAMIC** permits the column to be variable-width, and **DEFAULT**
causes the column to use fixed-width or variable-width storage as determined by the column’s data type (possibly overridden by a `ROW_FORMAT` specifier).

For NDB tables, the default value for `COLUMN_FORMAT` is `FIXED`.

In NDB Cluster, the maximum possible offset for a column defined with `COLUMN_FORMAT=FIXED` is 8188 bytes. For more information and possible workarounds, see Section 23.2.7.5, “Limits Associated with Database Objects in NDB Cluster”.

`COLUMN_FORMAT` currently has no effect on columns of tables using storage engines other than NDB. MySQL 8.2 silently ignores `COLUMN_FORMAT`.

- `ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` options are used to specify column attributes for primary and secondary storage engines. The options are reserved for future use.

Permitted values are a string literal containing a valid JSON document or an empty string (""). Invalid JSON is rejected.

```sql
CREATE TABLE t1 (c1 INT ENGINE_ATTRIBUTE='{"key":"value"}');
```

`ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` values can be repeated without error. In this case, the last specified value is used.

`ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` values are not checked by the server, nor are they cleared when the table’s storage engine is changed.

- `STORAGE` For NDB tables, it is possible to specify whether the column is stored on disk or in memory by using a `STORAGE` clause. `STORAGE DISK` causes the column to be stored on disk, and `STORAGE MEMORY` causes in-memory storage to be used. The `CREATE TABLE` statement used must still include a `TABLESPACE` clause:

```sql
mysql> CREATE TABLE t1 (  
  ->  c1 INT STORAGE DISK,  
  ->  c2 INT STORAGE MEMORY  
  -> ) ENGINE NDB;
ERROR 1005 (HY000): Can't create table 'c.t1' (errno: 140)

mysql> CREATE TABLE t1 (  
  ->  c1 INT STORAGE DISK,  
  ->  c2 INT STORAGE MEMORY  
  -> ) TABLESPACE ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.06 sec)
```

For NDB tables, `STORAGE DEFAULT` is equivalent to `STORAGE MEMORY`.

The `STORAGE` clause has no effect on tables using storage engines other than NDB. The `STORAGE` keyword is supported only in the build of `mysqld` that is supplied with NDB Cluster; it is not recognized in any other version of MySQL, where any attempt to use the `STORAGE` keyword causes a syntax error.

- `GENERATED ALWAYS`

Used to specify a generated column expression. For information about `generated columns`, see Section 13.1.20.8, “CREATE TABLE and Generated Columns”.

`Stored generated columns` can be indexed. InnoDB supports secondary indexes on `virtual generated columns`. See Section 13.1.20.9, “Secondary Indexes and Generated Columns”.

2687
Indexes, Foreign Keys, and CHECK Constraints

Several keywords apply to creation of indexes, foreign keys, and CHECK constraints. For general background in addition to the following descriptions, see Section 13.1.15, “CREATE INDEX Statement”, Section 13.1.20.5, “FOREIGN KEY Constraints”, and Section 13.1.20.6, “CHECK Constraints”.

• CONSTRAINT symbol

The CONSTRAINT symbol clause may be given to name a constraint. If the clause is not given, or a symbol is not included following the CONSTRAINT keyword, MySQL automatically generates a constraint name, with the exception noted below. The symbol value, if used, must be unique per schema (database), per constraint type. A duplicate symbol results in an error. See also the discussion about length limits of generated constraint identifiers at Section 9.2.1, “Identifier Length Limits”.

Note

If the CONSTRAINT symbol clause is not given in a foreign key definition, or a symbol is not included following the CONSTRAINT keyword, MySQL automatically generates a constraint name.

The SQL standard specifies that all types of constraints (primary key, unique index, foreign key, check) belong to the same namespace. In MySQL, each constraint type has its own namespace per schema. Consequently, names for each type of constraint must be unique per schema, but constraints of different types can have the same name.

• PRIMARY KEY

A unique index where all key columns must be defined as NOT NULL. If they are not explicitly declared as NOT NULL, MySQL declares them so implicitly (and silently). A table can have only one PRIMARY KEY. The name of a PRIMARY KEY is always PRIMARY, which thus cannot be used as the name for any other kind of index.

If you do not have a PRIMARY KEY and an application asks for the PRIMARY KEY in your tables, MySQL returns the first UNIQUE index that has no NULL columns as the PRIMARY KEY.

In InnoDB tables, keep the PRIMARY KEY short to minimize storage overhead for secondary indexes. Each secondary index entry contains a copy of the primary key columns for the corresponding row. (See Section 15.6.2.1, “Clustered and Secondary Indexes”.)

In the created table, a PRIMARY KEY is placed first, followed by all UNIQUE indexes, and then the nonunique indexes. This helps the MySQL optimizer to prioritize which index to use and also more quickly to detect duplicated UNIQUE keys.

A PRIMARY KEY can be a multiple-column index. However, you cannot create a multiple-column index using the PRIMARY KEY key attribute in a column specification. Doing so only marks that single column as primary. You must use a separate PRIMARY KEY(key_part, ...) clause.

If a table has a PRIMARY KEY or UNIQUE NOT NULL index that consists of a single column that has an integer type, you can use _rowid to refer to the indexed column in SELECT statements, as described in Unique Indexes.

In MySQL, the name of a PRIMARY KEY is PRIMARY. For other indexes, if you do not assign a name, the index is assigned the same name as the first indexed column, with an optional suffix (_2, _3, ...) to make it unique. You can see index names for a table using SHOW INDEX FROM tbl_name. See Section 13.7.7.23, “SHOW INDEX Statement”.

2688
CREATE TABLE Statement

• **KEY | INDEX**

  **KEY** is normally a synonym for **INDEX**. The key attribute **PRIMARY KEY** can also be specified as just **KEY** when given in a column definition. This was implemented for compatibility with other database systems.

• **UNIQUE**

  A **UNIQUE** index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a **UNIQUE** index permits multiple **NULL** values for columns that can contain **NULL**. If you specify a prefix value for a column in a **UNIQUE** index, the column values must be unique within the prefix length.

  If a table has a **PRIMARY KEY** or **UNIQUE NOT NULL** index that consists of a single column that has an integer type, you can use `_rowid` to refer to the indexed column in **SELECT** statements, as described in **Unique Indexes**.

• **FULLTEXT**

  A **FULLTEXT** index is a special type of index used for full-text searches. Only the **InnoDB** and **MyISAM** storage engines support **FULLTEXT** indexes. They can be created only from **CHAR**, **VARCHAR**, and **TEXT** columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See Section 12.9, “Full-Text Search Functions”, for details of operation. A **WITH PARSER** clause can be specified as an **index_option** value to associate a parser plugin with the index if full-text indexing and searching operations need special handling. This clause is valid only for **FULLTEXT** indexes. **InnoDB** and **MyISAM** support full-text parser plugins. See Full-Text Parser Plugins and Writing Full-Text Parser Plugins for more information.

• **SPATIAL**

  You can create **SPATIAL** indexes on spatial data types. Spatial types are supported only for **InnoDB** and **MyISAM** tables, and indexed columns must be declared as **NOT NULL**. See Section 11.4, “Spatial Data Types”.

• **FOREIGN KEY**

  MySQL supports foreign keys, which let you cross-reference related data across tables, and foreign key constraints, which help keep this spread-out data consistent. For definition and option information, see reference_definition, and reference_option.

  Partitioned tables employing the **InnoDB** storage engine do not support foreign keys. See Section 24.6, “Restrictions and Limitations on Partitioning”, for more information.

• **CHECK**

  The **CHECK** clause enables the creation of constraints to be checked for data values in table rows. See Section 13.1.20.6, “CHECK Constraints”.
CREATE TABLE Statement

- **key_part**
  
  A **key_part** specification can end with **ASC** or **DESC** to specify whether index values are stored in ascending or descending order. The default is ascending if no order specifier is given.

  Prefixes, defined by the **length** attribute, can be up to 767 bytes long for **InnoDB** tables that use the **RENDUNDANT** or **COMPACT** row format. The prefix length limit is 3072 bytes for **InnoDB** tables that use the **DYNAMIC** or **COMPRESSED** row format. For **MyISAM** tables, the prefix length limit is 1000 bytes.

  Prefix **limits** are measured in bytes. However, prefix **lengths** for index specifications in **CREATE TABLE**, **ALTER TABLE**, and **CREATE INDEX** statements are interpreted as number of characters for nonbinary string types (**CHAR**, **VARCHAR**, **TEXT**) and number of bytes for binary string types (**BINARY**, **VARBINARY**, **BLOB**). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

  The **expr** for a **key_part** specification can take the form (CAST |json_path| AS |type| ARRAY) to create a multi-valued index on a **JSON** column. **Multi-Valued Indexes**, provides detailed information regarding creation of, usage of, and restrictions and limitations on multi-valued indexes.

- **index_type**

Some storage engines permit you to specify an index type when creating an index. The syntax for the **index_type** specifier is **USING type_name**.

Example:

```sql
CREATE TABLE lookup
(id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

The preferred position for **USING** is after the index column list. It can be given before the column list, but support for use of the option in that position is deprecated and you should expect it to be removed in a future MySQL release.

- **index_option**

  **index_option** values specify additional options for an index.

  - **KEY_BLOCK_SIZE**

    For **MyISAM** tables, **KEY_BLOCK_SIZE** optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A **KEY_BLOCK_SIZE** value specified for an individual index definition overrides the table-level **KEY_BLOCK_SIZE** value.

    For information about the table-level **KEY_BLOCK_SIZE** attribute, see **Table Options**.

  - **WITH PARSER**

    The **WITH PARSER** option can be used only with **FULLTEXT** indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. **InnoDB** and **MyISAM**
CREATE TABLE Statement

support full-text parser plugins. If you have a MyISAM table with an associated full-text parser plugin, you can convert the table to InnoDB using ALTER TABLE.

• COMMENT

Index definitions can include an optional comment of up to 1024 characters.

You can set the InnoDB MERGE_THRESHOLD value for an individual index using the index_option COMMENT clause. See Section 15.8.11, “Configuring the Merge Threshold for Index Pages”.

• VISIBLE, INVISIBLE

Specify index visibility. Indexes are visible by default. An invisible index is not used by the optimizer. Specification of index visibility applies to indexes other than primary keys (either explicit or implicit). For more information, see Section 8.3.12, “Invisible Indexes”.

• ENGINE_ATTRIBUTE and SECONDARY_ENGINE_ATTRIBUTE options are used to specify index attributes for primary and secondary storage engines. The options are reserved for future use.

For more information about permissible index_option values, see Section 13.1.15, “CREATE INDEX Statement”. For more information about indexes, see Section 8.3.1, “How MySQL Uses Indexes”.

• reference_definition

For reference_definition syntax details and examples, see Section 13.1.20.5, “FOREIGN KEY Constraints”.

InnoDB and NDB tables support checking of foreign key constraints. The columns of the referenced table must always be explicitly named. Both ON DELETE and ON UPDATE actions on foreign keys are supported. For more detailed information and examples, see Section 13.1.20.5, “FOREIGN KEY Constraints”.

For other storage engines, MySQL Server parses and ignores the FOREIGN KEY syntax in CREATE TABLE statements.

Important

For users familiar with the ANSI/ISO SQL Standard, please note that no storage engine, including InnoDB, recognizes or enforces the MATCH clause used in referential integrity constraint definitions. Use of an explicit MATCH clause does not have the specified effect, and also causes ON DELETE and ON UPDATE clauses to be ignored. For these reasons, specifying MATCH should be avoided.

The MATCH clause in the SQL standard controls how NULL values in a composite (multiple-column) foreign key are handled when comparing to a primary key. InnoDB essentially implements the semantics defined by MATCH SIMPLE, which permit a foreign key to be all or partially NULL. In that case, the (child table) row containing such a foreign key is permitted to be inserted, and does not match any row in the referenced (parent) table. It is possible to implement other semantics using triggers.

Additionally, MySQL requires that the referenced columns be indexed for performance. However, InnoDB does not enforce any requirement that the referenced columns be declared UNIQUE or NOT NULL. The handling of foreign key references to nonunique keys or keys that contain NULL values is not well defined for operations such as UPDATE or DELETE CASCADE. You are advised
CREATE TABLE Statement
to use foreign keys that reference only keys that are both UNIQUE (or PRIMARY) and NOT NULL.
MySQL parses but ignores “inline REFERENCES specifications” (as defined in the SQL standard) where the references are defined as part of the column specification. MySQL accepts REFERENCES clauses only when specified as part of a separate FOREIGN KEY specification. For more information, see Section 1.6.2.3, “FOREIGN KEY Constraint Differences”.

• reference_option

For information about the RESTRICT, CASCADE, SET NULL, NO ACTION, and SET DEFAULT options, see Section 13.1.20.5, “FOREIGN KEY Constraints”.

Table Options
Table options are used to optimize the behavior of the table. In most cases, you do not have to specify any of them. These options apply to all storage engines unless otherwise indicated. Options that do not apply to a given storage engine may be accepted and remembered as part of the table definition. Such options then apply if you later use ALTER TABLE to convert the table to use a different storage engine.

• ENGINE

Specifies the storage engine for the table, using one of the names shown in the following table. The engine name can be unquoted or quoted. The quoted name 'DEFAULT' is recognized but ignored.

<table>
<thead>
<tr>
<th>Storage Engine</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>InnoDB</td>
<td>Transaction-safe tables with row locking and foreign keys. The default storage engine for new tables. See Chapter 15, The InnoDB Storage Engine, and in particular Section 15.1, “Introduction to InnoDB” if you have MySQL experience but are new to InnoDB.</td>
</tr>
<tr>
<td>MyISAM</td>
<td>The binary portable storage engine that is primarily used for read-only or read-mostly workloads. See Section 16.2, “The MyISAM Storage Engine”.</td>
</tr>
<tr>
<td>MEMORY</td>
<td>The data for this storage engine is stored only in memory. See Section 16.3, “The MEMORY Storage Engine”.</td>
</tr>
<tr>
<td>CSV</td>
<td>Tables that store rows in comma-separated values format. See Section 16.4, “The CSV Storage Engine”.</td>
</tr>
<tr>
<td>ARCHIVE</td>
<td>The archiving storage engine. See Section 16.5, “The ARCHIVE Storage Engine”.</td>
</tr>
<tr>
<td>EXAMPLE</td>
<td>An example engine. See Section 16.9, “The EXAMPLE Storage Engine”.</td>
</tr>
<tr>
<td>FEDERATED</td>
<td>Storage engine that accesses remote tables. See Section 16.8, “The FEDERATED Storage Engine”.</td>
</tr>
<tr>
<td>HEAP</td>
<td>This is a synonym for MEMORY.</td>
</tr>
<tr>
<td>MERGE</td>
<td>A collection of MyISAM tables used as one table. Also known as MRG_MyISAM. See Section 16.7, “The MERGE Storage Engine”.</td>
</tr>
</tbody>
</table>
CREATE TABLE Statement

<table>
<thead>
<tr>
<th>Storage Engine</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB</td>
<td>Clustered, fault-tolerant, memory-based tables, supporting transactions and foreign keys. Also known as NDBCLUSTER. See Chapter 23, MySQL NDB Cluster 8.2.</td>
</tr>
</tbody>
</table>

By default, if a storage engine is specified that is not available, the statement fails with an error. You can override this behavior by removing NO_ENGINE_SUBSTITUTION from the server SQL mode (see Section 5.1.11, “Server SQL Modes”) so that MySQL allows substitution of the specified engine with the default storage engine instead. Normally in such cases, this is InnoDB, which is the default value for the default_storage_engine system variable. When NO_ENGINE_SUBSTITUTION is disabled, a warning occurs if the storage engine specification is not honored.

• AUTOEXTEND_SIZE

Defines the amount by which InnoDB extends the size of the tablespace when it becomes full. The setting must be a multiple of 4MB. The default setting is 0, which causes the tablespace to be extended according to the implicit default behavior. For more information, see Section 15.6.3.9, “Tablespace AUTOEXTEND_SIZE Configuration”.

• AUTO_INCREMENT

The initial AUTO_INCREMENT value for the table. In MySQL 8.2, this works for MyISAM, MEMORY, InnoDB, and ARCHIVE tables. To set the first auto-increment value for engines that do not support the AUTO_INCREMENT table option, insert a “dummy” row with a value one less than the desired value after creating the table, and then delete the dummy row.

For engines that support the AUTO_INCREMENT table option in CREATE TABLE statements, you can also use ALTER TABLE tbl_name AUTO_INCREMENT = n to reset the AUTO_INCREMENT value. The value cannot be set lower than the maximum value currently in the column.

• AVG_ROW_LENGTH

An approximation of the average row length for your table. You need to set this only for large tables with variable-size rows.

When you create a MyISAM table, MySQL uses the product of the MAX_ROWS and AVG_ROW_LENGTH options to decide how big the resulting table is. If you don't specify either option, the maximum size for MyISAM data and index files is 256TB by default. (If your operating system does not support files that large, table sizes are constrained by the file size limit.) If you want to keep down the pointer sizes to make the index smaller and faster and you don't really need big files, you can decrease the default pointer size by setting the myisam_data_pointer_size system variable. (See Section 5.1.8, “Server System Variables”.) If you want all your tables to be able to grow above the default limit and are willing to have your tables slightly slower and larger than necessary, you can increase the default pointer size by setting this variable. Setting the value to 7 permits table sizes up to 65,536TB.

• [DEFAULT] CHARACTER SET

Specifies a default character set for the table. CHARSET is a synonym for CHARACTER_SET. If the character set name is DEFAULT, the database character set is used.

• CHECKSUM

Set this to 1 if you want MySQL to maintain a live checksum for all rows (that is, a checksum that MySQL updates automatically as the table changes). This makes the table a little slower to update, but also
CREATE TABLE Statement

makes it easier to find corrupted tables. The CHECKSUM TABLE statement reports the checksum. (MyISAM only.)

- [DEFAULT] COLLATE

Specifies a default collation for the table.

- COMMENT

A comment for the table, up to 2048 characters long.

You can set the InnoDB MERGE_THRESHOLD value for a table using the table_option COMMENT clause. See Section 15.8.11, “Configuring the Merge Threshold for Index Pages”.

Setting NDB_TABLE options. The table comment in a CREATE TABLE that creates an NDB table or an ALTER TABLE statement which alters one can also be used to specify one to four of the NDB_TABLE options NOLOGGING, READ_BACKUP, PARTITION_BALANCE, or FULLY_REPLICATED as a set of name-value pairs, separated by commas if need be, immediately following the string NDB_TABLE= that begins the quoted comment text. An example statement using this syntax is shown here (emphasized text):

CREATE TABLE t1 (  
c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
c2 VARCHAR(100),  
c3 VARCHAR(100) )  
ENGINE=NDB  
COMMENT="NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RP_BY_NODE";

Spaces are not permitted within the quoted string. The string is case-insensitive.

The comment is displayed as part of the output of SHOW CREATE TABLE. The text of the comment is also available as the TABLE_COMMENT column of the MySQL Information Schema TABLES table.

This comment syntax is also supported with ALTER TABLE statements for NDB tables. Keep in mind that a table comment used with ALTER TABLE replaces any existing comment which the table might have had previously.

Setting the MERGE_THRESHOLD option in table comments is not supported for NDB tables (it is ignored).

For complete syntax information and examples, see Section 13.1.20.12, “Setting NDB Comment Options”.

- COMPRESSION

The compression algorithm used for page level compression for InnoDB tables. Supported values include Zlib, LZ4, and None. The COMPRESSION attribute was introduced with the transparent page compression feature. Page compression is only supported with InnoDB tables that reside in file-per-table tablespaces, and is only available on Linux and Windows platforms that support sparse files and hole punching. For more information, see Section 15.9.2, “InnoDB Page Compression”.

- CONNECTION

The connection string for a FEDERATED table.

Note

Older versions of MySQL used a COMMENT option for the connection string.

- DATA DIRECTORY, INDEX DIRECTORY
For InnoDB, the `DATA DIRECTORY='directory'` clause permits creating tables outside of the data directory. The `innodb_file_per_table` variable must be enabled to use the `DATA DIRECTORY` clause. The full directory path must be specified, and known to InnoDB. For more information, see Section 15.6.1.2, “Creating Tables Externally”.

When creating MyISAM tables, you can use the `DATA DIRECTORY='directory'` clause, the `INDEX DIRECTORY='directory'` clause, or both. They specify where to put a MyISAM table's data file and index file, respectively. Unlike InnoDB tables, MySQL does not create subdirectories that correspond to the database name when creating a MyISAM table with a `DATA DIRECTORY` or `INDEX DIRECTORY` option. Files are created in the directory that is specified.

You must have the `FILE` privilege to use the `DATA DIRECTORY` or `INDEX DIRECTORY` table option.

**Important**
Table-level `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored for partitioned tables. (Bug #32091)

These options work only when you are not using the `--skip-symbolic-links` option. Your operating system must also have a working, thread-safe `realpath()` call. See Section 8.12.2.2, “Using Symbolic Links for MyISAM Tables on Unix”, for more complete information.

If a MyISAM table is created with no `DATA DIRECTORY` option, the `.MYD` file is created in the database directory. By default, if MyISAM finds an existing `.MYD` file in this case, it overwrites it. The same applies to `.MYI` files for tables created with no `INDEX DIRECTORY` option. To suppress this behavior, start the server with the `--keep_files_on_create` option, in which case MyISAM does not overwrite existing files and returns an error instead.

If a MyISAM table is created with a `DATA DIRECTORY` or `INDEX DIRECTORY` option and an existing `.MYD` or `.MYI` file is found, MyISAM always returns an error, and does not overwrite a file in the specified directory.

**Important**
You cannot use path names that contain the MySQL data directory with `DATA DIRECTORY` or `INDEX DIRECTORY`. This includes partitioned tables and individual table partitions. (See Bug #32167.)

- **DELAY_KEY_WRITE**
  Set this to 1 if you want to delay key updates for the table until the table is closed. See the description of the `delay_key_write` system variable in Section 5.1.8, “Server System Variables”. (MyISAM only.)

- **ENCRYPTION**
  The `ENCRYPTION` clause enables or disables page-level data encryption for an InnoDB table. A keyring plugin must be installed and configured before encryption can be enabled. The `ENCRYPTION` clause can be specified when creating a table in an a file-per-table tablespace, or when creating a table in a general tablespace.

  A table inherits the default schema encryption if an `ENCRYPTION` clause is not specified. If the `table_encryption_privilege_check` variable is enabled, the `TABLE_ENCRYPTION_ADMIN` privilege is required to create a table with an `ENCRYPTION` clause setting that differs from the default
CREATE TABLE Statement

schema encryption. When creating a table in a general tablespace, table and tablespace encryption must match.

Specifying an ENCRYPTION clause with a value other than 'N' or '' is not permitted when using a storage engine that does not support encryption.

For more information, see Section 15.13, “InnoDB Data-at-Rest Encryption”.

• The ENGINE_ATTRIBUTE and SECONDARY_ENGINE_ATTRIBUTE options are used to specify table attributes for primary and secondary storage engines. The options are reserved for future use.

Permitted values are a string literal containing a valid JSON document or an empty string (''). Invalid JSON is rejected.

CREATE TABLE t1 (c1 INT) ENGINE_ATTRIBUTE='{"key":"value"}';

ENGINE_ATTRIBUTE and SECONDARY_ENGINE_ATTRIBUTE values can be repeated without error. In this case, the last specified value is used.

ENGINE_ATTRIBUTE and SECONDARY_ENGINE_ATTRIBUTE values are not checked by the server, nor are they cleared when the table’s storage engine is changed.

• INSERT_METHOD

If you want to insert data into a MERGE table, you must specify with INSERT_METHOD the table into which the row should be inserted. INSERT_METHOD is an option useful for MERGE tables only. Use a value of FIRST or LAST to have inserts go to the first or last table, or a value of NO to prevent inserts. See Section 16.7, “The MERGE Storage Engine”.

• KEY_BLOCK_SIZE

For MyISAM tables, KEY_BLOCK_SIZE optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A KEY_BLOCK_SIZE value specified for an individual index definition overrides the table-level KEY_BLOCK_SIZE value.

For InnoDB tables, KEY_BLOCK_SIZE specifies the page size in kilobytes to use for compressed InnoDB tables. The KEY_BLOCK_SIZE value is treated as a hint; a different size could be used by InnoDB if necessary. KEY_BLOCK_SIZE can only be less than or equal to the innodb_page_size value. A value of 0 represents the default compressed page size, which is half of the innodb_page_size value. Depending on innodb_page_size, possible KEY_BLOCK_SIZE values include 0, 1, 2, 4, 8, and 16. See Section 15.9.1, “InnoDB Table Compression” for more information.

Oracle recommends enabling innodb_strict_mode when specifying KEY_BLOCK_SIZE for InnoDB tables. When innodb_strict_mode is enabled, specifying an invalid KEY_BLOCK_SIZE value returns an error. If innodb_strict_mode is disabled, an invalid KEY_BLOCK_SIZE value results in a warning, and the KEY_BLOCK_SIZE option is ignored.

The Create_options column in response to SHOW TABLE STATUS reports the actual KEY_BLOCK_SIZE used by the table, as does SHOW CREATE TABLE.

InnoDB only supports KEY_BLOCK_SIZE at the table level.

KEY_BLOCK_SIZE is not supported with 32KB and 64KB innodb_page_size values. InnoDB table compression does not support these page sizes.

InnoDB does not support the KEY_BLOCK_SIZE option when creating temporary tables.
CREATE TABLE Statement

• **MAX_ROWS**

The maximum number of rows you plan to store in the table. This is not a hard limit, but rather a hint to the storage engine that the table must be able to store at least this many rows.

⚠️ **Important**

The use of **MAX_ROWS** with NDB tables to control the number of table partitions is deprecated. It remains supported in later versions for backward compatibility, but is subject to removal in a future release. Use PARTITION_BALANCE instead; see Setting NDB_TABLE options.

The NDB storage engine treats this value as a maximum. If you plan to create very large NDB Cluster tables (containing millions of rows), you should use this option to insure that NDB allocates sufficient number of index slots in the hash table used for storing hashes of the table’s primary keys by setting **MAX_ROWS = 2 * rows**, where **rows** is the number of rows that you expect to insert into the table.

The maximum **MAX_ROWS** value is 4294967295; larger values are truncated to this limit.

• **MIN_ROWS**

The minimum number of rows you plan to store in the table. The MEMORY storage engine uses this option as a hint about memory use.

• **PACK_KEYS**

Takes effect only with MyISAM tables. Set this option to 1 if you want to have smaller indexes. This usually makes updates slower and reads faster. Setting the option to 0 disables all packing of keys. Setting it to **DEFAULT** tells the storage engine to pack only long CHAR, VARCHAR, BINARY, or VARBINARY columns.

If you do not use **PACK_KEYS**, the default is to pack strings, but not numbers. If you use **PACK_KEYS=1**, numbers are packed as well.

When packing binary number keys, MySQL uses prefix compression:

• Every key needs one extra byte to indicate how many bytes of the previous key are the same for the next key.

• The pointer to the row is stored in high-byte-first order directly after the key, to improve compression.

This means that if you have many equal keys on two consecutive rows, all following “same” keys usually only take two bytes (including the pointer to the row). Compare this to the ordinary case where the following keys takes **storage_size_for_key + pointer_size** (where the pointer size is usually 4). Conversely, you get a significant benefit from prefix compression only if you have many numbers that are the same. If all keys are totally different, you use one byte more per key, if the key is not a key that can have NULL values. (In this case, the packed key length is stored in the same byte that is used to mark if a key is NULL.)

• **PASSWORD**

This option is unused.
CREATE TABLE Statement

- **ROW_FORMAT**

Defines the physical format in which the rows are stored.

When creating a table with strict mode disabled, the storage engine's default row format is used if the specified row format is not supported. The actual row format of the table is reported in the `Row_format` column in response to `SHOW TABLE STATUS`. The `Create_options` column shows the row format that was specified in the `CREATE TABLE` statement, as does `SHOW CREATE TABLE`.

Row format choices differ depending on the storage engine used for the table.

For **InnoDB** tables:

- The default row format is defined by `innodb_default_row_format`, which has a default setting of `DYNAMIC`. The default row format is used when the `ROW_FORMAT` option is not defined or when `ROW_FORMAT=DEFAULT` is used.

  If the `ROW_FORMAT` option is not defined, or if `ROW_FORMAT=DEFAULT` is used, operations that rebuild a table also silently change the row format of the table to the default defined by `innodb_default_row_format`. For more information, see Defining the Row Format of a Table.

- For more efficient **InnoDB** storage of data types, especially `BLOB` types, use the `DYNAMIC`. See DYNAMIC Row Format for requirements associated with the `DYNAMIC` row format.

- To enable compression for **InnoDB** tables, specify `ROW_FORMAT=COMPRESSED`. The `ROW_FORMAT=COMPRESSED` option is not supported when creating temporary tables. See Section 15.9, “InnoDB Table and Page Compression” for requirements associated with the `COMPRESSED` row format.

- The row format used in older versions of MySQL can still be requested by specifying the `REDUNDANT` row format.

- When you specify a non-default `ROW_FORMAT` clause, consider also enabling the `innodb_strict_mode` configuration option.

  - `ROW_FORMAT=FIXED` is not supported. If `ROW_FORMAT=FIXED` is specified while `innodb_strict_mode` is disabled, **InnoDB** issues a warning and assumes `ROW_FORMAT=DYNAMIC`. If `ROW_FORMAT=FIXED` is specified while `innodb_strict_mode` is enabled, which is the default, **InnoDB** returns an error.

- For additional information about **InnoDB** row formats, see Section 15.10, “InnoDB Row Formats”.

For **MyISAM** tables, the option value can be `FIXED` or `DYNAMIC` for static or variable-length row format. `myisampack` sets the type to `COMPRESSED`. See Section 16.2.3, “MyISAM Table Storage Formats”.

For **NDB** tables, the default `ROW_FORMAT` is `DYNAMIC`.

- **START TRANSACTION**

This is an internal-use table option, used to permit `CREATE TABLE ... SELECT` to be logged as a single, atomic transaction in the binary log when using row-based replication with a storage engine that supports atomic DDL. Only `BINLOG`, `COMMIT`, and `ROLLBACK` statements are permitted after `CREATE TABLE ... START TRANSACTION`. For related information, see Section 13.1.1, “Atomic Data Definition Statement Support”.

2698
CREATE TABLE Statement

- **STATS_AUTO_RECALC**

  Specifies whether to automatically recalculate persistent statistics for an InnoDB table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_auto_recalc` configuration option. The value `1` causes statistics to be recalculated when 10% of the data in the table has changed. The value `0` prevents automatic recalculation for this table; with this setting, issue an `ANALYZE TABLE` statement to recalculate the statistics after making substantial changes to the table. For more information about the persistent statistics feature, see Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”.

- **STATS_PERSISTENT**

  Specifies whether to enable persistent statistics for an InnoDB table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_persistent` configuration option. The value `1` enables persistent statistics for the table, while the value `0` turns off this feature. After enabling persistent statistics through a `CREATE TABLE` or `ALTER TABLE` statement, issue an `ANALYZE TABLE` statement to calculate the statistics, after loading representative data into the table. For more information about the persistent statistics feature, see Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”.

- **STATS_SAMPLE_PAGES**

  The number of index pages to sample when estimating cardinality and other statistics for an indexed column, such as those calculated by `ANALYZE TABLE`. For more information, see Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”.

- **TABLESPACE**

  The `TABLESPACE` clause can be used to create an InnoDB table in an existing general tablespace, a file-per-table tablespace, or the system tablespace.

  ```sql
  CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name
  ```

  The general tablespace that you specify must exist prior to using the `TABLESPACE` clause. For information about general tablespaces, see Section 15.6.3.3, “General Tablespaces”.

  The `tablespace_name` is a case-sensitive identifier. It may be quoted or unquoted. The forward slash character ("/") is not permitted. Names beginning with "innodb_" are reserved for special use.

  To create a table in the system tablespace, specify `innodb_system` as the tablespace name.

  ```sql
  CREATE TABLE tbl_name ... TABLESPACE [=] innodb_system
  ```

  Using `TABLESPACE [=] innodb_system`, you can place a table of any uncompressed row format in the system tablespace regardless of the `innodb_file_per_table` setting. For example, you can add a table with `ROW_FORMAT=DYNAMIC` to the system tablespace using `TABLESPACE [=] innodb_system`.

  To create a table in a file-per-table tablespace, specify `innodb_file_per_table` as the tablespace name.

  ```sql
  CREATE TABLE tbl_name ... TABLESPACE [=] innodb_file_per_table
  ```

  **Note**

  If `innodb_file_per_table` is enabled, you need not specify `TABLESPACE=innodb_file_per_table` to create an InnoDB file-per-table.
CREATE TABLE Statement

tablespace. InnoDB tables are created in file-per-table tablespaces by default when innodb_file_per_table is enabled.

The **DATA DIRECTORY** clause is permitted with `CREATE TABLE ... TABLESPACE=innodb_file_per_table` but is otherwise not supported for use in combination with the **TABLESPACE** clause. The directory specified in a **DATA DIRECTORY** clause must be known to InnoDB. For more information, see Using the DATA DIRECTORY Clause.

Note

Support for **TABLESPACE = innodb_file_per_table** and **TABLESPACE = innodb_temporary** clauses with `CREATE TEMPORARY TABLE` is deprecated; expect it to be removed in a future version of MySQL.

The **STORAGE** table option is employed only with NDB tables. **STORAGE** determines the type of storage used, and can be either of **DISK** or **MEMORY**.

**TABLESPACE ... STORAGE DISK** assigns a table to an NDB Cluster Disk Data tablespace. **STORAGE DISK** cannot be used in **CREATE TABLE** unless preceded by **TABLESPACE** `tablespace_name`.

For **STORAGE MEMORY**, the tablespace name is optional, thus, you can use **TABLESPACE tablespace_name STORAGE MEMORY** or simply **STORAGE MEMORY** to specify explicitly that the table is in-memory.

See Section 23.6.11, “NDB Cluster Disk Data Tables”, for more information.

- **UNION**

    Used to access a collection of identical MyISAM tables as one. This works only with MERGE tables. See Section 16.7, “The MERGE Storage Engine”.

    You must have **SELECT**, **UPDATE**, and **DELETE** privileges for the tables you map to a MERGE table.

Note

Formerly, all tables used had to be in the same database as the MERGE table itself. This restriction no longer applies.

Table Partitioning

**partition_options** can be used to control partitioning of the table created with **CREATE TABLE**.

Not all options shown in the syntax for **partition_options** at the beginning of this section are available for all partitioning types. Please see the listings for the following individual types for information specific to each type, and see Chapter 24, Partitioning, for more complete information about the workings of and uses for partitioning in MySQL, as well as additional examples of table creation and other statements relating to MySQL partitioning.

Partitions can be modified, merged, added to tables, and dropped from tables. For basic information about the MySQL statements to accomplish these tasks, see Section 13.1.9, “ALTER TABLE Statement”. For more detailed descriptions and examples, see Section 24.3, “Partition Management”.

- **PARTITION BY**

    If used, a **partition_options** clause begins with **PARTITION BY**. This clause contains the function that is used to determine the partition; the function returns an integer value ranging from 1 to `num`, where `num` is the number of partitions. (The maximum number of user-defined partitions which a table
may contain is 1024; the number of subpartitions—discussed later in this section—is included in this maximum.)

Note

The expression \( \text{expr} \) used in a `PARTITION BY` clause cannot refer to any columns not in the table being created; such references are specifically not permitted and cause the statement to fail with an error. (Bug #29444)

- **HASH(expr)**

  Hashes one or more columns to create a key for placing and locating rows. \( \text{expr} \) is an expression using one or more table columns. This can be any valid MySQL expression (including MySQL functions) that yields a single integer value. For example, these are both valid `CREATE TABLE` statements using `PARTITION BY HASH`:

  ```sql
  CREATE TABLE t1 (col1 INT, col2 CHAR(5))
  PARTITION BY HASH(col1);
  CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATETIME)
  PARTITION BY HASH ( YEAR(col3) );
  ```

  You may not use either `VALUES LESS THAN` or `VALUES IN` clauses with `PARTITION BY HASH`.

  `PARTITION BY HASH` uses the remainder of \( \text{expr} \) divided by the number of partitions (that is, the modulus). For examples and additional information, see Section 24.2.4, “HASH Partitioning”.

  The `LINEAR` keyword entails a somewhat different algorithm. In this case, the number of the partition in which a row is stored is calculated as the result of one or more logical `AND` operations. For discussion and examples of linear hashing, see Section 24.2.4.1, “LINEAR HASH Partitioning”.

- **KEY(column_list)**

  This is similar to `HASH`, except that MySQL supplies the hashing function so as to guarantee an even data distribution. The `column_list` argument is simply a list of 1 or more table columns (maximum: 16). This example shows a simple table partitioned by key, with 4 partitions:

  ```sql
  CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
  PARTITION BY KEY(col3)
  PARTITIONS 4;
  ```

  For tables that are partitioned by key, you can employ linear partitioning by using the `LINEAR` keyword. This has the same effect as with tables that are partitioned by `HASH`. That is, the partition number is found using the `&` operator rather than the modulus (see Section 24.2.4.1, “LINEAR HASH Partitioning”, and Section 24.2.5, “KEY Partitioning”, for details). This example uses linear partitioning by key to distribute data between 5 partitions:

  ```sql
  CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
  PARTITION BY LINEAR KEY(col3)
  PARTITIONS 5;
  ```

  The `ALGORITHM={1 | 2}` option is supported with `[SUB]PARTITION BY [LINEAR] KEY.`

  `ALGORITHM=1` causes the server to use the same key-hashing functions as MySQL 5.1; `ALGORITHM=2` means that the server employs the key-hashing functions implemented and used by default for new `KEY` partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a MySQL 5.1 server.) Not specifying the option has the same effect as using `ALGORITHM=2`. This option is intended for use chiefly when upgrading or downgrading `[LINEAR] KEY` partitioned tables between MySQL 5.1 and later MySQL versions, or for
CREATE TABLE Statement

Creating tables partitioned by KEY or LINEAR KEY on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server. For more information, see Section 13.1.9.1, “ALTER TABLE Partition Operations”.

`mysqldump` writes this option encased in versioned comments.

`ALGORITHM=1` is shown when necessary in the output of SHOW CREATE TABLE using versioned comments in the same manner as `mysqldump`. `ALGORITHM=2` is always omitted from SHOW CREATE TABLE output, even if this option was specified when creating the original table.

You may not use either VALUES LESS THAN or VALUES IN clauses with PARTITION BY KEY.

- **RANGE(expr)**

  In this case, `expr` shows a range of values using a set of VALUES LESS THAN operators. When using range partitioning, you must define at least one partition using VALUES LESS THAN. You cannot use VALUES IN with range partitioning.

  **Note**

  For tables partitioned by RANGE, VALUES LESS THAN must be used with either an integer literal value or an expression that evaluates to a single integer value. In MySQL 8.2, you can overcome this limitation in a table that is defined using PARTITION BY RANGE COLUMNS, as described later in this section.

Suppose that you have a table that you wish to partition on a column containing year values, according to the following scheme.

<table>
<thead>
<tr>
<th>Partition Number:</th>
<th>Years Range:</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1990 and earlier</td>
</tr>
<tr>
<td>1</td>
<td>1991 to 1994</td>
</tr>
<tr>
<td>2</td>
<td>1995 to 1998</td>
</tr>
<tr>
<td>3</td>
<td>1999 to 2002</td>
</tr>
<tr>
<td>4</td>
<td>2003 to 2005</td>
</tr>
<tr>
<td>5</td>
<td>2006 and later</td>
</tr>
</tbody>
</table>

A table implementing such a partitioning scheme can be realized by the CREATE TABLE statement shown here:

```sql
CREATE TABLE t1 (    
    year_col INT,    
    some_data INT   
)    
PARTITION BY RANGE (year_col) {    
    PARTITION p0 VALUES LESS THAN (1991),    
    PARTITION p1 VALUES LESS THAN (1995),    
    PARTITION p2 VALUES LESS THAN (1999),    
    PARTITION p3 VALUES LESS THAN (2002),    
    PARTITION p4 VALUES LESS THAN (2006),    
    PARTITION p5 VALUES LESS THAN MAXVALUE
```
CREATE TABLE rc (  
a INT NOT NULL,  
b INT NOT NULL
)
PARTITION BY RANGE COLUMNS(a,b) (  
    PARTITION p0 VALUES LESS THAN (10,5),  
    PARTITION p1 VALUES LESS THAN (20,10),  
    PARTITION p2 VALUES LESS THAN (50,MAXVALUE),  
    PARTITION p3 VALUES LESS THAN (65,MAXVALUE),  
    PARTITION p4 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);
CREATE TABLE Statement

- LIST(expr)

This is useful when assigning partitions based on a table column with a restricted set of possible values, such as a state or country code. In such a case, all rows pertaining to a certain state or country can be assigned to a single partition, or a partition can be reserved for a certain set of states or countries. It is similar to RANGE, except that only VALUES IN may be used to specify permissible values for each partition.

VALUES IN is used with a list of values to be matched. For instance, you could create a partitioning scheme such as the following:

```sql
CREATE TABLE client_firms (
    id   INT,
    name VARCHAR(35)
) PARTITION BY LIST (id) (
    PARTITION r0 VALUES IN (1, 5, 9, 13, 17, 21),
    PARTITION r1 VALUES IN (2, 6, 10, 14, 18, 22),
    PARTITION r2 VALUES IN (3, 7, 11, 15, 19, 23),
    PARTITION r3 VALUES IN (4, 8, 12, 16, 20, 24)
);
```

When using list partitioning, you must define at least one partition using VALUES IN. You cannot use VALUES LESS THAN with PARTITION BY LIST.

Note

For tables partitioned by LIST, the value list used with VALUES IN must consist of integer values only. In MySQL 8.2, you can overcome this limitation using partitioning by LIST COLUMNS, which is described later in this section.

- LIST COLUMNS(column_list)

This variant on LIST facilitates partition pruning for queries using comparison conditions on multiple columns (that is, having conditions such as \( a = 5 \) AND \( b = 5 \) or \( a = 1 \) AND \( b = 10 \) AND \( c = 5 \)). It enables you to specify values in multiple columns by using a list of columns in the COLUMNS clause and a set of column values in each PARTITION ... VALUES IN (value_list) partition definition clause.

The rules governing regarding data types for the column list used in LIST COLUMNS(column_list) and the value list used in VALUES IN(value_list) are the same as those for the column list used in RANGE COLUMNS(column_list) and the value list used in VALUES LESS THAN(value_list), respectively, except that in the VALUES IN clause, MAXVALUE is not permitted, and you may use NULL.

There is one important difference between the list of values used for VALUES IN with PARTITION BY LIST COLUMNS as opposed to when it is used with PARTITION BY LIST. When used with PARTITION BY LIST COLUMNS, each element in the VALUES IN clause must be a set of column values; the number of values in each set must be the same as the number of columns used in the COLUMNS clause, and the data types of these values must match those of the columns (and occur in the same order). In the simplest case, the set consists of a single column. The maximum number of columns that can be used in the column_list and in the elements making up the value_list is 16.

The table defined by the following CREATE TABLE statement provides an example of a table using LIST COLUMNS partitioning:

```sql
CREATE TABLE lc (
    a INT NULL,
    b INT NULL
)
```
CREATE TABLE Statement

PARTITION BY LIST COLUMNS(a,b) (  
    PARTITION p0 VALUES IN( (0,0), (NULL,NULL) ),
    PARTITION p1 VALUES IN( (0,1), (0,2), (0,3), (1,1), (1,2) ),
    PARTITION p2 VALUES IN( (1,0), (2,0), (2,1), (3,0), (3,1) ),
    PARTITION p3 VALUES IN( (1,3), (2,2), (2,3), (3,2), (3,3) )
);

• PARTITIONS num

The number of partitions may optionally be specified with a PARTITIONS num clause, where num is the number of partitions. If both this clause and any PARTITION clauses are used, num must be equal to the total number of any partitions that are declared using PARTITION clauses.

Note

Whether or not you use a PARTITIONS clause in creating a table that is partitioned by RANGE or LIST, you must still include at least one PARTITION VALUES clause in the table definition (see below).

• SUBPARTITION BY

A partition may optionally be divided into a number of subpartitions. This can be indicated by using the optional SUBPARTITION BY clause. Subpartitioning may be done by HASH or KEY. Either of these may be LINEAR. These work in the same way as previously described for the equivalent partitioning types. (It is not possible to subpartition by LIST or RANGE.)

The number of subpartitions can be indicated using the SUBPARTITIONS keyword followed by an integer value.

• Rigorous checking of the value used in PARTITIONS or SUBPARTITIONS clauses is applied and this value must adhere to the following rules:

  • The value must be a positive, nonzero integer.
  • No leading zeros are permitted.
  • The value must be an integer literal, and cannot not be an expression. For example, PARTITIONS 0.2E+01 is not permitted, even though 0.2E+01 evaluates to 2. (Bug #15890)

• partition_definition

Each partition may be individually defined using a partition_definition clause. The individual parts making up this clause are as follows:

  • PARTITION partition_name

    Specifies a logical name for the partition.

  • VALUES

    For range partitioning, each partition must include a VALUES LESS THAN clause; for list partitioning, you must specify a VALUES IN clause for each partition. This is used to determine which rows are
CREATE TABLE Statement
to be stored in this partition. See the discussions of partitioning types in Chapter 24, Partitioning, for syntax examples.

• [STORAGE] ENGINE

MySQL accepts a [STORAGE] ENGINE option for both PARTITION and SUBPARTITION. Currently, the only way in which this option can be used is to set all partitions or all subpartitions to the same storage engine, and an attempt to set different storage engines for partitions or subpartitions in the same table raises the error ERROR 1469 (HY000): The mix of handlers in the partitions is not permitted in this version of MySQL.

• COMMENT

An optional COMMENT clause may be used to specify a string that describes the partition. Example:

<table>
<thead>
<tr>
<th>COMMENT = 'Data for the years previous to 1999'</th>
</tr>
</thead>
</table>

The maximum length for a partition comment is 1024 characters.

• DATA DIRECTORY and INDEX DIRECTORY

DATA DIRECTORY and INDEX DIRECTORY may be used to indicate the directory where, respectively, the data and indexes for this partition are to be stored. Both the data_dir and the index_dir must be absolute system path names.

The directory specified in a DATA DIRECTORY clause must be known to InnoDB. For more information, see Using the DATA DIRECTORY Clause.

You must have the FILE privilege to use the DATA DIRECTORY or INDEX DIRECTORY partition option.

Example:

```sql
CREATE TABLE th (id INT, name VARCHAR(30), adate DATE)
PARTITION BY LIST(YEAR(adate))
(
    DATA DIRECTORY = '/var/appdata/95/data'
    INDEX DIRECTORY = '/var/appdata/95/idx',
    DATA DIRECTORY = '/var/appdata/96/data'
    INDEX DIRECTORY = '/var/appdata/96/idx',
    DATA DIRECTORY = '/var/appdata/97/data'
    INDEX DIRECTORY = '/var/appdata/97/idx',
    DATA DIRECTORY = '/var/appdata/98/data'
    INDEX DIRECTORY = '/var/appdata/98/idx'
)```
CREATE TABLE Statement

`DATA DIRECTORY` and `INDEX DIRECTORY` behave in the same way as in the `CREATE TABLE` statement's `table_option` clause as used for `MyISAM` tables.

One data directory and one index directory may be specified per partition. If left unspecified, the data and indexes are stored by default in the table’s database directory.

The `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored for creating partitioned tables if `NO_DIR_IN_CREATE` is in effect.

- **MAX_ROWS** and **MIN_ROWS**

  May be used to specify, respectively, the maximum and minimum number of rows to be stored in the partition. The values for `max_number_of_rows` and `min_number_of_rows` must be positive integers. As with the table-level options with the same names, these act only as “suggestions” to the server and are not hard limits.

- **TABLESPACE**

  May be used to designate an `InnoDB` file-per-table tablespace for the partition by specifying `TABLESPACE `innodb_file_per_table`. All partitions must belong to the same storage engine.

  Placing `InnoDB` table partitions in shared `InnoDB` tablespaces is not supported. Shared tablespaces include the `InnoDB` system tablespace and general tablespaces.

- **subpartition_definition**

  The partition definition may optionally contain one or more `subpartition_definition` clauses. Each of these consists at a minimum of the `SUBPARTITION name`, where `name` is an identifier for the subpartition. Except for the replacement of the `PARTITION` keyword with `SUBPARTITION`, the syntax for a subpartition definition is identical to that for a partition definition.

  Subpartitioning must be done by `HASH` or `KEY`, and can be done only on `RANGE` or `LIST` partitions. See Section 24.2.6, “Subpartitioning”.

**Partitioning by Generated Columns**

Partitioning by generated columns is permitted. For example:

```sql
CREATE TABLE t1 (  
  s1 INT,  
  s2 INT AS (EXP(s1)) STORED  
)  
PARTITION BY LIST (s2) {  
  PARTITION p1 VALUES IN (1)  
};
```

Partitioning sees a generated column as a regular column, which enables workarounds for limitations on functions that are not permitted for partitioning (see Section 24.6.3, “Partitioning Limitations Relating to Functions”). The preceding example demonstrates this technique: `EXP()` cannot be used directly in the `PARTITION BY` clause, but a generated column defined using `EXP()` is permitted.

**13.1.20.1 Files Created by CREATE TABLE**

For an `InnoDB` table created in a file-per-table tablespace or general tablespace, table data and associated indexes are stored in a `.ibd` file in the database directory. When an `InnoDB` table is created in the system tablespace, table data and indexes are stored in the `ibdata*` files that represent the system.
CREATE TABLE Statement

tablespace. The innodb_file_per_table option controls whether tables are created in file-per-table tablespaces or the system tablespace, by default. The TABLESPACE option can be used to place a table in a file-per-table tablespace, general tablespace, or the system tablespace, regardless of the innodb_file_per_table setting.

For MyISAM tables, the storage engine creates data and index files. Thus, for each MyISAM table tbl_name, there are two disk files.

<table>
<thead>
<tr>
<th>File</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>tbl_name.MYD</td>
<td>Data file</td>
</tr>
<tr>
<td>tbl_name.MYI</td>
<td>Index file</td>
</tr>
</tbody>
</table>

Chapter 16, Alternative Storage Engines, describes what files each storage engine creates to represent tables. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in Section 9.2.4, “Mapping of Identifiers to File Names”.

13.1.20.2 CREATE TEMPORARY TABLE Statement

You can use the TEMPORARY keyword when creating a table. A TEMPORARY table is visible only within the current session, and is dropped automatically when the session is closed. This means that two different sessions can use the same temporary table name without conflicting with each other or with an existing non-TEMPORARY table of the same name. (The existing table is hidden until the temporary table is dropped.)

InnoDB does not support compressed temporary tables. When innodb_strict_mode is enabled (the default), CREATE TEMPORARY TABLE returns an error if ROW_FORMAT=COMPRESSED or KEY_BLOCK_SIZE is specified. If innodb_strict_mode is disabled, warnings are issued and the temporary table is created using a non-compressed row format. The innodb_file_per_table option does not affect the creation of InnoDB temporary tables.

CREATE TABLE causes an implicit commit, except when used with the TEMPORARY keyword. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

TEMPORARY tables have a very loose relationship with databases (schemas). Dropping a database does not automatically drop any TEMPORARY tables created within that database.

To create a temporary table, you must have the CREATE TEMPORARY TABLES privilege. After a session has created a temporary table, the server performs no further privilege checks on the table. The creating session can perform any operation on the table, such as DROP TABLE, INSERT, UPDATE, or SELECT.

One implication of this behavior is that a session can manipulate its temporary tables even if the current user has no privilege to create them. Suppose that the current user does not have the CREATE TEMPORARY TABLES privilege but is able to execute a definer-context stored procedure that executes with the privileges of a user who does have CREATE TEMPORARY TABLES and that creates a temporary table.

While the procedure executes, the session uses the privileges of the defining user. After the procedure returns, the effective privileges revert to those of the current user, which can still see the temporary table and perform any operation on it.

You cannot use CREATE TEMPORARY TABLE ... LIKE to create an empty table based on the definition of a table that resides in the mysql tablespace, InnoDB system tablespace (innodb_system), or a general tablespace. The tablespace definition for such a table includes a TABLESPACE attribute that defines the tablespace where the table resides, and the aforementioned tablespaces do not support temporary tables. To create a temporary table based on the definition of such a table, use this syntax instead:

```
CREATE TEMPORARY TABLE new_tbl SELECT * FROM orig_tbl LIMIT 0;
```
Important

You cannot execute CREATE TABLE or CREATE TABLE ... LIKE while a LOCK TABLES statement is in effect.

CREATE TABLE ... LIKE makes the same checks as CREATE TABLE. This means that if the current SQL mode is different from the mode in effect when the original table was created, the table definition might be considered invalid for the new mode and cause the statement to fail.

For CREATE TABLE ... LIKE, the destination table preserves generated column information from the original table.

For CREATE TABLE ... LIKE, the destination table preserves expression default values from the original table.

For CREATE TABLE ... LIKE, the destination table preserves CHECK constraints from the original table, except that all the constraint names are generated.

CREATE TABLE ... LIKE does not preserve any DATA DIRECTORY or INDEX DIRECTORY table options that were specified for the original table, or any foreign key definitions.

If the original table is a TEMPORARY table, CREATE TABLE ... LIKE does not preserve TEMPORARY. To create a TEMPORARY destination table, use CREATE TEMPORARY TABLE ... LIKE.

Tables created in the mysql tablespace, the InnoDB system tablespace (innodb_system), or general tablespaces include a TABLESPACE attribute in the table definition, which defines the tablespace where the table resides. Due to a temporary regression, CREATE TABLE ... LIKE preserves the TABLESPACE attribute and creates the table in the defined tablespace regardless of the innodb_file_per_table setting. To avoid the TABLESPACE attribute when creating an empty table based on the definition of such a table, use this syntax instead:

CREATE TABLE new_tbl SELECT * FROM orig_tbl LIMIT 0;

CREATE TABLE ... LIKE operations apply all ENGINE_ATTRIBUTE and SECONDARY_ENGINE_ATTRIBUTE values to the new table.

13.1.20.4 CREATE TABLE ... SELECT Statement

You can create one table from another by adding a SELECT statement at the end of the CREATE TABLE statement:
CREATE TABLE new_tbl [AS] SELECT * FROM orig_tbl;

MySQL creates new columns for all elements in the SELECT. For example:

```
mysql> CREATE TABLE test (a INT NOT NULL AUTO_INCREMENT,
                   PRIMARY KEY (a), KEY(b))
                   ENGINE=InnoDB SELECT b,c FROM test2;
```

This creates an InnoDB table with three columns, a, b, and c. The ENGINE option is part of the CREATE TABLE statement, and should not be used following the SELECT; this would result in a syntax error. The same is true for other CREATE TABLE options such as CHARSET.

Notice that the columns from the SELECT statement are appended to the right side of the table, not overlapped onto it. Take the following example:

```
mysql> SELECT * FROM foo;
+---+
| n |
+---+
| 1 |
+---+
mysql> CREATE TABLE bar (m INT) SELECT n FROM foo;
Query OK, 1 row affected (0.02 sec)
Records: 1  Duplicates: 0  Warnings: 0
mysql> SELECT * FROM bar;
+------+
| m    |
| n    |
+------+
| NULL |
| 1    |
+------+
1 row in set (0.00 sec)
```

For each row in table foo, a row is inserted in bar with the values from foo and default values for the new columns.

In a table resulting from CREATE TABLE ... SELECT, columns named only in the CREATE TABLE part come first. Columns named in both parts or only in the SELECT part come after that. The data type of SELECT columns can be overridden by also specifying the column in the CREATE TABLE part.

For storage engines that support both atomic DDL and foreign key constraints, creation of foreign keys is not permitted in CREATE TABLE ... SELECT statements when row-based replication is in use. Foreign key constraints can be added later using ALTER TABLE.

You can precede the SELECT by IGNORE or REPLACE to indicate how to handle rows that duplicate unique key values. With IGNORE, rows that duplicate an existing row on a unique key value are discarded. With REPLACE, new rows replace rows that have the same unique key value. If neither IGNORE nor REPLACE is specified, duplicate unique key values result in an error. For more information, see The Effect of IGNORE on Statement Execution.

You can also use a VALUES statement in the SELECT part of CREATE TABLE ... SELECT; the VALUES portion of the statement must include a table alias using an AS clause. To name the columns coming from VALUES, supply column aliases with the table alias; otherwise, the default column names column_0, column_1, column_2, ..., are used.

Otherwise, naming of columns in the table thus created follows the same rules as described previously in this section. Examples:

```
mysql> CREATE TABLE tv1
   >   SELECT * FROM (VALUES ROW(1,3,5), ROW(2,4,6)) AS v;
```
CREATE TABLE Statement

```sql
mysql> CREATE TABLE tv1;
+----------+----------+----------+
<table>
<thead>
<tr>
<th>column_0</th>
<th>column_1</th>
<th>column_2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3</td>
<td>5</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>6</td>
</tr>
</tbody>
</table>
+----------+----------+----------+

mysql> CREATE TABLE tv2
    > SELECT * FROM (VALUES ROW(1,3,5), ROW(2,4,6)) AS v(x,y,z);

mysql> CREATE TABLE tv3 (a INT, b INT, c INT)
    > SELECT * FROM (VALUES ROW(1,3,5), ROW(2,4,6)) AS v(x,y,z);

mysql> CREATE TABLE tv4 (a INT, b INT, c INT)
    > SELECT * FROM (VALUES ROW(1,3,5), ROW(2,4,6)) AS v(x,y,z);

mysql> CREATE TABLE tv5 (a INT, b INT, c INT)
    > SELECT * FROM (VALUES ROW(1,3,5), ROW(2,4,6)) AS v(a,b,c);
```

When selecting all columns and using the default column names, you can omit `SELECT *`, so the statement just used to create table `tv1` can also be written as shown here:

```sql
mysql> CREATE TABLE tv1 VALUES ROW(1,3,5), ROW(2,4,6);
```

When using `VALUES` as the source of the `SELECT`, all columns are always selected into the new table, and individual columns cannot be selected as they can be when selecting from a named table; each of the following statements produces an error (`ER_OPERAND_COLUMNS`):

```sql
CREATE TABLE tvx
SELECT (x,z) FROM (VALUES ROW(1,3,5), ROW(2,4,6)) AS v(x,y,z);
```
CREATE TABLE tvx (a INT, c INT)
SELECT (x,z) FROM (VALUES ROW(1,3,5), ROW(2,4,6)) AS v(x,y,z);

Similarly, you can use a TABLE statement in place of the SELECT. This follows the same rules as with VALUES; all columns of the source table and their names in the source table are always inserted into the new table. Examples:

```
mysql> TABLE t1;
+----+----+
| a  | b  |
+----+----+
| 1  | 2 |
| 6  | 7 |
| 10 | -4 |
| 14 | 6 |
+----+----+

mysql> CREATE TABLE tt1 TABLE t1;

mysql> TABLE tt1;
+----+----+
| a  | b  |
+----+----+
| 1  | 2 |
| 6  | 7 |
| 10 | -4 |
| 14 | 6 |
+----+----+

mysql> CREATE TABLE tt2 (x INT) TABLE t1;

mysql> TABLE tt2;
+-----+----+----+
| x    | a  | b  |
+-----+----+----+
| NULL | 1  | 2 |
| NULL | 6  | 7 |
| NULL | 10 | -4 |
| NULL | 14 | 6 |
+-----+----+----+
```

Because the ordering of the rows in the underlying SELECT statements cannot always be determined, CREATE TABLE ... IGNORE SELECT and CREATE TABLE ... REPLACE SELECT statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using MIXED mode. See also Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

CREATE TABLE ... SELECT does not automatically create any indexes for you. This is done intentionally to make the statement as flexible as possible. If you want to have indexes in the created table, you should specify these before the SELECT statement:

```
mysql> CREATE TABLE bar (UNIQUE (n)) SELECT n FROM foo;
```

For CREATE TABLE ... SELECT, the destination table does not preserve information about whether columns in the selected-from table are generated columns. The SELECT part of the statement cannot assign values to generated columns in the destination table.

For CREATE TABLE ... SELECT, the destination table does preserve expression default values from the original table.

Some conversion of data types might occur. For example, the AUTO_INCREMENT attribute is not preserved, and VARCHAR columns can become CHAR columns. Retrained attributes are NULL (or NOT...
CREATE TABLE artists_and_works
    SELECT artist.name, COUNT(work.artist_id) AS number_of_works
    FROM artist LEFT JOIN work ON artist.id = work.artist_id
    GROUP BY artist.id;

You can also explicitly specify the data type for a column in the created table:

CREATE TABLE foo (a TINYINT NOT NULL) SELECT b+1 AS a FROM bar;

For CREATE TABLE ... SELECT, if IF NOT EXISTS is given and the target table exists, nothing is inserted into the destination table, and the statement is not logged.

To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts during CREATE TABLE ... SELECT. For more information, see Section 13.1.1, “Atomic Data Definition Statement Support”.

You cannot use FOR UPDATE as part of the SELECT in a statement such as CREATE TABLE new_table SELECT ... FROM old_table .... If you attempt to do so, the statement fails.

CREATE TABLE ... SELECT operations apply ENGINE_ATTRIBUTE and SECONDARY_ENGINE_ATTRIBUTE values to columns only. Table and index ENGINE_ATTRIBUTE and SECONDARY_ENGINE_ATTRIBUTE values are not applied to the new table unless specified explicitly.

13.1.20.5 FOREIGN KEY Constraints

MySQL supports foreign keys, which permit cross-referencing related data across tables, and foreign key constraints, which help keep the related data consistent.

A foreign key relationship involves a parent table that holds the initial column values, and a child table with column values that reference the parent column values. A foreign key constraint is defined on the child table.

The essential syntax for a defining a foreign key constraint in a CREATE TABLE or ALTER TABLE statement includes the following:

[CONSTRAINT [symbol]] FOREIGN KEY
    REFERENCES tbi_name (col_name,...)
    [ON DELETE reference_option]
    [ON UPDATE reference_option]

reference_option:
    RESTRICT | CASCADE | SET NULL | NO ACTION | SET DEFAULT

Foreign key constraint usage is described under the following topics in this section:

• Identifiers

• Conditions and Restrictions

• Referential Actions

• Foreign Key Constraint Examples
CREATE TABLE Statement

- Adding Foreign Key Constraints
- Dropping Foreign Key Constraints
- Foreign Key Checks
- Locking
- Foreign Key Definitions and Metadata
- Foreign Key Errors

Identifiers

Foreign key constraint naming is governed by the following rules:

- The `CONSTRAINT symbol` value is used, if defined.

- If the `CONSTRAINT symbol` clause is not defined, or a symbol is not included following the `CONSTRAINT` keyword, a constraint name name is generated automatically.

  If the `CONSTRAINT symbol` clause is not defined, or a symbol is not included following the `CONSTRAINT` keyword, both InnoDB and NDB storage engines ignore `FOREIGN_KEY index_name`.

- The `CONSTRAINT symbol` value, if defined, must be unique in the database. A duplicate symbol results in an error similar to: `ERROR 1005 (HY000): Can't create table 'test.fk1' (errno: 121)`.

- NDB Cluster stores foreign key names using the same lettercase with which they are created.

Table and column identifiers in a `FOREIGN KEY ... REFERENCES` clause can be quoted within backticks (``). Alternatively, double quotation marks (") can be used if the ANSI_QUOTES SQL mode is enabled. The `lower_case_table_names` system variable setting is also taken into account.

Conditions and Restrictions

Foreign key constraints are subject to the following conditions and restrictions:

- Parent and child tables must use the same storage engine, and they cannot be defined as temporary tables.

- Creating a foreign key constraint requires the `REFERENCES` privilege on the parent table.

- Corresponding columns in the foreign key and the referenced key must have similar data types. The size and sign of fixed precision types such as `INTEGER` and `DECIMAL` must be the same. The length of string types need not be the same. For nonbinary (character) string columns, the character set and collation must be the same.

- MySQL supports foreign key references between one column and another within a table. (A column cannot have a foreign key reference to itself.) In these cases, a "child table record" refers to a dependent record within the same table.

- MySQL requires indexes on foreign keys and referenced keys so that foreign key checks can be fast and not require a table scan. In the referencing table, there must be an index where the foreign key columns are listed as the first columns in the same order. Such an index is created on the referencing table automatically if it does not exist. This index might be silently dropped later if you create another index that can be used to enforce the foreign key constraint. `index_name`, if given, is used as described previously.
**CREATE TABLE Statement**

- **InnoDB** permits a foreign key to reference any index column or group of columns. However, in the referenced table, there must be an index where the referenced columns are the *first* columns in the same order. Hidden columns that **InnoDB** adds to an index are also considered (see Section 15.6.2.1, “Clustered and Secondary Indexes”).

**NDB** requires an explicit unique key (or primary key) on any column referenced as a foreign key. **InnoDB** does not, which is an extension of standard SQL.

- Index prefixes on foreign key columns are not supported. Consequently, **BLOB** and **TEXT** columns cannot be included in a foreign key because indexes on those columns must always include a prefix length.

- **InnoDB** does not currently support foreign keys for tables with user-defined partitioning. This includes both parent and child tables.

This restriction does not apply for **NDB** tables that are partitioned by **KEY** or **LINEAR KEY** (the only user partitioning types supported by the **NDB** storage engine); these may have foreign key references or be the targets of such references.

- A table in a foreign key relationship cannot be altered to use another storage engine. To change the storage engine, you must drop any foreign key constraints first.

- A foreign key constraint cannot reference a virtual generated column.

For information about how the MySQL implementation of foreign key constraints differs from the SQL standard, see Section 1.6.2.3, “FOREIGN KEY Constraint Differences”.

**Referential Actions**

When an **UPDATE** or **DELETE** operation affects a key value in the parent table that has matching rows in the child table, the result depends on the referential action specified by **ON UPDATE** and **ON DELETE** subclauses of the **FOREIGN KEY** clause. Referential actions include:

- **CASCADE**: Delete or update the row from the parent table and automatically delete or update the matching rows in the child table. Both **ON DELETE CASCADE** and **ON UPDATE CASCADE** are supported. Between two tables, do not define several **ON UPDATE CASCADE** clauses that act on the same column in the parent table or in the child table.

If a **FOREIGN KEY** clause is defined on both tables in a foreign key relationship, making both tables a parent and child, an **ON UPDATE CASCADE** or **ON DELETE CASCADE** subclause defined for one **FOREIGN KEY** clause must be defined for the other in order for cascading operations to succeed. If an **ON UPDATE CASCADE** or **ON DELETE CASCADE** subclause is only defined for one **FOREIGN KEY** clause, cascading operations fail with an error.

**Note**

Cascaded foreign key actions do not activate triggers.

- **SET NULL**: Delete or update the row from the parent table and set the foreign key column or columns in the child table to **NULL**. Both **ON DELETE SET NULL** and **ON UPDATE SET NULL** clauses are supported.

If you specify a **SET NULL** action, *make sure that you have not declared the columns in the child table as NOT NULL*.

- **RESTRICT**: Rejects the delete or update operation for the parent table. Specifying **RESTRICT** (or **NO ACTION**) is the same as omitting the **ON DELETE** or **ON UPDATE** clause.
CREATE TABLE Statement

• **NO ACTION**: A keyword from standard SQL. For InnoDB, this is equivalent to RESTRICT; the delete or update operation for the parent table is immediately rejected if there is a related foreign key value in the referenced table. NDB supports deferred checks, and NO ACTION specifies a deferred check; when this is used, constraint checks are not performed until commit time. Note that for NDB tables, this causes all foreign key checks made for both parent and child tables to be deferred.

• **SET DEFAULT**: This action is recognized by the MySQL parser, but both InnoDB and NDB reject table definitions containing ON DELETE SET DEFAULT or ON UPDATE SET DEFAULT clauses.

For storage engines that support foreign keys, MySQL rejects any INSERT or UPDATE operation that attempts to create a foreign key value in a child table if there is no matching candidate key value in the parent table.

For an ON DELETE or ON UPDATE that is not specified, the default action is always NO ACTION.

As the default, an ON DELETE NO ACTION or ON UPDATE NO ACTION clause that is specified explicitly does not appear in SHOW CREATE TABLE output or in tables dumped with mysqldump. RESTRICT, which is an equivalent non-default keyword, appears in SHOW CREATE TABLE output and in tables dumped with mysqldump.

For NDB tables, ON UPDATE CASCADE is not supported where the reference is to the parent table's primary key.

For NDB tables, ON DELETE CASCADE is not supported where the child table contains one or more columns of any of the TEXT or BLOB types. (Bug #89511, Bug #27484882)

InnoDB performs cascading operations using a depth-first search algorithm on the records of the index that corresponds to the foreign key constraint.

A foreign key constraint on a stored generated column cannot use CASCADE, SET NULL, or SET DEFAULT as ON UPDATE referential actions, nor can it use SET NULL or SET DEFAULT as ON DELETE referential actions.

A foreign key constraint on the base column of a stored generated column cannot use CASCADE, SET NULL, or SET DEFAULT as ON UPDATE or ON DELETE referential actions.

**Foreign Key Constraint Examples**

This simple example relates parent and child tables through a single-column foreign key:

```sql
CREATE TABLE parent {
    id INT NOT NULL,
    PRIMARY KEY (id)
} ENGINE=INNODB;

CREATE TABLE child {
    id INT,
    parent_id INT,
    INDEX par_ind (parent_id),
    FOREIGN KEY (parent_id)
        REFERENCES parent(id)
        ON DELETE CASCADE
} ENGINE=INNODB;
```

This is a more complex example in which a product_order table has foreign keys for two other tables. One foreign key references a two-column index in the product table. The other references a single-column index in the customer table:

```sql
CREATE TABLE product {
    category INT NOT NULL, id INT NOT NULL,
```
Adding Foreign Key Constraints

You can add a foreign key constraint to an existing table using the following `ALTER TABLE` syntax:

```
ALTER TABLE tbl_name
ADD [CONSTRAINT [symbol]] FOREIGN KEY
[index_name] (col_name, ...)
REFERENCES tbl_name (col_name,...)
[ON DELETE reference_option]
[ON UPDATE reference_option]
```

The foreign key can be self referential (referring to the same table). When you add a foreign key constraint to a table using `ALTER TABLE`, remember to first create an index on the column(s) referenced by the foreign key.

Dropping Foreign Key Constraints

You can drop a foreign key constraint using the following `ALTER TABLE` syntax:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

If the `FOREIGN KEY` clause defined a `CONSTRAINT` name when you created the constraint, you can refer to that name to drop the foreign key constraint. Otherwise, a constraint name was generated internally, and you must use that value. To determine the foreign key constraint name, use `SHOW CREATE TABLE`:
Adding and dropping a foreign key in the same `ALTER TABLE` statement is supported for `ALTER TABLE ... ALGORITHM=INPLACE`. It is not supported for `ALTER TABLE ... ALGORITHM=COPY`.

**Foreign Key Checks**

In MySQL, InnoDB and NDB tables support checking of foreign key constraints. Foreign key checking is controlled by the `foreign_key_checks` variable, which is enabled by default. Typically, you leave this variable enabled during normal operation to enforce referential integrity. The `foreign_key_checks` variable has the same effect on NDB tables as it does for InnoDB tables.

The `foreign_key_checks` variable is dynamic and supports both global and session scopes. For information about using system variables, see Section 5.1.9, “Using System Variables”.

Disabling foreign key checking is useful when:

- Dropping a table that is referenced by a foreign key constraint. A referenced table can only be dropped after `foreign_key_checks` is disabled. When you drop a table, constraints defined on the table are also dropped.

- Reloading tables in different order than required by their foreign key relationships. For example, `mysqldump` produces correct definitions of tables in the dump file, including foreign key constraints for child tables. To make it easier to reload dump files for tables with foreign key relationships, `mysqldump` automatically includes a statement in the dump output that disables `foreign_key_checks`. This enables you to import the tables in any order in case the dump file contains tables that are not correctly ordered for foreign keys. Disabling `foreign_key_checks` also speeds up the import operation by avoiding foreign key checks.

- Executing `LOAD DATA` operations, to avoid foreign key checking.

- Performing an `ALTER TABLE` operation on a table that has a foreign key relationship.

When `foreign_key_checks` is disabled, foreign key constraints are ignored, with the following exceptions:

- Recreating a table that was previously dropped returns an error if the table definition does not conform to the foreign key constraints that reference the table. The table must have the correct column names and types. It must also have indexes on the referenced keys. If these requirements are not satisfied, MySQL returns Error 1005 that refers to `errno: 150` in the error message, which means that a foreign key constraint was not correctly formed.

- Altering a table returns an error (`errno: 150`) if a foreign key definition is incorrectly formed for the altered table.

- Dropping an index required by a foreign key constraint. The foreign key constraint must be removed before dropping the index.

- Creating a foreign key constraint where a column references a nonmatching column type.

Disabling `foreign_key_checks` has these additional implications:

- It is permitted to drop a database that contains tables with foreign keys that are referenced by tables outside the database.

- It is permitted to drop a table with foreign keys referenced by other tables.

- Enabling `foreign_key_checks` does not trigger a scan of table data, which means that rows added to a table while `foreign_key_checks` is disabled are not checked for consistency when `foreign_key_checks` is re-enabled.
CREATE TABLE Statement

Locking

MySQL extends metadata locks, as necessary, to tables that are related by a foreign key constraint. Extending metadata locks prevents conflicting DML and DDL operations from executing concurrently on related tables. This feature also enables updates to foreign key metadata when a parent table is modified. In earlier MySQL releases, foreign key metadata, which is owned by the child table, could not be updated safely.

If a table is locked explicitly with `LOCK TABLES`, any tables related by a foreign key constraint are opened and locked implicitly. For foreign key checks, a shared read-only lock (`LOCK TABLES READ`) is taken on related tables. For cascading updates, a shared-nothing write lock (`LOCK TABLES WRITE`) is taken on related tables that are involved in the operation.

Foreign Key Definitions and Metadata

To view a foreign key definition, use `SHOW CREATE TABLE`:

```
mysql> SHOW CREATE TABLE child
+-------------------+-------------------+-------------------+-------------------+
| TABLE_SCHEMA      | TABLE_NAME        | COLUMN_NAME       | CONSTRAINT_NAME   |
+-------------------+-------------------+-------------------+-------------------+
| test              | child             | parent_id         | child_ibfk_1      |
+-------------------+-------------------+-------------------+-------------------+
```

You can obtain information about foreign keys from the Information Schema `KEY_COLUMN_USAGE` table. An example of a query against this table is shown here:

```
mysql> SELECT TABLE_SCHEMA, TABLE_NAME, COLUMN_NAME, CONSTRAINT_NAME
FROM INFORMATION_SCHEMA.KEY_COLUMN_USAGE
WHERE REFERENCED_TABLE_SCHEMA IS NOT NULL;
+-------------------+-------------------+-------------------+-------------------+
| TABLE_SCHEMA      | TABLE_NAME        | COLUMN_NAME       | CONSTRAINT_NAME   |
+-------------------+-------------------+-------------------+-------------------+
| test              | child             | parent_id         | child_ibfk_1      |
+-------------------+-------------------+-------------------+-------------------+
```

You can obtain information specific to InnoDB foreign keys from the `INNODB_FOREIGN` and `INNODB_FOREIGN_COLS` tables. Example queries are show here:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FOREIGN;
+-------------------+-------------------+----------------------------+
| ID                | FOR_NAME          | REF_NAME                   |
+-------------------+-------------------+----------------------------+
| test/child_ibfk_1 | test/child        | test/parent                |
+-------------------+-------------------+----------------------------+
```

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FOREIGN_COLS;
+-------------------+-------------------+-------------------+
| ID                | FOR_COL_NAME      | REF_COL_NAME      |
+-------------------+-------------------+-------------------+
| test/child_ibfk_1 | parent_id         | id                |
+-------------------+-------------------+-------------------+
```

Foreign Key Errors

In the event of a foreign key error involving InnoDB tables (usually Error 150 in the MySQL Server), information about the latest foreign key error can be obtained by checking `SHOW ENGINE INNODB STATUS` output.
CREATE TABLE Statement

mysql> SHOW ENGINE INNODB STATUS\G
...  
----------------------------------------
LATEST FOREIGN KEY ERROR
----------------------------------------
2018-04-12 14:57:24 0x7f97a9c91700 Transaction:
TRANSACTION 7717, ACTIVE 0 sec inserting
mysql tables in use 1, locked 1
4 lock struct(s), heap size 1136, 3 row lock(s), undo log entries 3
MySQL thread id 8, OS thread handle 140289365317376, query id 14 localhost root update
INSERT INTO child VALUES (NULL, 1), (NULL, 2), (NULL, 3), (NULL, 4), (NULL, 5), (NULL, 6)
Foreign key constraint fails for table `test`.`child`:

CONTRAINT `child_ibfk_1` FOREIGN KEY (`parent_id`) REFERENCES `parent` (`id`) ON DELETE CASCADE ON UPDATE CASCADE

Trying to add in child table, in index par_ind tuple:
DATA TUPLE: 2 fields;
0: len 4; hex 80000003; asc ;;
1: len 4; hex 80000003; asc ;;

But in parent table `test`.`parent`, in index PRIMARY,
the closest match we can find is record:
PHYSICAL RECORD: n_fields 3; compact format; info bits 0
0: len 4; hex 80000004; asc ;;
1: len 6; hex 00000001e19; asc ;;
2: len 7; hex 81000001110137; asc 7;;
...

Warning
If a user has table-level privileges for all parent tables,
ER_NO_REFERENCED_ROW_2 and ER_ROW_IS_REFERENCED_2 error messages
for foreign key operations expose information about parent tables. If a user does not
have table-level privileges for all parent tables, more generic error messages are
displayed instead (ER_NO_REFERENCED_ROW and ER_ROW_IS_REFERENCED).

An exception is that, for stored programs defined to execute with DEFINER
privileges, the user against which privileges are assessed is the user in the
program DEFINER clause, not the invoking user. If that user has table-level parent
table privileges, parent table information is still displayed. In this case, it is the
responsibility of the stored program creator to hide the information by including
appropriate condition handlers.

13.1.20.6 CHECK Constraints

CREATE TABLE permits the core features of table and column CHECK constraints, for all storage engines.
CREATE TABLE permits the following CHECK constraint syntax, for both table constraints and column
constraints:

[CONSTRAINT [symbol]] CHECK (expr) [[NOT] ENFORCED]

The optional symbol specifies a name for the constraint. If omitted, MySQL generates a name from the
table name, a literal _chk_, and an ordinal number (1, 2, 3, ...). Constraint names have a maximum length
of 64 characters. They are case-sensitive, but not accent-sensitive.

expr specifies the constraint condition as a boolean expression that must evaluate to TRUE or UNKNOWN
(for NULL values) for each row of the table. If the condition evaluates to FALSE, it fails and a constraint
violation occurs. The effect of a violation depends on the statement being executed, as described later in
this section.

The optional enforcement clause indicates whether the constraint is enforced:
CREATE TABLE Statement

- If omitted or specified as **ENFORCED**, the constraint is created and enforced.
- If specified as **NOT ENFORCED**, the constraint is created but not enforced.

A **CHECK** constraint is specified as either a table constraint or column constraint:

- A table constraint does not appear within a column definition and can refer to any table column or columns. Forward references are permitted to columns appearing later in the table definition.
- A column constraint appears within a column definition and can refer only to that column.

Consider this table definition:

```sql
CREATE TABLE t1
(
  c1 INT CHECK (c1 > 10),
  c2 INT CONSTRAINT c2_positive CHECK (c2 > 0),
  c3 INT CHECK (c3 < 100),
  CONSTRAINT c1_nonzero CHECK (c1 <> 0),
  CHECK (c1 > c3)
);
```

The definition includes table constraints and column constraints, in named and unnamed formats:

- The first constraint is a table constraint: It occurs outside any column definition, so it can (and does) refer to multiple table columns. This constraint contains forward references to columns not defined yet. No constraint name is specified, so MySQL generates a name.
- The next three constraints are column constraints: Each occurs within a column definition, and thus can refer only to the column being defined. One of the constraints is named explicitly. MySQL generates a name for each of the other two.
- The last two constraints are table constraints. One of them is named explicitly. MySQL generates a name for the other one.

As mentioned, MySQL generates a name for any **CHECK** constraint specified without one. To see the names generated for the preceding table definition, use **SHOW CREATE TABLE**:

```
mysql> SHOW CREATE TABLE t1;
```

The SQL standard specifies that all types of constraints (primary key, unique index, foreign key, check) belong to the same namespace. In MySQL, each constraint type has its own namespace per schema (database). Consequently, **CHECK** constraint names must be unique per schema; no two tables in the same schema can share a **CHECK** constraint name. (Exception: A **TEMPORARY** table hides a non-**TEMPORARY** table of the same name, so it can have the same **CHECK** constraint names as well.)

Beginning generated constraint names with the table name helps ensure schema uniqueness because table names also must be unique within the schema.
CHECK condition expressions must adhere to the following rules. An error occurs if an expression contains disallowed constructs.

- Nongenerated and generated columns are permitted, except columns with the \texttt{AUTO_INCREMENT} attribute and columns in other tables.

- Literals, deterministic built-in functions, and operators are permitted. A function is deterministic if, given the same data in tables, multiple invocations produce the same result, independently of the connected user. Examples of functions that are nondeterministic and fail this definition: \texttt{CONNECTION_ID()}, \texttt{CURRENT_USER()}, \texttt{NOW()}.

- Stored functions and loadable functions are not permitted.

- Stored procedure and function parameters are not permitted.

- Variables (system variables, user-defined variables, and stored program local variables) are not permitted.

- Subqueries are not permitted.

Foreign key referential actions (\texttt{ON UPDATE}, \texttt{ON DELETE}) are prohibited on columns used in \texttt{CHECK} constraints. Likewise, \texttt{CHECK} constraints are prohibited on columns used in foreign key referential actions.

\texttt{CHECK} constraints are evaluated for \texttt{INSERT}, \texttt{UPDATE}, \texttt{REPLACE}, \texttt{LOAD DATA}, and \texttt{LOAD XML} statements and an error occurs if a constraint evaluates to \texttt{FALSE}. If an error occurs, handling of changes already applied differs for transactional and nontransactional storage engines, and also depends on whether strict SQL mode is in effect, as described in Strict SQL Mode.

\texttt{CHECK} constraints are evaluated for \texttt{INSERT IGNORE}, \texttt{UPDATE IGNORE}, \texttt{LOAD DATA ... IGNORE}, and \texttt{LOAD XML ... IGNORE} statements and a warning occurs if a constraint evaluates to \texttt{FALSE}. The insert or update for any offending row is skipped.

If the constraint expression evaluates to a data type that differs from the declared column type, implicit coercion to the declared type occurs according to the usual MySQL type-conversion rules. See Section 12.3, “Type Conversion in Expression Evaluation”. If type conversion fails or results in a loss of precision, an error occurs.

\begin{quote}
\textbf{Note}
Constraint expression evaluation uses the SQL mode in effect at evaluation time. If any component of the expression depends on the SQL mode, different results may occur for different uses of the table unless the SQL mode is the same during all uses.
\end{quote}

The Information Schema \texttt{CHECK_CONSTRAINTS} table provides information about \texttt{CHECK} constraints defined on tables. See Section 26.3.5, “The INFORMATION_SCHEMA CHECK_CONSTRAINTS Table”.

\section*{13.1.20.7 Silent Column Specification Changes}

In some cases, MySQL silently changes column specifications from those given in a \texttt{CREATE TABLE} or \texttt{ALTER TABLE} statement. These might be changes to a data type, to attributes associated with a data type, or to an index specification.

All changes are subject to the internal row-size limit of 65,535 bytes, which may cause some attempts at data type changes to fail. See Section 8.4.7, “Limits on Table Column Count and Row Size”.

- Columns that are part of a \texttt{PRIMARY KEY} are made \texttt{NOT NULL} even if not declared that way.
CREATE TABLE Statement

- Trailing spaces are automatically deleted from `ENUM` and `SET` member values when the table is created.

- MySQL maps certain data types used by other SQL database vendors to MySQL types. See Section 11.9, "Using Data Types from Other Database Engines".

- If you include a `USING` clause to specify an index type that is not permitted for a given storage engine, but there is another index type available that the engine can use without affecting query results, the engine uses the available type.

- If strict SQL mode is not enabled, a `VARCHAR` column with a length specification greater than 65535 is converted to `TEXT`, and a `VARBINARY` column with a length specification greater than 65535 is converted to `BLOB`. Otherwise, an error occurs in either of these cases.

- Specifying the `CHARACTER SET binary` attribute for a character data type causes the column to be created as the corresponding binary data type: `CHAR` becomes `BINARY`, `VARCHAR` becomes `VARBINARY`, and `TEXT` becomes `BLOB`. For the `ENUM` and `SET` data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

```sql
CREATE TABLE t
(
  c1 VARCHAR(10) CHARACTER SET binary,
  c2 TEXT CHARACTER SET binary,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

The resulting table has this definition:

```sql
CREATE TABLE t
(
  c1 VARBINARY(10),
  c2 BLOB,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

To see whether MySQL used a data type other than the one you specified, issue a `DESCRIBE` or `SHOW CREATE TABLE` statement after creating or altering the table.

- Certain other data type changes can occur if you compress a table using `myisampack`. See Section 16.2.3.3, “Compressed Table Characteristics”.

### 13.1.20.8 CREATE TABLE and Generated Columns

`CREATE TABLE` supports the specification of generated columns. Values of a generated column are computed from an expression included in the column definition.

Generated columns are also supported by the `NDB` storage engine.

The following simple example shows a table that stores the lengths of the sides of right triangles in the `sidea` and `sideb` columns, and computes the length of the hypotenuse in `sidec` (the square root of the sums of the squares of the other sides):

```sql
CREATE TABLE triangle (sidea DOUBLE, sideb DOUBLE, sidec DOUBLE AS (SQRT(sidea * sidea + sideb * sideb)));
INSERT INTO triangle (sidea, sideb) VALUES(1,1),(3,4),(6,8);
```

Selecting from the table yields this result:
CREATE TABLE Statement

<table>
<thead>
<tr>
<th>sidea</th>
<th>sideb</th>
<th>sidec</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1.4142135623730951</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>5</td>
</tr>
<tr>
<td>6</td>
<td>8</td>
<td>10</td>
</tr>
</tbody>
</table>

Any application that uses the `triangle` table has access to the hypotenuse values without having to specify the expression that calculates them.

Generated column definitions have this syntax:

```sql
col_name data_type [GENERATED ALWAYS] AS (expr) 
[VIRTUAL | STORED] [NOT NULL | NULL] 
[UNIQUE [KEY]] [[PRIMARY] KEY] 
[COMMENT 'string']
```

`AS (expr)` indicates that the column is generated and defines the expression used to compute column values. `AS` may be preceded by `GENERATED ALWAYS` to make the generated nature of the column more explicit. Constructs that are permitted or prohibited in the expression are discussed later.

The `VIRTUAL` or `STORED` keyword indicates how column values are stored, which has implications for column use:

- **VIRTUAL**: Column values are not stored, but are evaluated when rows are read, immediately after any `BEFORE` triggers. A virtual column takes no storage.

  InnoDB supports secondary indexes on virtual columns. See Section 13.1.20.9, “Secondary Indexes and Generated Columns”.

- **STORED**: Column values are evaluated and stored when rows are inserted or updated. A stored column does require storage space and can be indexed.

The default is `VIRTUAL` if neither keyword is specified.

It is permitted to mix `VIRTUAL` and `STORED` columns within a table.

Other attributes may be given to indicate whether the column is indexed or can be `NULL`, or provide a comment.

Generated column expressions must adhere to the following rules. An error occurs if an expression contains disallowed constructs.

- Literals, deterministic built-in functions, and operators are permitted. A function is deterministic if, given the same data in tables, multiple invocations produce the same result, independently of the connected user. Examples of functions that are nondeterministic and fail this definition: `CONNECTION_ID()`, `CURRENT_USER()`, `NOW()`.

- Stored functions and loadable functions are not permitted.

- Stored procedure and function parameters are not permitted.

- Variables (system variables, user-defined variables, and stored program local variables) are not permitted.

- Subqueries are not permitted.
CREATE TABLE Statement

- A generated column definition can refer to other generated columns, but only those occurring earlier in the table definition. A generated column definition can refer to any base (nongenerated) column in the table whether its definition occurs earlier or later.

- The AUTO_INCREMENT attribute cannot be used in a generated column definition.

- An AUTO_INCREMENT column cannot be used as a base column in a generated column definition.

- If expression evaluation causes truncation or provides incorrect input to a function, the CREATE TABLE statement terminates with an error and the DDL operation is rejected.

If the expression evaluates to a data type that differs from the declared column type, implicit coercion to the declared type occurs according to the usual MySQL type-conversion rules. See Section 12.3, “Type Conversion in Expression Evaluation”.

If a generated column uses the TIMESTAMP data type, the setting for explicit_defaults_for_timestamp is ignored. In such cases, if this variable is disabled then NULL is not converted to CURRENT_TIMESTAMP. If the column is also declared as NOT NULL, attempting to insert NULL is explicitly rejected with ER_BAD_NULL_ERROR.

**Note**

Expression evaluation uses the SQL mode in effect at evaluation time. If any component of the expression depends on the SQL mode, different results may occur for different uses of the table unless the SQL mode is the same during all uses.

For CREATE TABLE ... LIKE, the destination table preserves generated column information from the original table.

For CREATE TABLE ... SELECT, the destination table does not preserve information about whether columns in the selected-from table are generated columns. The SELECT part of the statement cannot assign values to generated columns in the destination table.

Partitioning by generated columns is permitted. See Table Partitioning.

A foreign key constraint on a stored generated column cannot use CASCADE, SET NULL, or SET DEFAULT as ON UPDATE referential actions, nor can it use SET NULL or SET DEFAULT as ON DELETE referential actions.

A foreign key constraint on the base column of a stored generated column cannot use CASCADE, SET NULL, or SET DEFAULT as ON UPDATE or ON DELETE referential actions.

A foreign key constraint cannot reference a virtual generated column.

Triggers cannot use NEW.col_name or use OLD.col_name to refer to generated columns.

For INSERT, REPLACE, and UPDATE, if a generated column is inserted into, replaced, or updated explicitly, the only permitted value is DEFAULT.

A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is DEFAULT.

Generated columns have several use cases, such as these:

- Virtual generated columns can be used as a way to simplify and unify queries. A complicated condition can be defined as a generated column and referred to from multiple queries on the table to ensure that all of them use exactly the same condition.
CREATE TABLE Statement

- Stored generated columns can be used as a materialized cache for complicated conditions that are costly to calculate on the fly.

- Generated columns can simulate functional indexes: Use a generated column to define a functional expression and index it. This can be useful for working with columns of types that cannot be indexed directly, such as JSON columns; see Indexing a Generated Column to Provide a JSON Column Index, for a detailed example.

For stored generated columns, the disadvantage of this approach is that values are stored twice; once as the value of the generated column and once in the index.

- If a generated column is indexed, the optimizer recognizes query expressions that match the column definition and uses indexes from the column as appropriate during query execution, even if a query does not refer to the column directly by name. For details, see Section 8.3.11, “Optimizer Use of Generated Column Indexes”.

Example:

Suppose that a table \( t_1 \) contains \( \text{first\_name} \) and \( \text{last\_name} \) columns and that applications frequently construct the full name using an expression like this:

\[
\text{SELECT CONCAT(first\_name,' ',last\_name) AS full\_name FROM t1;}
\]

One way to avoid writing out the expression is to create a view \( v_1 \) on \( t_1 \), which simplifies applications by enabling them to select \( \text{full\_name} \) directly without using an expression:

\[
\begin{align*}
\text{CREATE VIEW v1 AS} \\
\text{SELECT *}, \text{CONCAT(first\_name,' ',last\_name) AS full\_name FROM t1;}
\end{align*}
\]

A generated column also enables applications to select \( \text{full\_name} \) directly without the need to define a view:

\[
\begin{align*}
\text{CREATE TABLE t1} \\
\quad \text{(first\_name VARCHAR(10),} \\
\quad \text{last\_name VARCHAR(10),} \\
\quad \text{full\_name VARCHAR(255) AS (CONCAT(first\_name,' ',last\_name))} \\
\); \\
\text{SELECT full\_name FROM t1;}
\end{align*}
\]

13.1.20.9 Secondary Indexes and Generated Columns

\textbf{InnoDB} supports secondary indexes on virtual generated columns. Other index types are not supported. A secondary index defined on a virtual column is sometimes referred to as a “virtual index”.

A secondary index may be created on one or more virtual columns or on a combination of virtual columns and regular columns or stored generated columns. Secondary indexes that include virtual columns may be defined as \texttt{UNIQUE}.

When a secondary index is created on a virtual generated column, generated column values are materialized in the records of the index. If the index is a covering index (one that includes all the columns retrieved by a query), generated column values are retrieved from materialized values in the index structure instead of computed “on the fly”.

There are additional write costs to consider when using a secondary index on a virtual column due to computation performed when materializing virtual column values in secondary index records during \texttt{INSERT} and \texttt{UPDATE} operations. Even with additional write costs, secondary indexes on virtual columns
CREATE TABLE Statement

may be preferable to generated *stored* columns, which are materialized in the clustered index, resulting in larger tables that require more disk space and memory. If a secondary index is not defined on a virtual column, there are additional costs for reads, as virtual column values must be computed each time the column's row is examined.

Values of an indexed virtual column are MVCC-logged to avoid unnecessary recomputation of generated column values during rollback or during a purge operation. The data length of logged values is limited by the index key limit of 767 bytes for *COMPACT* and *REDUNDANT* row formats, and 3072 bytes for *DYNAMIC* and *COMPRESSED* row formats.

Adding or dropping a secondary index on a virtual column is an in-place operation.

### Indexing a Generated Column to Provide a JSON Column Index

As noted elsewhere, *JSON* columns cannot be indexed directly. To create an index that references such a column indirectly, you can define a generated column that extracts the information that should be indexed, then create an index on the generated column, as shown in this example:

```sql
mysql> CREATE TABLE jemp (  ->  c JSON,  ->  g INT GENERATED ALWAYS AS (c->"$.id"),  ->  INDEX i (g)  -> );
Query OK, 0 rows affected (0.28 sec)

mysql> INSERT INTO jemp (c) VALUES
>  ('{"id": "1", "name": "Fred"}'), ('{"id": "2", "name": "Wilma"}'),
>  ('{"id": "3", "name": "Barney"}'), ('{"id": "4", "name": "Betty"}');
Query OK, 4 rows affected (0.04 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT c->"$.name" AS name
>  FROM jemp WHERE g > 2;
```

```
+--------+
<table>
<thead>
<tr>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Barney</td>
</tr>
<tr>
<td>Betty</td>
</tr>
</tbody>
</table>
+--------+
2 rows in set (0.00 sec)
```

```sql
mysql> EXPLAIN SELECT c->"$.name" AS name
>  FROM jemp WHERE g > 2;
```

```
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: jemp
partitions: NULL
type: range
possible_keys: i
key: i
key_len: 5
ref: NULL
rows: 2
filtered: 100.00
Extra: Using where
1 row in set, 1 warning (0.00 sec)
```
(We have wrapped the output from the last statement in this example to fit the viewing area.)

When you use `EXPLAIN` on a `SELECT` or other SQL statement containing one or more expressions that use the `->` or `->>` operator, these expressions are translated into their equivalents using `JSON_EXTRACT()` and (if needed) `JSON_UNQUOTE()` instead, as shown here in the output from `SHOW WARNINGS` immediately following this `EXPLAIN` statement:

```
mysql> EXPLAIN SELECT c->"$.name"
   > FROM jemp WHERE g > 2 ORDER BY c->"$.name"

*************************** 1. row ***************************
  id: 1
  select_type: SIMPLE
  table: jemp
  partitions: NULL
  type: range
  possible_keys: i
  key: i
  key_len: 5
  ref: NULL
  rows: 2
  filtered: 100.00
  Extra: Using where; Using filesort

1 row in set, 1 warning (0.00 sec)
```

```
mysql> SHOW WARNINGS

*************************** 1. row ***************************
  Level: Note
  Code: 1003
  Message: /* select#1 */ select json_unquote(json_extract(`test`.`jemp`.`c`,'$.name')) AS c->"$.name" from `test`.`jemp` where (`test`.`jemp`.`g` > 2) order by json_extract(`test`.`jemp`.`c`,'$.name')

1 row in set (0.00 sec)
```

See the descriptions of the `->` and `->>>` operators, as well as those of the `JSON_EXTRACT()` and `JSON_UNQUOTE()` functions, for additional information and examples.

This technique also can be used to provide indexes that indirectly reference columns of other types that cannot be indexed directly, such as `GEOMETRY` columns.

It is also possible to create an index on a `JSON` column using the `JSON_VALUE()` function with an expression that can be used to optimize queries employing the expression. See the description of that function for more information and examples.

**JSON columns and indirect indexing in NDB Cluster**

It is also possible to use indirect indexing of JSON columns in MySQL NDB Cluster, subject to the following conditions:

1. **NDB** handles a `JSON` column value internally as a `BLOB`. This means that any **NDB** table having one or more JSON columns must have a primary key, else it cannot be recorded in the binary log.

2. The **NDB** storage engine does not support indexing of virtual columns. Since the default for generated columns is `VIRTUAL`, you must specify explicitly the generated column to which to apply the indirect index as `STORED`.

The `CREATE TABLE` statement used to create the table `jempn` shown here is a version of the `jemp` table shown previously, with modifications making it compatible with **NDB**:

```
CREATE TABLE jempn (  
a BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
```
CREATE TABLE Statement

c JSON DEFAULT NULL,
g INT GENERATED ALWAYS AS (c->"$.id") STORED,
INDEX i (g)
) ENGINE=NDB;

We can populate this table using the following INSERT statement:
INSERT INTO jempn (c) VALUES
('{"id": "1", "name": "Fred"}'),
('{"id": "2", "name": "Wilma"}'),
('{"id": "3", "name": "Barney"}'),
('{"id": "4", "name": "Betty"}');

Now NDB can use index i, as shown here:
mysql> EXPLAIN SELECT c->>"$.name" AS name
->
FROM jempn WHERE g > 2\G
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: jempn
partitions: p0,p1,p2,p3
type: range
possible_keys: i
key: i
key_len: 5
ref: NULL
rows: 3
filtered: 100.00
Extra: Using pushed condition (`test`.`jempn`.`g` > 2)
1 row in set, 1 warning (0.01 sec)
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Note
Code: 1003
Message: /* select#1 */ select
json_unquote(json_extract(`test`.`jempn`.`c`,'$.name')) AS `name` from
`test`.`jempn` where (`test`.`jempn`.`g` > 2)
1 row in set (0.00 sec)

You should keep in mind that a stored generated column, as well as any index on such a column, uses
DataMemory.

13.1.20.10 Invisible Columns
MySQL 8.2 supports invisible columns. An invisible column is normally hidden to queries, but can be
accessed if explicitly referenced.
As an illustration of when invisible columns may be useful, suppose that an application uses SELECT *
queries to access a table, and must continue to work without modification even if the table is altered to add
a new column that the application does not expect to be there. In a SELECT * query, the * evaluates to
all table columns, except those that are invisible, so the solution is to add the new column as an invisible
column. The column remains “hidden” from SELECT * queries, and the application continues to work as
previously. A newer version of the application can refer to the invisible column if necessary by explicitly
referencing it.
The following sections detail how MySQL treats invisible columns.
• DDL Statements and Invisible Columns
• DML Statements and Invisible Columns

2729


CREATE TABLE Statement

- Invisible Column Metadata
- The Binary Log and Invisible Columns

**DDL Statements and Invisible Columns**

Columns are visible by default. To explicitly specify visibility for a new column, use a `VISIBLE` or `INVISIBLE` keyword as part of the column definition for `CREATE TABLE` or `ALTER TABLE`:

```sql
CREATE TABLE t1 (
    i INT,
    j DATE INVISIBLE
) ENGINE = InnoDB;
```

ALTER TABLE t1 ADD COLUMN k INT INVISIBLE;

To alter the visibility of an existing column, use a `VISIBLE` or `INVISIBLE` keyword with one of the `ALTER TABLE` column-modification clauses:

```sql
ALTER TABLE t1 CHANGE COLUMN j j DATE VISIBLE;
ALTER TABLE t1 MODIFY COLUMN j DATE INVISIBLE;
ALTER TABLE t1 ALTER COLUMN j SET VISIBLE;
```

A table must have at least one visible column. Attempting to make all columns invisible produces an error.

Invisible columns support the usual column attributes: `NULL`, `NOT NULL`, `AUTO_INCREMENT`, and so forth.

Generated columns can be invisible.

Index definitions can name invisible columns, including definitions for `PRIMARY KEY` and `UNIQUE` indexes. Although a table must have at least one visible column, an index definition need not have any visible columns.

An invisible column dropped from a table is dropped in the usual way from any index definition that names the column.

Foreign key constraints can be defined on invisible columns, and foreign key constraints can reference invisible columns.

`CHECK` constraints can be defined on invisible columns. For new or modified rows, violation of a `CHECK` constraint on an invisible column produces an error.

`CREATE TABLE ... LIKE` includes invisible columns, and they are invisible in the new table.

`CREATE TABLE ... SELECT` does not include invisible columns, unless they are explicitly referenced in the `SELECT` part. However, even if explicitly referenced, a column that is invisible in the existing table is visible in the new table:

```sql
mysql> CREATE TABLE t1 (col1 INT, col2 INT INVISIBLE);
mysql> CREATE TABLE t2 AS SELECT col1, col2 FROM t1;
mysql> SHOW CREATE TABLE t2\G
```

If invisibility should be preserved, provide a definition for the invisible column in the `CREATE TABLE` part of the `CREATE TABLE ... SELECT` statement:

```sql
mysql> CREATE TABLE t1 (col1 INT, col2 INT INVISIBLE);
```
CREATE TABLE Statement

CREATE TABLE t2 (col2 INT INVISIBLE) AS SELECT col1, col2 FROM t1;

SHOW CREATE TABLE t2\G

*************************** 1. row ***************************
Table: t2
Create Table: CREATE TABLE `t2` (
  `col1` int DEFAULT NULL,
  `col2` int DEFAULT NULL /*!80023 INVISIBLE */
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci

Views can refer to invisible columns by explicitly referencing them in the SELECT statement that defines the view. Changing a column's visibility subsequent to defining a view that references the column does not change view behavior.

DML Statements and Invisible Columns

For SELECT statements, an invisible column is not part of the result set unless explicitly referenced in the select list. In a select list, the * and tbl_name.* shorthands do not include invisible columns. Natural joins do not include invisible columns.

Consider the following statement sequence:

CREATE TABLE t1 (col1 INT, col2 INT INVISIBLE);
INSERT INTO t1 (col1, col2) VALUES(1, 2), (3, 4);
SELECT * FROM t1;
SELECT col1, col2 FROM t1;

The first SELECT does not reference the invisible column col2 in the select list (because * does not include invisible columns), so col2 does not appear in the statement result. The second SELECT explicitly references col2, so the column appears in the result.

The statement TABLE t1 produces the same output as the first SELECT statement. Since there is no way to specify columns in a TABLE statement, TABLE never displays invisible columns.

For statements that create new rows, an invisible column is assigned its implicit default value unless explicitly referenced and assigned a value. For information about implicit defaults, see Implicit Default Handling.

For INSERT (and REPLACE, for non-replaced rows), implicit default assignment occurs with a missing column list, an empty column list, or a nonempty column list that does not include the invisible column:

CREATE TABLE t1 (col1 INT, col2 INT INVISIBLE);
INSERT INTO t1 VALUES(...);
INSERT INTO t1 () VALUES(...);
INSERT INTO t1 (col1) VALUES(...);

For the first two INSERT statements, the VALUES() list must provide a value for each visible column and no invisible column. For the third INSERT statement, the VALUES() list must provide the same number
CREATE TABLE Statement

of values as the number of named columns; the same is true when you use VALUES ROW() rather than VALUES().

For LOAD DATA and LOAD XML, implicit default assignment occurs with a missing column list or a nonempty column list that does not include the invisible column. Input rows should not include a value for the invisible column.

To assign a value other than the implicit default for the preceding statements, explicitly name the invisible column in the column list and provide a value for it.

INSERT INTO ... SELECT * and REPLACE INTO ... SELECT * do not include invisible columns because * does not include invisible columns. Implicit default assignment occurs as described previously.

For statements that insert or ignore new rows, or that replace or modify existing rows, based on values in a PRIMARY KEY or UNIQUE index, MySQL treats invisible columns the same as visible columns: Invisible columns participate in key value comparisons. Specifically, if a new row has the same value as an existing row for a unique key value, these behaviors occur whether the index columns are visible or invisible:

• With the IGNORE modifier, INSERT, LOAD DATA, and LOAD XML ignore the new row.
• REPLACE replaces the existing row with the new row. With the REPLACE modifier, LOAD DATA and LOAD XML do the same.
• INSERT ... ON DUPLICATE KEY UPDATE updates the existing row.

To update invisible columns for UPDATE statements, name them and assign a value, just as for visible columns.

Invisible Column Metadata

Information about whether a column is visible or invisible is available from the EXTRA column of the Information Schema COLUMNS table or SHOW COLUMNS output. For example:

```
mysql> SELECT TABLE_NAME, COLUMN_NAME, EXTRA
    > FROM INFORMATION_SCHEMA.COLUMNS
    > WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 't1';
+------------+-------------+-----------+
<table>
<thead>
<tr>
<th>TABLE_NAME</th>
<th>COLUMN_NAME</th>
<th>EXTRA</th>
</tr>
</thead>
<tbody>
<tr>
<td>t1</td>
<td>i</td>
<td></td>
</tr>
<tr>
<td>t1</td>
<td>j</td>
<td></td>
</tr>
<tr>
<td>t1</td>
<td>k</td>
<td>INVISIBLE</td>
</tr>
</tbody>
</table>
+------------+-------------+-----------+
```

Columns are visible by default, so in that case, EXTRA displays no visibility information. For invisible columns, EXTRA displays INVISIBLE.

SHOW CREATE TABLE displays invisible columns in the table definition, with the INVISIBLE keyword in a version-specific comment:

```
mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
Table: t1
Create Table: CREATE TABLE `t1` (
  `i` int DEFAULT NULL,
  `j` int DEFAULT NULL,
  `k` int DEFAULT NULL/*!80023 INVISIBLE */
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
```

mysqldump and mysqlpump use SHOW CREATE TABLE, so they include invisible columns in dumped table definitions. They also include invisible column values in dumped data.
Reload a dump file into an older version of MySQL that does not support invisible columns causes the version-specific comment to be ignored, which creates any invisible columns as visible.

**The Binary Log and Invisible Columns**

MySQL treats invisible columns as follows with respect to events in the binary log:

- **Table-creation events** include the INVISIBLE attribute for invisible columns.
- Invisible columns are treated like visible columns in row events. They are included if needed according to the binlog_row_image system variable setting.
- When row events are applied, invisible columns are treated like visible columns in row events. In particular, the algorithm and index to use are chosen according to the slave_rows_search_algorithms system variable setting.
- Invisible columns are treated like visible columns when computing writesets. In particular, writesets include indexes defined on invisible columns.
- The mysqlbinlog command includes visibility in column metadata.

### 13.1.20.11 Generated Invisible Primary Keys

MySQL 8.2 supports generated invisible primary keys for any InnoDB table that is created without an explicit primary key. When the sql_generate_invisible_primary_key server system variable is set to ON, the MySQL server automatically adds a generated invisible primary key (GIPK) to any such table.

By default, the value of sql_generate_invisible_primary_key is OFF, meaning that the automatic addition of GIPKs is disabled. To illustrate how this affects table creation, we begin by creating two identical tables, neither having a primary key, the only difference being that the first (table auto_0) is created with sql_generate_invisible_primary_key set to OFF, and the second (auto_1) after setting it to ON, as shown here:

```sql
mysql> SELECT @@sql_generate_invisible_primary_key;
+--------------------------------------+
| @@sql_generate_invisible_primary_key | 0 |
+--------------------------------------+
1 row in set (0.00 sec)

mysql> CREATE TABLE auto_0 (c1 VARCHAR(50), c2 INT);
Query OK, 0 rows affected (0.02 sec)

mysql> SET sql_generate_invisible_primary_key=ON;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@sql_generate_invisible_primary_key;
+--------------------------------------+
| @@sql_generate_invisible_primary_key | 1 |
+--------------------------------------+
1 row in set (0.00 sec)

mysql> CREATE TABLE auto_1 (c1 VARCHAR(50), c2 INT);
Query OK, 0 rows affected (0.04 sec)
```

Compare the output of these SHOW CREATE TABLE statements to see the difference in how the tables were actually created:
Since `auto_1` had no primary key specified by the `CREATE TABLE` statement used to create it, setting `sql_generate_invisible_primary_key = ON` causes MySQL to add both the invisible column `my_row_id` to this table and a primary key on that column. Since `sql_generate_invisible_primary_key` was `OFF` at the time that `auto_0` was created, no such additions were performed on that table.

When a primary key is added to a table by the server, the column and key name is always `my_row_id`. For this reason, when enabling generated invisible primary keys in this way, you cannot create a table having a column named `my_row_id` unless the table creation statement also specifies an explicit primary key. (You are not required to name the column or key `my_row_id` in such cases.)

`my_row_id` is an invisible column, which means it is not shown in the output of `SELECT *` or `TABLE`; the column must be selected explicitly by name. See Section 13.1.20.10, “Invisible Columns”.

When GIPKs are enabled, a generated primary key cannot be altered other than to switch it between `VISIBLE` and `INVISIBLE`. To make the generated invisible primary key on `auto_1` visible, execute this `ALTER TABLE` statement:

```
mysql> ALTER TABLE auto_1 ALTER COLUMN my_row_id SET VISIBLE;
Query OK, 0 rows affected (0.02 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

To make this generated primary key invisible again, issue `ALTER TABLE auto_1 ALTER COLUMN my_row_id SET INVISIBLE`.

A generated invisible primary key is always invisible by default.

Whenever GIPKs are enabled, you cannot drop a generated primary key if either of the following 2 conditions would result:

- The table is left with no primary key.
CREATE TABLE Statement

- The primary key is dropped, but not the primary key column.

The effects of `sql_generate_invisible_primary_key` apply to tables using the InnoDB storage engine only. You can use an `ALTER TABLE` statement to change the storage engine used by a table that has a generated invisible primary key; in this case, the primary key and column remain in place, but the table and key no longer receive any special treatment.

By default, GIPKs are shown in the output of `SHOW CREATE TABLE`, `SHOW COLUMNS`, and `SHOW INDEX`, and are visible in the Information Schema `COLUMNS` and `STATISTICS` tables. You can cause generated invisible primary keys to be hidden instead in such cases by setting the `show_gipk_in_create_table_and_information_schema` system variable to OFF. By default, this variable is ON, as shown here:

```sql
mysql> SELECT @@show_gipk_in_create_table_and_information_schema;
+----------------------------------------------------+
| @@show_gipk_in_create_table_and_information_schema |
+----------------------------------------------------+
|                                                  1 |
+----------------------------------------------------+
1 row in set (0.00 sec)
```

As can be seen from the following query against the `COLUMNS` table, `my_row_id` is visible among the columns of `auto_1`:

```sql
mysql> SELECT COLUMN_NAME, ORDINAL_POSITION, DATA_TYPE, COLUMN_KEY
    -> FROM INFORMATION_SCHEMA.COLUMNS
    -> WHERE TABLE_NAME = "auto_1";
+-------------+------------------+-----------+------------+
| COLUMN_NAME | ORDINAL_POSITION | DATA_TYPE | COLUMN_KEY |
| my_row_id   |                1 | bigint    | PRI        |
| c1          |                2 | varchar   |            |
| c2          |                3 | int       |            |
+-------------+------------------+-----------+------------+
3 rows in set (0.01 sec)
```

After `show_gipk_in_create_table_and_information_schema` is set to OFF, `my_row_id` can no longer be seen in the `COLUMNS` table, as shown here:

```sql
mysql> SET show_gipk_in_create_table_and_information_schema = OFF;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @@show_gipk_in_create_table_and_information_schema;
+----------------------------------------------------+
| @@show_gipk_in_create_table_and_information_schema |
+----------------------------------------------------+
|                                                  0 |
+----------------------------------------------------+
1 row in set (0.00 sec)
mysql> SELECT COLUMN_NAME, ORDINAL_POSITION, DATA_TYPE, COLUMN_KEY
    -> FROM INFORMATION_SCHEMA.COLUMNS
    -> WHERE TABLE_NAME = "auto_1";
+-------------+------------------+-----------+------------+
| COLUMN_NAME | ORDINAL_POSITION | DATA_TYPE | COLUMN_KEY |
| c1          |                2 | varchar   |            |
| c2          |                3 | int       |            |
+-------------+------------------+-----------+------------+
2 rows in set (0.00 sec)
```

The setting for `sql_generate_invisible_primary_key` is not replicated, and is ignored by replication applier threads. This means that the setting of this variable on the source has no effect on the
replica. You can cause the replica to add a GIPK for tables replicated without primary keys on a given replication channel using `REQUIRE_TABLE_PRIMARY_KEY_CHECK = GENERATE` as part of a `CHANGE REPLICATION SOURCE` statement.

GIPKs work with row-based replication of `CREATE TABLE ... SELECT`; the information written to the binary log for this statement in such cases includes the GIPK definition, and thus is replicated correctly. Statement-based replication of `CREATE TABLE ... SELECT` is not supported with `sql_generate_invisible_primary_key = ON`.

When creating or importing backups of installations where GIPKs are in use, it is possible to exclude generated invisible primary key columns and values. The `--skip-generated-invisible-primary-key` option for `mysqldump` causes GIPK information to be excluded in the program's output. If you are importing a dump file that contains generated invisible primary keys and values, you can also use `--skip-generated-invisible-primary-key` with `mysqlpump` to cause these to be suppressed (and thus not imported).

### 13.1.20.12 Setting NDB Comment Options

- **NDB_COLUMN Options**
- **NDB_TABLE Options**

It is possible to set a number of options specific to NDB Cluster in the table comment or column comments of an NDB table. Table-level options for controlling read from any replica and partition balance can be embedded in a table comment using `NDB_TABLE`.

`NDB_COLUMN` can be used in a column comment to set the size of the blob parts table column used for storing parts of blob values by NDB to its maximum. This works for `BLOB`, `MEDIUMBLOB`, `LONGBLOB`, `TEXT`, `MEDIUMTEXT`, `LONGTEXT`, and `JSON` columns. A column comment can also be used to control the inline size of a blob column. `NDB_COLUMN` comments do not support `TINYBLOB` or `TINYTEXT` columns, since these have an inline part (only) of fixed size, and no separate parts to store elsewhere.

`NDB_TABLE` can be used in a table comment to set options relating to partition balance and whether the table is fully replicated, among others.

The remainder of this section describes these options and their use.

#### NDB_COLUMN Options

In NDB Cluster, a column comment in a `CREATE TABLE` or `ALTER TABLE` statement can also be used to specify an `NDB_COLUMN` option. NDB supports two column comment options `BLOB_INLINE_SIZE` and `MAX_BLOB_PART_SIZE`. Syntax for these options is shown here:

```sql
COMMENT 'NDB_COLUMN=speclist'
speclist ::= spec[, spec]
spec ::= BLOB_INLINE_SIZE=value | MAX_BLOB_PART_SIZE={0|1}
```

`BLOB_INLINE_SIZE` specifies the number of bytes to be stored inline by the column; its expected value is an integer in the range 1 - 29980, inclusive. Setting a value greater than 29980 raises an error; setting a value less than 1 is allowed, but causes the default inline size for the column type to be used.

You should be aware that the maximum value for this option is actually the maximum number of bytes that can be stored in one row of an NDB table; every column in the row contributes to this total.
You should also keep in mind, especially when working with TEXT columns, that the value set by MAX_BLOB_PART_SIZE or BLOB_INLINE_SIZE represents column size in bytes. It does not indicate the number of characters, which varies according to the character set and collation used by the column.

To see the effects of this option, first create a table with two BLOB columns, one (b1) with no extra options, and another (b2) with a setting for BLOB_INLINE_SIZE, as shown here:

```sql
mysql> CREATE TABLE t1 (a INT NOT NULL PRIMARY KEY, b1 BLOB, b2 BLOB COMMENT 'NDB_COLUMN=BLOB_INLINE_SIZE=8000') ENGINE NDB;
Query OK, 0 rows affected (0.32 sec)
```

You can see the BLOB_INLINE_SIZE settings for the BLOB columns by querying the ndbinfo.blobs table, like this:

```sql
mysql> SELECT column_name AS 'Column Name', inline_size AS 'Inline Size', part_size AS 'Blob Part Size' FROM ndbinfo.blobs WHERE table_name = 't1';
```

```
+-------------+-------------+----------------+
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Inline Size</th>
<th>Blob Part Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>b1</td>
<td>256</td>
<td>2000</td>
</tr>
<tr>
<td>b2</td>
<td>8000</td>
<td>2000</td>
</tr>
</tbody>
</table>
+-------------+-------------+----------------+
```

You can also check the output from the ndb_desc utility, as shown here, with the relevant lines displayed using emphasized text:

```bash
$> ndb_desc -d test t1
-- t --
Version: 1
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 3
Number of primary keys: 1
Length of frm data: 945
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
PartitionCount: 2
FragmentCount: 2
PartitionBalance: FOR_RP_BY_LDM
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options: readbackup
HashMap: DEFAULT-HASHMAP-3840-2
-- Attributes --
a Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY
b1 Blob(256,2000,0) NULL AT=_MEDIUM_VAR ST=MEMORY BV=2 BT=NDB$BLOB_64_1
b2 Blob(8000,2000,0) NULL AT=_MEDIUM_VAR ST=MEMORY BV=2 BT=NDB$BLOB_64_2
-- Indexes --
PRIMARY KEY(a) = UniqueHashIndex
PRIMARY(a) = OrderedIndex
```
CREATE TABLE Statement

For `MAX_BLOB_PART_SIZE`, the = sign and the value following it are optional. Using any value other than 0 or 1 results in a syntax error.

The effect of using `MAX_BLOB_PART_SIZE` in a column comment is to set the blob part size of a `TEXT` or `BLOB` column to the maximum number of bytes supported for this by `NDB` (13948). This option can be applied to any blob column type supported by MySQL except `TINYBLOB` or `TINYTEXT` (`BLOB`, `MEDIUMBLOB`, `LONGBLOB`, `TEXT`, `MEDIUMTEXT`, `LONGTEXT`). Unlike `BLOB_INLINE_SIZE`, `MAX_BLOB_PART_SIZE` has no effect on `JSON` columns.

To see the effects of this option, we first run the following SQL statement in the `mysql` client to create a table with two `BLOB` columns, one (`c1`) with no extra options, and another (`c2`) with `MAX_BLOB_PART_SIZE`:

```sql
mysql> CREATE TABLE test.t2 (
    -> p INT PRIMARY KEY,
    -> c1 BLOB,
    -> c2 BLOB COMMENT 'NDB_COLUMN=MAX_BLOB_PART_SIZE'
    -> ) ENGINE NDB;
Query OK, 0 rows affected (0.32 sec)
```

From the system shell, run the `ndb_desc` utility to obtain information about the table just created, as shown in this example:

```bash
$> ndb_desc -d test t2
-- t --
Version: 1
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 3
Number of primary keys: 1
Length of frm data: 324
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
HashMap: DEFAULT-HASHMAP-3840-2
-- Attributes --
p Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY
  c1 Blob(256,2000,0) NULL AT=MEDIUM_VAR ST=MEMORY BV=2 BT=NDB$BLOB_22_1
  c2 Blob(256,13948,0) NULL AT=MEDIUM_VAR ST=MEMORY BV=2 BT=NDB$BLOB_22_2
-- Indexes --
PRIMARY KEY(p) - UniqueHashIndex
PRIMARY(p) - OrderedIndex
```

Column information in the output is listed under `Attributes`; for columns `c1` and `c2` it is displayed here in emphasized text. For `c1`, the blob part size is 2000, the default value; for `c2`, it is 13948, as set by `MAX_BLOB_PART_SIZE`.

You can also query the `ndbinfo.blobs` table to see this, as shown here:

```sql
mysql> SELECT
    -> column_name AS 'Column Name',
    -> inline_size AS 'Inline Size',
    -> part_size AS 'Blob Part Size'
    -> FROM ndbinfo.blobs
```
You can change the blob part size for a given blob column of an NDB table using an `ALTER TABLE` statement such as this one, and verifying the changes afterwards using `SHOW CREATE TABLE`:

```sql
mysql> ALTER TABLE test.t2
    ->    DROP COLUMN c1,
    ->     ADD COLUMN c1 BLOB COMMENT 'NDB_COLUMN=MAX_BLOB_PART_SIZE',
    ->     CHANGE COLUMN c2 c2 BLOB AFTER c1;
Query OK, 0 rows affected (0.47 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

```sql
mysql> SHOW CREATE TABLE test.t2\G
*************************** 1. row ***************************
Table: t
Create Table: CREATE TABLE `t2` (  
`p` int(11) NOT NULL,  
`c1` blob COMMENT 'NDB_COLUMN=MAX_BLOB_PART_SIZE',  
`c2` blob,  
PRIMARY KEY (`p`)  ) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

You can also see the change by running the query against `ndbinfoblobs` again:

```sql
$> ndb_desc -d t test t2
-- t --
Version: 16777220
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 3
Number of primary keys: 1
Length of frm data: 324
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
HashMap: DEFAULT-HASHMAP-3840-2
-- Attributes --
p Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY  
c1 Blob(256,13948,0) NULL AT=MEDIUM_VAR ST=MEMORY BV=2 BT=NDB$BLOB_26_1  
c2 Blob(256,2000,0) NULL AT=MEDIUM_VAR ST=MEMORY BV=2 BT=NDB$BLOB_26_2
-- Indexes --
PRIMARY KEY(p) - UniqueHashIndex
PRIMARY(p) - OrderedIndex
NDBT_ProgramExit: 0 - OK
```

You can also see the change by running the query against `ndbinfoblobs` again:
CREATE TABLE Statement

```
mysql> SELECT
    ->     column_name AS 'Column Name',
    ->     inline_size AS 'Inline Size',
    ->     part_size AS 'Blob Part Size'
    ->     FROM ndbinfo.blobs
    ->     WHERE table_name = 't2';
+-------------+-------------+----------------+
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Inline Size</th>
<th>Blob Part Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>c1</td>
<td>256</td>
<td>13948</td>
</tr>
<tr>
<td>c2</td>
<td>256</td>
<td>2000</td>
</tr>
</tbody>
</table>
+-------------+-------------+----------------+
2 rows in set (0.00 sec)
```

It is possible to set both `BLOB_INLINE_SIZE` and `MAX_BLOB_PART_SIZE` for a blob column, as shown in this `CREATE TABLE` statement:

```
mysql> CREATE TABLE test.t3 (p INT NOT NULL PRIMARY KEY, c1 JSON, c2 JSON COMMENT 'NDB_COLUMN=BLOB_INLINE_SIZE=5000,MAX_BLOB_PART_SIZE') ENGINE NDB;
Query OK, 0 rows affected (0.28 sec)
```

Querying the `blobs` table shows us that the statement worked as expected:

```
mysql> SELECT
    ->     column_name AS 'Column Name',
    ->     inline_size AS 'Inline Size',
    ->     part_size AS 'Blob Part Size'
    ->     FROM ndbinfo.blobs
    ->     WHERE table_name = 't3';
+-------------+-------------+----------------+
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Inline Size</th>
<th>Blob Part Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>c1</td>
<td>4000</td>
<td>8100</td>
</tr>
<tr>
<td>c2</td>
<td>5000</td>
<td>8100</td>
</tr>
</tbody>
</table>
+-------------+-------------+----------------+
2 rows in set (0.00 sec)
```

You can also verify that the statement worked by checking the output of `ndb_desc`.

Changing a column’s blob part size must be done using a copying `ALTER TABLE`; this operation cannot be performed online (see Section 23.6.12, “Online Operations with ALTER TABLE in NDB Cluster”).

For more information about how NDB stores columns of blob types, see String Type Storage Requirements.

**NDB_TABLE Options**

In MySQL NDB Cluster, the table comment in a `CREATE TABLE` or `ALTER TABLE` option, which consists of one or more name-value pairs, separated by commas if need be, following the string `NDB_TABLE=`. Complete syntax for names and values syntax is shown here:

```
COMMENT="NDB_TABLE=ndb_table_option[,ndb_table_option][,...]"
```

```
ndb_table_option: { NOLOGGING={1 | 0} | READ_BACKUP={1 | 0} | PARTITION_BALANCE={FOR_RP_BY_NODE | FOR_RA_BY_NODE | FOR_RP_BY_LDM | FOR_RA_BY_LDM | FOR_RA_BY_LDM_X_2 | FOR_RA_BY_LDM_X_3 | FOR_RA_BY_LDM_X_4} | FULLY_REPLICATED={1 | 0} }
```
Spaces are not permitted within the quoted string. The string is case-insensitive.

The four NDB table options that can be set as part of a comment in this way are described in more detail in the next few paragraphs.

NOLOGGING: Using 1 corresponds to having ndb_table_no_logging enabled, but has no actual effect. Provided as a placeholder, mostly for completeness of ALTER TABLE statements.

READ_BACKUP: Setting this option to 1 has the same effect as though ndb_read_backup were enabled; enables reading from any replica. Doing so greatly improves the performance of reads from the table at a relatively small cost to write performance. 1 is the default for READ_BACKUP, and the default for ndb_read_backup is ON (previously, read from any replica was disabled by default).

You can set READ_BACKUP for an existing table online, using an ALTER TABLE statement similar to one of those shown here:

```
ALTER TABLE ... ALGORITHM=INPLACE, COMMENT="NDB_TABLE=READ_BACKUP=1";
ALTER TABLE ... ALGORITHM=INPLACE, COMMENT="NDB_TABLE=READ_BACKUP=0";
```

For more information about the ALGORITHM option for ALTER TABLE, see Section 23.6.12, “Online Operations with ALTER TABLE in NDB Cluster”.

PARTITION_BALANCE: Provides additional control over assignment and placement of partitions. The following four schemes are supported:

1. FOR_RP_BY_NODE: One partition per node.
   Only one LDM on each node stores a primary partition. Each partition is stored in the same LDM (same ID) on all nodes.

2. FOR_RA_BY_NODE: One partition per node group.
   Each node stores a single partition, which can be either a primary replica or a backup replica. Each partition is stored in the same LDM on all nodes.

3. FOR_RP_BY_LDM: One partition for each LDM on each node; the default.
   This is the setting used if READ_BACKUP is set to 1.

4. FOR_RA_BY_LDM: One partition per LDM in each node group.
   These partitions can be primary or backup partitions.

5. FOR_RA_BY_LDM_X_2: Two partitions per LDM in each node group.
   These partitions can be primary or backup partitions.

6. FOR_RA_BY_LDM_X_3: Three partitions per LDM in each node group.
   These partitions can be primary or backup partitions.

7. FOR_RA_BY_LDM_X_4: Four partitions per LDM in each node group.
   These partitions can be primary or backup partitions.

PARTITION_BALANCE is the preferred interface for setting the number of partitions per table. Using MAX_ROWS to force the number of partitions is deprecated but continues to be supported for backward compatibility; it is subject to removal in a future release of MySQL NDB Cluster. (Bug #81759, Bug #23544301)
FULLY_REPLICATED controls whether the table is fully replicated, that is, whether each data node has a complete copy of the table. To enable full replication of the table, use FULLY_REPLICATED=1.

This setting can also be controlled using the ndb_fully_replicated system variable. Setting it to ON enables the option by default for all new NDB tables; the default is OFF. The ndb_data_node_neighbour system variable is also used for fully replicated tables, to ensure that when a fully replicated table is accessed, we access the data node which is local to this MySQL Server.

An example of a CREATE TABLE statement using such a comment when creating an NDB table is shown here:

```sql
mysql> CREATE TABLE t1 (  
  > c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
  > c2 VARCHAR(100),  
  > c3 VARCHAR(100)  
  > ENGINE=NDB  
  > COMMENT="NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RP_BY_NODE";
```

The comment is displayed as part of the output of SHOW CREATE TABLE. The text of the comment is also available from querying the MySQL Information Schema TABLES table, as in this example:

```sql
mysql> SELECT TABLE_NAME, TABLE_SCHEMA, TABLE_COMMENT  
> FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_NAME="t1"\G
*************************** 1. row ***************************  
TABLE_NAME: t1  
TABLE_SCHEMA: test  
TABLE_COMMENT: NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RP_BY_NODE  
1 row in set (0.01 sec)
```

This comment syntax is also supported with ALTER TABLE statements for NDB tables, as shown here:

```sql
mysql> ALTER TABLE t1 COMMENT="NDB_TABLE=PARTITION_BALANCE=FOR_RA_BY_NODE";
Query OK, 0 rows affected (0.40 sec)  
Records: 0  Duplicates: 0  Warnings: 0
```

The TABLE_COMMENT column displays the comment that is required to re-create the table as it is following the ALTER TABLE statement, like this:

```sql
mysql> SELECT TABLE_NAME, TABLE_SCHEMA, TABLE_COMMENT  
> FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_NAME="t1"\G
*************************** 1. row ***************************  
TABLE_NAME: t1  
TABLE_SCHEMA: test  
TABLE_COMMENT: NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RP_BY_NODE  
1 row in set (0.01 sec)
```

```sql
mysql> SELECT TABLE_NAME, TABLE_SCHEMA, TABLE_COMMENT  
> FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_NAME="t1";
+------------+--------------+--------------------------------------------------+
<table>
<thead>
<tr>
<th>TABLE_NAME</th>
<th>TABLE_SCHEMA</th>
<th>TABLE_COMMENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>t1</td>
<td>c</td>
<td>NDB_TABLE=PARTITION_BALANCE=FOR_RA_BY_NODE</td>
</tr>
<tr>
<td>t1</td>
<td>d</td>
<td></td>
</tr>
</tbody>
</table>
+------------+--------------+--------------------------------------------------+
2 rows in set (0.01 sec)
```

Keep in mind that a table comment used with ALTER TABLE replaces any existing comment which the table might have.

```sql
mysql> ALTER TABLE t1 COMMENT="NDB_TABLE=PARTITION_BALANCE=FOR_RA_BY_NODE";
Query OK, 0 rows affected (0.40 sec)  
Records: 0  Duplicates: 0  Warnings: 0
```
You can also see the value of the `PARTITION_BALANCE` option in the output of `ndb_desc`. `ndb_desc` also shows whether the `READ_BACKUP` and `FULLY_REPLICATED` options are set for the table. See the description of this program for more information.

### 13.1.21 CREATE TABLESPACE Statement

```sql
CREATE [UNDO] TABLESPACE tablespace_name

InnoDB and NDB:
[ADD DATAFILE 'file_name']
[AUTOEXTEND_SIZE [+] value]

InnoDB only:
[FILE_BLOCK_SIZE = value]
[ENCRYPTION [+] {'Y' | 'N'}]

NDB only:
USE LOGFILE GROUP logfile_group
[EXTENT_SIZE [+] extent_size]
[INITIAL_SIZE [+] initial_size]
[MAX_SIZE [+] max_size]
[NODEGROUP [+] nodegroup_id]
[WAIT]
[COMMENT [+] 'string']

InnoDB and NDB:
[ENGINE [+] engine_name]

Reserved for future use:
[ENGINE_ATTRIBUTE [+] 'string']
```

This statement is used to create a tablespace. The precise syntax and semantics depend on the storage engine used. In standard MySQL releases, this is always an **InnoDB** tablespace. MySQL NDB Cluster also supports tablespaces using the **NDB** storage engine.

- **Considerations for InnoDB**
- **Considerations for NDB Cluster**
- **Options**
- **Notes**
- **InnoDB Examples**
- **NDB Example**

**Considerations for InnoDB**

`CREATE TABLESPACE` syntax is used to create general tablespaces or undo tablespaces. The `UNDO` keyword must be specified to create an undo tablespace.
CREATE TABLESPACE Statement

A general tablespace is a shared tablespace. It can hold multiple tables, and supports all table row formats. General tablespaces can be created in a location relative to or independent of the data directory.

After creating an InnoDB general tablespace, use CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name or ALTER TABLE tbl_name TABLESPACE [=] tablespace_name to add tables to the tablespace. For more information, see Section 15.6.3.3, “General Tablespaces”.

Undo tablespaces contain undo logs. Undo tablespaces can be created in a chosen location by specifying a fully qualified data file path. For more information, see Section 15.6.3.4, “Undo Tablespaces”.

Considerations for NDB Cluster

This statement is used to create a tablespace, which can contain one or more data files, providing storage space for NDB Cluster Disk Data tables (see Section 23.6.11, “NDB Cluster Disk Data Tables”). One data file is created and added to the tablespace using this statement. Additional data files may be added to the tablespace by using the ALTER TABLESPACE statement (see Section 13.1.10, “ALTER TABLESPACE Statement”).

Note

All NDB Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group with the same name, or a tablespace and a data file with the same name.

A log file group of one or more UNDO log files must be assigned to the tablespace to be created with the USE LOGFILE GROUP clause. logfile_group must be an existing log file group created with CREATE LOGFILE GROUP (see Section 13.1.16, “CREATE LOGFILE GROUP Statement”). Multiple tablespaces may use the same log file group for UNDO logging.

When setting EXTENT_SIZE or INITIAL_SIZE, you may optionally follow the number with a one-letter abbreviation for an order of magnitude, similar to those used in my.cnf. Generally, this is one of the letters M (for megabytes) or G (for gigabytes).

INITIAL_SIZE and EXTENT_SIZE are subject to rounding as follows:

- EXTENT_SIZE is rounded up to the nearest whole multiple of 32K.
- INITIAL_SIZE is rounded down to the nearest whole multiple of 32K; this result is rounded up to the nearest whole multiple of EXTENT_SIZE (after any rounding).

Note

NDB reserves 4% of a tablespace for data node restart operations. This reserved space cannot be used for data storage.

The rounding just described is done explicitly, and a warning is issued by the MySQL Server when any such rounding is performed. The rounded values are also used by the NDB kernel for calculating INFORMATION_SCHEMA.FILES column values and other purposes. However, to avoid an unexpected result, we suggest that you always use whole multiples of 32K in specifying these options.

When CREATE TABLESPACE is used with ENGINE [=] NDB, a tablespace and associated data file are created on each Cluster data node. You can verify that the data files were created and obtain information about them by querying the Information Schema FILES table. (See the example later in this section.)

(See Section 26.3.15, “The INFORMATION_SCHEMA FILES Table”.)
CREATE TABLESPACE Statement

Options

- **ADD DATAFILE**: Defines the name of a tablespace data file. This option is always required when creating an **NDB** tablespace; for **InnoDB**, it is required only when creating an undo tablespace. The `file_name`, including any specified path, must be quoted with single or double quotation marks. File names (not counting the file extension) and directory names must be at least one byte in length. Zero length file names and directory names are not supported.

Because there are considerable differences in how **InnoDB** and **NDB** treat data files, the two storage engines are covered separately in the discussion that follows.

**InnoDB data files.** An **InnoDB** tablespace supports only a single data file, whose name must include an `.ibd` extension.

To place an **InnoDB** general tablespace data file in a location outside of the data directory, include a fully qualified path or a path relative to the data directory. Only a fully qualified path is permitted for undo tablespaces. If you do not specify a path, a general tablespace is created in the data directory. An undo tablespace created without specifying a path is created in the directory defined by the `innodb_undo_directory` variable. If the `innodb_undo_directory` variable is undefined, undo tablespaces are created in the data directory.

To avoid conflicts with implicitly created file-per-table tablespaces, creating an **InnoDB** general tablespace in a subdirectory under the data directory is not supported. When creating a general tablespace or undo tablespace outside of the data directory, the directory must exist and must be known to **InnoDB** prior to creating the tablespace. To make a directory known to **InnoDB**, add it to the `innodb_directories` value or to one of the variables whose values are appended to the `innodb_directories` value. `innodb_directories` is a read-only variable. Configuring it requires restarting the server.

If the **ADD DATAFILE** clause is not specified when creating an **InnoDB** tablespace, a tablespace data file with a unique file name is created implicitly. The unique file name is a 128 bit UUID formatted into five groups of hexadecimal numbers separated by dashes (`aaaaaaaa-bbbb-cccc-dddd-eeeee`). A file extension is added if required by the storage engine. An `.ibd` file extension is added for **InnoDB** general tablespace data files. In a replication environment, the data file name created on the replication source server is not the same as the data file name created on the replica.

The **ADD DATAFILE** clause does not permit circular directory references when creating an **InnoDB** tablespace. For example, the circular directory reference (`/../`) in the following statement is not permitted:

```
CREATE TABLESPACE ts1 ADD DATAFILE ts1.ibd 'any_directory/../ts1.ibd';
```

An exception to this restriction exists on Linux, where a circular directory reference is permitted if the preceding directory is a symbolic link. For example, the data file path in the example above is permitted if `any_directory` is a symbolic link. (It is still permitted for data file paths to begin with `../`).

**NDB data files.** An **NDB** tablespace supports multiple data files which can have any legal file names; more data files can be added to an **NDB** Cluster tablespace following its creation by using an **ALTER TABLESPACE** statement.

An **NDB** tablespace data file is created by default in the data node file system directory—that is, the directory named `ndb_nodeid_fs/TS` under the data node's data directory (`DataDir`), where `nodeid` is the data node's `NodeId`. To place the data file in a location other than the default, include an absolute directory path or a path relative to the default location. If the directory specified does not exist, **NDB** attempts to create it; the system user account under which the data node process is running must have the appropriate permissions to do so.
When determining the path used for a data file, NDB does not expand the ~ (tilde) character.

When multiple data nodes are run on the same physical host, the following considerations apply:

- You cannot specify an absolute path when creating a data file.

- It is not possible to create tablespace data files outside the data node file system directory, unless each data node has a separate data directory.

- If each data node has its own data directory, data files can be created anywhere within this directory.

- If each data node has its own data directory, it may also be possible to create a data file outside the node's data directory using a relative path, as long as this path resolves to a unique location on the host file system for each data node running on that host.

- **FILE_BLOCK_SIZE**: This option—which is specific to InnoDB general tablespaces, and is ignored by NDB—defines the block size for the tablespace data file. Values can be specified in bytes or kilobytes. For example, an 8 kilobyte file block size can be specified as 8192 or 8K. If you do not specify this option, FILE_BLOCK_SIZE defaults to the innodb_page_size value. FILE_BLOCK_SIZE is required when you intend to use the tablespace for storing compressed InnoDB tables (ROW_FORMAT=COMPRESSED). In this case, you must define the tablespace FILE_BLOCK_SIZE when creating the tablespace.

  If FILE_BLOCK_SIZE is equal the innodb_page_size value, the tablespace can contain only tables having an uncompressed row format (COMPACT, REDUNDANT, and DYNAMIC). Tables with a COMPRESSED row format have a different physical page size than uncompressed tables. Therefore, compressed tables cannot coexist in the same tablespace as uncompressed tables.

  For a general tablespace to contain compressed tables, FILE_BLOCK_SIZE must be specified, and the FILE_BLOCK_SIZE value must be a valid compressed page size in relation to the innodb_page_size value. Also, the physical page size of the compressed table (KEY_BLOCK_SIZE) must be equal to FILE_BLOCK_SIZE/1024. For example, if innodb_page_size=16K, and FILE_BLOCK_SIZE=8K, the KEY_BLOCK_SIZE of the table must be 8. For more information, see Section 15.6.3.3, “General Tablespaces”.

- **USE LOGFILE GROUP**: Required for NDB, this is the name of a log file group previously created using CREATE LOGFILE GROUP. Not supported for InnoDB, where it fails with an error.

- **EXTENT_SIZE**: This option is specific to NDB, and is not supported by InnoDB, where it fails with an error. EXTENT_SIZE sets the size, in bytes, of the extents used by any files belonging to the tablespace. The default value is 1M. The minimum size is 32K, and theoretical maximum is 2G, although the practical maximum size depends on a number of factors. In most cases, changing the extent size does not have any measurable effect on performance, and the default value is recommended for all but the most unusual situations.

  An extent is a unit of disk space allocation. One extent is filled with as much data as that extent can contain before another extent is used. In theory, up to 65,535 (64K) extents may used per data file; however, the recommended maximum is 32,768 (32K). The recommended maximum size for a single data file is 32G—that is, 32K extents × 1 MB per extent. In addition, once an extent is allocated to a given partition, it cannot be used to store data from a different partition; an extent cannot store data from more than one partition. This means, for example that a tablespace having a single datafile whose
CREATE TABLESPACE Statement

**INITIAL_SIZE** (described in the following item) is 256 MB and whose **EXTENT_SIZE** is 128M has just two extents, and so can be used to store data from at most two different disk data table partitions.

You can see how many extents remain free in a given data file by querying the Information Schema **FILES** table, and so derive an estimate for how much space remains free in the file. For further discussion and examples, see Section 26.3.15, “The INFORMATION_SCHEMA FILES Table”.

- **INITIAL_SIZE**: This option is specific to NDB, and is not supported by InnoDB, where it fails with an error.

  The **INITIAL_SIZE** parameter sets the total size in bytes of the data file that was specific using **ADD DATATFILE**. Once this file has been created, its size cannot be changed; however, you can add more data files to the tablespace using **ALTER TABLESPACE ... ADD DATATFILE**.

  **INITIAL_SIZE** is optional; its default value is 134217728 (128 MB).

On 32-bit systems, the maximum supported value for **INITIAL_SIZE** is 4294967296 (4 GB).

- **AUTOEXTEND_SIZE**: Defines the amount by which InnoDB extends the size of the tablespace when it becomes full. The setting must be a multiple of 4MB. The default setting is 0, which causes the tablespace to be extended according to the implicit default behavior. For more information, see Section 15.6.3.9, “Tablespace AUTOEXTEND_SIZE Configuration”.

  Has no effect in any release of MySQL NDB Cluster, regardless of the storage engine used.

- **MAX_SIZE**: Currently ignored by MySQL; reserved for possible future use. Has no effect in any release of MySQL or MySQL NDB Cluster, regardless of the storage engine used.

- **NODEGROUP**: Currently ignored by MySQL; reserved for possible future use. Has no effect in any release of MySQL or MySQL NDB Cluster, regardless of the storage engine used.

- **WAIT**: Currently ignored by MySQL; reserved for possible future use. Has no effect in any release of MySQL or MySQL NDB Cluster, regardless of the storage engine used.

- **COMMENT**: Currently ignored by MySQL; reserved for possible future use. Has no effect in any release of MySQL or MySQL NDB Cluster, regardless of the storage engine used.

- **The ENCRYPTION clause** enables or disables page-level data encryption for an InnoDB general tablespace.

  If the **ENCRYPTION** clause is not specified, the **default_table_encryption** setting controls whether encryption is enabled. The **ENCRYPTION** clause overrides the **default_table_encryption** setting. However, if the **table_encryption_privilege_check** variable is enabled, the **TABLE_ENCRYPTION_ADMIN** privilege is required to use an **ENCRYPTION** clause setting that differs from the **default_table_encryption** setting.

  A keyring plugin must be installed and configured before an encryption-enabled tablespace can be created.

  When a general tablespace is encrypted, all tables residing in the tablespace are encrypted. Likewise, a table created in an encrypted tablespace is encrypted.

  For more information, see Section 15.13, “InnoDB Data-at-Rest Encryption”

- **ENGINE**: Defines the storage engine which uses the tablespace, where **engine_name** is the name of the storage engine. Currently, only the InnoDB storage engine is supported by standard MySQL 8.2 releases. MySQL NDB Cluster supports both NDB and InnoDB tablespaces. The value of the **default_storage_engine** system variable is used for **ENGINE** if the option is not specified.
CREATE TABLESPACE Statement

- The ENGINE_ATTRIBUTE option is used to specify tablespace attributes for primary storage engines. The option is reserved for future use.

Permitted values are a string literal containing a valid JSON document or an empty string (""). Invalid JSON is rejected.

```
CREATE TABLESPACE ts1 ENGINE_ATTRIBUTE='{"key":"value"}';
```

ENGINE_ATTRIBUTE values can be repeated without error. In this case, the last specified value is used.

Notes

- For the rules covering the naming of MySQL tablespaces, see Section 9.2, "Schema Object Names". In addition to these rules, the slash character ("/") is not permitted, nor can you use names beginning with innodb_, as this prefix is reserved for system use.

- Creation of temporary general tablespaces is not supported.

- General tablespaces do not support temporary tables.

- The TABLESPACE option may be used with CREATE TABLE or ALTER TABLE to assign an InnoDB table partition or subpartition to a file-per-table tablespace. All partitions must belong to the same storage engine. Assigning table partitions to shared InnoDB tablespaces is not supported. Shared tablespaces include the InnoDB system tablespace and general tablespaces.

- General tablespaces support the addition of tables of any row format using CREATE TABLE ... TABLESPACE. innodb_file_per_table does not need to be enabled.

- innodb_strict_mode is not applicable to general tablespaces. Tablespace management rules are strictly enforced independently of innodb_strict_mode. If CREATE TABLESPACE parameters are incorrect or incompatible, the operation fails regardless of the innodb_strict_mode setting. When a table is added to a general tablespace using CREATE TABLE ... TABLESPACE or ALTER TABLE ... TABLESPACE, innodb_strict_mode is ignored but the statement is evaluated as if innodb_strict_mode is enabled.

- Use DROP TABLESPACE to remove a tablespace. All tables must be dropped from a tablespace using DROP TABLE prior to dropping the tablespace. Before dropping an NDB Cluster tablespace you must also remove all its data files using one or more ALTER TABLESPACE ... DROP DATATFILE statements. See Section 23.6.11.1, “NDB Cluster Disk Data Objects”.

- All parts of an InnoDB table added to an InnoDB general tablespace reside in the general tablespace, including indexes and BLOB pages.

For an NDB table assigned to a tablespace, only those columns which are not indexed are stored on disk, and actually use the tablespace data files. Indexes and indexed columns for all NDB tables are always kept in memory.

- Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace .ibd data file which can only be used for new InnoDB data. Space is not released back to the operating system as it is for file-per-table tablespaces.

- A general tablespace is not associated with any database or schema.

- ALTER TABLE ... DISCARD TABLESPACE and ALTER TABLE ... IMPORT TABLESPACE are not supported for tables that belong to a general tablespace.
CREATE TABLESPACE Statement

- The server uses tablespace-level metadata locking for DDL that references general tablespaces. By comparison, the server uses table-level metadata locking for DDL that references file-per-table tablespaces.

- A generated or existing tablespace cannot be changed to a general tablespace.

- There is no conflict between general tablespace names and file-per-table tablespace names. The “/” character, which is present in file-per-table tablespace names, is not permitted in general tablespace names.

- `mysqldump` and `mysqlpump` do not dump InnoDB CREATE TABLESPACE statements.

InnoDB Examples

This example demonstrates creating a general tablespace and adding three uncompressed tables of different row formats.

```
CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' ENGINE=INNODB;
CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=REDUNDANT;
CREATE TABLE t2 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=COMPACT;
CREATE TABLE t3 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=DYNAMIC;
```

This example demonstrates creating a general tablespace and adding a compressed table. The example assumes a default `innodb_page_size` value of 16K. The `FILE_BLOCK_SIZE` of 8192 requires that the compressed table have a `KEY_BLOCK_SIZE` of 8.

```
CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;
CREATE TABLE t4 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED KEY_BLOCK_SIZE=8;
```

This example demonstrates creating a general tablespace without specifying the `ADD DATAFILE` clause, which is optional:

```
CREATE TABLESPACE `ts3` ENGINE=INNODB;
```

This example demonstrates creating an undo tablespace:

```
CREATE UNDO TABLESPACE `undo_003` ADD DATAFILE 'undo_003.ibu';
```

NDB Example

Suppose that you wish to create an NDB Cluster Disk Data tablespace named `myts` using a datafile named `mydata-1.dat`. An NDB tablespace always requires the use of a log file group consisting of one or more undo log files. For this example, we first create a log file group named `mylg` that contains one undo long file named `myundo-1.dat`, using the `CREATE LOGFILE GROUP` statement shown here:

```
CREATE LOGFILE GROUP mylg
    -> ADD UNDOFILE 'myundo-1.dat'
    -> ENGINE=NDB;
Query OK, 0 rows affected (3.29 sec)
```

Now you can create the tablespace previously described using the following statement:

```
CREATE TABLESPACE myts
    -> ADD DATAFILE 'mydata-1.dat'
    -> USE LOGFILE GROUP mylg
    -> ENGINE=NDB;
```
CREATE TRIGGER Statement

You can now create a Disk Data table using a `CREATE TABLE` statement with the `TABLESPACE` and `STORAGE DISK` options, similar to what is shown here:

```sql
mysql> CREATE TABLE mytable (
  -> id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
  -> lname VARCHAR(50) NOT NULL,
  -> fname VARCHAR(50) NOT NULL,
  -> dob DATE NOT NULL,
  -> joined DATE NOT NULL,
  -> INDEX(last_name, first_name)
  ->)
  -> TABLESPACE myts STORAGE DISK
  -> ENGINE=NDB;
Query OK, 0 rows affected (1.41 sec)
```

It is important to note that only the `dob` and `joined` columns from `mytable` are actually stored on disk, due to the fact that the `id`, `lname`, and `fname` columns are all indexed.

As mentioned previously, when `CREATE TABLESPACE` is used with `ENGINE [=] NDB`, a tablespace and associated data file are created on each NDB Cluster data node. You can verify that the data files were created and obtain information about them by querying the Information Schema `FILES` table, as shown here:

```sql
mysql> SELECT FILE_NAME, FILE_TYPE, LOGFILE_GROUP_NAME, STATUS, EXTRA
  -> FROM INFORMATION_SCHEMA.FILES
  -> WHERE TABLESPACE_NAME = 'myts';
```

<table>
<thead>
<tr>
<th>file_name</th>
<th>file_type</th>
<th>logfile_group_name</th>
<th>status</th>
<th>extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>mydata-1.dat</td>
<td>DATAFILE</td>
<td>mylg</td>
<td>NORMAL</td>
<td>CLUSTER_NODE=5</td>
</tr>
<tr>
<td>mydata-1.dat</td>
<td>DATAFILE</td>
<td>mylg</td>
<td>NORMAL</td>
<td>CLUSTER_NODE=6</td>
</tr>
<tr>
<td>NULL</td>
<td>TABLESPACE</td>
<td>mylg</td>
<td>NORMAL</td>
<td>NULL</td>
</tr>
</tbody>
</table>

3 rows in set (0.01 sec)

For additional information and examples, see Section 23.6.11.1, “NDB Cluster Disk Data Objects”.

### 13.1.22 CREATE TRIGGER Statement

```sql
CREATE
  [DEFINER = user]
  TRIGGER [IF NOT EXISTS] trigger_name
  trigger_time trigger_event
  ON tbl_name FOR EACH ROW
  [trigger_order]
  trigger_body
```

This statement creates a new trigger. A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. The trigger becomes associated with the table named `tbl_name`, which must refer to a permanent table. You cannot associate a trigger with a `TEMPORARY` table or a view.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.
CREATE TRIGGER Statement

**IF NOT EXISTS** prevents an error from occurring if a trigger having the same name, on the same table, exists in the same schema.

This section describes **CREATE TRIGGER** syntax. For additional discussion, see Section 25.3.1, “Trigger Syntax and Examples”.

**CREATE TRIGGER** requires the **TRIGGER** privilege for the table associated with the trigger. If the **DEFINER** clause is present, the privileges required depend on the **user** value, as discussed in Section 25.6, “Stored Object Access Control”. If binary logging is enabled, **CREATE TRIGGER** might require the **SUPER** privilege, as discussed in Section 25.7, “Stored Program Binary Logging”.

The **DEFINER** clause determines the security context to be used when checking access privileges at trigger activation time, as described later in this section.

**trigger_time** is the trigger action time. It can be **BEFORE** or **AFTER** to indicate that the trigger activates before or after each row to be modified.

Basic column value checks occur prior to trigger activation, so you cannot use **BEFORE** triggers to convert values inappropriate for the column type to valid values.

**trigger_event** indicates the kind of operation that activates the trigger. These **trigger_event** values are permitted:

- **INSERT**: The trigger activates whenever a new row is inserted into the table (for example, through **INSERT**, **LOAD DATA**, and **REPLACE** statements).
- **UPDATE**: The trigger activates whenever a row is modified (for example, through **UPDATE** statements).
- **DELETE**: The trigger activates whenever a row is deleted from the table (for example, through **DELETE** and **REPLACE** statements). **DROP TABLE** and **TRUNCATE TABLE** statements on the table do not activate this trigger, because they do not use **DELETE**. Dropping a partition does not activate **DELETE** triggers, either.

The **trigger_event** does not represent a literal type of SQL statement that activates the trigger so much as it represents a type of table operation. For example, an **INSERT** trigger activates not only for **INSERT** statements but also **LOAD DATA** statements because both statements insert rows into a table.

A potentially confusing example of this is the **INSERT INTO ... ON DUPLICATE KEY UPDATE ...** syntax: a **BEFORE INSERT** trigger activates for every row, followed by either an **AFTER INSERT** trigger or both the **BEFORE UPDATE** and **AFTER UPDATE** triggers, depending on whether there was a duplicate key for the row.

**Note**
Cascaded foreign key actions do not activate triggers.

It is possible to define multiple triggers for a given table that have the same trigger event and action time. For example, you can have two **BEFORE UPDATE** triggers for a table. By default, triggers that have the same trigger event and action time activate in the order they were created. To affect trigger order, specify a **trigger_order** clause that indicates **FOLLOWS** or **PRECEDES** and the name of an existing trigger that also has the same trigger event and action time. With **FOLLOWS**, the new trigger activates after the existing trigger. With **PRECEDES**, the new trigger activates before the existing trigger.

**trigger_body** is the statement to execute when the trigger activates. To execute multiple statements, use the **BEGIN ... END** compound statement construct. This also enables you to use the same
CREATE VIEW Statement

statements that are permitted within stored routines. See Section 13.6.1, “BEGIN ... END Compound Statement”. Some statements are not permitted in triggers; see Section 25.8, “Restrictions on Stored Programs”.

Within the trigger body, you can refer to columns in the subject table (the table associated with the trigger) by using the aliases OLD and NEW. OLD.col_name refers to a column of an existing row before it is updated or deleted. NEW.col_name refers to the column of a new row to be inserted or an existing row after it is updated.

Triggers cannot use NEW.col_name or use OLD.col_name to refer to generated columns. For information about generated columns, see Section 13.1.20.8, “CREATE TABLE and Generated Columns”.

MySQL stores the sql_mode system variable setting in effect when a trigger is created, and always executes the trigger body with this setting in force, regardless of the current server SQL mode when the trigger begins executing.

The DEFINER clause specifies the MySQL account to be used when checking access privileges at trigger activation time. If the DEFINER clause is present, the user value should be a MySQL account specified as 'user_name'@'host_name', CURRENT_USER, or CURRENT_USER(). The permitted user values depend on the privileges you hold, as discussed in Section 25.6, “Stored Object Access Control”. Also see that section for additional information about trigger security.

If the DEFINER clause is omitted, the default definer is the user who executes the CREATE TRIGGER statement. This is the same as specifying DEFINER = CURRENT_USER explicitly.

MySQL takes the DEFINER user into account when checking trigger privileges as follows:

• At CREATE TRIGGER time, the user who issues the statement must have the TRIGGER privilege.

• At trigger activation time, privileges are checked against the DEFINER user. This user must have these privileges:

  • The TRIGGER privilege for the subject table.
  
  • The SELECT privilege for the subject table if references to table columns occur using OLD.col_name or NEW.col_name in the trigger body.
  
  • The UPDATE privilege for the subject table if table columns are targets of SET NEW.col_name = value assignments in the trigger body.
  
  • Whatever other privileges normally are required for the statements executed by the trigger.

Within a trigger body, the CURRENT_USER function returns the account used to check privileges at trigger activation time. This is the DEFINER user, not the user whose actions caused the trigger to be activated. For information about user auditing within triggers, see Section 6.2.23, “SQL-Based Account Activity Auditing”.

If you use LOCK TABLES to lock a table that has triggers, the tables used within the trigger are also locked, as described in LOCK TABLES and Triggers.

For additional discussion of trigger use, see Section 25.3.1, “Trigger Syntax and Examples”.

13.1.23 CREATE VIEW Statement

CREATE

[OR REPLACE]
CREATE VIEW Statement

The `CREATE VIEW` statement creates a new view, or replaces an existing view if the `OR REPLACE` clause is given. If the view does not exist, `CREATE OR REPLACE VIEW` is the same as `CREATE VIEW`. If the view does exist, `CREATE OR REPLACE VIEW` replaces it.

For information about restrictions on view use, see Section 25.9, “Restrictions on Views”.

The `select_statement` is a `SELECT` statement that provides the definition of the view. (Selecting from the view selects, in effect, using the `SELECT` statement.) The `select_statement` can select from base tables or from other views. The `SELECT` statement can use a `VALUES` statement as its source, or can be replaced with a `TABLE` statement, as with `CREATE TABLE ... SELECT`.

The view definition is “frozen” at creation time and is not affected by subsequent changes to the definitions of the underlying tables. For example, if a view is defined as `SELECT *` on a table, new columns added to the table later do not become part of the view, and columns dropped from the table result in an error when selecting from the view.

The `ALGORITHM` clause affects how MySQL processes the view. The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at view invocation time. The `WITH CHECK OPTION` clause can be given to constrain inserts or updates to rows in tables referenced by the view. These clauses are described later in this section.

The `CREATE VIEW` statement requires the `CREATE VIEW` privilege for the view, and some privilege for each column selected by the `SELECT` statement. For columns used elsewhere in the `SELECT` statement, you must have the `SELECT` privilege. If the `OR REPLACE` clause is present, you must also have the `DROP` privilege for the view. If the `DEFINER` clause is present, the privileges required depend on the `user` value, as discussed in Section 25.6, “Stored Object Access Control”.

When a view is referenced, privilege checking occurs as described later in this section.

A view belongs to a database. By default, a new view is created in the default database. To create the view explicitly in a given database, use `db_name.view_name` syntax to qualify the view name with the database name:

```
CREATE VIEW test.v AS SELECT * FROM t;
```

Unqualified table or view names in the `SELECT` statement are also interpreted with respect to the default database. A view can refer to tables or views in other databases by qualifying the table or view name with the appropriate database name.

Within a database, base tables and views share the same namespace, so a base table and a view cannot have the same name.

Columns retrieved by the `SELECT` statement can be simple references to table columns, or expressions that use functions, constant values, operators, and so forth.

A view must have unique column names with no duplicates, just like a base table. By default, the names of the columns retrieved by the `SELECT` statement are used for the view column names. To define explicit names for the view columns, specify the optional `column_list` clause as a list of comma-separated identifiers. The number of names in `column_list` must be the same as the number of columns retrieved by the `SELECT` statement.
A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables:

```
CREATE VIEW v_today (today) AS SELECT CURRENT_DATE;
```

The following example defines a view that selects two columns from another table as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+------+-------+-------+
<table>
<thead>
<tr>
<th>qty</th>
<th>price</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>50</td>
<td>150</td>
</tr>
</tbody>
</table>
+------+-------+-------+
```

A view definition is subject to the following restrictions:

- The `SELECT` statement cannot refer to system variables or user-defined variables.
- Within a stored program, the `SELECT` statement cannot refer to program parameters or local variables.
- The `SELECT` statement cannot refer to prepared statement parameters.
- Any table or view referred to in the definition must exist. If, after the view has been created, a table or view that the definition refers to is dropped, use of the view results in an error. To check a view definition for problems of this kind, use the `CHECK TABLE` statement.
- The definition cannot refer to a `TEMPORARY` table, and you cannot create a `TEMPORARY` view.
- You cannot associate a trigger with a view.
- Aliases for column names in the `SELECT` statement are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).

`ORDER BY` is permitted in a view definition, but it is ignored if you select from a view using a statement that has its own `ORDER BY`.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a `LIMIT` clause, and you select from the view using a statement that has its own `LIMIT` clause, it is undefined which limit applies. This same principle applies to options such as `ALL`, `DISTINCT`, or `SQL_SMALL_RESULT` that follow the `SELECT` keyword, and to clauses such as `INTO`, `FOR UPDATE`, `FOR SHARE`, `LOCK IN SHARE MODE`, and `PROCEDURE`.

The results obtained from a view may be affected if you change the query processing environment by changing system variables:

```
mysql> CREATE VIEW v (mycol) AS SELECT 'abc';
Query OK, 0 rows affected (0.01 sec)
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT "mycol" FROM v;
+-------+
| mycol |
+-------+
```
The **DEFINER** and **SQL SECURITY** clauses determine which MySQL account to use when checking access privileges for the view when a statement is executed that references the view. The valid **SQL SECURITY** characteristic values are **DEFINER** (the default) and **INVOKER**. These indicate that the required privileges must be held by the user who defined or invoked the view, respectively.

If the **DEFINER** clause is present, the **user** value should be a MySQL account specified as `'{user_name}@{host_name}', CURRENT_USER, or CURRENT_USER()` . The permitted **user** values depend on the privileges you hold, as discussed in Section 25.6, “Stored Object Access Control”. Also see that section for additional information about view security.

If the **DEFINER** clause is omitted, the default definer is the user who executes the **CREATE VIEW** statement. This is the same as specifying **DEFINER = CURRENT_USER** explicitly.

Within a view definition, the **CURRENT_USER** function returns the view's **DEFINER** value by default. For views defined with the **SQL SECURITY INVOKER** characteristic, **CURRENT_USER** returns the account for the view's invoker. For information about user auditing within views, see Section 6.2.23, “SQL-Based Account Activity Auditing”.

Within a stored routine that is defined with the **SQL SECURITY DEFINER** characteristic, **CURRENT_USER** returns the routine's **DEFINER** value. This also affects a view defined within such a routine, if the view definition contains a **DEFINER** value of **CURRENT_USER**.

MySQL checks view privileges like this:

- At view definition time, the view creator must have the privileges needed to use the top-level objects accessed by the view. For example, if the view definition refers to table columns, the creator must have some privilege for each column in the select list of the definition, and the **SELECT** privilege for each column used elsewhere in the definition. If the definition refers to a stored function, only the privileges needed to invoke the function can be checked. The privileges required at function invocation time can be checked only as it executes: For different invocations, different execution paths within the function might be taken.

- The user who references a view must have appropriate privileges to access it (**SELECT** to select from it, **INSERT** to insert into it, and so forth.)

- When a view has been referenced, privileges for objects accessed by the view are checked against the privileges held by the view **DEFINER** account or invoker, depending on whether the **SQL SECURITY** characteristic is **DEFINER** or **INVOKER**, respectively.

- If reference to a view causes execution of a stored function, privilege checking for statements executed within the function depend on whether the function **SQL SECURITY** characteristic is **DEFINER** or **INVOKER**. If the security characteristic is **DEFINER**, the function runs with the privileges of the **DEFINER** account. If the characteristic is **INVOKER**, the function runs with the privileges determined by the view's **SQL SECURITY** characteristic.
Example: A view might depend on a stored function, and that function might invoke other stored routines. For example, the following view invokes a stored function \( f() \):

```
CREATE VIEW v AS SELECT * FROM t WHERE t.id = f(t.name);
```

Suppose that \( f() \) contains a statement such as this:

```
IF name IS NULL then
  CALL p1();
ELSE
  CALL p2();
END IF;
```

The privileges required for executing statements within \( f() \) need to be checked when \( f() \) executes. This might mean that privileges are needed for \( p1() \) or \( p2() \), depending on the execution path within \( f() \). Those privileges must be checked at runtime, and the user who must possess the privileges is determined by the SQL SECURITY values of the view \( v \) and the function \( f() \).

The DEFINER and SQL SECURITY clauses for views are extensions to standard SQL. In standard SQL, views are handled using the rules for SQL SECURITY DEFINER. The standard says that the definer of the view, which is the same as the owner of the view's schema, gets applicable privileges on the view (for example, SELECT) and may grant them. MySQL has no concept of a schema “owner”, so MySQL adds a clause to identify the definer. The DEFINER clause is an extension where the intent is to have what the standard has; that is, a permanent record of who defined the view. This is why the default DEFINER value is the account of the view creator.

The optional ALGORITHM clause is a MySQL extension to standard SQL. It affects how MySQL processes the view. ALGORITHM takes three values: MERGE, TEMPTABLE, or UNDEFINED. For more information, see Section 25.5.2, “View Processing Algorithms”, as well as Section 8.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”.

Some views are updatable. That is, you can use them in statements such as UPDATE, DELETE, or INSERT to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable.

A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is DEFAULT. For information about generated columns, see Section 13.1.20.8, “CREATE TABLE and Generated Columns”.

The WITH CHECK OPTION clause can be given for an updatable view to prevent inserts or updates to rows except those for which the WHERE clause in the select_statement is true.

In a WITH CHECK OPTION clause for an updatable view, the LOCAL and CASCADED keywords determine the scope of check testing when the view is defined in terms of another view. The LOCAL keyword restricts the CHECK OPTION only to the view being defined. CASCADED causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is CASCADED.

For more information about updatable views and the WITH CHECK OPTION clause, see Section 25.5.3, “Updatable and Insertable Views”, and Section 25.5.4, “The View WITH CHECK OPTION Clause”.

13.1.24 DROP DATABASE Statement

```
DROP {DATABASE | SCHEMA} [IF EXISTS] db_name
```

DROP DATABASE drops all tables in the database and deletes the database. Be very careful with this statement! To use DROP DATABASE, you need the DROP privilege on the database. DROP SCHEMA is a synonym for DROP DATABASE.
Important

When a database is dropped, privileges granted specifically for the database are not automatically dropped. They must be dropped manually. See Section 13.7.1.6, “GRANT Statement”.

**IF EXISTS** is used to prevent an error from occurring if the database does not exist.

If the default database is dropped, the default database is unset (the `DATABASE()` function returns NULL).

If you use `DROP DATABASE` on a symbolically linked database, both the link and the original database are deleted.

`DROP DATABASE` returns the number of tables that were removed.

The `DROP DATABASE` statement removes from the given database directory those files and directories that MySQL itself may create during normal operation. This includes all files with the extensions shown in the following list:

- `.BAK`
- `.DAT`
- `.HSH`
- `.MRG`
- `.MYD`
- `.MYI`
- `.cfg`
- `.db`
- `.ibd`
- `.ndb`

If other files or directories remain in the database directory after MySQL removes those just listed, the database directory cannot be removed. In this case, you must remove any remaining files or directories manually and issue the `DROP DATABASE` statement again.

Dropping a database does not remove any `TEMPORARY` tables that were created in that database. `TEMPORARY` tables are automatically removed when the session that created them ends. See Section 13.1.20.2, “CREATE TEMPORARY TABLE Statement”.

You can also drop databases with `mysqladmin`. See Section 4.5.2, "mysqladmin — A MySQL Server Administration Program".

### 13.1.25 DROP EVENT Statement

```
DROP EVENT [IF EXISTS] event_name
```

This statement drops the event named `event_name`. The event immediately ceases being active, and is deleted completely from the server.

If the event does not exist, the error `ERROR 1517 (HY000): Unknown event 'event_name'` results. You can override this and cause the statement to generate a warning for nonexistent events instead using **IF EXISTS**.
DROP FUNCTION Statement

This statement requires the EVENT privilege for the schema to which the event to be dropped belongs.

13.1.26 DROP FUNCTION Statement

The DROP FUNCTION statement is used to drop stored functions and loadable functions:

- For information about dropping stored functions, see Section 13.1.29, "DROP PROCEDURE and DROP FUNCTION Statements".
- For information about dropping loadable functions, see Section 13.7.4.2, "DROP FUNCTION Statement for Loadable Functions".

13.1.27 DROP INDEX Statement

DROP INDEX index_name ON tbl_name

algorithm_option: ALGORITHM [=] {DEFAULT | INPLACE | COPY}

lock_option: LOCK [=] {DEFAULT | NONE | SHARED | EXCLUSIVE}

DROP INDEX drops the index named index_name from the table tbl_name. This statement is mapped to an ALTER TABLE statement to drop the index. See Section 13.1.9, "ALTER TABLE Statement".

To drop a primary key, the index name is always PRIMARY, which must be specified as a quoted identifier because PRIMARY is a reserved word:

DROP INDEX `PRIMARY` ON t;

Indexes on variable-width columns of NDB tables are dropped online; that is, without any table copying. The table is not locked against access from other NDB Cluster API nodes, although it is locked against other operations on the same API node for the duration of the operation. This is done automatically by the server whenever it determines that it is possible to do so; you do not have to use any special SQL syntax or server options to cause it to happen.

ALGORITHM and LOCK clauses may be given to influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the same meaning as for the ALTER TABLE statement. For more information, see Section 13.1.9, "ALTER TABLE Statement".

MySQL NDB Cluster supports online operations using the same ALGORITHM=INPLACE syntax supported in the standard MySQL Server. See Section 23.6.12, "Online Operations with ALTER TABLE in NDB Cluster", for more information.

13.1.28 DROP LOGFILE GROUP Statement

DROP LOGFILE GROUP logfile_group

ENGINE [=] engine_name

This statement drops the log file group named logfile_group. The log file group must already exist or an error results. (For information on creating log file groups, see Section 13.1.16, "CREATE LOGFILE GROUP Statement".)

Important
Before dropping a log file group, you must drop all tablespaces that use that log file group for UNDO logging.
The required ENGINE clause provides the name of the storage engine used by the log file group to be dropped. Currently, the only permitted values for engine_name are NDB and NDBCLUSTER.

DROP LOGFILE GROUP is useful only with Disk Data storage for NDB Cluster. See Section 23.6.11, “NDB Cluster Disk Data Tables”.

### 13.1.29 DROP PROCEDURE and DROP FUNCTION Statements

```sql
DROP {PROCEDURE | FUNCTION} [IF EXISTS] sp_name
```

These statements are used to drop a stored routine (a stored procedure or function). That is, the specified routine is removed from the server. (DROP FUNCTION is also used to drop loadable functions; see Section 13.7.4.2, “DROP FUNCTION Statement for Loadable Functions”.)

To drop a stored routine, you must have the ALTER ROUTINE privilege for it. (If the automatic_sp_privileges system variable is enabled, that privilege and EXECUTE are granted automatically to the routine creator when the routine is created and dropped from the creator when the routine is dropped. See Section 25.2.2, “Stored Routines and MySQL Privileges”.)

In addition, if the definer of the routine has the SYSTEM_USER privilege, the user dropping it must also have this privilege.

The IF EXISTS clause is a MySQL extension. It prevents an error from occurring if the procedure or function does not exist. A warning is produced that can be viewed with SHOW WARNINGS.

DROP FUNCTION is also used to drop loadable functions (see Section 13.7.4.2, “DROP FUNCTION Statement for Loadable Functions”).

### 13.1.30 DROP SERVER Statement

```sql
DROP SERVER [ IF EXISTS ] server_name
```

Drops the server definition for the server named server_name. The corresponding row in the mysql.servers table is deleted. This statement requires the SUPER privilege.

Dropping a server for a table does not affect any FEDERATED tables that used this connection information when they were created. See Section 13.1.18, “CREATE SERVER Statement”.

DROP SERVER causes an implicit commit. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

DROP SERVER is not written to the binary log, regardless of the logging format that is in use.

### 13.1.31 DROP SPATIAL REFERENCE SYSTEM Statement

```sql
DROP SPATIAL REFERENCE SYSTEM
  [IF EXISTS] srid
```

srid: 32-bit unsigned integer

This statement removes a spatial reference system (SRS) definition from the data dictionary. It requires the SUPER privilege.

Example:
DROP SPATIAL REFERENCE SYSTEM 4120;

If no SRS definition with the SRID value exists, an error occurs unless **IF EXISTS** is specified. In that case, a warning occurs rather than an error.

If the SRID value is used by some column in an existing table, an error occurs. For example:

```sql
mysql> DROP SPATIAL REFERENCE SYSTEM 4326;
ERROR 3716 (SR005): Can't modify SRID 4326. There is at least one column depending on it.
```

To identify which column or columns use the SRID, use this query:

```sql
SELECT * FROM INFORMATION_SCHEMA.ST_GEOMETRY_COLUMNS WHERE SRS_ID=4326;
```

SRID values must be in the range of 32-bit unsigned integers, with these restrictions:

- SRID 0 is a valid SRID but cannot be used with **DROP SPATIAL REFERENCE SYSTEM**.
- If the value is in a reserved SRID range, a warning occurs. Reserved ranges are [0, 32767] (reserved by EPSG), [60,000,000, 69,999,999] (reserved by EPSG), and [2,000,000,000, 2,147,483,647] (reserved by MySQL). EPSG stands for the European Petroleum Survey Group.
- Users should not drop SRSs with SRIDs in the reserved ranges. If system-installed SRSs are dropped, the SRS definitions may be recreated for MySQL upgrades.

### 13.1.32 DROP TABLE Statement

```sql
DROP [TEMPORARY] TABLE [IF EXISTS] 
  tbl_name [, tbl_name] ...
  [RESTRICT | CASCADE]
```

**DROP TABLE** removes one or more tables. You must have the **DROP** privilege for each table.

*Be careful* with this statement! For each table, it removes the table definition and all table data. If the table is partitioned, the statement removes the table definition, all its partitions, all data stored in those partitions, and all partition definitions associated with the dropped table.

Dropping a table also drops any triggers for the table.

**DROP TABLE** causes an implicit commit, except when used with the **TEMPORARY** keyword. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

---

**Important**

When a table is dropped, privileges granted specifically for the table are *not* automatically dropped. They must be dropped manually. See Section 13.7.1.6, “GRANT Statement”.

If any tables named in the argument list do not exist, **DROP TABLE** behavior depends on whether the **IF EXISTS** clause is given:

- **Without IF EXISTS**, the statement fails with an error indicating which nonexistent tables it was unable to drop, and no changes are made.

- **With IF EXISTS**, no error occurs for nonexistent tables. The statement drops all named tables that do exist, and generates a **NOTE** diagnostic for each nonexistent table. These notes can be displayed with **SHOW WARNINGS**. See Section 13.7.7.44, “SHOW WARNINGS Statement”.

---
**DROP TABLESPACE Statement**

*IF EXISTS* can also be useful for dropping tables in unusual circumstances under which there is an entry in the data dictionary but no table managed by the storage engine. (For example, if an abnormal server exit occurs after removal of the table from the storage engine but before removal of the data dictionary entry.)

The **TEMPORARY** keyword has the following effects:

- The statement drops only **TEMPORARY** tables.
- The statement does not cause an implicit commit.
- No access rights are checked. A **TEMPORARY** table is visible only with the session that created it, so no check is necessary.

Including the **TEMPORARY** keyword is a good way to prevent accidentally dropping non-**TEMPORARY** tables.

The **RESTRICT** and **CASCADE** keywords do nothing. They are permitted to make porting easier from other database systems.

**DROP TABLE** is not supported with all **innodb_force_recovery** settings. See Section 15.21.3, “Forcing InnoDB Recovery”.

### 13.1.33 DROP TABLESPACE Statement

```sql
DROP [UNDO] TABLESPACE tablespace_name
    [ENGINE [=] engine_name]
```

This statement drops a tablespace that was previously created using **CREATE TABLESPACE**. It is supported by the **NDB** and **InnoDB** storage engines.

The **UNDO** keyword must be specified to drop an undo tablespace. Only undo tablespaces created using **CREATE UNDO TABLESPACE** syntax can be dropped. An undo tablespace must be in an empty state before it can be dropped. For more information, see Section 15.6.3.4, “Undo Tablespaces”.

**ENGINE** sets the storage engine that uses the tablespace, where `engine_name` is the name of the storage engine. Currently, the values **InnoDB** and **NDB** are supported. If not set, the value of **default_storage_engine** is used. If it is not the same as the storage engine used to create the tablespace, the **DROP TABLESPACE** statement fails.

**tablespace_name** is a case-sensitive identifier in MySQL.

For an **InnoDB** general tablespace, all tables must be dropped from the tablespace prior to a **DROP TABLESPACE** operation. If the tablespace is not empty, **DROP TABLESPACE** returns an error.

An **NDB** tablespace to be dropped must not contain any data files; in other words, before you can drop an **NDB** tablespace, you must first drop each of its data files using **ALTER TABLESPACE ... DROP DATAFILE**.

**Notes**

- A general **InnoDB** tablespace is not deleted automatically when the last table in the tablespace is dropped. The tablespace must be dropped explicitly using **DROP TABLESPACE tablespace_name**.
- A **DROP DATABASE** operation can drop tables that belong to a general tablespace but it cannot drop the tablespace, even if the operation drops all tables that belong to the tablespace. The tablespace must be dropped explicitly using **DROP TABLESPACE tablespace_name**.
- Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace `.ibd data file` which can only be used for new **InnoDB** data. Space is not released back to the operating system as it is for file-per-table tablespaces.
InnoDB Examples

This example demonstrates how to drop an InnoDB general tablespace. The general tablespace ts1 is created with a single table. Before dropping the tablespace, the table must be dropped.

```sql
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 Engine=InnoDB;
mysql> DROP TABLE t1;
mysql> DROP TABLESPACE ts1;
```

This example demonstrates dropping an undo tablespace. An undo tablespace must be in an empty state before it can be dropped. For more information, see Section 15.6.3.4, “Undo Tablespaces”.

```sql
mysql> DROP UNDO TABLESPACE undo_003;
```

NDB Example

This example shows how to drop an NDB tablespace myts having a data file named mydata-1.dat after first creating the tablespace, and assumes the existence of a log file group named mylg (see Section 13.1.16, “CREATE LOGFILE GROUP Statement”).

```sql
mysql> CREATE TABLESPACE myts
->     ADD DATAFILE 'mydata-1.dat'
->     USE LOGFILE GROUP mylg
->     ENGINE=NDB;
```

You must remove all data files from the tablespace using ALTER TABLESPACE, as shown here, before it can be dropped:

```sql
mysql> ALTER TABLESPACE myts
->     DROP DATAFILE 'mydata-1.dat'
->     ENGINE=NDB;
mysql> DROP TABLESPACE myts;
```

13.1.34 DROP TRIGGER Statement

DROP TRIGGER [IF EXISTS] [schema_name.]trigger_name

This statement drops a trigger. The schema (database) name is optional. If the schema is omitted, the trigger is dropped from the default schema. DROP TRIGGER requires the TRIGGER privilege for the table associated with the trigger.

Use IF EXISTS to prevent an error from occurring for a trigger that does not exist. A NOTE is generated for a nonexistent trigger when using IF EXISTS. See Section 13.7.7.44, “SHOW WARNINGS Statement”.

Triggers for a table are also dropped if you drop the table.

13.1.35 DROP VIEW Statement

DROP VIEW [IF EXISTS] view_name [, view_name] ...
[RESTRICT | CASCADE]

DROP VIEW removes one or more views. You must have the DROP privilege for each view.
If any views named in the argument list do not exist, the statement fails with an error indicating by name which nonexisting views it was unable to drop, and no changes are made.

**Note**

In MySQL 8.1 and earlier, `DROP VIEW` returns an error if any views named in the argument list do not exist, but also drops all views in the list that do exist. Due to the change in behavior in MySQL 8.2, a partially completed `DROP VIEW` operation on a MySQL 8.1 replication source server fails when replicated on a MySQL 8.2 replica. To avoid this failure scenario, use `IF EXISTS` syntax in `DROP VIEW` statements to prevent an error from occurring for views that do not exist. For more information, see Section 13.1.1, “Atomic Data Definition Statement Support”.

The `IF EXISTS` clause prevents an error from occurring for views that don't exist. When this clause is given, a `NOTE` is generated for each nonexistent view. See Section 13.7.7.44, “SHOW WARNINGS Statement”.

`RESTRICT` and `CASCADE`, if given, are parsed and ignored.

**13.1.36 RENAME TABLE Statement**

```
RENAME TABLE
    tbl_name TO new_tbl_name
 [, tbl_name2 TO new_tbl_name2] ...
```

`RENAME TABLE` renames one or more tables. You must have `ALTER` and `DROP` privileges for the original table, and `CREATE` and `INSERT` privileges for the new table.

For example, to rename a table named `old_table` to `new_table`, use this statement:

```
RENAME TABLE old_table TO new_table;
```

That statement is equivalent to the following `ALTER TABLE` statement:

```
ALTER TABLE old_table RENAME new_table;
```

`RENAME TABLE`, unlike `ALTER TABLE`, can rename multiple tables within a single statement:

```
RENAME TABLE
    old_table1 TO new_table1,
    old_table2 TO new_table2,
    old_table3 TO new_table3;
```

Renaming operations are performed left to right. Thus, to swap two table names, do this (assuming that a table with the intermediary name `tmp_table` does not already exist):

```
RENAME TABLE old_table TO tmp_table,
    new_table TO old_table,
    tmp_table TO new_table;
```

Metadata locks on tables are acquired in name order, which in some cases can make a difference in operation outcome when multiple transactions execute concurrently. See Section 8.11.4, “Metadata Locking”.

You can rename tables locked with a `LOCK TABLES` statement, provided that they are locked with a `WRITE` lock or are the product of renaming `WRITE`-locked tables from earlier steps in a multiple-table rename operation. For example, this is permitted:

```
LOCK TABLE old_table1 WRITE;
RENAME TABLE old_table1 TO new_table1;
```
RENAME TABLE Statement

new_table1 TO new_table2;

This is not permitted:

LOCK TABLE old_table1 READ;
RENAME TABLE old_table1 TO new_table1,
    new_table1 TO new_table2;

With the transaction table locking conditions satisfied, the rename operation is done atomically; no other session can access any of the tables while the rename is in progress.

If any errors occur during a RENAME TABLE, the statement fails and no changes are made.

You can use RENAME TABLE to move a table from one database to another:

RENAME TABLE current_db.tbl_name TO other_db.tbl_name;

Using this method to move all tables from one database to a different one in effect renames the database (an operation for which MySQL has no single statement), except that the original database continues to exist, albeit with no tables.

Like RENAME TABLE, ALTER TABLE ... RENAME can also be used to move a table to a different database. Regardless of the statement used, if the rename operation would move the table to a database located on a different file system, the success of the outcome is platform specific and depends on the underlying operating system calls used to move table files.

If a table has triggers, attempts to rename the table into a different database fail with a Trigger in wrong schema (ER_TRG_IN_WRONG_SCHEMA) error.

An unencrypted table can be moved to an encryption-enabled database and vice versa. However, if the table_encryption_privilege_check variable is enabled, the TABLE_ENCRYPTION_ADMIN privilege is required if the table encryption setting differs from the default database encryption.

To rename TEMPORARY tables, RENAME TABLE does not work. Use ALTER TABLE instead.

RENAME TABLE works for views, except that views cannot be renamed into a different database.

Any privileges granted specifically for a renamed table or view are not migrated to the new name. They must be changed manually.

RENAME TABLE tbl_name TO new_tbl_name changes internally generated foreign key constraint names and user-defined foreign key constraint names that begin with the string "tbl_name_ibfk_" to reflect the new table name. InnoDB interprets foreign key constraint names that begin with the string "tbl_name_ibfk_" as internally generated names.

Foreign key constraint names that point to the renamed table are automatically updated unless there is a conflict, in which case the statement fails with an error. A conflict occurs if the renamed constraint name already exists. In such cases, you must drop and re-create the foreign keys for them to function properly.

RENAME TABLE tbl_name TO new_tbl_name changes internally generated and user-defined CHECK constraint names that begin with the string “tbl_name_chk_” to reflect the new table name. MySQL interprets CHECK constraint names that begin with the string “tbl_name_chk_” as internally generated names. Example:

mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
Table: t1
TRUNCATE TABLE Statement

13.1.37 TRUNCATE TABLE Statement

TRUNCATE [TABLE] tbl_name

TRUNCATE TABLE empties a table completely. It requires the DROP privilege. Logically, TRUNCATE TABLE is similar to a DELETE statement that deletes all rows, or a sequence of DROP TABLE and CREATE TABLE statements.

To achieve high performance, TRUNCATE TABLE bypasses the DML method of deleting data. Thus, it does not cause ON DELETE triggers to fire, it cannot be performed for InnoDB tables with parent-child foreign key relationships, and it cannot be rolled back like a DML operation. However, TRUNCATE TABLE operations on tables that use an atomic DDL-supported storage engine are either fully committed or rolled back if the server halts during their operation. For more information, see Section 13.1.1, “Atomic Data Definition Statement Support”.

Although TRUNCATE TABLE is similar to DELETE, it is classified as a DDL statement rather than a DML statement. It differs from DELETE in the following ways:

• Truncate operations drop and re-create the table, which is much faster than deleting rows one by one, particularly for large tables.

• Truncate operations cause an implicit commit, and so cannot be rolled back. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

• Truncation operations cannot be performed if the session holds an active table lock.

• TRUNCATE TABLE fails for an InnoDB table or NDB table if there are any FOREIGN KEY constraints from other tables that reference the table. Foreign key constraints between columns of the same table are permitted.

• Truncation operations do not return a meaningful value for the number of deleted rows. The usual result is “0 rows affected,” which should be interpreted as “no information.”

• As long as the table definition is valid, the table can be re-created as an empty table with TRUNCATE TABLE, even if the data or index files have become corrupted.

• Any AUTO_INCREMENT value is reset to its start value. This is true even for MyISAM and InnoDB, which normally do not reuse sequence values.
When used with partitioned tables, `TRUNCATE TABLE` preserves the partitioning; that is, the data and index files are dropped and re-created, while the partition definitions are unaffected.

The `TRUNCATE TABLE` statement does not invoke ON DELETE triggers.

Truncating a corrupted InnoDB table is supported.

`TRUNCATE TABLE` is treated for purposes of binary logging and replication as DDL rather than DML, and is always logged as a statement.

`TRUNCATE TABLE` for a table closes all handlers for the table that were opened with HANDLER OPEN.

`TRUNCATE TABLE` can be used with Performance Schema summary tables, but the effect is to reset the summary columns to 0 or NULL, not to remove rows. See Section 27.12.20, "Performance Schema Summary Tables".

Truncating an InnoDB table that resides in a file-per-table tablespace drops the existing tablespace and creates a new one. If the tablespace was created with an earlier version and resides in an unknown directory, InnoDB creates the new tablespace in the default location and writes the following warning to the error log: The DATA DIRECTORY location must be in a known directory. The DATA DIRECTORY location will be ignored and the file will be put into the default datadir location. Known directories are those defined by the datadir, innodb_data_home_dir, and innodb_directories variables. To have `TRUNCATE TABLE` create the tablespace in its current location, add the directory to the innodb_directories setting before running `TRUNCATE TABLE`.

13.2 Data Manipulation Statements

13.2.1 CALL Statement

```
CALL sp_name([parameter[,...]])
CALL sp_name()
```

The `CALL` statement invokes a stored procedure that was defined previously with `CREATE PROCEDURE`.

Stored procedures that take no arguments can be invoked without parentheses. That is, `CALL p()` and `CALL p` are equivalent.

`CALL` can pass back values to its caller using parameters that are declared as OUT or INOUT parameters. When the procedure returns, a client program can also obtain the number of rows affected for the final statement executed within the routine: At the SQL level, call the `ROW_COUNT()` function; from the C API, call the `mysql_affected_rows()` function.

For information about the effect of unhandled conditions on procedure parameters, see Section 13.6.7.8, "Condition Handling and OUT or INOUT Parameters".

To get back a value from a procedure using an OUT or INOUT parameter, pass the parameter by means of a user variable, and then check the value of the variable after the procedure returns. (If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an IN or INOUT parameter.) For an INOUT parameter, initialize its value before passing it to the procedure. The following procedure has an OUT parameter that the procedure sets to the current server version, and an INOUT value that the procedure increments by one from its current value:

```
DELIMITER //

CREATE PROCEDURE p (OUT ver_param VARCHAR(25), INOUT incr_param INT)
BEGIN
  # Set value of OUT parameter
  ver_param = "2766";
  incr_param = incr_param + 1;
END;
```

2766
DELETE Statement

```sql
SELECT VERSION() INTO ver_param;
# Increment value of INOUT parameter
SET incr_param = incr_param + 1;
END //
DELIMITER ;
```

Before calling the procedure, initialize the variable to be passed as the INOUT parameter. After calling the procedure, you can see that the values of the two variables are set or modified:

```sql
mysql> SET @increment = 10;
mysql> CALL p(@version, @increment);
mysql> SELECT @version, @increment;
+----------+------------+
<table>
<thead>
<tr>
<th>@version</th>
<th>@increment</th>
</tr>
</thead>
<tbody>
<tr>
<td>8.2.0</td>
<td>11</td>
</tr>
</tbody>
</table>
+----------+------------+
```

In prepared CALL statements used with PREPARE and EXECUTE, placeholders can be used for IN parameters, OUT, and INOUT parameters. These types of parameters can be used as follows:

```sql
mysql> SET @increment = 10;
mysql> PREPARE s FROM 'CALL p(?, ?)';
mysql> EXECUTE s USING @version, @increment;
mysql> SELECT @version, @increment;
+----------+------------+
<table>
<thead>
<tr>
<th>@version</th>
<th>@increment</th>
</tr>
</thead>
<tbody>
<tr>
<td>8.2.0</td>
<td>11</td>
</tr>
</tbody>
</table>
+----------+------------+
```

To write C programs that use the CALL SQL statement to execute stored procedures that produce result sets, the CLIENT_MULTI_RESULTS flag must be enabled. This is because each CALL returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. CLIENT_MULTI_RESULTS must also be enabled if CALL is used to execute any stored procedure that contains prepared statements. It cannot be determined when such a procedure is loaded whether those statements produce result sets, so it is necessary to assume that they do so.

CLIENT_MULTI_RESULTS can be enabled when you call mysql_real_connect(), either explicitly by passing the CLIENT_MULTI_RESULTS flag itself, or implicitly by passing CLIENT_MULTI_STATEMENTS (which also enables CLIENT_MULTI_RESULTS). CLIENT_MULTI_RESULTS is enabled by default.

To process the result of a CALL statement executed using mysql_query() or mysql_real_query(), use a loop that calls mysql_next_result() to determine whether there are more results. For an example, see Multiple Statement Execution Support.

C programs can use the prepared-statement interface to execute CALL statements and access OUT and INOUT parameters. This is done by processing the result of a CALL statement using a loop that calls mysql_stmt_next_result() to determine whether there are more results. For an example, see Prepared CALL Statement Support. Languages that provide a MySQL interface can use prepared CALL statements to directly retrieve OUT and INOUT procedure parameters.

Metadata changes to objects referred to by stored programs are detected and cause automatic reparsing of the affected statements when the program is next executed. For more information, see Section 8.10.3, “Caching of Prepared Statements and Stored Programs”.

### 13.2.2 DELETE Statement

DELETE is a DML statement that removes rows from a table.
A **DELETE** statement can start with a **WITH** clause to define common table expressions accessible within the **DELETE**. See Section 13.2.20, “WITH (Common Table Expressions)”. 

**Single-Table Syntax**

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE] FROM tbl_name [[AS] tbl_alias]
  [PARTITION (partition_name [, partition_name] ...)]
  [WHERE where_condition]
  [ORDER BY ...]
  [LIMIT row_count]
```

The **DELETE** statement deletes rows from `tbl_name` and returns the number of deleted rows. To check the number of deleted rows, call the **ROW_COUNT()** function described in Section 12.15, “Information Functions”.

**Main Clauses**

The conditions in the optional **WHERE** clause identify which rows to delete. With no **WHERE** clause, all rows are deleted.

`where_condition` is an expression that evaluates to true for each row to be deleted. It is specified as described in Section 13.2.13, “SELECT Statement”.

If the **ORDER BY** clause is specified, the rows are deleted in the order that is specified. The **LIMIT** clause places a limit on the number of rows that can be deleted. These clauses apply to single-table deletes, but not multi-table deletes.

**Multiple-Table Syntax**

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
  tbl_name[.*] [, tbl_name[.*]] ... FROM table_references
WHERE where_condition
```

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
  FROM tbl_name[.*] [, tbl_name[.*]] ...
  USING table_references
WHERE where_condition
```

**Privileges**

You need the **DELETE** privilege on a table to delete rows from it. You need only the **SELECT** privilege for any columns that are only read, such as those named in the **WHERE** clause.

**Performance**

When you do not need to know the number of deleted rows, the **TRUNCATE TABLE** statement is a faster way to empty a table than a **DELETE** statement with no **WHERE** clause. Unlike **DELETE**, **TRUNCATE TABLE** cannot be used within a transaction or if you have a lock on the table. See Section 13.1.37, “TRUNCATE TABLE Statement” and Section 13.3.6, “LOCK TABLES and UNLOCK TABLES Statements”.

The speed of delete operations may also be affected by factors discussed in Section 8.2.5.3, “Optimizing DELETE Statements”.

To ensure that a given **DELETE** statement does not take too much time, the MySQL-specific **LIMIT row_count** clause for **DELETE** specifies the maximum number of rows to be deleted. If the number of rows to delete is larger than the limit, repeat the **DELETE** statement until the number of affected rows is less than the **LIMIT** value.
DELETE Statement

Subqueries

You cannot delete from a table and select from the same table in a subquery.

Partitioned Table Support

DELETE supports explicit partition selection using the PARTITION clause, which takes a list of the comma-separated names of one or more partitions or subpartitions (or both) from which to select rows to be dropped. Partitions not included in the list are ignored. Given a partitioned table `t` with a partition named `p0`, executing the statement `DELETE FROM t PARTITION (p0)` has the same effect on the table as executing `ALTER TABLE t TRUNCATE PARTITION (p0)`; in both cases, all rows in partition `p0` are dropped.

`PARTITION` can be used along with a `WHERE` condition, in which case the condition is tested only on rows in the listed partitions. For example, `DELETE FROM t PARTITION (p0) WHERE c < 5` deletes rows only from partition `p0` for which the condition `c < 5` is true; rows in any other partitions are not checked and thus not affected by the `DELETE`.

The `PARTITION` clause can also be used in multiple-table DELETE statements. You can use up to one such option per table named in the `FROM` option.

For more information and examples, see Section 24.5, “Partition Selection”.

Auto-Increment Columns

If you delete the row containing the maximum value for an AUTO_INCREMENT column, the value is not reused for a MyISAM or InnoDB table. If you delete all rows in the table with `DELETE FROM tbl_name` (without a `WHERE` clause) in `autocommit` mode, the sequence starts over for all storage engines except InnoDB and MyISAM. There are some exceptions to this behavior for InnoDB tables, as discussed in Section 15.6.1.6, “AUTO_INCREMENT Handling in InnoDB”.

For MyISAM tables, you can specify an AUTO_INCREMENT secondary column in a multiple-column key. In this case, reuse of values deleted from the top of the sequence occurs even for MyISAM tables. See Section 3.6.9, “Using AUTO_INCREMENT”.

Modifiers

The DELETE statement supports the following modifiers:

- If you specify the LOW_PRIORITY modifier, the server delays execution of the DELETE until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE).

- For MyISAM tables, if you use the QUICK modifier, the storage engine does not merge index leaves during delete, which may speed up some kinds of delete operations.

- The IGNORE modifier causes MySQL to ignore ignorable errors during the process of deleting rows. (Errors encountered during the parsing stage are processed in the usual manner.) Errors that are ignored due to the use of IGNORE are returned as warnings. For more information, see The Effect of IGNORE on Statement Execution.

Order of Deletion

If the DELETE statement includes an ORDER BY clause, rows are deleted in the order specified by the clause. This is useful primarily in conjunction with LIMIT. For example, the following statement finds rows matching the WHERE clause, sorts them by timestamp_column, and deletes the first (oldest) one:
DELETE Statement

```sql
DELETE FROM somelog WHERE user = 'jcole'
ORDER BY timestamp_column LIMIT 1;
```

ORDER BY also helps to delete rows in an order required to avoid referential integrity violations.

**InnoDB Tables**

If you are deleting many rows from a large table, you may exceed the lock table size for an InnoDB table. To avoid this problem, or simply to minimize the time that the table remains locked, the following strategy (which does not use DELETE at all) might be helpful:

1. Select the rows not to be deleted into an empty table that has the same structure as the original table:
   ```sql
   INSERT INTO t_copy SELECT * FROM t WHERE ... ;
   ```

2. Use RENAME TABLE to atomically move the original table out of the way and rename the copy to the original name:
   ```sql
   RENAME TABLE t TO t_old, t_copy TO t;
   ```

3. Drop the original table:
   ```sql
   DROP TABLE t_old;
   ```

No other sessions can access the tables involved while RENAME TABLE executes, so the rename operation is not subject to concurrency problems. See Section 13.1.36, “RENAME TABLE Statement”.

**MyISAM Tables**

In MyISAM tables, deleted rows are maintained in a linked list and subsequent INSERT operations reuse old row positions. To reclaim unused space and reduce file sizes, use the OPTIMIZE TABLE statement or the myisamchk utility to reorganize tables. OPTIMIZE TABLE is easier to use, but myisamchk is faster. See Section 13.7.3.4, “OPTIMIZE TABLE Statement”, and Section 4.6.4, “myisamchk — MyISAM Table-Maintenance Utility”.

The QUICK modifier affects whether index leaves are merged for delete operations. DELETE QUICK is most useful for applications where index values for deleted rows are replaced by similar index values from rows inserted later. In this case, the holes left by deleted values are reused.

DELETE QUICK is not useful when deleted values lead to underfilled index blocks spanning a range of index values for which new inserts occur again. In this case, use of QUICK can lead to wasted space in the index that remains unreclaimed. Here is an example of such a scenario:

1. Create a table that contains an indexed AUTO_INCREMENT column.

2. Insert many rows into the table. Each insert results in an index value that is added to the high end of the index.

3. Delete a block of rows at the low end of the column range using DELETE QUICK.

In this scenario, the index blocks associated with the deleted index values become underfilled but are not merged with other index blocks due to the use of QUICK. They remain underfilled when new inserts occur, because new rows do not have index values in the deleted range. Furthermore, they remain underfilled even if you later use DELETE without QUICK, unless some of the deleted index values happen to lie in index blocks within or adjacent to the underfilled blocks. To reclaim unused index space under these circumstances, use OPTIMIZE TABLE.

If you are going to delete many rows from a table, it might be faster to use DELETE QUICK followed by OPTIMIZE TABLE. This rebuilds the index rather than performing many index block merge operations.
Multi-Table Deletes

You can specify multiple tables in a `DELETE` statement to delete rows from one or more tables depending on the condition in the `WHERE` clause. You cannot use `ORDER BY` or `LIMIT` in a multiple-table `DELETE`. The `table_references` clause lists the tables involved in the join, as described in Section 13.2.13.2, “JOIN Clause”.

For the first multiple-table syntax, only matching rows from the tables listed before the `FROM` clause are deleted. For the second multiple-table syntax, only matching rows from the tables listed in the `FROM` clause (before the `USING` clause) are deleted. The effect is that you can delete rows from many tables at the same time and have additional tables that are used only for searching:

```
DELETE t1, t2 FROM t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

Or:

```
DELETE FROM t1, t2 USING t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

These statements use all three tables when searching for rows to delete, but delete matching rows only from tables `t1` and `t2`.

The preceding examples use `INNER JOIN`, but multiple-table `DELETE` statements can use other types of join permitted in `SELECT` statements, such as `LEFT JOIN`. For example, to delete rows that exist in `t1` that have no match in `t2`, use a `LEFT JOIN`:

```
DELETE t1 FROM t1 LEFT JOIN t2 ON t1.id=t2.id WHERE t2.id IS NULL;
```

The syntax permits `. *` after each `tbl_name` for compatibility with `Access`.

If you use a multiple-table `DELETE` statement involving `InnoDB` tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, you should delete from a single table and rely on the `ON DELETE` capabilities that `InnoDB` provides to cause the other tables to be modified accordingly.

**Note**

If you declare an alias for a table, you must use the alias when referring to the table:

```
DELETE t1 FROM test AS t1, test2 WHERE ...
```

Table aliases in a multiple-table `DELETE` should be declared only in the `table_references` part of the statement. Elsewhere, alias references are permitted but not alias declarations.

Correct:

```
DELETE a1, a2 FROM t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;
```

```
DELETE FROM a1, a2 USING t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;
```

Incorrect:

```
DELETE t1 AS a1, t2 AS a2 FROM t1 INNER JOIN t2
WHERE a1.id=a2.id;
```
DO Statement

DELETE FROM t1 AS a1, t2 AS a2 USING t1 INNER JOIN t2
WHERE a1.id=a2.id;

Table aliases are also supported for single-table DELETE statements.

13.2.3 DO Statement

DO expr [, expr] ...  

DO executes the expressions but does not return any results. In most respects, DO is shorthand for SELECT expr, ..., but has the advantage that it is slightly faster when you do not care about the result.

DO is useful primarily with functions that have side effects, such as RELEASE_LOCK().

Example: This SELECT statement pauses, but also produces a result set:

```
mysql> SELECT SLEEP(5);
+----------+
| SLEEP(5) |
+----------+
| 0        |
+----------+
1 row in set (5.02 sec)
```

DO, on the other hand, pauses without producing a result set:.

```
mysql> DO SLEEP(5);
Query OK, 0 rows affected (4.99 sec)
```

This could be useful, for example in a stored function or trigger, which prohibit statements that produce result sets.

DO only executes expressions. It cannot be used in all cases where SELECT can be used. For example, DO id FROM t1 is invalid because it references a table.

13.2.4 EXCEPT Clause

```
query_expression_body EXCEPT [ALL | DISTINCT] query_expression_body  
[EXCEPT [ALL | DISTINCT] query_expression_body]
[...]
```

query_expression_body:
See Section 13.2.14, “Set Operations with UNION, INTERSECT, and EXCEPT”

EXCEPT limits the result from the first query block to those rows which are (also) not found in the second. As with UNION and INTERSECT, either query block can make use of any of SELECT, TABLE, or VALUES. An example using the tables a, b, and c defined in Section 13.2.8, “INTERSECT Clause”, is shown here:

```
mysql> TABLE a EXCEPT TABLE b;
+------+------+
| m    | n    |
+------+------+
| 2    | 3    |
+------+------+
1 row in set (0.00 sec)
```

```
mysql> TABLE a EXCEPT TABLE c;
+------+------+
<table>
<thead>
<tr>
<th>m</th>
<th>n</th>
</tr>
</thead>
</table>
+------+------|
```
As with `UNION` and `INTERSECT`, if neither `DISTINCT` nor `ALL` is specified, the default is `DISTINCT`.

`DISTINCT` removes duplicates found on either side of the relation, as shown here:

```sql
mysql> TABLE c EXCEPT DISTINCT TABLE a;
+-----+-----+
| m   | n   |
|-----+-----|
| 1   | 3   |
+-----+-----+
1 row in set (0.00 sec)

mysql> TABLE c EXCEPT ALL TABLE a;
+-----+-----+
| m   | n   |
|-----+-----|
| 1   | 3   |
| 1   | 3   |
+-----+-----+
2 rows in set (0.00 sec)
```

(The first statement has the same effect as `TABLE c EXCEPT TABLE a`.)

Unlike `UNION` or `INTERSECT`, `EXCEPT` is *not* commutative—that is, the result depends on the order of the operands, as shown here:

```sql
mysql> TABLE a EXCEPT TABLE c;
+-----+-----+
| m   | n   |
|-----+-----|
| 1   | 2   |
| 2   | 3   |
+-----+-----+
2 rows in set (0.00 sec)

mysql> TABLE c EXCEPT TABLE a;
+-----+-----+
| m   | n   |
|-----+-----|
| 1   | 3   |
+-----+-----+
1 row in set (0.00 sec)
```

As with `UNION`, the result sets to be compared must have the same number of columns. Result set column types are also determined as for `UNION`.

### 13.2.5 HANDLER Statement

```
HANDLER tbl_name OPEN [ [AS] alias]
HANDLER tbl_name READ index_name { = | <= | >= | < | > } (value1,value2,...)
```
The **HANDLER** statement provides direct access to table storage engine interfaces. It is available for **InnoDB** and **MyISAM** tables.

The **HANDLER** ... **OPEN** statement opens a table, making it accessible using subsequent **HANDLER** ... **READ** statements. This table object is not shared by other sessions and is not closed until the session calls **HANDLER** ... **CLOSE** or the session terminates.

If you open the table using an alias, further references to the open table with other **HANDLER** statements must use the alias rather than the table name. If you do not use an alias, but open the table using a table name qualified by the database name, further references must use the unqualified table name. For example, for a table opened using `mydb.mytable`, further references must use `mytable`.

The first **HANDLER** ... **READ** syntax fetches a row where the index specified satisfies the given values and the **WHERE** condition is met. If you have a multiple-column index, specify the index column values as a comma-separated list. Either specify values for all the columns in the index, or specify values for a leftmost prefix of the index columns. Suppose that an index `my_idx` includes three columns named `col_a`, `col_b`, and `col_c`, in that order. The **HANDLER** statement can specify values for all three columns in the index, or for the columns in a leftmost prefix. For example:

```sql
HANDLER ... READ my_idx = (col_a_val,col_b_val,col_c_val) ...
HANDLER ... READ my_idx = (col_a_val,col_b_val) ...
HANDLER ... READ my_idx = (col_a_val) ...
```

To employ the **HANDLER** interface to refer to a table’s **PRIMARY KEY**, use the quoted identifier `'PRIMARY'`:

```sql
HANDLER ... READ `PRIMARY` ...
```

The second **HANDLER** ... **READ** syntax fetches a row from the table in index order that matches the **WHERE** condition.

The third **HANDLER** ... **READ** syntax fetches a row from the table in natural row order that matches the **WHERE** condition. It is faster than **HANDLER** tbl_name READ index_name when a full table scan is desired. Natural row order is the order in which rows are stored in a **MyISAM** table data file. This statement works for **InnoDB** tables as well, but there is no such concept because there is no separate data file.

Without a **LIMIT** clause, all forms of **HANDLER** ... **READ** fetch a single row if one is available. To return a specific number of rows, include a **LIMIT** clause. It has the same syntax as for the **SELECT** statement. See Section 13.2.13, “SELECT Statement”.

**HANDLER** ... **CLOSE** closes a table that was opened with **HANDLER** ... **OPEN**.

There are several reasons to use the **HANDLER** interface instead of normal **SELECT** statements:

- **HANDLER** is faster than **SELECT**:
  - A designated storage engine handler object is allocated for the **HANDLER** ... **OPEN**. The object is reused for subsequent **HANDLER** statements for that table; it need not be reinitialized for each one.
  - There is less parsing involved.
• There is no optimizer or query-checking overhead.

• The handler interface does not have to provide a consistent look of the data (for example, dirty reads are permitted), so the storage engine can use optimizations that `SELECT` does not normally permit.

• `HANDLER` makes it easier to port to MySQL applications that use a low-level `ISAM`-like interface. (See Section 15.20, “InnoDB memcached Plugin” for an alternative way to adapt applications that use the key-value store paradigm.)

• `HANDLER` enables you to traverse a database in a manner that is difficult (or even impossible) to accomplish with `SELECT`. The `HANDLER` interface is a more natural way to look at data when working with applications that provide an interactive user interface to the database.

`HANDLER` is a somewhat low-level statement. For example, it does not provide consistency. That is, `HANDLER ... OPEN` does not take a snapshot of the table, and does not lock the table. This means that after a `HANDLER ... OPEN` statement is issued, table data can be modified (by the current session or other sessions) and these modifications might be only partially visible to `HANDLER ... NEXT` or `HANDLER ... PREV` scans.

An open handler can be closed and marked for reopen, in which case the handler loses its position in the table. This occurs when both of the following circumstances are true:

• Any session executes `FLUSH TABLES` or DDL statements on the handler’s table.

• The session in which the handler is open executes non-`HANDLER` statements that use tables.

`TRUNCATE TABLE` for a table closes all handlers for the table that were opened with `HANDLER OPEN`.

If a table is flushed with `FLUSH TABLES tbl_name WITH READ LOCK` was opened with `HANDLER`, the handler is implicitly flushed and loses its position.

### 13.2.6 IMPORT TABLE Statement

```
IMPORT TABLE FROM sdi_file [, sdi_file] ...
```

The `IMPORT TABLE` statement imports `MyISAM` tables based on information contained in `.sdi` (serialized dictionary information) metadata files. `IMPORT TABLE` requires the `FILE` privilege to read the `.sdi` and table content files, and the `CREATE` privilege for the table to be created.

Tables can be exported from one server using `mysqldump` to write a file of SQL statements and imported into another server using `mysql` to process the dump file. `IMPORT TABLE` provides a faster alternative using the “raw” table files.

Prior to import, the files that provide the table content must be placed in the appropriate schema directory for the import server, and the `.sdi` file must be located in a directory accessible to the server. For example, the `.sdi` file can be placed in the directory named by the `secure_file_priv` system variable, or (if `secure_file_priv` is empty) in a directory under the server data directory.

The following example describes how to export `MyISAM` tables named `employees` and `managers` from the `hr` schema of one server and import them into the `hr` schema of another server. The example uses these assumptions (to perform a similar operation on your own system, modify the path names as appropriate):

• For the export server, `export_basedir` represents its base directory, and its data directory is `export_basedir/data`. 
For the import server, `import_basedir` represents its base directory, and its data directory is `import_basedir/data`.

Table files are exported from the export server into the `/tmp/export` directory and this directory is secure (not accessible to other users).

The import server uses `/tmp/mysql-files` as the directory named by its `secure_file_priv` system variable.

To export tables from the export server, use this procedure:

1. Ensure a consistent snapshot by executing this statement to lock the tables so that they cannot be modified during export:

   ```
   mysql> FLUSH TABLES hr.employees, hr.managers WITH READ LOCK;
   ```

   While the lock is in effect, the tables can still be used, but only for read access.

2. At the file system level, copy the `.sdi` and table content files from the `hr` schema directory to the secure export directory:

   - The `.sdi` file is located in the `hr` schema directory, but might not have exactly the same basename as the table name. For example, the `.sdi` files for the `employees` and `managers` tables might be named `employees_125.sdi` and `managers_238.sdi`.
   - For a MyISAM table, the content files are its `.MYD` data file and `.MYI` index file.

   Given those file names, the copy commands look like this:

   ```
   $> cd export_basedir/data/hr
   $> cp employees_125.sdi /tmp/export
   $> cp managers_238.sdi /tmp/export
   $> cp employees.{MYD,MYI} /tmp/export
   $> cp managers.{MYD,MYI} /tmp/export
   ```

3. Unlock the tables:

   ```
   mysql> UNLOCK TABLES;
   ```

To import tables into the import server, use this procedure:

1. The import schema must exist. If necessary, execute this statement to create it:

   ```
   mysql> CREATE SCHEMA hr;
   ```

2. At the file system level, copy the `.sdi` files to the import server `secure_file_priv` directory, `/tmp/mysql-files`. Also, copy the table content files to the `hr` schema directory:

   ```
   $> cd /tmp/export
   $> cp employees_125.sdi /tmp/mysql-files
   $> cp managers_238.sdi /tmp/mysql-files
   $> cp employees.{MYD,MYI} import_basedir/data/hr
   $> cp managers.{MYD,MYI} import_basedir/data/hr
   ```

3. Import the tables by executing an `IMPORT TABLE` statement that names the `.sdi` files:

   ```
   mysql> IMPORT TABLE FROM
   ' /tmp/mysql-files/employees.sdi',
   ' /tmp/mysql-files/managers.sdi';
   ```

   The `.sdi` file need not be placed in the import server directory named by the `secure_file_priv` system variable if that variable is empty; it can be in any directory accessible to the server, including the schema
IMPORT TABLE Statement

directory for the imported table. If the .sdi file is placed in that directory, however, it may be rewritten; the import operation creates a new .sdi file for the table, which overwrites the old .sdi file if the operation uses the same file name for the new file.

Each sdi_file value must be a string literal that names the .sdi file for a table or is a pattern that matches .sdi files. If the string is a pattern, any leading directory path and the .sdi file name suffix must be given literally. Pattern characters are permitted only in the base name part of the file name:

• ? matches any single character
• * matches any sequence of characters, including no characters

Using a pattern, the previous IMPORT TABLE statement could have been written like this (assuming that the /tmp/mysql-files directory contains no other .sdi files matching the pattern):

```
IMPORT TABLE FROM '/tmp/mysql-files/*.sdi';
```

To interpret the location of .sdi file path names, the server uses the same rules for IMPORT TABLE as the server-side rules for LOAD DATA (that is, the non-LOCAL rules). See Section 13.2.9, “LOAD DATA Statement”, paying particular attention to the rules used to interpret relative path names.

IMPORT TABLE fails if the .sdi or table files cannot be located. After importing a table, the server attempts to open it and reports as warnings any problems detected. To attempt a repair to correct any reported issues, use REPAIR TABLE.

IMPORT TABLE is not written to the binary log.

Restrictions and Limitations

IMPORT TABLE applies only to non-TEMPORARY MyISAM tables. It does not apply to tables created with a transactional storage engine, tables created with CREATE TEMPORARY TABLE, or views.

An .sdi file used in an import operation must be generated on a server with the same data dictionary version and sdi version as the import server. The version information of the generating server is found in the .sdi file:

```
{
  "mysqld_version_id":80019,
  "dd_version":80017,
  "sdi_version":80016,
  ...
}
```

To determine the data dictionary and sdi version of the import server, you can check the .sdi file of a recently created table on the import server.

The table data and index files must be placed in the schema directory for the import server prior to the import operation, unless the table as defined on the export server uses the DATA DIRECTORY or INDEX DIRECTORY table options. In that case, modify the import procedure using one of these alternatives before executing the IMPORT TABLE statement:

• Put the data and index files into the same directory on the import server host as on the export server host, and create symlinks in the import server schema directory to those files.

• Put the data and index files into an import server host directory different from that on the export server host, and create symlinks in the import server schema directory to those files. In addition, modify the .sdi file to reflect the different file locations.
• Put the data and index files into the schema directory on the import server host, and modify the .sdi file to remove the data and index directory table options.

Any collation IDs stored in the .sdi file must refer to the same collations on the export and import servers.

Trigger information for a table is not serialized into the table .sdi file, so triggers are not restored by the import operation.

Some edits to an .sdi file are permissible prior to executing the IMPORT TABLE statement, whereas others are problematic or may even cause the import operation to fail:

• Changing the data directory and index directory table options is required if the locations of the data and index files differ between the export and import servers.

• Changing the schema name is required to import the table into a different schema on the import server than on the export server.

• Changing schema and table names may be required to accommodate differences between file system case-sensitivity semantics on the export and import servers or differences in lower_case_table_names settings. Changing the table names in the .sdi file may require renaming the table files as well.

• In some cases, changes to column definitions are permitted. Changing data types is likely to cause problems.

13.2.7 INSERT Statement

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name
[PARTITION (partition_name [, partition_name] ...)]
[(col_name [, col_name] ...)]
{ {VALUES | VALUE} (value_list) [, (value_list)] ... }
[AS row_alias[(col_alias [, col_alias] ...)]]
[ON DUPLICATE KEY UPDATE assignment_list]

INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name
[PARTITION (partition_name [, partition_name] ...)]
SET assignment_list
[AS row_alias[(col_alias [, col_alias] ...)]]
[ON DUPLICATE KEY UPDATE assignment_list]

INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name
[PARTITION (partition_name [, partition_name] ...)]
[(col_name [, col_name] ...)]
{ SELECT ...
  | TABLE table_name
  | VALUES row_constructor_list
}
[ON DUPLICATE KEY UPDATE assignment_list]

value: {expr | DEFAULT}

value_list: value [, value] ...

row_constructor_list:
  ROW(value_list)[, ROW(value_list)][, ...]

assignment:
```
**INSERT Statement**

```
col_name =
  value
  [row_alias.]col_name
  [tbl_name.]col_name
  [row_alias.]col_alias

assignment_list:
  assignment [, assignment] ... 
```

**INSERT** inserts new rows into an existing table. The **INSERT ... VALUES, INSERT ... VALUES ROW(), and INSERT ... SET** forms of the statement insert rows based on explicitly specified values. The **INSERT ... SELECT** form inserts rows selected from another table or tables. You can also use **INSERT ... TABLE** to insert rows from a single table. **INSERT** with an **ON DUPLICATE KEY UPDATE** clause enables existing rows to be updated if a row to be inserted would cause a duplicate value in a **UNIQUE** index or **PRIMARY KEY**. A row alias with one or more optional column aliases can be used with **ON DUPLICATE KEY UPDATE** to refer to the row to be inserted.

For additional information about **INSERT ... SELECT** and **INSERT ... ON DUPLICATE KEY UPDATE**, see Section 13.2.7.1, "INSERT ... SELECT Statement", and Section 13.2.7.2, "INSERT ... ON DUPLICATE KEY UPDATE Statement".

In MySQL 8.2, the **DELAYED** keyword is accepted but ignored by the server. For the reasons for this, see Section 13.2.7.3, “INSERT DELAYED Statement”.

Inserting into a table requires the **INSERT** privilege for the table. If the **ON DUPLICATE KEY UPDATE** clause is used and a duplicate key causes an **UPDATE** to be performed instead, the statement requires the **UPDATE** privilege for the columns to be updated. For columns that are read but not modified you need only the **SELECT** privilege (such as for a column referenced only on the right hand side of an `col_name=expr` assignment in an **ON DUPLICATE KEY UPDATE** clause).

When inserting into a partitioned table, you can control which partitions and subpartitions accept new rows. The **PARTITION** clause takes a list of the comma-separated names of one or more partitions or subpartitions (or both) of the table. If any of the rows to be inserted by a given **INSERT** statement do not match one of the partitions listed, the **INSERT** statement fails with the error **Found a row not matching the given partition set**. For more information and examples, see Section 24.5, “Partition Selection”.

**tbl_name** is the table into which rows should be inserted. Specify the columns for which the statement provides values as follows:

- Provide a parenthesized list of comma-separated column names following the table name. In this case, a value for each named column must be provided by the **VALUES** list, **VALUES ROW()** list, or **SELECT** statement. For the **INSERT TABLE** form, the number of columns in the source table must match the number of columns to be inserted.

- If you do not specify a list of column names for **INSERT ... VALUES** or **INSERT ... SELECT**, values for every column in the table must be provided by the **VALUES** list, **SELECT** statement, or **TABLE** statement. If you do not know the order of the columns in the table, use **DESCRIBE tbl_name** to find out.

- A **SET** clause indicates columns explicitly by name, together with the value to assign each one.

Column values can be given in several ways:

- If strict SQL mode is not enabled, any column not explicitly given a value is set to its default (explicit or implicit) value. For example, if you specify a column list that does not name all the columns in the table, unnamed columns are set to their default values. Default value assignment is described in Section 11.6, “Data Type Default Values”. See also Section 1.6.3.3, “Enforced Constraints on Invalid Data”.
If strict SQL mode is enabled, an **INSERT** statement generates an error if it does not specify an explicit value for every column that has no default value. See Section 5.1.11, “Server SQL Modes”.

- If both the column list and the **VALUES** list are empty, **INSERT** creates a row with each column set to its default value:

```sql
INSERT INTO tbl_name () VALUES();
```

If strict mode is not enabled, MySQL uses the implicit default value for any column that has no explicitly defined default. If strict mode is enabled, an error occurs if any column has no default value.

- Use the keyword **DEFAULT** to set a column explicitly to its default value. This makes it easier to write **INSERT** statements that assign values to all but a few columns, because it enables you to avoid writing an incomplete **VALUES** list that does not include a value for each column in the table. Otherwise, you must provide the list of column names corresponding to each value in the **VALUES** list.

- If a generated column is inserted into explicitly, the only permitted value is **DEFAULT**. For information about generated columns, see Section 13.1.20.8, “CREATE TABLE and Generated Columns”.

- In expressions, you can use **DEFAULT**(col_name) to produce the default value for column col_name.

- Type conversion of an expression expr that provides a column value might occur if the expression data type does not match the column data type. Conversion of a given value can result in different inserted values depending on the column type. For example, inserting the string '1999.0e-2' into an **INT**, **FLOAT**, **DECIMAL(10,6)**, or **YEAR** column inserts the value 1999, 19.9921, 19.992100, or 1999, respectively. The value stored in the **INT** and **YEAR** columns is 1999 because the string-to-number conversion looks only at as much of the initial part of the string as may be considered a valid integer or year. For the **FLOAT** and **DECIMAL** columns, the string-to-number conversion considers the entire string a valid numeric value.

- An expression expr can refer to any column that was set earlier in a value list. For example, you can do this because the value for col2 refers to col1, which has previously been assigned:

```
INSERT INTO tbl_name (col1,col2) VALUES(15,col1*2);
```

But the following is not legal, because the value for col1 refers to col2, which is assigned after col1:

```
INSERT INTO tbl_name (col1,col2) VALUES(col2*2,15);
```

An exception occurs for columns that contain **AUTO_INCREMENT** values. Because **AUTO_INCREMENT** values are generated after other value assignments, any reference to an **AUTO_INCREMENT** column in the assignment returns a 0.

**INSERT** statements that use **VALUES** syntax can insert multiple rows. To do this, include multiple lists of comma-separated column values, with lists enclosed within parentheses and separated by commas. Example:

```
INSERT INTO tbl_name (a,b,c)
VALUES(1,2,3), (4,5,6), (7,8,9);
```

Each values list must contain exactly as many values as are to be inserted per row. The following statement is invalid because it contains one list of nine values, rather than three lists of three values each:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3,4,5,6,7,8,9);
```

**VALUE** is a synonym for **VALUES** in this context. Neither implies anything about the number of values lists, nor about the number of values per list. Either may be used whether there is a single values list or multiple lists, and regardless of the number of values per list.
**INSERT Statement**

**INSERT** statements using **VALUES ROW()** syntax can also insert multiple rows. In this case, each value list must be contained within a **ROW()** (row constructor), like this:

```sql
INSERT INTO tbl_name (a,b,c) VALUES ROW(1,2,3), ROW(4,5,6), ROW(7,8,9);
```

The affected-rows value for an **INSERT** can be obtained using the **ROW_COUNT()** SQL function or the **mysql_affected_rows()** C API function. See Section 12.15, “Information Functions”, and **mysql_affected_rows()**.

If you use **INSERT ... VALUES** or **INSERT ... VALUES ROW()** with multiple value lists, or **INSERT ... SELECT** or **INSERT ... TABLE**, the statement returns an information string in this format:

```
Records: N1 Duplicates: N2 Warnings: N3
```

If you are using the C API, the information string can be obtained by invoking the **mysql_info()** function. See **mysql_info()**.

**Records** indicates the number of rows processed by the statement. (This is not necessarily the number of rows actually inserted because **Duplicates** can be nonzero.) **Duplicates** indicates the number of rows that could not be inserted because they would duplicate some existing unique index value. **Warnings** indicates the number of attempts to insert column values that were problematic in some way. Warnings can occur under any of the following conditions:

- Inserting **NULL** into a column that has been declared **NOT NULL**. For multiple-row **INSERT** statements or **INSERT INTO ... SELECT** statements, the column is set to the implicit default value for the column data type. This is 0 for numeric types, the empty string (""") for string types, and the “zero” value for date and time types. **INSERT INTO ... SELECT** statements are handled the same way as multiple-row inserts because the server does not examine the result set from the **SELECT** to see whether it returns a single row. (For a single-row **INSERT**, no warning occurs when **NULL** is inserted into a **NOT NULL** column. Instead, the statement fails with an error.)

- Setting a numeric column to a value that lies outside the column range. The value is clipped to the closest endpoint of the range.

- Assigning a value such as '10.34 a' to a numeric column. The trailing nonnumeric text is stripped off and the remaining numeric part is inserted. If the string value has no leading numeric part, the column is set to 0.

- Inserting a string into a string column (**CHAR**, **VARCHAR**, **TEXT**, or **BLOB**) that exceeds the column maximum length. The value is truncated to the column maximum length.

- Inserting a value into a date or time column that is illegal for the data type. The column is set to the appropriate zero value for the type.

- For **INSERT** examples involving **AUTO_INCREMENT** column values, see Section 3.6.9, “Using **AUTO_INCREMENT**”.

If **INSERT** inserts a row into a table that has an **AUTO_INCREMENT** column, you can find the value used for that column by using the **LAST_INSERT_ID()** SQL function or the **mysql_insert_id()** C API function.

**Note**

These two functions do not always behave identically. The behavior of **INSERT** statements with respect to **AUTO_INCREMENT** columns is discussed further in Section 12.15, “Information Functions”, and **mysql_insert_id()**.
The **INSERT** statement supports the following modifiers:

- **If you use the** **LOW_PRIORITY** **modifier**, execution of the **INSERT** is delayed until no other clients are reading from the table. This includes other clients that began reading while existing clients are reading, and while the **INSERT LOW_PRIORITY** statement is waiting. It is possible, therefore, for a client that issues an **INSERT LOW_PRIORITY** statement to wait for a very long time.

  **LOW_PRIORITY** affects only storage engines that use only table-level locking (such as **MyISAM**, **MEMORY**, and **MERGE**).

  **Note**

  **LOW_PRIORITY** should normally not be used with **MyISAM** tables because doing so disables concurrent inserts. See **Section 8.11.3, “Concurrent Inserts”**.

- **If you specify** **HIGH_PRIORITY**, it overrides the effect of the **--low-priority-updates** option if the server was started with that option. It also causes concurrent inserts not to be used. See **Section 8.11.3, “Concurrent Inserts”**.

  **HIGH_PRIORITY** affects only storage engines that use only table-level locking (such as **MyISAM**, **MEMORY**, and **MERGE**).

- **If you use the** **IGNORE** **modifier**, ignorable errors that occur while executing the **INSERT** statement are ignored. For example, without **IGNORE**, a row that duplicates an existing **UNIQUE** index or **PRIMARY KEY** value in the table causes a duplicate-key error and the statement is aborted. With **IGNORE**, the row is discarded and no error occurs. Ignored errors generate warnings instead.

  **IGNORE** has a similar effect on inserts into partitioned tables where no partition matching a given value is found. Without **IGNORE**, such **INSERT** statements are aborted with an error. When **INSERT IGNORE** is used, the insert operation fails silently for rows containing the unmatched value, but inserts rows that are matched. For an example, see **Section 24.2.2, “LIST Partitioning”**.

  Data conversions that would trigger errors abort the statement if **IGNORE** is not specified. With **IGNORE**, invalid values are adjusted to the closest values and inserted; warnings are produced but the statement does not abort. You can determine with the **mysql_info()** C API function how many rows were actually inserted into the table.

  For more information, see **The Effect of IGNORE on Statement Execution**.

  You can use **REPLACE** instead of **INSERT** to overwrite old rows. **REPLACE** is the counterpart to **INSERT IGNORE** in the treatment of new rows that contain unique key values that duplicate old rows: The new rows replace the old rows rather than being discarded. See **Section 13.2.12, “REPLACE Statement”**.

- **If you specify** **ON DUPLICATE KEY UPDATE**, and a row is inserted that would cause a duplicate value in a **UNIQUE** index or **PRIMARY KEY**, an **UPDATE** of the old row occurs. The affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the **CLIENT_FOUND_ROWS** flag to the **mysql_real_connect()** C API function when connecting to **mysqld**, the affected-rows value is 1 (not 0) if an existing row is set to its current values. See **Section 13.2.7.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”**.

- **INSERT DELAYED** was deprecated in MySQL 5.6, and is scheduled for eventual removal. In MySQL 8.2, the **DELAYED** modifier is accepted but ignored. Use **INSERT** (without **DELAYED**) instead. See **Section 13.2.7.3, “INSERT DELAYED Statement”**.

### 13.2.7.1 INSERT ... SELECT Statement

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
```
INSERT Statement

With INSERT ... SELECT, you can quickly insert many rows into a table from the result of a SELECT statement, which can select from one or many tables. For example:

```
INSERT INTO tbl_temp2 (fld_id)
SELECT tbl_temp1.fld_order_id
FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

**TABLE statement in place of SELECT**, as shown here:

```
INSERT INTO ta TABLE tb;
```

**TABLE tb** is equivalent to SELECT * FROM tb. It can be useful when inserting all columns from the source table into the target table, and no filtering with WHERE is required. In addition, the rows from TABLE can be ordered by one or more columns using ORDER BY, and the number of rows inserted can be limited using a LIMIT clause. For more information, see Section 13.2.16, “TABLE Statement”.

The following conditions hold for INSERT ... SELECT statements, and, except where noted, for INSERT ... TABLE as well:

- Specify **IGNORE** to ignore rows that would cause duplicate-key violations.
- The target table of the INSERT statement may appear in the FROM clause of the SELECT part of the query, or as the table named by TABLE. However, you cannot insert into a table and select from the same table in a subquery.

When selecting from and inserting into the same table, MySQL creates an internal temporary table to hold the rows from the SELECT and then inserts those rows into the target table. However, you cannot use INSERT INTO t ... SELECT ... FROM t when t is a TEMPORARY table, because TEMPORARY tables cannot be referred to twice in the same statement. For the same reason, you cannot use INSERT INTO t ... TABLE t when t is a temporary table. See Section 8.4.4, “Internal Temporary Table Use in MySQL”, and Section B.3.6.2, “TEMPORARY Table Problems”.

- **AUTO_INCREMENT** columns work as usual.
INSERT Statement

• To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts for `INSERT ... SELECT` or `INSERT ... TABLE` statements (see Section 8.11.3, “Concurrent Inserts”).

• To avoid ambiguous column reference problems when the `SELECT` and the `INSERT` refer to the same table, provide a unique alias for each table used in the `SELECT` part, and qualify column names in that part with the appropriate alias.

The `TABLE` statement does not support aliases.

You can explicitly select which partitions or subpartitions (or both) of the source or target table (or both) are to be used with a `PARTITION` clause following the name of the table. When `PARTITION` is used with the name of the source table in the `SELECT` portion of the statement, rows are selected only from the partitions or subpartitions named in its partition list. When `PARTITION` is used with the name of the target table for the `INSERT` portion of the statement, it must be possible to insert all rows selected into the partitions or subpartitions named in the partition list following the option. Otherwise, the `INSERT ... SELECT` statement fails. For more information and examples, see Section 24.5, “Partition Selection”.

`TABLE` does not support a `PARTITION` clause.

For `INSERT ... SELECT` statements, see Section 13.2.7.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement” for conditions under which the `SELECT` columns can be referred to in an `ON DUPLICATE KEY UPDATE` clause. This also works for `INSERT ... TABLE`. The order in which a `SELECT` or `TABLE` statement with no `ORDER BY` clause returns rows is nondeterministic. This means that, when using replication, there is no guarantee that such a `SELECT` returns rows in the same order on the source and the replica, which can lead to inconsistencies between them. To prevent this from occurring, always write `INSERT ... SELECT` or `INSERT ... TABLE` statements that are to be replicated using an `ORDER BY` clause that produces the same row order on the source and the replica. See also Section 17.5.1.18, “Replication and LIMIT”.

Due to this issue, `INSERT ... SELECT ON DUPLICATE KEY UPDATE` and `INSERTIGNORE ... SELECT` statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using `MIXED` mode. (Bug #11758262, Bug #50439)

See also Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

13.2.7.2 INSERT ... ON DUPLICATE KEY UPDATE Statement

If you specify an `ON DUPLICATE KEY UPDATE` clause and a row to be inserted would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row occurs. For example, if column `a` is declared as `UNIQUE` and contains the value `1`, the following two statements have similar effect:

```sql
INSERT INTO t1 (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=c+1;
```

```sql
UPDATE t1 SET c=c+1 WHERE a=1;
```

The effects are not quite identical: For an InnoDB table where `a` is an auto-increment column, the `INSERT` statement increases the auto-increment value but the `UPDATE` does not.

If column `b` is also unique, the `INSERT` is equivalent to this `UPDATE` statement instead:

```sql
UPDATE t1 SET c=c+1 WHERE a=1 OR b=2 LIMIT 1;
```
If \( a=1 \ OR \ b=2 \) matches several rows, only one row is updated. In general, you should try to avoid using an ON DUPLICATE KEY UPDATE clause on tables with multiple unique indexes.

With ON DUPLICATE KEY UPDATE, the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the CLIENT_FOUND_ROWS flag to the mysql_real_connect() C API function when connecting to mysqld, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

If a table contains an AUTO_INCREMENT column and INSERT ... ON DUPLICATE KEY UPDATE inserts or updates a row, the LAST_INSERT_ID() function returns the AUTO_INCREMENT value.

The ON DUPLICATE KEY UPDATE clause can contain multiple column assignments, separated by commas.

In assignment value expressions in the ON DUPLICATE KEY UPDATE clause, you can use the VALUES(col_name) function to refer to column values from the INSERT portion of the INSERT ... ON DUPLICATE KEY UPDATE statement. In other words, VALUES(col_name) in the ON DUPLICATE KEY UPDATE clause refers to the value of col_name that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The VALUES() function is meaningful only in the ON DUPLICATE KEY UPDATE clause or INSERT statements and returns NULL otherwise.

Example:

<table>
<thead>
<tr>
<th>INSERT INTO t1 (a,b,c) VALUES (1,2,3),(4,5,6) ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);</th>
</tr>
</thead>
</table>

That statement is identical to the following two statements:

| INSERT INTO t1 (a,b,c) VALUES (1,2,3) ON DUPLICATE KEY UPDATE c=3; |
| INSERT INTO t1 (a,b,c) VALUES (4,5,6) ON DUPLICATE KEY UPDATE c=9; |

Note

The use of VALUES() to refer to the new row and columns is deprecated, and subject to removal in a future version of MySQL. Instead, use row and column aliases, as described in the next few paragraphs of this section.

It is possible to use an alias for the row, with, optionally, one or more of its columns to be inserted, following the VALUES or SET clause, and preceded by the AS keyword. Using the row alias new, the statement shown previously using VALUES() to access the new column values can be written in the form shown here:

| INSERT INTO t1 (a,b,c) VALUES (1,2,3),(4,5,6) AS new ON DUPLICATE KEY UPDATE c = new.a+new.b; |

If, in addition, you use the column aliases m, n, and p, you can omit the row alias in the assignment clause and write the same statement like this:

| INSERT INTO t1 (a,b,c) VALUES (1,2,3),(4,5,6) AS new(m,n,p) ON DUPLICATE KEY UPDATE c = m+n; |

When using column aliases in this fashion, you must still use a row alias following the VALUES clause, even if you do not make direct use of it in the assignment clause.

An INSERT ... SELECT ... ON DUPLICATE KEY UPDATE statement that uses VALUES() in the UPDATE clause, like this one, throws a warning:

| INSERT INTO t1 |
You can eliminate such warnings by using a subquery instead, like this:

```sql
INSERT INTO t1
  SELECT * FROM (SELECT c, c+d AS e FROM t2) AS dt
ON DUPLICATE KEY UPDATE b = e;
```

You can also use row and column aliases with a `SET` clause, as mentioned previously. Employing `SET` instead of `VALUES` in the two `INSERT ... ON DUPLICATE KEY UPDATE` statements just shown can be done as shown here:

```sql
INSERT INTO t1 SET a=1,b=2,c=3 AS new
  ON DUPLICATE KEY UPDATE c = new.a+new.b;

INSERT INTO t1 SET a=1,b=2,c=3 AS new(m,n,p)
  ON DUPLICATE KEY UPDATE c = m+n;
```

The row alias must not be the same as the name of the table. If column aliases are not used, or if they are the same as the column names, they must be distinguished using the row alias in the `ON DUPLICATE KEY UPDATE` clause. Column aliases must be unique with regard to the row alias to which they apply (that is, no column aliases referring to columns of the same row may be the same).

For `INSERT ... SELECT` statements, these rules apply regarding acceptable forms of `SELECT` query expressions that you can refer to in an `ON DUPLICATE KEY UPDATE` clause:

- References to columns from queries on a single table, which may be a derived table.
- References to columns from queries on a join over multiple tables.
- References to columns from `DISTINCT` queries.
- References to columns in other tables, as long as the `SELECT` does not use `GROUP BY`. One side effect is that you must qualify references to nonunique column names.

References to columns from a `UNION` are not supported. To work around this restriction, rewrite the `UNION` as a derived table so that its rows can be treated as a single-table result set. For example, this statement produces an error:

```sql
INSERT INTO t1 (a, b)
  SELECT c, d FROM t2
  UNION
    SELECT e, f FROM t3
ON DUPLICATE KEY UPDATE b = b + c;
```

Instead, use an equivalent statement that rewrites the `UNION` as a derived table:

```sql
INSERT INTO t1 (a, b)
  SELECT * FROM
    (SELECT c, d FROM t2
    UNION
      SELECT e, f FROM t3) AS dt
  ON DUPLICATE KEY UPDATE b = b + c;
```

The technique of rewriting a query as a derived table also enables references to columns from `GROUP BY` queries.

Because the results of `INSERT ... SELECT` statements depend on the ordering of rows from the `SELECT` and this order cannot always be guaranteed, it is possible when logging `INSERT ... SELECT`
ON DUPLICATE KEY UPDATE statements for the source and the replica to diverge. Thus, INSERT ... SELECT ON DUPLICATE KEY UPDATE statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using MIXED mode. An INSERT ... ON DUPLICATE KEY UPDATE statement against a table having more than one unique or primary key is also marked as unsafe. (Bug #11765650, Bug #58637)

See also Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

13.2.7.3 INSERT DELAYED Statement

The DELAYED option for the INSERT statement is a MySQL extension to standard SQL. In previous versions of MySQL, it can be used for certain kinds of tables (such as MyISAM), such that when a client uses INSERT DELAYED, it gets an okay from the server at once, and the row is queued to be inserted when the table is not in use by any other thread.

DELAYED inserts and replaces were deprecated in MySQL 5.6. In MySQL 8.2, DELAYED is not supported. The server recognizes but ignores the DELAYED keyword, handles the insert as a nondelayed insert, and generates an ER_WARN_LEGACY_SYNTAX_CONVERTED warning: INSERT DELAYED is no longer supported. The statement was converted to INSERT. The DELAYED keyword is scheduled for removal in a future release.

13.2.8 INTERSECT Clause

INTERSECT limits the result from multiple query blocks to those rows which are common to all. Example:

```
mysql> TABLE a;
+------+------+
| m    | n    |
|------+------+
| 1    | 2    |
| 2    | 3    |
| 3    | 4    |
+------+------+
3 rows in set (0.00 sec)
mysql> TABLE b;
+------+------+
| m    | n    |
|------+------+
| 1    | 2    |
| 1    | 3    |
| 3    | 4    |
+------+------+
3 rows in set (0.00 sec)
mysql> TABLE c;
+------+------+
| m    | n    |
|------+------+
| 1    | 3    |
+------+------+
```
3 rows in set (0.00 sec)

```
mysql> TABLE a INTERSECT TABLE b;
+------+------+
<table>
<thead>
<tr>
<th>m</th>
<th>n</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
</tr>
</tbody>
</table>
+------+------+
2 rows in set (0.00 sec)

mysql> TABLE a INTERSECT TABLE c;
+------+------+
<table>
<thead>
<tr>
<th>m</th>
<th>n</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>4</td>
</tr>
</tbody>
</table>
+------+------+
1 row in set (0.00 sec)
```

As with `UNION` and `EXCEPT`, if neither `DISTINCT` nor `ALL` is specified, the default is `DISTINCT`.

`DISTINCT` can remove duplicates from either side of the intersection, as shown here:

```
mysql> TABLE c INTERSECT DISTINCT TABLE c;
+------+------+
<table>
<thead>
<tr>
<th>m</th>
<th>n</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
</tr>
</tbody>
</table>
+------+------+
2 rows in set (0.00 sec)

mysql> TABLE c INTERSECT ALL TABLE c;
+------+------+
<table>
<thead>
<tr>
<th>m</th>
<th>n</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
</tr>
</tbody>
</table>
+------+------+
3 rows in set (0.00 sec)
```

(TABLE c INTERSECT TABLE c is the equivalent of the first of the two statements just shown.)

As with `UNION`, the operands must have the same number of columns. Result set column types are also determined as for `UNION`.

`INTERSECT` has greater precedence than and is evaluated before `UNION` and `EXCEPT`, so that the two statements shown here are equivalent:

```
TABLE r EXCEPT TABLE s INTERSECT TABLE t;
TABLE r EXCEPT (TABLE s INTERSECT TABLE t);
```

For `INTERSECT ALL`, the maximum supported number of duplicates of any unique row in the left hand table is 4294967295.

### 13.2.9 LOAD DATA Statement

```
LOAD DATA
```
The `LOAD DATA` statement reads rows from a text file into a table at a very high speed. The file can be read from the server host or the client host, depending on whether the `LOCAL` modifier is given. `LOCAL` also affects data interpretation and error handling.

`LOAD DATA` is the complement of `SELECT ... INTO OUTFILE`. (See Section 13.2.13.1, “SELECT ... INTO Statement”.) To write data from a table to a file, use `SELECT ... INTO OUTFILE`. To read the file back into a table, use `LOAD DATA`. The syntax of the `FIELDS` and `LINES` clauses is the same for both statements.

The `mysqlimport` utility provides another way to load data files; it operates by sending a `LOAD DATA` statement to the server. See Section 4.5.5, “mysqlimport — A Data Import Program”.

For information about the efficiency of `INSERT` versus `LOAD DATA` and speeding up `LOAD DATA`, see Section 8.2.5.1, “Optimizing INSERT Statements”.

LOAD DATA Statement

- Replication Considerations
- Miscellaneous Topics

Non-LOCAL Versus LOCAL Operation

The **LOCAL** modifier affects these aspects of **LOAD DATA**, compared to non-LOCAL operation:

- It changes the expected location of the input file; see **Input File Location**.
- It changes the statement security requirements; see **Security Requirements**.
- It has the same effect as the **IGNORE** modifier on the interpretation of input file contents and error handling; see **Duplicate-Key and Error Handling**, and **Column Value Assignment**.

**LOCAL** works only if the server and your client both have been configured to permit it. For example, if **mysqlld** was started with the **local_infile** system variable disabled, **LOCAL** produces an error. See Section 6.1.6, “Security Considerations for LOAD DATA LOCAL”.

Input File Character Set

The file name must be given as a literal string. On Windows, specify backslashes in path names as forward slashes or doubled backslashes. The server interprets the file name using the character set indicated by the **character_set_filesystem** system variable.

By default, the server interprets the file contents using the character set indicated by the **character_set_database** system variable. If the file contents use a character set different from this default, it is a good idea to specify that character set by using the **CHARACTER SET** clause. A character set of **binary** specifies “no conversion.”

**SET NAMES** and the setting of **character_set_client** do not affect interpretation of file contents.

**LOAD DATA** interprets all fields in the file as having the same character set, regardless of the data types of the columns into which field values are loaded. For proper interpretation of the file, you must ensure that it was written with the correct character set. For example, if you write a data file with **mysqldump -T** or by issuing a **SELECT ... INTO OUTFILE** statement in **mysql**, be sure to use a **--default-character-set** option to write output in the character set to be used when the file is loaded with **LOAD DATA**.

Note

It is not possible to load data files that use the **ucs2**, **utf16**, **utf16le**, or **utf32** character set.

Input File Location

These rules determine the **LOAD DATA** input file location:

- If **LOCAL** is not specified, the file must be located on the server host. The server reads the file directly, locating it as follows:
  - If the file name is an absolute path name, the server uses it as given.
  - If the file name is a relative path name with leading components, the server looks for the file relative to its data directory.
  - If the file name has no leading components, the server looks for the file in the database directory of the default database.
LOAD DATA Statement

• If LOCAL is specified, the file must be located on the client host. The client program reads the file, locating it as follows:
  • If the file name is an absolute path name, the client program uses it as given.
  • If the file name is a relative path name, the client program looks for the file relative to its invocation directory.

When LOCAL is used, the client program reads the file and sends its contents to the server. The server creates a copy of the file in the directory where it stores temporary files. See Section B.3.3.5, “Where MySQL Stores Temporary Files”. Lack of sufficient space for the copy in this directory can cause the LOAD DATA LOCAL statement to fail.

The non-LOCAL rules mean that the server reads a file named as ./myfile.txt relative to its data directory, whereas it reads a file named as myfile.txt from the database directory of the default database. For example, if the following LOAD DATA statement is executed while db1 is the default database, the server reads the file data.txt from the database directory for db1, even though the statement explicitly loads the file into a table in the db2 database:

```sql
LOAD DATA INFILE 'data.txt' INTO TABLE db2.my_table;
```

Note
The server also uses the non-LOCAL rules to locate .sdi files for the IMPORT TABLE statement.

Security Requirements

For a non-LOCAL load operation, the server reads a text file located on the server host, so these security requirements must be satisfied:

• You must have the FILE privilege. See Section 6.2.2, “Privileges Provided by MySQL”.

• The operation is subject to the secure_file_priv system variable setting:
  • If the variable value is a nonempty directory name, the file must be located in that directory.
  • If the variable value is empty (which is insecure), the file need only be readable by the server.

For a LOCAL load operation, the client program reads a text file located on the client host. Because the file contents are sent over the connection by the client to the server, using LOCAL is a bit slower than when the server accesses the file directly. On the other hand, you do not need the FILE privilege, and the file can be located in any directory the client program can access.

Duplicate-Key and Error Handling

The REPLACE and IGNORE modifiers control handling of new (input) rows that duplicate existing table rows on unique key values (PRIMARY KEY or UNIQUE index values):

• With REPLACE, new rows that have the same value as a unique key value in an existing row replace the existing row. See Section 13.2.12, “REPLACE Statement”.

• With IGNORE, new rows that duplicate an existing row on a unique key value are discarded. For more information, see The Effect of IGNORE on Statement Execution.

The LOCAL modifier has the same effect as IGNORE. This occurs because the server has no way to stop transmission of the file in the middle of the operation.
LOAD DATA Statement

If none of REPLACE, IGNORE, or LOCAL is specified, an error occurs when a duplicate key value is found, and the rest of the text file is ignored.

In addition to affecting duplicate-key handling as just described, IGNORE and LOCAL also affect error handling:

• With neither IGNORE nor LOCAL, data-interpretation errors terminate the operation.
• With IGNORE or LOCAL, data-interpretation errors become warnings and the load operation continues, even if the SQL mode is restrictive. For examples, see Column Value Assignment.

Index Handling

To ignore foreign key constraints during the load operation, execute a SET foreign_key_checks = 0 statement before executing LOAD DATA.

If you use LOAD DATA on an empty MyISAM table, all nonunique indexes are created in a separate batch (as for REPAIR TABLE). Normally, this makes LOAD DATA much faster when you have many indexes. In some extreme cases, you can create the indexes even faster by turning them off with ALTER TABLE ... DISABLE KEYS before loading the file into the table and re-creating the indexes with ALTER TABLE ... ENABLE KEYS after loading the file. See Section 8.2.5.1, “Optimizing INSERT Statements”.

Field and Line Handling

For both the LOAD DATA and SELECT ... INTO OUTFILE statements, the syntax of the FIELDS and LINES clauses is the same. Both clauses are optional, but FIELDS must precede LINES if both are specified.

If you specify a FIELDS clause, each of its subclauses (TERMINATED BY, [OPTIONALLY] ENCLOSED BY, and ESCAPED BY) is also optional, except that you must specify at least one of them. Arguments to these clauses are permitted to contain only ASCII characters.

If you specify no FIELDS or LINES clause, the defaults are the same as if you had written this:

```
FIELDS TERMINATED BY '	' ENCLOSED BY '' ESCAPED BY '\'
LINES TERMINATED BY '
' STARTING BY ''
```

Backslash is the MySQL escape character within strings in SQL statements. Thus, to specify a literal backslash, you must specify two backslashes for the value to be interpreted as a single backslash. The escape sequences '\t' and '\n' specify tab and newline characters, respectively.

In other words, the defaults cause LOAD DATA to act as follows when reading input:

• Look for line boundaries at newlines.
• Do not skip any line prefix.
• Break lines into fields at tabs.
• Do not expect fields to be enclosed within any quoting characters.
• Interpret characters preceded by the escape character \ as escape sequences. For example, \t, \n, and \\ signify tab, newline, and backslash, respectively. See the discussion of FIELDS ESCAPED BY later for the full list of escape sequences.

Conversely, the defaults cause SELECT ... INTO OUTFILE to act as follows when writing output:

• Write tabs between fields.
LOAD DATA Statement

• Do not enclose fields within any quoting characters.
• Use \ to escape instances of tab, newline, or \ that occur within field values.
• Write newlines at the ends of lines.

**Note**

For a text file generated on a Windows system, proper file reading might require LINES TERMINATED BY '"\r\n"' because Windows programs typically use two characters as a line terminator. Some programs, such as WordPad, might use \r as a line terminator when writing files. To read such files, use LINES TERMINATED BY '"\r"'.

If all the input lines have a common prefix that you want to ignore, you can use LINES STARTING BY 'prefix_string' to skip the prefix and anything before it. If a line does not include the prefix, the entire line is skipped. Suppose that you issue the following statement:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test
    FIELDS TERMINATED BY ',' LINES STARTING BY 'xxx';
```

If the data file looks like this:

```
xxx"abc",1
something xxx"def",2
"ghi",3
```

The resulting rows are ("abc", 1) and ("def", 2). The third row in the file is skipped because it does not contain the prefix.

The IGNORE number LINES clause can be used to ignore lines at the start of the file. For example, you can use IGNORE 1 LINES to skip an initial header line containing column names:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test IGNORE 1 LINES;
```

When you use SELECT ... INTO OUTFILE in tandem with LOAD DATA to write data from a database into a file and then read the file back into the database later, the field- and line-handling options for both statements must match. Otherwise, LOAD DATA does not interpret the contents of the file properly. Suppose that you use SELECT ... INTO OUTFILE to write a file with fields delimited by commas:

```
SELECT * INTO OUTFILE 'data.txt'
    FIELDS TERMINATED BY ','
    FROM table2;
```

To read the comma-delimited file, the correct statement is:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
    FIELDS TERMINATED BY ',';
```

If instead you tried to read the file with the statement shown following, it would not work because it instructs LOAD DATA to look for tabs between fields:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
    FIELDS TERMINATED BY '\t';
```

The likely result is that each input line would be interpreted as a single field.

LOAD DATA can be used to read files obtained from external sources. For example, many programs can export data in comma-separated values (CSV) format, such that lines have fields separated by commas.
and enclosed within double quotation marks, with an initial line of column names. If the lines in such a file are terminated by carriage return/newline pairs, the statement shown here illustrates the field- and line-handling options you would use to load the file:

```
LOAD DATA INFILE 'data.txt' INTO TABLE tbl_name
  FIELDS TERMINATED BY ',' ENCLOSED BY '"'
  LINES TERMINATED BY '\r\n'
  IGNORE 1 LINES;
```

If the input values are not necessarily enclosed within quotation marks, use `OPTIONALLY` before the `ENCLOSED BY` option.

Any of the field- or line-handling options can specify an empty string (""). If not empty, the `FIELDS [OPTIONALLY] ENCLOSED BY` and `FIELDS ESCAPED BY` values must be a single character. The `FIELDS TERMINATED BY`, `LINES STARTING BY`, and `LINES TERMINATED BY` values can be more than one character. For example, to write lines that are terminated by carriage return/linefeed pairs, or to read a file containing such lines, specify a `LINES TERMINATED BY '\r\n'` clause.

To read a file containing jokes that are separated by lines consisting of "%%", you can do this:

```
CREATE TABLE jokes
  (a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
   joke TEXT NOT NULL);
LOAD DATA INFILE '/tmp/jokes.txt' INTO TABLE jokes
  FIELDS TERMINATED BY ''
  LINES TERMINATED BY '\n%%\n' (joke);
```

`FIELDS [OPTIONALLY] ENCLOSED BY` controls quoting of fields. For output (SELECT ... INTO OUTFILE), if you omit the word `OPTIONALLY`, all fields are enclosed by the `ENCLOSED BY` character. An example of such output (using a comma as the field delimiter) is shown here:

```
"1","a string","100.20"
"2","a string containing a , comma","102.20"
"3","a string containing a \" quote","102.20"
"4","a string containing a ", quote and comma","102.20"
```

If you specify `OPTIONALLY`, the `ENCLOSED BY` character is used only to enclose values from columns that have a string data type (such as `CHAR`, `BINARY`, `TEXT`, or `ENUM`):

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a \" quote",102.20
4,"a string containing a ", quote and comma",102.20
```

Occurrences of the `ENCLOSED BY` character within a field value are escaped by prefixing them with the `ESCAPED BY` character. Also, if you specify an empty `ESCAPED BY` value, it is possible to inadvertently generate output that cannot be read properly by `LOAD DATA`. For example, the preceding output just shown would appear as follows if the escape character is empty. Observe that the second field in the fourth line contains a comma following the quote, which (erroneously) appears to terminate the field:

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a * quote",102.20
4,"a string containing a *, quote and comma",102.20
```

For input, the `ENCLOSED BY` character, if present, is stripped from the ends of field values. (This is true regardless of whether `OPTIONALLY` is specified; `OPTIONALLY` has no effect on input interpretation.) Occurrences of the `ENCLOSED BY` character preceded by the `ESCAPED BY` character are interpreted as part of the current field value.
If the field begins with the `ENCLOSED BY` character, instances of that character are recognized as terminating a field value only if followed by the field or line `TERMINATED BY` sequence. To avoid ambiguity, occurrences of the `ENCLOSED BY` character within a field value can be doubled and are interpreted as a single instance of the character. For example, if `ENCLOSED BY '"'` is specified, quotation marks are handled as shown here:

```
"The ""BIG"" boss"  -> The "BIG" boss
The "BIG" boss    -> The "BIG" boss
The ""BIG"" boss   -> The ""BIG"" boss
```

`FIELDS ESCAPED BY` controls how to read or write special characters:

- For input, if the `FIELDS ESCAPED BY` character is not empty, occurrences of that character are stripped and the following character is taken literally as part of a field value. Some two-character sequences that are exceptions, where the first character is the escape character. These sequences are shown in the following table (using `\` for the escape character). The rules for `NULL` handling are described later in this section.

<table>
<thead>
<tr>
<th>Character</th>
<th>Escape Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>\0</td>
<td>An ASCII NUL (X'00') character</td>
</tr>
<tr>
<td>\b</td>
<td>A backspace character</td>
</tr>
<tr>
<td>\n</td>
<td>A newline (linefeed) character</td>
</tr>
<tr>
<td>\r</td>
<td>A carriage return character</td>
</tr>
<tr>
<td>\t</td>
<td>A tab character.</td>
</tr>
<tr>
<td>\Z</td>
<td>ASCII 26 (Control+Z)</td>
</tr>
<tr>
<td>\N</td>
<td>NULL</td>
</tr>
</tbody>
</table>

For more information about \-escape syntax, see Section 9.1.1, “String Literals”.

If the `FIELDS ESCAPED BY` character is empty, escape-sequence interpretation does not occur.

- For output, if the `FIELDS ESCAPED BY` character is not empty, it is used to prefix the following characters on output:

  - The `FIELDS ESCAPED BY` character.
  - The `FIELDS [OPTIONALLY] ENCLOSED BY` character.
  - The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values, if the `ENCLOSED BY` character is empty or unspecified.
  - ASCII 0 (what is actually written following the escape character is ASCII 0, not a zero-valued byte).

If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

In certain cases, field- and line-handling options interact:

- If `LINES TERMINATED BY` is an empty string and `FIELDS TERMINATED BY` is nonempty, lines are also terminated with `FIELDS TERMINATED BY`.

- If the `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` values are both empty (""'), a fixed-row (nondelimited) format is used. With fixed-row format, no delimiters are used between fields (but you can
still have a line terminator). Instead, column values are read and written using a field width wide enough to hold all values in the field. For TINYINT, SMALLINT, MEDIUMINT, INT, and BIGINT, the field widths are 4, 6, 8, 11, and 20, respectively, no matter what the declared display width is.

`LINES TERMINATED BY` is still used to separate lines. If a line does not contain all fields, the rest of the columns are set to their default values. If you do not have a line terminator, you should set this to '' In this case, the text file must contain all fields for each row.

Fixed-row format also affects handling of `NULL` values, as described later.

---

**Note**

Fixed-size format does not work if you are using a multibyte character set.

Handling of `NULL` values varies according to the `FIELDS` and `LINES` options in use:

- For the default `FIELDS` and `LINES` values, `NULL` is written as a field value of `\N` for output, and a field value of `\N` is read as `NULL` for input (assuming that the `ESCAPED BY` character is `\`).

- If `FIELDS ENCLOSED BY` is not empty, a field containing the literal word `NULL` as its value is read as a `NULL` value. This differs from the word `NULL` enclosed within `FIELDS ENCLOSED BY` characters, which is read as the string `'NULL'`.

- If `FIELDS ESCAPED BY` is empty, `NULL` is written as the word `NULL`.

- With fixed-row format (which is used when `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` are both empty), `NULL` is written as an empty string. This causes both `NULL` values and empty strings in the table to be indistinguishable when written to the file because both are written as empty strings. If you need to be able to tell the two apart when reading the file back in, you should not use fixed-row format.

An attempt to load `NULL` into a `NOT NULL` column produces either a warning or an error according to the rules described in [Column Value Assignment](#).

Some cases are not supported by `LOAD DATA`:

- Fixed-size rows (`FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` both empty) and `BLOB` or `TEXT` columns.

- If you specify one separator that is the same as or a prefix of another, `LOAD DATA` cannot interpret the input properly. For example, the following `FIELDS` clause would cause problems:

```sql
FIELDS TERMINATED BY ''; ENCLOSED BY ''
```

- If `FIELDS ESCAPED BY` is empty, a field value that contains an occurrence of `FIELDS ENCLOSED BY` or `LINES TERMINATED BY` followed by the `FIELDS TERMINATED BY` value causes `LOAD DATA` to stop reading a field or line too early. This happens because `LOAD DATA` cannot properly determine where the field or line value ends.

**Column List Specification**

The following example loads all columns of the `persondata` table:

```sql
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata;
```

By default, when no column list is provided at the end of the `LOAD DATA` statement, input lines are expected to contain a field for each table column. If you want to load only some of a table's columns, specify a column list:
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata
(col_name_or_user_var [, col_name_or_user_var] ...);

You must also specify a column list if the order of the fields in the input file differs from the order of the columns in the table. Otherwise, MySQL cannot tell how to match input fields with table columns.

**Input Preprocessing**

Each instance of `col_name_or_user_var` in LOAD DATA syntax is either a column name or a user variable. With user variables, the SET clause enables you to perform preprocessing transformations on their values before assigning the result to columns.

User variables in the SET clause can be used in several ways. The following example uses the first input column directly for the value of `t1.column1`, and assigns the second input column to a user variable that is subjected to a division operation before being used for the value of `t1.column2`:

```sql
LOAD DATA INFILE 'file.txt'
INTO TABLE t1
(column1, @var1)
SET column2 = @var1/100;
```

The SET clause can be used to supply values not derived from the input file. The following statement sets `column3` to the current date and time:

```sql
LOAD DATA INFILE 'file.txt'
INTO TABLE t1
(column1, column2)
SET column3 = CURRENT_TIMESTAMP;
```

You can also discard an input value by assigning it to a user variable and not assigning the variable to any table column:

```sql
LOAD DATA INFILE 'file.txt'
INTO TABLE t1
(column1, @dummy, column2, @dummy, column3);
```

Use of the column/variable list and SET clause is subject to the following restrictions:

- Assignments in the SET clause should have only column names on the left hand side of assignment operators.

- You can use subqueries in the right hand side of SET assignments. A subquery that returns a value to be assigned to a column may be a scalar subquery only. Also, you cannot use a subquery to select from the table that is being loaded.

- Lines ignored by an IGNORE number LINES clause are not processed for the column/variable list or SET clause.

- User variables cannot be used when loading data with fixed-row format because user variables do not have a display width.

**Column Value Assignment**

To process an input line, LOAD DATA splits it into fields and uses the values according to the column/variable list and the SET clause, if they are present. Then the resulting row is inserted into the table. If there are BEFORE INSERT or AFTER INSERT triggers for the table, they are activated before or after inserting the row, respectively.

Interpretation of field values and assignment to table columns depends on these factors:
LOAD DATA Statement

- The SQL mode (the value of the `sql_mode` system variable). The mode can be nonrestrictive, or restrictive in various ways. For example, strict SQL mode can be enabled, or the mode can include values such as `NO_ZERO_DATE` or `NO_ZERO_IN_DATE`.

- Presence or absence of the `IGNORE` and `LOCAL` modifiers.

Those factors combine to produce restrictive or nonrestrictive data interpretation by `LOAD DATA`:

- Data interpretation is restrictive if the SQL mode is restrictive and neither the `IGNORE` nor the `LOCAL` modifier is specified. Errors terminate the load operation.

- Data interpretation is nonrestrictive if the SQL mode is nonrestrictive or the `IGNORE` or `LOCAL` modifier is specified. (In particular, either modifier if specified overrides a restrictive SQL mode when the `REPLACE` modifier is omitted.) Errors become warnings and the load operation continues.

Restrictive data interpretation uses these rules:

- Too many or too few fields results an error.

- Assigning `NULL` (that is, `\N`) to a non-NULL column results in an error.

- A value that is out of range for the column data type results in an error.

- Invalid values produce errors. For example, a value such as `'x'` for a numeric column results in an error, not conversion to 0.

By contrast, nonrestrictive data interpretation uses these rules:

- If an input line has too many fields, the extra fields are ignored and the number of warnings is incremented.

- If an input line has too few fields, the columns for which input fields are missing are assigned their default values. Default value assignment is described in Section 11.6, “Data Type Default Values”.

- Assigning `NULL` (that is, `\N`) to a non-NULL column results in assignment of the implicit default value for the column data type. Implicit default values are described in Section 11.6, “Data Type Default Values”.

- Invalid values produce warnings rather than errors, and are converted to the “closest” valid value for the column data type. Examples:
  - A value such as `'x'` for a numeric column results in conversion to 0.
  - An out-of-range numeric or temporal value is clipped to the closest endpoint of the range for the column data type.
  - An invalid value for a `DATETIME`, `DATE`, or `TIME` column is inserted as the implicit default value, regardless of the SQL mode `NO_ZERO_DATE` setting. The implicit default is the appropriate “zero” value for the type (`'0000-00-00 00:00:00'`, `'0000-00-00'`, or `'00:00:00'`). See Section 11.2, “Date and Time Data Types”.

- `LOAD DATA` interprets an empty field value differently from a missing field:
  - For string types, the column is set to the empty string.
  - For numeric types, the column is set to 0.
  - For date and time types, the column is set to the appropriate “zero” value for the type. See Section 11.2, “Date and Time Data Types”.
These are the same values that result if you assign an empty string explicitly to a string, numeric, or date or time type explicitly in an INSERT or UPDATE statement.

TIMESTAMP columns are set to the current date and time only if there is a NULL value for the column (that is, \n) and the column is not declared to permit NULL values, or if the TIMESTAMP column default value is the current timestamp and it is omitted from the field list when a field list is specified.

LOAD DATA regards all input as strings, so you cannot use numeric values for ENUM or SET columns the way you can with INSERT statements. All ENUM and SET values must be specified as strings.

BIT values cannot be loaded directly using binary notation (for example, b'011010'). To work around this, use the SET clause to strip off the leading b' and trailing ' and perform a base-2 to base-10 conversion so that MySQL loads the values into the BIT column properly:

```
$> cat /tmp/bit_test.txt
b'10'
b'1111111'
$> mysql test
mysql> LOAD DATA INFILE '/tmp/bit_test.txt'
INTO TABLE bit_test (@var1)
SET b = CAST(CONV(MID(@var1, 3, LENGTH(@var1)-3), 2, 10) AS UNSIGNED);
Query OK, 2 rows affected (0.00 sec)
Records: 2  Deleted: 0  Skipped: 0  Warnings: 0
mysql>
```

For BIT values in 0b binary notation (for example, 0b011010), use this SET clause instead to strip off the leading 0b:

```
SET b = CAST(CONV(MID(@var1, 3, LENGTH(@var1)-2), 2, 10) AS UNSIGNED)
```

**Partitioned Table Support**

LOAD DATA supports explicit partition selection using the PARTITION clause with a list of one or more comma-separated names of partitions, subpartitions, or both. When this clause is used, if any rows from the file cannot be inserted into any of the partitions or subpartitions named in the list, the statement fails with the error Found a row not matching the given partition set. For more information and examples, see Section 24.5, “Partition Selection”.

**Concurrency Considerations**

With the LOW_PRIORITY modifier, execution of the LOAD DATA statement is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE).

With the CONCURRENT modifier and a MyISAM table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other threads can retrieve data from the table while LOAD DATA is executing. This modifier affects the performance of LOAD DATA a bit, even if no other thread is using the table at the same time.

**Statement Result Information**

When the LOAD DATA statement finishes, it returns an information string in the following format:
LOAD XML Statement

Warnings occur under the same circumstances as when values are inserted using the INSERT statement (see Section 13.2.7, “INSERT Statement”), except that LOAD DATA also generates warnings when there are too few or too many fields in the input row.

You can use SHOW WARNINGS to get a list of the first max_error_count warnings as information about what went wrong. See Section 13.7.7.44, “SHOW WARNINGS Statement”.

If you are using the C API, you can get information about the statement by calling the mysql_info() function. See mysql_info().

Replication Considerations

LOAD DATA is considered unsafe for statement-based replication. If you use LOAD DATA with binlog_format=STATEMENT, each replica on which the changes are to be applied creates a temporary file containing the data. This temporary file is not encrypted, even if binary log encryption is active on the source. If encryption is required, use row-based or mixed binary logging format instead, for which replicas do not create the temporary file. For more information on the interaction between LOAD DATA and replication, see Section 17.5.1.19, “Replication and LOAD DATA”.

Miscellaneous Topics

On Unix, if you need LOAD DATA to read from a pipe, you can use the following technique (the example loads a listing of the / directory into the table db1.t1):

```
mkfifo /mysql/data/db1/ls.dat
chmod 666 /mysql/data/db1/ls.dat
find / -ls > /mysql/data/db1/ls.dat &
mysql -e "LOAD DATA INFILE 'ls.dat' INTO TABLE t1" db1
```

Here you must run the command that generates the data to be loaded and the mysql commands either on separate terminals, or run the data generation process in the background (as shown in the preceding example). If you do not do this, the pipe blocks until data is read by the mysql process.

13.2.10 LOAD XML Statement

```
LOAD XML
  [LOW_PRIORITY | CONCURRENT] [LOCAL]
  INFILE 'file_name'
  [REPLACE | IGNORE]
  INTO TABLE [db_name.]tbl_name
  [CHARACTER SET charset_name]
  [ROWS IDENTIFIED BY '<tagname>']
  [IGNORE number {LINES | ROWS}]
  [{field_name_or_user_var}
   [, field_name_or_user_var] ...]
  [SET col_name={expr | DEFAULT}]
   [, col_name={expr | DEFAULT}] ...
```

The LOAD XML statement reads data from an XML file into a table. The file_name must be given as a literal string. The tagname in the optional ROWS IDENTIFIED BY clause must also be given as a literal string, and must be surrounded by angle brackets (< and >).

LOAD XML acts as the complement of running the mysql client in XML output mode (that is, starting the client with the --xml option). To write data from a table to an XML file, you can invoke the mysql client with the --xml and -e options from the system shell, as shown here:
LOAD XML Statement

```bash
$> mysql --xml -e 'SELECT * FROM mydb.mytable' > file.xml
```

To read the file back into a table, use LOAD XML. By default, the `<row>` element is considered to be the equivalent of a database table row; this can be changed using the `ROWS IDENTIFIED BY` clause.

This statement supports three different XML formats:

- **Column names as attributes and column values as attribute values:**
  ```xml
  <row column1="value1" column2="value2" .../>
  ```

- **Column names as tags and column values as the content of these tags:**
  ```xml
  <row>
    <column1>value1</column1>
    <column2>value2</column2>
  </row>
  ```

- **Column names are the `name` attributes of `<field>` tags, and values are the contents of these tags:**
  ```xml
  <row>
    <field name='column1'>value1</field>
    <field name='column2'>value2</field>
  </row>
  ```

  This is the format used by other MySQL tools, such as `mysqldump`.

All three formats can be used in the same XML file; the import routine automatically detects the format for each row and interprets it correctly. Tags are matched based on the tag or attribute name and the column name.

The following clauses work essentially the same way for LOAD XML as they do for LOAD DATA:

- **LOW_PRIORITY** or **CONCURRENT**
- **LOCAL**
- **REPLACE** or **IGNORE**
- **CHARACTER SET**
- **SET**

See Section 13.2.9, “LOAD DATA Statement”, for more information about these clauses.

`(field_name_or_user_var, ...)` is a list of one or more comma-separated XML fields or user variables. The name of a user variable used for this purpose must match the name of a field from the XML file, prefixed with `@`. You can use field names to select only desired fields. User variables can be employed to store the corresponding field values for subsequent re-use.

The `IGNORE number LINES` or `IGNORE number ROWS` clause causes the first `number` rows in the XML file to be skipped. It is analogous to the `LOAD DATA` statement's `IGNORE ... LINES` clause.

Suppose that we have a table named `person`, created as shown here:

```sql
USE test;
CREATE TABLE person (
    person_id INT NOT NULL PRIMARY KEY,
```
Suppose further that this table is initially empty.

Now suppose that we have a simple XML file `person.xml`, whose contents are as shown here:

```xml
<list>
  <person person_id="1" fname="Kapek" lname="Sainnouine"/>
  <person person_id="2" fname="Sajon" lname="Rondela"/>
  <person person_id="3" fname="Likame" lname="Örrtmons"/>
  <person person_id="4" fname="Slar" lname="Manlanth"/>
  <person person_id="5" field="person_id">5</field> field="fname">Stoma</field>
  <field name="lname">MILU</field>
  <person person_id="6" field="person_id">6</field> field="fname">Nirtam</field>
  <field name="lname">SKLOD</field>
  <person person_id="7" fname="Sungam" lname="Dubâd"/>
  <person person_id="8" fname="Sraref" lname="Encmelt"/>
</list>
```

Each of the permissible XML formats discussed previously is represented in this example file.

To import the data in `person.xml` into the `person` table, you can use this statement:

```sql
mysql> LOAD XML LOCAL INFILE 'person.xml'
    -> INTO TABLE person
    -> ROWS IDENTIFIED BY '<person>';
```

Here, we assume that `person.xml` is located in the MySQL data directory. If the file cannot be found, the following error results:

```
ERROR 2 (HY000): File '/person.xml' not found (Errcode: 2)
```

The `ROWS IDENTIFIED BY '<person>'` clause means that each `<person>` element in the XML file is considered equivalent to a row in the table into which the data is to be imported. In this case, this is the `person` table in the `test` database.

As can be seen by the response from the server, 8 rows were imported into the `test.person` table. This can be verified by a simple `SELECT` statement:

```sql
mysql> SELECT * FROM person;
```

```
+-----------+--------+------------+---------------------+
<table>
<thead>
<tr>
<th>person_id</th>
<th>.fname</th>
<th>lname</th>
<th>created</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Kapek</td>
<td>Sainnouine</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>2</td>
<td>Sajon</td>
<td>Rondela</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>3</td>
<td>Likame</td>
<td>Örrtmons</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>4</td>
<td>Slar</td>
<td>Manlanth</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>5</td>
<td>Stoma</td>
<td>MILU</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>6</td>
<td>Nirtam</td>
<td>SKLOD</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>7</td>
<td>Sungam</td>
<td>Dubâd</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>8</td>
<td>Sraref</td>
<td>Encmelt</td>
<td>2007-07-13 16:18:47</td>
</tr>
</tbody>
</table>
+-----------+--------+------------+---------------------+
8 rows in set (0.00 sec)
```

This shows, as stated earlier in this section, that any or all of the 3 permitted XML formats may appear in a single file and be read using `LOAD XML`.

```sql
LOAD XML Statement
```
The inverse of the import operation just shown—that is, dumping MySQL table data into an XML file—can be accomplished using the `mysql` client from the system shell, as shown here:

```bash
$> mysql --xml -e "SELECT * FROM test.person" > person-dump.xml
$> cat person-dump.xml

<?xml version="1.0"?>
<resultset statement="SELECT * FROM test.person" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <row>
    <field name="person_id">1</field>
    <field name="fname">Kapek</field>
    <field name="lname">Sainnouine</field>
  </row>
  <row>
    <field name="person_id">2</field>
    <field name="fname">Sajon</field>
    <field name="lname">Rondela</field>
  </row>
  <row>
    <field name="person_id">3</field>
    <field name="fname">Likema</field>
    <field name="lname">Örrtmons</field>
  </row>
  <row>
    <field name="person_id">4</field>
    <field name="fname">Slar</field>
    <field name="lname">Manlanth</field>
  </row>
  <row>
    <field name="person_id">5</field>
    <field name="fname">Stoma</field>
    <field name="lname">Nilu</field>
  </row>
  <row>
    <field name="person_id">6</field>
    <field name="fname">Nirtam</field>
    <field name="lname">Sklöd</field>
  </row>
  <row>
    <field name="person_id">7</field>
    <field name="fname">Sungam</field>
    <field name="lname">Dulbåd</field>
  </row>
  <row>
    <field name="person_id">8</field>
    <field name="fname">Sreraf</field>
    <field name="lname">Encmelt</field>
  </row>
</resultset>
```

Note

The `--xml` option causes the `mysql` client to use XML formatting for its output; the `--e` option causes the client to execute the SQL statement immediately following the option. See Section 4.5.1, "mysql — The MySQL Command-Line Client".

You can verify that the dump is valid by creating a copy of the `person` table and importing the dump file into the new table, like this:
LOAD XML Statement

mysql> USE test;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE person2 LIKE person;
Query OK, 0 rows affected (0.00 sec)

mysql> LOAD XML LOCAL INFILE 'person-dump.xml'
-> INTO TABLE person2;
Query OK, 8 rows affected (0.01 sec)
Records: 8  Deleted: 0  Skipped: 0  Warnings: 0

mysql> SELECT * FROM person2;
+-----------+--------+------------+---------------------+
| person_id | fname  | lname      | created             |
|-----------+--------+------------+---------------------|
|         1 | Kapek  | Sainnouine | 2007-07-13 16:18:47 |
|         2 | Sajon  | Rondela    | 2007-07-13 16:18:47 |
|         3 | Likema | Örrtmons   | 2007-07-13 16:18:47 |
|         4 | Slar   | Manlanth   | 2007-07-13 16:18:47 |
|         5 | Stoma  | Nilu       | 2007-07-13 16:18:47 |
|         6 | Nirtam | Sklöd      | 2007-07-13 16:18:47 |
|         7 | Sungam | Dubbåd     | 2007-07-13 16:18:47 |
|         8 | Sreraf | Encmelt    | 2007-07-13 16:18:47 |
+-----------+--------+------------+---------------------+
8 rows in set (0.00 sec)

There is no requirement that every field in the XML file be matched with a column in the corresponding table. Fields which have no corresponding columns are skipped. You can see this by first emptying the person2 table and dropping the created column, then using the same LOAD XML statement we just employed previously, like this:

mysql> TRUNCATE person2;
Query OK, 8 rows affected (0.26 sec)

mysql> ALTER TABLE person2 DROP COLUMN created;
Query OK, 0 rows affected (0.52 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> SHOW CREATE TABLE person2;
*************************** 1. row ***************************
Table: person2
Create Table: CREATE TABLE `person2` (    `person_id` int NOT NULL,    `fname` varchar(40) DEFAULT NULL,    `lname` varchar(40) DEFAULT NULL, PRIMARY KEY (`person_id`) ) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
1 row in set (0.00 sec)

mysql> LOAD XML LOCAL INFILE 'person-dump.xml'
-> INTO TABLE person2;
Query OK, 8 rows affected (0.01 sec)
Records: 8  Deleted: 0  Skipped: 0  Warnings: 0

mysql> SELECT * FROM person2;
+-----------+--------+------------+
| person_id | fname  | lname      |
|-----------+--------+------------|
|         1 | Kapek  | Sainnouine |
|         2 | Sajon  | Rondela    |
|         3 | Likema | Örrtmons   |
|         4 | Slar   | Manlanth   |
|         5 | Stoma  | Nilu       |
|         6 | Nirtam | Sklöd      |
|         7 | Sungam | Dubbåd     |
|         8 | Sreraf | Encmelt    |
+-----------+--------+------------+
8 rows in set (0.00 sec)
The order in which the fields are given within each row of the XML file does not affect the operation of LOAD XML; the field order can vary from row to row, and is not required to be in the same order as the corresponding columns in the table.

As mentioned previously, you can use a (field_name_or_user_var, ...) list of one or more XML fields (to select desired fields only) or user variables (to store the corresponding field values for later use). User variables can be especially useful when you want to insert data from an XML file into table columns whose names do not match those of the XML fields. To see how this works, we first create a table named individual whose structure matches that of the person table, but whose columns are named differently:

```sql
CREATE TABLE individual (  
  individual_id INT NOT NULL PRIMARY KEY,  
  name1 VARCHAR(40) NULL,  
  name2 VARCHAR(40) NULL,  
  made TIMESTAMP
);  
```

In this case, you cannot simply load the XML file directly into the table, because the field and column names do not match:

```sql
LOAD XML INFILE '../bin/person-dump.xml' INTO TABLE test.individual;  
ERROR 1263 (22004): Column set to default value; NULL supplied to NOT NULL column 'individual_id' at row 1
```

This happens because the MySQL server looks for field names matching the column names of the target table. You can work around this problem by selecting the field values into user variables, then setting the target table's columns equal to the values of those variables using SET. You can perform both of these operations in a single statement, as shown here:

```sql
LOAD XML INFILE '../bin/person-dump.xml'  
  INTO TABLE test.individual (@person_id, @fname, @lname, @created)  
  SET individual_id=@person_id, name1=@fname, name2=@lname, made=@created;  
```

The names of the user variables must match those of the corresponding fields from the XML file, with the addition of the required @ prefix to indicate that they are variables. The user variables need not be listed or assigned in the same order as the corresponding fields.

Using a ROWS IDENTIFIED BY '<tagname>' clause, it is possible to import data from the same XML file into database tables with different definitions. For this example, suppose that you have a file named address.xml which contains the following XML:

```xml
<?xml version="1.0"?>
```
You can again use the test.person table as defined previously in this section, after clearing all the existing records from the table and then showing its structure as shown here:

```sql
mysql< TRUNCATE person;
Query OK, 0 rows affected (0.04 sec)
```

```sql
mysql< SHOW CREATE TABLE person\G
*************************** 1. row ***************************
Table: person
Create Table: CREATE TABLE `person` (
`person_id` int(11) NOT NULL,
`fname` varchar(40) DEFAULT NULL,
`lname` varchar(40) DEFAULT NULL,
`created` timestamp NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
PRIMARY KEY (`person_id`)
) ENGINE=MyISAM DEFAULT CHARSET=utf8mb4
1 row in set (0.00 sec)
```

Now create an address table in the test database using the following CREATE TABLE statement:

```sql
CREATE TABLE address (
  address_id INT NOT NULL PRIMARY KEY,
  person_id INT NULL,
  street VARCHAR(40) NULL,
  zip INT NULL,
  city VARCHAR(40) NULL,
  created TIMESTAMP
);```

To import the data from the XML file into the person table, execute the following LOAD XML statement, which specifies that rows are to be specified by the <person> element, as shown here:

```sql
mysql> LOAD XML LOCAL INFILE 'address.xml'
-> INTO TABLE person
-> ROWS IDENTIFIED BY '<person>';
Query OK, 2 rows affected (0.00 sec)
Records: 2 Deleted: 0 Skipped: 0 Warnings: 0
```

You can verify that the records were imported using a SELECT statement:

```sql
mysql> SELECT * FROM person;
+-----------+--------+-------+---------------------+
<table>
<thead>
<tr>
<th>person_id</th>
<th>fname</th>
<th>lname</th>
<th>created</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Robert</td>
<td>Jones</td>
<td>2007-07-24 17:37:06</td>
</tr>
<tr>
<td>2</td>
<td>Mary</td>
<td>Smith</td>
<td>2007-07-24 17:37:06</td>
</tr>
</tbody>
</table>
+-----------+--------+-------+---------------------+
2 rows in set (0.00 sec)
```
Since the `<address>` elements in the XML file have no corresponding columns in the `person` table, they are skipped.

To import the data from the `<address>` elements into the `address` table, use the `LOAD XML` statement shown here:

```
mysql> LOAD XML LOCAL INFILE 'address.xml'
    -> INTO TABLE address
    -> ROWS IDENTIFIED BY '<address>'';
Query OK, 3 rows affected (0.00 sec)
Records: 3  Deleted: 0  Skipped: 0  Warnings: 0
```

You can see that the data was imported using a `SELECT` statement such as this one:

```
mysql> SELECT * FROM address;
+------------+-----------+-----------------+-------+--------------+---------------------+
<table>
<thead>
<tr>
<th>address_id</th>
<th>person_id</th>
<th>street</th>
<th>zip</th>
<th>city</th>
<th>created</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>Mill Creek Road</td>
<td>45365</td>
<td>Sidney</td>
<td>2007-07-24 17:37:37</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>Main Street</td>
<td>28681</td>
<td>Taylorsville</td>
<td>2007-07-24 17:37:37</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>River Road</td>
<td>80239</td>
<td>Denver</td>
<td>2007-07-24 17:37:37</td>
</tr>
</tbody>
</table>
+------------+-----------+-----------------+-------+--------------+---------------------+
3 rows in set (0.00 sec)
```

The data from the `<address>` element that is enclosed in XML comments is not imported. However, since there is a `person_id` column in the `address` table, the value of the `person_id` attribute from the parent `<person>` element for each `<address>` is imported into the `address` table.

**Security Considerations.** As with the `LOAD DATA` statement, the transfer of the XML file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server's choosing rather than the file named by the client in the `LOAD XML` statement. Such a server could access any file on the client host to which the client user has read access.

In a Web environment, clients usually connect to MySQL from a Web server. A user that can run any command against the MySQL server can use `LOAD XML LOCAL` to read any files to which the Web server process has read access. In this environment, the client with respect to the MySQL server is actually the Web server, not the remote program being run by the user who connects to the Web server.

You can disable loading of XML files from clients by starting the server with `--local-infile=0` or `--local-infile=OFF`. This option can also be used when starting the `mysql` client to disable `LOAD XML` for the duration of the client session.

To prevent a client from loading XML files from the server, do not grant the `FILE` privilege to the corresponding MySQL user account, or revoke this privilege if the client user account already has it.

**Important**

Revoking the `FILE` privilege (or not granting it in the first place) keeps the user only from executing the `LOAD XML` statement (as well as the `LOAD_FILE()` function); it does not prevent the user from executing `LOAD XML LOCAL`. To disallow this statement, you must start the server or the client with `--local-infile=OFF`.

In other words, the `FILE` privilege affects only whether the client can read files on the server; it has no bearing on whether the client can read files on the local file system.

### 13.2.11 Parenthesized Query Expressions
Parenthesized Query Expressions

MySQL 8.2 supports parenthesized query expressions according to the preceding syntax. At its simplest, a parenthesized query expression contains a single `SELECT` or other statement returning a result set and no following optional clauses:

```sql
(SELECT 1);
(SELECT * FROM INFORMATION_SCHEMA.SCHEMATA WHERE SCHEMA_NAME = 'mysql');
TABLE t;
VALUES ROW(2, 3, 4), ROW(1, -2, 3);
```

A parenthesized query expression can also contain queries linked by one or more set operations such as `UNION`, and end with any or all of the optional clauses:

```sql
mysql> (SELECT 1 AS result UNION SELECT 2); |
+--------+
<table>
<thead>
<tr>
<th>result</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
</tbody>
</table>
mysql> (SELECT 1 AS result UNION SELECT 2) LIMIT 1;
+--------+
| result |
+--------|
|   1    |
mysql> (SELECT 1 AS result UNION SELECT 2) LIMIT 1 OFFSET 1;
+--------+
| result |
+--------|
|   2    |
mysql> (SELECT 1 AS result UNION SELECT 2) ORDER BY result DESC LIMIT 1;
+--------+
| result |
+--------|
|   2    |
```
Parenthesized Query Expressions

mysql> (SELECT 1 AS result UNION SELECT 2)
ORDER BY result DESC LIMIT 1 OFFSET 1;
+--------+
| result |
+--------+
|      1 |
+--------+

mysql> (SELECT 1 AS result UNION SELECT 3 UNION SELECT 2)
ORDER BY result LIMIT 1 OFFSET 1 INTO @var;

mysql> SELECT @var;
+------+
| @var |
+------+
|    2 |
+------+

**INTERSECT** acts before **UNION** and **EXCEPT**, so that the following two statements are equivalent:

```
SELECT a FROM t1 EXCEPT SELECT b FROM t2 INTERSECT SELECT c FROM t3;
SELECT a FROM t1 EXCEPT (SELECT b FROM t2 INTERSECT SELECT c FROM t3);
```

Parenthesized query expressions are also used as query expressions, so a query expression, usually composed of query blocks, may also consist of parenthesized query expressions:

```
(TABLE t1 ORDER BY a) UNION (TABLE t2 ORDER BY b) ORDER BY z;
```

Query blocks may have trailing **ORDER BY** and **LIMIT** clauses, which are applied before the outer set operation, **ORDER BY**, and **LIMIT**.

You cannot have a query block with a trailing **ORDER BY** or **LIMIT** without wrapping it in parentheses but parentheses may be used for enforcement in various ways:

- **To enforce LIMIT** on each query block:
  
  ```
  (SELECT 1 LIMIT 1) UNION (VALUES ROW(2) LIMIT 1);
  (VALUES ROW(1), ROW(2) LIMIT 2) EXCEPT (SELECT 2 LIMIT 1);
  ```

- **To enforce LIMIT** on both query blocks and the entire query expression:
  
  ```
  (SELECT 1 LIMIT 1) UNION (SELECT 2 LIMIT 1) LIMIT 1;
  ```

- **To enforce LIMIT** on the entire query expression (with no parentheses):
  
  ```
  VALUES ROW(1), ROW(2) INTERSECT VALUES ROW(2), ROW(1) LIMIT 1;
  ```

- **Hybrid enforcement**: **LIMIT** on the first query block and on the entire query expression:
  
  ```
  (SELECT 1 LIMIT 1) UNION SELECT 2 LIMIT 1;
  ```

The syntax described in this section is subject to certain restrictions:

- A trailing **INTO** clause for a query expression is not permitted if there is another **INTO** clause inside parentheses.

- **An ORDER BY** or **LIMIT** within a parenthesized query expression which is also applied in the outer query is handled in accordance with the SQL standard.

Nested parenthesized query expressions are permitted. The maximum level of nesting supported is 63; this is after any simplifications or merges have been performed by the parser.
An example of such a statement is shown here:

```sql
mysql> (SELECT 'a' UNION SELECT 'b' LIMIT 2) LIMIT 3;
+---+
| a |
| a |
| b |
+---+
2 rows in set (0.00 sec)
```

You should be aware that, when collapsing parenthesized expression bodies, MySQL follows SQL standard semantics, so that a higher outer limit cannot override an inner lower one. For example, `(SELECT ... LIMIT 5) LIMIT 10` can return no more than five rows.

### 13.2.12 REPLACE Statement

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [PARTITION (partition_name [, partition_name] ...)]
  [(col_name [, col_name] ...)]
  { {VALUES | VALUE} (value_list) [, (value_list)] ... |
    VALUES row_constructor_list
  }
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [PARTITION (partition_name [, partition_name] ...)]
  SET assignment_list
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [PARTITION (partition_name [, partition_name] ...)]
  [(col_name [, col_name] ...)]
  {SELECT ... | TABLE table_name}
```

`REPLACE` works exactly like `INSERT`, except that if an old row in the table has the same value as a new row for a `PRIMARY KEY` or a `UNIQUE` index, the old row is deleted before the new row is inserted. See Section 13.2.7, “INSERT Statement”.

`REPLACE` is a MySQL extension to the SQL standard. It either inserts, or deletes and inserts. For another MySQL extension to standard SQL—that either inserts or updates—see Section 13.2.7.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”.

`DELAYED` inserts and replaces were deprecated in MySQL 5.6. In MySQL 8.2, `DELAYED` is not supported. The server recognizes but ignores the `DELAYED` keyword, handles the replace as a nondelayed replace,
and generates an `ER_WARN_LEGACY_SYNTAX_CONVERTED` warning: REPLACE DELAYED is no longer supported. The statement was converted to REPLACE. The DELAYED keyword is scheduled for removal in a future release.

**Note**

REPLACE makes sense only if a table has a PRIMARY KEY or UNIQUE index. Otherwise, it becomes equivalent to INSERT, because there is no index to be used to determine whether a new row duplicates another.

Values for all columns are taken from the values specified in the REPLACE statement. Any missing columns are set to their default values, just as happens for INSERT. You cannot refer to values from the current row and use them in the new row. If you use an assignment such as `SET col_name = col_name + 1`, the reference to the column name on the right hand side is treated as `DEFAULT(col_name)`, so the assignment is equivalent to `SET col_name = DEFAULT(col_name) + 1`.

You can specify the column values that REPLACE attempts to insert using `VALUES ROW()`.

To use REPLACE, you must have both the INSERT and DELETE privileges for the table.

If a generated column is replaced explicitly, the only permitted value is `DEFAULT`. For information about generated columns, see Section 13.1.20.8, "CREATE TABLE and Generated Columns".

REPLACE supports explicit partition selection using the PARTITION clause with a list of comma-separated names of partitions, subpartitions, or both. As with INSERT, if it is not possible to insert the new row into any of these partitions or subpartitions, the REPLACE statement fails with the error `Found a row not matching the given partition set`. For more information and examples, see Section 24.5, "Partition Selection".

The REPLACE statement returns a count to indicate the number of rows affected. This is the sum of the rows deleted and inserted. If the count is 1 for a single-row REPLACE, a row was inserted and no rows were deleted. If the count is greater than 1, one or more old rows were deleted before the new row was inserted. It is possible for a single row to replace more than one old row if the table contains multiple unique indexes and the new row duplicates values for different old rows in different unique indexes.

The affected-rows count makes it easy to determine whether REPLACE only added a row or whether it also replaced any rows: Check whether the count is 1 (added) or greater (replaced).

If you are using the C API, the affected-rows count can be obtained using the `mysql_affected_rows()` function.

You cannot replace into a table and select from the same table in a subquery.

MySQL uses the following algorithm for REPLACE (and LOAD DATA ... REPLACE):

1. Try to insert the new row into the table
2. While the insertion fails because a duplicate-key error occurs for a primary key or unique index:
   a. Delete from the table the conflicting row that has the duplicate key value
   b. Try again to insert the new row into the table

It is possible that in the case of a duplicate-key error, a storage engine may perform the REPLACE as an update rather than a delete plus insert, but the semantics are the same. There are no user-visible effects other than a possible difference in how the storage engine increments `Handler_xxx` status variables.
Because the results of `REPLACE ... SELECT` statements depend on the ordering of rows from the `SELECT` and this order cannot always be guaranteed, it is possible when logging these statements for the source and the replica to diverge. For this reason, `REPLACE ... SELECT` statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using MIXED mode. See also Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

MySQL 8.2 supports `TABLE` as well as `SELECT` with `REPLACE`, just as it does with `INSERT`. See Section 13.2.7.1, “INSERT ... SELECT Statement”, for more information and examples.

When modifying an existing table that is not partitioned to accommodate partitioning, or, when modifying the partitioning of an already partitioned table, you may consider altering the table’s primary key (see Section 24.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”). You should be aware that, if you do this, the results of `REPLACE` statements may be affected, just as they would be if you modified the primary key of a nonpartitioned table. Consider the table created by the following `CREATE TABLE` statement:

```sql
CREATE TABLE test (  
    id INT UNSIGNED NOT NULL AUTO_INCREMENT,  
    data VARCHAR(64) DEFAULT NULL,  
    ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,  
    PRIMARY KEY (id)  
);
```

When we create this table and run the statements shown in the `mysql` client, the result is as follows:

```sql
mysql> REPLACE INTO test VALUES (1, 'Old', '2014-08-20 18:47:00');  
Query OK, 1 row affected (0.04 sec)  
mysql> REPLACE INTO test VALUES (1, 'New', '2014-08-20 18:47:42');  
Query OK, 2 rows affected (0.04 sec)  
```

```sql
mysql> SELECT * FROM test;  
+----+------+---------------------+  
| id | data | ts                  |  
+----+------+---------------------+  
|  1 | New  | 2014-08-20 18:47:42 |  
+----+------+---------------------+  
1 row in set (0.00 sec)
```

Now we create a second table almost identical to the first, except that the primary key now covers 2 columns, as shown here (emphasized text):

```sql
CREATE TABLE test2 (  
    id INT UNSIGNED NOT NULL AUTO_INCREMENT,  
    data VARCHAR(64) DEFAULT NULL,  
    ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,  
    PRIMARY KEY (id, ts)  
);
```

When we run on `test2` the same two `REPLACE` statements as we did on the original `test` table, we obtain a different result:

```sql
mysql> REPLACE INTO test2 VALUES (1, 'Old', '2014-08-20 18:47:00');  
Query OK, 1 row affected (0.05 sec)  
mysql> REPLACE INTO test2 VALUES (1, 'New', '2014-08-20 18:47:42');  
Query OK, 1 row affected (0.06 sec)  
```

```sql
mysql> SELECT * FROM test2;  
+----+------+---------------------+  
| id | data | ts                  |  
+----+------+---------------------+  
|  1 | New  | 2014-08-20 18:47:42 |  
+----+------+---------------------+  
1 row in set (0.00 sec)
```
This is due to the fact that, when run on test2, both the id and ts column values must match those of an existing row for the row to be replaced; otherwise, a row is inserted.

### 13.2.13 SELECT Statement

```sql
SELECT
  [ALL | DISTINCT | DISTINCTROW ]
  [HIGH_PRIORITY]
  [STRAIGHT_JOIN]
  [SQL_SMALL_RESULT] [SQL_BIG_RESULT] [SQL_BUFFER_RESULT]
  [SQL_NO_CACHE] [SQL_CALC_FOUND_ROWS]
  select_expr [, select_expr] ... [into_option]
  [FROM table_references
  [PARTITION partition_list]]
  [WHERE where_condition]
  [GROUP BY {col_name | expr | position}, ... [WITH ROLLUP]]
  [HAVING where_condition]
  [WINDOW window_name AS (window_spec)
  [, window_name AS (window_spec)] ...]
  [ORDER BY {col_name | expr | position}
  [ASC | DESC], ... [WITH ROLLUP]]
  [LIMIT [{offset,} row_count | row_count OFFSET offset}]
  [into_option]
  [FOR {UPDATE | SHARE}
  [OF tbl_name [, tbl_name]] ...]
  [NOWAIT | SKIP LOCKED]
  [LOCK IN SHARE MODE]
  [into_option]

into_option: {
  INTO OUTFILE 'file_name'
  [CHARACTER SET charset_name]
  export_options
  | INTO DUMPFILE 'file_name'
  INTO var_name [, var_name] ...
}
```

**SELECT** is used to retrieve rows selected from one or more tables, and can include **UNION** operations and subqueries. **INTERSECT** and **EXCEPT** operations are also supported. The **UNION**, **INTERSECT**, and **EXCEPT** operators are described in more detail later in this section. See also **Section 13.2.15**, “Subqueries”.

A **SELECT** statement can start with a **WITH** clause to define common table expressions accessible within the **SELECT**. See **Section 13.2.20**, “WITH (Common Table Expressions)”.

The most commonly used clauses of **SELECT** statements are these:

- Each **select_expr** indicates a column that you want to retrieve. There must be at least one **select_expr**.

- **table_references** indicates the table or tables from which to retrieve rows. Its syntax is described in **Section 13.2.13.2**, “JOIN Clause”.

- **SELECT** supports explicit partition selection using the **PARTITION** clause with a list of partitions or subpartitions (or both) following the name of the table in a **table_reference** (see **Section 13.2.13.2**, “JOIN Clause”). In this case, rows are selected only from the partitions listed, and any other partitions of the table are ignored. For more information and examples, see **Section 24.5**, “Partition Selection”.
**SELECT Statement**

- The **WHERE** clause, if given, indicates the condition or conditions that rows must satisfy to be selected. *where_condition* is an expression that evaluates to true for each row to be selected. The statement selects all rows if there is no **WHERE** clause.

  In the **WHERE** expression, you can use any of the functions and operators that MySQL supports, except for aggregate (group) functions. See Section 9.5, “Expressions”, and Chapter 12, *Functions and Operators*.

**SELECT** can also be used to retrieve rows computed without reference to any table.

For example:

```sql
mysql> SELECT 1 + 1;
+-----+
|     |
+-----+
| 2   |
+-----+
```

You are permitted to specify **DUAL** as a dummy table name in situations where no tables are referenced:

```sql
mysql> SELECT 1 + 1 FROM DUAL;
+-----+
|     |
+-----+
| 2   |
+-----+
```

**DUAL** is purely for the convenience of people who require that all **SELECT** statements should have **FROM** and possibly other clauses. MySQL may ignore the clauses. MySQL does not require **FROM DUAL** if no tables are referenced.

In general, clauses used must be given in exactly the order shown in the syntax description. For example, a **HAVING** clause must come after any **GROUP BY** clause and before any **ORDER BY** clause. The **INTO** clause, if present, can appear in any position indicated by the syntax description, but within a given statement can appear only once, not in multiple positions. For more information about **INTO**, see Section 13.2.13.1, “SELECT ... INTO Statement”.

The list of **select_expr** terms comprises the select list that indicates which columns to retrieve. Terms specify a column or expression or can use ***-shorthand**:

- A select list consisting only of a single unqualified *** can be used as shorthand to select all columns from all tables:

  ```sql
  SELECT * FROM t1 INNER JOIN t2 ...
  ```

- **tbl_name.** can be used as a qualified shorthand to select all columns from the named table:

  ```sql
  SELECT t1.*, t2.* FROM t1 INNER JOIN t2 ...
  ```

- If a table has invisible columns, **.* do not include them. To be included, invisible columns must be referenced explicitly.

- Use of an unqualified *** with other items in the select list may produce a parse error. For example:

  ```sql
  SELECT id, * FROM t1
  ```

  To avoid this problem, use a qualified **tbl_name.** reference:

  ```sql
  SELECT id, t1.* FROM t1
  ```

  Use qualified **tbl_name.** references for each table in the select list:

  ```sql
  SELECT AVG(score), t1.* FROM t1 ...
  ```

The following list provides additional information about other **SELECT** clauses:

- A **select_expr** can be given an alias using **AS alias_name**. The alias is used as the expression's column name and can be used in **GROUP BY**, **ORDER BY**, or **HAVING** clauses. For example:
SELECT CONCAT(last_name, ', ', first_name) AS full_name
FROM mytable ORDER BY full_name;

The **AS** keyword is optional when aliasing a **select_expr** with an identifier. The preceding example could have been written like this:

```
SELECT CONCAT(last_name, ', ', first_name) full_name
FROM mytable ORDER BY full_name;
```

However, because the **AS** is optional, a subtle problem can occur if you forget the comma between two **select_expr** expressions: MySQL interprets the second as an alias name. For example, in the following statement, `columnb` is treated as an alias name:

```
SELECT columna columnb FROM mytable;
```

For this reason, it is good practice to be in the habit of using **AS** explicitly when specifying column aliases.

It is not permissible to refer to a column alias in a **WHERE** clause, because the column value might not yet be determined when the **WHERE** clause is executed. See Section B.3.4.4, “Problems with Column Aliases”.

- The **FROM** **table_references** clause indicates the table or tables from which to retrieve rows. If you name more than one table, you are performing a join. For information on join syntax, see Section 13.2.13.2, “JOIN Clause”. For each table specified, you can optionally specify an alias.

```
tbl_name [[AS] alias] [index_hint]
```

The use of index hints provides the optimizer with information about how to choose indexes during query processing. For a description of the syntax for specifying these hints, see Section 8.9.4, “Index Hints”.

You can use **SET max_seeks_for_key=value** as an alternative way to force MySQL to prefer key scans instead of table scans. See Section 5.1.8, “Server System Variables”.

- You can refer to a table within the default database as `tbl_name`, or as `db_name.tbl_name` to specify a database explicitly. You can refer to a column as `col_name`, `tbl_name.col_name`, or `db_name.tbl_name.col_name`. You need not specify a `tbl_name` or `db_name.tbl_name` prefix for a column reference unless the reference would be ambiguous. See Section 9.2.2, “Identifier Qualifiers”, for examples of ambiguity that require the more explicit column reference forms.

- A table reference can be aliased using `tbl_name AS alias_name` or `tbl_name alias_name`. These statements are equivalent:

```
SELECT t1.name, t2.salary FROM employee AS t1, info AS t2
WHERE t1.name = t2.name;
```

```
SELECT t1.name, t2.salary FROM employee t1, info t2
WHERE t1.name = t2.name;
```

- Columns selected for output can be referred to in **ORDER BY** and **GROUP BY** clauses using column names, column aliases, or column positions. Column positions are integers and begin with 1:

```
SELECT college, region, seed FROM tournament
ORDER BY region, seed;
```

```
SELECT college, region AS r, seed AS s FROM tournament
ORDER BY r, s;
```

```
SELECT college, region, seed FROM tournament
```
SELECT Statement

ORDER BY 2, 3;

To sort in reverse order, add the **DESC** (descending) keyword to the name of the column in the **ORDER BY** clause that you are sorting by. The default is ascending order; this can be specified explicitly using the **ASC** keyword.

If **ORDER BY** occurs within a parenthesized query expression and also is applied in the outer query, the results are undefined and may change in a future version of MySQL.

Use of column positions is deprecated because the syntax has been removed from the SQL standard.

- When you use **ORDER BY** or **GROUP BY** to sort a column in a **SELECT**, the server sorts values using only the initial number of bytes indicated by the **max_sort_length** system variable.

- MySQL extends the use of **GROUP BY** to permit selecting fields that are not mentioned in the **GROUP BY** clause. If you are not getting the results that you expect from your query, please read the description of **GROUP BY** found in Section 12.19, "Aggregate Functions".

- The **HAVING** clause, like the **WHERE** clause, specifies selection conditions. The **WHERE** clause specifies conditions on columns in the select list, but cannot refer to aggregate functions. The **HAVING** clause specifies conditions on groups, typically formed by the **GROUP BY** clause. The query result includes only groups satisfying the **HAVING** conditions. (If no **GROUP BY** is present, all rows implicitly form a single aggregate group.)

The **HAVING** clause is applied nearly last, just before items are sent to the client, with no optimization. (**LIMIT** is applied after **HAVING**.)

The SQL standard requires that **HAVING** must reference only columns in the **GROUP BY** clause or columns used in aggregate functions. However, MySQL supports an extension to this behavior, and permits **HAVING** to refer to columns in the **SELECT** list and columns in outer subqueries as well.

If the **HAVING** clause refers to a column that is ambiguous, a warning occurs. In the following statement, **col2** is ambiguous because it is used as both an alias and a column name:

```
SELECT COUNT (col1) AS col2 FROM t GROUP BY col2 HAVING col2 = 2;
```

Preference is given to standard SQL behavior, so if a **HAVING** column name is used both in **GROUP BY** and as an aliased column in the select column list, preference is given to the column in the **GROUP BY** column.

- Do not use **HAVING** for items that should be in the **WHERE** clause. For example, do not write the following:

```
SELECT col_name FROM tbl_name HAVING col_name > 0;
```

Write this instead:

```
SELECT col_name FROM tbl_name WHERE col_name > 0;
```

- The **HAVING** clause can refer to aggregate functions, which the **WHERE** clause cannot:

```
SELECT user, MAX(salary) FROM users
GROUP BY user HAVING MAX(salary) > 10;
```

(This did not work in some older versions of MySQL.)

- MySQL permits duplicate column names. That is, there can be more than one **select_expr** with the same name. This is an extension to standard SQL. Because MySQL also permits **GROUP BY** and **HAVING** to refer to **select_expr** values, this can result in an ambiguity:

```
SELECT col1, col1 FROM tbl_name
```
SELECT Statement

SELECT 12 AS a, a FROM t GROUP BY a;

In that statement, both columns have the name a. To ensure that the correct column is used for grouping, use different names for each select_expr.

- The WINDOW clause, if present, defines named windows that can be referred to by window functions. For details, see Section 12.20.4, “Named Windows”.

- MySQL resolves unqualified column or alias references in ORDER BY clauses by searching in the select_expr values, then in the columns of the tables in the FROM clause. For GROUP BY or HAVING clauses, it searches the FROM clause before searching in the select_expr values. (For GROUP BY and HAVING, this differs from the pre-MySQL 5.0 behavior that used the same rules as for ORDER BY.)

- The LIMIT clause can be used to constrain the number of rows returned by the SELECT statement. LIMIT takes one or two numeric arguments, which must both be nonnegative integer constants, with these exceptions:
  - Within prepared statements, LIMIT parameters can be specified using ? placeholder markers.
  - Within stored programs, LIMIT parameters can be specified using integer-valued routine parameters or local variables.

With two arguments, the first argument specifies the offset of the first row to return, and the second specifies the maximum number of rows to return. The offset of the initial row is 0 (not 1):

```
SELECT * FROM tbl LIMIT 5,10;  # Retrieve rows 6-15
```

To retrieve all rows from a certain offset up to the end of the result set, you can use some large number for the second parameter. This statement retrieves all rows from the 96th row to the last:

```
SELECT * FROM tbl LIMIT 95,18446744073709551615;
```

With one argument, the value specifies the number of rows to return from the beginning of the result set:

```
SELECT * FROM tbl LIMIT 5;     # Retrieve first 5 rows
```

In other words, LIMIT row_count is equivalent to LIMIT 0, row_count.

For prepared statements, you can use placeholders. The following statements return one row from the tbl table:

```
SET @a=1;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?';
EXECUTE STMT USING @a;
```

The following statements return the second to sixth rows from the tbl table:

```
SET @skip=1; SET @numrows=5;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?, ?';
EXECUTE STMT USING @skip, @numrows;
```

For compatibility with PostgreSQL, MySQL also supports the LIMIT row_count OFFSET offset syntax.

If LIMIT occurs within a parenthesized query expression and also is applied in the outer query, the results are undefined and may change in a future version of MySQL.

- The SELECT ... INTO form of SELECT enables the query result to be written to a file or stored in variables. For more information, see Section 13.2.13.1, “SELECT ... INTO Statement”.
SELECT Statement

- If you use `FOR UPDATE` with a storage engine that uses page or row locks, rows examined by the query are write-locked until the end of the current transaction.

You cannot use `FOR UPDATE` as part of the `SELECT` in a statement such as `CREATE TABLE new_table SELECT ... FROM old_table ....` (If you attempt to do so, the statement is rejected with the error `Can't update table 'old_table' while 'new_table' is being created`.)

`FOR SHARE` and `LOCK IN SHARE MODE` set shared locks that permit other transactions to read the examined rows but not to update or delete them. `FOR SHARE` and `LOCK IN SHARE MODE` are equivalent. However, `FOR SHARE`, like `FOR UPDATE`, supports `NOWAIT`, `SKIP LOCKED`, and `OF tbl_name` options. `FOR SHARE` is a replacement for `LOCK IN SHARE MODE`, but `LOCK IN SHARE MODE` remains available for backward compatibility.

`NOWAIT` causes a `FOR UPDATE` or `FOR SHARE` query to execute immediately, returning an error if a row lock cannot be obtained due to a lock held by another transaction.

`SKIP LOCKED` causes a `FOR UPDATE` or `FOR SHARE` query to execute immediately, excluding rows from the result set that are locked by another transaction.

`NOWAIT` and `SKIP LOCKED` options are unsafe for statement-based replication.

**Note**

Queries that skip locked rows return an inconsistent view of the data. `SKIP LOCKED` is therefore not suitable for general transactional work. However, it may be used to avoid lock contention when multiple sessions access the same queue-like table.

`OF tbl_name` applies for `FOR UPDATE` and `FOR SHARE` queries to named tables. For example:

```sql
SELECT * FROM t1, t2 FOR SHARE OF t1 FOR UPDATE OF t2;
```

All tables referenced by the query block are locked when `OF tbl_name` is omitted. Consequently, using a locking clause without `OF tbl_name` in combination with another locking clause returns an error. Specifying the same table in multiple locking clauses returns an error. If an alias is specified as the table name in the `SELECT` statement, a locking clause may only use the alias. If the `SELECT` statement does not specify an alias explicitly, the locking clause may only specify the actual table name.

For more information about `FOR UPDATE` and `FOR SHARE`, see Section 15.7.2.4, “Locking Reads”. For additional information about `NOWAIT` and `SKIP LOCKED` options, see Locking Read Concurrency with `NOWAIT` and `SKIP LOCKED`.

Following the `SELECT` keyword, you can use a number of modifiers that affect the operation of the statement. `HIGH_PRIORITY`, `STRAIGHT_JOIN`, and modifiers beginning with `SQL_` are MySQL extensions to standard SQL.

- The `ALL` and `DISTINCT` modifiers specify whether duplicate rows should be returned. `ALL` (the default) specifies that all matching rows should be returned, including duplicates. `DISTINCT` specifies removal of duplicate rows from the result set. It is an error to specify both modifiers. `DISTINCTROW` is a synonym for `DISTINCT`.

`DISTINCT` can be used with a query that also uses `WITH ROLLUP`.

- `HIGH_PRIORITY` gives the `SELECT` higher priority than a statement that updates a table. You should use this only for queries that are very fast and must be done at once. A `SELECT HIGH_PRIORITY` query that is issued while the table is locked for reading runs even if there is an update statement waiting
for the table to be free. This affects only storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE).

**HIGH_PRIORITY** cannot be used with SELECT statements that are part of a UNION.

- **STRAIGHT_JOIN** forces the optimizer to join the tables in the order in which they are listed in the FROM clause. You can use this to speed up a query if the optimizer joins the tables in nonoptimal order. STRAIGHT_JOIN also can be used in the table_references list. See Section 13.2.13.2, "JOIN Clause".

STRAIGHT_JOIN does not apply to any table that the optimizer treats as a const or system table. Such a table produces a single row, is read during the optimization phase of query execution, and references to its columns are replaced with the appropriate column values before query execution proceeds. These tables appear first in the query plan displayed by EXPLAIN. See Section 8.8.1, "Optimizing Queries with EXPLAIN". This exception may not apply to const or system tables that are used on the NULL-complemented side of an outer join (that is, the right-side table of a LEFT JOIN or the left-side table of a RIGHT JOIN).

- **SQL_BIG_RESULT** or **SQL_SMALL_RESULT** can be used with GROUP BY or DISTINCT to tell the optimizer that the result set has many rows or is small, respectively. For SQL_BIG_RESULT, MySQL directly uses disk-based temporary tables if they are created, and prefers sorting to using a temporary table with a key on the GROUP BY elements. For SQL_SMALL_RESULT, MySQL uses in-memory temporary tables to store the resulting table instead of using sorting. This should not normally be needed.

- **SQL_BUFFER_RESULT** forces the result to be put into a temporary table. This helps MySQL free the table locks early and helps in cases where it takes a long time to send the result set to the client. This modifier can be used only for top-level SELECT statements, not for subqueries or following UNION.

- **SQL_CALC_FOUND_ROWS** tells MySQL to calculate how many rows there would be in the result set, disregarding any LIMIT clause. The number of rows can then be retrieved with SELECT FOUND_ROWS(). See Section 12.15, “Information Functions”.

### Note

The **SQL_CALC_FOUND_ROWS** query modifier and accompanying **FOUND_ROWS()** function are deprecated; expect them to be removed in a future version of MySQL. See the description of **FOUND_ROWS()** for information about an alternative strategy.

- The **SQL_CACHE** and **SQL_NO_CACHE** modifiers were used with the query cache prior to MySQL 8.2. The query cache was removed in MySQL 8.2. The **SQL_CACHE** modifier was removed as well. **SQL_NO_CACHE** is deprecated, and has no effect; expect it to be removed in a future MySQL release.

### 13.2.13.1 SELECT ... INTO Statement

The **SELECT ... INTO** form of SELECT enables a query result to be stored in variables or written to a file:

- **SELECT ... INTO var_list** selects column values and stores them into variables.

- **SELECT ... INTO OUTFILE** writes the selected rows to a file. Column and line terminators can be specified to produce a specific output format.

- **SELECT ... INTO DUMPFILE** writes a single row to a file without any formatting.
A given `SELECT` statement can contain at most one `INTO` clause, although as shown by the `SELECT` syntax description (see Section 13.2.13, “SELECT Statement”), the `INTO` can appear in different positions:

- **Before FROM.** Example:
  ```sql
  SELECT * INTO @myvar FROM t1;
  ```

- **Before a trailing locking clause.** Example:
  ```sql
  SELECT * FROM t1 INTO @myvar FOR UPDATE;
  ```

- **At the end of the SELECT.** Example:
  ```sql
  SELECT * FROM t1 FOR UPDATE INTO @myvar;
  ```

The `INTO` position at the end of the statement is the preferred position. The position before a locking clause is deprecated; expect support for it to be removed in a future version of MySQL. In other words, `INTO` after `FROM` but not at the end of the `SELECT` produces a warning.

An `INTO` clause should not be used in a nested `SELECT` because such a `SELECT` must return its result to the outer context. There are also constraints on the use of `INTO` within `UNION` statements; see Section 13.2.18, “UNION Clause”.

For the `INTO var_list` variant:

- `var_list` names a list of one or more variables, each of which can be a user-defined variable, stored procedure or function parameter, or stored program local variable. (Within a prepared `SELECT ... INTO var_list` statement, only user-defined variables are permitted; see Section 13.6.4.2, “Local Variable Scope and Resolution”.)

  - The selected values are assigned to the variables. The number of variables must match the number of columns. The query should return a single row. If the query returns no rows, a warning with error code 1329 occurs (`No data`), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (`Result consisted of more than one row`). If it is possible that the statement may retrieve multiple rows, you can use `LIMIT 1` to limit the result set to a single row.

  ```sql
  SELECT id, data INTO @x, @y FROM test.t1 LIMIT 1;
  ```

`INTO var_list` can also be used with a `TABLE` statement, subject to these restrictions:

- The number of variables must match the number of columns in the table.
- If the table contains more than one row, you must use `LIMIT 1` to limit the result set to a single row. `LIMIT 1` must precede the `INTO` keyword.

An example of such a statement is shown here:

```sql
TABLE employees ORDER BY lname DESC LIMIT 1
  INTO @id, @fname, @lname, @hired, @separated, @job_code, @store_id;
```

You can also select values from a `VALUES` statement that generates a single row into a set of user variables. In this case, you must employ a table alias, and you must assign each value from the value list to a variable. Each of the two statements shown here is equivalent to `SET @x=2, @y=4, @z=8`:

```sql
SELECT * FROM (VALUES ROW(2,4,8)) AS t INTO @x,@y,@z;
SELECT * FROM (VALUES ROW(2,4,8)) AS t(a,b,c) INTO @x,@y,@z;
```

User variable names are not case-sensitive. See Section 9.4, “User-Defined Variables”.
The `SELECT ... INTO OUTFILE 'file_name'` form of `SELECT` writes the selected rows to a file. The file is created on the server host, so you must have the `FILE` privilege to use this syntax. `file_name` cannot be an existing file, which among other things prevents files such as `/etc/passwd` and database tables from being modified. The `character_set_filesystem` system variable controls the interpretation of the file name.

The `SELECT ... INTO OUTFILE` statement is intended to enable dumping a table to a text file on the server host. To create the resulting file on some other host, `SELECT ... INTO OUTFILE` normally is unsuitable because there is no way to write a path to the file relative to the server host file system, unless the location of the file on the remote host can be accessed using a network-mapped path on the server host file system.

Alternatively, if the MySQL client software is installed on the remote host, you can use a client command such as `mysql -e "SELECT ..." > file_name` to generate the file on that host.

`SELECT ... INTO OUTFILE` is the complement of `LOAD DATA`. Column values are written converted to the character set specified in the `CHARACTER SET` clause. If no such clause is present, values are dumped using the `binary` character set. In effect, there is no character set conversion. If a result set contains columns in several character sets, so is the output data file, and it may not be possible to reload the file correctly.

The syntax for the `export_options` part of the statement consists of the same `FIELDS` and `LINES` clauses that are used with the `LOAD DATA` statement. For information about the `FIELDS` and `LINES` clauses, including their default values and permissible values, see Section 13.2.9, “LOAD DATA Statement”.

`FIELDS ESCAPED BY` controls how to write special characters. If the `FIELDS ESCAPED BY` character is not empty, it is used when necessary to avoid ambiguity as a prefix that precedes following characters on output:

- The `FIELDS ESCAPED BY` character
- The `FIELDS [OPTIONALLY] ENCLOSED BY` character
- The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values
- ASCII `NUL` (the zero-valued byte; what is actually written following the escape character is ASCII 0, not a zero-valued byte)

The `FIELDS TERMINATED BY`, `ENCLOSED BY`, `ESCAPED BY`, or `LINES TERMINATED BY` characters must be escaped so that you can read the file back in reliably. ASCII `NUL` is escaped to make it easier to view with some pagers.

The resulting file need not conform to SQL syntax, so nothing else need be escaped.

If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

`INTO OUTFILE` can also be used with a `TABLE` statement when you want to dump all columns of a table into a text file. In this case, the ordering and number of rows can be controlled using `ORDER BY` and `LIMIT`; these clauses must precede `INTO OUTFILE`. `TABLE ... INTO OUTFILE` supports the same `export_options` as does `SELECT ... INTO OUTFILE`, and it is subject to the same restrictions on writing to the file system. An example of such a statement is shown here:

```sql
TABLE employees ORDER BY lname LIMIT 1000
INTO OUTFILE '/tmp/employee_data_1.txt'
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"', ESCAPED BY '\'
LINES TERMINATED BY '\n';
```
You can also use `SELECT ... INTO OUTFILE` with a `VALUES` statement to write values directly into a file. An example is shown here:

```sql
SELECT * FROM (VALUES ROW(1,2,3),ROW(4,5,6),ROW(7,8,9)) AS t
    INTO OUTFILE '/tmp/select-values.txt';
```

You must use a table alias; column aliases are also supported, and can optionally be used to write values only from desired columns. You can also use any or all of the export options supported by `SELECT ... INTO OUTFILE` to format the output to the file.

Here is an example that produces a file in the comma-separated values (CSV) format used by many programs:

```sql
SELECT a,b,a+b INTO OUTFILE '/tmp/result.txt'
    FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
    LINES TERMINATED BY '\n'
    FROM test_table;
```

If you use `INTO DUMPFILE` instead of `INTO OUTFILE`, MySQL writes only one row into the file, without any column or line termination and without performing any escape processing. This is useful for selecting a `BLOB` value and storing it in a file.

`TABLE` also supports `INTO DUMPFILE`. If the table contains more than one row, you must also use `LIMIT 1` to limit the output to a single row. `INTO DUMPFILE` can also be used with `SELECT * FROM (VALUES ROW(),[,...]) AS table_alias [LIMIT 1]`. See Section 13.2.19, “VALUES Statement”.

**Note**

Any file created by `INTO OUTFILE` or `INTO DUMPFILE` is owned by the operating system user under whose account `mysqld` runs. (You should *never* run `mysqld` as `root` for this and other reasons.) The umask for file creation is 0640; you must have sufficient access privileges to manipulate the file contents.

If the `secure_file_priv` system variable is set to a nonempty directory name, the file to be written must be located in that directory.

In the context of `SELECT ... INTO` statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For additional information, see Section 25.4.5, “Event Scheduler Status”.

Support is provided for periodic synchronization of output files written to by `SELECT INTO OUTFILE` and `SELECT INTO DUMPFILE`, enabled by setting the `select_into_disk_sync` server system variable introduced in that version. Output buffer size and optional delay can be set using, respectively, `select_into_buffer_size` and `select_into_disk_sync_delay`. For more information, see the descriptions of these system variables.

### 13.2.13.2 JOIN Clause

MySQL supports the following `JOIN` syntax for the `table_references` part of `SELECT` statements and multiple-table `DELETE` and `UPDATE` statements:

```sql
table_references:
    escaped_table_reference [,, escaped_table_reference] ...

escaped_table_reference: {
    table_reference
    | { OJ table_reference }
}
```
A table reference is also known as a join expression.

A table reference (when it refers to a partitioned table) may contain a PARTITION clause, including a list of comma-separated partitions, subpartitions, or both. This option follows the name of the table and precedes any alias declaration. The effect of this option is that rows are selected only from the listed partitions or subpartitions. Any partitions or subpartitions not named in the list are ignored. For more information and examples, see Section 24.5, "Partition Selection".

The syntax of table_factor is extended in MySQL in comparison with standard SQL. The standard accepts only table_reference, not a list of them inside a pair of parentheses.

This is a conservative extension if each comma in a list of table_reference items is considered as equivalent to an inner join. For example:

```
SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
  ON (t2.a = t1.a AND t3.b = t1.b AND t4.c = t1.c)
```

is equivalent to:

```
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
  ON (t2.a = t1.a AND t3.b = t1.b AND t4.c = t1.c)
```

In MySQL, JOIN, CROSS JOIN, and INNER JOIN are syntactic equivalents (they can replace each other). In standard SQL, they are not equivalent. INNER JOIN is used with an ON clause, CROSS JOIN is used otherwise.
In general, parentheses can be ignored in join expressions containing only inner join operations. MySQL also supports nested joins. See Section 8.2.1.8, “Nested Join Optimization”.

Index hints can be specified to affect how the MySQL optimizer makes use of indexes. For more information, see Section 8.9.4, “Index Hints”. Optimizer hints and the optimizer_switch system variable are other ways to influence optimizer use of indexes. See Section 8.9.3, “Optimizer Hints”, and Section 8.9.2, “Switchable Optimizations”.

The following list describes general factors to take into account when writing joins:

• A table reference can be aliased using `tbl_name AS alias_name` or `tbl_name alias_name`:

```sql
SELECT t1.name, t2.salary
FROM employee AS t1 INNER JOIN info AS t2 ON t1.name = t2.name;
```

```sql
SELECT t1.name, t2.salary
FROM employee t1 INNER JOIN info t2 ON t1.name = t2.name;
```

• A `table_subquery` is also known as a derived table or subquery in the `FROM` clause. See Section 13.2.15.8, “Derived Tables”. Such subqueries must include an alias to give the subquery result a table name, and may optionally include a list of table column names in parentheses. A trivial example follows:

```sql
SELECT * FROM (SELECT 1, 2, 3) AS t1;
```

• The maximum number of tables that can be referenced in a single join is 61. This includes a join handled by merging derived tables and views in the `FROM` clause into the outer query block (see Section 8.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”).

• `INNER JOIN` and `, (comma)` are semantically equivalent in the absence of a join condition: both produce a Cartesian product between the specified tables (that is, each and every row in the first table is joined to each and every row in the second table).

However, the precedence of the comma operator is less than that of `INNER JOIN, CROSS JOIN, LEFT JOIN`, and so on. If you mix comma joins with the other join types when there is a join condition, an error of the form `Unknown column 'col_name' in 'on clause'` may occur. Information about dealing with this problem is given later in this section.

• The `search_condition` used with `ON` is any conditional expression of the form that can be used in a `WHERE` clause. Generally, the `ON` clause serves for conditions that specify how to join tables, and the `WHERE` clause restricts which rows to include in the result set.

• If there is no matching row for the right table in the `ON` or `USING` part in a `LEFT JOIN`, a row with all columns set to `NULL` is used for the right table. You can use this fact to find rows in a table that have no counterpart in another table:

```sql
SELECT left_tbl.*
FROM left_tbl LEFT JOIN right_tbl ON left_tbl.id = right_tbl.id
WHERE right_tbl.id IS NULL;
```

This example finds all rows in `left_tbl` with an `id` value that is not present in `right_tbl` (that is, all rows in `left_tbl` with no corresponding row in `right_tbl`). See Section 8.2.1.9, “Outer Join Optimization”.

• The `USING(join_column_list)` clause names a list of columns that must exist in both tables. If tables `a` and `b` both contain columns `c1, c2, and c3`, the following join compares corresponding columns from the two tables:

```sql
a LEFT JOIN b USING (c1, c2, c3)
```
• The **NATURAL [LEFT] JOIN** of two tables is defined to be semantically equivalent to an **INNER JOIN** or a **LEFT JOIN** with a **USING** clause that names all columns that exist in both tables.

• **RIGHT JOIN** works analogously to **LEFT JOIN**. To keep code portable across databases, it is recommended that you use **LEFT JOIN** instead of **RIGHT JOIN**.

• The `{ OJ ... }` syntax shown in the join syntax description exists only for compatibility with ODBC. The curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

```sql
SELECT left_tbl.*
FROM { OJ left_tbl LEFT OUTER JOIN right_tbl
    ON left_tbl.id = right_tbl.id }
WHERE right_tbl.id IS NULL;
```

You can use other types of joins within `{ OJ ... }`, such as **INNER JOIN** or **RIGHT OUTER JOIN**. This helps with compatibility with some third-party applications, but is not official ODBC syntax.

• **STRAIGHT_JOIN** is similar to **JOIN**, except that the left table is always read before the right table. This can be used for those (few) cases for which the join optimizer processes the tables in a suboptimal order.

Some join examples:

```sql
SELECT * FROM table1, table2;
SELECT * FROM table1 INNER JOIN table2 ON table1.id = table2.id;
SELECT * FROM table1 LEFT JOIN table2 ON table1.id = table2.id;
SELECT * FROM table1 LEFT JOIN table2 USING (id);
SELECT * FROM table1 LEFT JOIN table2 ON table1.id = table2.id
    LEFT JOIN table3 ON table2.id = table3.id;
```

Natural joins and joins with **USING**, including outer join variants, are processed according to the SQL:2003 standard:

• Redundant columns of a **NATURAL** join do not appear. Consider this set of statements:

```sql
CREATE TABLE t1 (i INT, j INT);
CREATE TABLE t2 (k INT, j INT);
INSERT INTO t1 VALUES(1, 1);
INSERT INTO t2 VALUES(1, 1);
SELECT * FROM t1 NATURAL JOIN t2;
SELECT * FROM t1 JOIN t2 USING (j);
```

In the first **SELECT** statement, column **j** appears in both tables and thus becomes a join column, so, according to standard SQL, it should appear only once in the output, not twice. Similarly, in the second **SELECT** statement, column **j** is named in the **USING** clause and should appear only once in the output, not twice.

Thus, the statements produce this output:

```
+----+----+----+
| j  | i  | k  |
|----+----+----|
| 1  | 1  | 1  |
+----+----+----+
| j  | i  | k  |
|----+----+----|
| 1  | 1  | 1  |
+----+----+----+
```
Redundant column elimination and column ordering occurs according to standard SQL, producing this display order:

- First, coalesced common columns of the two joined tables, in the order in which they occur in the first table
- Second, columns unique to the first table, in order in which they occur in that table
- Third, columns unique to the second table, in order in which they occur in that table

The single result column that replaces two common columns is defined using the coalesce operation. That is, for two \( t1.a \) and \( t2.a \) the resulting single join column \( a \) is defined as

\[
a = \text{COALESCE}(t1.a, t2.a)
\]

where:

\[
\text{COALESCE}(x, y) = \begin{cases} 
  x & \text{if } x \text{ is not NULL} \\
  y & \text{otherwise}
\end{cases}
\]

If the join operation is any other join, the result columns of the join consist of the concatenation of all columns of the joined tables.

A consequence of the definition of coalesced columns is that, for outer joins, the coalesced column contains the value of the non-NULL column if one of the two columns is always NULL. If neither or both columns are NULL, both common columns have the same value, so it doesn't matter which one is chosen as the value of the coalesced column. A simple way to interpret this is to consider that a coalesced column of an outer join is represented by the common column of the inner table of a JOIN. Suppose that the tables \( t1(a, b) \) and \( t2(a, c) \) have the following contents:

<table>
<thead>
<tr>
<th>t1</th>
<th>t2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>x</td>
</tr>
<tr>
<td>2</td>
<td>y</td>
</tr>
<tr>
<td>1</td>
<td>z</td>
</tr>
<tr>
<td>2</td>
<td>w</td>
</tr>
</tbody>
</table>

Then, for this join, column \( a \) contains the values of \( t1.a \):

```
mysql> SELECT * FROM t1 NATURAL LEFT JOIN t2;
+----+------+------+------+
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>c</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>x</td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>y</td>
<td>z</td>
<td></td>
</tr>
</tbody>
</table>
+----+------+------+------+
```

By contrast, for this join, column \( a \) contains the values of \( t2.a \):

```
mysql> SELECT * FROM t1 NATURAL RIGHT JOIN t2;
+----+------|------|
<table>
<thead>
<tr>
<th>a</th>
<th>c</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>z</td>
<td>y</td>
</tr>
<tr>
<td>3</td>
<td>w</td>
<td>NULL</td>
</tr>
</tbody>
</table>
+----+------|------+
```

Compare those results to the otherwise equivalent queries with JOIN ... ON:

```
mysql> SELECT * FROM t1 LEFT JOIN t2 ON (t1.a = t2.a);
+----+---+---+---+
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>a</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>x</td>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>2</td>
<td>y</td>
<td>2</td>
<td>z</td>
</tr>
</tbody>
</table>
+----+---+---+---+
```
A **USING** clause can be rewritten as an **ON** clause that compares corresponding columns. However, although **USING** and **ON** are similar, they are not quite the same. Consider the following two queries:

```
a LEFT JOIN b USING (c1, c2, c3)
a LEFT JOIN b ON a.c1 = b.c1 AND a.c2 = b.c2 AND a.c3 = b.c3
```

With respect to determining which rows satisfy the join condition, both joins are semantically identical.

With respect to determining which columns to display for **SELECT** * expansion, the two joins are not semantically identical. The **USING** join selects the coalesced value of corresponding columns, whereas the **ON** join selects all columns from all tables. For the **USING** join, **SELECT** * selects these values:

```
COALESCE(a.c1, b.c1), COALESCE(a.c2, b.c2), COALESCE(a.c3, b.c3)
```

For the **ON** join, **SELECT** * selects these values:

```
a.c1, a.c2, a.c3, b.c1, b.c2, b.c3
```

With an inner join, **COALESCE(a.c1, b.c1)** is the same as either a.c1 or b.c1 because both columns have the same value. With an outer join (such as **LEFT JOIN**), one of the two columns can be **NULL**. That column is omitted from the result.

• An **ON** clause can refer only to its operands.

Example:

```
CREATE TABLE t1 (i1 INT);
CREATE TABLE t2 (i2 INT);
CREATE TABLE t3 (i3 INT);
SELECT * FROM t1 JOIN t2 JOIN t3 ON (i1 = i3);
```

The statement fails with an **Unknown column 'i3' in 'on clause'** error because i3 is a column in t3, which is not an operand of the **ON** clause. To enable the join to be processed, rewrite the statement as follows:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (i1 = i3);
```

• **JOIN** has higher precedence than the comma operator (,), so the join expression **t1, t2 JOIN t3** is interpreted as **(t1, (t2 JOIN t3))**, not as **((t1, t2) JOIN t3)**. This affects statements that use an **ON** clause because that clause can refer only to columns in the operands of the join, and the precedence affects interpretation of what those operands are.

Example:

```
CREATE TABLE t1 (i1 INT, j1 INT);
CREATE TABLE t2 (i2 INT, j2 INT);
CREATE TABLE t3 (i3 INT, j3 INT);
INSERT INTO t1 VALUES(1, 1);
INSERT INTO t2 VALUES(1, 1);
INSERT INTO t3 VALUES(1, 1);
```
SELECT * FROM t1, t2 JOIN t3 ON (t1.i1 = t3.i3);

The JOIN takes precedence over the comma operator, so the operands for the ON clause are t2 and t3. Because t1.i1 is not a column in either of the operands, the result is an Unknown column 't1.i1' in 'on clause' error.

To enable the join to be processed, use either of these strategies:

- Group the first two tables explicitly with parentheses so that the operands for the ON clause are (t1, t2) and t3:
  
  SELECT * FROM (t1, t2) JOIN t3 ON (t1.i1 = t3.i3);

- Avoid the use of the comma operator and use JOIN instead:
  
  SELECT * FROM t1 JOIN t2 JOIN t3 ON (t1.i1 = t3.i3);

The same precedence interpretation also applies to statements that mix the comma operator with INNER JOIN, CROSS JOIN, LEFT JOIN, and RIGHT JOIN, all of which have higher precedence than the comma operator.

- A MySQL extension compared to the SQL:2003 standard is that MySQL permits you to qualify the common (coalesced) columns of NATURAL or USING joins, whereas the standard disallows that.

## 13.2.14 Set Operations with UNION, INTERSECT, and EXCEPT

- **Result Set Column Names and Data Types**
- **Set Operations with TABLE and VALUES Statements**
- **Set Operations using DISTINCT and ALL**
- **Set Operations with ORDER BY and LIMIT**
- **Limitations of Set Operations**

SQL set operations combine the results of multiple query blocks into a single result. A query block, sometimes also known as a simple table, is any SQL statement that returns a result set, such as SELECT. MySQL 8.2 also supports TABLE and VALUES statements. See the individual descriptions of these statements elsewhere in this chapter for additional information.

The SQL standard defines the following three set operations:

- **UNION**: Combine all results from two query blocks into a single result, omitting any duplicates.
- **INTERSECT**: Combine only those rows which the results of two query blocks have in common, omitting any duplicates.
- **EXCEPT**: For two query blocks A and B, return all results from A which are not also present in B, omitting any duplicates.

(Some database systems, such as Oracle, use MINUS for the name of this operator. This is not supported in MySQL.)

MySQL supports UNION, INTERSECT, and EXCEPT.

Each of these set operators supports an ALL modifier. When the ALL keyword follows a set operator, this causes duplicates to be included in the result. See the following sections covering the individual operators for more information and examples.
All three set operators also support a \texttt{DISTINCT} keyword, which suppresses duplicates in the result. Since this is the default behavior for set operators, it is usually not necessary to specify \texttt{DISTINCT} explicitly.

In general, query blocks and set operations can be combined in any number and order. A greatly simplified representation is shown here:

\begin{verbatim}
query_block [set_op query_block] [set_op query_block] ...

query_block:
   SELECT | TABLE | VALUES

set_op:
   UNION | INTERSECT | EXCEPT
\end{verbatim}

This can be represented more accurately, and in greater detail, like this:

\begin{verbatim}
query_expression:
    [with_clause] /* WITH clause */
query_expression_body
    [order_by_clause] [limit_clause] [into_clause]
query_expression_body:
    query_term
    | query_expression_body UNION [ALL | DISTINCT] query_term
    | query_expression_body EXCEPT [ALL | DISTINCT] query_term
query_term:
    query_primary
    | query_term INTERSECT [ALL | DISTINCT] query_primary
query_primary:
    query_block
    | '(' query_expression_body [order_by_clause] [limit_clause] [into_clause] ')'
query_block:
    /* also known as a simple table */
    query_specification /* SELECT statement */
    | table_value_constructor /* VALUES statement */
    | explicit_table /* TABLE statement */
\end{verbatim}

You should be aware that \texttt{INTERSECT} is evaluated before \texttt{UNION} or \texttt{EXCEPT}. This means that, for example, \texttt{TABLE x UNION TABLE y INTERSECT TABLE z} is always evaluated as \texttt{TABLE x UNION (TABLE y INTERSECT TABLE z)}. See Section 13.2.8, “INTERSECT Clause”, for more information.

In addition, you should keep in mind that, while the \texttt{UNION} and \texttt{INTERSECT} set operators are commutative (ordering is not significant), \texttt{EXCEPT} is not (order of operands affects the outcome). In other words, all of the following statements are true:

- \texttt{TABLE x UNION TABLE y} and \texttt{TABLE y UNION TABLE x} produce the same result, although the ordering of the rows may differ. You can force them to be the same using \texttt{ORDER BY}; see \texttt{ORDER BY and LIMIT in Unions}.

- \texttt{TABLE x INTERSECT TABLE y} and \texttt{TABLE y INTERSECT TABLE x} return the same result.

- \texttt{TABLE x EXCEPT TABLE y} and \texttt{TABLE y EXCEPT TABLE x} do not yield the same result. See Section 13.2.4, “EXCEPT Clause”, for an example.

More information and examples can be found in the sections that follow.

\section*{Result Set Column Names and Data Types}

The column names for the result of a set operation are taken from the column names of the first query block. Example:

\begin{verbatim}
mysql> CREATE TABLE t1 (x INT, y INT);
\end{verbatim}
Set Operations with UNION, INTERSECT, and EXCEPT

This is true for **UNION**, **EXCEPT**, and **INTERSECT** queries.

Selected columns listed in corresponding positions of each query block should have the same data type. For example, the first column selected by the first statement should have the same type as the first column selected by the other statements. If the data types of corresponding result columns do not match, the types and lengths of the columns in the result take into account the values retrieved by all of the query blocks. For example, the column length in the result set is not constrained to the length of the value from the first statement, as shown here:

```
mysql> SELECT REPEAT('a',1) UNION SELECT REPEAT('b',20);
+----------------------+
| REPEAT('a',1)        |
+----------------------+
| a                    |
| bbbbbbbbbbbbbbbbbbbb |
+----------------------+
```

**Set Operations with TABLE and VALUES Statements**

You can also use a **TABLE** statement or **VALUES** statement wherever you can employ the equivalent **SELECT** statement. Assume that tables **t1** and **t2** are created and populated as shown here:

```
CREATE TABLE t1 (x INT, y INT);
INSERT INTO t1 VALUES ROW(4,-2), ROW(5,9);

CREATE TABLE t2 (a INT, b INT);
INSERT INTO t2 VALUES ROW(1,2), ROW(3,4);
```

The preceding being the case, and disregarding the column names in the output of the queries beginning with **VALUES**, all of the following **UNION** queries yield the same result:
### Set Operations with UNION, INTERSECT, and EXCEPT

**SELECT * FROM t1 UNION SELECT * FROM t2;**
**TABLE t1 UNION SELECT * FROM t2;**
**VALUES ROW(4,-2), ROW(5,9) UNION SELECT * FROM t2;**
**SELECT * FROM t1 UNION TABLE t2;**
**TABLE t1 UNION TABLE t2;**
**VALUES ROW(4,-2), ROW(5,9) UNION TABLE t2;**
**SELECT * FROM t1 UNION VALUES ROW(4,-2),ROW(5,9);**
**TABLE t1 UNION VALUES ROW(4,-2),ROW(5,9);**
**VALUES ROW(4,-2), ROW(5,9) UNION VALUES ROW(4,-2),ROW(5,9);**

To force the column names to be the same, wrap the query block on the left-hand side in a **SELECT** statement, and use aliases, like this:

```sql
mysql> SELECT * FROM (TABLE t2) AS t(x,y) UNION TABLE t1;
```

<table>
<thead>
<tr>
<th>x</th>
<th>y</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
</tr>
<tr>
<td>4</td>
<td>-2</td>
</tr>
<tr>
<td>5</td>
<td>9</td>
</tr>
</tbody>
</table>

4 rows in set (0.00 sec)

### Set Operations using DISTINCT and ALL

By default, duplicate rows are removed from results of set operations. The optional **DISTINCT** keyword has the same effect but makes it explicit. With the optional **ALL** keyword, duplicate-row removal does not occur and the result includes all matching rows from all queries in the union.

You can mix **ALL** and **DISTINCT** in the same query. Mixed types are treated such that a set operation using **DISTINCT** overrides any such operation using **ALL** to its left. A **DISTINCT** set can be produced explicitly by using **DISTINCT** with **UNION**, **INTERSECT**, or **EXCEPT**, or implicitly by using the set operations with no following **DISTINCT** or **ALL** keyword.

Set operations work the same way when one or more **TABLE** statements, **VALUES** statements, or both, are used to generate the set.

### Set Operations with ORDER BY and LIMIT

To apply an **ORDER BY** or **LIMIT** clause to an individual query block used as part of a union, intersection, or other set operation, parenthesize the query block, placing the clause inside the parentheses, like this:

```sql
(SELECT a FROM t1 WHERE a=10 AND b=1 ORDER BY a LIMIT 10)
UNION
(SELECT a FROM t2 WHERE a=11 AND b=2 ORDER BY a LIMIT 10);
```

```sql
(TABLE t1 ORDER BY a LIMIT 10)
INTERSECT
(TABLE t2 ORDER BY a LIMIT 10);
```

Use of **ORDER BY** for individual query blocks or statements implies nothing about the order in which the rows appear in the final result because the rows produced by a set operation are by default unordered. Therefore, **ORDER BY** in this context typically is used in conjunction with **LIMIT**, to determine the subset of the selected rows to retrieve, even though it does not necessarily affect the order of those rows in the final result. If **ORDER BY** appears without **LIMIT** within a query block, it is optimized away because it has no effect in any case.

To use an **ORDER BY** or **LIMIT** clause to sort or limit the entire result of a set operation, place the **ORDER BY** or **LIMIT** after the last statement:
Set Operations with UNION, INTERSECT, and EXCEPT

```
SELECT a FROM t1
EXCEPT
SELECT a FROM t2 WHERE a=11 AND b=2
ORDER BY a LIMIT 10;

TABLE t1
UNION
TABLE t2
ORDER BY a LIMIT 10;
```

If one or more individual statements make use of `ORDER BY, LIMIT`, or both, and, in addition, you wish to apply an `ORDER BY, LIMIT`, or both to the entire result, then each such individual statement must be enclosed in parentheses.

```
(SELECT a FROM t1 WHERE a=10 AND b=1)
EXCEPT
(SELECT a FROM t2 WHERE a=11 AND b=2)
ORDER BY a LIMIT 10;

(TABLE t1 ORDER BY a LIMIT 10)
UNION
TABLE t2
ORDER BY a LIMIT 10;
```

A statement with no `ORDER BY` or `LIMIT` clause does need to be parenthesized; replacing `TABLE t2` with `(TABLE t2)` in the second statement of the two just shown does not alter the result of the `UNION`.

You can also use `ORDER BY` and `LIMIT` with `VALUES` statements in set operations, as shown in this example using the `mysql` client:

```
mysql> VALUES ROW(4,-2), ROW(5,9), ROW(-1,3)
    -> UNION
    -> VALUES ROW(1,2), ROW(3,4), ROW(-1,3)
    -> ORDER BY column_0 DESC LIMIT 3;
```

<table>
<thead>
<tr>
<th>column_0</th>
<th>column_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>9</td>
</tr>
<tr>
<td>4</td>
<td>-2</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
</tr>
</tbody>
</table>

3 rows in set (0.00 sec)

(You should keep in mind that neither `TABLE` statements nor `VALUES` statements accept a `WHERE` clause.)

This kind of `ORDER BY` cannot use column references that include a table name (that is, names in `tbl_name.col_name` format). Instead, provide a column alias in the first query block, and refer to the alias in the `ORDER BY` clause. (You can also refer to the column in the `ORDER BY` clause using its column position, but such use of column positions is deprecated, and thus subject to eventual removal in a future MySQL release.)

If a column to be sorted is aliased, the `ORDER BY` clause must refer to the alias, not the column name.

The first of the following statements is permitted, but the second fails with an `Unknown column 'a' in 'order clause'` error:

```
(SELECT a AS b FROM t) UNION (SELECT ...) ORDER BY b;
(SELECT a AS b FROM t) UNION (SELECT ...) ORDER BY a;
```

To cause rows in a `UNION` result to consist of the sets of rows retrieved by each query block one after the other, select an additional column in each query block to use as a sort column and add an `ORDER BY` clause that sorts on that column following the last query block:
Subqueries

To maintain sort order within individual results, add a secondary column to the `ORDER BY` clause:

```sql
(SELECT 1 AS sort_col, col1a, col1b, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col, col1a;
```

Use of an additional column also enables you to determine which query block each row comes from. Extra columns can provide other identifying information as well, such as a string that indicates a table name.

## Limitations of Set Operations

Set operations in MySQL are subject to some limitations, which are described in the next few paragraphs.

Set operations including `SELECT` statements have the following limitations:

- **HIGH_PRIORITY** in the first `SELECT` has no effect. `HIGH_PRIORITY` in any subsequent `SELECT` produces a syntax error.
- Only the last `SELECT` statement can use an `INTO` clause. However, the entire `UNION` result is written to the `INTO` output destination.

These two `UNION` variants containing `INTO` are deprecated; you should expect support for them to be removed in a future version of MySQL:

- In the trailing query block of a query expression, use of `INTO` before `FROM` produces a warning. Example:
  ```sql
  ... UNION SELECT * INTO OUTFILE 'file_name' FROM table_name;
  ```

- In a parenthesized trailing block of a query expression, use of `INTO` (regardless of its position relative to `FROM`) produces a warning. Example:
  ```sql
  ... UNION (SELECT * INTO OUTFILE 'file_name' FROM table_name);
  ```

Those variants are deprecated because they are confusing, as if they collect information from the named table rather than the entire query expression (the `UNION`).

Set operations with an aggregate function in an `ORDER BY` clause are rejected with `ER_AGGREGATE_ORDER_FOR_UNION`. Although the error name might suggest that this is exclusive to `UNION` queries, the preceding is also true for `EXCEPT` and `INTERSECT` queries, as shown here:

```sql
mysql> TABLE t1 INTERSECT TABLE t2 ORDER BY MAX(x);
ERROR 3028 (HY000): Expression #1 of ORDER BY contains aggregate function and applies to a UNION, EXCEPT or INTERSECT query.
```

A locking clause (such as `FOR UPDATE` or `LOCK IN SHARE MODE`) applies to the query block it follows. This means that, in a `SELECT` statement used with set operations, a locking clause can be used only if the query block and locking clause are enclosed in parentheses.

### 13.2.15 Subqueries

A subquery is a `SELECT` statement within another statement.

All subquery forms and operations that the SQL standard requires are supported, as well as a few features that are MySQL-specific.
Subqueries

Here is an example of a subquery:

```sql
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

In this example, `SELECT * FROM t1` ... is the outer query (or outer statement), and `(SELECT column1 FROM t2)` is the subquery. We say that the subquery is nested within the outer query, and in fact it is possible to nest subqueries within other subqueries, to a considerable depth. A subquery must always appear within parentheses.

The main advantages of subqueries are:

- They allow queries that are structured so that it is possible to isolate each part of a statement.
- They provide alternative ways to perform operations that would otherwise require complex joins and unions.
- Many people find subqueries more readable than complex joins or unions. Indeed, it was the innovation of subqueries that gave people the original idea of calling the early SQL “Structured Query Language.”

Here is an example statement that shows the major points about subquery syntax as specified by the SQL standard and supported in MySQL:

```sql
DELETE FROM t1
WHERE s11 > ANY
(SELECT COUNT(*) /* no hint */ FROM t2
WHERE NOT EXISTS
(SELECT * FROM t3
WHERE ROW(5*t2.s1,77)=
(SELECT 50,11*s1 FROM t4 UNION SELECT 50,77 FROM
(SELECT * FROM t5) AS t5)));
```

A subquery can return a scalar (a single value), a single row, a single column, or a table (one or more rows of one or more columns). These are called scalar, column, row, and table subqueries. Subqueries that return a particular kind of result often can be used only in certain contexts, as described in the following sections.

There are few restrictions on the type of statements in which subqueries can be used. A subquery can contain many of the keywords or clauses that an ordinary `SELECT` can contain: `DISTINCT`, `GROUP BY`, `ORDER BY`, `LIMIT`, `joins`, `index hints`, `UNION` constructs, `comments`, `functions`, and so on.

`TABLE` and `VALUES` statements can be used in subqueries. Subqueries using `VALUES` are generally more verbose versions of subqueries that can be rewritten more compactly using set notation, or with `SELECT` or `TABLE` syntax; assuming that table `ts` is created using the statement `CREATE TABLE ts VALUES ROW(2), ROW(4), ROW(6)`, the statements shown here are all equivalent:

```sql
SELECT * FROM tt
WHERE b > ANY (VALUES ROW(2), ROW(4), ROW(6));
SELECT * FROM tt
WHERE b > ANY (SELECT * FROM ts);
SELECT * FROM tt
WHERE b > ANY (TABLE ts);
```

Examples of `TABLE` subqueries are shown in the sections that follow.

A subquery's outer statement can be any one of: `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `SET`, or `DO`.

For information about how the optimizer handles subqueries, see Section 8.2.2, “Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions”. For a discussion of restrictions on
Subqueries

subquery use, including performance issues for certain forms of subquery syntax, see Section 13.2.15.12, “Restrictions on Subqueries”.

13.2.15.1 The Subquery as Scalar Operand

In its simplest form, a subquery is a scalar subquery that returns a single value. A scalar subquery is a simple operand, and you can use it almost anywhere a single column value or literal is legal, and you can expect it to have those characteristics that all operands have: a data type, a length, an indication that it can be NULL, and so on. For example:

```sql
CREATE TABLE t1 (s1 INT, s2 CHAR(5) NOT NULL);
INSERT INTO t1 VALUES(100, 'abcde');
SELECT (SELECT s2 FROM t1);
```

The subquery in this `SELECT` returns a single value (`'abcde'`) that has a data type of `CHAR`, a length of 5, a character set and collation equal to the defaults in effect at `CREATE TABLE` time, and an indication that the value in the column can be NULL. Nullability of the value selected by a scalar subquery is not copied because if the subquery result is empty, the result is NULL. For the subquery just shown, if `t1` were empty, the result would be NULL even though `s2` is NOT NULL.

There are a few contexts in which a scalar subquery cannot be used. If a statement permits only a literal value, you cannot use a subquery. For example, `LIMIT` requires literal integer arguments, and `LOAD DATA` requires a literal string file name. You cannot use subqueries to supply these values.

When you see examples in the following sections that contain the rather spartan construct `(SELECT column1 FROM t1)`, imagine that your own code contains much more diverse and complex constructions.

Suppose that we make two tables:

```sql
CREATE TABLE t1 (s1 INT);
INSERT INTO t1 VALUES (1);
CREATE TABLE t2 (s1 INT);
INSERT INTO t2 VALUES (2);
```

Then perform a `SELECT`:

```sql
SELECT (SELECT s1 FROM t2) FROM t1;
```

The result is 2 because there is a row in `t2` containing a column `s1` that has a value of 2.

The preceding query can also be written like this, using `TABLE`:

```sql
SELECT (TABLE t2) FROM t1;
```

A scalar subquery can be part of an expression, but remember the parentheses, even if the subquery is an operand that provides an argument for a function. For example:

```sql
SELECT UPPER((SELECT s1 FROM t1)) FROM t2;
```

The same result can be obtained using `SELECT UPPER((TABLE t1)) FROM t2`.

13.2.15.2 Comparisons Using Subqueries

The most common use of a subquery is in the form:

```sql
non_subquery_operand comparison_operator (subquery)
```

Where `comparison_operator` is one of these operators:
Subqueries

For example:

```sql
... WHERE 'a' = (SELECT column1 FROM t1)
```

MySQL also permits this construct:

```sql
non_subquery_operand LIKE (subquery)
```

At one time the only legal place for a subquery was on the right side of a comparison, and you might still find some old DBMSs that insist on this.

Here is an example of a common-form subquery comparison that you cannot do with a join. It finds all the rows in table `t1` for which the `column1` value is equal to a maximum value in table `t2`:

```sql
SELECT * FROM t1
WHERE column1 = (SELECT MAX(column2) FROM t2);
```

Here is another example, which again is impossible with a join because it involves aggregating for one of the tables. It finds all rows in table `t1` containing a value that occurs twice in a given column:

```sql
SELECT * FROM t1 AS t
WHERE 2 = (SELECT COUNT(*) FROM t1 WHERE t1.id = t.id);
```

For a comparison of the subquery to a scalar, the subquery must return a scalar. For a comparison of the subquery to a row constructor, the subquery must be a row subquery that returns a row with the same number of values as the row constructor. See Section 13.2.15.5, “Row Subqueries”.

### 13.2.15.3 Subqueries with ANY, IN, or SOME

#### Syntax:

- `operand comparison_operator ANY (subquery)`
- `operand IN (subquery)`
- `operand comparison_operator SOME (subquery)`

Where `comparison_operator` is one of these operators:

```sql
=  >  <  >=  <=  <>  !=  <=>
```

The **ANY** keyword, which must follow a comparison operator, means “return **TRUE** if the comparison is **TRUE** for **ANY** of the values in the column that the subquery returns.” For example:

```sql
SELECT s1 FROM t1 WHERE s1 > ANY (SELECT s1 FROM t2);
```

Suppose that there is a row in table `t1` containing `(10)`. The expression is **TRUE** if table `t2` contains `(21,14,7)` because there is a value 7 in `t2` that is less than 10. The expression is **FALSE** if table `t2` contains `(20,10)`, or if table `t2` is empty. The expression is **unknown** (that is, **NULL**) if table `t2` contains `(NULL,NULL,NULL)`.

When used with a subquery, the word **IN** is an alias for **= ANY**. Thus, these two statements are the same:

```sql
SELECT s1 FROM t1 WHERE s1 = ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 IN (SELECT s1 FROM t2);
```

**IN** and **= ANY** are not synonyms when used with an expression list. **IN** can take an expression list, but **= ANY** cannot. See Section 12.4.2, “Comparison Functions and Operators”.
NOT IN is not an alias for <> ANY, but for <> ALL. See Section 13.2.15.4, “Subqueries with ALL”.

The word SOME is an alias for ANY. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 <> SOME (SELECT s1 FROM t2);
```

Use of the word SOME is rare, but this example shows why it might be useful. To most people, the English phrase “a is not equal to any b” means “there is no b which is equal to a,” but that is not what is meant by the SQL syntax. The syntax means “there is some b to which a is not equal.” Using <> SOME instead helps ensure that everyone understands the true meaning of the query.

You can use TABLE in a scalar IN, ANY, or SOME subquery provided the table contains only a single column. If t2 has only one column, the statements shown previously in this section can be written as shown here, in each case substituting TABLE t2 for SELECT s1 FROM t2:

```
SELECT s1 FROM t1 WHERE s1 > ANY (TABLE t2);
SELECT s1 FROM t1 WHERE s1 = ANY (TABLE t2);
SELECT s1 FROM t1 WHERE s1 IN (TABLE t2);
SELECT s1 FROM t1 WHERE s1 <> ANY (TABLE t2);
SELECT s1 FROM t1 WHERE s1 <> SOME (TABLE t2);
```

### 13.2.15.4 Subqueries with ALL

Syntax:

```
operand comparison_operator ALL (subquery)
```

The word ALL, which must follow a comparison operator, means “return TRUE if the comparison is TRUE for ALL of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ALL (SELECT s1 FROM t2);
```

Suppose that there is a row in table t1 containing (10). The expression is TRUE if table t2 contains (-5, 0, +5) because 10 is greater than all three values in t2. The expression is FALSE if table t2 contains (12, 6, NULL, -100) because there is a single value 12 in table t2 that is greater than 10. The expression is unknown (that is, NULL) if table t2 contains (0, NULL, 1).

Finally, the expression is TRUE if table t2 is empty. So, the following expression is TRUE when table t2 is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT s1 FROM t2);
```

But this expression is NULL when table t2 is empty:

```
SELECT * FROM t1 WHERE 1 > (SELECT s1 FROM t2);
```

In addition, the following expression is NULL when table t2 is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT MAX(s1) FROM t2);
```

In general, tables containing NULL values and empty tables are “edge cases.” When writing subqueries, always consider whether you have taken those two possibilities into account.

NOT IN is an alias for <> ALL. Thus, these two statements are the same:
Subqueries

As with IN, ANY, and SOME, you can use TABLE with ALL and NOT IN provided that the following two conditions are met:

- The table in the subquery contains only one column
- The subquery does not depend on a column expression

For example, assuming that table t2 consists of a single column, the last two statements shown previously can be written using TABLE t2 like this:

```
SELECT s1 FROM t1 WHERE s1 <> ALL (TABLE t2);
SELECT s1 FROM t1 WHERE s1 NOT IN (TABLE t2);
```

A query such as SELECT * FROM t1 WHERE 1 > ALL (SELECT MAX(s1) FROM t2); cannot be written using TABLE t2 because the subquery depends on a column expression.

13.2.15.5 Row Subqueries

Scalar or column subqueries return a single value or a column of values. A row subquery is a subquery variant that returns a single row and can thus return more than one column value. Legal operators for row subquery comparisons are:

=  >  <  >=  <=  <>  !=  <=>

Here are two examples:

```
SELECT * FROM t1 WHERE (col1,col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);
```

For both queries, if the table t2 contains a single row with id = 10, the subquery returns a single row. If this row has col3 and col4 values equal to the col1 and col2 values of any rows in t1, the WHERE expression is TRUE and each query returns those t1 rows. If the t2 row col3 and col4 values are not equal the col1 and col2 values of any t1 row, the expression is FALSE and the query returns an empty result set. The expression is unknown (that is, NULL) if the subquery produces no rows. An error occurs if the subquery produces multiple rows because a row subquery can return at most one row.

For information about how each operator works for row comparisons, see Section 12.4.2, “Comparison Functions and Operators”.

The expressions (1,2) and ROW(1,2) are sometimes called row constructors. The two are equivalent. The row constructor and the row returned by the subquery must contain the same number of values.

A row constructor is used for comparisons with subqueries that return two or more columns. When a subquery returns a single column, this is regarded as a scalar value and not as a row, so a row constructor cannot be used with a subquery that does not return at least two columns. Thus, the following query fails with a syntax error:

```
SELECT * FROM t1 WHERE ROW(1) = (SELECT column1 FROM t2)
```

Row constructors are legal in other contexts. For example, the following two statements are semantically equivalent (and are handled in the same way by the optimizer):

```
SELECT * FROM t1 WHERE (column1,column2) = (1,1);
```
Subqueries

The following query answers the request, “find all rows in table t1 that also exist in table t2”:

```
SELECT column1, column2, column3
FROM t1
WHERE (column1, column2, column3) IN
  (SELECT column1, column2, column3 FROM t2);
```

For more information about the optimizer and row constructors, see Section 8.2.1.22, “Row Constructor Expression Optimization”

13.2.15.6 Subqueries with EXISTS or NOT EXISTS

If a subquery returns any rows at all, EXISTS subquery is TRUE, and NOT EXISTS subquery is FALSE. For example:

```
SELECT column1 FROM t1 WHERE EXISTS (SELECT * FROM t2);
```

Traditionally, an EXISTS subquery starts with SELECT *, but it could begin with SELECT 5 or SELECT column1 or anything at all. MySQL ignores the SELECT list in such a subquery, so it makes no difference.

For the preceding example, if t2 contains any rows, even rows with nothing but NULL values, the EXISTS condition is TRUE. This is actually an unlikely example because a [NOT] EXISTS subquery almost always contains correlations. Here are some more realistic examples:

- What kind of store is present in one or more cities?

```
SELECT DISTINCT store_type FROM stores
  WHERE EXISTS (SELECT * FROM cities_stores
    WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in no cities?

```
SELECT DISTINCT store_type FROM stores
  WHERE NOT EXISTS (SELECT * FROM cities_stores
    WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in all cities?

```
SELECT DISTINCT store_type FROM stores
  WHERE NOT EXISTS (
    SELECT * FROM cities WHERE NOT EXISTS (
      SELECT * FROM cities_stores
        WHERE cities_stores.city = cities.city
        AND cities_stores.store_type = stores.store_type));
```

The last example is a double-nested NOT EXISTS query. That is, it has a NOT EXISTS clause within a NOT EXISTS clause. Formally, it answers the question “does a city exist with a store that is not in Stores”? But it is easier to say that a nested NOT EXISTS answers the question “is x TRUE for all y?”

You can also use NOT EXISTS or NOT EXISTS with TABLE in the subquery, like this:

```
SELECT column1 FROM t1 WHERE EXISTS (TABLE t2);
```

The results are the same as when using SELECT * with no WHERE clause in the subquery.

13.2.15.7 Correlated Subqueries

A correlated subquery is a subquery that contains a reference to a table that also appears in the outer query. For example:
Subqueries

SELECT * FROM t1
  WHERE column1 = ANY (SELECT column1 FROM t2
                        WHERE t2.column2 = t1.column2);

Notice that the subquery contains a reference to a column of t1, even though the subquery's FROM clause does not mention a table t1. So, MySQL looks outside the subquery, and finds t1 in the outer query.

Suppose that table t1 contains a row where column1 = 5 and column2 = 6; meanwhile, table t2 contains a row where column1 = 5 and column2 = 7. The simple expression ... WHERE column1 = ANY (SELECT column1 FROM t2) would be TRUE, but in this example, the WHERE clause within the subquery is FALSE (because (5, 6) is not equal to (5, 7)), so the expression as a whole is FALSE.

Scoping rule: MySQL evaluates from inside to outside. For example:

SELECT column1 FROM t1 AS x
  WHERE x.column1 = (SELECT column1 FROM t2 AS x
                        WHERE x.column1 = (SELECT column1 FROM t3
                                                      WHERE x.column2 = t3.column1));

In this statement, x.column2 must be a column in table t2 because SELECT column1 FROM t2 AS x ... renames t2. It is not a column in table t1 because SELECT column1 FROM t1 ... is an outer query that is farther out.

The optimizer can transform a correlated scalar subquery to a derived table when the subquery_toDerived flag of the optimizer_switch variable is enabled. Consider the query shown here:

SELECT * FROM t1
  WHERE ( SELECT a FROM t2
            WHERE t2.a=t1.a ) > 0;

To avoid materializing several times for a given derived table, we can instead materialize—once—a derived table which adds a grouping on the join column from the table referenced in the inner query (t2.a) and then an outer join on the lifted predicate (t1.a = derived.a) in order to select the correct group to match up with the outer row. (If the subquery already has an explicit grouping, the extra grouping is added to the end of the grouping list.) The query previously shown can thus be rewritten like this:

SELECT t1.* FROM t1
  LEFT OUTER JOIN
    (SELECT a, COUNT(*) AS ct FROM t2 GROUP BY a) AS derived
  ON t1.a = derived.a
  AND
  REJECT_IF(
    (ct > 1),
    "ERROR 1242 (21000): Subquery returns more than 1 row"
  )
  WHERE derived.a > 0;

In the rewritten query, REJECT_IF() represents an internal function which tests a given condition (here, the comparison ct > 1) and raises a given error (in this case, ER_SUBQUERY_NO_1_ROW) if the condition is true. This reflects the cardinality check that the optimizer performs as part of evaluating the JOIN or WHERE clause, prior to evaluating any lifted predicate, which is done only if the subquery does not return more than one row.

This type of transformation can be performed, provided the following conditions are met:

- The subquery can be part of a SELECT list, WHERE condition, or HAVING condition, but cannot be part of a JOIN condition, and cannot contain a LIMIT or OFFSET clause. In addition, the subquery cannot contain any set operations such as UNION.
Subqueries

- The WHERE clause may contain one or more predicates, combined with AND. If the WHERE clause contains an OR clause, it cannot be transformed. At least one of the WHERE clause predicates must be eligible for transformation, and none of them may reject transformation.

- To be eligible for transformation, a WHERE clause predicate must be an equality predicate in which each operand should be a simple column reference. No other predicates—including other comparison predicates—are eligible for transformation. The predicate must employ the equality operator = for making the comparison; the null-safe ≪=≫ operator is not supported in this context.

- A WHERE clause predicate that contains only inner references is not eligible for transformation, since it can be evaluated before the grouping. A WHERE clause predicate that contains only outer references is eligible for transformation, even though it can be lifted up to the outer query block. This is made possible by adding a cardinality check without grouping in the derived table.

- To be eligible, a WHERE clause predicate must have one operand that contains only inner references and one operand that contains only outer references. If the predicate is not eligible due to this rule, transformation of the query is rejected.

- A correlated column can be present only in the subquery's WHERE clause (and not in the SELECT list, a JOIN or ORDER BY clause, a GROUP BY list, or a HAVING clause). Nor can there be any correlated column inside a derived table in the subquery's FROM list.

- A correlated column can not be contained in an aggregate function's list of arguments.

- A correlated column must be resolved in the query block directly containing the subquery being considered for transformation.

- A correlated column cannot be present in a nested scalar subquery in the WHERE clause.

- The subquery cannot contain any window functions, and must not contain any aggregate function which aggregates in a query block outer to the subquery. A COUNT() aggregate function, if contained in the SELECT list element of the subquery, must be at the topmost level, and cannot be part of an expression.

See also Section 13.2.15.8, “Derived Tables”.

13.2.15.8 Derived Tables

This section discusses general characteristics of derived tables. For information about lateral derived tables preceded by the LATERAL keyword, see Section 13.2.15.9, “Lateral Derived Tables”.

A derived table is an expression that generates a table within the scope of a query FROM clause. For example, a subquery in a SELECT statement FROM clause is a derived table:

```
SELECT ... FROM (subquery) [AS] tbl_name ...
```

The JSON_TABLE() function generates a table and provides another way to create a derived table:

```
SELECT * FROM JSON_TABLE(arg_list) [AS] tbl_name ...
```

The [AS] tbl_name clause is mandatory because every table in a FROM clause must have a name. Any columns in the derived table must have unique names. Alternatively, tbl_name may be followed by a parenthesized list of names for the derived table columns:

```
SELECT ... FROM (subquery) [AS] tbl_name (col_list) ...
```

The number of column names must be the same as the number of table columns.

For the sake of illustration, assume that you have this table:
CREATE TABLE t1 (s1 INT, s2 CHAR(5), s3 FLOAT);

Here is how to use a subquery in the `FROM` clause, using the example table:

```sql
INSERT INTO t1 VALUES (1,'1',1.0);
INSERT INTO t1 VALUES (2,'2',2.0);
SELECT sb1,sb2,sb3
FROM (SELECT s1 AS sb1, s2 AS sb2, s3*2 AS sb3 FROM t1) AS sb
WHERE sb1 > 1;
```

Result:

```
+------+------+------+
| sb1  | sb2  | sb3  |
+------+------+------+
|    2 | 2    |    4 |
+------+------+------+
```

Here is another example: Suppose that you want to know the average of a set of sums for a grouped table. This does not work:

```sql
SELECT AVG(SUM(column1)) FROM t1 GROUP BY column1;
```

However, this query provides the desired information:

```sql
SELECT AVG(sum_column1)
FROM (SELECT SUM(column1) AS sum_column1
FROM t1 GROUP BY column1) AS t1;
```

Notice that the column name used within the subquery (`sum_column1`) is recognized in the outer query.

The column names for a derived table come from its select list:

```sql
mysql> SELECT * FROM (SELECT 1, 2, 3, 4) AS dt;
```

```
+---+---+---+---+
| 1 | 2 | 3 | 4 |
+---+---+---+---+
| 1 | 2 | 3 | 4 |
```

To provide column names explicitly, follow the derived table name with a parenthesized list of column names:

```sql
mysql> SELECT * FROM (SELECT 1, 2, 3, 4) AS dt (a, b, c, d);
```

```
+---+---+---+---+
| a | b | c | d |
+---+---+---+---+
| 1 | 2 | 3 | 4 |
```

A derived table can return a scalar, column, row, or table.

Derived tables are subject to these restrictions:

- A derived table cannot contain references to other tables of the same `SELECT` (use a `LATERAL` derived table for that; see Section 13.2.15.9, “Lateral Derived Tables”).

The optimizer determines information about derived tables in such a way that `EXPLAIN` does not need to materialize them. See Section 8.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”.

2842
Subqueries

It is possible under certain circumstances that using `EXPLAIN SELECT` modifies table data. This can occur if the outer query accesses any tables and an inner query invokes a stored function that changes one or more rows of a table. Suppose that there are two tables `t1` and `t2` in database `d1`, and a stored function `f1` that modifies `t2`, created as shown here:

```sql
CREATE DATABASE d1;
USE d1;
CREATE TABLE t1 (c1 INT);
CREATE TABLE t2 (c1 INT);
CREATE FUNCTION f1(p1 INT) RETURNS INT
BEGIN
    INSERT INTO t2 VALUES (p1);
    RETURN p1;
END;
```

Referencing the function directly in an `EXPLAIN SELECT` has no effect on `t2`, as shown here:

```sql
mysql> SELECT * FROM t2;
Empty set (0.02 sec)
```

```sql
mysql> EXPLAIN SELECT f1(5)\G
*************************** 1. row ***************************
  id: 1
  select_type: SIMPLE
  table: NULL
  partitions: NULL
  type: NULL
  possible_keys: NULL
  key: NULL
  key_len: NULL
  ref: NULL
  rows: NULL
  filtered: NULL
  Extra: No tables used
1 row in set (0.01 sec)
```

```sql
mysql> SELECT * FROM t2;
Empty set (0.01 sec)
```

This is because the `SELECT` statement did not reference any tables, as can be seen in the `table` and `Extra` columns of the output. This is also true of the following nested `SELECT`:

```sql
mysql> EXPLAIN SELECT NOW() AS a1, (SELECT f1(5)) AS a2\G
*************************** 1. row ***************************
  id: 1
  select_type: PRIMARY
  table: NULL
  type: NULL
  possible_keys: NULL
  key: NULL
  key_len: NULL
  ref: NULL
  rows: NULL
  filtered: NULL
  Extra: No tables used
1 row in set, 1 warning (0.00 sec)
```

```sql
mysql> SHOW WARNINGS;
+-------+------+------------------------------------------+
| Level | Code | Message                                  |
|-------+------|------------------------------------------|
| Note  | 1249 | Select 2 was reduced during optimization |
+-------+------|------------------------------------------+
1 row in set (0.00 sec)
```
However, if the outer `SELECT` references any tables, the optimizer executes the statement in the subquery as well, with the result that `t2` is modified:

```
mysql> EXPLAIN SELECT * FROM t1 AS a1, (SELECT f1(5)) AS a2;
```

```
*************************** 1. row ***************************
id: 1
select_type: PRIMARY
table: <derived2>
partitions: NULL
type: system
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: 1
filtered: 100.00
Extra: NULL
*************************** 2. row ***************************
id: 1
select_type: PRIMARY
table: a1
partitions: NULL
type: ALL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: 1
filtered: 100.00
Extra: NULL
*************************** 3. row ***************************
id: 2
select_type: DERIVED
table: NULL
partitions: NULL
type: NULL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: NULL
filtered: NULL
Extra: No tables used
3 rows in set (0.00 sec)
```

```
mysql> SELECT * FROM t2;
+------+
| c1   |
+------+
|    5 |
+------+
1 row in set (0.00 sec)
```

The derived table optimization can also be employed with many correlated (scalar) subqueries. For more information and examples, see Section 13.2.15.7, “Correlated Subqueries”.

### 13.2.15.9 Lateral Derived Tables

A derived table cannot normally refer to (depend on) columns of preceding tables in the same `FROM` clause. A derived table may be defined as a lateral derived table to specify that such references are permitted.
Subqueries

Nonlateral derived tables are specified using the syntax discussed in Section 13.2.15.8, “Derived Tables”. The syntax for a lateral derived table is the same as for a nonlateral derived table except that the keyword LATERAL is specified before the derived table specification. The LATERAL keyword must precede each table to be used as a lateral derived table.

Lateral derived tables are subject to these restrictions:

• A lateral derived table can occur only in a FROM clause, either in a list of tables separated with commas or in a join specification (JOIN, INNER JOIN, CROSS JOIN, LEFT [OUTER] JOIN, or RIGHT [OUTER] JOIN).

• If a lateral derived table is in the right operand of a join clause and contains a reference to the left operand, the join operation must be an INNER JOIN, CROSS JOIN, or LEFT [OUTER] JOIN.

• If the table is in the left operand and contains a reference to the right operand, the join operation must be an INNER JOIN, CROSS JOIN, or RIGHT [OUTER] JOIN.

• If a lateral derived table references an aggregate function, the function’s aggregation query cannot be the one that owns the FROM clause in which the lateral derived table occurs.

• In accordance with the SQL standard, MySQL always treats a join with a table function such as JSON_TABLE() as though LATERAL had been used. Since the LATERAL keyword is implicit, it is not allowed before JSON_TABLE(); this is also according to the SQL standard.

The following discussion shows how lateral derived tables make possible certain SQL operations that cannot be done with nonlateral derived tables or that require less-efficient workarounds.

Suppose that we want to solve this problem: Given a table of people in a sales force (where each row describes a member of the sales force), and a table of all sales (where each row describes a sale: salesperson, customer, amount, date), determine the size and customer of the largest sale for each salesperson. This problem can be approached two ways.

First approach to solving the problem: For each salesperson, calculate the maximum sale size, and also find the customer who provided this maximum. In MySQL, that can be done like this:

```sql
SELECT
  salesperson.name,
  -- find maximum sale size for this salesperson
  (SELECT MAX(amount) AS amount
   FROM all_sales
   WHERE all_sales.salesperson_id = salesperson.id)
AS amount,
  -- find customer for this maximum size
  (SELECT customer_name
   FROM all_sales
   WHERE all_sales.salesperson_id = salesperson.id
   AND all_sales.amount =
   (SELECT MAX(amount) AS amount
    FROM all_sales
    WHERE all_sales.salesperson_id = salesperson.id))
AS customer_name
FROM
  salesperson;
```

That query is inefficient because it calculates the maximum size twice per salesperson (once in the first subquery and once in the second).

We can try to achieve an efficiency gain by calculating the maximum once per salesperson and "caching" it in a derived table, as shown by this modified query:

```sql
SELECT
  salesperson.name,
  -- find maximum sale size for this salesperson
  (SELECT MAX(amount) AS amount
   FROM all_sales
   WHERE all_sales.salesperson_id = salesperson.id)
AS amount,
  -- find customer for this maximum size
  (SELECT customer_name
   FROM all_sales
   WHERE all_sales.salesperson_id = salesperson.id
   AND all_sales.amount =
   (SELECT MAX(amount) AS amount
    FROM all_sales
    WHERE all_sales.salesperson_id = salesperson.id))
AS customer_name
FROM
  salesperson;
```
SUBQUERY

SELECT
  salesperson.name,
  max_sale.amount,
  max_sale_customer.customer_name
FROM
  salesperson,
  -- calculate maximum size, cache it in transient derived table max_sale
  (SELECT MAX(amount) AS amount
   FROM all_sales
   WHERE all_sales.salesperson_id = salesperson.id)
  AS max_sale,
  -- find customer, reusing cached maximum size
  (SELECT customer_name
   FROM all_sales
   WHERE all_sales.salesperson_id = salesperson.id
   AND all_sales.amount =
     -- the cached maximum size
     max_sale.amount)
  AS max_sale_customer;

However, the query is illegal in SQL-92 because derived tables cannot depend on other tables in the same
FROM clause. Derived tables must be constant over the query's duration, not contain references to columns
of other FROM clause tables. As written, the query produces this error:

ERROR 1054 (42S22): Unknown column 'salesperson.id' in 'where clause'

In SQL:1999, the query becomes legal if the derived tables are preceded by the LATERAL keyword (which
means "this derived table depends on previous tables on its left side"):

SELECT
  salesperson.name,
  max_sale.amount,
  max_sale_customer.customer_name
FROM
  salesperson,
  -- calculate maximum size, cache it in transient derived table max_sale
  LATERAL
  (SELECT MAX(amount) AS amount
   FROM all_sales
   WHERE all_sales.salesperson_id = salesperson.id)
  AS max_sale,
  -- find customer, reusing cached maximum size
  LATERAL
  (SELECT customer_name
   FROM all_sales
   WHERE all_sales.salesperson_id = salesperson.id
   AND all_sales.amount =
     -- the cached maximum size
     max_sale.amount)
  AS max_sale_customer;

A lateral derived table need not be constant and is brought up to date each time a new row from a
preceding table on which it depends is processed by the top query.

Second approach to solving the problem: A different solution could be used if a subquery in the SELECT list
could return multiple columns:

SELECT
  salesperson.name,
  -- find maximum size and customer at same time
  (SELECT amount, customer_name
   FROM all_sales
   WHERE all_sales.salesperson_id = salesperson.id
   ORDER BY amount DESC LIMIT 1)
  AS max_sale,
  -- find customer, reusing cached maximum size
  (SELECT customer_name
   FROM all_sales
   WHERE all_sales.salesperson_id = salesperson.id
   AND all_sales.amount =
     -- the cached maximum size
     max_sale.amount)
  AS max_sale_customer;
Subqueries

That is efficient but illegal. It does not work because such subqueries can return only a single column:

ERROR 1241 (21000): Operand should contain 1 column(s)

One attempt at rewriting the query is to select multiple columns from a derived table:

```
SELECT
  salesperson.name,
  max_sale.amount,
  max_sale.customer_name
FROM
  salesperson,
  -- find maximum size and customer at same time
  (SELECT amount, customer_name
   FROM all_sales
   WHERE all_sales.salesperson_id = salesperson.id
   ORDER BY amount DESC LIMIT 1)
AS max_sale;
```

However, that also does not work. The derived table is dependent on the `salesperson` table and thus fails without `LATERAL`:

ERROR 1054 (42S22): Unknown column 'salesperson.id' in 'where clause'

Adding the `LATERAL` keyword makes the query legal:

```
SELECT
  salesperson.name,
  max_sale.amount,
  max_sale.customer_name
FROM
  salesperson,
  -- find maximum size and customer at same time
  LATERAL
  (SELECT amount, customer_name
   FROM all_sales
   WHERE all_sales.salesperson_id = salesperson.id
   ORDER BY amount DESC LIMIT 1)
AS max_sale;
```

In short, `LATERAL` is the efficient solution to all drawbacks in the two approaches just discussed.

### 13.2.15.10 Subquery Errors

There are some errors that apply only to subqueries. This section describes them.

- Unsupported subquery syntax:

  ```
  ERROR 1235 (ER_NOT_SUPPORTED_YET)
  SQLSTATE = 42000
  Message = "This version of MySQL doesn't yet support 'LIMIT & IN/ALL/ANY/SOME subquery'"
  ```

  This means that MySQL does not support statements like the following:

  ```
  SELECT * FROM t1 WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1)
  ```

- Incorrect number of columns from subquery:

  ```
  ERROR 1241 (ER_OPERAND_COL)
  SQLSTATE = 21000
  ```
Subqueries

This error occurs in cases like this:

```
SELECT (SELECT column1, column2 FROM t2) FROM t1;
```

You may use a subquery that returns multiple columns, if the purpose is row comparison. In other contexts, the subquery must be a scalar operand. See Section 13.2.15.5, “Row Subqueries”.

- Incorrect number of rows from subquery:

```
ERROR 1242 (ER_SUBSELECT_NO_1_ROW)
SQLSTATE = 21000
Message = "Subquery returns more than 1 row"
```

This error occurs for statements where the subquery must return at most one row but returns multiple rows. Consider the following example:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

If `SELECT column1 FROM t2` returns just one row, the previous query works. If the subquery returns more than one row, error 1242 occurs. In that case, the query should be rewritten as:

```
SELECT * FROM t1 WHERE column1 = ANY (SELECT column1 FROM t2);
```

- Incorrectly used table in subquery:

```
Error 1093 (ER_UPDATE_TABLE_USED)
SQLSTATE = HY000
Message = "You can't specify target table 'x' for update in FROM clause"
```

This error occurs in cases such as the following, which attempts to modify a table and select from the same table in the subquery:

```
UPDATE t1 SET column2 = (SELECT MAX(column1) FROM t1);
```

You can use a common table expression or derived table to work around this. See Section 13.2.15.12, “Restrictions on Subqueries”.

All of the errors described in this section also apply when using `TABLE` in subqueries.

For transactional storage engines, the failure of a subquery causes the entire statement to fail. For nontransactional storage engines, data modifications made before the error was encountered are preserved.

13.2.15.11 Optimizing Subqueries

Development is ongoing, so no optimization tip is reliable for the long term. The following list provides some interesting tricks that you might want to play with. See also Section 8.2.2, “Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions”.

- Move clauses from outside to inside the subquery. For example, use this query:

```
SELECT * FROM t1
  WHERE s1 IN (SELECT s1 FROM t1 UNION ALL SELECT s1 FROM t2);
```

Instead of this query:

```
SELECT * FROM t1
  WHERE s1 IN (SELECT s1 FROM t1) OR s1 IN (SELECT s1 FROM t2);
```
For another example, use this query:

```
SELECT (SELECT column1 + 5 FROM t1) FROM t2;
```

Instead of this query:

```
SELECT (SELECT column1 FROM t1) + 5 FROM t2;
```

### 13.2.15.12 Restrictions on Subqueries

- In general, you cannot modify a table and select from the same table in a subquery. For example, this limitation applies to statements of the following forms:

  - `DELETE FROM t WHERE ... (SELECT ... FROM t ...);`
  - `UPDATE t ... WHERE col = (SELECT ... FROM t ...);`
  - `{INSERT|REPLACE} INTO t (SELECT ... FROM t ...);`

  Exception: The preceding prohibition does not apply if for the modified table you are using a derived table and that derived table is materialized rather than merged into the outer query. (See Section 8.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”.) Example:

  ```
  UPDATE t ... WHERE col = (SELECT * FROM (SELECT ... FROM t...) AS dt ...);
  ```

  Here the result from the derived table is materialized as a temporary table, so the relevant rows in `t` have already been selected by the time the update to `t` takes place.

  In general, you may be able to influence the optimizer to materialize a derived table by adding a `NO_MERGE` optimizer hint. See Section 8.9.3, “Optimizer Hints”.

- Row comparison operations are only partially supported:

  - For `expr [NOT] IN subquery, expr` can be an `n`-tuple (specified using row constructor syntax) and the subquery can return rows of `n`-tuples. The permitted syntax is therefore more specifically expressed as `row_constructor [NOT] IN table_subquery`

  - For `expr op {ALL|ANY|SOME} subquery, expr` must be a scalar value and the subquery must be a column subquery; it cannot return multiple-column rows.

  In other words, for a subquery that returns rows of `n`-tuples, this is supported:

    ```
    (expr_1, ..., expr_n) [NOT] IN table_subquery
    ```

  But this is not supported:

    ```
    (expr_1, ..., expr_n) op {ALL|ANY|SOME} subquery
    ```

  The reason for supporting row comparisons for `IN` but not for the others is that `IN` is implemented by rewriting it as a sequence of `=` comparisons and `AND` operations. This approach cannot be used for `ALL`, `ANY`, or `SOME`.

- MySQL does not support `LIMIT` in subqueries for certain subquery operators:

  ```
  mysql> SELECT * FROM t1
        WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1);
  ```

  ERROR 1235 (42000): This version of MySQL doesn't yet support 'LIMIT & IN/ALL/ANY/SOME subquery'

  See Section 13.2.15.10, “Subquery Errors”.
MySQL permits a subquery to refer to a stored function that has data-modifying side effects such as inserting rows into a table. For example, if \( f() \) inserts rows, the following query can modify data:

```
SELECT ... WHERE x IN (SELECT f() ...);
```

This behavior is an extension to the SQL standard. In MySQL, it can produce nondeterministic results because \( f() \) might be executed a different number of times for different executions of a given query depending on how the optimizer chooses to handle it.

For statement-based or mixed-format replication, one implication of this indeterminism is that such a query can produce different results on the source and its replicas.

### 13.2.16 TABLE Statement

**TABLE** is a DML statement which returns rows and columns of the named table.

```
TABLE table_name [ORDER BY column_name] [LIMIT number [OFFSET number]]
```

The **TABLE** statement in some ways acts like **SELECT**. Given the existence of a table named \( t \), the following two statements produce identical output:

```
TABLE t;
SELECT * FROM t;
```

You can order and limit the number of rows produced by **TABLE** using **ORDER BY** and **LIMIT** clauses, respectively. These function identically to the same clauses when used with **SELECT** (including an optional **OFFSET** clause with **LIMIT**), as you can see here:

```
mysql> TABLE t;
+----+----+
| a  | b  |
|----+----|
| 2  | 1  |
| 7  | 6  |
| 5  | 9  |
| -1 | 11 |
| 3  | 13 |
| 6  | 14 |
+----+----+
7 rows in set (0.00 sec)

mysql> TABLE t ORDER BY b;
+----+----+
| a  | b  |
|----+----|
| 10 | -4 |
| 11 | -1 |
| 2  | 1  |
| 3  | 13 |
| 5  | 9  |
| 6  | 14 |
| 7  | 6  |
+----+----+
7 rows in set (0.00 sec)

mysql> TABLE t LIMIT 3;
+----+----+
| a  | b  |
|----+----|
| 1  | 2  |
```

2850
**TABLE Statement**

| 6 | 7 |
| 9 | 5 |

3 rows in set (0.00 sec)

mysql> TABLE t ORDER BY b LIMIT 3;

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>-4</td>
</tr>
<tr>
<td>11</td>
<td>-1</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
</tr>
</tbody>
</table>

3 rows in set (0.00 sec)

mysql> TABLE t ORDER BY b LIMIT 3 OFFSET 2;

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>13</td>
<td>3</td>
</tr>
<tr>
<td>9</td>
<td>5</td>
</tr>
</tbody>
</table>

3 rows in set (0.00 sec)

**TABLE** differs from **SELECT** in two key respects:

- **TABLE** always displays all columns of the table.

  *Exception*: The output of **TABLE** does *not* include invisible columns. See Section 13.1.20.10, “Invisible Columns”.

- **TABLE** does not allow for any arbitrary filtering of rows; that is, **TABLE** does not support any **WHERE** clause.

For limiting which table columns are returned, filtering rows beyond what can be accomplished using **ORDER BY** and **LIMIT**, or both, use **SELECT**.

**TABLE** can be used with temporary tables.

**TABLE** can also be used in place of **SELECT** in a number of other constructs, including those listed here:

- With set operators such as **UNION**, as shown here:

  mysql> TABLE t1;
  +----+----+
  | a  | b  |
  +----+----+
  |  2 | 10 |
  |  5 |  3 |
  |  7 |  8 |
  +----+----+
  3 rows in set (0.00 sec)

  mysql> TABLE t2;
  +----+----+
  | a  | b  |
  +----+----+
  |  1 |  2 |
  |  3 |  4 |
  |  6 |  7 |
  +----+----+
  3 rows in set (0.00 sec)
The `UNION` just shown is equivalent to the following statement:

```sql
mysql> SELECT * FROM t1 UNION SELECT * FROM t2;
+---+----+
| a | b  |
+---+----+
| 2 | 10 |
| 5 |  3 |
| 7 |  8 |
| 1 |  2 |
| 3 |  4 |
| 6 |  7 |
+---+----+
6 rows in set (0.00 sec)
```

`TABLE` can also be used together in set operations with `SELECT` statements, `VALUES` statements, or both. See Section 13.2.18, “UNION Clause”, Section 13.2.4, “EXCEPT Clause”, and Section 13.2.8, “INTERSECT Clause”, for more information and examples. See also Section 13.2.14, “Set Operations with UNION, INTERSECT, and EXCEPT”.

- With `INTO` to populate user variables, and with `INTO OUTFILE` or `INTO DUMPFILE` to write table data to a file. See Section 13.2.13.1, “SELECT ... INTO Statement”, for more specific information and examples.

- In many cases where you can employ subqueries. Given any table `t1` with a column named `a`, and a second table `t2` having a single column, statements such as the following are possible:

```sql
SELECT * FROM t1 WHERE a IN (TABLE t2);
```

Assuming that the single column of table `t1` is named `x`, the preceding is equivalent to each of the statements shown here (and produces exactly the same result in either case):

```sql
SELECT * FROM t1 WHERE a IN (SELECT x FROM t2);
SELECT * FROM t1 WHERE a IN (SELECT * FROM t2);
```

See Section 13.2.15, “Subqueries”, for more information.

- With `INSERT` and `REPLACE` statements, where you would otherwise use `SELECT *`. See Section 13.2.7.1, “INSERT ... SELECT Statement”, for more information and examples.

- `TABLE` can also be used in many cases in place of the `SELECT` in `CREATE TABLE ... SELECT` or `CREATE VIEW ... SELECT`. See the descriptions of these statements for more information and examples.

## 13.2.17 UPDATE Statement

`UPDATE` is a DML statement that modifies rows in a table.
An UPDATE statement can start with a WITH clause to define common table expressions accessible within the UPDATE. See Section 13.2.20, “WITH (Common Table Expressions)”. 

Single-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_reference
    SET assignment_list
    [WHERE where_condition]
    [ORDER BY ...]
    [LIMIT row_count]
```

- **value:**
  - expr | DEFAULT
- **assignment:**
  - col_name = value
- **assignment_list:**
  - assignment [, assignment] ...

Multiple-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_references
    SET assignment_list
    [WHERE where_condition]
```

For the single-table syntax, the UPDATE statement updates columns of existing rows in the named table with new values. The SET clause indicates which columns to modify and the values they should be given. Each value can be given as an expression, or the keyword DEFAULT to set a column explicitly to its default value. The WHERE clause, if given, specifies the conditions that identify which rows to update. With no WHERE clause, all rows are updated. If the ORDER BY clause is specified, the rows are updated in the order that is specified. The LIMIT clause places a limit on the number of rows that can be updated.

For the multiple-table syntax, UPDATE updates rows in each table named in table_references that satisfy the conditions. Each matching row is updated once, even if it matches the conditions multiple times. For multiple-table syntax, ORDER BY and LIMIT cannot be used.

For partitioned tables, both the single-single and multiple-table forms of this statement support the use of a PARTITION clause as part of a table reference. This option takes a list of one or more partitions or subpartitions (or both). Only the partitions (or subpartitions) listed are checked for matches, and a row that is not in any of these partitions or subpartitions is not updated, whether it satisfies the where_condition or not.

**Note**

Unlike the case when using PARTITION with an INSERT or REPLACE statement, an otherwise valid UPDATE ... PARTITION statement is considered successful even if no rows in the listed partitions (or subpartitions) match the where_condition.

For more information and examples, see Section 24.5, “Partition Selection”.

where_condition is an expression that evaluates to true for each row to be updated. For expression syntax, see Section 9.5, “Expressions”.

table_references and where_condition are specified as described in Section 13.2.13, “SELECT Statement”.

You need the UPDATE privilege only for columns referenced in an UPDATE that are actually updated. You need only the SELECT privilege for any columns that are read but not modified.
The **UPDATE** statement supports the following modifiers:

- With the **LOW_PRIORITY** modifier, execution of the **UPDATE** is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as **MyISAM**, **MEMORY**, and **MERGE**).

- With the **IGNORE** modifier, the update statement does not abort even if errors occur during the update. Rows for which duplicate-key conflicts occur on a unique key value are not updated. Rows updated to values that would cause data conversion errors are updated to the closest valid values instead. For more information, see The Effect of IGNORE on Statement Execution.

**UPDATE** **IGNORE** statements, including those having an **ORDER BY** clause, are flagged as unsafe for statement-based replication. (This is because the order in which the rows are updated determines which rows are ignored.) Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using **MIXED** mode. (Bug #11758262, Bug #50439) See Section 17.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”, for more information.

If you access a column from the table to be updated in an expression, **UPDATE** uses the current value of the column. For example, the following statement sets **col1** to one more than its current value:

```
UPDATE t1 SET col1 = col1 + 1;
```

The second assignment in the following statement sets **col2** to the current (updated) **col1** value, not the original **col1** value. The result is that **col1** and **col2** have the same value. This behavior differs from standard SQL.

```
UPDATE t1 SET col1 = col1 + 1, col2 = col1;
```

Single-table **UPDATE** assignments are generally evaluated from left to right. For multiple-table updates, there is no guarantee that assignments are carried out in any particular order.

If you set a column to the value it currently has, MySQL notices this and does not update it.

If you update a column that has been declared **NOT NULL** by setting to **NULL**, an error occurs if strict SQL mode is enabled; otherwise, the column is set to the implicit default value for the column data type and the warning count is incremented. The implicit default value is 0 for numeric types, the empty string ("") for string types, and the “zero” value for date and time types. See Section 11.6, “Data Type Default Values”.

If a generated column is updated explicitly, the only permitted value is **DEFAULT**. For information about generated columns, see Section 13.1.20.8, “CREATE TABLE and Generated Columns”.

**UPDATE** returns the number of rows that were actually changed. The **mysql_info()** C API function returns the number of rows that were matched and updated and the number of warnings that occurred during the **UPDATE**.

You can use **LIMIT row_count** to restrict the scope of the **UPDATE**. A **LIMIT** clause is a rows-matched restriction. The statement stops as soon as it has found **row_count** rows that satisfy the **WHERE** clause, whether or not they actually were changed.

If an **UPDATE** statement includes an **ORDER BY** clause, the rows are updated in the order specified by the clause. This can be useful in certain situations that might otherwise result in an error. Suppose that a table **t** contains a column **id** that has a unique index. The following statement could fail with a duplicate-key error, depending on the order in which rows are updated:

```
UPDATE t SET id = id + 1;
```
UPDATE Statement

For example, if the table contains 1 and 2 in the id column and 1 is updated to 2 before 2 is updated to 3, an error occurs. To avoid this problem, add an ORDER BY clause to cause the rows with larger id values to be updated before those with smaller values:

```
UPDATE t SET id = id + 1 ORDER BY id DESC;
```

You can also perform UPDATE operations covering multiple tables. However, you cannot use ORDER BY or LIMIT with a multiple-table UPDATE. The table_references clause lists the tables involved in the join. Its syntax is described in Section 13.2.13.2, “JOIN Clause”. Here is an example:

```
UPDATE items,month SET items.price=month.price
WHERE items.id=month.id;
```

The preceding example shows an inner join that uses the comma operator, but multiple-table UPDATE statements can use any type of join permitted in SELECT statements, such as LEFT JOIN.

If you use a multiple-table UPDATE statement involving InnoDB tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, update a single table and rely on the ON UPDATE capabilities that InnoDB provides to cause the other tables to be modified accordingly. See Section 13.1.20.5, “FOREIGN KEY Constraints”.

You cannot update a table and select directly from the same table in a subquery. You can work around this by using a multi-table update in which one of the tables is derived from the table that you actually wish to update, and referring to the derived table using an alias. Suppose you wish to update a table named items which is defined using the statement shown here:

```
CREATE TABLE items (  
id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
wholesale DECIMAL(6,2) NOT NULL DEFAULT 0.00,  
retail DECIMAL(6,2) NOT NULL DEFAULT 0.00,  
quantity BIGINT NOT NULL DEFAULT 0  
);
```

To reduce the retail price of any items for which the markup is 30% or greater and of which you have fewer than one hundred in stock, you might try to use an UPDATE statement such as the one following, which uses a subquery in the WHERE clause. As shown here, this statement does not work:

```
mysql> UPDATE items
    > SET retail = retail * 0.9
    > WHERE id IN
    > (SELECT id FROM items
    > WHERE retail / wholesale >= 1.3 AND quantity > 100);
ERROR 1093 (HY000): You can't specify target table 'items' for update in FROM clause
```

Instead, you can employ a multi-table update in which the subquery is moved into the list of tables to be updated, using an alias to reference it in the outermost WHERE clause, like this:

```
UPDATE items,  
(SELECT id FROM items
 WHERE id IN
 (SELECT id FROM items
  WHERE retail / wholesale >= 1.3 AND quantity < 100)) AS discounted
SET items.retail = items.retail * 0.9
WHERE items.id = discounted.id;
```

Because the optimizer tries by default to merge the derived table discounted into the outermost query block, this works only if you force materialization of the derived table. You can do this by setting the derived_merge flag of the optimizer_switch system variable to off before running the update, or by using the NO_MERGE optimizer hint, as shown here:
The advantage of using the optimizer hint in such a case is that it applies only within the query block where it is used, so that it is not necessary to change the value of `optimizer_switch` again after executing the `UPDATE`.

Another possibility is to rewrite the subquery so that it does not use `IN` or `EXISTS`, like this:

```
UPDATE items,
(SELECT id, retail / wholesale AS markup, quantity FROM items)
AS discounted
SET items.retail = items.retail * 0.9
WHERE discounted.markup >= 1.3
AND discounted.quantity < 100
AND items.id = discounted.id;
```

In this case, the subquery is materialized by default rather than merged, so it is not necessary to disable merging of the derived table.

### 13.2.18 UNION Clause

```
query_expression_body UNION [ALL | DISTINCT] query_block
[UNION [ALL | DISTINCT] query_expression_body]
[...]
```

**query_expression_body:**

See Section 13.2.14, "Set Operations with UNION, INTERSECT, and EXCEPT"

**UNION** combines the result from multiple query blocks into a single result set. This example uses `SELECT` statements:

```
mysql> SELECT 1, 2;
+----+----+
| 1  | 2  |
+----+----+
| 1  | 2  |
+----+----+
mysql> SELECT 'a', 'b';
+----+----+
| a  | b  |
+----+----+
| a  | b  |
+----+----+
mysql> SELECT 1, 2 UNION SELECT 'a', 'b';
+----+----+
| 1  | 2  |
+----+----+
| 1  | 2  |
| a  | b  |
+----+----+
```

### 13.2.19 VALUES Statement

**VALUES** is a DML statement introduced in MySQL 8.0.19 which returns a set of one or more rows as a table. In other words, it is a table value constructor which also functions as a standalone SQL statement.

```
VALUES row_constructor_list [ORDER BY column_designator] [LIMIT number]
```
The **VALUES** statement consists of the `VALUES` keyword followed by a list of one or more row constructors, separated by commas. A row constructor consists of the `ROW()` row constructor clause with a value list of one or more scalar values enclosed in the parentheses. A value can be a literal of any MySQL data type or an expression that resolves to a scalar value.

`ROW()` cannot be empty (but each of the supplied scalar values can be **NULL**). Each `ROW()` in the same **VALUES** statement must have the same number of values in its value list.

The **DEFAULT** keyword is not supported by **VALUES** and causes a syntax error, except when it is used to supply values in an **INSERT** statement.

The output of **VALUES** is a table:

```
mysql> VALUES ROW(1, -2, 3), ROW(5, 7, 9), ROW(4, 6, 8);
+----------+----------+----------+
<table>
<thead>
<tr>
<th>column_0</th>
<th>column_1</th>
<th>column_2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>-2</td>
<td>3</td>
</tr>
<tr>
<td>5</td>
<td>7</td>
<td>9</td>
</tr>
<tr>
<td>4</td>
<td>6</td>
<td>8</td>
</tr>
</tbody>
</table>
+----------+----------+----------+
3 rows in set (0.00 sec)
```

The columns of the table output from **VALUES** have the implicitly named columns `column_0`, `column_1`, `column_2`, and so on, always beginning with 0. This fact can be used to order the rows by column using an optional **ORDER BY** clause in the same way that this clause works with a **SELECT** statement, as shown here:

```
mysql> VALUES ROW(1, -2, 3), ROW(5, 7, 9), ROW(4, 6, 8) ORDER BY column_1;
+----------+----------+----------+
<table>
<thead>
<tr>
<th>column_0</th>
<th>column_1</th>
<th>column_2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>-2</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td>6</td>
<td>8</td>
</tr>
<tr>
<td>5</td>
<td>7</td>
<td>9</td>
</tr>
</tbody>
</table>
+----------+----------+----------+
3 rows in set (0.00 sec)
```

**VALUES** statement also supports a **LIMIT** clause for limiting the number of rows in the output.

The **VALUES** statement is permissive regarding data types of column values; you can mix types within the same column, as shown here:

```
mysql> VALUES ROW("q", 42, '2019-12-18'),
    ->    ROW(23, "abc", 98.6),
    ->    ROW(27.0002, "Mary Smith", '{"a": 10, "b": 25}');
+----------+------------+--------------------+
| column_0 | column_1   | column_2           |
|----------|------------+--------------------|
| q        | 42         | 2019-12-18         |
| 23       | abc        | 98.6               |
| 27.0002  | Mary Smith | {"a": 10, "b": 25}|
+----------+------------+--------------------+
```
VALUES Statement

Important

VALUES with one or more instances of `ROW()` acts as a table value constructor; although it can be used to supply values in an `INSERT` or `REPLACE` statement, do not confuse it with the `VALUES` keyword that is also used for this purpose. You should also not confuse it with the `VALUES()` function that refers to column values in `INSERT ... ON DUPLICATE KEY UPDATE`.

You should also bear in mind that `ROW()` is a row value constructor (see Section 13.2.15.5, “Row Subqueries”), whereas `VALUES ROW()` is a table value constructor; the two cannot be used interchangeably.

`VALUES` can be used in many cases where you could employ `SELECT`, including those listed here:

- With `UNION`, as shown here:

  ```
  mysql> SELECT 1,2 UNION SELECT 10,15;
  +----+----+
  | 1  | 2  |
  +----+----+
  |  1 |  2 |
  | 10 | 15 |
  +----+----+
  2 rows in set (0.00 sec)

  mysql> VALUES ROW(1,2) UNION VALUES ROW(10,15);
  +----------+----------+
  | column_0 | column_1 |
  +----------+----------+
  |        1 |        2 |
  |       10 |       15 |
  +----------+----------+
  2 rows in set (0.00 sec)
  ```

  You can union together constructed tables having more than one row, like this:

  ```
  mysql> VALUES ROW(1,2), ROW(3,4), ROW(5,6) UNIUN VALUES ROW(10,15),ROW(20,25);
  +----------+----------+
  | column_0 | column_1 |
  +----------+----------+
  |        1 |        2 |
  |        3 |        4 |
  |        5 |        6 |
  |       10 |       15 |
  |       20 |       25 |
  +----------+----------+
  5 rows in set (0.00 sec)
  ```

  You can also (and it is usually preferable to) omit `UNION` altogether in such cases and use a single `VALUES` statement, like this:

  ```
  mysql> VALUES ROW(1,2), ROW(3,4), ROW(5,6), ROW(10,15), ROW(20,25);
  +----------+----------+
  | column_0 | column_1 |
  +----------+----------+
  |        1 |        2 |
  |        3 |        4 |
  |        5 |        6 |
  |       10 |       15 |
  |       20 |       25 |
  +----------+----------+
  ```
VALUES can also be used in unions with SELECT statements, TABLE statements, or both.

The constructed tables in the UNION must contain the same number of columns, just as if you were using SELECT. See Section 13.2.18, “UNION Clause”, for further examples.

You can use EXCEPT and INTERSECT with VALUES in much the same way as UNION, as shown here:

```sql
mysql> VALUES ROW(1,2), ROW(3,4), ROW(5,6)
-> INTERSECT
-> VALUES ROW(10,15), ROW(20,25), ROW(3,4);
+----------+----------+
<table>
<thead>
<tr>
<th>column_0</th>
<th>column_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>4</td>
</tr>
</tbody>
</table>
+----------+----------+
1 row in set (0.00 sec)

mysql> VALUES ROW(1,2), ROW(3,4), ROW(5,6)
-> EXCEPT
-> VALUES ROW(10,15), ROW(20,25), ROW(3,4);
+----------+----------+
<table>
<thead>
<tr>
<th>column_0</th>
<th>column_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>5</td>
<td>6</td>
</tr>
</tbody>
</table>
+----------+----------+
2 rows in set (0.00 sec)
```

See Section 13.2.4, “EXCEPT Clause”, and Section 13.2.8, “INTERSECT Clause”, for more information.

- In joins. See Section 13.2.13.2, “JOIN Clause”, for more information and examples.
- In place of VALUES() in an INSERT or REPLACE statement, in which case its semantics differ slightly from what is described here. See Section 13.2.7, “INSERT Statement”, for details.
- In place of the source table in CREATE TABLE ... SELECT and CREATE VIEW ... SELECT. See the descriptions of these statements for more information and examples.

13.2.20 WITH (Common Table Expressions)

A common table expression (CTE) is a named temporary result set that exists within the scope of a single statement and that can be referred to later within that statement, possibly multiple times. The following discussion describes how to write statements that use CTEs.

- Common Table Expressions
- Recursive Common Table Expressions
- Limiting Common Table Expression Recursion
- Recursive Common Table Expression Examples
- Common Table Expressions Compared to Similar Constructs

For information about CTE optimization, see Section 8.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”.

Common Table Expressions

To specify common table expressions, use a WITH clause that has one or more comma-separated subclauses. Each subclause provides a subquery that produces a result set, and associates a name with
WITH (Common Table Expressions)

the subquery. The following example defines CTEs named cte1 and cte2 in the WITH clause, and refers to them in the top-level SELECT that follows the WITH clause:

```sql
WITH
  cte1 AS (SELECT a, b FROM table1),
  cte2 AS (SELECT c, d FROM table2)
SELECT b, d FROM cte1 JOIN cte2
WHERE cte1.a = cte2.c;
```

In the statement containing the WITH clause, each CTE name can be referenced to access the corresponding CTE result set.

A CTE name can be referenced in other CTEs, enabling CTEs to be defined based on other CTEs.

A CTE can refer to itself to define a recursive CTE. Common applications of recursive CTEs include series generation and traversal of hierarchical or tree-structured data.

Common table expressions are an optional part of the syntax for DML statements. They are defined using a WITH clause:

```sql
WITH [RECURSIVE]
  cte_name [(col_name [, col_name] ...)] AS (subquery)
[, cte_name [(col_name [, col_name] ...)] AS (subquery)] ...
```

`cte_name` names a single common table expression and can be used as a table reference in the statement containing the WITH clause.

The subquery part of AS (subquery) is called the “subquery of the CTE” and is what produces the CTE result set. The parentheses following AS are required.

A common table expression is recursive if its subquery refers to its own name. The RECURSIVE keyword must be included if any CTE in the WITH clause is recursive. For more information, see Recursive Common Table Expressions.

Determination of column names for a given CTE occurs as follows:

- If a parenthesized list of names follows the CTE name, those names are the column names:

```sql
WITH cte (col1, col2) AS
  (SELECT 1, 2
   UNION ALL
   SELECT 3, 4)
SELECT col1, col2 FROM cte;
```

The number of names in the list must be the same as the number of columns in the result set.

- Otherwise, the column names come from the select list of the first SELECT within the AS (subquery) part:

```sql
WITH cte AS
  (SELECT 1 AS col1, 2 AS col2
   UNION ALL
   SELECT 3, 4)
SELECT col1, col2 FROM cte;
```

A WITH clause is permitted in these contexts:
WITH (Common Table Expressions)

- At the beginning of **SELECT**, **UPDATE**, and **DELETE** statements:

  ```sql
  WITH ... SELECT ... 
  WITH ... UPDATE ... 
  WITH ... DELETE ... 
  ```

- At the beginning of subqueries (including derived table subqueries):

  ```sql
  SELECT ... WHERE id IN (WITH ... SELECT ...) ... 
  SELECT * FROM (WITH ... SELECT ...) AS dt ... 
  ```

- Immediately preceding **SELECT** for statements that include a **SELECT** statement:

  ```sql
  INSERT ... WITH ... SELECT ... 
  REPLACE ... WITH ... SELECT ... 
  CREATE TABLE ... WITH ... SELECT ... 
  CREATE VIEW ... WITH ... SELECT ... 
  DECLARE CURSOR ... WITH ... SELECT ... 
  EXPLAIN ... WITH ... SELECT ... 
  ```

  Only one **WITH** clause is permitted at the same level. **WITH** followed by **WITH** at the same level is not permitted, so this is illegal:

  ```sql
  WITH cte1 AS (...) WITH cte2 AS (...) SELECT ... 
  ```

  To make the statement legal, use a single **WITH** clause that separates the subclauses by a comma:

  ```sql
  WITH cte1 AS (...) AS cte2 AS (...) SELECT ... 
  ```

  However, a statement can contain multiple **WITH** clauses if they occur at different levels:

  ```sql
  WITH cte1 AS (SELECT 1) 
  SELECT * FROM (WITH cte2 AS (SELECT 2) SELECT * FROM cte2 JOIN cte1) AS dt; 
  ```

  A **WITH** clause can define one or more common table expressions, but each CTE name must be unique to the clause. This is illegal:

  ```sql
  WITH cte1 AS (...) AS cte1 AS (...) SELECT ... 
  ```

  To make the statement legal, define the CTEs with unique names:

  ```sql
  WITH cte1 AS (...) AS cte2 AS (...) SELECT ... 
  ```

  A CTE can refer to itself or to other CTEs:

  - A self-referencing CTE is recursive.
  - A CTE can refer to CTEs defined earlier in the same **WITH** clause, but not those defined later.

    This constraint rules out mutually-recursive CTEs, where **cte1** references **cte2** and **cte2** references **cte1**. One of those references must be to a CTE defined later, which is not permitted.

    A CTE in a given query block can refer to CTEs defined in query blocks at a more outer level, but not CTEs defined in query blocks at a more inner level.

    For resolving references to objects with the same names, derived tables hide CTEs; and CTEs hide base tables, **TEMPORARY** tables, and views. Name resolution occurs by searching for objects in the same query block, then proceeding to outer blocks in turn while no object with the name is found.

    For additional syntax considerations specific to recursive CTEs, see **Recursive Common Table Expressions**.
Recursive Common Table Expressions

A recursive common table expression is one having a subquery that refers to its own name. For example:

```sql
WITH RECURSIVE cte (n) AS
(
    SELECT 1
    UNION ALL
    SELECT n + 1 FROM cte WHERE n < 5
)
SELECT * FROM cte;
```

When executed, the statement produces this result, a single column containing a simple linear sequence:

<table>
<thead>
<tr>
<th>n</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>3</td>
</tr>
<tr>
<td>4</td>
</tr>
<tr>
<td>5</td>
</tr>
</tbody>
</table>

A recursive CTE has this structure:

- The `WITH` clause must begin with `WITH RECURSIVE` if any CTE in the `WITH` clause refers to itself. (If no CTE refers to itself, `RECURSIVE` is permitted but not required.)

  If you forget `RECURSIVE` for a recursive CTE, this error is a likely result:

  ```sql
  ERROR 1146 (42S02): Table 'cte_name' doesn't exist
  ```

- The recursive CTE subquery has two parts, separated by `UNION ALL` or `UNION [DISTINCT]`:

  ```sql
  SELECT ... -- return initial row set
  UNION ALL
  SELECT ... -- return additional row sets
  ```

  The first `SELECT` produces the initial row or rows for the CTE and does not refer to the CTE name. The second `SELECT` produces additional rows and recurses by referring to the CTE name in its `FROM` clause. Recursion ends when this part produces no new rows. Thus, a recursive CTE consists of a nonrecursive `SELECT` part followed by a recursive `SELECT` part.

  Each `SELECT` part can itself be a union of multiple `SELECT` statements.

  - The types of the CTE result columns are inferred from the column types of the nonrecursive `SELECT` part only, and the columns are all nullable. For type determination, the recursive `SELECT` part is ignored.

  - If the nonrecursive and recursive parts are separated by `UNION DISTINCT`, duplicate rows are eliminated. This is useful for queries that perform transitive closures, to avoid infinite loops.

  - Each iteration of the recursive part operates only on the rows produced by the previous iteration. If the recursive part has multiple query blocks, iterations of each query block are scheduled in unspecified order, and each query block operates on rows that have been produced either by its previous iteration or by other query blocks since that previous iteration's end.

  The recursive CTE subquery shown earlier has this nonrecursive part that retrieves a single row to produce the initial row set:

  ```sql
  SELECT 1
  ```
The CTE subquery also has this recursive part:

```sql
SELECT n + 1 FROM cte WHERE n < 5
```

At each iteration, that `SELECT` produces a row with a new value one greater than the value of `n` from the previous row set. The first iteration operates on the initial row set (1) and produces \(1 + 1 = 2\); the second iteration operates on the first iteration's row set (2) and produces \(2 + 1 = 3\); and so forth. This continues until recursion ends, which occurs when `n` is no longer less than 5.

If the recursive part of a CTE produces wider values for a column than the nonrecursive part, it may be necessary to widen the column in the nonrecursive part to avoid data truncation. Consider this statement:

```sql
WITH RECURSIVE cte AS
  (SELECT 1 AS n, 'abc' AS str
   UNION ALL
   SELECT n + 1, CONCAT(str, str) FROM cte WHERE n < 3
  )
SELECT * FROM cte;
```

In nonstrict SQL mode, the statement produces this output:

```plaintext
+------+------+
<table>
<thead>
<tr>
<th>n</th>
<th>str</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>abc</td>
</tr>
<tr>
<td>2</td>
<td>abc</td>
</tr>
<tr>
<td>3</td>
<td>abc</td>
</tr>
</tbody>
</table>
```

The `str` column values are all 'abc' because the nonrecursive `SELECT` determines the column widths. Consequently, the wider `str` values produced by the recursive `SELECT` are truncated.

In strict SQL mode, the statement produces an error:

```
ERROR 1406 (22001): Data too long for column 'str' at row 1
```

To address this issue, so that the statement does not produce truncation or errors, use `CAST()` in the nonrecursive `SELECT` to make the `str` column wider:

```sql
WITH RECURSIVE cte AS
  (SELECT 1 AS n, CAST('abc' AS CHAR(20)) AS str
   UNION ALL
   SELECT n + 1, CONCAT(str, str) FROM cte WHERE n < 3
  )
SELECT * FROM cte;
```

Now the statement produces this result, without truncation:

```plaintext
+-----+------------+
<table>
<thead>
<tr>
<th>n</th>
<th>str</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>abc</td>
</tr>
<tr>
<td>2</td>
<td>abcabc</td>
</tr>
<tr>
<td>3</td>
<td>abcabcabcabc</td>
</tr>
</tbody>
</table>
```

Columns are accessed by name, not position, which means that columns in the recursive part can access columns in the nonrecursive part that have a different position, as this CTE illustrates:
WITH (Common Table Expressions)

```sql
(
  SELECT 1 AS n, 1 AS p, -1 AS q
  UNION ALL
  SELECT n + 1, q * 2, p * 2 FROM cte WHERE n < 5
)
SELECT * FROM cte;
```

Because \( p \) in one row is derived from \( q \) in the previous row, and vice versa, the positive and negative values swap positions in each successive row of the output:

<table>
<thead>
<tr>
<th>n</th>
<th>p</th>
<th>q</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>-1</td>
</tr>
<tr>
<td>2</td>
<td>-2</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>-4</td>
</tr>
<tr>
<td>4</td>
<td>-8</td>
<td>8</td>
</tr>
<tr>
<td>5</td>
<td>16</td>
<td>-16</td>
</tr>
</tbody>
</table>

Some syntax constraints apply within recursive CTE subqueries:

- The recursive `SELECT` part must not contain these constructs:
  - Aggregate functions such as `SUM()`
  - Window functions
  - `GROUP BY`
  - `ORDER BY`
  - `DISTINCT`

  The recursive `SELECT` part of a recursive CTE can also use a `LIMIT` clause, along with an optional `OFFSET` clause. The effect on the result set is the same as when using `LIMIT` in the outermost `SELECT`, but is also more efficient, since using it with the recursive `SELECT` stops the generation of rows as soon as the requested number of them has been produced.

  The prohibition on `DISTINCT` applies only to `UNION` members; `UNION DISTINCT` is permitted.

- The recursive `SELECT` part must reference the CTE only once and only in its `FROM` clause, not in any subquery. It can reference tables other than the CTE and join them with the CTE. If used in a join like this, the CTE must not be on the right side of a `LEFT JOIN`.

These constraints come from the SQL standard, other than the MySQL-specific exclusions mentioned previously.

For recursive CTEs, `EXPLAIN` output rows for recursive `SELECT` parts display `Recursive` in the `Extra` column.

Cost estimates displayed by `EXPLAIN` represent cost per iteration, which might differ considerably from total cost. The optimizer cannot predict the number of iterations because it cannot predict at what point the `WHERE` clause becomes false.

CTE actual cost may also be affected by result set size. A CTE that produces many rows may require an internal temporary table large enough to be converted from in-memory to on-disk format and may suffer a performance penalty. If so, increasing the permitted in-memory temporary table size may improve performance; see Section 8.4.4, “Internal Temporary Table Use in MySQL”.

2864
WITH (Common Table Expressions)

Limiting Common Table Expression Recursion

It is important for recursive CTEs that the recursive SELECT part include a condition to terminate recursion. As a development technique to guard against a runaway recursive CTE, you can force termination by placing a limit on execution time:

• The `cte_max_recursion_depth` system variable enforces a limit on the number of recursion levels for CTEs. The server terminates execution of any CTE that recurses more levels than the value of this variable.

• The `max_execution_time` system variable enforces an execution timeout for SELECT statements executed within the current session.

• The `MAX_EXECUTION_TIME` optimizer hint enforces a per-query execution timeout for the SELECT statement in which it appears.

Suppose that a recursive CTE is mistakenly written with no recursion execution termination condition:

```sql
WITH RECURSIVE cte (n) AS
  (SELECT 1
   UNION ALL
   SELECT n + 1 FROM cte)
SELECT * FROM cte;
```

By default, `cte_max_recursion_depth` has a value of 1000, causing the CTE to terminate when it recurses past 1000 levels. Applications can change the session value to adjust for their requirements:

```sql
SET SESSION cte_max_recursion_depth = 10; -- permit only shallow recursion
SET SESSION cte_max_recursion_depth = 1000000; -- permit deeper recursion
```

You can also set the global `cte_max_recursion_depth` value to affect all sessions that begin subsequently.

For queries that execute and thus recurse slowly or in contexts for which there is reason to set the `cte_max_recursion_depth` value very high, another way to guard against deep recursion is to set a per-session timeout. To do so, execute a statement like this prior to executing the CTE statement:

```sql
SET max_execution_time = 1000; -- impose one second timeout
```

Alternatively, include an optimizer hint within the CTE statement itself:

```sql
WITH RECURSIVE cte (n) AS
  (SELECT 1
   UNION ALL
   SELECT n + 1 FROM cte)
SELECT /*+ SET_VAR(cte_max_recursion_depth = 1M) */ * FROM cte;
```

You can also use `LIMIT` within the recursive query to impose a maximum number of rows to be returned to the outermost SELECT, for example:
WITH (Common Table Expressions)

WITH RECURSIVE cte (n) AS
  (SELECT 1
   UNION ALL
   SELECT n + 1 FROM cte LIMIT 10000 )
SELECT * FROM cte;

You can do this in addition to or instead of setting a time limit. Thus, the following CTE terminates after returning ten thousand rows or running for one second (1000 milliseconds), whichever occurs first:

WITH RECURSIVE cte (n) AS
  (SELECT 1
   UNION ALL
   SELECT n + 1 FROM cte LIMIT 10000 )
SELECT /*+ MAX_EXECUTION_TIME(1000) */ * FROM cte;

If a recursive query without an execution time limit enters an infinite loop, you can terminate it from another session using KILL QUERY. Within the session itself, the client program used to run the query might provide a way to kill the query. For example, in mysql, typing Control+C interrupts the current statement.

Recursive Common Table Expression Examples

As mentioned previously, recursive common table expressions (CTEs) are frequently used for series generation and traversing hierarchical or tree-structured data. This section shows some simple examples of these techniques.

- **Fibonacci Series Generation**
- **Date Series Generation**
- **Hierarchical Data Traversal**

**Fibonacci Series Generation**

A Fibonacci series begins with the two numbers 0 and 1 (or 1 and 1) and each number after that is the sum of the previous two numbers. A recursive common table expression can generate a Fibonacci series if each row produced by the recursive SELECT has access to the two previous numbers from the series. The following CTE generates a 10-number series using 0 and 1 as the first two numbers:

WITH RECURSIVE fibonacci (n, fib_n, next_fib_n) AS
  (SELECT 1, 0, 1
   UNION ALL
   SELECT n + 1, next_fib_n, fib_n + next_fib_n
   FROM fibonacci WHERE n < 10 )
SELECT * FROM fibonacci;

The CTE produces this result:

```
+----+-----+----------+
| n  | fib_n| next_fib_n|
+----+-----+----------+
| 1  |  0  |       1  |
| 2  |  1  |       1  |
| 3  |  1  |       2  |
| 4  |  2  |       3  |
| 5  |  3  |       5  |
```
WITH (Common Table Expressions)

|   6  |   5  |   8  |
|  7   |  8   | 13   |
|  8   | 13   | 21   |
|  9   | 21   | 34   |
| 10   | 34   | 55   |

How the CTE works:

• \( n \) is a display column to indicate that the row contains the \( n \)-th Fibonacci number. For example, the 8th Fibonacci number is 13.

• The \( \text{fib}_n \) column displays Fibonacci number \( n \).

• The \( \text{next}_\text{fib}_n \) column displays the next Fibonacci number after number \( n \). This column provides the next series value to the next row, so that row can produce the sum of the two previous series values in its \( \text{fib}_n \) column.

• Recursion ends when \( n \) reaches 10. This is an arbitrary choice, to limit the output to a small set of rows.

The preceding output shows the entire CTE result. To select just part of it, add an appropriate \texttt{WHERE} clause to the top-level \texttt{SELECT}. For example, to select the 8th Fibonacci number, do this:

\[
\texttt{mysql> WITH RECURSIVE fibonacci ...}
\]
\[
\ldots
\]
\[
\texttt{SELECT fib}_n \texttt{ FROM fibonacci WHERE n = 8;}
\]
\[
\begin{array}{|c|}
\hline
\text{fib}_n \\
\hline
13 \\
\hline
\end{array}
\]

Date Series Generation

A common table expression can generate a series of successive dates, which is useful for generating summaries that include a row for all dates in the series, including dates not represented in the summarized data.

Suppose that a table of sales numbers contains these rows:

\[
\texttt{mysql> SELECT * FROM sales ORDER BY date, price;}
\]
\[
\begin{array}{|c|c|}
\hline
date & price \\
\hline
2017-01-03 & 100.00 \\
2017-01-03 & 200.00 \\
2017-01-06 & 50.00 \\
2017-01-08 & 10.00 \\
2017-01-08 & 20.00 \\
2017-01-08 & 150.00 \\
2017-01-10 & 5.00 \\
\hline
\end{array}
\]

This query summarizes the sales per day:

\[
\texttt{mysql> SELECT date, SUM(price) AS \textit{sum}_price}
\]
\[
\texttt{FROM sales}
\]
\[
\texttt{GROUP BY date}
\]
\[
\texttt{ORDER BY date;}
\]
\[
\begin{array}{|c|c|}
\hline
date & \textit{sum}_price \\
\hline
2017-01-03 & 300.00 \\
2017-01-06 & 60.00 \\
2017-01-08 & 170.00 \\
2017-01-10 & 5.00 \\
\hline
\end{array}
\]
WITH (Common Table Expressions)

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>2017-01-03</td>
<td>300.00</td>
</tr>
<tr>
<td>2017-01-06</td>
<td>50.00</td>
</tr>
<tr>
<td>2017-01-08</td>
<td>180.00</td>
</tr>
<tr>
<td>2017-01-10</td>
<td>5.00</td>
</tr>
</tbody>
</table>

However, that result contains “holes” for dates not represented in the range of dates spanned by the table. A result that represents all dates in the range can be produced using a recursive CTE to generate that set of dates, joined with a **LEFT JOIN** to the sales data.

Here is the CTE to generate the date range series:

```sql
WITH RECURSIVE dates (date) AS
(
  SELECT MIN(date) FROM sales
  UNION ALL
  SELECT date + INTERVAL 1 DAY FROM dates
  WHERE date + INTERVAL 1 DAY <= (SELECT MAX(date) FROM sales)
)

SELECT * FROM dates;
```

The CTE produces this result:

<table>
<thead>
<tr>
<th>date</th>
</tr>
</thead>
<tbody>
<tr>
<td>2017-01-03</td>
</tr>
<tr>
<td>2017-01-04</td>
</tr>
<tr>
<td>2017-01-05</td>
</tr>
<tr>
<td>2017-01-06</td>
</tr>
<tr>
<td>2017-01-07</td>
</tr>
<tr>
<td>2017-01-08</td>
</tr>
<tr>
<td>2017-01-09</td>
</tr>
<tr>
<td>2017-01-10</td>
</tr>
</tbody>
</table>

How the CTE works:

- The nonrecursive **SELECT** produces the lowest date in the date range spanned by the **sales** table.
- Each row produced by the recursive **SELECT** adds one day to the date produced by the previous row.
- Recursion ends after the dates reach the highest date in the date range spanned by the **sales** table.

Joining the CTE with a **LEFT JOIN** against the **sales** table produces the sales summary with a row for each date in the range:

```sql
WITH RECURSIVE dates (date) AS
(
  SELECT MIN(date) FROM sales
  UNION ALL
  SELECT date + INTERVAL 1 DAY FROM dates
  WHERE date + INTERVAL 1 DAY <= (SELECT MAX(date) FROM sales)
)

SELECT dates.date, COALESCE(SUM(price), 0) AS sum_price
FROM dates LEFT JOIN sales ON dates.date = sales.date
GROUP BY dates.date
ORDER BY dates.date;
```

The output looks like this:

<table>
<thead>
<tr>
<th>date</th>
<th>sum_price</th>
</tr>
</thead>
<tbody>
<tr>
<td>2017-01-03</td>
<td>300.00</td>
</tr>
<tr>
<td>2017-01-04</td>
<td>50.00</td>
</tr>
<tr>
<td>2017-01-05</td>
<td>180.00</td>
</tr>
<tr>
<td>2017-01-06</td>
<td>5.00</td>
</tr>
</tbody>
</table>

2868
Some points to note:

- Are the queries inefficient, particularly the one with the `MAX()` subquery executed for each row in the recursive `SELECT`? `EXPLAIN` shows that the subquery containing `MAX()` is evaluated only once and the result is cached.

- The use of `COALESCE()` avoids displaying `NULL` in the `sum_price` column on days for which no sales data occur in the `sales` table.

Hierarchical Data Traversal

Recursive common table expressions are useful for traversing data that forms a hierarchy. Consider these statements that create a small data set that shows, for each employee in a company, the employee name and ID number, and the ID of the employee’s manager. The top-level employee (the CEO), has a manager ID of `NULL` (no manager).

```sql
CREATE TABLE employees {
    id INT PRIMARY KEY NOT NULL,
    name VARCHAR(100) NOT NULL,
    manager_id INT NULL,
    INDEX (manager_id),
    FOREIGN KEY (manager_id) REFERENCES employees (id)
};
INSERT INTO employees VALUES
    (333, "Yasmina", NULL),  # Yasmina is the CEO (manager_id is NULL)
    (198, "John", 333),      # John has ID 198 and reports to 333 (Yasmina)
    (692, "Tarek", 333),
    (29, "Pedro", 198),
    (4610, "Sarah", 29),
    (72, "Pierre", 29),
    (123, "Adil", 692);
```

The resulting data set looks like this:

```sql
mysql> SELECT * FROM employees ORDER BY id;
+------+---------+------------+
<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>manager_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>29</td>
<td>Pedro</td>
<td>198</td>
</tr>
<tr>
<td>72</td>
<td>Pierre</td>
<td>29</td>
</tr>
<tr>
<td>123</td>
<td>Adil</td>
<td>692</td>
</tr>
<tr>
<td>198</td>
<td>John</td>
<td>333</td>
</tr>
<tr>
<td>333</td>
<td>Yasmina</td>
<td>NULL</td>
</tr>
<tr>
<td>692</td>
<td>Tarek</td>
<td>333</td>
</tr>
<tr>
<td>4610</td>
<td>Sarah</td>
<td>29</td>
</tr>
</tbody>
</table>
+------+---------+------------+
```

To produce the organizational chart with the management chain for each employee (that is, the path from CEO to employee), use a recursive CTE:

```sql
WITH RECURSIVE employee_paths (id, name, path) AS
(
    SELECT id, name, CAST(id AS CHAR(200))
)
WITH (Common Table Expressions)

FROM employees
WHERE manager_id IS NULL
UNION ALL
SELECT e.id, e.name, CONCAT(ep.path, ',', e.id)
FROM employee_paths AS ep JOIN employees AS e
ON ep.id = e.manager_id
)
SELECT * FROM employee_paths ORDER BY path;

The CTE produces this output:

<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>path</th>
</tr>
</thead>
<tbody>
<tr>
<td>333</td>
<td>Yasmina</td>
<td>333</td>
</tr>
<tr>
<td>198</td>
<td>John</td>
<td>333,198</td>
</tr>
<tr>
<td>29</td>
<td>Pedro</td>
<td>333,198,29</td>
</tr>
<tr>
<td>4610</td>
<td>Sarah</td>
<td>333,198,29,4610</td>
</tr>
<tr>
<td>72</td>
<td>Pierre</td>
<td>333,198,29,72</td>
</tr>
<tr>
<td>692</td>
<td>Tarek</td>
<td>333,692</td>
</tr>
<tr>
<td>123</td>
<td>Adil</td>
<td>333,692,123</td>
</tr>
</tbody>
</table>

How the CTE works:

• The nonrecursive SELECT produces the row for the CEO (the row with a NULL manager ID).

  The path column is widened to CHAR(200) to ensure that there is room for the longer path values produced by the recursive SELECT.

• Each row produced by the recursive SELECT finds all employees who report directly to an employee produced by a previous row. For each such employee, the row includes the employee ID and name, and the employee management chain. The chain is the manager’s chain, with the employee ID added to the end.

• Recursion ends when employees have no others who report to them.

To find the path for a specific employee or employees, add a WHERE clause to the top-level SELECT. For example, to display the results for Tarek and Sarah, modify that SELECT like this:

```
mysql> WITH RECURSIVE ...
    ... SELECT * FROM employees_extended
    WHERE id IN (692, 4610)
    ORDER BY path;
```

<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>path</th>
</tr>
</thead>
<tbody>
<tr>
<td>4610</td>
<td>Sarah</td>
<td>333,198,29,4610</td>
</tr>
<tr>
<td>692</td>
<td>Tarek</td>
<td>333,692</td>
</tr>
</tbody>
</table>

Common Table Expressions Compared to Similar Constructs

Common table expressions (CTEs) are similar to derived tables in some ways:

• Both constructs are named.

• Both constructs exist for the scope of a single statement.

Because of these similarities, CTEs and derived tables often can be used interchangeably. As a trivial example, these statements are equivalent:
CTEs are similar to tables created with `CREATE [TEMPORARY] TABLE` but need not be defined or dropped explicitly. For a CTE, you need no privileges to create tables.

### 13.3 Transactional and Locking Statements

MySQL supports local transactions (within a given client session) through statements such as `SET autocommit`, `START TRANSACTION`, `COMMIT`, and `ROLLBACK`. See Section 13.3.1, "START TRANSACTION, COMMIT, and ROLLBACK Statements". XA transaction support enables MySQL to participate in distributed transactions as well. See Section 13.3.8, "XA Transactions".

#### 13.3.1 START TRANSACTION, COMMIT, and ROLLBACK Statements

```sql
START TRANSACTION [\transaction_characteristic [, \transaction_characteristic] ...]

\transaction_characteristic: {
  WITH CONSISTENT SNAPSHOT
  | READ WRITE
  | READ ONLY
}

BEGIN [\work]

COMMIT [\work] [AND [\no] \chain] [[\no] \release]

ROLLBACK [\work] [AND [\no] \chain] [[\no] \release]

\set autocommit = \{0 | 1\}
```

These statements provide control over use of transactions:

- **START TRANSACTION** or **BEGIN** start a new transaction.
- **COMMIT** commits the current transaction, making its changes permanent.
- **ROLLBACK** rolls back the current transaction, canceling its changes.
- **SET autocommit** disables or enables the default autocommit mode for the current session.

By default, MySQL runs with **autocommit** mode enabled. This means that, when not otherwise inside a transaction, each statement is atomic, as if it were surrounded by **START TRANSACTION** and **COMMIT**. You cannot use **ROLLBACK** to undo the effect; however, if an error occurs during statement execution, the statement is rolled back.

To disable autocommit mode implicitly for a single series of statements, use the **START TRANSACTION** statement:
START TRANSACTION;  
SELECT @A:=SUM(salary) FROM table1 WHERE type=1;  
UPDATE table2 SET summary=@A WHERE type=1;  
COMMIT;

With **START TRANSACTION**, autocommit remains disabled until you end the transaction with **COMMIT** or **ROLLBACK**. The autocommit mode then reverts to its previous state.

**START TRANSACTION** permits several modifiers that control transaction characteristics. To specify multiple modifiers, separate them by commas.

- The **WITH CONSISTENT_SNAPSHOT** modifier starts a consistent read for storage engines that are capable of it. This applies only to **InnoDB**. The effect is the same as issuing a **START TRANSACTION** followed by a **SELECT** from any **InnoDB** table. See Section 15.7.2.3, “Consistent Nonlocking Reads”. The **WITH CONSISTENT_SNAPSHOT** modifier does not change the current transaction isolation level, so it provides a consistent snapshot only if the current isolation level is one that permits a consistent read. The only isolation level that permits a consistent read is **REPEATABLE_READ**. For all other isolation levels, the **WITH CONSISTENT_SNAPSHOT** clause is ignored. A warning is generated when the **WITH CONSISTENT_SNAPSHOT** clause is ignored.

- The **READ WRITE** and **READ ONLY** modifiers set the transaction access mode. They permit or prohibit changes to tables used in the transaction. The **READ ONLY** restriction prevents the transaction from modifying or locking both transactional and nontransactional tables that are visible to other transactions; the transaction can still modify or lock temporary tables.

MySQL enables extra optimizations for queries on **InnoDB** tables when the transaction is known to be read-only. Specifying **READ ONLY** ensures these optimizations are applied in cases where the read-only status cannot be determined automatically. See Section 8.5.3, “Optimizing InnoDB Read-Only Transactions” for more information.

If no access mode is specified, the default mode applies. Unless the default has been changed, it is read/write. It is not permitted to specify both **READ WRITE** and **READ ONLY** in the same statement.

In read-only mode, it remains possible to change tables created with the **TEMPORARY** keyword using DML statements. Changes made with DDL statements are not permitted, just as with permanent tables.

For additional information about transaction access mode, including ways to change the default mode, see Section 13.3.7, “SET TRANSACTION Statement”.

If the **read_only** system variable is enabled, explicitly starting a transaction with **START TRANSACTION READ WRITE** requires the **CONNECTION_ADMIN** privilege (or the deprecated **SUPER** privilege).

### Important

Many APIs used for writing MySQL client applications (such as JDBC) provide their own methods for starting transactions that can (and sometimes should) be used instead of sending a **START TRANSACTION** statement from the client. See Chapter 29, Connectors and APIs, or the documentation for your API, for more information.

To disable autocommit mode explicitly, use the following statement:

```
SET autocommit=0;
```

After disabling autocommit mode by setting the **autocommit** variable to zero, changes to transaction-safe tables (such as those for **InnoDB** or **NDB**) are not made permanent immediately. You must use **COMMIT** to store your changes to disk or **ROLLBACK** to ignore the changes.
autocommit is a session variable and must be set for each session. To disable autocommit mode for each new connection, see the description of the autocommit system variable at Section 5.1.8, “Server System Variables”.

BEGIN and BEGIN WORK are supported as aliases of START TRANSACTION for initiating a transaction. START TRANSACTION is standard SQL syntax, is the recommended way to start an ad-hoc transaction, and permits modifiers that BEGIN does not.

The BEGIN statement differs from the use of the BEGIN keyword that starts a BEGIN ... END compound statement. The latter does not begin a transaction. See Section 13.6.1, “BEGIN ... END Compound Statement”.

The optional WORK keyword is supported for COMMIT and ROLLBACK, as are the CHAIN and RELEASE clauses. CHAIN and RELEASE can be used for additional control over transaction completion. The value of the completion_type system variable determines the default completion behavior. See Section 5.1.8, “Server System Variables”.

The AND CHAIN clause causes a new transaction to begin as soon as the current one ends, and the new transaction has the same isolation level as the just-terminated transaction. The new transaction also uses the same access mode (READ WRITE or READ ONLY) as the just-terminated transaction. The RELEASE clause causes the server to disconnect the current client session after terminating the current transaction. Including the NO keyword suppresses CHAIN or RELEASE completion, which can be useful if the completion_type system variable is set to cause chaining or release completion by default.

Beginning a transaction causes any pending transaction to be committed. See Section 13.3.3, “Statements That Cause an Implicit Commit”, for more information.

Beginning a transaction also causes table locks acquired with LOCK TABLES to be released, as though you had executed UNLOCK TABLES. Beginning a transaction does not release a global read lock acquired with FLUSH TABLES WITH READ LOCK.

For best results, transactions should be performed using only tables managed by a single transaction-safe storage engine. Otherwise, the following problems can occur:

- If you use tables from more than one transaction-safe storage engine (such as InnoDB), and the transaction isolation level is not SERIALIZABLE, it is possible that when one transaction commits, another ongoing transaction that uses the same tables sees only some of the changes made by the first transaction. That is, the atomicity of transactions is not guaranteed with mixed engines and inconsistencies can result. (If mixed-engine transactions are infrequent, you can use SET TRANSACTION ISOLATION LEVEL to set the isolation level to SERIALIZABLE on a per-transaction basis as necessary.)

- If you use tables that are not transaction-safe within a transaction, changes to those tables are stored at once, regardless of the status of autocommit mode.

- If you issue a ROLLBACK statement after updating a nontransactional table within a transaction, an ER_WARNING_NOT_COMPLETE_ROLLBACK warning occurs. Changes to transaction-safe tables are rolled back, but not changes to nontransaction-safe tables.

Each transaction is stored in the binary log in one chunk, upon COMMIT. Transactions that are rolled back are not logged. (Exception: Modifications to nontransactional tables cannot be rolled back. If a transaction
that is rolled back includes modifications to nontransactional tables, the entire transaction is logged with a ROLLBACK statement at the end to ensure that modifications to the nontransactional tables are replicated.) See Section 5.4.4, “The Binary Log”.

You can change the isolation level or access mode for transactions with the SET TRANSACTION statement. See Section 13.3.7, “SET TRANSACTION Statement”.

Rolling back can be a slow operation that may occur implicitly without the user having explicitly asked for it (for example, when an error occurs). Because of this, SHOW PROCESSLIST displays Rolling back in the State column for the session, not only for explicit rollbacks performed with the ROLLBACK statement but also for implicit rollbacks.

Note

In MySQL 8.2, BEGIN, COMMIT, and ROLLBACK are not affected by --replicate-do-db or --replicate-ignore-db rules.

When InnoDB performs a complete rollback of a transaction, all locks set by the transaction are released. If a single SQL statement within a transaction rolls back as a result of an error, such as a duplicate key error, locks set by the statement are preserved while the transaction remains active. This happens because InnoDB stores row locks in a format such that it cannot know afterward which lock was set by which statement.

If a SELECT statement within a transaction calls a stored function, and a statement within the stored function fails, that statement rolls back. If ROLLBACK is executed for the transaction subsequently, the entire transaction rolls back.

13.3.2 Statements That Cannot Be Rolled Back

Some statements cannot be rolled back. In general, these include data definition language (DDL) statements, such as those that create or drop databases, those that create, drop, or alter tables or stored routines.

You should design your transactions not to include such statements. If you issue a statement early in a transaction that cannot be rolled back, and then another statement later fails, the full effect of the transaction cannot be rolled back in such cases by issuing a ROLLBACK statement.

13.3.3 Statements That Cause an Implicit Commit

The statements listed in this section (and any synonyms for them) implicitly end any transaction active in the current session, as if you had done a COMMIT before executing the statement.

Most of these statements also cause an implicit commit after executing. The intent is to handle each such statement in its own special transaction. Transaction-control and locking statements are exceptions: If an implicit commit occurs before execution, another does not occur after.

• Data definition language (DDL) statements that define or modify database objects. ALTER EVENT, ALTER FUNCTION, ALTER PROCEDURE, ALTER SERVER, ALTER TABLE, ALTER TABLESPACE, ALTERT VIEW, CREATE DATABASE, CREATE EVENT, CREATE FUNCTION, CREATE INDEX, CREATE PROCEDURE, CREATE ROLE, CREATE SERVER, CREATE SPATIAL REFERENCE SYSTEM, CREATE TABLE, CREATE TABLESPACE, CREATE TRIGGER, CREATE VIEW, DROP DATABASE, DROP EVENT, DROP FUNCTION, DROP INDEX, DROP PROCEDURE, DROP ROLE, DROP SERVER, DROP SPATIAL REFERENCE SYSTEM, DROP TABLE, DROP TABLESPACE, DROP TRIGGER, DROP VIEW, INSTALL PLUGIN, RENAME TABLE, TRUNCATE TABLE, UNINSTALL PLUGIN.
CREATE TABLE and DROP TABLE statements do not commit a transaction if the TEMPORARY keyword is used. (This does not apply to other operations on temporary tables such as ALTER TABLE and CREATE INDEX, which do cause a commit.) However, although no implicit commit occurs, neither can the statement be rolled back, which means that the use of such statements causes transactional atomicity to be violated. For example, if you use CREATE TEMPORARY TABLE and then roll back the transaction, the table remains in existence.

The CREATE TABLE statement in InnoDB is processed as a single transaction. This means that a ROLLBACK from the user does not undo CREATE TABLE statements the user made during that transaction.

CREATE TABLE ... SELECT causes an implicit commit before and after the statement is executed when you are creating non-temporary tables. (No commit occurs for CREATE TEMPORARY TABLE ... SELECT.)

• Statements that implicitly use or modify tables in the mysql database: ALTER USER, CREATE USER, DROP USER, GRANT, RENAME USER, REVOKE, SET PASSWORD.

• Transaction-control and locking statements: BEGIN, LOCK TABLES, SET autocommit = 1 (if the value is not already 1), START TRANSACTION, UNLOCK TABLES.

UNLOCK TABLES commits a transaction only if any tables currently have been locked with LOCK TABLES to acquire non-transactional table locks. A commit does not occur for UNLOCK TABLES following FLUSH TABLES WITH READ LOCK because the latter statement does not acquire table-level locks.

Transactions cannot be nested. This is a consequence of the implicit commit performed for any current transaction when you issue a START TRANSACTION statement or one of its synonyms.

Statements that cause an implicit commit cannot be used in an XA transaction while the transaction is in an ACTIVE state.

The BEGIN statement differs from the use of the BEGIN keyword that starts a BEGIN ... END compound statement. The latter does not cause an implicit commit. See Section 13.6.1, “BEGIN ... END Compound Statement”.

• Data loading statements: LOAD DATA. LOAD DATA causes an implicit commit only for tables using the NDB storage engine.

• Administrative statements: ANALYZE TABLE, CACHE INDEX, CHECK TABLE, FLUSH, LOAD INDEX INTO CACHE, OPTIMIZE TABLE, REPAIR TABLE, RESET (but not RESET PERSIST).

• Replication control statements: START REPLICA, STOP REPLICA, RESET REPLICA, CHANGE REPLICA SOURCE TO.

13.3.4 SAVEPOINT, ROLLBACK TO SAVEPOINT, and RELEASE SAVEPOINT Statements

SAVEPOINT identifier
ROLLBACK [WORK] TO [SAVEPOINT] identifier
RELEASE SAVEPOINT identifier

InnoDB supports the SQL statements SAVEPOINT, ROLLBACK TO SAVEPOINT, RELEASE SAVEPOINT and the optional WORK keyword for ROLLBACK.

The SAVEPOINT statement sets a named transaction savepoint with a name of identifier. If the current transaction has a savepoint with the same name, the old savepoint is deleted and a new one is set.
The **ROLLBACK TO SAVEPOINT** statement rolls back a transaction to the named savepoint without terminating the transaction. Modifications that the current transaction made to rows after the savepoint was set are undone in the rollback, but InnoDB **does not** release the row locks that were stored in memory after the savepoint. (For a new inserted row, the lock information is carried by the transaction ID stored in the row; the lock is not separately stored in memory. In this case, the row lock is released in the undo.) Savepoints that were set at a later time than the named savepoint are deleted.

If the **ROLLBACK TO SAVEPOINT** statement returns the following error, it means that no savepoint with the specified name exists:

```
ERROR 1305 (42000): SAVEPOINT identifier does not exist
```

The **RELEASE SAVEPOINT** statement removes the named savepoint from the set of savepoints of the current transaction. No commit or rollback occurs. It is an error if the savepoint does not exist.

All savepoints of the current transaction are deleted if you execute a **COMMIT**, or a **ROLLBACK** that does not name a savepoint.

A new savepoint level is created when a stored function is invoked or a trigger is activated. The savepoints on previous levels become unavailable and thus do not conflict with savepoints on the new level. When the function or trigger terminates, any savepoints it created are released and the previous savepoint level is restored.

### 13.3.5 LOCK INSTANCE FOR BACKUP and UNLOCK INSTANCE Statements

**LOCK INSTANCE FOR BACKUP** acquires an instance-level **backup lock** that permits DML during an online backup while preventing operations that could result in an inconsistent snapshot.

Executing the **LOCK INSTANCE FOR BACKUP** statement requires the **BACKUP_ADMIN** privilege. The **BACKUP_ADMIN** privilege is automatically granted to users with the **RELOAD** privilege when performing an in-place upgrade to MySQL 8.2 from an earlier version.

Multiple sessions can hold a backup lock simultaneously.

**UNLOCK INSTANCE** releases a backup lock held by the current session. A backup lock held by a session is also released if the session is terminated.

**LOCK INSTANCE FOR BACKUP** prevents files from being created, renamed, or removed. **REPAIR TABLE**, **TRUNCATE TABLE**, **OPTIMIZE TABLE**, and account management statements are blocked. See [Section 13.7.1, “Account Management Statements”](#). Operations that modify InnoDB files that are not recorded in the InnoDB redo log are also blocked.

**LOCK INSTANCE FOR BACKUP** permits DDL operations that only affect user-created temporary tables. In effect, files that belong to user-created temporary tables can be created, renamed, or removed while a backup lock is held. Creation of binary log files is also permitted.

**PURGE BINARY LOGS** cannot be issued while a **LOCK INSTANCE FOR BACKUP** statement is in effect for the instance, because it contravenes the rules of the backup lock by removing files from the server.

A backup lock acquired by **LOCK INSTANCE FOR BACKUP** is independent of transactional locks and locks taken by **FLUSH TABLES tbl_name [, tbl_name] ... WITH READ LOCK**, and the following sequences of statements are permitted:
LOCK TABLES and UNLOCK TABLES Statements

LOCK INSTANCE FOR BACKUP;
FLUSH TABLES tbl_name [, tbl_name] ... WITH READ LOCK;
UNLOCK TABLES;
UNLOCK INSTANCE;
FLUSH TABLES tbl_name [, tbl_name] ... WITH READ LOCK;
LOCK INSTANCE FOR BACKUP;
UNLOCK INSTANCE;
UNLOCK TABLES;

The lock_wait_timeout setting defines the amount of time that a LOCK INSTANCE FOR BACKUP statement waits to acquire a lock before giving up.

13.3.6 LOCK TABLES and UNLOCK TABLES Statements

MySQL enables client sessions to acquire table locks explicitly for the purpose of cooperating with other sessions for access to tables, or to prevent other sessions from modifying tables during periods when a session requires exclusive access to them. A session can acquire or release locks only for itself. One session cannot acquire locks for another session or release locks held by another session.

Locks may be used to emulate transactions or to get more speed when updating tables. This is explained in more detail in Table-Locking Restrictions and Conditions.

LOCK TABLES
  tbl_name [(AS] alias] lock_type
  [, tbl_name [(AS] alias] lock_type] ...

lock_type: {
  READ [LOCAL]
  | (LOW_PRIORITY) WRITE
}

UNLOCK TABLES

LOCK TABLES explicitly acquires table locks for the current client session. Table locks can be acquired for base tables or views. You must have the LOCK TABLES privilege, and the SELECT privilege for each object to be locked.

For view locking, LOCK TABLES adds all base tables used in the view to the set of tables to be locked and locks them automatically. For tables underlying any view being locked, LOCK TABLES checks that the view definer (for SQL SECURITY DEFINER views) or invoker (for all views) has the proper privileges on the tables.

If you lock a table explicitly with LOCK TABLES, any tables used in triggers are also locked implicitly, as described in LOCK TABLES and Triggers.

If you lock a table explicitly with LOCK TABLES, any tables related by a foreign key constraint are opened and locked implicitly. For foreign key checks, a shared read-only lock (LOCK TABLES READ) is taken on related tables. For cascading updates, a shared-nothing write lock (LOCK TABLES WRITE) is taken on related tables that are involved in the operation.

UNLOCK TABLES explicitly releases any table locks held by the current session. LOCK TABLES implicitly releases any table locks held by the current session before acquiring new locks.

Another use for UNLOCK TABLES is to release the global read lock acquired with the FLUSH TABLES WITH READ LOCK statement, which enables you to lock all tables in all databases. See Section 13.7.8.3, “FLUSH Statement”. (This is a very convenient way to get backups if you have a file system such as Veritas that can take snapshots in time.)
A table lock protects only against inappropriate reads or writes by other sessions. A session holding a `WRITE` lock can perform table-level operations such as `DROP TABLE` or `TRUNCATE TABLE`. For sessions holding a `READ` lock, `DROP TABLE` and `TRUNCATE TABLE` operations are not permitted.

The following discussion applies only to non-`TEMPORARY` tables. `LOCK TABLES` is permitted (but ignored) for a `TEMPORARY` table. The table can be accessed freely by the session within which it was created, regardless of what other locking may be in effect. No lock is necessary because no other session can see the table.

- **Table Lock Acquisition**
- **Table Lock Release**
- **Interaction of Table Locking and Transactions**
- **LOCK TABLES and Triggers**
- **Table-Locking Restrictions and Conditions**

### Table Lock Acquisition

To acquire table locks within the current session, use the `LOCK TABLES` statement, which acquires metadata locks (see Section 8.11.4, “Metadata Locking”).

The following lock types are available:

- **READ [LOCAL]** lock:
  - The session that holds the lock can read the table (but not write it).
  - Multiple sessions can acquire a `READ` lock for the table at the same time.
  - Other sessions can read the table without explicitly acquiring a `READ` lock.
  - The `LOCAL` modifier enables nonconflicting `INSERT` statements (concurrent inserts) by other sessions to execute while the lock is held. (See Section 8.11.3, “Concurrent Inserts”.) However, `READ LOCAL` cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock. For InnoDB tables, `READ LOCAL` is the same as `READ`.

- **[LOW_PRIORITY] WRITE** lock:
  - The session that holds the lock can read and write the table.
  - Only the session that holds the lock can access the table. No other session can access it until the lock is released.
  - Lock requests for the table by other sessions block while the `WRITE` lock is held.
  - The `LOW_PRIORITY` modifier has no effect. In previous versions of MySQL, it affected locking behavior, but this is no longer true. It is now deprecated and its use produces a warning. Use `WRITE` without `LOW_PRIORITY` instead.

`WRITE` locks normally have higher priority than `READ` locks to ensure that updates are processed as soon as possible. This means that if one session obtains a `READ` lock and then another session requests a `WRITE` lock, subsequent `READ` lock requests wait until the session that requested the `WRITE` lock has obtained the lock and released it. (An exception to this policy can occur for small values of the `max_write_lock_count` system variable; see Section 8.11.4, “Metadata Locking”.)
If the `LOCK TABLES` statement must wait due to locks held by other sessions on any of the tables, it blocks until all locks can be acquired.

A session that requires locks must acquire all the locks that it needs in a single `LOCK TABLES` statement. While the locks thus obtained are held, the session can access only the locked tables. For example, in the following sequence of statements, an error occurs for the attempt to access \textit{t2} because it was not locked in the `LOCK TABLES` statement:

\begin{verbatim}
mysql> LOCK TABLES t1 READ;
mysql> SELECT COUNT(*) FROM t1;
+----------+
| COUNT(*) |
+----------+
|        3 |
+----------+
mysql> SELECT COUNT(*) FROM t2;
ERROR 1100 (HY000): Table 't2' was not locked with LOCK TABLES
\end{verbatim}

Tables in the \textit{INFORMATION_SCHEMA} database are an exception. They can be accessed without being locked explicitly even while a session holds table locks obtained with `LOCK TABLES`.

You cannot refer to a locked table multiple times in a single query using the same name. Use aliases instead, and obtain a separate lock for the table and each alias:

\begin{verbatim}
mysql> LOCK TABLE t WRITE, t AS t1 READ;
mysql> INSERT INTO t SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> INSERT INTO t SELECT * FROM t AS t1;
\end{verbatim}

The error occurs for the first `INSERT` because there are two references to the same name for a locked table. The second `INSERT` succeeds because the references to the table use different names.

If your statements refer to a table by means of an alias, you must lock the table using that same alias. It does not work to lock the table without specifying the alias:

\begin{verbatim}
mysql> LOCK TABLE t READ;
mysql> SELECT * FROM t AS myalias;
ERROR 1100: Table 'myalias' was not locked with LOCK TABLES
\end{verbatim}

Conversely, if you lock a table using an alias, you must refer to it in your statements using that alias:

\begin{verbatim}
mysql> LOCK TABLE t AS myalias READ;
mysql> SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> SELECT * FROM t AS myalias;
\end{verbatim}

**Table Lock Release**

When the table locks held by a session are released, they are all released at the same time. A session can release its locks explicitly, or locks may be released implicitly under certain conditions.

- A session can release its locks explicitly with `UNLOCK TABLES`.
- If a session issues a `LOCK TABLES` statement to acquire a lock while already holding locks, its existing locks are released implicitly before the new locks are granted.
- If a session begins a transaction (for example, with `START TRANSACTION`), an implicit `UNLOCK TABLES` is performed, which causes existing locks to be released. (For additional information about the interaction between table locking and transactions, see \textit{Interaction of Table Locking and Transactions}.)
If the connection for a client session terminates, whether normally or abnormally, the server implicitly releases all table locks held by the session (transactional and nontransactional). If the client reconnects, the locks are no longer in effect. In addition, if the client had an active transaction, the server rolls back the transaction upon disconnect, and if reconnect occurs, the new session begins with autocommit enabled. For this reason, clients may wish to disable auto-reconnect. With auto-reconnect in effect, the client is not notified if reconnect occurs but any table locks or current transaction are lost. With auto-reconnect disabled, if the connection drops, an error occurs for the next statement issued. The client can detect the error and take appropriate action such as reacquiring the locks or redoing the transaction. See Automatic Reconnection Control.

Note

If you use `ALTER TABLE` on a locked table, it may become unlocked. For example, if you attempt a second `ALTER TABLE` operation, the result may be an error `Table 'tbl_name' was not locked with LOCK TABLES`. To handle this, lock the table again prior to the second alteration. See also Section B.3.6.1, “Problems with `ALTER TABLE`”.

Interaction of Table Locking and Transactions

`LOCK TABLES` and `UNLOCK TABLES` interact with the use of transactions as follows:

- **LOCK TABLES** is not transaction-safe and implicitly commits any active transaction before attempting to lock the tables.

- **UNLOCK TABLES** implicitly commits any active transaction, but only if **LOCK TABLES** has been used to acquire table locks. For example, in the following set of statements, **UNLOCK TABLES** releases the global read lock but does not commit the transaction because no table locks are in effect:

```
FLUSH TABLES WITH READ LOCK;
START TRANSACTION;
SELECT ...;
UNLOCK TABLES;
```

- Beginning a transaction (for example, with `START TRANSACTION`) implicitly commits any current transaction and releases existing table locks.

- **FLUSH TABLES WITH READ LOCK** acquires a global read lock and not table locks, so it is not subject to the same behavior as **LOCK TABLES** and **UNLOCK TABLES** with respect to table locking and implicit commits. For example, `START TRANSACTION` does not release the global read lock. See Section 13.7.8.3, “FLUSH Statement”.

- Other statements that implicitly cause transactions to be committed do not release existing table locks. For a list of such statements, see Section 13.3.3, “Statements That Cause an Implicit Commit”.

- The correct way to use **LOCK TABLES** and **UNLOCK TABLES** with transactional tables, such as InnoDB tables, is to begin a transaction with `SET autocommit = 0` (not `START TRANSACTION`) followed by **LOCK TABLES**, and to not call **UNLOCK TABLES** until you commit the transaction explicitly. For example, if you need to write to table `t1` and read from table `t2`, you can do this:

```
SET autocommit=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
... do something with tables t1 and t2 here ...
COMMIT;
UNLOCK TABLES;
```

When you call **LOCK TABLES**, InnoDB internally takes its own table lock, and MySQL takes its own table lock. InnoDB releases its internal table lock at the next commit, but for MySQL to release its table lock, the transaction must be committed explicitly.
LOCK TABLES and UNLOCK TABLES Statements

You should not have autocommit = 1, because then InnoDB releases its internal table lock immediately after the call of LOCK TABLES, and deadlocks can very easily happen. InnoDB does not acquire the internal table lock at all if autocommit = 1, to help old applications avoid unnecessary deadlocks.

- ROLLBACK does not release table locks.

LOCK TABLES and Triggers

If you lock a table explicitly with LOCK TABLES, any tables used in triggers are also locked implicitly:

- The locks are taken as the same time as those acquired explicitly with the LOCK TABLES statement.
- The lock on a table used in a trigger depends on whether the table is used only for reading. If so, a read lock suffices. Otherwise, a write lock is used.
- If a table is locked explicitly for reading with LOCK TABLES, but needs to be locked for writing because it might be modified within a trigger, a write lock is taken rather than a read lock. (That is, an implicit write lock needed due to the table's appearance within a trigger causes an explicit read lock request for the table to be converted to a write lock request.)

Suppose that you lock two tables, t1 and t2, using this statement:

```sql
LOCK TABLES t1 WRITE, t2 READ;
```

If t1 or t2 have any triggers, tables used within the triggers are also locked. Suppose that t1 has a trigger defined like this:

```sql
CREATE TRIGGER t1_a_ins AFTER INSERT ON t1 FOR EACH ROW
BEGIN
  UPDATE t4 SET count = count+1
  WHERE id = NEW.id AND EXISTS (SELECT a FROM t3);
  INSERT INTO t2 VALUES(1, 2);
END;
```

The result of the LOCK TABLES statement is that t1 and t2 are locked because they appear in the statement, and t3 and t4 are locked because they are used within the trigger:

- t1 is locked for writing per the WRITE lock request.
- t2 is locked for writing, even though the request is for a READ lock. This occurs because t2 is inserted into within the trigger, so the READ request is converted to a WRITE request.
- t3 is locked for reading because it is only read from within the trigger.
- t4 is locked for writing because it might be updated within the trigger.

Table-Locking Restrictions and Conditions

You can safely use KILL to terminate a session that is waiting for a table lock. See Section 13.7.8.4, “KILL Statement”.

LOCK TABLES and UNLOCK TABLES cannot be used within stored programs.

Tables in the performance_schema database cannot be locked with LOCK TABLES, except the setup_xxx tables.

The scope of a lock generated by LOCK TABLES is a single MySQL server. It is not compatible with NDB Cluster, which has no way of enforcing an SQL-level lock across multiple instances of mysqld. You can
enforce locking in an API application instead. See Section 23.2.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”, for more information.

The following statements are prohibited while a LOCK TABLES statement is in effect: CREATE TABLE, CREATE TABLE ... LIKE, CREATE VIEW, DROP VIEW, and DDL statements on stored functions and procedures and events.

For some operations, system tables in the mysql database must be accessed. For example, the HELP statement requires the contents of the server-side help tables, and CONVERT_TZ() might need to read the time zone tables. The server implicitly locks the system tables for reading as necessary so that you need not lock them explicitly. These tables are treated as just described:

- mysql.help_category
- mysql.help_keyword
- mysql.help_relation
- mysql.help_topic
- mysql.time_zone
- mysql.time_zone_leap_second
- mysql.time_zone_name
- mysql.time_zone_transition
- mysql.time_zone_transition_type

If you want to explicitly place a WRITE lock on any of those tables with a LOCK TABLES statement, the table must be the only one locked; no other table can be locked with the same statement.

Normally, you do not need to lock tables, because all single UPDATE statements are atomic; no other session can interfere with any other currently executing SQL statement. However, there are a few cases when locking tables may provide an advantage:

- If you are going to run many operations on a set of MyISAM tables, it is much faster to lock the tables you are going to use. Locking MyISAM tables speeds up inserting, updating, or deleting on them because MySQL does not flush the key cache for the locked tables until UNLOCK TABLES is called. Normally, the key cache is flushed after each SQL statement.

  The downside to locking the tables is that no session can update a READ-locked table (including the one holding the lock) and no session can access a WRITE-locked table other than the one holding the lock.

- If you are using tables for a nontransactional storage engine, you must use LOCK TABLES if you want to ensure that no other session modifies the tables between a SELECT and an UPDATE. The example shown here requires LOCK TABLES to execute safely:

  LOCK TABLES trans READ, customer WRITE;
  SELECT SUM(value) FROM trans WHERE customer_id=some_id;
  UPDATE customer
  SET total_value=sum_from_previous_statement
  WHERE customer_id=some_id;
  UNLOCK TABLES;

Without LOCK TABLES, it is possible that another session might insert a new row in the trans table between execution of the SELECT and an UPDATE statements.

You can avoid using LOCK TABLES in many cases by using relative updates (UPDATE customer SET value=value+new_value) or the LAST_INSERT_ID() function.

You can also avoid locking tables in some cases by using the user-level advisory lock functions GET_LOCK() and RELEASE_LOCK(). These locks are saved in a hash table in the server and implemented with pthread_mutex_lock() and pthread_mutex_unlock() for high speed. See Section 12.14, “Locking Functions”.

See Section 8.11.1, “Internal Locking Methods”, for more information on locking policy.
13.3.7 SET TRANSACTION Statement

\[
\text{SET [GLOBAL | SESSION] TRANSACTION} \\
\quad \text{transaction_characteristic [, transaction_characteristic]} \ldots
\]

\[
\text{transaction_characteristic:} \{ \\
\quad \text{ISOLATION LEVEL level} \\
\quad \text{access_mode}
\}
\]

\[
\text{level:} \{ \\
\quad \text{REPEATABLE READ} \\
\quad \text{READ COMMITTED} \\
\quad \text{READ UNCOMMITTED} \\
\quad \text{SERIALIZABLE}
\}
\]

\[
\text{access_mode:} \{ \\
\quad \text{READ WRITE} \\
\quad \text{READ ONLY}
\}
\]

This statement specifies transaction characteristics. It takes a list of one or more characteristic values separated by commas. Each characteristic value sets the transaction isolation level or access mode. The isolation level is used for operations on InnoDB tables. The access mode specifies whether transactions operate in read/write or read-only mode.

In addition, `SET TRANSACTION` can include an optional `GLOBAL` or `SESSION` keyword to indicate the scope of the statement.

- **Transaction Isolation Levels**
- **Transaction Access Mode**
- **Transaction Characteristic Scope**

**Transaction Isolation Levels**

To set the transaction isolation level, use an `ISOLATION LEVEL level` clause. It is not permitted to specify multiple `ISOLATION LEVEL` clauses in the same `SET TRANSACTION` statement.

The default isolation level is `REPEATABLE READ`. Other permitted values are `READ COMMITTED`, `READ UNCOMMITTED`, and `SERIALIZABLE`. For information about these isolation levels, see Section 15.7.2.1, “Transaction Isolation Levels”.

**Transaction Access Mode**

To set the transaction access mode, use a `READ WRITE` or `READ ONLY` clause. It is not permitted to specify multiple access-mode clauses in the same `SET TRANSACTION` statement.

By default, a transaction takes place in read/write mode, with both reads and writes permitted to tables used in the transaction. This mode may be specified explicitly using `SET TRANSACTION` with an access mode of `READ WRITE`.

If the transaction access mode is set to `READ ONLY`, changes to tables are prohibited. This may enable storage engines to make performance improvements that are possible when writes are not permitted.

In read-only mode, it remains possible to change tables created with the `TEMPORARY` keyword using DML statements. Changes made with DDL statements are not permitted, just as with permanent tables.
The **READ WRITE** and **READ ONLY** access modes also may be specified for an individual transaction using the **START TRANSACTION** statement.

### Transaction Characteristic Scope

You can set transaction characteristics globally, for the current session, or for the next transaction only:

- **With the **GLOBAL** keyword:**
  - The statement applies globally for all subsequent sessions.
  - Existing sessions are unaffected.

- **With the **SESSION** keyword:**
  - The statement applies to all subsequent transactions performed within the current session.
  - The statement is permitted within transactions, but does not affect the current ongoing transaction.
  - If executed between transactions, the statement overrides any preceding statement that sets the next-transaction value of the named characteristics.

- **Without any **SESSION or **GLOBAL** keyword:**
  - The statement applies only to the next single transaction performed within the session.
  - Subsequent transactions revert to using the session value of the named characteristics.
  - The statement is not permitted within transactions:

```sql
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.02 sec)

mysql> SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
ERROR 1568 (25001): Transaction characteristics can't be changed while a transaction is in progress
```

A change to global transaction characteristics requires the **CONNECTION_ADMIN** privilege (or the deprecated **SUPER** privilege). Any session is free to change its session characteristics (even in the middle of a transaction), or the characteristics for its next transaction (prior to the start of that transaction).

To set the global isolation level at server startup, use the `--transaction-isolation=level` option on the command line or in an option file. Values of `level` for this option use dashes rather than spaces, so the permissible values are **READ-UNCOMMITTED**, **READ-COMMITTED**, **REPEATABLE-READ**, or **SERIALIZABLE**.

Similarly, to set the global transaction access mode at server startup, use the `--transaction-read-only` option. The default is **OFF** (read/write mode) but the value can be set to **ON** for a mode of read only.

For example, to set the isolation level to **REPEATABLE READ** and the access mode to **READ WRITE**, use these lines in the `[mysqld]` section of an option file:

```
[mysqld]
transaction-isolation = REPEATABLE-READ
transaction-read-only = OFF
```

At runtime, characteristics at the global, session, and next-transaction scope levels can be set indirectly using the **SET TRANSACTION** statement, as described previously. They can also be set directly using the **SET** statement to assign values to the **transaction_isolation** and **transaction_read_only** system variables:
• **SET TRANSACTION** permits optional **GLOBAL** and **SESSION** keywords for setting transaction characteristics at different scope levels.

• The **SET** statement for assigning values to the **transaction_isolation** and **transaction_read_only** system variables has syntaxes for setting these variables at different scope levels.

The following tables show the characteristic scope level set by each **SET TRANSACTION** and variable-assignment syntax.

**Table 13.9 SET TRANSACTION Syntax for Transaction Characteristics**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Affected Characteristic Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SET GLOBAL TRANSACTION transaction_characteristic</code></td>
<td>Global</td>
</tr>
<tr>
<td><code>SET SESSION TRANSACTION transaction_characteristic</code></td>
<td>Session</td>
</tr>
<tr>
<td><code>SET TRANSACTION transaction_characteristic</code></td>
<td>Next transaction only</td>
</tr>
</tbody>
</table>

**Table 13.10 SET Syntax for Transaction Characteristics**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Affected Characteristic Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SET GLOBAL var_name = value</code></td>
<td>Global</td>
</tr>
<tr>
<td><code>SET @@GLOBAL.var_name = value</code></td>
<td>Global</td>
</tr>
<tr>
<td><code>SET PERSIST var_name = value</code></td>
<td>Global</td>
</tr>
<tr>
<td><code>SET @@PERSIST.var_name = value</code></td>
<td>Global</td>
</tr>
<tr>
<td><code>SET PERSIST_ONLY var_name = value</code></td>
<td>No runtime effect</td>
</tr>
<tr>
<td><code>SET @@PERSIST_ONLY.var_name = value</code></td>
<td>No runtime effect</td>
</tr>
<tr>
<td><code>SET SESSION var_name = value</code></td>
<td>Session</td>
</tr>
<tr>
<td><code>SET @@SESSION.var_name = value</code></td>
<td>Session</td>
</tr>
<tr>
<td><code>SET var_name = value</code></td>
<td>Session</td>
</tr>
<tr>
<td><code>SET @@var_name = value</code></td>
<td>Next transaction only</td>
</tr>
</tbody>
</table>

It is possible to check the global and session values of transaction characteristics at runtime:

```sql
SELECT @@GLOBAL.transaction_isolation, @@GLOBAL.transaction_read_only;
SELECT @@SESSION.transaction_isolation, @@SESSION.transaction_read_only;
```

**13.3.8 XA Transactions**

On the client side, there are no special requirements. The XA interface to a MySQL server consists of SQL statements that begin with the **XA** keyword. MySQL client programs must be able to send SQL statements and to understand the semantics of the XA statement interface. They do not need be linked against a recent client library. Older client libraries also work.
Among the MySQL Connectors, MySQL Connector/J 5.0.0 and higher supports XA directly, by means of a class interface that handles the XA SQL statement interface for you.

XA supports distributed transactions, that is, the ability to permit multiple separate transactional resources to participate in a global transaction. Transactional resources often are RDBMSs but may be other kinds of resources.

A global transaction involves several actions that are transactional in themselves, but that all must either complete successfully as a group, or all be rolled back as a group. In essence, this extends ACID properties “up a level” so that multiple ACID transactions can be executed in concert as components of a global operation that also has ACID properties. (As with nondistributed transactions, \textit{SERIALIZABLE} may be preferred if your applications are sensitive to read phenomena. \textit{REPEATABLE READ} may not be sufficient for distributed transactions.)

Some examples of distributed transactions:

- An application may act as an integration tool that combines a messaging service with an RDBMS. The application makes sure that transactions dealing with message sending, retrieval, and processing that also involve a transactional database all happen in a global transaction. You can think of this as “transactional email.”

- An application performs actions that involve different database servers, such as a MySQL server and an Oracle server (or multiple MySQL servers), where actions that involve multiple servers must happen as part of a global transaction, rather than as separate transactions local to each server.

- A bank keeps account information in an RDBMS and distributes and receives money through automated teller machines (ATMs). It is necessary to ensure that ATM actions are correctly reflected in the accounts, but this cannot be done with the RDBMS alone. A global transaction manager integrates the ATM and database resources to ensure overall consistency of financial transactions.

Applications that use global transactions involve one or more Resource Managers and a Transaction Manager:

- A Resource Manager (RM) provides access to transactional resources. A database server is one kind of resource manager. It must be possible to either commit or roll back transactions managed by the RM.

- A Transaction Manager (TM) coordinates the transactions that are part of a global transaction. It communicates with the RMs that handle each of these transactions. The individual transactions within a global transaction are “branches” of the global transaction. Global transactions and their branches are identified by a naming scheme described later.

The MySQL implementation of XA enables a MySQL server to act as a Resource Manager that handles XA transactions within a global transaction. A client program that connects to the MySQL server acts as the Transaction Manager.

To carry out a global transaction, it is necessary to know which components are involved, and bring each component to a point when it can be committed or rolled back. Depending on what each component reports about its ability to succeed, they must all commit or roll back as an atomic group. That is, either all components must commit, or all components must roll back. To manage a global transaction, it is necessary to take into account that any component or the connecting network might fail.

The process for executing a global transaction uses two-phase commit (2PC). This takes place after the actions performed by the branches of the global transaction have been executed.

1. In the first phase, all branches are prepared. That is, they are told by the TM to get ready to commit. Typically, this means each RM that manages a branch records the actions for the branch in stable
XA Transactions

storage. The branches indicate whether they are able to do this, and these results are used for the second phase.

2. In the second phase, the TM tells the RMs whether to commit or roll back. If all branches indicated when they were prepared that they were able to commit, all branches are told to commit. If any branch indicated when it was prepared that it was not able to commit, all branches are told to roll back.

In some cases, a global transaction might use one-phase commit (1PC). For example, when a Transaction Manager finds that a global transaction consists of only one transactional resource (that is, a single branch), that resource can be told to prepare and commit at the same time.

13.3.8.1 XA Transaction SQL Statements

To perform XA transactions in MySQL, use the following statements:

```
XA {START|BEGIN} xid [JOIN|RESUME]
XA END xid [SUSPEND [FOR MIGRATE]]
XA PREPARE xid
XA COMMIT xid [ONE PHASE]
XA ROLLBACK xid
XA RECOVER [CONVERT XID]
```

For `XA START`, the `JOIN` and `RESUME` clauses are recognized but have no effect.

For `XA END` the `SUSPEND [FOR MIGRATE]` clause is recognized but has no effect.

Each XA statement begins with the `XA` keyword, and most of them require an `xid` value. An `xid` is an XA transaction identifier. It indicates which transaction the statement applies to. `xid` values are supplied by the client, or generated by the MySQL server. An `xid` value has from one to three parts:

```
xid: gtrid [, bqual [, formatID ]]
```

`gtrid` is a global transaction identifier, `bqual` is a branch qualifier, and `formatID` is a number that identifies the format used by the `gtrid` and `bqual` values. As indicated by the syntax, `bqual` and `formatID` are optional. The default `bqual` value is '' if not given. The default `formatID` value is 1 if not given.

`gtrid` and `bqual` must be string literals, each up to 64 bytes (not characters) long. `gtrid` and `bqual` can be specified in several ways. You can use a quoted string ('ab'), hex string (X'6162', 0x6162), or bit value (b'nnnn').

`formatID` is an unsigned integer.

The `gtrid` and `bqual` values are interpreted in bytes by the MySQL server's underlying XA support routines. However, while an SQL statement containing an XA statement is being parsed, the server works with some specific character set. To be safe, write `gtrid` and `bqual` as hex strings.

`xid` values typically are generated by the Transaction Manager. Values generated by one TM must be different from values generated by other TMs. A given TM must be able to recognize its own `xid` values in a list of values returned by the `XA RECOVER` statement.

`XA START xid` starts an XA transaction with the given `xid` value. Each XA transaction must have a unique `xid` value, so the value must not currently be used by another XA transaction. Uniqueness is
assessed using the gtrid and bqual values. All following XA statements for the XA transaction must be specified using the same xid value as that given in the XA START statement. If you use any of those statements but specify an xid value that does not correspond to some existing XA transaction, an error occurs.

XA START, XA BEGIN, XA END, XA COMMIT, and XA ROLLBACK statements are not filtered by the default database when the server is running with --replicate-do-db or --replicate-ignore-db.

One or more XA transactions can be part of the same global transaction. All XA transactions within a given global transaction must use the same gtrid value in the xid value. For this reason, gtrid values must be globally unique so that there is no ambiguity about which global transaction a given XA transaction is part of. The bqual part of the xid value must be different for each XA transaction within a global transaction. (The requirement that bqual values be different is a limitation of the current MySQL XA implementation. It is not part of the XA specification.)

The XA RECOVER statement returns information for those XA transactions on the MySQL server that are in the PREPARED state. (See Section 13.3.8.2, “XA Transaction States”.) The output includes a row for each such XA transaction on the server, regardless of which client started it.

XA RECOVER requires the XA_RECOVER_ADMIN privilege. This privilege requirement prevents users from discovering the XID values for outstanding prepared XA transactions other than their own. It does not affect normal commit or rollback of an XA transaction because the user who started it knows its XID.

XA RECOVER output rows look like this (for an example xid value consisting of the parts 'abc', 'def', and 7):

```
mysql> XA RECOVER;
+----------+--------------+--------------+--------+
<table>
<thead>
<tr>
<th>formatID</th>
<th>gtrid_length</th>
<th>bqual_length</th>
<th>data</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>3</td>
<td>3</td>
<td>abcdef</td>
</tr>
</tbody>
</table>
```

The output columns have the following meanings:

- **formatID** is the formatID part of the transaction xid
- **gtrid_length** is the length in bytes of the gtrid part of the xid
- **bqual_length** is the length in bytes of the bqual part of the xid
- **data** is the concatenation of the gtrid and bqual parts of the xid

XID values may contain nonprintable characters. XA RECOVER permits an optional CONVERT XID clause so that clients can request XID values in hexadecimal.

### 13.3.8.2 XA Transaction States

An XA transaction progresses through the following states:

1. Use XA START to start an XA transaction and put it in the ACTIVE state.
2. For an ACTIVE XA transaction, issue the SQL statements that make up the transaction, and then issue an XA END statement. XA END puts the transaction in the IDLE state.
3. For an IDLE XA transaction, you can issue either an XA PREPARE statement or an XA COMMIT ... ONE PHASE statement:
• **XA PREPARE** puts the transaction in the **PREPARED** state. An **XA RECOVER** statement at this point includes the transaction’s `xid` value in its output, because **XA RECOVER** lists all XA transactions that are in the **PREPARED** state.

• **XA COMMIT ... ONE PHASE** prepares and commits the transaction. The `xid` value is not listed by **XA RECOVER** because the transaction terminates.

4. For a **PREPARED** XA transaction, you can issue an **XA COMMIT** statement to commit and terminate the transaction, or **XA ROLLBACK** to roll back and terminate the transaction.

Here is a simple XA transaction that inserts a row into a table as part of a global transaction:

```sql
mysql> XA START 'xatest';
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO mytable (i) VALUES(10);
Query OK, 1 row affected (0.04 sec)
mysql> XA END 'xatest';
Query OK, 0 rows affected (0.00 sec)
mysql> XA PREPARE 'xatest';
Query OK, 0 rows affected (0.00 sec)
mysql> XA COMMIT 'xatest';
Query OK, 0 rows affected (0.00 sec)
```

MySQL 8.2 supports detached XA transactions, enabled by the `xa_detach_on_prepare` system variable (**ON** by default). Detached transactions are disconnected from the current session following execution of **XA PREPARE** (and can be committed or rolled back by another connection). This means that the current session is free to start a new local transaction or XA transaction without having to wait for the prepared XA transaction to be committed or rolled back.

When XA transactions are detached, a connection has no special knowledge of any XA transaction that it has prepared. If the current session tries to commit or roll back a given XA transaction (even one which it prepared) after another connection has already done so, the attempt is rejected with an invalid XID error (**ER_XAER_NOTA**) since the requested `xid` no longer exists.

**Note**
Detached XA transactions cannot use temporary tables.

When detached XA transactions are disabled (`xa_detach_on_prepare` set to **OFF**), an XA transaction remains connected until it is committed or rolled back by the originating connection. Disabling detached XA transactions is not recommended for a MySQL server instance used in group replication; see **Server Instance Configuration**, for more information.

If an XA transaction is in the **ACTIVE** state, you cannot issue any statements that cause an implicit commit. That would violate the XA contract because you could not roll back the XA transaction. Trying to execute such a statement raises the following error:

```
ERROR 1399 (XAE07): XAER_RMFAIL: The command cannot be executed when global transaction is in the ACTIVE state
```

Statements to which the preceding remark applies are listed at **Section 13.3.3, “Statements That Cause an Implicit Commit”**.

### 13.3.8.3 Restrictions on XA Transactions
XA Transactions

XA transaction support is limited to the InnoDB storage engine.

For "external XA," a MySQL server acts as a Resource Manager and client programs act as Transaction Managers. For "Internal XA", storage engines within a MySQL server act as RMs, and the server itself acts as a TM. Internal XA support is limited by the capabilities of individual storage engines. Internal XA is required for handling XA transactions that involve more than one storage engine. The implementation of internal XA requires that a storage engine support two-phase commit at the table handler level, and currently this is true only for InnoDB.

For **XA START**, the **JOIN** and **RESUME** clauses are recognized but have no effect.

For **XA END** the **SUSPEND [FOR MIGRATE]** clause is recognized but has no effect.

The requirement that the `bqual` part of the `xid` value be different for each XA transaction within a global transaction is a limitation of the current MySQL XA implementation. It is not part of the XA specification.

An XA transaction is written to the binary log in two parts. When **XA PREPARE** is issued, the first part of the transaction up to **XA PREPARE** is written using an initial GTID. A `XA_prepare_log_event` is used to identify such transactions in the binary log. When **XA COMMIT** or **XA ROLLBACK** is issued, a second part of the transaction containing only the **XA COMMIT** or **XA ROLLBACK** statement is written using a second GTID. Note that the initial part of the transaction, identified by `XA_prepare_log_event`, is not necessarily followed by its **XA COMMIT** or **XA ROLLBACK**, which can cause interleaved binary logging of any two XA transactions. The two parts of the XA transaction can even appear in different binary log files. This means that an XA transaction in **PREPARED** state is now persistent until an explicit **XA COMMIT** or **XA ROLLBACK** statement is issued, ensuring that XA transactions are compatible with replication.

On a replica, immediately after the XA transaction is prepared, it is detached from the replication applier thread, and can be committed or rolled back by any thread on the replica. This means that the same XA transaction can appear in the `events_transactions_current` table with different states on different threads. The `events_transactions_current` table displays the current status of the most recent monitored transaction event on the thread, and does not update this status when the thread is idle. So the XA transaction can still be displayed in the **PREPARED** state for the original applier thread, after it has been processed by another thread. To positively identify XA transactions that are still in the **PREPARED** state and need to be recovered, use the **XA RECOVER** statement rather than the Performance Schema transaction tables.

The following restrictions exist for using XA transactions:

- The use of replication filters or binary log filters in combination with XA transactions is not supported. Filtering of tables could cause an XA transaction to be empty on a replica, and empty XA transactions are not supported. Also, with the replica's connection metadata repository and applier metadata repository stored in InnoDB tables (the default), the internal state of the data engine transaction is changed following a filtered XA transaction, and can become inconsistent with the replication transaction context state.

  The error **ER_XA_REPLICATION_FILTERS** is logged whenever an XA transaction is impacted by a replication filter, whether or not the transaction was empty as a result. If the transaction is not empty, the replica is able to continue running, but you should take steps to discontinue the use of replication filters with XA transactions in order to avoid potential issues. If the transaction is empty, the replica stops. In that event, the replica might be in an undetermined state in which the consistency of the replication process might be compromised. In particular, the `gtid_executed` set on a replica of the replica might be inconsistent with that on the source. To resolve this situation, isolate the source and stop all replication, then check GTID consistency across the replication topology. Undo the XA transaction that generated the error message, then restart replication.
• XA transactions are considered unsafe for statement-based replication. If two XA transactions committed in parallel on the source are being prepared on the replica in the inverse order, locking dependencies can occur that cannot be safely resolved, and it is possible for replication to fail with deadlock on the replica. This situation can occur for a single-threaded or multithreaded replica. When `binlog_format=STATEMENT` is set, a warning is issued for DML statements inside XA transactions. When `binlog_format=MIXED` or `binlog_format=ROW` is set, DML statements inside XA transactions are logged using row-based replication, and the potential issue is not present.

• You should be aware that, when the same transaction XID is used to execute XA transactions sequentially and a break occurs during the processing of XA COMMIT ... ONE PHASE, it may no longer be possible to synchronize the state between the binary log and the storage engine. This can occur if the series of events just described takes place after this transaction has been prepared in the storage engine, while the XA COMMIT statement is still executing. This is a known issue.

13.4 Replication Statements

Replication can be controlled through the SQL interface using the statements described in this section. Statements are split into a group which controls source servers, a group which controls replica servers, and a group which can be applied to any replication servers.

13.4.1 SQL Statements for Controlling Source Servers

This section discusses statements for managing replication source servers. Section 13.4.2, “SQL Statements for Controlling Replica Servers”, discusses statements for managing replica servers.

In addition to the statements described here, the following `SHOW` statements are used with source servers in replication. For information about these statements, see Section 13.7.7, “SHOW Statements”.

• `SHOW BINARY LOGS`
• `SHOW BINLOG EVENTS`
• `SHOW BINARY LOG STATUS`
• `SHOW REPLICAS`

13.4.1.1 PURGE BINARY LOGS Statement

```
PURGE { BINARY | MASTER } LOGS {  
    TO 'log_name'  
    | BEFORE datetime_expr  
}  
```

The binary log is a set of files that contain information about data modifications made by the MySQL server. The log consists of a set of binary log files, plus an index file (see Section 5.4.4, “The Binary Log”).

The `PURGE BINARY LOGS` statement deletes all the binary log files listed in the log index file prior to the specified log file name or date. `BINARY` and `MASTER` are synonyms. Deleted log files also are removed from the list recorded in the index file, so that the given log file becomes the first in the list.

`PURGE BINARY LOGS` requires the `BINLOG_ADMIN` privilege. This statement has no effect if the server was not started with the `--log-bin` option to enable binary logging.

Examples:

```
PURGE BINARY LOGS TO 'mysql-bin.010';
PURGE BINARY LOGS BEFORE '2019-04-02 22:46:26';
```
The **BEFORE** variant's *datetime_expr* argument should evaluate to a **DATETIME** value (a value in 'yyyy-mm-dd hh:mm:ss' format).

**PURGE BINARY LOGS** is safe to run while replicas are replicating. You need not stop them. If you have an active replica that currently is reading one of the log files you are trying to delete, this statement does not delete the log file that is in use or any log files later than that one, but it deletes any earlier log files. A warning message is issued in this situation. However, if a replica is not connected and you happen to purge one of the log files it has yet to read, the replica cannot replicate after it reconnects.

**PURGE BINARY LOGS** cannot be issued while a **LOCK INSTANCE FOR BACKUP** statement is in effect for the instance, because it contravenes the rules of the backup lock by removing files from the server.

To safely purge binary log files, follow this procedure:

1. On each replica, use **SHOW REPLICA STATUS** to check which log file it is reading.
2. Obtain a listing of the binary log files on the source with **SHOW BINARY LOGS**.
3. Determine the earliest log file among all the replicas. This is the target file. If all the replicas are up to date, this is the last log file on the list.
4. Make a backup of all the log files you are about to delete. (This step is optional, but always advisable.)
5. Purge all log files up to but not including the target file.

**PURGE BINARY LOGS TO** and **PURGE BINARY LOGS BEFORE** both fail with an error when binary log files listed in the .index file had been removed from the system by some other means (such as using `rm` on Linux). (Bug #18199, Bug #18453) To handle such errors, edit the .index file (which is a simple text file) manually to ensure that it lists only the binary log files that are actually present, then run again the **PURGE BINARY LOGS** statement that failed.

Binary log files are automatically removed after the server's binary log expiration period. Removal of the files can take place at startup and when the binary log is flushed. The default binary log expiration period is 30 days. You can specify an alternative expiration period using the **binlog_expire_logs_seconds** system variable. If you are using replication, you should specify an expiration period that is no lower than the maximum amount of time your replicas might lag behind the source.

### 13.4.1.2 **RESET BINARY LOGS AND GTIDS Statement**

**RESET BINARY LOGS AND GTIDS** [TO *binary_log_file_index_number*]

This statement is added in MySQL 8.2.0 as a replacement for **RESET MASTER**, which is now deprecated.

**Warning**

Use this statement with caution to ensure you do not lose any wanted binary log file data and GTID execution history.

**RESET BINARY LOGS AND GTIDS** requires the **RELOAD** privilege.

For a server where binary logging is enabled (*log_bin* is **ON**), **RESET BINARY LOGS AND GTIDS** deletes all existing binary log files and resets the binary log index file, resetting the server to its state before binary logging was started. A new empty binary log file is created so that binary logging can be restarted.

For a server where GTIDs are in use (*gtid_mode* is **ON**), issuing **RESET BINARY LOGS AND GTIDS** resets the GTID execution history. The value of the **gtid_purged** system variable is set to an empty string (**''**), the global value (but not the session value) of the **gtid_executed** system variable is set to an empty string, and the **mysql.gtid_executed** table is cleared (see **mysql.gtid_executed Table**). If
the GTID-enabled server has binary logging enabled, `RESET BINARY LOGS AND GTIDS` also resets the binary log as described above. Note that `RESET BINARY LOGS AND GTIDS` is the method to reset the GTID execution history even if the GTID-enabled server is a replica where binary logging is disabled; `RESET REPLICA` has no effect on the GTID execution history. For more information on resetting the GTID execution history, see *Resetting the GTID Execution History.*

Issuing `RESET BINARY LOGS AND GTIDS` without the optional `TO` clause deletes all binary log files listed in the index file, resets the binary log index file to be empty, and creates a new binary log file starting at 1. Use the optional `TO` clause to start the binary log file index from a number other than 1 after the reset.

Using `RESET BINARY LOGS AND GTIDS` with the `TO` clause to specify a binary log file index number to start from simplifies failover by providing a single statement alternative to the `FLUSH BINARY LOGS` and `PURGE BINARY LOGS TO` statements. Check that you are using a reasonable value for the index number. If you enter an incorrect value, you can correct this by issuing another `RESET BINARY LOGS AND GTIDS` statement with or without the `TO` clause. If you do not correct a value that is out of range, the server cannot be restarted.

The following example demonstrates `TO` clause usage:

```sql
RESET BINARY LOGS AND GTIDS TO 1234;
SHOW BINARY LOGS;
```

```
+-------------------+-----------+-----------+
| Log_name          | File_size | Encrypted |
+-------------------+-----------+-----------+
| source-bin.001234 |       154 | No        |
```

**Important**

The effects of `RESET BINARY LOGS AND GTIDS` without the `TO` clause differ from those of `PURGE BINARY LOGS` in 2 key ways:

1. `RESET BINARY LOGS AND GTIDS` removes all binary log files that are listed in the index file, leaving only a single, empty binary log file with a numeric suffix of `.000001`, whereas the numbering is not reset by `PURGE BINARY LOGS`.

2. `RESET BINARY LOGS AND GTIDS` is *not* intended to be used while any replicas are running. The behavior of `RESET BINARY LOGS AND GTIDS` when used while replicas are running is undefined (and thus unsupported), whereas `PURGE BINARY LOGS` may be safely used while replicas are running.

See also Section 13.4.1.1, “PURGE BINARY LOGS Statement”.

`RESET BINARY LOGS AND GTIDS` without the `TO` clause can prove useful when you first set up a source and replica, so that you can verify the setup as follows:

1. Start the source and replica, and start replication (see Section 17.1.2, “Setting Up Binary Log File Position Based Replication”).

2. Execute a few test queries on the source.

3. Check that the queries were replicated to the replica.

4. When replication is running correctly, issue `STOP REPLICA` followed by `RESET REPLICA` on the replica, then verify that no unwanted data from the test queries exists on the replica.

5. Issue `RESET BINARY LOGS AND GTIDS` on the source to clean up the test queries. You should also verify that there is no unwanted data left over on the master.
After verifying the setup, resetting the source and replica and ensuring that no unwanted data or binary log files generated by testing remain on the source or replica, you can start the replica and begin replicating.

### 13.4.1.3 RESET MASTER Statement

**RESET MASTER**

```
RESET MASTER [TO binary_log_file_index_number]
```

This statement is deprecated and subject to removal in a future release of MySQL. In MySQL 8.2.0 and later, use **RESET BINARY LOGS AND GTIDS** instead.

**Warning**

Use this statement with caution to ensure you do not lose any wanted binary log file data and GTID execution history.

**RESET MASTER** requires the **RELOAD** privilege.

For a server where binary logging is enabled (**log_bin** is **ON**), **RESET MASTER** deletes all existing binary log files and resets the binary log index file, resetting the server to its state before binary logging was started. A new empty binary log file is created so that binary logging can be restarted.

For a server where GTIDs are in use (**gtid_mode** is **ON**), issuing **RESET MASTER** resets the GTID execution history. The value of the **gtid_purged** system variable is set to an empty string (**''**), the global value (but not the session value) of the **gtid_executed** system variable is set to an empty string, and the **mysql.gtid_executed** table is cleared (see **mysql.gtid_executed Table**). If the GTID-enabled server has binary logging enabled, **RESET MASTER** also resets the binary log as described above. Note that **RESET MASTER** is the method to reset the GTID execution history even if the GTID-enabled server is a replica where binary logging is disabled; **RESET REPLICA** has no effect on the GTID execution history. For more information on resetting the GTID execution history, see [Resetting the GTID Execution History](#).

Issuing **RESET MASTER** without the optional **TO** clause deletes all binary log files listed in the index file, resets the binary log index file to be empty, and creates a new binary log file starting at **1**. Use the optional **TO** clause to start the binary log file index from a number other than **1** after the reset.

Using **RESET MASTER** with the **TO** clause to specify a binary log file index number to start from simplifies failover by providing a single statement alternative to the **FLUSH BINARY LOGS** and **PURGE BINARY LOGS TO** statements. Check that you are using a reasonable value for the index number. If you enter an incorrect value, you can correct this by issuing another **RESET MASTER** statement with or without the **TO** clause. If you do not correct a value that is out of range, the server cannot be restarted.

The following example demonstrates **TO** clause usage:

```
RESET MASTER TO 1234;
SHOW BINARY LOGS;
```

<table>
<thead>
<tr>
<th>Log_name</th>
<th>File_size</th>
<th>Encrypted</th>
</tr>
</thead>
<tbody>
<tr>
<td>source-bin.001234</td>
<td>154</td>
<td>No</td>
</tr>
</tbody>
</table>

**Important**

The effects of **RESET MASTER** without the **TO** clause differ from those of **PURGE BINARY LOGS** in 2 key ways:

1. **RESET MASTER** removes all binary log files that are listed in the index file, leaving only a single, empty binary log file with a numeric suffix of **.000001**, whereas the numbering is not reset by **PURGE BINARY LOGS**. 
2. **RESET MASTER** is not intended to be used while any replicas are running. The behavior of **RESET MASTER** when used while replicas are running is undefined (and thus unsupported), whereas **PURGE BINARY LOGS** may be safely used while replicas are running.

**RESET MASTER** without the **TO** clause can prove useful when you first set up a source and replica, so that you can verify the setup as follows:

1. Start the source and replica, and start replication (see Section 17.1.2, “Setting Up Binary Log File Position Based Replication”).
2. Execute a few test queries on the source.
3. Check that the queries were replicated to the replica.
4. When replication is running correctly, issue **STOP REPLICA** followed by **RESET REPLICA** on the replica, then verify that no unwanted data from the test queries exists on the replica.
5. Issue **RESET MASTER** on the source to clean up the test queries.

After verifying the setup, resetting the source and replica and ensuring that no unwanted data or binary log files generated by testing remain on the source or replica, you can start the replica and begin replicating.

### 13.4.1.4 SET sql_log_bin Statement

```
SET sql_log_bin = {OFF|ON}
```

The **sql_log_bin** variable controls whether logging to the binary log is enabled for the current session (assuming that the binary log itself is enabled). The default value is **ON**. To disable or enable binary logging for the current session, set the session **sql_log_bin** variable to **OFF** or **ON**.

Set this variable to **OFF** for a session to temporarily disable binary logging while making changes to the source that you do not want replicated to the replica.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

It is not possible to set the session value of **sql_log_bin** within a transaction or subquery.

*Setting this variable to **OFF** prevents new GTIDs from being assigned to transactions in the binary log.*

If you are using GTIDs for replication, this means that even when binary logging is later enabled again, the GTIDs written into the log from this point do not account for any transactions that occurred in the meantime, so in effect those transactions are lost.

**mysql dump** adds a **SET @@SESSION.sql_log_bin=0** statement to a dump file from a server where GTIDs are in use, which disables binary logging while the dump file is being reloaded. The statement prevents new GTIDs from being generated and assigned to the transactions in the dump file as they are executed, so that the original GTIDs for the transactions are used.

### 13.4.2 SQL Statements for Controlling Replica Servers

This section discusses statements for managing replica servers. Section 13.4.1, “SQL Statements for Controlling Source Servers”, discusses statements for managing source servers.
SQL Statements for Controlling Replica Servers

In addition to the statements described here, **SHOW REPLICA STATUS** and **SHOW RELAYLOG EVENTS** are also used with replicas. For information about these statements, see Section 13.7.7.37, “SHOW REPLICA STATUS Statement”, and Section 13.7.7.34, “SHOW RELAYLOG EVENTS Statement”.

### 13.4.2.1 CHANGE MASTER TO Statement

**CHANGE MASTER TO**

```sql
option [, option] ... [ channel_option ]
```

**option**: {
  MASTER_BIND = 'interface_name'
  MASTER_HOST = 'host_name'
  MASTER_USER = 'user_name'
  MASTER_PASSWORD = 'password'
  MASTER_PORT = port_num
  PRIVILEGE_CHECKS_USER = { 'account' | NULL }
  REQUIRE_ROW_FORMAT = {0|1}
  REQUIRE_TABLE_PRIMARY_KEY_CHECK = {STREAM | ON | OFF}
  ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS = {OFF | LOCAL | uuid}
  MASTER_LOG_FILE = 'source_log_name'
  MASTER_LOG_POS = source_log_pos
  MASTER_AUTO_POSITION = {0|1}
  RELAY_LOG_FILE = 'relay_log_name'
  RELAY_LOG_POS = relay_log_pos
  MASTER_HEARTBEAT_PERIOD = interval
  MASTER_CONNECT_RETRY = interval
  MASTER_RETRY_COUNT = count
  SOURCE_CONNECTION_AUTO_FAILOVER = {0|1}
  MASTER_DELAY = interval
  MASTER_COMPRESSION_ALGORITHMS = 'algorithm[,algorithm][,algorithm]'
  MASTER_ZSTD_COMPRESSION_LEVEL = level
  MASTER_SSL = {0|1}
  MASTER_SSL_CA = 'ca_file_name'
  MASTER_SSL_CERT = 'cert_file_name'
  MASTER_SSL_CRL = 'crl_file_name'
  MASTER_SSL_CRLPATH = 'crl_directory_name'
  MASTER_SSL_KEY = 'key_file_name'
  MASTER_SSL_CIPHER = 'cipher_list'
  MASTER_SSL_VERIFY_SERVER_CERT = {0|1}
  MASTER_TLS_VERSION = 'protocol_list'
  MASTER_TLS_CIPHERSUITES = 'ciphersuite_list'
  MASTER_PUBLIC_KEY_PATH = 'key_file_name'
  IGNORE_SERVER_IDS = (server_id_list),
  GTID_ONLY = {0|1}
}
```

**channel_option**: 
  FOR CHANNEL channel

**server_id_list**: 
  [server_id [, server_id] ... ]

Deprecated alias for **CHANGE REPLICATION SOURCE TO**.

### 13.4.2.2 CHANGE REPLICATION FILTER Statement

**CHANGE REPLICATION FILTER**

```sql
filter[, filter] [, ...] [FOR CHANNEL channel]
```

**filter**: {
  REPLICATE_DO_DB = (db_list)
  REPLICATE_IGNORE_DB = (db_list)
  REPLICATE_DO_TABLE = (tbl_list)
}
SQL Statements for Controlling Replica Servers

```sql
REPLICATE_IGNORE_TABLE = (tbl_list)
REPLICATE_WILD_DO_TABLE = (wild_tbl_list)
REPLICATE_WILD_IGNORE_TABLE = (wild_tbl_list)
REPLICATE_REWRITE_DB = (db_pair_list)
}
```

- `db_list`: `db_name[, db_name][, ...]`
- `tbl_list`: `db_name.table_name[, db_name.table_name][, ...]`
- `wild_tbl_list`: `"db_pattern.table_pattern", "db_pattern.table_pattern"[, ...]`
- `db_pair_list`: `({db_pair}[, (db_pair)][, ...]`
- `db_pair`: `from_db, to_db`

**CHANGE REPLICATION FILTER** sets one or more replication filtering rules on the replica in the same way as starting the replica `mysqld` with replication filtering options such as `--replicate-do-db` or `--replicate-wild-ignore-table`. Filters set using this statement differ from those set using the server options in two key respects:

1. The statement does not require restarting the server to take effect, only that the replication SQL thread be stopped using `STOP REPLICA SQL_THREAD` first (and restarted with `START REPLICA SQL_THREAD` afterwards).
2. The effects of the statement are not persistent; any filters set using `CHANGE REPLICATION FILTER` are lost following a restart of the replica `mysqld`.

**CHANGE REPLICATION FILTER** requires the `REPLICATION_SLAVE_ADMIN` privilege (or the deprecated `SUPER` privilege).

Use the `FOR CHANNEL channel` clause to make a replication filter specific to a replication channel, for example on a multi-source replica. Filters applied without a specific `FOR CHANNEL` clause are considered global filters, meaning that they are applied to all replication channels.

**Note**
Global replication filters cannot be set on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be set on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replica to a source that is outside the group. They cannot be set on the `group_replication_applier` or `group_replication_recovery` channels.

The following list shows the **CHANGE REPLICATION FILTER** options and how they relate to `--replicate-*` server options:

- **REPLICATE_DO_DB**: Include updates based on database name. Equivalent to `--replicate-do-db`.
- **REPLICATE_IGNORE_DB**: Exclude updates based on database name. Equivalent to `--replicate-ignore-db`.
- **REPLICATE_DO_TABLE**: Include updates based on table name. Equivalent to `--replicate-do-table`.
• **REPLICATE_IGNORE_TABLE**: Exclude updates based on table name. Equivalent to `--replicate-ignore-table`.

• **REPLICATE_WILD_DO_TABLE**: Include updates based on wildcard pattern matching table name. Equivalent to `--replicate-wild-do-table`.

• **REPLICATE_WILD_IGNORE_TABLE**: Exclude updates based on wildcard pattern matching table name. Equivalent to `--replicate-wild-ignore-table`.

• **REPLICATE_REWRITE_DB**: Perform updates on replica after substituting new name on replica for specified database on source. Equivalent to `--replicate-rewrite-db`.

The precise effects of **REPLICATE_DO_DB** and **REPLICATE_IGNORE_DB** filters are dependent on whether statement-based or row-based replication is in effect. See Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”, for more information.

Multiple replication filtering rules can be created in a single `CHANGE REPLICATION FILTER` statement by separating the rules with commas, as shown here:

```
CHANGE REPLICATION FILTER
    REPLICATE_DO_DB = (d1), REPLICATE_IGNORE_DB = (d2);
```

Issuing the statement just shown is equivalent to starting the replica `mysqld` with the options `--replicate-do-db=d1 --replicate-ignore-db=d2`.

On a multi-source replica, which uses multiple replication channels to process transaction from different sources, use the `FOR CHANNEL` clause to set a replication filter on a replication channel:

```
CHANGE REPLICATION FILTER REPLICATE_DO_DB = (d1) FOR CHANNEL channel_1;
```

This enables you to create a channel specific replication filter to filter out selected data from a source. When a `FOR CHANNEL` clause is provided, the replication filter statement acts on that replication channel, removing any existing replication filter which has the same filter type as the specified replication filters, and replacing them with the specified filter. Filter types not explicitly listed in the statement are not modified. If issued against a replication channel which is not configured, the statement fails with an `ER_SLAVE_CONFIGURATION` error. If issued against Group Replication channels, the statement fails with an `ER_SLAVE_CHANNEL_OPERATION_NOT_ALLOWED` error.

On a replica with multiple replication channels configured, issuing `CHANGE REPLICATION FILTER` with no `FOR CHANNEL` clause configures the replication filter for every configured replication channel, and for the global replication filters. For every filter type, if the filter type is listed in the statement, then any existing filter rules of that type are replaced by the filter rules specified in the most recently issued statement, otherwise the old value of the filter type is retained. For more information see Section 17.2.5.4, “Replication Channel Based Filters”.

If the same filtering rule is specified multiple times, only the last such rule is actually used. For example, the two statements shown here have exactly the same effect, because the first **REPLICATE_DO_DB** rule in the first statement is ignored:

```
CHANGE REPLICATION FILTER
    REPLICATE_DO_DB = (db1, db2), REPLICATE_DO_DB = (db3, db4);
```

```
CHANGE REPLICATION FILTER
    REPLICATE_DO_DB = (db3, db4);
```

---

**Caution**

This behavior differs from that of the `--replicate-*` filter options where specifying the same option multiple times causes the creation of multiple filter rules.
SQL Statements for Controlling Replica Servers

Names of tables and databases not containing any special characters need not be quoted. Values used with `REPLICATION_WILD_TABLE` and `REPLICATION_WILD_IGNORE_TABLE` are string expressions, possibly containing (special) wildcard characters, and so must be quoted. This is shown in the following example statements:

```sql
CHANGE REPLICATION FILTER
  REPLICATE_WILD_DO_TABLE = ('db1.old%');

CHANGE REPLICATION FILTER
  REPLICATE_WILD_IGNORE_TABLE = ('db1.new%', 'db2.new%');
```

Values used with `REPLICATE_REWRITE_DB` represent pairs of database names; each such value must be enclosed in parentheses. The following statement rewrites statements occurring on database `db1` on the source to database `db2` on the replica:

```sql
CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB = ((db1, db2));
```

The statement just shown contains two sets of parentheses, one enclosing the pair of database names, and the other enclosing the entire list. This is perhaps more easily seen in the following example, which creates two `rewrite-db` rules, one rewriting database `dbA` to `dbB`, and one rewriting database `dbC` to `dbD`:

```sql
CHANGE REPLICATION FILTER
  REPLICATE_REWRITE_DB = ((dbA, dbB), (dbC, dbD));
```

The `CHANGE REPLICATION FILTER` statement replaces replication filtering rules only for the filter types and replication channels affected by the statement, and leaves other rules and channels unchanged. If you want to unset all filters of a given type, set the filter's value to an explicitly empty list, as shown in this example, which removes all existing `REPLICATE_DO_DB` and `REPLICATE_IGNORE_DB` rules:

```sql
CHANGE REPLICATION FILTER
  REPLICATE_DO_DB = (), REPLICATE_IGNORE_DB = ();
```

Setting a filter to empty in this way removes all existing rules, does not create any new ones, and does not restore any rules set at `mysqld` startup using `--replicate-*` options on the command line or in the configuration file.

The `RESET REPLICA ALL` statement removes channel specific replication filters that were set on channels deleted by the statement. When the deleted channel or channels are recreated, any global replication filters specified for the replica are copied to them, and no channel specific replication filters are applied.

For more information, see Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”.

13.4.2.3 CHANGE REPLICATION SOURCE TO Statement

```sql
CHANGE REPLICATION SOURCE TO option [, option] ... [ channel_option ]
```

**option:**

- `SOURCE_BIND = 'interface_name'`
- `SOURCE_HOST = 'host_name'`
- `SOURCE_USER = 'user_name'`
- `SOURCE_PASSWORD = 'password'`
- `SOURCE_PORT = port_num`
- `PRIVILEGE_CHECKS_USER = {NULL | 'account'}`
- `REQUIRE_ROW_FORMAT = {0|1}`
- `REQUIRE_TABLE_PRIMARY_KEY_CHECK = {STREAM | ON | OFF | GENERATE}`
- `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS = {OFF | LOCAL | uuid}`
- `SOURCE_LOG_FILE = 'source_log_name'`
- `SOURCE_LOG_POS = source_log_pos`
SQL Statements for Controlling Replica Servers

```sql
channel_option:
  FOR CHANNEL channel

server_id_list:
  [server_id {, server_id} ... ]

CHANGE REPLICATION SOURCE TO changes the parameters that the replica server uses for connecting to the source and reading data from the source. It also updates the contents of the replication metadata repositories (see Section 17.2.4, “Relay Log and Replication Metadata Repositories”).

CHANGE REPLICATION SOURCE TO requires the REPLICATION_SLAVE_ADMIN privilege (or the deprecated SUPER privilege).

Options that you do not specify on a CHANGE REPLICATION SOURCE TO statement retain their value, except as indicated in the following discussion. In most cases, there is therefore no need to specify options that do not change.

Values used for SOURCE_HOST and other CHANGE REPLICATION SOURCE TO options are checked for linefeed (\n or 0x0A) characters. The presence of such characters in these values causes the statement to fail with an error.

The optional FOR CHANNEL channel clause lets you name which replication channel the statement applies to. Providing a FOR CHANNEL channel clause applies the CHANGE REPLICATION SOURCE TO statement to a specific replication channel, and is used to add a new channel or modify an existing channel. For example, to add a new channel called channel2:

```sql
CHANGE REPLICATION SOURCE TO SOURCE_HOST=host1, SOURCE_PORT=3002 FOR CHANNEL 'channel2';
```

If no clause is named and no extra channels exist, a CHANGE REPLICATION SOURCE TO statement applies to the default channel, whose name is the empty string (“”). When you have set up multiple replication channels, every CHANGE REPLICATION SOURCE TO statement must name a channel using the FOR CHANNEL channel clause. See Section 17.2.2, “Replication Channels” for more information.

For some of the options of the CHANGE REPLICATION SOURCE TO statement, you must issue a STOP REPLICA statement prior to issuing a CHANGE REPLICATION SOURCE TO statement (and a START REPLICA statement afterwards).
REPLICA statement afterwards). Sometimes, you only need to stop the replication SQL (applier) thread or the replication I/O (receiver) thread, not both:

- When the applier thread is stopped, you can execute CHANGE REPLICATION SOURCE TO using any combination that is otherwise allowed of RELAY_LOG_FILE, RELAY_LOG_POS, and SOURCE_DELAY options, even if the replication receiver thread is running. No other options may be used with this statement when the receiver thread is running.

- When the receiver thread is stopped, you can execute CHANGE REPLICATION SOURCE TO using any of the options for this statement (in any allowed combination) except RELAY_LOG_FILE, RELAY_LOG_POS, SOURCE_DELAY, or SOURCE_AUTO_POSITION = 1 even when the applier thread is running.

- Both the receiver thread and the applier thread must be stopped before issuing a CHANGE REPLICATION SOURCE TO statement that employs SOURCE_AUTO_POSITION = 1, GTID_ONLY = 1, or ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS.

You can check the current state of the replication applier thread and replication receiver thread using SHOW REPLICA STATUS. Note that the Group Replication applier channel (group_replication_applier) has no receiver thread, only an applier thread.

CHANGE REPLICATION SOURCE TO statements have a number of side-effects and interactions that you should be aware of beforehand:

- CHANGE REPLICATION SOURCE TO causes an implicit commit of an ongoing transaction. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

- CHANGE REPLICATION SOURCE TO causes the previous values for SOURCE_HOST, SOURCE_PORT, SOURCE_LOG_FILE, and SOURCE_LOG_POS to be written to the error log, along with other information about the replica's state prior to execution.

- If you are using statement-based replication and temporary tables, it is possible for a CHANGE REPLICATION SOURCE TO statement following a STOP REPLICA statement to leave behind temporary tables on the replica. A warning (ER_WARN_OPEN_TEMP_TABLES_MUST_BE_ZERO) is issued whenever this occurs. You can avoid this in such cases by making sure that the value of the Replica_open_temp_tables system status variable is equal to 0 prior to executing such a CHANGE REPLICATION SOURCE TO statement.

- When using a multithreaded replica (replica_parallel_workers > 0), stopping the replica can cause gaps in the sequence of transactions that have been executed from the relay log, regardless of whether the replica was stopped intentionally or otherwise. In MySQL 8.2, these can be resolved using GTID auto-positioning.

The following options are available for CHANGE REPLICATION SOURCE TO statements:

- ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS = {OFF | LOCAL | uuid}

  Makes the replication channel assign a GTID to replicated transactions that do not have one, enabling replication from a source that does not use GTID-based replication, to a replica that does. For a multi-source replica, you can have a mix of channels that use ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS, and channels that do not. The default is OFF, meaning that the feature is not used.

  LOCAL assigns a GTID including the replica's own UUID (the server_uuid setting). uuid assigns a GTID including the specified UUID, such as the server_uuid setting for the replication source server. Using a nonlocal UUID lets you differentiate between transactions that originated on the replica and
transactions that originated on the source, and for a multi-source replica, between transactions that originated on different sources. The UUID you choose only has significance for the replica’s own use. If any of the transactions sent by the source do have a GTID already, that GTID is retained.

Channels specific to Group Replication cannot use `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS`, but an asynchronous replication channel for another source on a server instance that is a Group Replication group member can do so. In that case, do not specify the Group Replication group name as the UUID for creating the GTIDs.

To set `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` to `LOCAL` or `uuid`, the replica must have `gtid_mode=ON` set, and this cannot be changed afterwards. This option is for use with a source that has binary log file position based replication, so `SOURCE_AUTO_POSITION=1` cannot be set for the channel. Both the replication SQL thread and the replication I/O (receiver) thread must be stopped before setting this option.

**Important**

A replica set up with `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` on any channel cannot be promoted to replace the replication source server in the event that a failover is required, and a backup taken from the replica cannot be used to restore the replication source server. The same restriction applies to replacing or restoring other replicas that use `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` on any channel.

For further restrictions and information, see Section 17.1.3.6, “Replication From a Source Without GTIDs to a Replica With GTIDs”.

- **GET_SOURCE_PUBLIC_KEY = {0|1}**

  Enables RSA key pair-based password exchange by requesting the public key from the source. The option is disabled by default.

  This option applies to replicas that authenticate with the `caching_sha2_password` authentication plugin. For connections by accounts that authenticate using this plugin, the source does not send the public key unless requested, so it must be requested or specified in the client. If `SOURCE_PUBLIC_KEY_PATH` is given and specifies a valid public key file, it takes precedence over `GET_SOURCE_PUBLIC_KEY`. If you are using a replication user account that authenticates with the `caching_sha2_password` plugin (the default), and you are not using a secure connection, you must specify either this option or the `SOURCE_PUBLIC_KEY_PATH` option to provide the RSA public key to the replica.

- **GTID_ONLY = {0|1}**

  Stops the replication channel persisting file names and file positions in the replication metadata repositories. `GTID_ONLY` is disabled by default for asynchronous replication channels, but is enabled by default for Group Replication channels, for which it cannot be disabled.

  For replication channels with this setting, in-memory file positions are still tracked, and file positions can still be observed for debugging purposes in error messages and through interfaces such as `SHOW REPLICA STATUS` statements (where they are shown as being invalid if they are out of date). However, the writes and reads required to persist and check the file positions are avoided in situations where GTID-based replication does not actually require them, including the transaction queuing and application process.

  This option can be used only if both the replication SQL (applier) thread and replication I/O (receiver) thread are stopped. To set `GTID_ONLY = 1` for a replication channel, GTIDs must be in use.
on the server (gtid_mode = ON), and row-based binary logging must be in use on the source
(statement-based replication is not supported). The options REQUIRE_ROW_FORMAT = 1 and
SOURCE_AUTO_POSITION = 1 must be set for the replication channel.

When GTID_ONLY = 1 is set, the replica uses replica_parallel_workers=1 if that system
variable is set to zero for the server, so it is always technically a multi-threaded applier. This is because
a multi-threaded applier uses saved positions rather than the replication metadata repositories to locate
the start of a transaction that it needs to reapply.

If you disable GTIDONLY after setting it, the existing relay logs are deleted and the existing known
binary log file positions are persisted, even if they are stale. The file positions for the binary log and relay
log in the replication metadata repositories might be invalid, and a warning is returned if this is the case.
Provided that SOURCE_AUTO_POSITION is still enabled, GTID auto-positioning is used to provide the
correct positioning.

If you also disable SOURCE_AUTO_POSITION, the file positions for the binary log and relay log in the
replication metadata repositories are used for positioning if they are valid. If they are marked as invalid,
you must provide a valid binary log file name and position (SOURCE_LOG_FILE and
SOURCE_LOG_POS). If you also provide a relay log file name and position (RELAY_LOG_FILE and RELAY_LOG_POS),
the relay logs are preserved and the applier position is set to the stated position. GTID auto-skip ensures
that any transactions already applied are skipped even if the eventual applier position is not correct.

- IGNORE_SERVER_IDS = (server_id_list)

Makes the replica ignore events originating from the specified servers. The option takes a comma-
separated list of 0 or more server IDs. Log rotation and deletion events from the servers are not ignored,
and are recorded in the relay log.

In circular replication, the originating server normally acts as the terminator of its own events, so that
they are not applied more than once. Thus, this option is useful in circular replication when one of the
servers in the circle is removed. Suppose that you have a circular replication setup with 4 servers,
having server IDs 1, 2, 3, and 4, and server 3 fails. When bridging the gap by starting replication from
server 2 to server 4, you can include IGNORE_SERVER_IDS = (3) in the CHANGE_REPLICATION
SOURCE TO statement that you issue on server 4 to tell it to use server 2 as its source instead of server
3. Doing so causes it to ignore and not to propagate any statements that originated with the server that is
no longer in use.

If IGNORE_SERVER_IDS contains the server's own ID and the server was started with the --
replicate-same-server-id option enabled, an error results.

Note

When global transaction identifiers (GTIDs) are used for replication, transactions that have already been applied are automatically ignored, so
the IGNORE_SERVER_IDS function is not required and is deprecated. If
`gtid_mode=ON` is set for the server, a deprecation warning is issued if you
include the IGNORE_SERVER_IDS option in a CHANGE_REPLICATION SOURCE TO statement.

The source metadata repository and the output of `SHOW REPLICA STATUS` provide the list of
servers that are currently ignored. For more information, see Section 17.2.4.2, “Replication Metadata
Repositories”, and Section 13.7.7.37, “SHOW REPLICA STATUS Statement”.

If a CHANGE_REPLICATION SOURCE TO statement is issued without any IGNORE_SERVER_IDS option,
any existing list is preserved. To clear the list of ignored servers, it is necessary to use the option with an
empty list:
SQL Statements for Controlling Replica Servers

```
CHANGE REPLICA SOURCE TO IGNORE_SERVER_IDS = ();

RESET REPLICA ALL clears IGNORE_SERVER_IDS.
```

**Note**

A deprecation warning is issued if `SET GTID_MODE=ON` is issued when any channel has existing server IDs set with `IGNORE_SERVER_IDS`. Before starting GTID-based replication, check for and clear all ignored server ID lists on the servers involved. The `SHOW REPLICA STATUS` statement displays the list of ignored IDs, if there is one. If you do receive the deprecation warning, you can still clear a list after `gtid_mode=ON` is set by issuing a `CHANGE REPLICA SOURCE TO` statement containing the `IGNORE_SERVER_IDS` option with an empty list.

- `NETWORK_NAMESPACE = 'namespace'`

  The network namespace to use for TCP/IP connections to the replication source server or, if the MySQL communication stack is in use, for Group Replication’s group communication connections. The maximum length of the string value is 64 characters. If this option is omitted, connections from the replica use the default (global) namespace. On platforms that do not implement network namespace support, failure occurs when the replica attempts to connect to the source. For information about network namespaces, see Section 5.1.14, “Network Namespace Support”.

- `PRIVILEGE_CHECKS_USER = {NULL | 'account'}`

  Names a user account that supplies a security context for the specified channel. `NULL`, which is the default, means no security context is used.

  The user name and host name for the user account must follow the syntax described in Section 6.2.4, “Specifying Account Names”, and the user must not be an anonymous user (with a blank user name) or the `CURRENT_USER`. The account must have the `REPLICATION_APPLIER` privilege, plus the required privileges to execute the transactions replicated on the channel. For details of the privileges required by the account, see Section 17.3.3, “Replication Privilege Checks”. When you restart the replication channel, the privilege checks are applied from that point on. If you do not specify a channel and no other channels exist, the statement is applied to the default channel.

  The use of row-based binary logging is strongly recommended when `PRIVILEGE_CHECKS_USER` is set, and you can set `REQUIRE_ROW_FORMAT` to enforce this. For example, to start privilege checks on the channel `channel_1` on a running replica, issue the following statements:

```
STOP REPLICA FOR CHANNEL 'channel_1';

CHANGE REPLICA SOURCE TO
  PRIVILEGE_CHECKS_USER = 'user'@'host',
  REQUIRE_ROW_FORMAT = 1,
  FOR CHANNEL 'channel_1';

START REPLICA FOR CHANNEL 'channel_1';
```

- `RELAY_LOG_FILE = 'relay_log_file', RELAY_LOG_POS = 'relay_log_pos'`

  The relay log file name, and the location in that file, at which the replication SQL thread begins reading from the replica’s relay log the next time the thread starts. `RELAY_LOG_FILE` can use either an absolute
or relative path, and uses the same base name as `SOURCE_LOG_FILE`. The maximum length of the string value is 511 characters.

A `CHANGE_REPLICATION_SOURCE_TO` statement using `RELAY_LOG_FILE`, `RELAY_LOG_POS`, or both options can be executed on a running replica when the replication SQL (applier) thread is stopped. Relay logs are preserved if at least one of the replication applier thread and the replication I/O (receiver) thread is running. If both threads are stopped, all relay log files are deleted unless at least one of `RELAY_LOG_FILE` or `RELAY_LOG_POS` is specified. For the Group Replication applier channel (`group_replication_applier`), which only has an applier thread and no receiver thread, this is the case if the applier thread is stopped, but with that channel you cannot use the `RELAY_LOG_FILE` and `RELAY_LOG_POS` options.

- `REQUIRE_ROW_FORMAT = \{0 \mid 1\}`

Permits only row-based replication events to be processed by the replication channel. This option prevents the replication applier from taking actions such as creating temporary tables and executing `LOAD DATA INFILE` requests, which increases the security of the channel. The `REQUIRE_ROW_FORMAT` option is disabled by default for asynchronous replication channels, but it is enabled by default for Group Replication channels, and it cannot be disabled for them. For more information, see Section 17.3.3, “Replication Privilege Checks”.

- `REQUIRE_TABLE_PRIMARY_KEY_CHECK = \{STREAM \mid ON \mid OFF \mid GENERATE\}`

This option lets a replica set its own policy for primary key checks, as follows:

- **ON**: The replica sets `sql_require_primary_key = ON`; any replicated `CREATE_TABLE` or `ALTER_TABLE` statement must result in a table that contains a primary key.

- **OFF**: The replica sets `sql_require_primary_key = OFF`; no replicated `CREATE_TABLE` or `ALTER_TABLE` statement is checked for the presence of a primary key.

- **STREAM**: The replica uses whatever value of `sql_require_primary_key` is replicated from the source for each transaction. This is the default value, and the default behavior.

- **GENERATE**: Causes the replica to generate an invisible primary key for any InnoDB table that, as replicated, lacks a primary key. See Section 13.1.20.11, “Generated Invisible Primary Keys”, for more information.

`GENERATE` is not compatible with Group Replication; you can use `ON`, `OFF`, or `STREAM`.

A divergence based on the presence of a generated invisible primary key solely on a source or replica table is supported by MySQL Replication as long as the source supports GIPKs and the replica uses MySQL version 8.0.32 or later. If you use GIPKs on a replica with the source using an earlier version of MySQL, such divergences in schema, other than the extra GIPK on the replica, are not supported and may result in replication errors.

For multisource replication, setting `REQUIRE_TABLE_PRIMARY_KEY_CHECK` to `ON` or `OFF` lets the replica normalize behavior across replication channels for different sources, and to keep a consistent setting for `sql_require_primary_key`. Using `ON` safeguards against the accidental loss of primary keys when multiple sources update the same set of tables. Using `OFF` lets sources that can manipulate primary keys to work alongside sources that cannot.

In the case of multiple replicas, when `REQUIRE_TABLE_PRIMARY_KEY_CHECK` is set to `GENERATE`, the generated invisible primary key added by a given replica is independent of any such key added on any other replica. This means that, if generated invisible primary keys are in use, the values in the generated
primary key columns on different replicas are not guaranteed to be the same. This may be an issue when failing over to such a replica.

When PRIVILEGE_CHECKS_USER is NULL (the default), the user account does not need administration level privileges to set restricted session variables. Setting this option to a value other than NULL means that, when REQUIRE_TABLE_PRIMARY_KEY_CHECK is ON or OFF, the user account does not require session administration level privileges to set restricted session variables such as sql_require_primary_key, avoiding the need to grant the account such privileges. (Such privileges are required when PRIVILEGE_CHECKS_USER is STREAM or GENERATE.) For more information, see Section 17.3.3, “Replication Privilege Checks”.

• SOURCE_AUTO_POSITION = {0|1}

Makes the replica attempt to connect to the source using the auto-positioning feature of GTID-based replication, rather than a binary log file based position. This option is used to start a replica using GTID-based replication. The default is 0, meaning that GTID auto-positioning and GTID-based replication are not used. This option can be used with CHANGE REPLICATION SOURCE TO only if both the replication SQL (applier) thread and replication I/O (receiver) thread are stopped.

Both the replica and the source must have GTIDs enabled (GTID_MODE=ON, ON_PERMISSIVE, or OFF_PERMISSIVE on the replica, and GTID_MODE=ON on the source). SOURCE_LOG_FILE, SOURCE_LOG_POS, RELAY_LOG_FILE, and RELAY_LOG_POS cannot be specified together with SOURCE_AUTO_POSITION = 1. If multi-source replication is enabled on the replica, you need to set the SOURCE_AUTO_POSITION = 1 option for each applicable replication channel.

With SOURCE_AUTO_POSITION = 1 set, in the initial connection handshake, the replica sends a GTID set containing the transactions that it has already received, committed, or both. The source responds by sending all transactions recorded in its binary log whose GTID is not included in the GTID set sent by the replica. This exchange ensures that the source only sends the transactions with a GTID that the replica has not already recorded or committed. If the replica receives transactions from more than one source, as in the case of a diamond topology, the auto-skip function ensures that the transactions are not applied twice. For details of how the GTID set sent by the replica is computed, see Section 17.1.3.3, “GTID Auto-Positioning”.

If any of the transactions that should be sent by the source have been purged from the source’s binary log, or added to the set of GTIDs in the gtid_purged system variable by another method, the source sends the error ER_MASTER_HAS_PURGED_REQUIRED_GTIDS to the replica, and replication does not start. The GTIDs of the missing purged transactions are identified and listed in the source’s error log in the warning message ER_FOUND_MISSING_GTIDS. Also, if during the exchange of transactions it is found that the replica has recorded or committed transactions with the source’s UUID in the GTID, but the source itself has not committed them, the source sends the error ER_SLAVE_HAS_MORE_GTIDS_THAN_MASTER to the replica and replication does not start. For information on how to handle these situations, see Section 17.1.3.3, “GTID Auto-Positioning”.

You can see whether replication is running with GTID auto-positioning enabled by checking the Performance Schema replication_connection_status table or the output of SHOW REPLICA STATUS. Disabling the SOURCE_AUTO_POSITION option again makes the replica revert to file-based replication.
• **SOURCE_BIND = 'interface_name'**

Determines which of the replica's network interfaces is chosen for connecting to the source, for use on replicas that have multiple network interfaces. Specify the IP address of the network interface. The maximum length of the string value is 255 characters.

The IP address configured with this option, if any, can be seen in the **Source_Bind** column of the output from **SHOW REPLICA STATUS**. In the source metadata repository table **mysql.slave_master_info**, the value can be seen as the **Source_bind** column. The ability to bind a replica to a specific network interface is also supported by NDB Cluster.

• **SOURCE_COMPRESSION_ALGORITHMS = 'algorithm[,algorithm][,algorithm]'**

Specifies one, two, or three of the permitted compression algorithms for connections to the replication source server, separated by commas. The maximum length of the string value is 99 characters. The default value is **uncompressed**.

The available algorithms are **zlib**, **zstd**, and **uncompressed**, the same as for the **protocol_compression_algorithms** system variable. The algorithms can be specified in any order, but it is not an order of preference - the algorithm negotiation process attempts to use **zlib**, then **zstd**, then **uncompressed**, if they are specified.

The value of **SOURCE_COMPRESSION_ALGORITHMS** applies only if the **replica_compressed_protocol** system variable is disabled. If **replica_compressed_protocol** is enabled, it takes precedence over **SOURCE_COMPRESSION_ALGORITHMS** and connections to the source use **zlib** compression if both source and replica support that algorithm. For more information, see Section 4.2.8, “Connection Compression Control”.

Binary log transaction compression is activated by the **binlog_transaction_compression** system variable, and can also be used to save bandwidth. If you do this in combination with connection compression, connection compression has less opportunity to act on the data, but can still compress headers and those events and transaction payloads that are uncompressed. For more information on binary log transaction compression, see Section 5.4.4.5, “Binary Log Transaction Compression”.

• **SOURCE_CONNECT_RETRY = interval**

Specifies the interval in seconds between the reconnection attempts that the replica makes after the connection to the source times out. The default interval is 60.

The number of attempts is limited by the **SOURCE_RETRY_COUNT** option. If both the default settings are used, the replica waits 60 seconds between reconnection attempts (**SOURCE_CONNECT_RETRY=60**), and keeps attempting to reconnect at this rate for 10 minutes (**SOURCE_RETRY_COUNT=10**). These values are recorded in the source metadata repository and shown in the **replication_connection_configuration** Performance Schema table.

• **SOURCE_CONNECTION_AUTO_FAILOVER = {0|1}**

Activates the asynchronous connection failover mechanism for a replication channel if one or more alternative replication source servers are available (so when there are multiple MySQL servers or groups of servers that share the replicated data). The default is 0, meaning that the mechanism is not activated. For full information and instructions to set up this feature, see Section 17.4.9.2, “Asynchronous Connection Failover for Replicas”.

The asynchronous connection failover mechanism takes over after the reconnection attempts controlled by **SOURCE_CONNECT_RETRY** and **SOURCE_RETRY_COUNT** are exhausted. It reconnects the replica to an alternative source chosen from a specified source list, which you can
manage using the functions `asynchronous_connection_failover_add_source()` and `asynchronous_connection_failover_delete_source()`. To add and remove managed groups of servers, use `asynchronous_connection_failover_add_managed()` and `asynchronous_connection_failover_delete_managed()` instead. For more information, see Section 17.4.9, “Switching Sources and Replicas with Asynchronous Connection Failover”.

**Important**

1. You can only set `SOURCE_CONNECTION_AUTO_FAILOVER = 1` when GTID auto-positioning is in use (`SOURCE_AUTO_POSITION = 1`).

2. When you set `SOURCE_CONNECTION_AUTO_FAILOVER = 1`, set `SOURCE_RETRY_COUNT` and `SOURCE_CONNECT_RETRY` to minimal numbers that just allow a few retry attempts with the same source, in case the connection failure is caused by a transient network outage. Otherwise the asynchronous connection failover mechanism cannot be activated promptly. Suitable values are `SOURCE_RETRY_COUNT=3` and `SOURCE_CONNECT_RETRY=10`, which make the replica retry the connection 3 times with 10-second intervals between.

3. When you set `SOURCE_CONNECTION_AUTO_FAILOVER = 1`, the replication metadata repositories must contain the credentials for a replication user account that can be used to connect to all the servers on the source list for the replication channel. The account must also have `SELECT` permissions on the Performance Schema tables. These credentials can be set using the `CHANGE_REPLICATION_SOURCE_TO` statement with the `SOURCE_USER` and `SOURCE_PASSWORD` options. For more information, see Section 17.4.9, “Switching Sources and Replicas with Asynchronous Connection Failover”.

4. When you set `SOURCE_CONNECTION_AUTO_FAILOVER = 1`, asynchronous connection failover for replicas is automatically activated if this replication channel is on a Group Replication primary in a group in single-primary mode. With this function active, if the primary that is replicating goes offline or into an error state, the new primary starts replication on the same channel when it is elected. If you want to use the function, this replication channel must also be set up on all the secondary servers in the replication group, and on any new joining members. (If the servers are provisioned using MySQL’s clone functionality, this all happens automatically.) If you do not want to use the function, disable it by using the `group_replication_disable_member_action()` function to disable the Group Replication member action `mysql_start_failover_channels_if_primary`, which is enabled by default. For more information, see Section 17.4.9.2, “Asynchronous Connection Failover for Replicas”.

- **SOURCE_DELAY = interval**

  Specifies how many seconds behind the source the replica must lag. An event received from the source is not executed until at least `interval` seconds later than its execution on the source. `interval` must be a nonnegative integer in the range from 0 to $2^{31} - 1$. The default is 0. For more information, see Section 17.4.11, “Delayed Replication”.

  A `CHANGE_REPLICATION_SOURCE_TO` statement using the `SOURCE_DELAY` option can be executed on a running replica when the replication SQL thread is stopped.
• **SOURCE_HEARTBEAT_PERIOD = interval**

Controls the heartbeat interval, which stops the connection timeout occurring in the absence of data if the connection is still good. A heartbeat signal is sent to the replica after that number of seconds, and the waiting period is reset whenever the source's binary log is updated with an event. Heartbeats are therefore sent by the source only if there are no unsent events in the binary log file for a period longer than this.

The heartbeat interval *interval* is a decimal value having the range 0 to 4294967 seconds and a resolution in milliseconds; the smallest nonzero value is 0.001. Setting *interval* to 0 disables heartbeats altogether. The heartbeat interval defaults to half the value of the *replica_net_timeout* system variable. It is recorded in the source metadata repository and shown in the *replication_connection_configuration* Performance Schema table.

The *replica_net_timeout* system variable specifies the number of seconds that the replica waits for either more data or a heartbeat signal from the source, before the replica considers the connection broken, aborts the read, and tries to reconnect. The default value is 60 seconds (one minute). Note that a change to the value or default setting of *replica_net_timeout* does not automatically change the heartbeat interval, whether that has been set explicitly or is using a previously calculated default. A warning is issued if you set the global value of *replica_net_timeout* to a value less than that of the current heartbeat interval. If *replica_net_timeout* is changed, you must also issue `CHANGE REPLICATION SOURCE TO` to adjust the heartbeat interval to an appropriate value so that the heartbeat signal occurs before the connection timeout. If you do not do this, the heartbeat signal has no effect, and if no data is received from the source, the replica can make repeated reconnection attempts, creating zombie dump threads.

• **SOURCE_HOST = 'host_name'**

The host name or IP address of the replication source server. The replica uses this to connect to the source. The maximum length of the string value is 255 characters.

If you specify *SOURCE_HOST* or *SOURCE_PORT*, the replica assumes that the source server is different from before (even if the option value is the same as its current value.) In this case, the old values for the source's binary log file name and position are considered no longer applicable, so if you do not specify *SOURCE_LOG_FILE* and *SOURCE_LOG_POS* in the statement, *SOURCE_LOG_FILE=''* and *SOURCE_LOG_POS=4* are silently appended to it.

Setting *SOURCE_HOST=''* (that is, setting its value explicitly to an empty string) is *not* the same as not setting *SOURCE_HOST* at all. Trying to set *SOURCE_HOST* to an empty string fails with an error.
SQL Statements for Controlling Replica Servers

- **SOURCE_LOG_FILE = 'source_log_name', SOURCE_LOG_POS = source_log_pos**

  The binary log file name, and the location in that file, at which the replication I/O (receiver) thread begins reading from the source's binary log the next time the thread starts. Specify these options if you are using binary log file position based replication.

  **SOURCE_LOG_FILE** must include the numeric suffix of a specific binary log file that is available on the source server, for example, **SOURCE_LOG_FILE='binlog.000145'**. The maximum length of the string value is 511 characters.

  **SOURCE_LOG_POS** is the numeric position for the replica to start reading in that file. **SOURCE_LOG_POS=4** represents the start of the events in a binary log file.

  If you specify either of **SOURCE_LOG_FILE** or **SOURCE_LOG_POS**, you cannot specify **SOURCE_AUTO_POSITION = 1**, which is for GTID-based replication.

  If neither of **SOURCE_LOG_FILE** or **SOURCE_LOG_POS** is specified, the replica uses the last coordinates of the replication SQL thread before **CHANGE REPLICATION SOURCE TO** was issued. This ensures that there is no discontinuity in replication, even if the replication SQL (applier) thread was late compared to the replication I/O (receiver) thread.

- **SOURCE_PASSWORD = 'password'**

  The password for the replication user account to use for connecting to the replication source server. The maximum length of the string value is 32 characters. If you specify **SOURCE_PASSWORD**, **SOURCE_USER** is also required.

  The password used for a replication user account in a **CHANGE REPLICATION SOURCE TO** statement is limited to 32 characters in length. Trying to use a password of more than 32 characters causes **CHANGE REPLICATION SOURCE TO** to fail.

  The password is masked in MySQL Server’s logs, Performance Schema tables, and **SHOW PROCESSLIST** statements.

- **SOURCE_PORT = port_num**

  The TCP/IP port number that the replica uses to connect to the replication source server.

  **Note**

  Replication cannot use Unix socket files. You must be able to connect to the replication source server using TCP/IP.

  If you specify **SOURCE_HOST** or **SOURCE_PORT**, the replica assumes that the source server is different from before (even if the option value is the same as its current value.) In this case, the old values for the source's binary log file name and position are considered no longer applicable, so if you do not specify **SOURCE_LOG_FILE** and **SOURCE_LOG_POS** in the statement, **SOURCE_LOG_FILE=''** and **SOURCE_LOG_POS=4** are silently appended to it.

- **SOURCE_PUBLIC_KEY_PATH = 'key_file_name'**

  Enables RSA key pair-based password exchange by providing the path name to a file containing a replica-side copy of the public key required by the source. The file must be in PEM format. The maximum length of the string value is 511 characters.

  This option applies to replicas that authenticate with the **sha256_password** or **caching_sha2_password** authentication plugin. (For **sha256_password**,}
**SOURCE_PUBLIC_KEY_PATH** can be used only if MySQL was built using OpenSSL.) If you are using a replication user account that authenticates with the *caching_sha2_password* plugin (the default), and you are not using a secure connection, you must specify either this option or the *GET_SOURCE_PUBLIC_KEY=1* option to provide the RSA public key to the replica.

- **SOURCE_RETRY_COUNT = count**

Sets the maximum number of reconnection attempts that the replica makes after the connection to the source times out, as determined by the *replica_net_timeout* system variable. If the replica does need to reconnect, the first retry occurs immediately after the timeout. The default is 10 attempts.

**Note**

The default value for **SOURCE_RETRY_COUNT** in MySQL 8.1 is 10; this differs from previous releases.

The interval between the attempts is specified by the **SOURCE_CONNECT_RETRY** option. If both the default settings are used, the replica waits 60 seconds between reconnection attempts (**SOURCE_CONNECT_RETRY=60**), and keeps attempting to reconnect at this rate for 10 minutes (**SOURCE_RETRY_COUNT=10**). A setting of 0 for **SOURCE_RETRY_COUNT** means that there is no limit on the number of reconnection attempts, so the replica keeps trying to reconnect indefinitely.

The values for **SOURCE_CONNECT_RETRY** and **SOURCE_RETRY_COUNT** are recorded in the source metadata repository and shown in the *replication_connection_configuration* Performance Schema table. **SOURCE_RETRY_COUNT** supersedes the **--master-retry-count** server startup option.

- **SOURCE_SSL = {0|1}**

Specify whether the replica encrypts the replication connection. The default is 0, meaning that the replica does not encrypt the replication connection. If you set **SOURCE_SSL=1**, you can configure the encryption using the **SOURCE_SSL_***xxx*** and **SOURCE_TLS_***xxx*** options.

Setting **SOURCE_SSL=1** for a replication connection and then setting no further **SOURCE_SSL_***xxx*** options corresponds to setting **--ssl-mode=REQUIRED** for the client, as described in Command Options for Encrypted Connections. With **SOURCE_SSL=1**, the connection attempt only succeeds if an encrypted connection can be established. A replication connection does not fall back to an unencrypted connection, so there is no setting corresponding to the **--ssl-mode=PREFERRED** setting for replication. If **SOURCE_SSL=0** is set, this corresponds to **--ssl-mode=DISABLED**.

**Important**

To help prevent sophisticated man-in-the-middle attacks, it is important for the replica to verify the server’s identity. You can specify additional **SOURCE_SSL_***xxx*** options to correspond to the settings **--ssl-mode=VERIFY_CA** and **--ssl-mode=VERIFY_IDENTITY**, which are a better choice than the default setting to help prevent this type of attack. With these settings, the replica checks that the server’s certificate is valid, and checks that the host name the replica is using matches the identity in the server’s certificate.

To implement one of these levels of verification, you must first ensure that the CA certificate for the server is reliably available to the replica, otherwise availability issues will result. For this reason, they are not the default setting.
• **SOURCE_SSL_xxx**, **SOURCE_TLS_xxx**

Specify how the replica uses encryption and ciphers to secure the replication connection. These options can be changed even on replicas that are compiled without SSL support. They are saved to the source metadata repository, but are ignored if the replica does not have SSL support enabled. The maximum length of the value for the string-valued `SOURCE_SSL_xxx` and `SOURCE_TLS_xxx` options is 511 characters, with the exception of `SOURCE_TLS_CIPHERSUITES`, for which it is 4000 characters.

The `SOURCE_SSL_xxx` and `SOURCE_TLS_xxx` options perform the same functions as the `--ssl-xxx` and `--tls-xxx` client options described in [Command Options for Encrypted Connections](#). The correspondence between the two sets of options, and the use of the `SOURCE_SSL_xxx` and `SOURCE_TLS_xxx` options to set up a secure connection, is explained in [Section 17.3.1, “Setting Up Replication to Use Encrypted Connections”](#).

• **SOURCE_USER = 'user_name'**

The user name for the replication user account to use for connecting to the replication source server. The maximum length of the string value is 96 characters.

For Group Replication, this account must exist on every member of the replication group. It is used for distributed recovery if the XCom communication stack is in use for the group, and also used for group communication connections if the MySQL communication stack is in use for the group. With the MySQL communication stack, the account must have the `GROUP_REPLICATION_STREAM` permission.

It is possible to set an empty user name by specifying `SOURCE_USER=''`, but the replication channel cannot be started with an empty user name. It is valid to set an empty `SOURCE_USER` user name and use the channel afterwards if you always provide user credentials using the `START REPLICA` statement or `START GROUP_REPLICATION` statement that starts the replication channel. This approach means that the replication channel always needs operator intervention to restart, but the user credentials are not recorded in the replication metadata repositories.

---

⚠️ **Important**

To connect to the source using a replication user account that authenticates with the `caching_sha2_password` plugin, you must either set up a secure connection as described in [Section 17.3.1, “Setting Up Replication to Use Encrypted Connections”](#), or enable the unencrypted connection to support password exchange using an RSA key pair. The `caching_sha2_password` authentication plugin is the default for new users (see [Section 6.4.1.2, “Caching SHA-2 Pluggable Authentication”](#)). If the user account that you create or use for replication uses this authentication plugin, and you are not using a secure connection, you must enable RSA key pair-based password exchange for a successful connection. You can do this using either the `SOURCE_PUBLIC_KEY_PATH` option or the `GET_SOURCE_PUBLIC_KEY=1` option for this statement.

• **SOURCE_ZSTD_COMPRESSION_LEVEL = level**

The compression level to use for connections to the replication source server that use the `zstd` compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression. The default level is 3.

The compression level setting has no effect on connections that do not use `zstd` compression. For more information, see [Section 4.2.8, “Connection Compression Control”](#).
Examples

**CHANGE REPLICATION SOURCE TO** is useful for setting up a replica when you have the snapshot of the source and have recorded the source's binary log coordinates corresponding to the time of the snapshot. After loading the snapshot into the replica to synchronize it with the source, you can run **CHANGE REPLICATION SOURCE TO** on the replica to specify the coordinates at which the replica should begin reading the source's binary log. The following example changes the source server the replica uses and establishes the source's binary log coordinates from which the replica begins reading:

```
CHANGE REPLICATION SOURCE TO
  SOURCE_HOST='source2.example.com',
  SOURCE_USER='replication',
  SOURCE_PASSWORD='password',
  SOURCE_PORT=3306,
  SOURCE_LOG_FILE='source2-bin.001',
  SOURCE_LOG_POS=4,
  SOURCE_CONNECT_RETRY=10;
```

For the procedure to switch an existing replica to a new source during failover, see Section 17.4.8, “Switching Sources During Failover”.

When GTIDs are in use on the source and the replica, specify GTID auto-positioning instead of giving the binary log file position, as in the following example. For full instructions to configure and start GTID-based replication on new or stopped servers, online servers, or additional replicas, see Section 17.1.3, “Replication with Global Transaction Identifiers”.

```
CHANGE REPLICATION SOURCE TO
  SOURCE_HOST='source3.example.com',
  SOURCE_USER='replication',
  SOURCE_PASSWORD='password',
  SOURCE_PORT=3306,
  SOURCE_AUTO_POSITION = 1,
  FOR CHANNEL "source_3";
```

In this example, multi-source replication is in use, and the **CHANGE REPLICATION SOURCE TO** statement is applied to the replication channel "source_3" that connects the replica to the specified host. For guidance on setting up multi-source replication, see Section 17.1.5, “MySQL Multi-Source Replication”.

The next example shows how to make the replica apply transactions from relay log files that you want to repeat. To do this, the source need not be reachable. You can use **CHANGE REPLICATION SOURCE TO** to locate the relay log position where you want the replica to start reapplying transactions, and then start the SQL thread:

```
CHANGE REPLICATION SOURCE TO
  RELAY_LOG_FILE='replica-relay-bin.006',
  RELAY_LOG_POS=4025;
START REPLICA SQL_THREAD;
```

**CHANGE REPLICATION SOURCE TO** can also be used to skip over transactions in the binary log that are causing replication to stop. The appropriate method to do this depends on whether GTIDs are in use or not. For instructions to skip transactions using **CHANGE REPLICATION SOURCE TO** or another method, see Section 17.1.7.3, “Skipping Transactions”.

### 13.4.2.4 RESET REPLICA Statement

**RESET REPLICA [ALL] [channel_option]**

**channel_option:**
- **FOR CHANNEL channel**
**RESET REPLICA** makes the replica forget its position in the source’s binary log.

This statement is meant to be used for a clean start; it clears the replication metadata repositories, deletes all the relay log files, and starts a new relay log file. It also resets to 0 the replication delay specified with the **SOURCE_DELAY** option of the **CHANGE REPLICATION SOURCE TO** statement.

**Note**

All relay log files are deleted, even if they have not been completely executed by the replication SQL thread. (This is a condition likely to exist on a replica if you have issued a **STOP REPLICA** statement or if the replica is highly loaded.)

For a server where GTIDs are in use (**gtid_mode** is **ON**), issuing **RESET REPLICA** has no effect on the GTID execution history. The statement does not change the values of **gtid_executed** or **gtid_purged**, or the **mysql.gtid_executed** table. If you need to reset the GTID execution history, use **RESET BINARY LOGS AND GTIDS**, even if the GTID-enabled server is a replica where binary logging is disabled.

**RESET REPLICA** requires the **RELOAD** privilege.

To use **RESET REPLICA**, the replication SQL thread and replication I/O (receiver) thread must be stopped, so on a running replica use **STOP REPLICA** before issuing **RESET REPLICA**. To use **RESET REPLICA** on a Group Replication group member, the member status must be **OFFLINE**, meaning that the plugin is loaded but the member does not currently belong to any group. A group member can be taken offline by using a **STOP GROUP REPLICATION** statement.

The optional **FOR CHANNEL channel** clause enables you to name which replication channel the statement applies to. Providing a **FOR CHANNEL channel** clause applies the **RESET REPLICA** statement to a specific replication channel. Combining a **FOR CHANNEL channel** clause with the **ALL** option deletes the specified channel. If no channel is named and no extra channels exist, the statement applies to the default channel. Issuing a **RESET REPLICA ALL** statement without a **FOR CHANNEL channel** clause when multiple replication channels exist deletes all replication channels and recreates only the default channel. See Section 17.2.2, "Replication Channels" for more information.

**RESET REPLICA** does not change any replication connection parameters, which include the source’s host name and port, the replication user account and its password, the **PRIVILEGE_CHECKS_USER** account, the **REQUIRE_ROW_FORMAT** option, the **REQUIRE_TABLE_PRIMARY_KEY_CHECK** option, and the **ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS** option. If you want to change any of the replication connection parameters, you can do this using a **CHANGE REPLICATION SOURCE TO** statement after the server starts. If you want to remove all of the replication connection parameters, use **RESET REPLICA ALL**. **RESET REPLICA ALL** also clears the **IGNORE_SERVER_IDS** list set by **CHANGE REPLICATION SOURCE TO**. When you have used **RESET REPLICA ALL**, if you want to use the instance as a replica again, you need to issue a **CHANGE REPLICATION SOURCE TO** statement after the server start to specify new connection parameters.

You can set the **GTID_ONLY** option on the **CHANGE REPLICATION SOURCE TO** statement to stop a replication channel from persisting file names and file positions in the replication metadata repositories. When you issue **RESET REPLICA**, the replication metadata repositories are synchronized. **RESET REPLICA ALL** deletes rather than updates the repositories, so they are synchronized implicitly.

In the event of an unexpected server exit or deliberate restart after issuing **RESET REPLICA** but before issuing **START REPLICA**, retention of the replication connection parameters depends on the repository used for the replication metadata:

- When **master_info_repository** and **relay_log_info_repository** are both set to **TABLE** on the server (the default), replication connection parameters are preserved in the crash-safe InnoDB
tables mysql.slave_master_info and mysql.slave_relay_log_info as part of the **RESET REPLICA** operation. They are also retained in memory. In the event of an unexpected server exit or deliberate restart after issuing **RESET REPLICA** but before issuing **START REPLICA**, the replication connection parameters are retrieved from the tables and reapplied to the channel. This applies for both the connection and applier metadata repositories.

- If `master_info_repository` and `relay_log_info_repository` are both set to `FILE` on the server (deprecated; not recommended), replication connection parameters are retained in memory only. If the replica `mysqld` is restarted immediately after issuing **RESET REPLICA** due to an unexpected server exit or deliberate restart, the connection parameters are lost. In that case, you must issue a `CHANGE REPLICATION SOURCE TO` statement after the server starts to respecify the connection parameters before issuing **START REPLICA**.

**RESET REPLICA** does not change any replication filter settings (such as `--replicate-ignore-table`) for channels affected by the statement. However, **RESET REPLICA ALL** removes the replication filters that were set on the channels deleted by the statement. When the deleted channel or channels are recreated, any global replication filters specified for the replica are copied to them, and no channel specific replication filters are applied. For more information see Section 17.2.5.4, “Replication Channel Based Filters”.

**RESET REPLICA** causes an implicit commit of an ongoing transaction. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

If the replication SQL thread was in the middle of replicating temporary tables when it was stopped, and **RESET REPLICA** is issued, these replicated temporary tables are deleted on the replica.

---

### Note

When used on an NDB Cluster replica SQL node, **RESET REPLICA** clears the `mysql.ndb_apply_status` table. You should keep in mind when using this statement that `ndb_apply_status` uses the NDB storage engine and so is shared by all SQL nodes attached to the cluster.

You can override this behavior by issuing `SET GLOBAL @@ndb_clear_apply_status=OFF` prior to executing **RESET REPLICA**, which keeps the replica from purging the `ndb_apply_status` table in such cases.

---

#### 13.4.2.5 **RESET SLAVE Statement**

```sql
RESET SLAVE [ALL] [channel_option]
```

**channel_option**:  
FOR CHANNEL channel

Deprecated alias for **RESET REPLICA**.

#### 13.4.2.6 **START REPLICA Statement**

```sql
START REPLICA [thread_types] [until_option] [connection_options] [channel_option]
```

**thread_types**:  
[thread_type [, thread_type] ... ]

**thread_type**:  
IO_THREAD | SQL_THREAD

**until_option**:  
UNTIL { {SQL_BEFORE_GTIDS | SQL_AFTER_GTIDS} = gtid_set

---

2915
START REPLICA starts the replication threads, either together or separately.

START REPLICA requires the REPLICATION_SLAVE_ADMIN privilege (or the deprecated SUPER privilege). START REPLICA causes an implicit commit of an ongoing transaction. See Section 13.3.3, "Statements That Cause an Implicit Commit".

For the thread type options, you can specify IO_THREAD, SQL_THREAD, both of these, or neither of them. Only the threads that are started are affected by the statement.

- **START REPLICA** with no thread type options starts all of the replication threads, and so does **START REPLICA** with both of the thread type options.

- **IO_THREAD** starts the replication receiver thread, which reads events from the source server and stores them in the relay log.

- **SQL_THREAD** starts the replication applier thread, which reads events from the relay log and executes them. A multithreaded replica (with replica_parallel_workers > 0) applies transactions using a coordinator thread and multiple applier threads, and **SQL_THREAD** starts all of these.

### Important

START REPLICA sends an acknowledgment to the user after all the replication threads have started. However, the replication receiver thread might not yet have connected to the source successfully, or an applier thread might stop when applying an event right after starting. START REPLICA does not continue to monitor the threads after they are started, so it does not warn you if they subsequently stop or cannot connect. You must check the replica’s error log for error messages generated by the replication threads, or check that they are running satisfactorily with **SHOW REPLICA STATUS**. A successful **START REPLICA** statement causes **SHOW REPLICA STATUS** to show **Replica_SQL_Running=Yes**, but it might or might not show **Replica_IO_Running=Yes**, because...
Replica_IO_Running=Yes is only shown if the receiver thread is both running and connected. For more information, see Section 17.1.7.1, “Checking Replication Status”.

The optional FOR CHANNEL channel clause enables you to name which replication channel the statement applies to. Providing a FOR CHANNEL channel clause applies the START REPLICA statement to a specific replication channel. If no clause is named and no extra channels exist, the statement applies to the default channel. If a START REPLICA statement does not have a channel defined when using multiple channels, this statement starts the specified threads for all channels. See Section 17.2.2, “Replication Channels” for more information.

The replication channels for Group Replication (group_replication_applier and group_replication_recovery) are managed automatically by the server instance. START REPLICA cannot be used at all with the group_replication_recovery channel, and should only be used with the group_replication_applier channel when Group Replication is not running. The group_replication_applier channel only has an applier thread and has no receiver thread, so it can be started if required by using the SQL_THREAD option without the IO_THREAD option.

START REPLICA supports pluggable user-password authentication (see Section 6.2.17, “Pluggable Authentication”) with the USER, PASSWORD, DEFAULT_AUTH and PLUGIN_DIR options, as described in the following list. When you use these options, you must start the receiver thread (IO_THREAD option) or all the replication threads; you cannot start the replication applier thread (SQL_THREAD option) alone.

- **USER**
  The user name for the account. You must set this if PASSWORD is used. The option cannot be set to an empty or null string.

- **PASSWORD**
  The password for the named user account.

- **DEFAULT_AUTH**
  The name of the authentication plugin. The default is MySQL native authentication.

- **PLUGIN_DIR**
  The location of the authentication plugin.

**Important**

The password that you set using START REPLICA is masked when it is written to MySQL Server’s logs, Performance Schema tables, and SHOW PROCESSLIST statements. However, it is sent in plain text over the connection to the replica server instance. To protect the password in transit, use SSL/TLS encryption, an SSH tunnel, or another method of protecting the connection from unauthorized viewing, for the connection between the replica server instance and the client that you use to issue START REPLICA.

The UNTIL clause makes the replica start replication, then process transactions up to the point that you specify in the UNTIL clause, then stop again. The UNTIL clause can be used to make a replica proceed until just before the point where you want to skip a transaction that is unwanted, and then skip the transaction as described in Section 17.1.7.3, “Skipping Transactions”. To identify a transaction, you can use mysqlbinlog with the source’s binary log or the replica’s relay log, or use a SHOW BINLOG EVENTS statement.

You can also use the UNTIL clause for debugging replication by processing transactions one at a time or in sections. If you are using the UNTIL clause to do this, start the replica with --skip-replica-start to prevent the SQL thread from running when the replica server starts. Remove the option or system variable setting after the procedure is complete, so that it is not forgotten in the event of an unexpected server restart.
The `SHOW REPLICA STATUS` statement includes output fields that display the current values of the `UNTIL` condition. The `UNTIL` condition lasts for as long as the affected threads are still running, and is removed when they stop.

The `UNTIL` clause operates on the replication applier thread (`SQL_THREAD` option). You can use the `SQL_THREAD` option or let the replica default to starting both threads. If you use the `IO_THREAD` option alone, the `UNTIL` clause is ignored because the applier thread is not started.

The point that you specify in the `UNTIL` clause can be any one (and only one) of the following options:

- `SOURCE_LOG_FILE` and `SOURCE_LOG_POS`
  These options make the replication applier process transactions up to a position in its relay log, identified by the file name and file position of the corresponding point in the binary log on the source server. The applier thread finds the nearest transaction boundary at or after the specified position, finishes applying the transaction, and stops there. For compressed transaction payloads, specify the end position of the compressed `Transaction_payload_event`.

- `RELAY_LOG_FILE` and `RELAY_LOG_POS`
  These options make the replication applier process transactions up to a position in the replica's relay log, identified by the relay log file name and a position in that file. The applier thread finds the nearest transaction boundary at or after the specified position, finishes applying the transaction, and stops there. For compressed transaction payloads, specify the end position of the compressed `Transaction_payload_event`.

- `SQL_BEFORE_GTIDS`
  This option makes the replication applier start processing transactions and stop when it encounters any transaction that is in the specified GTID set. The encountered transaction from the GTID set is not applied, and nor are any of the other transactions in the GTID set. The option takes a GTID set containing one or more global transaction identifiers as an argument (see GTID Sets). Transactions in a GTID set do not necessarily appear in the replication stream in the order of their GTIDs, so the transaction before which the applier stops is not necessarily the earliest.

- `SQL_AFTER_GTIDS`
  This option makes the replication applier start processing transactions and stop when it has processed all of the transactions in a specified GTID set. The option takes a GTID set containing one or more global transaction identifiers as an argument (see GTID Sets).

  With `SQL_AFTER_GTIDS`, the replication threads stop after they have processed all transactions in the GTID set. Transactions are processed in the order received, so it is possible that these include
transactions which are not part of the GTID set, but which are received (and processed) before all transactions in the set have been committed. For example, executing \texttt{START REPLICA UNTIL SQL\_AFTER\_GTIDS = 3E11FA47-71CA-11E1-9E33-C80AA9429562:11-56} causes the replica to obtain (and process) all transactions from the source until all of the transactions having the sequence numbers 11 through 56 have been processed, and then to stop without processing any additional transactions after that point has been reached.

Previously, this option could not be used with \texttt{replica\_parallel\_workers > 1}. Beginning with MySQL 8.2.0, this is no longer an issue, and \texttt{SQL\_AFTER\_GTIDS} can be used without causing the replica to fall back into single-threaded mode.

\textbf{SQL\_AFTER\_MTS\_GAPS}

For a multithreaded replica only (with \texttt{replica\_parallel\_workers > 0}), this option makes the replica process transactions up to the point where there are no more gaps in the sequence of transactions executed from the relay log. When using a multithreaded replica, there is a chance of gaps occurring in the following situations:

\begin{itemize}
  \item The coordinator thread is stopped.
  \item An error occurs in the applier threads.
  \item \texttt{mysql} shuts down unexpectedly.
\end{itemize}

When a replication channel has gaps, the replica’s database is in a state that might never have existed on the source. The replica tracks the gaps internally and disallows \texttt{CHANGE REPLICATION SOURCE TO} statements that would remove the gap information if they executed.

All replicas are multithreaded by default. When \texttt{replica\_preserve\_commit\_order=ON} on the replica (the default), gaps should not occur except in the specific situations listed in the description for this variable. If \texttt{replica\_preserve\_commit\_order} is \texttt{OFF}, the commit order of transactions is not preserved, so the chance of gaps occurring is much larger.

If GTIDs are not in use and you need to change a failed multithreaded replica to single-threaded mode, you can issue the following series of statements, in the order shown:

\begin{verbatim}
START REPLICA UNTIL SQL\_AFTER\_MTS\_GAPS;
SET @@GLOBAL.replica\_parallel\_workers = 0;
START REPLICA SQL\_THREAD;
\end{verbatim}

\section*{13.4.2.7 START SLAVE Statement}

\texttt{START SLAVE [thread\_types] [until\_option] [connection\_options] [channel\_option]}

\texttt{thread\_types:}

\begin{verbatim}
  [thread\_type [, thread\_type] ... ]
\end{verbatim}

\texttt{thread\_type:}

\begin{verbatim}
  IO\_THREAD | SQL\_THREAD
\end{verbatim}

\texttt{until\_option:}

\begin{verbatim}
  UNTIL { SQL\_BEFORE\_GTIDS | SQL\_AFTER\_GTIDS} = gtid\_set
\end{verbatim}
SQL Statements for Controlling Replica Servers

```
MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos
SOURCE_LOG_FILE = 'log_name', SOURCE_LOG_POS = log_pos
RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos
SQL_AFTER_MTS_GAPS }
```

collection_options:  
[USER='user_name'] [PASSWORD='user_pass'] [DEFAULT_AUTH='plugin_name'] [PLUGIN_DIR='plugin_dir']

channel_option:  
   FOR CHANNEL channel

gtid_set:  
   uuid_set [, uuid_set] ...  
   ' '
    
   uuid_set:  
       uuid:interval[:interval]...
   
   uuid:  
       hhhhhhhh-hhhh-hhhh-hhhh-hhhhhhhhhhh
   
   h:  
       [0-9,A-F]
   
   interval:  
       n[-n]
   
   (n >= 1)

Deprecated alias for START REPLICA.

13.4.2.8 STOP REPLICA Statement

```
STOP REPLICA [thread_types] [channel_option]
```

thread_types:  
   [thread_type [, thread_type] ... ]

thread_type:  
   IO_THREAD | SQL_THREAD

channel_option:  
   FOR CHANNEL channel

Stops the replication threads.

STOP REPLICA requires the REPLICATION_SLAVE_ADMIN privilege (or the deprecated SUPER privilege). Recommended best practice is to execute STOP REPLICA on the replica before stopping the replica server (see Section 5.1.19, “The Server Shutdown Process”, for more information).

Like START REPLICA, this statement may be used with the IO_THREAD and SQL_THREAD options to name the replication thread or threads to be stopped. Note that the Group Replication applier channel (group_replication_applier) has no replication I/O (receiver) thread, only a replication SQL (applier) thread. Using the SQL_THREAD option therefore stops this channel completely.

STOP REPLICA causes an implicit commit of an ongoing transaction. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

gtid_next must be set to AUTOMATIC before issuing this statement.

You can control how long STOP REPLICA waits before timing out by setting the system variable rpl_stop_replica_timeout. This can be used to avoid deadlocks between STOP REPLICA and other SQL statements using different client connections to the replica. When the timeout value is reached, the
issuing client returns an error message and stops waiting, but the `STOP REPLICA` instruction remains in effect. Once the replication threads are no longer busy, the `STOP REPLICA` statement is executed and the replica stops.

Some `CHANGE REPLICATION SOURCE TO` statements are allowed while the replica is running, depending on the states of the replication threads. However, using `STOP REPLICA` prior to executing a `CHANGE REPLICATION SOURCE TO` statement in such cases is still supported. See Section 13.4.2.3, “CHANGE REPLICATION SOURCE TO Statement”, Section 13.4.2.1, “CHANGE MASTER TO Statement”, and Section 17.4.8, “Switching Sources During Failover”, for more information.

The optional `FOR CHANNEL channel` clause enables you to name which replication channel the statement applies to. Providing a `FOR CHANNEL channel` clause applies the `STOP REPLICA` statement to a specific replication channel. If no channel is named and no extra channels exist, the statement applies to the default channel. If a `STOP REPLICA` statement does not name a channel when using multiple channels, this statement stops the specified threads for all channels. See Section 17.2.2, “Replication Channels” for more information.

The replication channels for Group Replication (`group_replication_applier` and `group_replication_recovery`) are managed automatically by the server instance. `STOP REPLICA` cannot be used at all with the `group_replication_recovery` channel, and should only be used with the `group_replication_applier` channel when Group Replication is not running. The `group_replication_applier` channel only has an applier thread and has no receiver thread, so it can be stopped if required by using the `SQL_THREAD` option without the `IO_THREAD` option.

When the replica is multithreaded (`replica_parallel_workers` is a nonzero value), any gaps in the sequence of transactions executed from the relay log are closed as part of stopping the worker threads. If the replica is stopped unexpectedly (for example due to an error in a worker thread, or another thread issuing `KILL`) while a `STOP REPLICA` statement is executing, the sequence of executed transactions from the relay log may become inconsistent. See Section 17.5.1.34, “Replication and Transaction Inconsistencies”, for more information.

When the source is using the row-based binary logging format, you should execute `STOP REPLICA` or `STOP REPLICA SQL_THREAD` on the replica prior to shutting down the replica server if you are replicating any tables that use a nontransactional storage engine. If the current replication event group has modified one or more nontransactional tables, `STOP REPLICA` waits for up to 60 seconds for the event group to complete, unless you issue a `KILL QUERY` or `KILL CONNECTION` statement for the replication SQL thread. If the event group remains incomplete after the timeout, an error message is logged.

When the source is using the statement-based binary logging format, changing the source while it has open temporary tables is potentially unsafe. This is one of the reasons why statement-based replication of temporary tables is not recommended. You can find out whether there are any temporary tables on the replica by checking the value of `Replica_open_temp_tables`. When using statement-based replication, this value should be 0 before executing `CHANGE REPLICATION SOURCE TO`. If there are any temporary tables open on the replica, issuing a `CHANGE REPLICATION SOURCE TO` statement after issuing a `STOP REPLICA` causes an `ER_WARN_OPEN_TEMP_TABLES_MUST_BE_ZERO` warning.

### 13.4.2.9 STOP SLAVE Statement

```
STOP SLAVE [thread_types] [channel_option]
```

**thread_types:**
- `[thread_type [, thread_type] ... ]`

**thread_type:** `IO_THREAD` | `SQL_THREAD`

**channel_option:**
- `FOR CHANNEL channel`

13.4.3 SQL Statements for Controlling Group Replication

This section provides information about the statements used for controlling group replication.

13.4.3.1 START GROUP_REPLICATION Statement

```
START GROUP_REPLICATION
  [USER='user_name']
  [, PASSWORD='user_pass']
  [, DEFAULT_AUTH='plugin_name']
```

Starts group replication. This statement requires the GROUP_REPLICATION_ADMIN privilege (or the deprecated SUPER privilege). If `super_read_only=ON` is set and the member should join as a primary, `super_read_only` is set to OFF once Group Replication successfully starts.

You can specify user credentials for distributed recovery in the `START GROUP_REPLICATION` statement using the USER, PASSWORD, and DEFAULT_AUTH options, as follows:

- **USER**: The replication user for distributed recovery. For instructions to set up this account, see Section 18.2.1.3, “User Credentials For Distributed Recovery”. You cannot specify an empty or null string, or omit the USER option if PASSWORD is specified.

- **PASSWORD**: The password for the replication user account. The password cannot be encrypted, but it is masked in the query log.

- **DEFAULT_AUTH**: The name of the authentication plugin used for the replication user account. If you do not specify this option, MySQL native authentication (the mysql_native_password plugin) is assumed. This option acts as a hint to the server, and the donor for distributed recovery overrides it if a different plugin is associated with the user account on that server. The authentication plugin used by default when you create user accounts in MySQL 8 is the caching SHA-2 authentication plugin (caching_sha2_password). See Section 6.2.17, “Pluggable Authentication” for more information on authentication plugins.

These credentials are used for distributed recovery on the `group_replication_recovery` channel. When you specify user credentials on `START GROUP_REPLICATION`, the credentials are saved in memory only, and are removed by a `STOP GROUP_REPLICATION` statement or server shutdown. You must issue a `START GROUP_REPLICATION` statement to provide the credentials again. This method is therefore not compatible with starting Group Replication automatically on server start, as specified by the `group_replication_start_on_boot` system variable.

User credentials specified on `START GROUP_REPLICATION` take precedence over any user credentials set for the `group_replication_recovery` channel using a `CHANGE REPLICATION SOURCE TO`. Note that user credentials set using these statements are stored in the replication metadata repositories, and are used when `START GROUP_REPLICATION` is specified without user credentials, including automatic starts if the `group_replication_start_on_boot` system variable is set to ON. To gain the security benefits of specifying user credentials on `START GROUP_REPLICATION`, ensure that `group_replication_start_on_boot` is set to OFF (the default is ON), and clear any user credentials previously set for the `group_replication_recovery` channel, following the instructions in Section 18.6.3, “Securing Distributed Recovery Connections”.

While a member is rejoining a replication group, its status can be displayed as OFFLINE or ERROR before the group completes the compatibility checks and accepts it as a member. When the member is catching up with the group’s transactions, its status is RECOVERING.

13.4.3.2 STOP GROUP_REPLICATION Statement
Prepared Statements

**STOP GROUP_REPLICATION**

Stops Group Replication. This statement requires the `GROUP_REPLICATION_ADMIN` privilege (or the deprecated `SUPER` privilege). As soon as you issue `STOP GROUP_REPLICATION` the member is set to `super_read_only=ON`, which ensures that no writes can be made to the member while Group Replication stops. Any other asynchronous replication channels running on the member are also stopped. Any user credentials that you specified in the `START GROUP_REPLICATION` statement when starting Group Replication on this member are removed from memory, and must be supplied when you start Group Replication again.

**Warning**

Use this statement with extreme caution because it removes the server instance from the group, meaning it is no longer protected by Group Replication's consistency guarantee mechanisms. To be completely safe, ensure that your applications can no longer connect to the instance before issuing this statement to avoid any chance of stale reads.

The `STOP GROUP_REPLICATION` statement stops asynchronous replication channels on the group member, but it does not implicitly commit transactions that are in progress on them like `STOP REPLICA` does. This is because on a Group Replication group member, an additional transaction committed during the shutdown operation would leave the member inconsistent with the group and cause an issue with rejoining. To avoid failed commits for transactions that are in progress while stopping Group Replication, the `STOP GROUP_REPLICATION` statement cannot be issued while a GTID is assigned as the value of the `gtid_next` system variable.

The `group_replication_components_stop_timeout` system variable specifies the time for which Group Replication waits for each of its modules to complete ongoing processes after this statement is issued. The timeout is used to resolve situations in which Group Replication components cannot be stopped normally, which can happen if the member is expelled from the group while it is in an error state, or while a process such as MySQL Enterprise Backup is holding a global lock on tables on the member. In such situations, the member cannot stop the applier thread or complete the distributed recovery process to rejoin. `STOP GROUP_REPLICATION` does not complete until either the situation is resolved (for example, by the lock being released), or the component timeout expires and the modules are shut down regardless of their status. The default value is 300 seconds; this means that Group Replication components are stopped after 5 minutes if the situation is not resolved before that time, allowing the member to be restarted and rejoin.

### 13.5 Prepared Statements

MySQL 8.2 provides support for server-side prepared statements. This support takes advantage of the efficient client/server binary protocol. Using prepared statements with placeholders for parameter values has the following benefits:

- Less overhead for parsing the statement each time it is executed. Typically, database applications process large volumes of almost-identical statements, with only changes to literal or variable values in clauses such as `WHERE` for queries and deletes, `SET` for updates, and `VALUES` for inserts.

- Protection against SQL injection attacks. The parameter values can contain unescaped SQL quote and delimiter characters.

The following sections provide an overview of the characteristics of prepared statements:

- **Prepared Statements in Application Programs**

- **Prepared Statements in SQL Scripts**
Prepared Statements in Application Programs

- PREPARE, EXECUTE, and DEALLOCATE PREPARE Statements
- SQL Syntax Permitted in Prepared Statements

Prepared Statements in Application Programs

You can use server-side prepared statements through client programming interfaces, including the MySQL C API client library for C programs, MySQL Connector/J for Java programs, and MySQL Connector/NET for programs using .NET technologies. For example, the C API provides a set of function calls that make up its prepared statement API. See C API Prepared Statement Interface. Other language interfaces can provide support for prepared statements that use the binary protocol by linking in the C client library, one example being the mysqli extension, available in PHP 5.0 and higher.

Prepared Statements in SQL Scripts

An alternative SQL interface to prepared statements is available. This interface is not as efficient as using the binary protocol through a prepared statement API, but requires no programming because it is available directly at the SQL level:

- You can use it when no programming interface is available to you.
- You can use it from any program that can send SQL statements to the server to be executed, such as the mysql client program.
- You can use it even if the client is using an old version of the client library.

SQL syntax for prepared statements is intended to be used for situations such as these:

- To test how prepared statements work in your application before coding it.
- To use prepared statements when you do not have access to a programming API that supports them.
- To interactively troubleshoot application issues with prepared statements.
- To create a test case that reproduces a problem with prepared statements, so that you can file a bug report.

PREPARE, EXECUTE, and DEALLOCATE PREPARE Statements

SQL syntax for prepared statements is based on three SQL statements:

- **PREPARE** prepares a statement for execution (see Section 13.5.1, “PREPARE Statement”).
- **EXECUTE** executes a prepared statement (see Section 13.5.2, “EXECUTE Statement”).
- **DEALLOCATE PREPARE** releases a prepared statement (see Section 13.5.3, “DEALLOCATE PREPARE Statement”).

The following examples show two equivalent ways of preparing a statement that computes the hypotenuse of a triangle given the lengths of the two sides.

The first example shows how to create a prepared statement by using a string literal to supply the text of the statement:

```
mysql> PREPARE stmt1 FROM 'SELECT SQRT(POW(?2) + POW(?2)) AS hypotenuse';
mysql> SET @a = 3;
mysql> SET @b = 4;
mysql> EXECUTE stmt1 USING @a, @b;
```

<table>
<thead>
<tr>
<th>hypotenuse</th>
</tr>
</thead>
<tbody>
<tr>
<td>2924</td>
</tr>
</tbody>
</table>
The second example is similar, but supplies the text of the statement as a user variable:

```sql
gsql>
SET @s = 'SELECT SQRT(Pow(?2) + Pow(?2)) AS hypotenuse';
gsql>
PREPARE stmt2 FROM @s;
gsql>
SET @a = 6;
gsql>
SET @b = 8;
gsql>
EXECUTE stmt2 USING @a, @b;
```

Here is an additional example that demonstrates how to choose the table on which to perform a query at runtime, by storing the name of the table as a user variable:

```sql
gsql>
USE test;
gsql>
CREATE TABLE t1 (a INT NOT NULL);
gsql>
INSERT INTO t1 VALUES (4), (8), (11), (32), (80);
gsql>
SET @table = 't1';
gsql>
SET @s = CONCAT('SELECT * FROM ', @table);

gsql>
PREPARE stmt3 FROM @s;
gsql>
EXECUTE stmt3;
```

A prepared statement is specific to the session in which it was created. If you terminate a session without deallocating a previously prepared statement, the server deallocates it automatically.

A prepared statement is also global to the session. If you create a prepared statement within a stored routine, it is not deallocated when the stored routine ends.

To guard against too many prepared statements being created simultaneously, set the `max_prepared_stmt_count` system variable. To prevent the use of prepared statements, set the value to 0.

### SQL Syntax Permitted in Prepared Statements

The following SQL statements can be used as prepared statements:

- `ALTER TABLE`
- `ALTER USER`
- `ANALYZE TABLE`
- `CACHE INDEX`
- `CALL`
- `CHANGE MASTER`
- `CHECKSUM {TABLE | TABLES}`
SQL Syntax Permitted in Prepared Statements

COMMIT
{CREATE | DROP} INDEX
{CREATE | RENAME | DROP} DATABASE
{CREATE | DROP} TABLE
{CREATE | RENAME | DROP} USER
{CREATE | DROP} VIEW
DELETE
DO
FLUSH (TABLE | TABLES | TABLES WITH READ LOCK | HOSTS | PRIVILEGES
| LOGS | STATUS | MASTER | SLAVE | USER_RESOURCES)
GRANT
INSERT
INSTALL PLUGIN
KILL
LOAD INDEX INTO CACHE
OPTIMIZE TABLE
RENAME TABLE
REPAIR TABLE
REPLACE
REVOKE {MASTER | SLAVE}
REVOKE
SELECT
SET
SHOW BINLOG EVENTS
SHOW CREATE {PROCEDURE | FUNCTION | EVENT | TABLE | VIEW}
SHOW {MASTER | BINARY} LOGS
SHOW {MASTER | SLAVE} STATUS
SLAVE {START | STOP}
TRUNCATE TABLE
UNINSTALL PLUGIN
UPDATE

Other statements are not supported.

For compliance with the SQL standard, which states that diagnostics statements are not preparable, MySQL does not support the following as prepared statements:

- SHOW WARNINGS, SHOW COUNT(*) WARNINGS
- SHOW ERRORS, SHOW COUNT(*) ERRORS
- Statements containing any reference to the warning_count or error_count system variable.

Generally, statements not permitted in SQL prepared statements are also not permitted in stored programs. Exceptions are noted in Section 25.8, “Restrictions on Stored Programs”.

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic repreparation of the statement when it is next executed. For more information, see Section 8.10.3, “Caching of Prepared Statements and Stored Programs”.

Placeholders can be used for the arguments of the LIMIT clause when using prepared statements. See Section 13.2.13, “SELECT Statement”.

In prepared CALL statements used with PREPARE and EXECUTE, placeholder support for OUT and INOUT parameters is available beginning with MySQL 8.2. See Section 13.2.1, “CALL Statement”, for an example and a workaround for earlier versions. Placeholders can be used for IN parameters regardless of version.

SQL syntax for prepared statements cannot be used in nested fashion. That is, a statement passed to PREPARE cannot itself be a PREPARE, EXECUTE, or DEALLOCATE PREPARE statement.

SQL syntax for prepared statements is distinct from using prepared statement API calls. For example, you cannot use the mysql_stmt_prepare() C API function to prepare a PREPARE, EXECUTE, or DEALLOCATE PREPARE statement.
SQL syntax for prepared statements can be used within stored procedures, but not in stored functions or triggers. However, a cursor cannot be used for a dynamic statement that is prepared and executed with PREPARE and EXECUTE. The statement for a cursor is checked at cursor creation time, so the statement cannot be dynamic.

SQL syntax for prepared statements does not support multi-statements (that is, multiple statements within a single string separated by ; characters).

To write C programs that use the CALL SQL statement to execute stored procedures that contain prepared statements, the CLIENT_MULTI_RESULTS flag must be enabled. This is because each CALL returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure.

CLIENT_MULTI_RESULTS can be enabled when you call mysql_real_connect(), either explicitly by passing the CLIENT_MULTI_RESULTS flag itself, or implicitly by passing CLIENT_MULTI_STATEMENTS (which also enables CLIENT_MULTI_RESULTS). For additional information, see Section 13.2.1, “CALL Statement”.

13.5.1 PREPARE Statement

PREPARE stmt_name FROM preparable_stmt

The PREPARE statement prepares a SQL statement and assigns it a name, stmt_name, by which to refer to the statement later. The prepared statement is executed with EXECUTE and released with DEALLOCATE PREPARE. For examples, see Section 13.5, “Prepared Statements”.

Statement names are not case-sensitive. preparable_stmt is either a string literal or a user variable that contains the text of the SQL statement. The text must represent a single statement, not multiple statements. Within the statement, ? characters can be used as parameter markers to indicate where data values are to be bound to the query later when you execute it. The ? characters should not be enclosed within quotation marks, even if you intend to bind them to string values. Parameter markers can be used only where data values should appear, not for SQL keywords, identifiers, and so forth.

If a prepared statement with the given name already exists, it is deallocated implicitly before the new statement is prepared. This means that if the new statement contains an error and cannot be prepared, an error is returned and no statement with the given name exists.

The scope of a prepared statement is the session within which it is created, which as several implications:

- A prepared statement created in one session is not available to other sessions.

- When a session ends, whether normally or abnormally, its prepared statements no longer exist. If auto-reconnect is enabled, the client is not notified that the connection was lost. For this reason, clients may wish to disable auto-reconnect. See Automatic Reconnection Control.

- A prepared statement created within a stored program continues to exist after the program finishes executing and can be executed outside the program later.

- A statement prepared in stored program context cannot refer to stored procedure or function parameters or local variables because they go out of scope when the program ends and would be unavailable were the statement to be executed later outside the program. As a workaround, refer instead to user-defined variables, which also have session scope; see Section 9.4, “User-Defined Variables”.

The type of a parameter used in a prepared statement is determined when the statement is first prepared; it retains this type whenever EXECUTE is invoked for this prepared statement (unless the statement is reprepared, as explained later in this section). Rules for determining a parameter's type are listed here:
A parameter which is an operand of a binary arithmetic operator has the same data type as the other operand.

If both operands of a binary arithmetic operator are parameters, the type of the parameters is decided by the context of the operator.

If a parameter is the operand of a unary arithmetic operator, the parameter's type is decided by the context of the operator.

If an arithmetic operator has no type-determining context, the derived type for any parameters involved is **DOUBLE PRECISION**. This can happen, for example, when the parameter is a top-level node in a **SELECT** list, or when it is part of a comparison operator.

A parameter which is an operand of a character string operator has the same derived type as the aggregated type of the other operands. If all operands of the operator are parameters, the derived type is **VARCHAR**; its collation is determined by the value of `collation_connection`.

A parameter which is an operand of a temporal operator has type **DATETIME** if the operator returns a **DATETIME**, **TIME** if the operator returns a **TIME**, and **DATE** if the operator returns a **DATE**.

A parameter which is an operand of a binary comparison operator has the same derived type as the other operand of the comparison.

A parameter that is an operand of a ternary comparison operator such as **BETWEEN** has the same derived type as the aggregated type of the other operands.

If all operands of a comparison operator are parameters, the derived type for each of them is **VARCHAR**, with collation determined by the value of `collation_connection`.

A parameter that is an output operand of any of **CASE**, **COALESCE**, **IF**, **IFNULL**, or **NULLIF** has the same derived type as the aggregated type of the operator's other output operands.

If all output operands of any of **CASE**, **COALESCE**, **IF**, **IFNULL**, or **NULLIF** are parameters, or they are all **NULL**, the type of the parameter is decided by the context of the operator.

If the parameter is an operand of any of **CASE**, **COALESCE()**, **IF**, or **IFNULL**, and has no type-determining context, the derived type for each of the parameters involved is **VARCHAR**, and its collation is determined by the value of `collation_connection`.

A parameter which is the operand of a **CAST()** has the same type as specified by the **CAST()**.

If a parameter is an immediate member of a **SELECT** list that is not part of an **INSERT** statement, the derived type of the parameter is **VARCHAR**, and its collation is determined by the value of `collation_connection`.

If a parameter is an immediate member of a **SELECT** list that is part of an **INSERT** statement, the derived type of the parameter is the type of the corresponding column into which the parameter is inserted.

If a parameter is used as source for an assignment in a **SET** clause of an **UPDATE** statement or in the **ON DUPLICATE KEY UPDATE** clause of an **INSERT** statement, the derived type of the parameter is the type of the corresponding column which is updated by the **SET** or **ON DUPLICATE KEY UPDATE** clause.

If a parameter is an argument of a function, the derived type depends on the function's return type.

For some combinations of actual type and derived type, an automatic repreparation of the statement is triggered, to ensure closer compatibility with previous versions of MySQL. Repreparation does not occur if any of the following conditions are true:

- **NULL** is used as the actual parameter value.
EXECUTE Statement

- A parameter is an operand of a CAST(). (Instead, a cast to the derived type is attempted, and an exception raised if the cast fails.)
- A parameter is a string. (In this case, an implicit CAST(? AS derived_type) is performed.)
- The derived type and actual type of the parameter are both INTEGER and have the same sign.
- The parameter's derived type is DECIMAL and its actual type is either DECIMAL or INTEGER.
- The derived type is DOUBLE and the actual type is any numeric type.
- Both the derived type and the actual type are string types.
- If the derived type is temporal and the actual type is temporal. Exceptions: The derived type is TIME and the actual type is not TIME; the derived type is DATE and the actual type is not DATE.
- The derived type is temporal and the actual type is numeric.

For cases other than those just listed, the statement is reprepared and the actual parameter types are used instead of the derived parameter types.

These rules also apply to a user variable referenced in a prepared statement.

Using a different data type for a given parameter or user variable within a prepared statement for executions of the statement subsequent to the first execution causes the statement to be reprepared. This is less efficient; it may also lead to the parameter's (or variable's) actual type to vary, and thus for results to be inconsistent, with subsequent executions of the prepared statement. For these reasons, it is advisable to use the same data type for a given parameter when re-executing a prepared statement.

13.5.2 EXECUTE Statement

```
EXECUTE stmt_name
    [USING @var_name [, @var_name] ...]
```

After preparing a statement with PREPARE, you execute it with an EXECUTE statement that refers to the prepared statement name. If the prepared statement contains any parameter markers, you must supply a USING clause that lists user variables containing the values to be bound to the parameters. Parameter values can be supplied only by user variables, and the USING clause must name exactly as many variables as the number of parameter markers in the statement.

You can execute a given prepared statement multiple times, passing different variables to it or setting the variables to different values before each execution.

For examples, see Section 13.5, “Prepared Statements”.

13.5.3 DEALLOCATE PREPARE Statement

```
{DEALLOCATE | DROP} PREPARE stmt_name
```

To deallocate a prepared statement produced with PREPARE, use a DEALLOCATE PREPARE statement that refers to the prepared statement name. Attempting to execute a prepared statement after deallocating it results in an error. If too many prepared statements are created and not deallocated by either the DEALLOCATE PREPARE statement or the end of the session, you might encounter the upper limit enforced by the max_prepared_statmnt system variable.

For examples, see Section 13.5, “Prepared Statements”.

13.6 Compound Statement Syntax
This section describes the syntax for the `BEGIN ... END` compound statement and other statements that can be used in the body of stored programs: Stored procedures and functions, triggers, and events. These objects are defined in terms of SQL code that is stored on the server for later invocation (see Chapter 25, *Stored Objects*).

A compound statement is a block that can contain other blocks; declarations for variables, condition handlers, and cursors; and flow control constructs such as loops and conditional tests.

### 13.6.1 BEGIN ... END Compound Statement

```
[begin_label:] BEGIN
  [statement_list]
END [end_label]
```

`BEGIN ... END` syntax is used for writing compound statements, which can appear within stored programs (stored procedures and functions, triggers, and events). A compound statement can contain multiple statements, enclosed by the `BEGIN` and `END` keywords. `statement_list` represents a list of one or more statements, each terminated by a semicolon (`;`) statement delimiter. The `statement_list` itself is optional, so the empty compound statement (`BEGIN END`) is legal.

`BEGIN ... END` blocks can be nested.

Use of multiple statements requires that a client is able to send statement strings containing the `;` statement delimiter. In the `mysql` command-line client, this is handled with the `delimiter` command. Changing the `;` end-of-statement delimiter (for example, to `//`) permit `;` to be used in a program body. For an example, see Section 25.1, "Defining Stored Programs".

A `BEGIN ... END` block can be labeled. See Section 13.6.2, "Statement Labels".

The optional `[NOT] ATOMIC` clause is not supported. This means that no transactional savepoint is set at the start of the instruction block and the `BEGIN` clause used in this context has no effect on the current transaction.

**Note**

Within all stored programs, the parser treats `BEGIN [WORK]` as the beginning of a `BEGIN ... END` block. To begin a transaction in this context, use `START TRANSACTION` instead.

### 13.6.2 Statement Labels

```
[begin_label:] BEGIN
  [statement_list]
END [end_label]

[begin_label:] LOOP
  statement_list
END LOOP [end_label]

[begin_label:] REPEAT
  statement_list
  UNTIL search_condition
END REPEAT [end_label]

[begin_label:] WHILE search_condition DO
  statement_list
END WHILE [end_label]
```

Labels are permitted for `BEGIN ... END` blocks and for the `LOOP`, `REPEAT`, and `WHILE` statements. Label use for those statements follows these rules:
• `begin_label` must be followed by a colon.

• `begin_label` can be given without `end_label`. If `end_label` is present, it must be the same as `begin_label`.

• `end_label` cannot be given without `begin_label`.

• Labels at the same nesting level must be distinct.

• Labels can be up to 16 characters long.

To refer to a label within the labeled construct, use an `ITERATE` or `LEAVE` statement. The following example uses those statements to continue iterating or terminate the loop:

```sql
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
  label1: LOOP
    SET p1 = p1 + 1;
    IF p1 < 10 THEN ITERATE label1; END IF;
    LEAVE label1;
  END LOOP label1;
END;
```

The scope of a block label does not include the code for handlers declared within the block. For details, see Section 13.6.7.2, “DECLARE ... HANDLER Statement”.

13.6.3 DECLARE Statement

The `DECLARE` statement is used to define various items local to a program:

• Local variables. See Section 13.6.4, “Variables in Stored Programs”.

• Conditions and handlers. See Section 13.6.7, “Condition Handling”.

• Cursors. See Section 13.6.6, “Cursors”.

`DECLARE` is permitted only inside a `BEGIN ... END` compound statement and must be at its start, before any other statements.

Declarations must follow a certain order. Cursor declarations must appear before handler declarations. Variable and condition declarations must appear before cursor or handler declarations.

13.6.4 Variables in Stored Programs

System variables and user-defined variables can be used in stored programs, just as they can be used outside stored-program context. In addition, stored programs can use `DECLARE` to define local variables, and stored routines (procedures and functions) can be declared to take parameters that communicate values between the routine and its caller.

• To declare local variables, use the `DECLARE` statement, as described in Section 13.6.4.1, “Local Variable DECLARE Statement”.

• Variables can be set directly with the `SET` statement. See Section 13.7.6.1, “SET Syntax for Variable Assignment”.

• Results from queries can be retrieved into local variables using `SELECT ... INTO var_list` or by opening a cursor and using `FETCH ... INTO var_list`. See Section 13.2.13.1, “SELECT ... INTO Statement”, and Section 13.6.6, “Cursors”. 
Variables in Stored Programs

For information about the scope of local variables and how MySQL resolves ambiguous names, see Section 13.6.4.2, “Local Variable Scope and Resolution”.

It is not permitted to assign the value `DEFAULT` to stored procedure or function parameters or stored program local variables (for example with a `SET var_name = DEFAULT` statement). In MySQL 8.2, this results in a syntax error.

13.6.4.1 Local Variable DECLARE Statement

```
DECLARE var_name [, var_name] ... type [DEFAULT value]
```

This statement declares local variables within stored programs. To provide a default value for a variable, include a `DEFAULT` clause. The value can be specified as an expression; it need not be a constant. If the `DEFAULT` clause is missing, the initial value is `NULL`.

Local variables are treated like stored routine parameters with respect to data type and overflow checking. See Section 13.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”.

Variable declarations must appear before cursor or handler declarations.

Local variable names are not case-sensitive. Permissible characters and quoting rules are the same as for other identifiers, as described in Section 9.2, “Schema Object Names”.

The scope of a local variable is the `BEGIN ... END` block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

For examples of variable declarations, see Section 13.6.4.2, “Local Variable Scope and Resolution”.

13.6.4.2 Local Variable Scope and Resolution

The scope of a local variable is the `BEGIN ... END` block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

Because local variables are in scope only during stored program execution, references to them are not permitted in prepared statements created within a stored program. Prepared statement scope is the current session, not the stored program, so the statement could be executed after the program ends, at which point the variables would no longer be in scope. For example, `SELECT ... INTO local_var` cannot be used as a prepared statement. This restriction also applies to stored procedure and function parameters. See Section 13.5.1, “PREPARE Statement”.

A local variable should not have the same name as a table column. If an SQL statement, such as a `SELECT ... INTO` statement, contains a reference to a column and a declared local variable with the same name, MySQL currently interprets the reference as the name of a variable. Consider the following procedure definition:

```
CREATE PROCEDURE sp1 (x VARCHAR(5))
BEGIN
  DECLARE xname VARCHAR(5) DEFAULT 'bob';
  DECLARE newname VARCHAR(5);
  DECLARE xid INT;
  SELECT xname, id INTO newname, xid
  FROM table1 WHERE xname = xname;
  SELECT newname;
END;
```
MySQL interprets \texttt{xname} in the \texttt{SELECT} statement as a reference to the \texttt{xname} variable rather than the \texttt{xname} column. Consequently, when the procedure \texttt{sp1()} is called, the \texttt{newname} variable returns the value 'bob' regardless of the value of the \texttt{table1.xname} column.

Similarly, the cursor definition in the following procedure contains a \texttt{SELECT} statement that refers to \texttt{xname}. MySQL interprets this as a reference to the variable of that name rather than a column reference.

\begin{verbatim}
CREATE PROCEDURE sp2 (x VARCHAR(5))
BEGIN
  DECLARE xname VARCHAR(5) DEFAULT 'bob';
  DECLARE newname VARCHAR(5);
  DECLARE xid INT;
  DECLARE done TINYINT DEFAULT 0;
  DECLARE cur1 CURSOR FOR SELECT xname, id FROM table1;
  DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = 1;

  OPEN cur1;
  read_loop: LOOP
    FETCH FROM cur1 INTO newname, xid;
    IF done THEN LEAVE read_loop; END IF;
    SELECT newname;
  END LOOP;
  CLOSE cur1;
END;
\end{verbatim}

See also Section 25.8, “Restrictions on Stored Programs”.

13.6.5 Flow Control Statements

MySQL supports the \texttt{IF}, \texttt{CASE}, \texttt{ITERATE}, \texttt{LEAVE LOOP}, \texttt{WHILE}, and \texttt{REPEAT} constructs for flow control within stored programs. It also supports \texttt{RETURN} within stored functions.

Many of these constructs contain other statements, as indicated by the grammar specifications in the following sections. Such constructs may be nested. For example, an \texttt{IF} statement might contain a \texttt{WHILE} loop, which itself contains a \texttt{CASE} statement.

MySQL does not support \texttt{FOR} loops.

13.6.5.1 CASE Statement

\begin{verbatim}
CASE case_value
  WHEN when_value THEN statement_list
  [WHEN when_value THEN statement_list] ...
  [ELSE statement_list]
END CASE
\end{verbatim}

Or:

\begin{verbatim}
CASE
  WHEN search_condition THEN statement_list
  [WHEN search_condition THEN statement_list] ...
  [ELSE statement_list]
END CASE
\end{verbatim}

The \texttt{CASE} statement for stored programs implements a complex conditional construct.

\begin{note}
There is also a \texttt{CASE} operator, which differs from the \texttt{CASE} statement described here. See Section 12.5, “Flow Control Functions”. The \texttt{CASE} statement cannot have an \texttt{ELSE NULL} clause, and it is terminated with \texttt{END CASE} instead of \texttt{END}.
\end{note}
For the first syntax, *case_value* is an expression. This value is compared to the *when_value* expression in each *WHEN* clause until one of them is equal. When an equal *when_value* is found, the corresponding *THEN* clause *statement_list* executes. If no *when_value* is equal, the *ELSE* clause *statement_list* executes, if there is one.

This syntax cannot be used to test for equality with *NULL* because *NULL = NULL* is false. See Section 3.3.4.6, “Working with NULL Values”.

For the second syntax, each *WHEN* clause *search_condition* expression is evaluated until one is true, at which point its corresponding *THEN* clause *statement_list* executes. If no *search_condition* is equal, the *ELSE* clause *statement_list* executes, if there is one.

If no *when_value* or *search_condition* matches the value tested and the *CASE* statement contains no *ELSE* clause, a *Case not found for CASE statement* error results.

Each *statement_list* consists of one or more SQL statements; an empty *statement_list* is not permitted.

To handle situations where no value is matched by any *WHEN* clause, use an *ELSE* containing an empty *BEGIN ... END* block, as shown in this example. (The indentation used here in the *ELSE* clause is for purposes of clarity only, and is not otherwise significant.)

```
DELIMITER |
CREATE PROCEDURE p()
BEGIN
  DECLARE v INT DEFAULT 1;
  CASE v
    WHEN 2 THEN SELECT v;
    WHEN 3 THEN SELECT 0;
    ELSE
      BEGIN
        END;
      END CASE;
  END;
| 13.6.5.2 IF Statement
```

The *IF* statement for stored programs implements a basic conditional construct.

**Note**

There is also an *IF() function*, which differs from the *IF statement* described here. See Section 12.5, “Flow Control Functions”. The *IF* statement can have *THEN*, *ELSE*, and *ELSEIF* clauses, and it is terminated with *END IF*.

If a given *search_condition* evaluates to true, the corresponding *THEN* or *ELSEIF* clause *statement_list* executes. If no *search_condition* matches, the *ELSE* clause *statement_list* executes.

Each *statement_list* consists of one or more SQL statements; an empty *statement_list* is not permitted.
An **IF ... END IF** block, like all other flow-control blocks used within stored programs, must be terminated with a semicolon, as shown in this example:

```
DELIMITER //
CREATE FUNCTION SimpleCompare(n INT, m INT)
RETURNS VARCHAR(20)
BEGIN
  DECLARE s VARCHAR(20);
  IF n > m THEN SET s = '>'; 
  ELSEIF n = m THEN SET s = '='; 
  ELSE SET s = '<'; 
  END IF;
  SET s = CONCAT(n, ' ', s, ' ', m);
  RETURN s;
END //
DELIMITER ;
```

As with other flow-control constructs, **IF ... END IF** blocks may be nested within other flow-control constructs, including other **IF** statements. Each **IF** must be terminated by its own **END IF** followed by a semicolon. You can use indentation to make nested flow-control blocks more easily readable by humans (although this is not required by MySQL), as shown here:

```
DELIMITER //
CREATE FUNCTION VerboseCompare (n INT, m INT)
RETURNS VARCHAR(50)
BEGIN
  DECLARE s VARCHAR(50);
  IF n = m THEN SET s = 'equals';
  ELSE
    IF n > m THEN SET s = 'greater';
    ELSE SET s = 'less';
    END IF;
    SET s = CONCAT('is ', s, ' than');
  END IF;
  SET s = CONCAT(n, ' ', s, ' ', m, '.');
  RETURN s;
END //
DELIMITER ;
```

In this example, the inner **IF** is evaluated only if \( n \) is not equal to \( m \).

### 13.6.5.3 ITERATE Statement

**ITERATE** can appear only within **LOOP**, **REPEAT**, and **WHILE** statements. **ITERATE** means “start the loop again.”

For an example, see Section 13.6.5.5, “LOOP Statement”.

### 13.6.5.4 LEAVE Statement
LEAVE label

This statement is used to exit the flow control construct that has the given label. If the label is for the outermost stored program block, LEAVE exits the program.

LEAVE can be used within BEGIN ... END or loop constructs (LOOP, REPEAT, WHILE).

For an example, see Section 13.6.5.5, "LOOP Statement".

13.6.5.5 LOOP Statement

```
[begin_label:] LOOP
  statement_list
END LOOP [end_label]
```

LOOP implements a simple loop construct, enabling repeated execution of the statement list, which consists of one or more statements, each terminated by a semicolon (;) statement delimiter. The statements within the loop are repeated until the loop is terminated. Usually, this is accomplished with a LEAVE statement. Within a stored function, RETURN can also be used, which exits the function entirely.

Neglecting to include a loop-termination statement results in an infinite loop.

A LOOP statement can be labeled. For the rules regarding label use, see Section 13.6.2, "Statement Labels".

Example:

```
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
  label1: LOOP
    SET p1 = p1 + 1;
    IF p1 < 10 THEN
      ITERATE label1;
    END IF;
    LEAVE label1;
  END LOOP label1;
  SET @x = p1;
END;
```

13.6.5.6 REPEAT Statement

```
[begin_label:] REPEAT
  statement_list
UNTIL search_condition
END REPEAT [end_label]
```

The statement list within a REPEAT statement is repeated until the search_condition expression is true. Thus, a REPEAT always enters the loop at least once. statement_list consists of one or more statements, each terminated by a semicolon (;) statement delimiter.

A REPEAT statement can be labeled. For the rules regarding label use, see Section 13.6.2, "Statement Labels".

Example:

```
mysql> delimiter //
mysql> CREATE PROCEDURE dorepeat(p1 INT)
    BEGIN
        SET @x = 0;
        REPEAT
            SET @x = @x + 1;
```

2936
### 13.6.5.7 RETURN Statement

**RETURN** *expr*

The `RETURN` statement terminates execution of a stored function and returns the value *expr* to the function caller. There must be at least one `RETURN` statement in a stored function. There may be more than one if the function has multiple exit points.

This statement is not used in stored procedures, triggers, or events. The `LEAVE` statement can be used to exit a stored program of those types.

### 13.6.5.8 WHILE Statement

```
[begin_label:] WHILE search_condition DO
   statement_list
END WHILE [end_label]
```

The statement list within a `WHILE` statement is repeated as long as the `search_condition` expression is true. `statement_list` consists of one or more SQL statements, each terminated by a semicolon (`;`) statement delimiter.

A `WHILE` statement can be labeled. For the rules regarding label use, see Section 13.6.2, “Statement Labels”.

Example:

```sql
CREATE PROCEDURE dowhile()
BEGIN
   DECLARE v1 INT DEFAULT 5;
   WHILE v1 > 0 DO
      ... 
      SET v1 = v1 - 1;
   END WHILE;
END;
```

### 13.6.6 Cursors

MySQL supports cursors inside stored programs. The syntax is as in embedded SQL. Cursors have these properties:

- Asensitive: The server may or may not make a copy of its result table
- Read only: Not updatable
- Nonscrollable: Can be traversed only in one direction and cannot skip rows
Cursor declarations must appear before handler declarations and after variable and condition declarations.

Example:

```sql
CREATE PROCEDURE curdemo()
BEGIN
    DECLARE done INT DEFAULT FALSE;
    DECLARE a CHAR(16);
    DECLARE b, c INT;
    DECLARE cur1 CURSOR FOR SELECT id, data FROM test.t1;
    DECLARE cur2 CURSOR FOR SELECT i FROM test.t2;
    DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = TRUE;

    OPEN cur1;
    OPEN cur2;

    read_loop: LOOP
        FETCH cur1 INTO a, b;
        FETCH cur2 INTO c;
        IF done THEN
            LEAVE read_loop;
        END IF;
        IF b < c THEN
            INSERT INTO test.t3 VALUES (a, b);
        ELSE
            INSERT INTO test.t3 VALUES (a, c);
        END IF;
    END LOOP;

    CLOSE cur1;
    CLOSE cur2;
END;
```

13.6.6.1 Cursor CLOSE Statement

```sql
CLOSE cursor_name
```

This statement closes a previously opened cursor. For an example, see Section 13.6.6, “Cursors”.

An error occurs if the cursor is not open.

If not closed explicitly, a cursor is closed at the end of the `BEGIN . . . END` block in which it was declared.

13.6.6.2 Cursor DECLARE Statement

```sql
DECLARE cursor_name CURSOR FOR select_statement
```

This statement declares a cursor and associates it with a `SELECT` statement that retrieves the rows to be traversed by the cursor. To fetch the rows later, use a `FETCH` statement. The number of columns retrieved by the `SELECT` statement must match the number of output variables specified in the `FETCH` statement.

The `SELECT` statement cannot have an `INTO` clause.

Cursor declarations must appear before handler declarations and after variable and condition declarations.

A stored program may contain multiple cursor declarations, but each cursor declared in a given block must have a unique name. For an example, see Section 13.6.6, “Cursors”.

For information available through `SHOW` statements, it is possible in many cases to obtain equivalent information by using a cursor with an `INFORMATION_SCHEMA` table.

13.6.6.3 Cursor FETCH Statement

```sql
FETCH [[NEXT] FROM] cursor_name INTO var_name [, var_name] ...
```
This statement fetches the next row for the `SELECT` statement associated with the specified cursor (which must be open), and advances the cursor pointer. If a row exists, the fetched columns are stored in the named variables. The number of columns retrieved by the `SELECT` statement must match the number of output variables specified in the `FETCH` statement.

If no more rows are available, a No Data condition occurs with SQLSTATE value '02000'. To detect this condition, you can set up a handler for it (or for a `NOT FOUND` condition). For an example, see Section 13.6.6, “Cursors”.

Be aware that another operation, such as a `SELECT` or another `FETCH`, may also cause the handler to execute by raising the same condition. If it is necessary to distinguish which operation raised the condition, place the operation within its own `BEGIN ... END` block so that it can be associated with its own handler.

### 13.6.6.4 Cursor OPEN Statement

```
OPEN cursor_name
```

This statement opens a previously declared cursor. For an example, see Section 13.6.6, “Cursors”.

### 13.6.6.5 Restrictions on Server-Side Cursors

Server-side cursors are implemented in the C API using the `mysql_stmt_attr_set()` function. The same implementation is used for cursors in stored routines. A server-side cursor enables a result set to be generated on the server side, but not transferred to the client except for those rows that the client requests. For example, if a client executes a query but is only interested in the first row, the remaining rows are not transferred.

In MySQL, a server-side cursor is materialized into an internal temporary table. Initially, this is a `MEMORY` table, but is converted to a `MyISAM` table when its size exceeds the minimum value of the `max_heap_table_size` and `tmp_table_size` system variables. The same restrictions apply to internal temporary tables created to hold the result set for a cursor as for other uses of internal temporary tables. See Section 8.4.4, “Internal Temporary Table Use in MySQL”. One limitation of the implementation is that for a large result set, retrieving its rows through a cursor might be slow.

Cursors are read only; you cannot use a cursor to update rows.

`UPDATE WHERE CURRENT OF` and `DELETE WHERE CURRENT OF` are not implemented, because updatable cursors are not supported.

Cursors are nonholdable (not held open after a commit).

Cursors are insensitive.

Cursors are nonscrollable.

Cursors are not named. The statement handler acts as the cursor ID.

You can have open only a single cursor per prepared statement. If you need several cursors, you must prepare several statements.

You cannot use a cursor for a statement that generates a result set if the statement is not supported in prepared mode. This includes statements such as `CHECK TABLE`, `HANDLER`, `READ`, and `SHOW BINLOG EVENTS`.

### 13.6.7 Condition Handling

Conditions may arise during stored program execution that require special handling, such as exiting the current program block or continuing execution. Handlers can be defined for general conditions such as...
Condition Handling

warnings or exceptions, or for specific conditions such as a particular error code. Specific conditions can be assigned names and referred to that way in handlers.

To name a condition, use the DECLARE ... CONDITION statement. To declare a handler, use the DECLARE ... HANDLER statement. See Section 13.6.7.1, “DECLARE ... CONDITION Statement”, and Section 13.6.7.2, “DECLARE ... HANDLER Statement”. For information about how the server chooses handlers when a condition occurs, see Section 13.6.7.6, “Scope Rules for Handlers”.

To raise a condition, use the SIGNAL statement. To modify condition information within a condition handler, use RESIGNAL. See Section 13.6.7.1, “DECLARE ... CONDITION Statement”, and Section 13.6.7.2, “DECLARE ... HANDLER Statement”.

To retrieve information from the diagnostics area, use the GET DIAGNOSTICS statement (see Section 13.6.7.3, “GET DIAGNOSTICS Statement”). For information about the diagnostics area, see Section 13.6.7.7, “The MySQL Diagnostics Area”.

13.6.7.1 DECLARE ... CONDITION Statement

DECLARE condition_name CONDITION FOR condition_value

column_value: {
    mysql_error_code
    | SQLSTATE [VALUE] sqlstate_value
}

The DECLARE ... CONDITION statement declares a named error condition, associating a name with a condition that needs specific handling. The name can be referred to in a subsequent DECLARE ... HANDLER statement (see Section 13.6.7.2, “DECLARE ... HANDLER Statement”).

Condition declarations must appear before cursor or handler declarations.

The column_value for DECLARE ... CONDITION indicates the specific condition or class of conditions to associate with the condition name. It can take the following forms:

• mysql_error_code: An integer literal indicating a MySQL error code.

    Do not use MySQL error code 0 because that indicates success rather than an error condition. For a list of MySQL error codes, see Server Error Message Reference.

• SQLSTATE [VALUE] sqlstate_value: A 5-character string literal indicating an SQLSTATE value.

    Do not use SQLSTATE values that begin with '00' because those indicate success rather than an error condition. For a list of SQLSTATE values, see Server Error Message Reference.

Condition names referred to in SIGNAL or use RESIGNAL statements must be associated with SQLSTATE values, not MySQL error codes.

Using names for conditions can help make stored program code clearer. For example, this handler applies to attempts to drop a nonexistent table, but that is apparent only if you know that 1051 is the MySQL error code for “unknown table”:

DECLARE CONTINUE HANDLER FOR 1051
    BEGIN
        -- body of handler
    END;

By declaring a name for the condition, the purpose of the handler is more readily seen:

DECLARE no_such_table CONDITION FOR 1051;
DECLARE CONTINUE HANDLER FOR no_such_table
    BEGIN
        -- body of handler
    END;
Here is a named condition for the same condition, but based on the corresponding SQLSTATE value rather than the MySQL error code:

```
DECLARE no_such_table CONDITION FOR SQLSTATE '42S02';
DECLARE CONTINUE HANDLER FOR no_such_table
BEGIN
    -- body of handler
END;
```

### 13.6.7.2 DECLARE ... HANDLER Statement

```
DECLARE handler_action HANDLER
    FOR condition_value [, condition_value] ...
    statement

handler_action: {
    CONTINUE
    | EXIT
    | UNDO
}

condition_value: {
    mysql_error_code
    | SQLSTATE [VALUE] sqlstate_value
    | condition_name
    | SQLWARNING
    | NOT FOUND
    | SQLEXCEPTION
}
```

The `DECLARE ... HANDLER` statement specifies a handler that deals with one or more conditions. If one of these conditions occurs, the specified `statement` executes. `statement` can be a simple statement such as `SET var_name = value`, or a compound statement written using `BEGIN` and `END` (see Section 13.6.1, “BEGIN ... END Compound Statement”).

Handler declarations must appear after variable or condition declarations.

The `handler_action` value indicates what action the handler takes after execution of the handler statement:

- **CONTINUE**: Execution of the current program continues.
- **EXIT**: Execution terminates for the `BEGIN ... END` compound statement in which the handler is declared. This is true even if the condition occurs in an inner block.
- **UNDO**: Not supported.

The `condition_value` for `DECLARE ... HANDLER` indicates the specific condition or class of conditions that activates the handler. It can take the following forms:

- **mysql_error_code**: An integer literal indicating a MySQL error code, such as 1051 to specify “unknown table”:

  ```
  DECLARE CONTINUE HANDLER FOR 1051
  BEGIN
    -- body of handler
  END;
  ```

  Do not use MySQL error code 0 because that indicates success rather than an error condition. For a list of MySQL error codes, see Server Error Message Reference.
Condition Handling

- **SQLSTATE [VALUE]** *sqlstate_value*: A 5-character string literal indicating an SQLSTATE value, such as `42S01` to specify “unknown table”:

  ```sql
  DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
  BEGIN
    -- body of handler
  END;
  ```

  Do not use SQLSTATE values that begin with '00' because those indicate success rather than an error condition. For a list of SQLSTATE values, see Server Error Message Reference.

- **condition_name**: A condition name previously specified with DECLARE ... CONDITION. A condition name can be associated with a MySQL error code or SQLSTATE value. See Section 13.6.7.1, “DECLARE ... CONDITION Statement”.

- **SQLWARNING**: Shorthand for the class of SQLSTATE values that begin with '01'.

  ```sql
  DECLARE CONTINUE HANDLER FOR SQLWARNING
  BEGIN
    -- body of handler
  END;
  ```

- **NOT FOUND**: Shorthand for the class of SQLSTATE values that begin with '02'. This is relevant within the context of cursors and is used to control what happens when a cursor reaches the end of a data set. If no more rows are available, a No Data condition occurs with SQLSTATE value '02000'. To detect this condition, you can set up a handler for it or for a NOT FOUND condition.

  ```sql
  DECLARE CONTINUE HANDLER FOR NOT FOUND
  BEGIN
    -- body of handler
  END;
  ```

  For another example, see Section 13.6.6, "Cursors". The NOT FOUND condition also occurs for SELECT ... INTO var_list statements that retrieve no rows.

- **SQLEXCEPTION**: Shorthand for the class of SQLSTATE values that do not begin with '00', '01', or '02'.

  ```sql
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
  BEGIN
    -- body of handler
  END;
  ```

  For information about how the server chooses handlers when a condition occurs, see Section 13.6.7.6, “Scope Rules for Handlers”.

  If a condition occurs for which no handler has been declared, the action taken depends on the condition class:

  - For SQLEXCEPTION conditions, the stored program terminates at the statement that raised the condition, as if there were an EXIT handler. If the program was called by another stored program, the calling program handles the condition using the handler selection rules applied to its own handlers.
  - For SQLWARNING conditions, the program continues executing, as if there were a CONTINUE handler.
  - For NOT FOUND conditions, if the condition was raised normally, the action is CONTINUE. If it was raised by SIGNAL or RESIGNAL, the action is EXIT.

  The following example uses a handler for SQLSTATE '23000', which occurs for a duplicate-key error:

  ```sql
  mysql> CREATE TABLE test.t (s1 INT, PRIMARY KEY (s1));
  ```
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter //

mysql> CREATE PROCEDURE handlerdemo ()
BEGIN
    DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;
    SET @x = 1;
    INSERT INTO test.t VALUES (1);
    SET @x = 2;
    INSERT INTO test.t VALUES (1);
    SET @x = 3;
    END;
//
Query OK, 0 rows affected (0.00 sec)

mysql> CALL handlerdemo()//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
+------+
| @x   |
+------+
| 3    |
+------+
1 row in set (0.00 sec)

Notice that @x is 3 after the procedure executes, which shows that execution continued to the end of the procedure after the error occurred. If the DECLARE ... HANDLER statement had not been present, MySQL would have taken the default action (EXIT) after the second INSERT failed due to the PRIMARY KEY constraint, and SELECT @x would have returned 2.

To ignore a condition, declare a CONTINUE handler for it and associate it with an empty block. For example:

DECLARE CONTINUE HANDLER FOR SQLWARNING BEGIN END;

The scope of a block label does not include the code for handlers declared within the block. Therefore, the statement associated with a handler cannot use ITERATE or LEAVE to refer to labels for blocks that enclose the handler declaration. Consider the following example, where the REPEAT block has a label of retry:

CREATE PROCEDURE p ()
BEGIN
    DECLARE i INT DEFAULT 3;
    retry:
    REPEAT
        BEGIN
            DECLARE CONTINUE HANDLER FOR SQLWARNING
            BEGIN
                ITERATE retry;  # illegal
            END;
            IF i < 0 THEN
                LEAVE retry;    # legal
            END IF;
            SET i = i - 1;
        END;
    UNTIL FALSE END REPEAT;
END;

The retry label is in scope for the IF statement within the block. It is not in scope for the CONTINUE handler, so the reference there is invalid and results in an error:

ERROR 1308 (42000): LEAVE with no matching label: retry
To avoid references to outer labels in handlers, use one of these strategies:

- To leave the block, use an `EXIT` handler. If no block cleanup is required, the `BEGIN ... END` handler body can be empty:

  DECLARE EXIT HANDLER FOR SQLWARNING BEGIN END;

  Otherwise, put the cleanup statements in the handler body:

  DECLARE EXIT HANDLER FOR SQLWARNING
  BEGIN
  block cleanup statements
  END;

- To continue execution, set a status variable in a `CONTINUE` handler that can be checked in the enclosing block to determine whether the handler was invoked. The following example uses the variable `done` for this purpose:

  CREATE PROCEDURE p ()
  BEGIN
  DECLARE i INT DEFAULT 3;
  DECLARE done INT DEFAULT FALSE;
  retry:
  REPEAT
  BEGIN
  DECLARE CONTINUE HANDLER FOR SQLWARNING
  BEGIN
  SET done = TRUE;
  END;
  IF done OR i < 0 THEN
  LEAVE retry;
  END IF;
  SET i = i - 1;
  END;
  UNTIL FALSE END REPEAT;
  END;

13.6.7.3 GET DIAGNOSTICS Statement

GET [CURRENT | STACKED] DIAGNOSTICS {
  statement_information_item
  [, statement_information_item] ...
  | CONDITION condition_number
  condition_information_item
  [, condition_information_item] ...
}

statement_information_item:
  target = statement_information_item_name

collection_information_item:
  target = collection_information_item_name

statement_information_item_name: {
  NUMBER
  | ROW_COUNT
}

collection_information_item_name: {
  CLASS_ORIGIN
  | SUBCLASS_ORIGIN
  | RETURNED_SQLSTATE
  | MESSAGE_TEXT
  | MYSQL_ERRNO
  | CONSTRAINT_CATALOG
}
Condition Handling

SQL statements produce diagnostic information that populates the diagnostics area. The `GET DIAGNOSTICS` statement enables applications to inspect this information. (You can also use `SHOW WARNINGS` or `SHOW ERRORS` to see conditions or errors.)

No special privileges are required to execute `GET DIAGNOSTICS`.

The keyword `CURRENT` means to retrieve information from the current diagnostics area. The keyword `STACKED` means to retrieve information from the second diagnostics area, which is available only if the current context is a condition handler. If neither keyword is given, the default is to use the current diagnostics area.

The `GET DIAGNOSTICS` statement is typically used in a handler within a stored program. It is a MySQL extension that `GET [CURRENT] DIAGNOSTICS` is permitted outside handler context to check the execution of any SQL statement. For example, if you invoke the `mysql` client program, you can enter these statements at the prompt:

```sql
mysql> DROP TABLE test.no_such_table;
ERROR 1051 (42S02): Unknown table 'test.no_such_table'
mysql> GET DIAGNOSTICS CONDITION 1
    @p1 = RETURNED_SQLSTATE, @p2 = MESSAGE_TEXT;
mysql> SELECT @p1, @p2;
```

<table>
<thead>
<tr>
<th>@p1</th>
<th>@p2</th>
</tr>
</thead>
<tbody>
<tr>
<td>42S02</td>
<td>Unknown table 'test.no_such_table'</td>
</tr>
</tbody>
</table>

This extension applies only to the current diagnostics area. It does not apply to the second diagnostics area because `GET STACKED DIAGNOSTICS` is permitted only if the current context is a condition handler. If that is not the case, a `GET STACKED DIAGNOSTICS when handler not active` error occurs.

For a description of the diagnostics area, see Section 13.6.7.7, “The MySQL Diagnostics Area”. Briefly, it contains two kinds of information:

- Statement information, such as the number of conditions that occurred or the affected-rows count.
- Condition information, such as the error code and message. If a statement raises multiple conditions, this part of the diagnostics area has a condition area for each one. If a statement raises no conditions, this part of the diagnostics area is empty.

For a statement that produces three conditions, the diagnostics area contains statement and condition information like this:

```
Statement information:
    row count
    ... other statement information items ...
Condition area list:
    Condition area 1:
        error code for condition 1
        error message for condition 1
```
GET DIAGNOSTICS can obtain either statement or condition information, but not both in the same statement:

- To obtain statement information, retrieve the desired statement items into target variables. This instance of GET DIAGNOSTICS assigns the number of available conditions and the rows-affected count to the user variables @p1 and @p2:

  ```sql
  GET DIAGNOSTICS @p1 = NUMBER, @p2 = ROW_COUNT;
  ```

- To obtain condition information, specify the condition number and retrieve the desired condition items into target variables. This instance of GET DIAGNOSTICS assigns the SQLSTATE value and error message to the user variables @p3 and @p4:

  ```sql
  GET DIAGNOSTICS CONDITION 1
  @p3 = RETURNED_SQLSTATE, @p4 = MESSAGE_TEXT;
  ```

The retrieval list specifies one or more target = item_name assignments, separated by commas. Each assignment names a target variable and either a statement_information_item_name or condition_information_item_name designator, depending on whether the statement retrieves statement or condition information.

Valid target designators for storing item information can be stored procedure or function parameters, stored program local variables declared with DECLARE, or user-defined variables.

Valid condition_number designators can be stored procedure or function parameters, stored program local variables declared with DECLARE, user-defined variables, system variables, or literals. A character literal may include a _charset introducer. A warning occurs if the condition number is not in the range from 1 to the number of condition areas that have information. In this case, the warning is added to the diagnostics area without clearing it.

When a condition occurs, MySQL does not populate all condition items recognized by GET DIAGNOSTICS. For example:

```sql
mysql> GET DIAGNOSTICS CONDITION 1
    > @p5 = SCHEMA_NAME, @p6 = TABLE_NAME;
mysql> SELECT @p5, @p6;
+--------+------+
| @p5    | @p6  |
|        |      |
+--------+------+
```

In standard SQL, if there are multiple conditions, the first condition relates to the SQLSTATE value returned for the previous SQL statement. In MySQL, this is not guaranteed. To get the main error, you cannot do this:

```sql
GET DIAGNOSTICS CONDITION 1 @errno = MYSQL_ERRNO;
```

Instead, retrieve the condition count first, then use it to specify which condition number to inspect:

```sql
GET DIAGNOSTICS @cno = NUMBER;
GET DIAGNOSTICS CONDITION @cno @errno = MYSQL_ERRNO;
```
Condition Handling

For information about permissible statement and condition information items, and which ones are populated when a condition occurs, see Diagnostics Area Information Items.

Here is an example that uses GET DIAGNOSTICS and an exception handler in stored procedure context to assess the outcome of an insert operation. If the insert was successful, the procedure uses GET DIAGNOSTICS to get the rows-affected count. This shows that you can use GET DIAGNOSTICS multiple times to retrieve information about a statement as long as the current diagnostics area has not been cleared.

CREATE PROCEDURE do_insert(value INT)
BEGIN
  -- Declare variables to hold diagnostics area information
  DECLARE code CHAR(5) DEFAULT '00000';
  DECLARE msg TEXT;
  DECLARE nrows INT;
  DECLARE result TEXT;
  -- Declare exception handler for failed insert
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
  BEGIN
    GET DIAGNOSTICS CONDITION 1
    code = RETURNED_SQLSTATE, msg = MESSAGE_TEXT;
  END;
  -- Perform the insert
  INSERT INTO t1 (int_col) VALUES(value);
  -- Check whether the insert was successful
  IF code = '00000' THEN
    GET DIAGNOSTICS nrows = ROW_COUNT;
    SET result = CONCAT('insert succeeded, row count = ',nrows);
  ELSE
    SET result = CONCAT('insert failed, error = ',code,', message = ',msg);
  END IF;
  -- Say what happened
  SELECT result;
END;

Suppose that t1.int_col is an integer column that is declared as NOT NULL. The procedure produces these results when invoked to insert non-NULL and NULL values, respectively:

mysql> CALL do_insert(1);
+-------------------------------+
| result                        |
| insert succeeded, row count = 1 |
+-------------------------------+

mysql> CALL do_insert(NULL);
+--------------------------------------------------------------------------------+
| result                                                                                                  |
| insert failed, error = 23000, message = Column 'int_col' cannot be null                                 |
+--------------------------------------------------------------------------------+

When a condition handler activates, a push to the diagnostics area stack occurs:

- The first (current) diagnostics area becomes the second (stacked) diagnostics area and a new current diagnostics area is created as a copy of it.

- GET [CURRENT] DIAGNOSTICS and GET STACKED DIAGNOSTICS can be used within the handler to access the contents of the current and stacked diagnostics areas.

- Initially, both diagnostics areas return the same result, so it is possible to get information from the current diagnostics area about the condition that activated the handler, as long as you execute no statements within the handler that change its current diagnostics area.
Condition Handling

• However, statements executing within the handler can modify the current diagnostics area, clearing and setting its contents according to the normal rules (see How the Diagnostics Area is Cleared and Populated).

A more reliable way to obtain information about the handler-activating condition is to use the stacked diagnostics area, which cannot be modified by statements executing within the handler except RESIGNAL. For information about when the current diagnostics area is set and cleared, see Section 13.6.7.7, “The MySQL Diagnostics Area”.

The next example shows how GET STACKED DIAGNOSTICS can be used within a handler to obtain information about the handled exception, even after the current diagnostics area has been modified by handler statements.

Within a stored procedure `p()`, we attempt to insert two values into a table that contains a TEXT NOT NULL column. The first value is a non-NULL string and the second is NULL. The column prohibits NULL values, so the first insert succeeds but the second causes an exception. The procedure includes an exception handler that maps attempts to insert NULL into inserts of the empty string:

```sql
DROP TABLE IF EXISTS t1;
CREATE TABLE t1 (c1 TEXT NOT NULL);
DROP PROCEDURE IF EXISTS p;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  -- Declare variables to hold diagnostics area information
  DECLARE errcount INT;
  DECLARE errno INT;
  DECLARE msg TEXT;
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    -- Here the current DA is nonempty because no prior statements
    -- executing within the handler have cleared it
    GET CURRENT DIAGNOSTICS CONDITION 1
    errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
    SELECT 'current DA before mapped insert' AS op, errno, msg;
    GET STACKED DIAGNOSTICS CONDITION 1
    errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
    SELECT 'stacked DA before mapped insert' AS op, errno, msg;
    -- Map attempted NULL insert to empty string insert
    INSERT INTO t1 (c1) VALUES('');
    -- Here the current DA should be empty (if the INSERT succeeded),
    -- so check whether there are conditions before attempting to
    -- obtain condition information
    GET CURRENT DIAGNOSTICS errcount = NUMBER;
    IF errcount = 0
    THEN
      SELECT 'mapped insert succeeded, current DA is empty' AS op;
    ELSE
      GET CURRENT DIAGNOSTICS CONDITION 1
      errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
      SELECT 'current DA after mapped insert' AS op, errno, msg;
    END IF;
    GET STACKED DIAGNOSTICS CONDITION 1
    errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
    SELECT 'stacked DA after mapped insert' AS op, errno, msg;
  END;
  INSERT INTO t1 (c1) VALUES('string 1');
  INSERT INTO t1 (c1) VALUES(NULL);
END;
//
delimiter ;
CALL p();
```
When the handler activates, a copy of the current diagnostics area is pushed to the diagnostics area stack. The handler first displays the contents of the current and stacked diagnostics areas, which are both the same initially:

```
+---------------------------------+-------+----------------------------+
| op                              | errno | msg                        |
| current DA before mapped insert |  1048 | Column 'c1' cannot be null |
+---------------------------------+-------+----------------------------+
```

Statements executing after the `GET DIAGNOSTICS` statements may reset the current diagnostics area. For example, the handler maps the `NULL` insert to an empty-string insert and displays the result. The new insert succeeds and clears the current diagnostics area, but the stacked diagnostics area remains unchanged and still contains information about the condition that activated the handler:

```
+----------------------------------------------+
| op                                           |
+----------------------------------------------+
| mapped insert succeeded, current DA is empty |
+----------------------------------------------+
```

When the condition handler ends, its current diagnostics area is popped from the stack and the stacked diagnostics area becomes the current diagnostics area in the stored procedure.

After the procedure returns, the table contains two rows. The empty row results from the attempt to insert `NULL` that was mapped to an empty-string insert:

```
+----------+
| c1       |
| string 1 |
+----------+
```

### 13.6.7.4 RESIGNAL Statement

RESIGNAL [condition_value]

```
[SET signal_information_item
    [, signal_information_item] ...]
```

**condition_value:**

```
SQLSTATE [VALUE] sqlstate_value  
| condition_name
```

**signal_information_item:**

```
condition_information_item_name = simple_value_specification
```

```
condition_information_item_name: [
```
RESIGNAL passes on the error condition information that is available during execution of a condition handler within a compound statement inside a stored procedure or function, trigger, or event. RESIGNAL may change some or all information before passing it on. RESIGNAL is related to SIGNAL, but instead of originating a condition as SIGNAL does, RESIGNAL relays existing condition information, possibly after modifying it.

RESIGNAL makes it possible to both handle an error and return the error information. Otherwise, by executing an SQL statement within the handler, information that caused the handler's activation is destroyed. RESIGNAL also can make some procedures shorter if a given handler can handle part of a situation, then pass the condition “up the line” to another handler.

No privileges are required to execute the RESIGNAL statement.

All forms of RESIGNAL require that the current context be a condition handler. Otherwise, RESIGNAL is illegal and a RESIGNAL when handler not active error occurs.

To retrieve information from the diagnostics area, use the GET DIAGNOSTICS statement (see Section 13.6.7.3, "GET DIAGNOSTICS Statement"). For information about the diagnostics area, see Section 13.6.7.7, “The MySQL Diagnostics Area”.

- RESIGNAL Overview
- RESIGNAL Alone
- RESIGNAL with New Signal Information
- RESIGNAL with a Condition Value and Optional New Signal Information
- RESIGNAL Requires Condition Handler Context

RESIGNAL Overview

For condition_value and signal_information_item, the definitions and rules are the same for RESIGNAL as for SIGNAL. For example, the condition_value can be an SQLSTATE value, and the value can indicate errors, warnings, or “not found.” For additional information, see Section 13.6.7.5, “SIGNAL Statement”.

The RESIGNAL statement takes condition_value and SET clauses, both of which are optional. This leads to several possible uses:

- RESIGNAL alone:

  RESIGNAL;
**Condition Handling**

- **RESIGNAL** with new signal information:

  ```
  RESIGNAL SET signal_information_item [, signal_information_item] ...;
  ```

- **RESIGNAL** with a condition value and possibly new signal information:

  ```
  RESIGNAL condition_value
  [SET signal_information_item [, signal_information_item] ...];
  ```

These use cases all cause changes to the diagnostics and condition areas:

- A diagnostics area contains one or more condition areas.

- A condition area contains condition information items, such as the `SQLSTATE` value, `MYSQL_ERRNO`, or `MESSAGE_TEXT`.

There is a stack of diagnostics areas. When a handler takes control, it pushes a diagnostics area to the top of the stack, so there are two diagnostics areas during handler execution:

- The first (current) diagnostics area, which starts as a copy of the last diagnostics area, but is overwritten by the first statement in the handler that changes the current diagnostics area.

- The last (stacked) diagnostics area, which has the condition areas that were set up before the handler took control.

The maximum number of condition areas in a diagnostics area is determined by the value of the `max_error_count` system variable. See [Diagnostics Area-Related System Variables](#).

**RESIGNAL** Alone

A simple **RESIGNAL** alone means “pass on the error with no change.” It restores the last diagnostics area and makes it the current diagnostics area. That is, it “pops” the diagnostics area stack.

Within a condition handler that catches a condition, one use for **RESIGNAL** alone is to perform some other actions, and then pass on without change the original condition information (the information that existed before entry into the handler).

Example:

```sql
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SET @error_count = @error_count + 1;
    IF @a = 0 THEN RESIGNAL; END IF;
  END;
  DROP TABLE xx;
END//
delimiter ;
SET @error_count = 0;
SET @a = 0;
CALL p();
```

Suppose that the `DROP TABLE xx` statement fails. The diagnostics area stack looks like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
```

Then execution enters the `EXIT` handler. It starts by pushing a diagnostics area to the top of the stack, which now looks like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
```
### Condition Handling

**DA 2. ERROR 1051 (42S02): Unknown table 'xx'**

At this point, the contents of the first (current) and second (stacked) diagnostics areas are the same. The first diagnostics area may be modified by statements executing subsequently within the handler.

Usually a procedure statement clears the first diagnostics area. **BEGIN** is an exception, it does not clear, it does nothing. **SET** is not an exception, it clears, performs the operation, and produces a result of “success.” The diagnostics area stack now looks like this:

| DA 1. ERROR 0000 (00000): Successful operation |
| DA 2. ERROR 1051 (42S02): Unknown table 'xx' |

At this point, if \( @a = 0 \), **RESIGNAL** pops the diagnostics area stack, which now looks like this:

| DA 1. ERROR 1051 (42S02): Unknown table 'xx' |

And that is what the caller sees.

If \( @a \) is not 0, the handler simply ends, which means that there is no more use for the current diagnostics area (it has been “handled”), so it can be thrown away, causing the stacked diagnostics area to become the current diagnostics area again. The diagnostics area stack looks like this:

| DA 1. ERROR 0000 (00000): Successful operation |

The details make it look complex, but the end result is quite useful: Handlers can execute without destroying information about the condition that caused activation of the handler.

### RESIGNAL with New Signal Information

**RESIGNAL** with a **SET** clause provides new signal information, so the statement means “pass on the error with changes”:

**RESIGNAL SET** \( \text{signal_information_item} [, \text{signal_information_item}] \) ...;

As with **RESIGNAL** alone, the idea is to pop the diagnostics area stack so that the original information goes out. Unlike **RESIGNAL** alone, anything specified in the **SET** clause changes.

**Example:**

```sql
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SET @error_count = @error_count + 1;
    IF @a = 0 THEN RESIGNAL SET MYSQL_ERRNO = 5; END IF;
  END;
  DROP TABLE xx;
END://
delimiter;
SET @error_count = 0;
SET @a = 0;
CALL p();
```

Remember from the previous discussion that **RESIGNAL** alone results in a diagnostics area stack like this:

| DA 1. ERROR 1051 (42S02): Unknown table 'xx' |

The **RESIGNAL SET MYSQL_ERRNO = 5** statement results in this stack instead, which is what the caller sees:

| DA 1. ERROR 5 (42S02): Unknown table 'xx' |
In other words, it changes the error number, and nothing else.

The **RESIGNAL** statement can change any or all of the signal information items, making the first condition area of the diagnostics area look quite different.

### RESIGNAL with a Condition Value and Optional New Signal Information

**RESIGNAL** with a condition value means "push a condition into the current diagnostics area." If the **SET** clause is present, it also changes the error information.

```sql
RESIGNAL condition_value
[SET signal_information_item [, signal_information_item] ...];
```

This form of **RESIGNAL** restores the last diagnostics area and makes it the current diagnostics area. That is, it "pops" the diagnostics area stack, which is the same as what a simple **RESIGNAL** alone would do. However, it also changes the diagnostics area depending on the condition value or signal information.

Example:

```sql
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
DECLARE EXIT HANDLER FOR SQLEXCEPTION
BEGIN
    SET @error_count = @error_count + 1;
    IF @a = 0 THEN RESIGNAL SQLSTATE '45000' SET MYSQL_ERRNO=5; END IF;
END;
DROP TABLE xx;
END//
delimiter ;
SET @error_count = 0;
SET @a = 0;
SET @@max_error_count = 2;
CALL p();
SHOW ERRORS;
```

This is similar to the previous example, and the effects are the same, except that if **RESIGNAL** happens, the current condition area looks different at the end. (The reason the condition adds to rather than replaces the existing condition is the use of a condition value.)

The **RESIGNAL** statement includes a condition value (**SQLSTATE '45000'**), so it adds a new condition area, resulting in a diagnostics area stack that looks like this:

<table>
<thead>
<tr>
<th>Level</th>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error</td>
<td>1051</td>
<td>Unknown table 'xx'</td>
</tr>
<tr>
<td>Error</td>
<td>5</td>
<td>Unknown table 'xx'</td>
</tr>
</tbody>
</table>

The result of **CALL p()** and **SHOW ERRORS** for this example is:

```sql
mysql> CALL p();
ERROR 5 (45000): Unknown table 'xx'
mysql> SHOW ERRORS;
```

### RESIGNAL Requires Condition Handler Context

All forms of **RESIGNAL** require that the current context be a condition handler. Otherwise, **RESIGNAL** is illegal and a **RESIGNAL when handler not active** error occurs. For example:
Here is a more difficult example:

```sql
delimiter //
CREATE FUNCTION f () RETURNS INT
BEGIN
  RESIGNAL;
  RETURN 5;
END//
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION SET @a=f();
  SIGNAL SQLSTATE '55555';
END//
delimiter ;
CALL p();
RESIGNAL
```

RESIGNAL occurs within the stored function `f()`. Although `f()` itself is invoked within the context of the EXIT handler, execution within `f()` has its own context, which is not handler context. Thus, RESIGNAL within `f()` results in a “handler not active” error.

13.6.7.5 SIGNAL Statement

```sql
SIGNAL condition_value
  [SET signal_information_item
   [, signal_information_item] ...]
```

condition_value: {
  SQLSTATE [VALUE] sqlstate_value
  | condition_name
}

signal_information_item:
  condition_information_item_name = simple_value_specification

condition_information_item_name: {
  CLASS_ORIGIN
  | SUBCLASS_ORIGIN
  | MESSAGE_TEXT
  | MYSQL_ERRNO
  | CONSTRAINT_CATALOG
  | CONSTRAINT_SCHEMA
  | CONSTRAINT_NAME
  | CATALOG_NAME
  | SCHEMA_NAME
  | TABLE_NAME
  | COLUMN_NAME
  | CURSOR_NAME
}

condition_name, simple_value_specification:
  (see following discussion)
```

**SIGNAL** is the way to “return” an error. **SIGNAL** provides error information to a handler, to an outer portion of the application, or to the client. Also, it provides control over the error’s characteristics (error number, SQLSTATE value, message). Without **SIGNAL**, it is necessary to resort to workarounds such as deliberately referring to a nonexistent table to cause a routine to return an error.

No privileges are required to execute the **SIGNAL** statement.
To retrieve information from the diagnostics area, use the \texttt{GET DIAGNOSTICS} statement (see Section 13.6.7.3, “GET DIAGNOSTICS Statement”). For information about the diagnostics area, see Section 13.6.7.7, “The MySQL Diagnostics Area”.

- SIGNAL Overview
- Signal Condition Information Items
- Effect of Signals on Handlers, Cursors, and Statements

\textbf{SIGNAL Overview}

The \texttt{condition\_value} in a \texttt{SIGNAL} statement indicates the error value to be returned. It can be an \texttt{SQLSTATE} value (a 5-character string literal) or a \texttt{condition\_name} that refers to a named condition previously defined with \texttt{DECLARE \ldots CONDITION} (see Section 13.6.7.1, “DECLARE ... CONDITION Statement”).

An \texttt{SQLSTATE} value can indicate errors, warnings, or “not found.” The first two characters of the value indicate its error class, as discussed in Signal Condition Information Items. Some signal values cause statement termination; see Effect of Signals on Handlers, Cursors, and Statements.

The \texttt{SQLSTATE} value for a \texttt{SIGNAL} statement should not start with ‘00’ because such values indicate success and are not valid for signaling an error. This is true whether the \texttt{SQLSTATE} value is specified directly in the \texttt{SIGNAL} statement or in a named condition referred to in the statement. If the value is invalid, a Bad \texttt{SQLSTATE} error occurs.

To signal a generic \texttt{SQLSTATE} value, use ‘45000’, which means “unhandled user-defined exception.”

The \texttt{SIGNAL} statement optionally includes a \texttt{SET} clause that contains multiple signal items, in a list of \texttt{condition\_information\_item\_name = simple\_value\_specification} assignments, separated by commas.

Each \texttt{condition\_information\_item\_name} may be specified only once in the \texttt{SET} clause. Otherwise, a Duplicate condition information item error occurs.

Valid \texttt{simple\_value\_specification} designators can be specified using stored procedure or function parameters, stored program local variables declared with \texttt{DECLARE}, user-defined variables, system variables, or literals. A character literal may include a \texttt{_charset} introducer.

For information about permissible \texttt{condition\_information\_item\_name} values, see Signal Condition Information Items.

The following procedure signals an error or warning depending on the value of \texttt{pval}, its input parameter:

```sql
CREATE PROCEDURE p (pval INT)
BEGIN
  DECLARE specialty CONDITION FOR SQLSTATE '45000';
  IF pval = 0 THEN
    SIGNAL SQLSTATE '01000';
  ELSEIF pval = 1 THEN
    SIGNAL SQLSTATE '45000'
    SET MESSAGE_TEXT = 'An error occurred';
  ELSEIF pval = 2 THEN
    SIGNAL specialty
    SET MESSAGE_TEXT = 'An error occurred';
  ELSE
    SIGNAL SQLSTATE '01000'
    SET MESSAGE_TEXT = 'A warning occurred', MYSQL_ERRNO = 1000;
    SIGNAL SQLSTATE '45000'
    SET MESSAGE_TEXT = 'An error occurred', MYSQL_ERRNO = 1001;
```
If `pval` is 0, `p()` signals a warning because `SQLSTATE` values that begin with '01' are signals in the warning class. The warning does not terminate the procedure, and can be seen with `SHOW WARNINGS` after the procedure returns.

If `pval` is 1, `p()` signals an error and sets the `MESSAGE_TEXT` condition information item. The error terminates the procedure, and the text is returned with the error information.

If `pval` is 2, the same error is signaled, although the `SQLSTATE` value is specified using a named condition in this case.

If `pval` is anything else, `p()` first signals a warning and sets the message text and error number condition information items. This warning does not terminate the procedure, so execution continues and `p()` then signals an error. The error does terminate the procedure. The message text and error number set by the warning are replaced by the values set by the error, which are returned with the error information.

`SIGNAL` is typically used within stored programs, but it is a MySQL extension that it is permitted outside handler context. For example, if you invoke the `mysql` client program, you can enter any of these statements at the prompt:

```
SIGNAL SQLSTATE '77777';
CREATE TRIGGER t_bi BEFORE INSERT ON t
  FOR EACH ROW SIGNAL SQLSTATE '77777';
CREATE EVENT e ON SCHEDULE EVERY 1 SECOND
  DO SIGNAL SQLSTATE '77777';
```

`SIGNAL` executes according to the following rules:

If the `SIGNAL` statement indicates a particular `SQLSTATE` value, that value is used to signal the condition specified. Example:

```
CREATE PROCEDURE p (divisor INT)
BEGIN
  IF divisor = 0 THEN
    SIGNAL SQLSTATE '22012';
  END IF;
END;
```

If the `SIGNAL` statement uses a named condition, the condition must be declared in some scope that applies to the `SIGNAL` statement, and must be defined using an `SQLSTATE` value, not a MySQL error number. Example:

```
CREATE PROCEDURE p (divisor INT)
BEGIN
  DECLARE divide_by_zero CONDITION FOR SQLSTATE '22012';
  IF divisor = 0 THEN
    SIGNAL divide_by_zero;
  END IF;
END;
```

If the named condition does not exist in the scope of the `SIGNAL` statement, an `Undefined CONDITION` error occurs.

If `SIGNAL` refers to a named condition that is defined with a MySQL error number rather than an `SQLSTATE` value, a `SIGNAL/RESIGNAL` can only use a `CONDITION` defined with `SQLSTATE` error occurs. The following statements cause that error because the named condition is associated with a MySQL error number:
DECLARE no_such_table CONDITION FOR 1051;
SIGNAL no_such_table;

If a condition with a given name is declared multiple times in different scopes, the declaration with the most
local scope applies. Consider the following procedure:

CREATE PROCEDURE p (divisor INT)
BEGIN
  DECLARE my_error CONDITION FOR SQLSTATE '45000';
  IF divisor = 0 THEN
    BEGIN
      DECLARE my_error CONDITION FOR SQLSTATE '22012';
      SIGNAL my_error;
    END;
  END IF;
  SIGNAL my_error;
END;

If \texttt{divisor} is 0, the first \texttt{SIGNAL} statement executes. The innermost \texttt{my_error} condition declaration
applies, raising SQLSTATE '22012'.

If \texttt{divisor} is not 0, the second \texttt{SIGNAL} statement executes. The outermost \texttt{my_error} condition declaration applies, raising SQLSTATE '45000'.

For information about how the server chooses handlers when a condition occurs, see Section 13.6.7.6,
“Scope Rules for Handlers”.

Signals can be raised within exception handlers:

CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SIGNAL SQLSTATE VALUE '99999'
    SET MESSAGE_TEXT = 'An error occurred';
  END;
  DROP TABLE no_such_table;
END;

\texttt{CALL p()} reaches the \texttt{DROP TABLE} statement. There is no table named \texttt{no_such_table}, so the error
handler is activated. The error handler destroys the original error ("no such table") and makes a new error
with SQLSTATE '99999' and message An error occurred.

\textbf{Signal Condition Information Items}

The following table lists the names of diagnostics area condition information items that can be set in a
\texttt{SIGNAL} (or \texttt{RESIGNAL}) statement. All items are standard SQL except \texttt{MYSQL_ERRNO}, which is a MySQL
extension. For more information about these items see Section 13.6.7.7, “The MySQL Diagnostics Area”.

<table>
<thead>
<tr>
<th>Item Name</th>
<th>Definition</th>

<td>SMALLINT UNSIGNED</td>
</tr>
</tbody>
</table>
Condition Handling

The character set for character items is UTF-8.

It is illegal to assign NULL to a condition information item in a SIGNAL statement.

A SIGNAL statement always specifies an SQLSTATE value, either directly, or indirectly by referring to a named condition defined with an SQLSTATE value. The first two characters of an SQLSTATE value are its class, and the class determines the default value for the condition information items:

- **Class = '00' (success)**
  - Illegal. SQLSTATE values that begin with '00' indicate success and are not valid for SIGNAL.
- **Class = '01' (warning)**
  - MESSAGE_TEXT = 'Unhandled user-defined warning condition';
  - MYSQL_ERRNO = ER_SIGNAL_WARN
- **Class = '02' (not found)**
  - MESSAGE_TEXT = 'Unhandled user-defined not found condition';
  - MYSQL_ERRNO = ER_SIGNAL_NOT_FOUND
- **Class > '02' (exception)**
  - MESSAGE_TEXT = 'Unhandled user-defined exception condition';
  - MYSQL_ERRNO = ER_SIGNAL_EXCEPTION

For legal classes, the other condition information items are set as follows:

- CLASS_ORIGIN = SUBCLASS_ORIGIN = '';
- CONSTRAINT_CATALOG = CONSTRAINT_SCHEMA = CONSTRAINT_NAME = '';
- CATALOG_NAME = SCHEMA_NAME = TABLE_NAME = COLUMN_NAME = '';
- CURSOR_NAME = '';

The error values that are accessible after SIGNAL executes are the SQLSTATE value raised by the SIGNAL statement and the MESSAGE_TEXT and MYSQL_ERRNO items. These values are available from the C API:

- mysql_sqlstate() returns the SQLSTATE value.
- mysql_errno() returns the MYSQL_ERRNO value.
- mysql_error() returns the MESSAGE_TEXT value.

At the SQL level, the output from SHOW WARNINGS and SHOW ERRORS indicates the MYSQL_ERRNO and MESSAGE_TEXT values in the Code and Message columns.

To retrieve information from the diagnostics area, use the GET DIAGNOSTICS statement (see Section 13.6.7.3, "GET DIAGNOSTICS Statement"). For information about the diagnostics area, see Section 13.6.7.7, “The MySQL Diagnostics Area”.

Effect of Signals on Handlers, Cursors, and Statements

Signals have different effects on statement execution depending on the signal class. The class determines how severe an error is. MySQL ignores the value of the sql_mode system variable; in particular, strict SQL mode does not matter. MySQL also ignores IGNORE: The intent of SIGNAL is to raise a user-generated error explicitly, so a signal is never ignored.

In the following descriptions, “unhandled” means that no handler for the signaled SQLSTATE value has been defined with DECLARE ... HANDLER.

- **Class = '00' (success)**
Illegal. *SQLSTATE* values that begin with '00' indicate success and are not valid for *SIGNAL*.

- **Class = '01'** (warning)
  
  The value of the *warning_count* system variable goes up. *SHOW WARNINGS* shows the signal. *SQLWARNING* handlers catch the signal.

  Warnings cannot be returned from stored functions because the *RETURN* statement that causes the function to return clears the diagnostic area. The statement thus clears any warnings that may have been present there (and resets *warning_count* to 0).

- **Class = '02'** (not found)
  
  *NOT FOUND* handlers catch the signal. There is no effect on cursors. If the signal is unhandled in a stored function, statements end.

- **Class > '02'** (exception)
  
  *SQLEXCEPTION* handlers catch the signal. If the signal is unhandled in a stored function, statements end.

- **Class = '40'**
  
  Treated as an ordinary exception.

### 13.6.7.6 Scope Rules for Handlers

A stored program may include handlers to be invoked when certain conditions occur within the program. The applicability of each handler depends on its location within the program definition and on the condition or conditions that it handles:

- A handler declared in a *BEGIN ... END* block is in scope only for the SQL statements following the handler declarations in the block. If the handler itself raises a condition, it cannot handle that condition, nor can any other handlers declared in the block. In the following example, handlers *H1* and *H2* are in scope for conditions raised by statements *stmt1* and *stmt2*. But neither *H1* nor *H2* are in scope for conditions raised in the body of *H1* or *H2*.

```sql
BEGIN -- outer block
    DECLARE EXIT HANDLER FOR ...; -- handler H1
    DECLARE EXIT HANDLER FOR ...; -- handler H2
    stmt1;
    stmt2;
END;
```

- A handler is in scope only for the block in which it is declared, and cannot be activated for conditions occurring outside that block. In the following example, handler *H1* is in scope for *stmt1* in the inner block, but not for *stmt2* in the outer block:

```sql
BEGIN -- outer block
    BEGIN -- inner block
        DECLARE EXIT HANDLER FOR ...; -- handler H1
        stmt1;
    END;
    stmt2;
END;
```

- A handler can be specific or general. A specific handler is for a MySQL error code, *SQLSTATE* value, or condition name. A general handler is for a condition in the *SQLWARNING*, *SQLEXCEPTION*, or *NOT FOUND* class. Condition specificity is related to condition precedence, as described later.
Multiple handlers can be declared in different scopes and with different specificities. For example, there might be a specific MySQL error code handler in an outer block, and a general SQLWARNING handler in an inner block. Or there might be handlers for a specific MySQL error code and the general SQLWARNING class in the same block.

Whether a handler is activated depends not only on its own scope and condition value, but on what other handlers are present. When a condition occurs in a stored program, the server searches for applicable handlers in the current scope (current `BEGIN ... END` block). If there are no applicable handlers, the search continues outward with the handlers in each successive containing scope (block). When the server finds one or more applicable handlers at a given scope, it chooses among them based on condition precedence:

- A MySQL error code handler takes precedence over an SQLSTATE value handler.
- An SQLSTATE value handler takes precedence over general SQLWARNING, SQLEXCEPTION, or NOT FOUND handlers.
- An SQLEXCEPTION handler takes precedence over an SQLWARNING handler.
- It is possible to have several applicable handlers with the same precedence. For example, a statement could generate multiple warnings with different error codes, for each of which an error-specific handler exists. In this case, the choice of which handler the server activates is nondeterministic, and may change depending on the circumstances under which the condition occurs.

One implication of the handler selection rules is that if multiple applicable handlers occur in different scopes, handlers with the most local scope take precedence over handlers in outer scopes, even over those for more specific conditions.

If there is no appropriate handler when a condition occurs, the action taken depends on the class of the condition:

- For SQLEXCEPTION conditions, the stored program terminates at the statement that raised the condition, as if there were an EXIT handler. If the program was called by another stored program, the calling program handles the condition using the handler selection rules applied to its own handlers.
- For SQLWARNING conditions, the program continues executing, as if there were a CONTINUE handler.
- For NOT FOUND conditions, if the condition was raised normally, the action is CONTINUE. If it was raised by SIGNAL or RESIGNAL, the action is EXIT.

The following examples demonstrate how MySQL applies the handler selection rules.

This procedure contains two handlers, one for the specific SQLSTATE value ('42S02') that occurs for attempts to drop a nonexistent table, and one for the general SQLEXCEPTION class:

```sql
CREATE PROCEDURE p1()
BEGIN
  DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
  SELECT 'SQLSTATE handler was activated' AS msg;
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
    SELECT 'SQLEXCEPTION handler was activated' AS msg;
  DROP TABLE test.t;
END;
```

Both handlers are declared in the same block and have the same scope. However, SQLSTATE handlers take precedence over SQLEXCEPTION handlers, so if the table `t` is nonexistent, the DROP TABLE statement raises a condition that activates the SQLSTATE handler.
This procedure contains the same two handlers. But this time, the DROP TABLE statement and SQLEXCEPTION handler are in an inner block relative to the SQLSTATE handler:

CREATE PROCEDURE p2()
BEGIN -- outer block
    DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
    SELECT 'SQLSTATE handler was activated' AS msg;
BEGIN -- inner block
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
    SELECT 'SQLEXCEPTION handler was activated' AS msg;
    DROP TABLE test.t; -- occurs within inner block
END;
END;

In this case, the handler that is more local to where the condition occurs takes precedence. The SQLEXCEPTION handler activates, even though it is more general than the SQLSTATE handler:

mysql> CALL p2();
+------------------------------------+
<table>
<thead>
<tr>
<th>msg</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLEXCEPTION handler was activated</td>
</tr>
</tbody>
</table>
+------------------------------------+

In this procedure, one of the handlers is declared in a block inner to the scope of the DROP TABLE statement:

CREATE PROCEDURE p3()
BEGIN -- outer block
    BEGIN -- inner block
        DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
        SELECT 'SQLEXCEPTION handler was activated' AS msg;
        BEGIN -- inner block
            DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
            SELECT 'SQLSTATE handler was activated' AS msg;
        END;
        DROP TABLE test.t; -- occurs within inner block
    END;
END;

Only the SQLEXCEPTION handler applies because the other one is not in scope for the condition raised by the DROP TABLE:

mysql> CALL p3();
+------------------------------------+
<table>
<thead>
<tr>
<th>msg</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLEXCEPTION handler was activated</td>
</tr>
</tbody>
</table>
+------------------------------------+

In this procedure, both handlers are declared in a block inner to the scope of the DROP TABLE statement:

CREATE PROCEDURE p4()
BEGIN -- outer block
    BEGIN -- inner block
        BEGIN -- inner block
            DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
            SELECT 'SQLEXCEPTION handler was activated' AS msg;
            DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
        END;
    END;
END;
Neither handler applies because they are not in scope for the `DROP TABLE`. The condition raised by the statement goes unhandled and terminates the procedure with an error:

```sql
mysql> CALL p4();
ERROR 1051 (42S02): Unknown table 'test.t'
```

### 13.6.7.7 The MySQL Diagnostics Area

SQL statements produce diagnostic information that populates the diagnostics area. Standard SQL has a diagnostics area stack, containing a diagnostics area for each nested execution context. Standard SQL also supports `GET STACKED DIAGNOSTICS` syntax for referring to the second diagnostics area during condition handler execution.

The following discussion describes the structure of the diagnostics area in MySQL, the information items recognized by MySQL, how statements clear and set the diagnostics area, and how diagnostics areas are pushed to and popped from the stack.

- **Diagnostics Area Structure**
- **Diagnostics Area Information Items**
- **How the Diagnostics Area is Cleared and Populated**
- **How the Diagnostics Area Stack Works**
- **Diagnostics Area-Related System Variables**

#### Diagnostics Area Structure

The diagnostics area contains two kinds of information:

- Statement information, such as the number of conditions that occurred or the affected-rows count.

- Condition information, such as the error code and message. If a statement raises multiple conditions, this part of the diagnostics area has a condition area for each one. If a statement raises no conditions, this part of the diagnostics area is empty.

For a statement that produces three conditions, the diagnostics area contains statement and condition information like this:

```sql
Statement information:
  row count
  ... other statement information items ...
Condition area list:
  Condition area 1:
    error code for condition 1
    error message for condition 1
    ... other condition information items ...
  Condition area 2:
    error code for condition 2:
    error message for condition 2
    ... other condition information items ...
  Condition area 3:
    error code for condition 3
    error message for condition 3
```
Diagnostics Area Information Items

The diagnostics area contains statement and condition information items. Numeric items are integers. The character set for character items is UTF-8. No item can be NULL. If a statement or condition item is not set by a statement that populates the diagnostics area, its value is 0 or the empty string, depending on the item data type.

The statement information part of the diagnostics area contains these items:

- **NUMBER**: An integer indicating the number of condition areas that have information.
- **ROW_COUNT**: An integer indicating the number of rows affected by the statement. ROW_COUNT has the same value as the `ROW_COUNT()` function (see Section 12.15, “Information Functions”).

The condition information part of the diagnostics area contains a condition area for each condition. Condition areas are numbered from 1 to the value of the NUMBER statement condition item. If NUMBER is 0, there are no condition areas.

Each condition area contains the items in the following list. All items are standard SQL except MYSQL_ERRNO, which is a MySQL extension. The definitions apply for conditions generated other than by a signal (that is, by a SIGNAL or RESIGNAL statement). For nonsignal conditions, MySQL populates only those condition items not described as always empty. The effects of signals on the condition area are described later.

- **CLASS_ORIGIN**: A string containing the class of the RETURNED_SQLSTATE value. If the RETURNED_SQLSTATE value begins with a class value defined in SQL standards document ISO 9075-2 (section 24.1, SQLSTATE), CLASS_ORIGIN is 'ISO 9075'. Otherwise, CLASS_ORIGIN is 'MySQL'.
- **SUBCLASS_ORIGIN**: A string containing the subclass of the RETURNED_SQLSTATE value. If CLASS_ORIGIN is 'ISO 9075' or RETURNED_SQLSTATE ends with '000', SUBCLASS_ORIGIN is 'ISO 9075'. Otherwise, SUBCLASS_ORIGIN is 'MySQL'.
- **RETURNED_SQLSTATE**: A string that indicates the SQLSTATE value for the condition.
- **MESSAGE_TEXT**: A string that indicates the error message for the condition.
- **MYSQL_ERRNO**: An integer that indicates the MySQL error code for the condition.
- **CONSTRAINT_CATALOG, CONSTRAINT_SCHEMA, CONSTRAINT_NAME**: Strings that indicate the catalog, schema, and name for a violated constraint. They are always empty.
- **CATALOG_NAME, SCHEMA_NAME, TABLE_NAME, COLUMN_NAME**: Strings that indicate the catalog, schema, table, and column related to the condition. They are always empty.
- **CURSOR_NAME**: A string that indicates the cursor name. This is always empty.

For the RETURNED_SQLSTATE, MESSAGE_TEXT, and MYSQL_ERRNO values for particular errors, see Server Error Message Reference.

If a SIGNAL (or RESIGNAL) statement populates the diagnostics area, its SET clause can assign to any condition information item except RETURNED_SQLSTATE any value that is legal for the item data type. SIGNAL also sets the RETURNED_SQLSTATE value, but not directly in its SET clause. That value comes from the SIGNAL statement SQLSTATE argument.

SIGNAL also sets statement information items. It sets NUMBER to 1. It sets ROW_COUNT to −1 for errors and 0 otherwise.
How the Diagnostics Area is Cleared and Populated

Nondiagnostic SQL statements populate the diagnostics area automatically, and its contents can be set explicitly with the `SIGNAL` and `RESIGNAL` statements. The diagnostics area can be examined with `GET DIAGNOSTICS` to extract specific items, or with `SHOW WARNINGS` or `SHOW ERRORS` to see conditions or errors.

SQL statements clear and set the diagnostics area as follows:

- When the server starts executing a statement after parsing it, it clears the diagnostics area for nondiagnostic statements. Diagnostic statements do not clear the diagnostics area. These statements are diagnostic:
  - `GET DIAGNOSTICS`
  - `SHOW ERRORS`
  - `SHOW WARNINGS`

- If a statement raises a condition, the diagnostics area is cleared of conditions that belong to earlier statements. The exception is that conditions raised by `GET DIAGNOSTICS` and `RESIGNAL` are added to the diagnostics area without clearing it.

Thus, even a statement that does not normally clear the diagnostics area when it begins executing clears it if the statement raises a condition.

The following example shows the effect of various statements on the diagnostics area, using `SHOW WARNINGS` to display information about conditions stored there.

This `DROP TABLE` statement clears the diagnostics area and populates it when the condition occurs:

```
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected, 1 warning (0.01 sec)
```

```
+-------+------+------------------------------------+
| Level | Code | Message                            |
|-------+------|------------------------------------|
| Note  | 1051 | Unknown table 'test.no_such_table' |
+-------+------+------------------------------------+
1 row in set (0.00 sec)
```

This `SET` statement generates an error, so it clears and populates the diagnostics area:

```
mysql> SET @x = @@x;
ERROR 1193 (HY000): Unknown system variable 'x'
```

```
+-------+------+------------------------------------+
| Level | Code | Message                            |
|-------+------|------------------------------------|
| Error | 1193 | Unknown system variable 'x'       |
+-------+------+------------------------------------+
1 row in set (0.00 sec)
```

The previous `SET` statement produced a single condition, so 1 is the only valid condition number for `GET DIAGNOSTICS` at this point. The following statement uses a condition number of 2, which produces a warning that is added to the diagnostics area without clearing it:

```
mysql> GET DIAGNOSTICS CONDITION 2 @p = MESSAGE_TEXT;
Query OK, 0 rows affected, 1 warning (0.00 sec)
```
Now there are two conditions in the diagnostics area, so the same `GET DIAGNOSTICS` statement succeeds:

```
mysql> GET DIAGNOSTICS CONDITION 2 @p = MESSAGE_TEXT;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @p;
+--------------------+
| @p                 |
+--------------------+
| Invalid condition number |
+--------------------+
1 row in set (0.01 sec)
```

### How the Diagnostics Area Stack Works

When a push to the diagnostics area stack occurs, the first (current) diagnostics area becomes the second (stacked) diagnostics area and a new current diagnostics area is created as a copy of it. Diagnostics areas are pushed to and popped from the stack under the following circumstances:

- **Execution of a stored program**

  A push occurs before the program executes and a pop occurs afterward. If the stored program ends while handlers are executing, there can be more than one diagnostics area to pop; this occurs due to an exception for which there are no appropriate handlers or due to `RETURN` in the handler.

  Any warning or error conditions in the popped diagnostics areas then are added to the current diagnostics area, except that, for triggers, only errors are added. When the stored program ends, the caller sees these conditions in its current diagnostics area.

- **Execution of a condition handler within a stored program**

  When a push occurs as a result of condition handler activation, the stacked diagnostics area is the area that was current within the stored program prior to the push. The new now-current diagnostics area is the handler's current diagnostics area. `GET [CURRENT] DIAGNOSTICS` and `GET STACKED DIAGNOSTICS` can be used within the handler to access the contents of the current (handler) and stacked (stored program) diagnostics areas. Initially, they return the same result, but statements executing within the handler may change the current diagnostics area, clearing and setting its contents according to the normal rules (see How the Diagnostics Area is Cleared and Populated). The stacked diagnostics area cannot be modified by statements executing within the handler except `RESIGNAL`.

  If the handler executes successfully, the current (handler) diagnostics area is popped and the stacked (stored program) diagnostics area again becomes the current diagnostics area. Conditions added to the handler diagnostics area during handler execution are added to the current diagnostics area.

- **Execution of `RESIGNAL`**

  The `RESIGNAL` statement passes on the error condition information that is available during execution of a condition handler within a compound statement inside a stored program. `RESIGNAL` may change some or all information before passing it on, modifying the diagnostics stack as described in Section 13.6.7.4, “RESIGNAL Statement”.
Diagnostics Area-Related System Variables

Certain system variables control or are related to some aspects of the diagnostics area:

- **max_error_count** controls the number of condition areas in the diagnostics area. If more conditions than this occur, MySQL silently discards information for the excess conditions. (Conditions added by **RESIGNAL** are always added, with older conditions being discarded as necessary to make room.)

- **warning_count** indicates the number of conditions that occurred. This includes errors, warnings, and notes. Normally, **NUMBER** and **warning_count** are the same. However, as the number of conditions generated exceeds **max_error_count**, the value of **warning_count** continues to rise whereas **NUMBER** remains capped at **max_error_count** because no additional conditions are stored in the diagnostics area.

- **error_count** indicates the number of errors that occurred. This value includes “not found” and exception conditions, but excludes warnings and notes. Like **warning_count**, its value can exceed **max_error_count**.

- If the **sql_notes** system variable is set to 0, notes are not stored and do not increment **warning_count**.

Example: If **max_error_count** is 10, the diagnostics area can contain a maximum of 10 condition areas. Suppose that a statement raises 20 conditions, 12 of which are errors. In that case, the diagnostics area contains the first 10 conditions, **NUMBER** is 10, **warning_count** is 20, and **error_count** is 12.

Changes to the value of **max_error_count** have no effect until the next attempt to modify the diagnostics area. If the diagnostics area contains 10 condition areas and **max_error_count** is set to 5, that has no immediate effect on the size or content of the diagnostics area.

### 13.6.7.8 Condition Handling and OUT or INOUT Parameters

If a stored procedure exits with an unhandled exception, modified values of **OUT** and **INOUT** parameters are not propagated back to the caller.

If an exception is handled by a **CONTINUE** or **EXIT** handler that contains a **RESIGNAL** statement, execution of **RESIGNAL** pops the Diagnostics Area stack, thus signalling the exception (that is, the information that existed before entry into the handler). If the exception is an error, the values of **OUT** and **INOUT** parameters are not propagated back to the caller.

### 13.6.8 Restrictions on Condition Handling

**SIGNAL**, **RESIGNAL**, and **GET DIAGNOSTICS** are not permissible as prepared statements. For example, this statement is invalid:

```sql
PREPARE stmt1 FROM 'SIGNAL SQLSTATE "02000"';
```

**SQLSTATE** values in class '04' are not treated specially. They are handled the same as other exceptions.

In standard SQL, the first condition relates to the **SQLSTATE** value returned for the previous SQL statement. In MySQL, this is not guaranteed, so to get the main error, you cannot do this:

```sql
GET DIAGNOSTICS CONDITION 1 @errno = MYSQL_ERRNO;
```

Instead, do this:

```sql
GET DIAGNOSTICS @cno = NUMBER;
```
13.7 Database Administration Statements

13.7.1 Account Management Statements

MySQL account information is stored in the tables of the `mysql` system schema. This database and the access control system are discussed extensively in Chapter 5, *MySQL Server Administration*, which you should consult for additional details.

Important

Some MySQL releases introduce changes to the grant tables to add new privileges or features. To make sure that you can take advantage of any new capabilities, update your grant tables to the current structure whenever you upgrade MySQL. See Section 2.10, “Upgrading MySQL”.

When the `read_only` system variable is enabled, account-management statements require the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege), in addition to any other required privileges. This is because they modify tables in the `mysql` system schema.

Account management statements are atomic and crash safe. For more information, see Section 13.1.1, “Atomic Data Definition Statement Support”.

13.7.1.1 ALTER USER Statement

```
ALTER USER [IF EXISTS]
user [auth_option] [, user [auth_option]] ...
(REQUIRE {NONE | tls_option [[AND] tls_option] ...})
[WITH resource_option [resource_option] ...]
[COMMENT 'comment_string' | ATTRIBUTE 'json_object']

ALTER USER [IF EXISTS]
USER() user_func_auth_option

ALTER USER [IF EXISTS]
user [registration_option]

ALTER USER [IF EXISTS]
USER() [registration_option]

ALTER USER [IF EXISTS]
user DEFAULT ROLE
{NONE | ALL | role [, role ] ...}

user:
(see Section 6.2.4, “Specifying Account Names”)

auth_option:
{ IDENTIFIED BY 'auth_string'
(REPLACE 'current_auth_string'
[REPLACE CURRENT PASSWORD])
| IDENTIFIED BY RANDOM PASSWORD
[REPLACE 'current_auth_string'
[REPLACE CURRENT PASSWORD])
| IDENTIFIED WITH auth_plugin
| IDENTIFIED WITH auth_plugin BY 'auth_string'
(REPLACE 'current_auth_string'
[REPLACE CURRENT PASSWORD])
| IDENTIFIED WITH auth_plugin BY RANDOM PASSWORD
[REPLACE 'current_auth_string']
```
The `ALTER USER` statement modifies MySQL accounts. It enables authentication, role, SSL/TLS, resource-limit, password-management, comment, and attribute properties to be modified for existing accounts. It can also be used to lock and unlock accounts.

In most cases, `ALTER USER` requires the global `CREATE_USER` privilege, or the `UPDATE` privilege for the `mysql` system schema. The exceptions are:
Any client who connects to the server using a nonanonymous account can change the password for that account. (In particular, you can change your own password.) To see which account the server authenticated you as, invoke the `CURRENT_USER()` function:

```
SELECT CURRENT_USER();
```

For `DEFAULT ROLE` syntax, `ALTER USER` requires these privileges:

- Setting the default roles for another user requires the global `CREATE USER` privilege, or the `UPDATE` privilege for the `mysql.default_roles` system table.
- Setting the default roles for yourself requires no special privileges, as long as the roles you want as the default have been granted to you.

Statements that modify secondary passwords require these privileges:

- The `APPLICATION_PASSWORD_ADMIN` privilege is required to use the `RETAIN CURRENT PASSWORD` or `DISCARD OLD PASSWORD` clause for `ALTER USER` statements that apply to your own account. The privilege is required to manipulate your own secondary password because most users require only one password.
- If an account is to be permitted to manipulate secondary passwords for all accounts, it requires the `CREATE USER` privilege rather than `APPLICATION_PASSWORD_ADMIN`.

When the `read_only` system variable is enabled, `ALTER USER` additionally requires the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege).

These additional privilege considerations also apply:

- The `authentication_policy` system variable places certain constraints on how the authentication-related clauses of `ALTER USER` statements may be used; for details, see the description of that variable. These constraints do not apply if you have the `AUTHENTICATION_POLICY_ADMIN` privilege.
- To modify an account that uses passwordless authentication, you must have the `PASSWORDLESS_USER_ADMIN` privilege.

By default, an error occurs if you try to modify a user that does not exist. If the `IF EXISTS` clause is given, the statement produces a warning for each named user that does not exist, rather than an error.

**Important**

Under some circumstances, `ALTER USER` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see Section 6.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 4.5.1.3, “mysql Client Logging”.

There are several aspects to the `ALTER USER` statement, described under the following topics:

- **ALTER USER Overview**
- **ALTER USER Authentication Options**
- **ALTER USER Multifactor Authentication Options**
- **ALTER USER Registration Options**
Account Management Statements

- ALTER USER Role Options
- ALTER USER SSL/TLS Options
- ALTER USER Resource-Limit Options
- ALTER USER Password-Management Options
- ALTER USER Comment and Attribute Options
- ALTER USER Account-Locking Options
- ALTER USER Binary Logging

**ALTER USER Overview**

For each affected account, **ALTER USER** modifies the corresponding row in the `mysql.user` system table to reflect the properties specified in the statement. Unspecified properties retain their current values.

Each account name uses the format described in Section 6.2.4, “Specifying Account Names”. The host name part of the account name, if omitted, defaults to '%'. It is also possible to specify CURRENT_USER or CURRENT_USER() to refer to the account associated with the current session.

In one case only, the account may be specified with the `USER()` function:

```
ALTER USER USER() IDENTIFIED BY 'auth_string';
```

This syntax enables changing your own password without naming your account literally. (The syntax also supports the REPLACE, RETAIN CURRENT PASSWORD, and DISCARD OLD PASSWORD clauses described at ALTER USER Authentication Options.)

For **ALTER USER** syntax that permits an auth_option value to follow a user value, auth_option indicates how the account authenticates by specifying an account authentication plugin, credentials (for example, a password), or both. Each auth_option value applies only to the account named immediately preceding it.

Following the user specifications, the statement may include options for SSL/TLS, resource-limit, password-management, and locking properties. All such options are global to the statement and apply to all accounts named in the statement.

Example: Change an account's password and expire it. As a result, the user must connect with the named password and choose a new one at the next connection:

```
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED BY 'new_password' PASSWORD EXPIRE;
```

Example: Modify an account to use the caching_sha2_password authentication plugin and the given password. Require that a new password be chosen every 180 days, and enable failed-login tracking, such that three consecutive incorrect passwords cause temporary account locking for two days:

```
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED WITH caching_sha2_password BY 'new_password'
  PASSWORD EXPIRE INTERVAL 180 DAY
  FAILED_LOGIN_ATTEMPTS 3 PASSWORD_LOCK_TIME 2;
```

Example: Lock or unlock an account:

```
ALTER USER 'jeffrey'@'localhost' ACCOUNT LOCK;
ALTER USER 'jeffrey'@'localhost' ACCOUNT UNLOCK;
```
Example: Require an account to connect using SSL and establish a limit of 20 connections per hour:

```
ALTER USER 'jeffrey'@'localhost'
    REQUIRE SSL WITH MAX_CONNECTIONS_PER_HOUR 20;
```

Example: Alter multiple accounts, specifying some per-account properties and some global properties:

```
ALTER USER
    'jeffrey'@'localhost'
        IDENTIFIED BY 'jeffrey_new_password',
    'jeanne'@'localhost',
    'josh'@'localhost'
        IDENTIFIED BY 'josh_new_password'
REPLACE 'josh_current_password'
    RETAIN CURRENT PASSWORD
REQUIRE SSL WITH MAX_USER_CONNECTIONS 2
    PASSWORD HISTORY 5;
```

The IDENTIFIED BY value following jeffrey applies only to its immediately preceding account, so it changes the password to 'jeffrey_new_password' only for jeffrey. For jeanne, there is no per-account value (thus leaving the password unchanged). For josh, IDENTIFIED BY establishes a new password ('josh_new_password'), REPLACE is specified to verify that the user issuing the ALTER USER statement knows the current password ('josh_current_password'), and that current password is also retained as the account secondary password. (As a result, josh can connect with either the primary or secondary password.)

The remaining properties apply globally to all accounts named in the statement, so for both accounts:

- Connections are required to use SSL.
- The account can be used for a maximum of two simultaneous connections.
- Password changes cannot reuse any of the five most recent passwords.

Example: Discard the secondary password for josh, leaving the account with only its primary password:

```
ALTER USER 'josh'@'localhost' DISCARD OLD PASSWORD;
```

In the absence of a particular type of option, the account remains unchanged in that respect. For example, with no locking option, the locking state of the account is not changed.

**ALTER USER Authentication Options**

An account name may be followed by an `auth_option` authentication option that specifies the account authentication plugin, credentials, or both. It may also include a password-verification clause that specifies the account current password to be replaced, and clauses that manage whether an account has a secondary password.

---

**Note**

Clauses for random password generation, password verification, and secondary passwords apply only to accounts that use an authentication plugin that stores credentials internally to MySQL. For accounts that use a plugin that performs authentication against a credentials system that is external to MySQL, password management must be handled externally against that system as well. For more information about internal credentials storage, see Section 6.2.15, “Password Management”.

- `auth_plugin` names an authentication plugin. The plugin name can be a quoted string literal or an unquoted name. Plugin names are stored in the `plugin` column of the `mysql.user` system table.
For **auth_option** syntax that does not specify an authentication plugin, the server assigns the default plugin, determined as described in The Default Authentication Plugin. For descriptions of each plugin, see Section 6.4.1, “Authentication Plugins”.

- Credentials that are stored internally are stored in the **mysql.user** system table. An **'auth_string'** value or **RANDOM PASSWORD** specifies account credentials, either as a cleartext (unencrypted) string or hashed in the format expected by the authentication plugin associated with the account, respectively:

  - For syntax that uses **BY 'auth_string'**, the string is cleartext and is passed to the authentication plugin for possible hashing. The result returned by the plugin is stored in the **mysql.user** table. A plugin may use the value as specified, in which case no hashing occurs.

  - For syntax that uses **BY RANDOM PASSWORD**, MySQL generates a random password and as cleartext and passes it to the authentication plugin for possible hashing. The result returned by the plugin is stored in the **mysql.user** table. A plugin may use the value as specified, in which case no hashing occurs.

    Randomly generated passwords have the characteristics described in Random Password Generation.

  - For syntax that uses **AS 'auth_string'**, the string is assumed to be already in the format the authentication plugin requires, and is stored as is in the **mysql.user** table. If a plugin requires a hashed value, the value must be already hashed in a format appropriate for the plugin; otherwise, the value cannot be used by the plugin and correct authentication of client connections does not occur.

    A hashed string can be either a string literal or a hexadecimal value. The latter corresponds to the type of value displayed by **SHOW CREATE USER** for password hashes containing unprintable characters when the **print_identified_with_as_hex** system variable is enabled.

    - If an authentication plugin performs no hashing of the authentication string, the **BY 'auth_string'** and **AS 'auth_string'** clauses have the same effect: The authentication string is stored as is in the **mysql.user** system table.

- The **REPLACE 'current_auth_string'** clause performs password verification. If given:

  - **REPLACE** specifies the account current password to be replaced, as a cleartext (unencrypted) string.

  - The clause must be given if password changes for the account are required to specify the current password, as verification that the user attempting to make the change actually knows the current password.

  - The clause is optional if password changes for the account may but need not specify the current password.

  - The statement fails if the clause is given but does not match the current password, even if the clause is optional.

  - **REPLACE** can be specified only when changing the account password for the current user.

    For more information about password verification by specifying the current password, see Section 6.2.15, “Password Management”.

- The **RETAINT CURRENT PASSWORD** and **DISCARD OLD PASSWORD** clauses implement dual-password capability. Both are optional, but if given, have the following effects:

  - **RETAINT CURRENT PASSWORD** retains an account current password as its secondary password, replacing any existing secondary password. The new password becomes the primary password, but
clients can use the account to connect to the server using either the primary or secondary password. (Exception: If the new password specified by the \texttt{ALTER USER} statement is empty, the secondary password becomes empty as well, even if \texttt{RETAIN CURRENT PASSWORD} is given.)

- If you specify \texttt{RETAIN CURRENT PASSWORD} for an account that has an empty primary password, the statement fails.

- If an account has a secondary password and you change its primary password without specifying \texttt{RETAIN CURRENT PASSWORD}, the secondary password remains unchanged.

- If you change the authentication plugin assigned to the account, the secondary password is discarded. If you change the authentication plugin and also specify \texttt{RETAIN CURRENT PASSWORD}, the statement fails.

- \texttt{DISCARD OLD PASSWORD} discards the secondary password, if one exists. The account retains only its primary password, and clients can use the account to connect to the server only with the primary password.

For more information about use of dual passwords, see Section 6.2.15, “Password Management”.

\texttt{ALTER USER} permits these \texttt{auth_option} syntaxes:

- \texttt{IDENTIFIED BY \char'92 auth_string\char'92 [REPLACE \char'92 current_auth_string\char'92] [RETAIN CURRENT PASSWORD]}

  Sets the account authentication plugin to the default plugin, passes the cleartext \texttt{auth_string} value to the plugin for possible hashing, and stores the result in the account row in the \texttt{mysql.user} system table.

  The \texttt{REPLACE} clause, if given, specifies the account current password, as described previously in this section.

  The \texttt{RETAIN CURRENT PASSWORD} clause, if given, causes the account current password to be retained as its secondary password, as described previously in this section.

- \texttt{IDENTIFIED BY RANDOM PASSWORD [REPLACE \char'92 current_auth_string\char'92] [RETAIN CURRENT PASSWORD]}

  Sets the account authentication plugin to the default plugin, generates a random password, passes the cleartext password value to the plugin for possible hashing, and stores the result in the account row in the \texttt{mysql.user} system table. The statement also returns the cleartext password in a result set to make it available to the user or application executing the statement. For details about the result set and characteristics of randomly generated passwords, see \texttt{Random Password Generation}.

  The \texttt{REPLACE} clause, if given, specifies the account current password, as described previously in this section.

  The \texttt{RETAIN CURRENT PASSWORD} clause, if given, causes the account current password to be retained as its secondary password, as described previously in this section.

- \texttt{IDENTIFIED WITH auth_plugin}

  Sets the account authentication plugin to \texttt{auth_plugin}, clears the credentials to the empty string (the credentials are associated with the old authentication plugin, not the new one), and stores the result in the account row in the \texttt{mysql.user} system table.

  In addition, the password is marked expired. The user must choose a new one when next connecting.
Account Management Statements

- **IDENTIFIED WITH auth_plugin BY 'auth_string' [REPLACE 'current_auth_string'] [RETAIN CURRENT PASSWORD]**

  Sets the account authentication plugin to `auth_plugin`, passes the cleartext `auth_string` value to the plugin for possible hashing, and stores the result in the account row in the `mysql.user` system table.

  The `REPLACE` clause, if given, specifies the account current password, as described previously in this section.

  The `RETAIN CURRENT PASSWORD` clause, if given, causes the account current password to be retained as its secondary password, as described previously in this section.

- **IDENTIFIED WITH auth_plugin BY RANDOM PASSWORD [REPLACE 'current_auth_string'] [RETAIN CURRENT PASSWORD]**

  Sets the account authentication plugin to `auth_plugin`, generates a random password, passes the cleartext password value to the plugin for possible hashing, and stores the result in the account row in the `mysql.user` system table. The statement also returns the cleartext password in a result set to make it available to the user or application executing the statement. For details about the result set and characteristics of randomly generated passwords, see Random Password Generation.

  The `REPLACE` clause, if given, specifies the account current password, as described previously in this section.

  The `RETAIN CURRENT PASSWORD` clause, if given, causes the account current password to be retained as its secondary password, as described previously in this section.

- **IDENTIFIED WITH auth_plugin AS 'auth_string'**

  Sets the account authentication plugin to `auth_plugin` and stores the `auth_string` value as is in the `mysql.user` account row. If the plugin requires a hashed string, the string is assumed to be already hashed in the format the plugin requires.

- **DISCARD OLD PASSWORD**

  Discards the account secondary password, if there is one, as described previously in this section.

Example: Specify the password as cleartext; the default plugin is used:

```
ALTER USER 'jeffrey'@'localhost'
    IDENTIFIED BY 'password';
```

Example: Specify the authentication plugin, along with a cleartext password value:

```
ALTER USER 'jeffrey'@'localhost'
    IDENTIFIED WITH mysql_native_password
    BY 'password';
```

Example: Like the preceding example, but in addition, specify the current password as a cleartext value to satisfy any account requirement that the user making the change knows that password:

```
ALTER USER 'jeffrey'@'localhost'
    IDENTIFIED WITH mysql_native_password
    BY 'password'
    REPLACE 'current_password';
```

The preceding statement fails unless the current user is `jeffrey` because `REPLACE` is permitted only for changes to the current user's password.
Example: Establish a new primary password and retain the existing password as the secondary password:

```
ALTER USER 'jeffrey'@'localhost'
IDENTIFIED BY 'new_password'
RETAIN CURRENT PASSWORD;
```

Example: Discard the secondary password, leaving the account with only its primary password:

```
ALTER USER 'jeffrey'@'localhost' DISCARD OLD PASSWORD;
```

Example: Specify the authentication plugin, along with a hashed password value:

```
ALTER USER 'jeffrey'@'localhost'
IDENTIFIED WITH mysql_native_password
AS '*6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4';
```

For additional information about setting passwords and authentication plugins, see Section 6.2.14, “Assigning Account Passwords”, and Section 6.2.17, “Pluggable Authentication”.

**ALTER USER Multifactor Authentication Options**

**ALTER USER** has **ADD, MODIFY, and DROP** clauses that enable authentication factors to be added, modified, or dropped. In each case, the clause specifies an operation to perform on one authentication factor, and optionally an operation on another authentication factor. For each operation, the **factor** item specifies the **FACTOR** keyword preceded by the number 2 or 3 to indicate whether the operation applies to the second or third authentication factor. (1 is not permitted in this context. To act on the first authentication factor, use the syntax described in **ALTER USER Authentication Options**.)

**ALTER USER** multifactor authentication clause constraints are defined by the **authentication_policy** system variable. For example, the **authentication_policy** setting controls the number of authentication factors that accounts may have, and for each factor, which authentication methods are permitted. See Configuring the Multifactor Authentication Policy.

When **ALTER USER** adds, modifies, or drops second and third factors in a single statement, operations are executed sequentially, but if any operation in the sequence fails the entire **ALTER USER** statement fails.

For **ADD**, each named factor must not already exist or it cannot be added. For **MODIFY** and **DROP**, each named factor must exist to be modified or dropped. If a second and third factor are defined, dropping the second factor causes the third factor to take its place as the second factor.

This statement drops authentication factors 2 and 3, which has the effect of converting the account from 3FA to 1FA:

```
ALTER USER 'user' DROP 2 FACTOR 3 FACTOR;
```

For additional **ADD, MODIFY, and DROP** examples, see Getting Started with Multifactor Authentication.

For information about factor-specific rules that determine the default authentication plugin for authentication clauses that do not name a plugin, see The Default Authentication Plugin.

**ALTER USER Registration Options**

**ALTER USER** has clauses that enable FIDO/FIDO2 devices to be registered and unregistered. For more information, see Using WebAuthn Authentication, Device Unregistration for WebAuthn, and the **mysql** client **--register-factor** option description.

The **mysql** client **--register-factor** option, used for FIDO/FIDO2 device registration, causes the **mysql** client to generate and execute **INITIATE REGISTRATION** and **FINISH REGISTRATION** statements. These statements are not intended for manual execution.
ALTER USER Role Options

ALTER USER ... DEFAULT ROLE defines which roles become active when the user connects to the server and authenticates, or when the user executes the SET ROLE DEFAULT statement during a session.

ALTER USER ... DEFAULT ROLE is alternative syntax for SET DEFAULT ROLE (see Section 13.7.1.9, “SET DEFAULT ROLE Statement”). However, ALTER USER can set the default for only a single user, whereas SET DEFAULT ROLE can set the default for multiple users. On the other hand, you can specify CURRENT_USER as the user name for the ALTER USER statement, whereas you cannot for SET DEFAULT ROLE.

Each user account name uses the format described previously.

Each role name uses the format described in Section 6.2.5, “Specifying Role Names”. For example:

ALTER USER 'joe'@'10.0.0.1' DEFAULT ROLE administrator, developer;

The host name part of the role name, if omitted, defaults to '%'.

The clause following the DEFAULT ROLE keywords permits these values:

- **NONE**: Set the default to NONE (no roles).
- **ALL**: Set the default to all roles granted to the account.
- **role [, role ] ...**: Set the default to the named roles, which must exist and be granted to the account at the time ALTER USER ... DEFAULT ROLE is executed.

ALTER USER SSL/TLS Options

MySQL can check X.509 certificate attributes in addition to the usual authentication that is based on the user name and credentials. For background information on the use of SSL/TLS with MySQL, see Section 6.3, “Using Encrypted Connections”.

To specify SSL/TLS-related options for a MySQL account, use a REQUIRE clause that specifies one or more tls_option values.

Order of REQUIRE options does not matter, but no option can be specified twice. The AND keyword is optional between REQUIRE options.

ALTER USER permits these tls_option values:

- **NONE**
  Indicates that all accounts named by the statement have no SSL or X.509 requirements. Unencrypted connections are permitted if the user name and password are valid. Encrypted connections can be used, at the client’s option, if the client has the proper certificate and key files.

  ALTER USER 'jeffrey'@'localhost' REQUIRE NONE;

  Clients attempt to establish a secure connection by default. For clients that have REQUIRE NONE, the connection attempt falls back to an unencrypted connection if a secure connection cannot be established. To require an encrypted connection, a client need specify only the --ssl-mode=REQUIRED option; the connection attempt fails if a secure connection cannot be established.

- **SSL**
  Tells the server to permit only encrypted connections for all accounts named by the statement.
ALTER USER 'jeffrey'@'localhost' REQUIRE SSL;

Clients attempt to establish a secure connection by default. For accounts that have REQUIRE SSL, the connection attempt fails if a secure connection cannot be established.

• **X509**

For all accounts named by the statement, requires that clients present a valid certificate, but the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates. Use of X.509 certificates always implies encryption, so the SSL option is unnecessary in this case.

ALTER USER 'jeffrey'@'localhost' REQUIRE X509;

For accounts with REQUIRE X509, clients must specify the --ssl-key and --ssl-cert options to connect. (It is recommended but not required that --ssl-ca also be specified so that the public certificate provided by the server can be verified.) This is true for ISSUER and SUBJECT as well because those REQUIRE options imply the requirements of X509.

• **ISSUER 'issuer'**

For all accounts named by the statement, requires that clients present a valid X.509 certificate issued by CA 'issuer'. If a client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X.509 certificates always implies encryption, so the SSL option is unnecessary in this case.

ALTER USER 'jeffrey'@'localhost'
   REQUIRE ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
   O=MySQL/CN=CA/emailAddress=ca@example.com';

Because ISSUER implies the requirements of X509, clients must specify the --ssl-key and --ssl-cert options to connect. (It is recommended but not required that --ssl-ca also be specified so that the public certificate provided by the server can be verified.)

• **SUBJECT 'subject'**

For all accounts named by the statement, requires that clients present a valid X.509 certificate containing the subject subject. If a client presents a certificate that is valid but has a different subject, the server rejects the connection. Use of X.509 certificates always implies encryption, so the SSL option is unnecessary in this case.

ALTER USER 'jeffrey'@'localhost'
   REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
   O=MySQL demo client certificate/
   CN=client/emailAddress=client@example.com';

MySQL does a simple string comparison of the 'subject' value to the value in the certificate, so lettercase and component ordering must be given exactly as present in the certificate.

Because SUBJECT implies the requirements of X509, clients must specify the --ssl-key and --ssl-cert options to connect. (It is recommended but not required that --ssl-ca also be specified so that the public certificate provided by the server can be verified.)

• **CIPHER 'cipher'**

For all accounts named by the statement, requires a specific cipher method for encrypting connections. This option is needed to ensure that ciphers and key lengths of sufficient strength are used. Encryption can be weak if old algorithms using short encryption keys are used.
ALTER USER 'jeffrey'@'localhost'
REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';

The SUBJECT, ISSUER, and CIPHER options can be combined in the REQUIRE clause:

ALTER USER 'jeffrey'@'localhost'
REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL demo client certificate/
  CN=client/emailAddress=client@example.com'
AND ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL/CN=CA/emailAddress=ca@example.com'
AND CIPHER 'EDH-RSA-DES-CBC3-SHA';

ALTER USER Resource-Limit Options

It is possible to place limits on use of server resources by an account, as discussed in Section 6.2.21,
“Setting Account Resource Limits”. To do so, use a WITH clause that specifies one or more
resource_option values.

Order of WITH options does not matter, except that if a given resource limit is specified multiple times, the
last instance takes precedence.

ALTER USER permits these resource_option values:

• MAX_QUERIES_PER_HOUR count, MAX_UPDATES_PER_HOUR count,
  MAX_CONNECTIONS_PER_HOUR count

  For all accounts named by the statement, these options restrict how many queries, updates, and
  connections to the server are permitted to each account during any given one-hour period. If count is 0
  (the default), this means that there is no limitation for the account.

• MAX_USER_CONNECTIONS count

  For all accounts named by the statement, restricts the maximum number of simultaneous connections
  to the server by each account. A nonzero count specifies the limit for the account explicitly. If count
  is 0 (the default), the server determines the number of simultaneous connections for the account from
  the global value of the max_user_connections system variable. If max_user_connections is also
  zero, there is no limit for the account.

Example:

ALTER USER 'jeffrey'@'localhost'
WITH MAX_QUERIES_PER_HOUR 500 MAX_UPDATES_PER_HOUR 100;

ALTER USER Password-Management Options

ALTER USER supports several password_option values for password management:

• Password expiration options: You can expire an account password manually and establish its password
  expiration policy. Policy options do not expire the password. Instead, they determine how the server
  applies automatic expiration to the account based on password age, which is assessed from the date
  and time of the most recent account password change.

• Password reuse options: You can restrict password reuse based on number of password changes, time
  elapsed, or both.

• Password verification-required options: You can indicate whether attempts to change an account
  password must specify the current password, as verification that the user attempting to make the change
  actually knows the current password.
Incorrect-password failed-login tracking options: You can cause the server to track failed login attempts and temporarily lock accounts for which too many consecutive incorrect passwords are given. The required number of failures and the lock time are configurable.

This section describes the syntax for password-management options. For information about establishing policy for password management, see Section 6.2.15, “Password Management”.

If multiple password-management options of a given type are specified, the last one takes precedence. For example, \texttt{PASSWORD EXPIRE DEFAULT PASSWORD EXPIRE NEVER} is the same as \texttt{PASSWORD EXPIRE NEVER}.

\textbf{Note}

Except for the options that pertain to failed-login tracking, password-management options apply only to accounts that use an authentication plugin that stores credentials internally to MySQL. For accounts that use a plugin that performs authentication against a credentials system that is external to MySQL, password management must be handled externally against that system as well. For more information about internal credentials storage, see Section 6.2.15, “Password Management”.

A client has an expired password if the account password was expired manually or the password age is considered greater than its permitted lifetime per the automatic expiration policy. In this case, the server either disconnects the client or restricts the operations permitted to it (see Section 6.2.16, “Server Handling of Expired Passwords”). Operations performed by a restricted client result in an error until the user establishes a new account password.

\textbf{Note}

Although it is possible to “reset” an expired password by setting it to its current value, it is preferable, as a matter of good policy, to choose a different password. DBAs can enforce non-reuse by establishing an appropriate password-reuse policy. See Password Reuse Policy.

\texttt{ALTER USER} permits these \texttt{password_option} values for controlling password expiration:

- \texttt{PASSWORD EXPIRE}
  
  Immediately marks the password expired for all accounts named by the statement.

  \begin{verbatim}
  ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE;
  \end{verbatim}

- \texttt{PASSWORD EXPIRE DEFAULT}
  
  Sets all accounts named by the statement so that the global expiration policy applies, as specified by the \texttt{default_password_lifetime} system variable.

  \begin{verbatim}
  ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
  \end{verbatim}

- \texttt{PASSWORD EXPIRE NEVER}
  
  This expiration option overrides the global policy for all accounts named by the statement. For each, it disables password expiration so that the password never expires.

  \begin{verbatim}
  ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
  \end{verbatim}

- \texttt{PASSWORD EXPIRE INTERVAL N DAY}

\begin{verbatim}
  ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 2979 DAY;
  \end{verbatim}
This expiration option overrides the global policy for all accounts named by the statement. For each, it sets the password lifetime to \(N\) days. The following statement requires the password to be changed every 180 days:

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 180 DAY;
```

ALTER USER permits these password_option values for controlling reuse of previous passwords based on required minimum number of password changes:

- **PASSWORD HISTORY DEFAULT**

  Sets all accounts named by the statement so that the global policy about password history length applies, to prohibit reuse of passwords before the number of changes specified by the `password_history` system variable.

  ```
  ALTER USER 'jeffrey'@'localhost' PASSWORD HISTORY DEFAULT;
  ```

- **PASSWORD HISTORY \(N\)**

  This history-length option overrides the global policy for all accounts named by the statement. For each, it sets the password history length to \(N\) passwords, to prohibit reusing any of the \(N\) most recently chosen passwords. The following statement prohibits reuse of any of the previous 6 passwords:

  ```
  ALTER USER 'jeffrey'@'localhost' PASSWORD HISTORY 6;
  ```

ALTER USER permits these password_option values for controlling reuse of previous passwords based on time elapsed:

- **PASSWORD REUSE INTERVAL DEFAULT**

  Sets all statements named by the account so that the global policy about time elapsed applies, to prohibit reuse of passwords newer than the number of days specified by the `password_reuse_interval` system variable.

  ```
  ALTER USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL DEFAULT;
  ```

- **PASSWORD REUSE INTERVAL \(N\) DAY**

  This time-elapsed option overrides the global policy for all accounts named by the statement. For each, it sets the password reuse interval to \(N\) days, to prohibit reuse of passwords newer than that many days. The following statement prohibits password reuse for 360 days:

  ```
  ALTER USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL 360 DAY;
  ```

ALTER USER permits these password_option values for controlling whether attempts to change an account password must specify the current password, as verification that the user attempting to make the change actually knows the current password:

- **PASSWORD REQUIRE CURRENT**

  This verification option overrides the global policy for all accounts named by the statement. For each, it requires that password changes specify the current password.

  ```
  ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT;
  ```

- **PASSWORD REQUIRE CURRENT OPTIONAL**

  ```
  ```
Account Management Statements

This verification option overrides the global policy for all accounts named by the statement. For each, it does not require that password changes specify the current password. (The current password may but need not be given.)

```
ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT OPTIONAL;
```

- **PASSWORD REQUIRE CURRENT DEFAULT**

Sets all statements named by the account so that the global policy about password verification applies, as specified by the `password_require_current` system variable.

```
ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT DEFAULT;
```

**ALTER USER** permits these `password_option` values for controlling failed-login tracking:

- **FAILED_LOGIN_ATTEMPTS N**

Whether to track account login attempts that specify an incorrect password. `N` must be a number from 0 to 32767. A value of 0 disables failed-login tracking. Values greater than 0 indicate how many consecutive password failures cause temporary account locking (if `PASSWORD_LOCK_TIME` is also nonzero).

- **PASSWORD_LOCK_TIME (N | UNBOUNDED)**

How long to lock the account after too many consecutive login attempts provide an incorrect password. `N` must be a number from 0 to 32767, or `UNBOUNDED`. A value of 0 disables temporary account locking. Values greater than 0 indicate how long to lock the account in days. A value of `UNBOUNDED` causes the account locking duration to be unbounded; once locked, the account remains in a locked state until unlocked. For information about the conditions under which unlocking occurs, see Failed-Login Tracking and Temporary Account Locking.

For failed-login tracking and temporary locking to occur, an account's `FAILED_LOGIN_ATTEMPTS` and `PASSWORD_LOCK_TIME` options both must be nonzero. The following statement modifies an account such that it remains locked for two days after four consecutive password failures:

```
ALTER USER 'jeffrey'@'localhost'
  FAILED_LOGIN_ATTEMPTS 4 PASSWORD_LOCK_TIME 2;
```

**ALTER USER Comment and Attribute Options**

MySQL 8.2 supports user comments and user attributes, as described in Section 13.7.1.3, “CREATE USER Statement”. These can be modified employing `ALTER USER` by means of the `COMMENT` and `ATTRIBUTE` options, respectively. You cannot specify both options in the same `ALTER USER` statement; attempting to do so results in a syntax error.

The user comment and user attribute are stored in the Information Schema `USER_ATTRIBUTES` table as a JSON object; the user comment is stored as the value for a `comment` key in the `ATTRIBUTE` column of this table, as shown later in this discussion. The `COMMENT` text can be any arbitrary quoted text, and replaces any existing user comment. The `ATTRIBUTE` value must be the valid string representation of a JSON object. This is merged with any existing user attribute as if the `JSON_MERGE_PATCH()` function had been used on the existing user attribute and the new one; for any keys that are re-used, the new value overwrites the old one, as shown here:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
  -> WHERE USER='bill' AND HOST='localhost';
```

```
+---------+---------+----------------+
| USER    | HOST    | ATTRIBUTE       |
|---------+---------+----------------+
| bill    | localhost | {"foo": "bar"}
```
Account Management Statements

+------+-----------+----------------+
1 row in set (0.11 sec)
mysql> ALTER USER 'bill'@'localhost' ATTRIBUTE '{"baz": "faz", "foo": "moo"}';
Query OK, 0 rows affected (0.22 sec)
mysql> SELECT * FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
->
WHERE USER='bill' AND HOST='localhost';
+------+-----------+------------------------------+
| USER | HOST
| ATTRIBUTE
|
+------+-----------+------------------------------+
| bill | localhost | {"baz": "faz", "foo": "moo"} |
+------+-----------+------------------------------+
1 row in set (0.00 sec)

To remove a key and its value from the user attribute, set the key to JSON null (must be lowercase and
unquoted), like this:
mysql> ALTER USER 'bill'@'localhost' ATTRIBUTE '{"foo": null}';
Query OK, 0 rows affected (0.08 sec)
mysql> SELECT * FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
->
WHERE USER='bill' AND HOST='localhost';
+------+-----------+----------------+
| USER | HOST
| ATTRIBUTE
|
+------+-----------+----------------+
| bill | localhost | {"baz": "faz"} |
+------+-----------+----------------+
1 row in set (0.00 sec)

To set an existing user comment to an empty string, use ALTER USER ... COMMENT ''. This leaves
an empty comment value in the USER_ATTRIBUTES table; to remove the user comment completely, use
ALTER USER ... ATTRIBUTE ... with the value for the column key set to JSON null (unquoted, in
lower case). This is illustrated by the following sequence of SQL statements:
mysql> ALTER USER 'bill'@'localhost' COMMENT 'Something about Bill';
Query OK, 0 rows affected (0.06 sec)
mysql> SELECT * FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
->
WHERE USER='bill' AND HOST='localhost';

ALTER USER Account-Locking Options

MySQL supports account locking and unlocking using the `ACCOUNT LOCK` and `ACCOUNT UNLOCK` options, which specify the locking state for an account. For additional discussion, see Section 6.2.20, “Account Locking”.

If multiple account-locking options are specified, the last one takes precedence.

`ALTER USER ... ACCOUNT UNLOCK` unlocks any account named by the statement that is temporarily locked due to too many failed logins. See Section 6.2.15, “Password Management”.

ALTER USER Binary Logging

`ALTER USER` is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named users. If the `IF EXISTS` clause is given, this includes even users that do not exist and were not altered.

If the original statement changes the credentials for a user, the statement written to the binary log specifies the applicable authentication plugin for that user, determined as follows:

- The plugin named in the original statement, if one was specified.
- Otherwise, the plugin associated with the user account if the user exists, or the default authentication plugin if the user does not exist. (If the statement written to the binary log must specify a particular authentication plugin for a user, include it in the original statement.)

If the server adds the default authentication plugin for any users in the statement written to the binary log, it writes a warning to the error log naming those users.

If the original statement specifies the `FAILED_LOGIN_ATTEMPTS` or `PASSWORD_LOCK_TIME` option, the statement written to the binary log includes the option.

ALTER USER statements with clauses that support multifactor authentication (MFA) are written to the binary log with the exception of `ALTER USER user factor INITIATE REGISTRATION` statements.

- `ALTER USER user factor FINISH REGISTRATION SET CHALLENGE_RESPONSE AS 'auth_string'` statements are written to the binary log as `ALTER USER user MODIFY factor IDENTIFIED WITH authentication_webauthn AS webauthn_hash_string`;
- In a replication context, the replication user requires `PASSWORDLESS_USER_ADMIN` privilege to execute `ALTER USER ... MODIFY` operations on accounts configured for passwordless authentication using the `authentication_webauthn` plugin.

13.7.1.2 CREATE ROLE Statement

`CREATE ROLE [IF NOT EXISTS] role [, role ] ...`

`CREATE ROLE` creates one or more roles, which are named collections of privileges. To use this statement, you must have the global `CREATE ROLE` or `CREATE USER` privilege. When the `read_only` system variable is enabled, `CREATE ROLE` additionally requires the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege).

A role when created is locked, has no password, and is assigned the default authentication plugin. (These role attributes can be changed later with the `ALTER USER` statement, by users who have the global `CREATE USER` privilege.)
**CREATE ROLE** either succeeds for all named roles or rolls back and has no effect if any error occurs. By default, an error occurs if you try to create a role that already exists. If the **IF NOT EXISTS** clause is given, the statement produces a warning for each named role that already exists, rather than an error.

The statement is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named roles. If the **IF NOT EXISTS** clause is given, this includes even roles that already exist and were not created.

Each role name uses the format described in [Section 6.2.5, “Specifying Role Names”](#). For example:

```
CREATE ROLE 'admin', 'developer';
CREATE ROLE 'webapp'@'localhost';
```

The host name part of the role name, if omitted, defaults to `%`.

For role usage examples, see [Section 6.2.10, “Using Roles”](#).

### 13.7.1.3 CREATE USER Statement

```
CREATE USER [IF NOT EXISTS]
    user [auth_option] [, user [auth_option]] ...
DEFAULT ROLE role [, role] ...
[REQUIRE {NONE | tls_option [AND tls_option] ...}
[WITH resource_option [resource_option] ...]
[COMMENT 'comment_string' | ATTRIBUTE 'json_object']
user:
    (see [Section 6.2.4, “Specifying Account Names”](#))
auth_option:
    |
    IDENTIFIED BY 'auth_string' [AND 2fa_auth_option]
    IDENTIFIED BY RANDOM PASSWORD [AND 2fa_auth_option]
    IDENTIFIED WITH auth_plugin BY 'auth_string' [AND 2fa_auth_option]
    IDENTIFIED WITH auth_plugin BY RANDOM PASSWORD [AND 2fa_auth_option]
    IDENTIFIED WITH auth_plugin AS 'auth_string' [AND 2fa_auth_option]
    IDENTIFIED WITH auth_plugin [initial_auth_option]
2fa_auth_option:
    |
    IDENTIFIED BY 'auth_string' [AND 3fa_auth_option]
    IDENTIFIED BY RANDOM PASSWORD [AND 3fa_auth_option]
    IDENTIFIED WITH auth_plugin [AND 3fa_auth_option]
    IDENTIFIED WITH auth_plugin BY 'auth_string' [AND 3fa_auth_option]
    IDENTIFIED WITH auth_plugin BY RANDOM PASSWORD [AND 3fa_auth_option]
    IDENTIFIED WITH auth_plugin AS 'auth_string' [AND 3fa_auth_option]
3fa_auth_option:
    |
    IDENTIFIED BY 'auth_string'
    IDENTIFIED BY RANDOM PASSWORD
    IDENTIFIED WITH auth_plugin
    IDENTIFIED WITH auth_plugin BY 'auth_string'
    IDENTIFIED WITH auth_plugin BY RANDOM PASSWORD
    IDENTIFIED WITH auth_plugin AS 'auth_string'
initial_auth_option:
    |
    INITIAL AUTHENTICATION IDENTIFIED BY {RANDOM PASSWORD | 'auth_string'}
    INITIAL AUTHENTICATION IDENTIFIED WITH auth_plugin AS 'auth_string'
```

```sql
tls_option: {
SSL
```
The `CREATE USER` statement creates new MySQL accounts. It enables authentication, role, SSL/TLS, resource-limit, password-management, comment, and attribute properties to be established for new accounts. It also controls whether accounts are initially locked or unlocked.

To use `CREATE USER`, you must have the global `CREATE USER` privilege, or the `INSERT` privilege for the `mysql` system schema. When the `read_only` system variable is enabled, `CREATE USER` additionally requires the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege).

These additional privilege considerations also apply:

- The `authentication_policy` system variable places certain constraints on how the authentication-related clauses of `CREATE USER` statements may be used; for details, see the description of that variable. These constraints do not apply if you have the `AUTHENTICATION_POLICY_ADMIN` privilege.

- To create an account that uses passwordless authentication, you must have the `PASSWORDLESS_USER_ADMIN` privilege.

`CREATE USER` fails with an error if any account to be created is named as the `DEFINER` attribute for any stored object. (That is, the statement fails if creating an account would cause the account to adopt a currently orphaned stored object.) To perform the operation anyway, you must have the `SET_USER_ID` privilege; in this case, the statement succeeds with a warning rather than failing with an error. Without `SET_USER_ID`, to perform the user-creation operation, drop the orphan objects, create the account and grant its privileges, and then re-create the dropped objects. For additional information, including how to identify which objects name a given account as the `DEFINER` attribute, see Orphan Stored Objects.

`CREATE USER` either succeeds for all named users or rolls back and has no effect if any error occurs. By default, an error occurs if you try to create a user that already exists. If the `IF NOT EXISTS` clause is given, the statement produces a warning for each named user that already exists, rather than an error.

---

Important

Under some circumstances, `CREATE USER` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information.
For information about the conditions under which this occurs for the server logs and how to control it, see Section 6.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 4.5.1.3, “mysql Client Logging”.

There are several aspects to the CREATE USER statement, described under the following topics:

- CREATE USER Overview
- CREATE USER Authentication Options
- CREATE USER Multifactor Authentication Options
- CREATE USER Role Options
- CREATE USER SSL/TLS Options
- CREATE USER Resource-Limit Options
- CREATE USER Password-Management Options
- CREATE USER Comment and Attribute Options
- CREATE USER Account-Locking Options
- CREATE USER Binary Logging

**CREATE USER Overview**

For each account, CREATE USER creates a new row in the mysql.user system table. The account row reflects the properties specified in the statement. Unspecified properties are set to their default values:

- **Authentication**: The default authentication plugin (determined as described in The Default Authentication Plugin), and empty credentials
- **Default role**: NONE
- **SSL/TLS**: NONE
- **Resource limits**: Unlimited
- **Password management**: PASSWORD EXPIRE DEFAULT PASSWORD HISTORY DEFAULT PASSWORD REUSE INTERVAL DEFAULT PASSWORD REQUIRE CURRENT DEFAULT; failed-login tracking and temporary account locking are disabled
- **Account locking**: ACCOUNT UNLOCK

An account when first created has no privileges and the default role NONE. To assign privileges or roles to this account, use one or more GRANT statements.

Each account name uses the format described in Section 6.2.4, “Specifying Account Names”. For example:

```sql
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
```

The host name part of the account name, if omitted, defaults to '%'. You should be aware that, while MySQL 8.2 treats grants made to such a user as though they had been granted to 'user'@'localhost', this behavior is deprecated as of MySQL 8.2.0, and thus subject to removal in a future version of MySQL.

Each user value naming an account may be followed by an optional auth_option value that indicates how the account authenticates. These values enable account authentication plugins and credentials (for
example, a password) to be specified. Each auth_option value applies only to the account named immediately preceding it.

Following the user specifications, the statement may include options for SSL/TLS, resource-limit, password-management, and locking properties. All such options are global to the statement and apply to all accounts named in the statement.

Example: Create an account that uses the default authentication plugin and the given password. Mark the password expired so that the user must choose a new one at the first connection to the server:

```
CREATE USER 'jeffrey'@'localhost'
    IDENTIFIED BY 'new_password' PASSWORD EXPIRE;
```

Example: Create an account that uses the caching_sha2_password authentication plugin and the given password. Require that a new password be chosen every 180 days, and enable failed-login tracking, such that three consecutive incorrect passwords cause temporary account locking for two days:

```
CREATE USER 'jeffrey'@'localhost'
    IDENTIFIED WITH caching_sha2_password BY 'new_password'
    PASSWORD EXPIRE INTERVAL 180 DAY
    FAILED_LOGIN_ATTEMPTS 3 PASSWORD_LOCK_TIME 2;
```

Example: Create multiple accounts, specifying some per-account properties and some global properties:

```
CREATE USER
    'jeffrey'@'localhost' IDENTIFIED WITH mysql_native_password
    BY 'new_password1',
    'jeanne'@'localhost' IDENTIFIED WITH caching_sha2_password
    BY 'new_password2'
    REQUIRE X509 WITH MAX_QUERIES_PER_HOUR 60
    PASSWORD HISTORY 5
    ACCOUNT LOCK;
```

Each auth_option value (IDENTIFIED WITH ... BY in this case) applies only to the account named immediately preceding it, so each account uses the immediately following authentication plugin and password.

The remaining properties apply globally to all accounts named in the statement, so for both accounts:

- Connections must be made using a valid X.509 certificate.
- Up to 60 queries per hour are permitted.
- Password changes cannot reuse any of the five most recent passwords.
- The account is locked initially, so effectively it is a placeholder and cannot be used until an administrator unlocks it.

**CREATE USER Authentication Options**

An account name may be followed by an auth_option authentication option that specifies the account authentication plugin, credentials, or both.

**Note**

MySQL 8.2 supports multifactor authentication (MFA), such that accounts can have up to three authentication methods. That is, accounts can use two-factor authentication (2FA) or three-factor authentication (3FA). The syntax and semantics of auth_option remain unchanged, but auth_option may be followed by specifications for additional authentication methods. This section describes auth_option. For details about the optional MFA-related following clauses, see CREATE USER Multifactor Authentication Options.
**Note**

Clauses for random password generation apply only to accounts that use an authentication plugin that stores credentials internally to MySQL. For accounts that use a plugin that performs authentication against a credentials system that is external to MySQL, password management must be handled externally against that system as well. For more information about internal credentials storage, see Section 6.2.15, "Password Management".

- **auth_plugin** names an authentication plugin. The plugin name can be a quoted string literal or an unquoted name. Plugin names are stored in the `plugin` column of the `mysql.user` system table.

  For **auth_option** syntax that does not specify an authentication plugin, the server assigns the default plugin, determined as described in The Default Authentication Plugin. For descriptions of each plugin, see Section 6.4.1, "Authentication Plugins".

- Credentials that are stored internally are stored in the `mysql.user` system table. An 'auth_string' value or **RANDOM PASSWORD** specifies account credentials, either as a cleartext (unencrypted) string or hashed in the format expected by the authentication plugin associated with the account, respectively:

  - For syntax that uses **BY 'auth_string'**, the string is cleartext and is passed to the authentication plugin for possible hashing. The result returned by the plugin is stored in the `mysql.user` table. A plugin may use the value as specified, in which case no hashing occurs.

  - For syntax that uses **BY RANDOM PASSWORD**, MySQL generates a random password and as cleartext and passes it to the authentication plugin for possible hashing. The result returned by the plugin is stored in the `mysql.user` table. A plugin may use the value as specified, in which case no hashing occurs.

  Randomly generated passwords have the characteristics described in Random Password Generation.

  - For syntax that uses **AS 'auth_string'**, the string is assumed to be already in the format the authentication plugin requires, and is stored as is in the `mysql.user` table. If a plugin requires a hashed value, the value must be already hashed in a format appropriate for the plugin; otherwise, the value cannot be used by the plugin and correct authentication of client connections does not occur.

  A hashed string can be either a string literal or a hexadecimal value. The latter corresponds to the type of value displayed by SHOW CREATE USER for password hashes containing unprintable characters when the `print_identified_with_as_hex` system variable is enabled.

  - If an authentication plugin performs no hashing of the authentication string, the **BY 'auth_string'** and **AS 'auth_string'** clauses have the same effect: The authentication string is stored as is in the `mysql.user` system table.

**CREATE USER** permits these **auth_option** syntaxes:

- **IDENTIFIED BY 'auth_string'**

  Sets the account authentication plugin to the default plugin, passes the cleartext 'auth_string' value to the plugin for possible hashing, and stores the result in the account row in the `mysql.user` system table.

- **IDENTIFIED BY RANDOM PASSWORD**

  Sets the account authentication plugin to the default plugin, generates a random password, passes the cleartext password value to the plugin for possible hashing, and stores the result in the account row in the `mysql.user` system table. The statement also returns the cleartext password in a result set to
Account Management Statements

make it available to the user or application executing the statement. For details about the result set and characteristics of randomly generated passwords, see Random Password Generation.

- **IDENTIFIED WITH auth_plugin**

  Sets the account authentication plugin to `auth_plugin`, clears the credentials to the empty string, and stores the result in the account row in the `mysql.user` system table.

- **IDENTIFIED WITH auth_plugin BY 'auth_string'**

  Sets the account authentication plugin to `auth_plugin`, passes the cleartext `'auth_string'` value to the plugin for possible hashing, and stores the result in the account row in the `mysql.user` system table.

- **IDENTIFIED WITH auth_plugin BY RANDOM PASSWORD**

  Sets the account authentication plugin to `auth_plugin`, generates a random password, passes the cleartext password value to the plugin for possible hashing, and stores the result in the account row in the `mysql.user` system table. The statement also returns the cleartext password in a result set to make it available to the user or application executing the statement. For details about the result set and characteristics of randomly generated passwords, see Random Password Generation.

- **IDENTIFIED WITH auth_plugin AS 'auth_string'**

  Sets the account authentication plugin to `auth_plugin` and stores the `'auth_string'` value as is in the `mysql.user` account row. If the plugin requires a hashed string, the string is assumed to be already hashed in the format the plugin requires.

Example: Specify the password as cleartext; the default plugin is used:

```
CREATE USER 'jeffrey'@'localhost'
    IDENTIFIED BY 'password';
```

Example: Specify the authentication plugin, along with a cleartext password value:

```
CREATE USER 'jeffrey'@'localhost'
    IDENTIFIED WITH mysql_native_password BY 'password';
```

In each case, the password value stored in the account row is the cleartext value `'password'` after it has been hashed by the authentication plugin associated with the account.

For additional information about setting passwords and authentication plugins, see Section 6.2.14, “Assigning Account Passwords”, and Section 6.2.17, “Pluggable Authentication”.

**CREATE USER Multifactor Authentication Options**

The `auth_option` part of `CREATE USER` defines an authentication method for one-factor/single-factor authentication (1FA/SFA). `CREATE USER` also supports multifactor authentication (MFA), such that accounts can have up to three authentication methods. That is, accounts can use two-factor authentication (2FA) or three-factor authentication (3FA).

The `authentication_policy` system variable defines constraints for `CREATE USER` statements with multifactor authentication (MFA) clauses. For example, the `authentication_policy` setting controls the number of authentication factors that accounts may have, and for each factor, which authentication methods are permitted. See Configuring the Multifactor Authentication Policy.

For information about factor-specific rules that determine the default authentication plugin for authentication clauses that name no plugin, see The Default Authentication Plugin.
Following `auth_option`, there may appear different optional MFA clauses:

- **2fa_auth_option**: Specifies a factor 2 authentication method. The following example defines `caching_sha2_password` as the factor 1 authentication method, and `authentication_ldap_sasl` as the factor 2 authentication method.

```sql
CREATE USER 'u1'@'localhost'
    IDENTIFIED WITH caching_sha2_password
    BY 'sha2_password'
    AND IDENTIFIED WITH authentication_ldap_sasl
    AS 'uid=u1_ldap,ou=People,dc=example,dc=com';
```

- **3fa_auth_option**: Following `2fa_auth_option`, there may appear a `3fa_auth_option` clause to specify a factor 3 authentication method. The following example defines `caching_sha2_password` as the factor 1 authentication method, `authentication_ldap_sasl` as the factor 2 authentication method, and `authentication_webauthn` as the factor 3 authentication method.

```sql
CREATE USER 'u1'@'localhost'
    IDENTIFIED WITH caching_sha2_password
    BY 'sha2_password'
    AND IDENTIFIED WITH authentication_ldap_sasl
    AS 'uid=u1_ldap,ou=People,dc=example,dc=com'
    AND IDENTIFIED WITH authentication_webauthn;
```

- **initial_auth_option**: Specifies an initial authentication method for configuring FIDO/FIDO2 passwordless authentication. As shown in the following, temporary authentication using either a generated random password or a user-specified `auth-string` is required to enable WebAuthn passwordless authentication.

```sql
CREATE USER user
    IDENTIFIED WITH authentication_webauthn
    INITIAL AUTHENTICATION IDENTIFIED BY {RANDOM PASSWORD | 'auth_string'};
```

For information about configuring passwordless authentication using WebAuthn pluggable authentication, see WebAuthn Passwordless Authentication.

### CREATE USER Role Options

The `DEFAULT ROLE` clause defines which roles become active when the user connects to the server and authenticates, or when the user executes the `SET ROLE DEFAULT` statement during a session.

Each role name uses the format described in Section 6.2.5, “Specifying Role Names”. For example:

```sql
CREATE USER 'joe'@'10.0.0.1' DEFAULT ROLE administrator, developer;
```

The host name part of the role name, if omitted, defaults to ' %'.

The `DEFAULT ROLE` clause permits a list of one or more comma-separated role names. These roles must exist at the time `CREATE USER` is executed; otherwise the statement raises an error (ER_USER_DOES_NOT_EXIST), and the user is not created.

### CREATE USER SSL/TLS Options

MySQL can check X.509 certificate attributes in addition to the usual authentication that is based on the user name and credentials. For background information on the use of SSL/TLS with MySQL, see Section 6.3, “Using Encrypted Connections”.

To specify SSL/TLS-related options for a MySQL account, use a `REQUIRE` clause that specifies one or more `tls_option` values.
Order of `REQUIRE` options does not matter, but no option can be specified twice. The `AND` keyword is optional between `REQUIRE` options.

CREATE USER permits these `tls_option` values:

- **NONE**
  
  Indicates that all accounts named by the statement have no SSL or X.509 requirements. Unencrypted connections are permitted if the user name and password are valid. Encrypted connections can be used, at the client's option, if the client has the proper certificate and key files.

  ```sql
  CREATE USER 'jeffrey'@'localhost' REQUIRE NONE;
  ```

  Clients attempt to establish a secure connection by default. For clients that have `REQUIRE NONE`, the connection attempt falls back to an unencrypted connection if a secure connection cannot be established. To require an encrypted connection, a client need specify only the `--ssl-mode=REQUIRED` option; the connection attempt fails if a secure connection cannot be established.

  **NONE** is the default if no SSL-related `REQUIRE` options are specified.

- **SSL**

  Tells the server to permit only encrypted connections for all accounts named by the statement.

  ```sql
  CREATE USER 'jeffrey'@'localhost' REQUIRE SSL;
  ```

  Clients attempt to establish a secure connection by default. For accounts that have `REQUIRE SSL`, the connection attempt fails if a secure connection cannot be established.

- **X509**

  For all accounts named by the statement, requires that clients present a valid certificate, but the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates. Use of X.509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

  ```sql
  CREATE USER 'jeffrey'@'localhost' REQUIRE X509;
  ```

  For accounts with `REQUIRE X509`, clients must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.) This is true for `ISSUER` and `SUBJECT` as well because those `REQUIRE` options imply the requirements of `X509`.

- **ISSUER 'issuer'**

  For all accounts named by the statement, requires that clients present a valid X.509 certificate issued by CA `issuer`. If a client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X.509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

  ```sql
  CREATE USER 'jeffrey'@'localhost'
  REQUIRE ISSUER '/C=SE/ST=Stockholm/L=Stockholm/O=MySQL/CN=CA/emailAddress=ca@example.com';
  ```

  Because `ISSUER` implies the requirements of `X509`, clients must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.)

- **SUBJECT 'subject'**
For all accounts named by the statement, requires that clients present a valid X.509 certificate containing
the subject \textit{subject}. If a client presents a certificate that is valid but has a different subject, the
server rejects the connection. Use of X.509 certificates always implies encryption, so the \textit{SSL} option is
unnecessary in this case.

\begin{verbatim}
CREATE USER 'jeffrey'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL demo client certificate/
  CN=client/emailAddress=client@example.com';
\end{verbatim}

MySQL does a simple string comparison of the \textit{subject} value to the value in the certificate, so
lettercase and component ordering must be given exactly as present in the certificate.

Because \textit{SUBJECT} implies the requirements of X509, clients must specify the \textit{--ssl-key} and \textit{--ssl-certificate} options to connect. (It is recommended but not required that \textit{--ssl-ca} also be specified so that
the public certificate provided by the server can be verified.)

- \textbf{CIPHER 'cipher'}

For all accounts named by the statement, requires a specific cipher method for encrypting connections.
This option is needed to ensure that ciphers and key lengths of sufficient strength are used. Encryption
can be weak if old algorithms using short encryption keys are used.

\begin{verbatim}
CREATE USER 'jeffrey'@'localhost'
  REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';
\end{verbatim}

The \textit{SUBJECT}, \textit{ISSUER}, and \textit{CIPHER} options can be combined in the \textit{REQUIRE} clause:

\begin{verbatim}
CREATE USER 'jeffrey'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL demo client certificate/
  CN=client/emailAddress=client@example.com'
  ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL/CN=CA/emailAddress=ca@example.com'
  CIPHER 'EDH-RSA-DES-CBC3-SHA';
\end{verbatim}

\section*{CREATE USER Resource-Limit Options}

It is possible to place limits on use of server resources by an account, as discussed in Section 6.2.21,
"Setting Account Resource Limits". To do so, use a \textit{WITH} clause that specifies one or more
\textit{resource_option} values.

Order of \textit{WITH} options does not matter, except that if a given resource limit is specified multiple times, the
last instance takes precedence.

\begin{verbatim}
CREATE USER permits these \textit{resource_option} values:
\end{verbatim}

- \textbf{MAX QUERIES PER HOUR \textit{count}, MAX UPDATES PER HOUR \textit{count},
  MAX CONNECTIONS PER HOUR \textit{count}}

For all accounts named by the statement, these options restrict how many queries, updates, and
connections to the server are permitted to each account during any given one-hour period. If \textit{count} is 0
(the default), this means that there is no limitation for the account.

- \textbf{MAX USER CONNECTIONS \textit{count}}

For all accounts named by the statement, restricts the maximum number of simultaneous connections
to the server by each account. A nonzero \textit{count} specifies the limit for the account explicitly. If \textit{count} is 0
(the default), the server determines the number of simultaneous connections for the account from
the global value of the `max_user_connections` system variable. If `max_user_connections` is also zero, there is no limit for the account.

Example:

```
CREATE USER 'jeffrey'@'localhost'
  WITH MAX_QUERIES_PER_HOUR 500 MAX_UPDATES_PER_HOUR 100;
```

**CREATE USER Password-Management Options**

`CREATE USER` supports several `password_option` values for password management:

- **Password expiration options:** You can expire an account password manually and establish its password expiration policy. Policy options do not expire the password. Instead, they determine how the server applies automatic expiration to the account based on password age, which is assessed from the date and time of the most recent account password change.

- **Password reuse options:** You can restrict password reuse based on number of password changes, time elapsed, or both.

- **Password verification-required options:** You can indicate whether attempts to change an account password must specify the current password, as verification that the user attempting to make the change actually knows the current password.

- **Incorrect-password failed-login tracking options:** You can cause the server to track failed login attempts and temporarily lock accounts for which too many consecutive incorrect passwords are given. The required number of failures and the lock time are configurable.

This section describes the syntax for password-management options. For information about establishing policy for password management, see Section 6.2.15, “Password Management”.

If multiple password-management options of a given type are specified, the last one takes precedence. For example, `PASSWORD EXPIRE DEFAULT PASSWORD EXPIRE NEVER` is the same as `PASSWORD EXPIRE NEVER`.

**Note**

Except for the options that pertain to failed-login tracking, password-management options apply only to accounts that use an authentication plugin that stores credentials internally to MySQL. For accounts that use a plugin that performs authentication against a credentials system that is external to MySQL, password management must be handled externally against that system as well. For more information about internal credentials storage, see Section 6.2.15, “Password Management”.

A client has an expired password if the account password was expired manually or the password age is considered greater than its permitted lifetime per the automatic expiration policy. In this case, the server either disconnects the client or restricts the operations permitted to it (see Section 6.2.16, “Server Handling of Expired Passwords”). Operations performed by a restricted client result in an error until the user establishes a new account password.

`CREATE USER` permits these `password_option` values for controlling password expiration:

- **PASSWORD EXPIRE**

  Immediately marks the password expired for all accounts named by the statement.

```
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE;
```
Account Management Statements

- **PASSWORD_EXPIRE_DEFAULT**
  
  Sets all accounts named by the statement so that the global expiration policy applies, as specified by the `default_password_lifetime` system variable.

  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
  ```

- **PASSWORD_EXPIRE_NEVER**
  
  This expiration option overrides the global policy for all accounts named by the statement. For each, it disables password expiration so that the password never expires.

  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
  ```

- **PASSWORD_EXPIRE_INTERVAL N DAY**
  
  This expiration option overrides the global policy for all accounts named by the statement. For each, it sets the password lifetime to `N` days. The following statement requires the password to be changed every 180 days:

  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 180 DAY;
  ```

CREATE USER permits these `password_option` values for controlling reuse of previous passwords based on required minimum number of password changes:

- **PASSWORD_HISTORY_DEFAULT**
  
  Sets all accounts named by the statement so that the global policy about password history length applies, to prohibit reuse of passwords before the number of changes specified by the `password_history` system variable.

  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD HISTORY DEFAULT;
  ```

- **PASSWORD_HISTORY N**
  
  This history-length option overrides the global policy for all accounts named by the statement. For each, it sets the password history length to `N` passwords, to prohibit reusing any of the `N` most recently chosen passwords. The following statement prohibits reuse of any of the previous 6 passwords:

  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD HISTORY 6;
  ```

CREATE USER permits these `password_option` values for controlling reuse of previous passwords based on time elapsed:

- **PASSWORD_REUSEINTERVAL_DEFAULT**
  
  Sets all statements named by the account so that the global policy about time elapsed applies, to prohibit reuse of passwords newer than the number of days specified by the `password_reuse_interval` system variable.

  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL DEFAULT;
  ```

- **PASSWORD_REUSE_INTERVAL N DAY**
  
  This time-elapsed option overrides the global policy for all accounts named by the statement. For each, it sets the password reuse interval to `N` days, to prohibit reuse of passwords newer than that many days. The following statement prohibits password reuse for 360 days:

  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL 360 DAY;
  ```
CREATE USER permits these password_option values for controlling whether attempts to change an account password must specify the current password, as verification that the user attempting to make the change actually knows the current password:

- **PASSWORD REQUIRE CURRENT**
  
  This verification option overrides the global policy for all accounts named by the statement. For each, it requires that password changes specify the current password.

```sql
CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT;
```

- **PASSWORD REQUIRE CURRENT OPTIONAL**
  
  This verification option overrides the global policy for all accounts named by the statement. For each, it does not require that password changes specify the current password. (The current password may but need not be given.)

```sql
CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT OPTIONAL;
```

- **PASSWORD REQUIRE CURRENT DEFAULT**
  
  Sets all statements named by the account so that the global policy about password verification applies, as specified by the `password_require_current` system variable.

```sql
CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT DEFAULT;
```

CREATE USER permits these password_option values for controlling failed-login tracking:

- **FAILED_LOGIN_ATTEMPTS N**
  
  Whether to track account login attempts that specify an incorrect password. \( N \) must be a number from 0 to 32767. A value of 0 disables failed-login tracking. Values greater than 0 indicate how many consecutive password failures cause temporary account locking (if `PASSWORD_LOCK_TIME` is also nonzero).

- **PASSWORD_LOCK_TIME (N | UNBOUNDED)**
  
  How long to lock the account after too many consecutive login attempts provide an incorrect password. \( N \) must be a number from 0 to 32767, or UNBOUNDED. A value of 0 disables temporary account locking. Values greater than 0 indicate how long to lock the account in days. A value of UNBOUNDED causes the account locking duration to be unbounded; once locked, the account remains in a locked state until unlocked. For information about the conditions under which unlocking occurs, see Failed-Login Tracking and Temporary Account Locking.

For failed-login tracking and temporary locking to occur, an account's `FAILED_LOGIN_ATTEMPTS` and `PASSWORD_LOCK_TIME` options both must be nonzero. The following statement creates an account that remains locked for two days after four consecutive password failures:

```sql
CREATE USER 'jeffrey'@'localhost'
  FAILED_LOGIN_ATTEMPTS 4 PASSWORD_LOCK_TIME 2;
```

**CREATE USER Comment and Attribute Options**

You can also include an optional comment or attribute when creating a user, as described here:

- **User comment**
  
  To set a user comment, add `COMMENT 'user_comment'` to the `CREATE USER` statement, where `user_comment` is the text of the user comment.
Account Management Statements

Example (omitting any other options):
CREATE USER 'jon'@'localhost' COMMENT 'Some information about Jon';

• User attribute
A user attribute is a JSON object made up of one or more key-value pairs, and is set by including
ATTRIBUTE 'json_object' as part of CREATE USER. json_object must be a valid JSON object.
Example (omitting any other options):
CREATE USER 'jim'@'localhost'
ATTRIBUTE '{"fname": "James", "lname": "Scott", "phone": "123-456-7890"}';

User comments and user attributes are stored together in the ATTRIBUTE column of the Information
Schema USER_ATTRIBUTES table. This query displays the row in this table inserted by the statement just
shown for creating the user jim@localhost:
mysql> SELECT * FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
->
WHERE USER = 'jim' AND HOST = 'localhost'\G
*************************** 1. row ***************************
USER: jim
HOST: localhost
ATTRIBUTE: {"fname": "James", "lname": "Scott", "phone": "123-456-7890"}
1 row in set (0.00 sec)

The COMMENT option in actuality provides a shortcut for setting a user attribute whose only element
has comment as its key and whose value is the argument supplied for the option. You can see this by
executing the statement CREATE USER 'jon'@'localhost' COMMENT 'Some information
about Jon', and observing the row which it inserts into the USER_ATTRIBUTES table:
mysql> CREATE USER 'jon'@'localhost' COMMENT 'Some information about Jon';
Query OK, 0 rows affected (0.06 sec)
mysql> SELECT * FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
->
WHERE USER = 'jon' AND HOST = 'localhost';
+------+-----------+-------------------------------------------+
| USER | HOST
| ATTRIBUTE
|
+------+-----------+-------------------------------------------+
| jon | localhost | {"comment": "Some information about Jon"} |
+------+-----------+-------------------------------------------+
1 row in set (0.00 sec)

You cannot use COMMENT and ATTRIBUTE together in the same CREATE USER statement; attempting
to do so causes a syntax error. To set a user comment concurrently with setting a user attribute, use
ATTRIBUTE and include in its argument a value with a comment key, like this:
mysql> CREATE USER 'bill'@'localhost'
->
ATTRIBUTE '{"fname":"William", "lname":"Schmidt",
->
"comment":"Website developer"}';
Query OK, 0 rows affected (0.16 sec)

Since the content of the ATTRIBUTE row is a JSON object, you can employ any appropriate MySQL JSON
functions or operators to manipulate it, as shown here:
mysql> SELECT
->
USER AS User,
->
HOST AS Host,
->
CONCAT(ATTRIBUTE->>"$.fname"," ",ATTRIBUTE->>"$.lname") AS 'Full Name',
->
ATTRIBUTE->>"$.comment" AS Comment
-> FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
-> WHERE USER='bill' AND HOST='localhost';

2996


Account Management Statements

<table>
<thead>
<tr>
<th>User</th>
<th>Host</th>
<th>Full Name</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>bill</td>
<td>localhost</td>
<td>William Schmidt</td>
<td>Website developer</td>
</tr>
</tbody>
</table>

To set or to make changes in the user comment or user attribute for an existing user, you can use a `COMMENT` or `ATTRIBUTE` option with an `ALTER USER` statement.

Because the user comment and user attribute are stored together internally in a single `JSON` column, this sets an upper limit on their maximum combined size; see `JSON Storage Requirements`, for more information.

See also the description of the Information Schema `USER_ATTRIBUTES` table for more information and examples.

**CREATE USER Account-Locking Options**

MySQL supports account locking and unlocking using the `ACCOUNT LOCK` and `ACCOUNT UNLOCK` options, which specify the locking state for an account. For additional discussion, see Section 6.2.20, "Account Locking".

If multiple account-locking options are specified, the last one takes precedence.

**CREATE USER Binary Logging**

`CREATE USER` is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named users. If the `IF NOT EXISTS` clause is given, this includes even users that already exist and were not created.

The statement written to the binary log specifies an authentication plugin for each user, determined as follows:

• The plugin named in the original statement, if one was specified.

• Otherwise, the default authentication plugin. In particular, if a user `u1` already exists and uses a nondefault authentication plugin, the statement written to the binary log for `CREATE USER IF NOT EXISTS u1` names the default authentication plugin. (If the statement written to the binary log must specify a nondefault authentication plugin for a user, include it in the original statement.)

If the server adds the default authentication plugin for any nonexisting users in the statement written to the binary log, it writes a warning to the error log naming those users.

If the original statement specifies the `FAILED_LOGIN_ATTEMPTS` or `PASSWORD_LOCK_TIME` option, the statement written to the binary log includes the option.

`CREATE USER` statements with clauses that support multifactor authentication (MFA) are written to the binary log.

• `CREATE USER ... IDENTIFIED WITH .. INITIAL AUTHENTICATION IDENTIFIED WITH ...` statements are written to the binary log as `CREATE USER .. IDENTIFIED WITH .. INITIAL AUTHENTICATION IDENTIFIED WITH .. AS 'password-hash'`, where the `password-hash` is the user-specified `auth-string` or the random password generated by server when the `RANDOM PASSWORD` clause is specified.

**13.7.1.4 DROP ROLE Statement**

DROP ROLE [IF EXISTS] role [, role ] ...
DROP ROLE removes one or more roles (named collections of privileges). To use this statement, you must have the global DROP ROLE or CREATE USER privilege. When the read_only system variable is enabled, DROP ROLE additionally requires the CONNECTION_ADMIN privilege (or the deprecated SUPER privilege).

Users who have the CREATE USER privilege can use this statement to drop accounts that are locked or unlocked. Users who have the DROP ROLE privilege can use this statement only to drop accounts that are locked (unlocked accounts are presumably user accounts used to log in to the server and not just as roles).

Roles named in the mandatory_roles system variable value cannot be dropped.

DROP ROLE either succeeds for all named roles or rolls back and has no effect if any error occurs. By default, an error occurs if you try to drop a role that does not exist. If the IF EXISTS clause is given, the statement produces a warning for each named role that does not exist, rather than an error.

The statement is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named roles. If the IF EXISTS clause is given, this includes even roles that do not exist and were not dropped.

Each role name uses the format described in Section 6.2.5, “Specifying Role Names”. For example:

```
DROP ROLE 'admin', 'developer';
DROP ROLE 'webapp'@'localhost';
```

The host name part of the role name, if omitted, defaults to '%'.

A dropped role is automatically revoked from any user account (or role) to which the role was granted. Within any current session for such an account, its adjusted privileges apply beginning with the next statement executed.

For role usage examples, see Section 6.2.10, “Using Roles”.

### 13.7.1.5 DROP USER Statement

The DROP USER statement removes one or more MySQL accounts and their privileges. It removes privilege rows for the account from all grant tables.

Roles named in the mandatory_roles system variable value cannot be dropped.

To use DROP USER, you must have the global CREATE USER privilege, or the DELETE privilege for the mysql system schema. When the read_only system variable is enabled, DROP USER additionally requires the CONNECTION_ADMIN privilege (or the deprecated SUPER privilege).

DROP USER fails with an error if any account to be dropped is named as the DEFINER attribute for any stored object. (That is, the statement fails if dropping an account would cause a stored object to become orphaned.) To perform the operation anyway, you must have the SET_USER_ID privilege; in this case, the statement succeeds with a warning rather than failing with an error. For additional information, including how to identify which objects name a given account as the DEFINER attribute, see Orphan Stored Objects.

DROP USER either succeeds for all named users or rolls back and has no effect if any error occurs. By default, an error occurs if you try to drop a user that does not exist. If the IF EXISTS clause is given, the statement produces a warning for each named user that does not exist, rather than an error.

The statement is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named users. If the IF EXISTS clause is given, this includes even users that do not exist and were not dropped.
Each account name uses the format described in Section 6.2.4, “Specifying Account Names”. For example:

```
DROP USER 'jeffrey'@'localhost';
```

The host name part of the account name, if omitted, defaults to '%'.

**Important**

**DROP USER** does not automatically close any open user sessions. Rather, in the event that a user with an open session is dropped, the statement does not take effect until that user's session is closed. Once the session is closed, the user is dropped, and that user's next attempt to log in fails. *This is by design.*

**DROP USER** does not automatically drop or invalidate databases or objects within them that the old user created. This includes stored programs or views for which the **DEFINER** attribute names the dropped user. Attempts to access such objects may produce an error if they execute in definer security context. (For information about security context, see Section 25.6, “Stored Object Access Control”.)

### 13.7.1.6 GRANT Statement

```sql
GRANT priv_type [[column_list]]
    [, priv_type [[column_list]]] ...
ON [object_type] priv_level
TO user_or_role [, user_or_role] ...
[WITH GRANT OPTION]
[AS user
    [WITH ROLE
        DEFAULT
        NONE
        ALL
        ALL EXCEPT role [, role ] ...
        role [, role ] ...
    ]
]
}
```

```sql
GRANT PROXY ON user_or_role
    TO user_or_role [, user_or_role] ...
[WITH GRANT OPTION]
```

```sql
GRANT role [, role] ...
    TO user_or_role [, user_or_role] ...
[WITH ADMIN OPTION]
```

**object_type:**

- TABLE
- FUNCTION
- PROCEDURE

**priv_level:**

- *
- **.*
- **db_name.**
- **db_name.tbl_name**
- **tbl_name**
- **db_name.routine_name**

**user_or_role:**

- **user** (see Section 6.2.4, “Specifying Account Names”)
- **role** (see Section 6.2.5, “Specifying Role Names”)}
The `GRANT` statement assigns privileges and roles to MySQL user accounts and roles. There are several aspects to the `GRANT` statement, described under the following topics:

- **GRANT General Overview**
- **Object Quoting Guidelines**
- **Account Names**
- **Privileges Supported by MySQL**
- **Global Privileges**
- **Database Privileges**
- **Table Privileges**
- **Column Privileges**
- **Stored Routine Privileges**
- **Proxy User Privileges**
- **Granting Roles**
- **The `AS` Clause and Privilege Restrictions**
- **Other Account Characteristics**
- **MySQL and Standard SQL Versions of GRANT**

### GRANT General Overview

The `GRANT` statement enables system administrators to grant privileges and roles, which can be granted to user accounts and roles. These syntax restrictions apply:

- `GRANT` cannot mix granting both privileges and roles in the same statement. A given `GRANT` statement must grant either privileges or roles.
- The `ON` clause distinguishes whether the statement grants privileges or roles:
  - With `ON`, the statement grants privileges.
  - Without `ON`, the statement grants roles.
- It is permitted to assign both privileges and roles to an account, but you must use separate `GRANT` statements, each with syntax appropriate to what is to be granted.

For more information about roles, see Section 6.2.10, "Using Roles".

To grant a privilege with `GRANT`, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are granting. (Alternatively, if you have the `UPDATE` privilege for the grant tables in the `mysql` system schema, you can grant any account any privilege.) When the `read_only` system variable is enabled, `GRANT` additionally requires the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege).

`GRANT` either succeeds for all named users and roles or rolls back and has no effect if any error occurs. The statement is written to the binary log only if it succeeds for all named users and roles.

The `REVOKE` statement is related to `GRANT` and enables administrators to remove account privileges. See Section 13.7.1.8, "REVOKE Statement".

3000
Account Management Statements

Each account name uses the format described in Section 6.2.4, “Specifying Account Names”. Each role name uses the format described in Section 6.2.5, “Specifying Role Names”. For example:

```
GRANT ALL ON db1.* TO 'jeffrey'@'localhost';
GRANT 'role1', 'role2' TO 'user1'@'localhost', 'user2'@'localhost';
GRANT SELECT ON world.* TO 'role3';
```

The host name part of the account or role name, if omitted, defaults to '%'.

Normally, a database administrator first uses `CREATE USER` to create an account and define its nonprivilege characteristics such as its password, whether it uses secure connections, and limits on access to server resources, then uses `GRANT` to define its privileges. `ALTER USER` may be used to change the nonprivilege characteristics of existing accounts. For example:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
GRANT ALL ON db1.* TO 'jeffrey'@'localhost';
GRANT SELECT ON db2.invoice TO 'jeffrey'@'localhost';
ALTER USER 'jeffrey'@'localhost' WITH MAX_QUERIES_PER_HOUR 90;
```

From the `mysql` program, `GRANT` responds with `Query OK, 0 rows affected` when executed successfully. To determine what privileges result from the operation, use `SHOW GRANTS`. See Section 13.7.22, “SHOW GRANTS Statement”.

**Important**

Under some circumstances, `GRANT` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see Section 6.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 4.5.1.3, “mysql Client Logging”.

`GRANT` supports host names up to 255 characters long. User names can be up to 32 characters. Database, table, column, and routine names can be up to 64 characters.

**Warning**

*Do not attempt to change the permissible length for user names by altering the `mysql.user` system table. Doing so results in unpredictable behavior which may even make it impossible for users to log in to the MySQL server.* Never alter the structure of tables in the `mysql` system schema in any manner except by means of the procedure described in Section 2.10, “Upgrading MySQL”.

### Object Quoting Guidelines

Several objects within `GRANT` statements are subject to quoting, although quoting is optional in many cases: Account, role, database, table, column, and routine names. For example, if a `user_name` or `host_name` value in an account name is legal as an unquoted identifier, you need not quote it. However, quotation marks are necessary to specify a `user_name` string containing special characters (such as `-`), or a `host_name` string containing special characters or wildcard characters such as `%` (for example, `'test-user'@'%.com'`). Quote the user name and host name separately.

To specify quoted values:

- Quote database, table, column, and routine names as identifiers.
- Quote user names and host names as identifiers or as strings.
- Quote passwords as strings.

**Important**

The use of the wildcard characters `%` and `_` as described in the next few paragraphs is deprecated as of MySQL 8.2.0 and thus subject to removal in a future version of MySQL.

The `_` and `%` wildcards are permitted when specifying database names in `GRANT` statements that grant privileges at the database level (`GRANT ... ON db_name.*`). This means, for example, that to use a `_` character as part of a database name, specify it using the \ escape character as `\_` in the `GRANT` statement, to prevent the user from being able to access additional databases matching the wildcard pattern (for example, `GRANT ... ON `foo\_bar`.* TO ...`).

Issuing multiple `GRANT` statements containing wildcards may not have the expected effect on DML statements; when resolving grants involving wildcards, MySQL takes only the first matching grant into consideration. In other words, if a user has two database-level grants using wildcards that match the same database, the grant which was created first is applied. Consider the database `db` and table `t` created using the statements shown here:

```sql
mysql> CREATE DATABASE db;
Query OK, 1 row affected (0.01 sec)

mysql> CREATE TABLE db.t (c INT);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO db.t VALUES ROW(1);
Query OK, 1 row affected (0.00 sec)
```

Next (assuming that the current account is the MySQL root account or another account having the necessary privileges), we create a user `u` then issue two `GRANT` statements containing wildcards, like this:

```sql
mysql> CREATE USER u;
Query OK, 0 rows affected (0.01 sec)

mysql> GRANT SELECT ON `d_`.* TO u;
Query OK, 0 rows affected (0.01 sec)

mysql> GRANT INSERT ON `d%`.* TO u;
Query OK, 0 rows affected (0.00 sec)

mysql> EXIT
Bye
```

If we end the session and then log in again with the `mysql` client, this time as `u`, we see that this account has only the privilege provided by the first matching grant, but not the second:

```
$> mysql -uu -hlocalhost
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 10
Server version: 8.2.0-tr Source distribution

Copyright (c) 2000, 2023, Oracle and/or its affiliates.
Oracle is a registered trademark of Oracle Corporation and/or its affiliates. Other names may be trademarks of their respective owners.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.
```
In privilege assignments, MySQL interprets occurrences of unescaped _ and % SQL wildcard characters in database names as literal characters under these circumstances:

- When a database name is not used to grant privileges at the database level, but as a qualifier for granting privileges to some other object such as a table or routine (for example, `GRANT ... ON db_name.tbl_name`).

- Enabling `partial_revokes` causes MySQL to interpret unescaped _ and % wildcard characters in database names as literal characters, just as if they had been escaped as \_ and \%. Because this changes how MySQL interprets privileges, it may be advisable to avoid unescaped wildcard characters in privilege assignments for installations where `partial_revokes` may be enabled. For more information, see Section 6.2.12, “Privilege Restriction Using Partial Revokes”.

### Account Names

A **user** value in a `GRANT` statement indicates a MySQL account to which the statement applies. To accommodate granting rights to users from arbitrary hosts, MySQL supports specifying the user value in the form `'user_name'@'host_name'`.

You can specify wildcards in the host name. For example, `'user_name'@'%.example.com'` applies to `user_name` for any host in the `example.com` domain, and `'user_name'@'198.51.100.1'` applies to `user_name` for any host in the `198.51.100` class C subnet.

The simple form `'user_name'` is a synonym for `'user_name'@'%.`.

**Note**

MySQL automatically assigns all privileges granted to `'username'@'.'` to the `'username'@'localhost'` account as well. This behavior is deprecated in MySQL 8.0.35 and later MySQL 8.0 releases, and is subject to removal in a future version of MySQL.

MySQL does not support wildcards in user names. To refer to an anonymous user, specify an account with an empty user name with the `GRANT` statement:

```
GRANT ALL ON test.* TO ''@'localhost' ...;
```

In this case, any user who connects from the local host with the correct password for the anonymous user is permitted access, with the privileges associated with the anonymous-user account.

For additional information about user name and host name values in account names, see Section 6.2.4, “Specifying Account Names”.

**Warning**

If you permit local anonymous users to connect to the MySQL server, you should also grant privileges to all local users as `'username'@'localhost'`. Otherwise, the anonymous user account for `localhost` in the `mysql.user` system table is
used when named users try to log in to the MySQL server from the local machine. For details, see Section 6.2.6, “Access Control, Stage 1: Connection Verification”.

To determine whether this issue applies to you, execute the following query, which lists any anonymous users:

```
SELECT Host, User FROM mysql.user WHERE User='';
```

To avoid the problem just described, delete the local anonymous user account using this statement:

```
DROP USER ''@'localhost';
```

### Privileges Supported by MySQL

The following tables summarize the permissible static and dynamic `priv_type` privilege types that can be specified for the `GRANT` and `REVOKE` statements, and the levels at which each privilege can be granted. For additional information about each privilege, see Section 6.2.2, “Privileges Provided by MySQL”. For information about the differences between static and dynamic privileges, see Static Versus Dynamic Privileges.

#### Table 13.11 Permissible Static Privileges for GRANT and REVOKE

<table>
<thead>
<tr>
<th>Privilege</th>
<th>Meaning and Grantable Levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL [PRIVILEGES]</td>
<td>Grant all privileges at specified access level except <code>GRANT OPTION</code> and <code>PROXY</code>.</td>
</tr>
<tr>
<td>ALTER</td>
<td>Enable use of <code>ALTER TABLE</code>. Levels: Global, database, table.</td>
</tr>
<tr>
<td>ALTER ROUTINE</td>
<td>Enable stored routines to be altered or dropped. Levels: Global, routine.</td>
</tr>
<tr>
<td>CREATE</td>
<td>Enable database and table creation. Levels: Global, database, table.</td>
</tr>
<tr>
<td>CREATE ROLE</td>
<td>Enable role creation. Level: Global.</td>
</tr>
<tr>
<td>CREATE ROUTINE</td>
<td>Enable stored routine creation. Levels: Global, database.</td>
</tr>
<tr>
<td>CREATE TABLESPACE</td>
<td>Enable tablespaces and log file groups to be created, altered, or dropped. Level: Global.</td>
</tr>
<tr>
<td>CREATE TEMPORARY TABLES</td>
<td>Enable use of <code>CREATE TEMPORARY TABLE</code>. Levels: Global, database.</td>
</tr>
<tr>
<td>CREATE USER</td>
<td>Enable use of <code>CREATE USER</code>, <code>DROP USER</code>, <code>RENAME USER</code>, and <code>REVOKE ALL PRIVILEGES</code>. Level: Global.</td>
</tr>
<tr>
<td>CREATE VIEW</td>
<td>Enable views to be created or altered. Levels: Global, database, table.</td>
</tr>
<tr>
<td>DELETE</td>
<td>Enable use of <code>DELETE</code>. Level: Global, database, table.</td>
</tr>
<tr>
<td>DROP</td>
<td>Enable databases, tables, and views to be dropped. Levels: Global, database, table.</td>
</tr>
<tr>
<td>DROP ROLE</td>
<td>Enable roles to be dropped. Level: Global.</td>
</tr>
<tr>
<td>EVENT</td>
<td>Enable use of events for the Event Scheduler. Levels: Global, database.</td>
</tr>
<tr>
<td>Privilege</td>
<td>Meaning and Grantable Levels</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>EXECUTE</td>
<td>Enable the user to execute stored routines. Levels: Global, database, routine.</td>
</tr>
<tr>
<td>FILE</td>
<td>Enable the user to cause the server to read or write files. Level: Global.</td>
</tr>
<tr>
<td>GRANT OPTION</td>
<td>Enable privileges to be granted to or removed from other accounts. Levels: Global, database, table, routine, proxy.</td>
</tr>
<tr>
<td>INDEX</td>
<td>Enable indexes to be created or dropped. Levels: Global, database, table.</td>
</tr>
<tr>
<td>INSERT</td>
<td>Enable use of INSERT. Levels: Global, database, table, column.</td>
</tr>
<tr>
<td>LOCK TABLES</td>
<td>Enable use of LOCK TABLES on tables for which you have the SELECT privilege. Levels: Global, database.</td>
</tr>
<tr>
<td>PROCESS</td>
<td>Enable the user to see all processes with SHOW PROCESSLIST. Level: Global.</td>
</tr>
<tr>
<td>PROXY</td>
<td>Enable user proxying. Level: From user to user.</td>
</tr>
<tr>
<td>REFERENCES</td>
<td>Enable foreign key creation. Levels: Global, database, table, column.</td>
</tr>
<tr>
<td>RELOAD</td>
<td>Enable use of FLUSH operations. Level: Global.</td>
</tr>
<tr>
<td>REPLICATION CLIENT</td>
<td>Enable the user to ask where source or replica servers are. Level: Global.</td>
</tr>
<tr>
<td>REPLICATION SLAVE</td>
<td>Enable replicas to read binary log events from the source. Level: Global.</td>
</tr>
<tr>
<td>SELECT</td>

</table>

A trigger is associated with a table. To create or drop a trigger, you must have the TRIGGER privilege for the table, not the trigger.

In GRANT statements, the ALL [PRIVILEGES] or PROXY privilege must be named by itself and cannot be specified along with other privileges. ALL [PRIVILEGES] stands for all privileges available for the level at which privileges are to be granted except for the GRANT OPTION and PROXY privileges.

MySQL account information is stored in the tables of the mysql system schema. For additional details, consult Section 6.2, “Access Control and Account Management”, which discusses the mysql system schema and the access control system extensively.

If the grant tables hold privilege rows that contain mixed-case database or table names and the lower_case_table_names system variable is set to a nonzero value, REVOKE cannot be used to revoke these privileges. It is necessary in such cases to manipulate the grant tables directly. (GRANT does not create such rows when lower_case_table_names is set, but such rows might have been created prior to setting that variable. The lower_case_table_names setting can only be configured at server startup.)

Privileges can be granted at several levels, depending on the syntax used for the ON clause. For REVOKE, the same ON syntax specifies which privileges to remove.

For the global, database, table, and routine levels, GRANT ALL assigns only the privileges that exist at the level you are granting. For example, GRANT ALL ON db_name.* is a database-level statement, so it does not grant any global-only privileges such as FILE. Granting ALL does not assign the GRANT OPTION or PROXY privilege.
The `object_type` clause, if present, should be specified as `TABLE`, `FUNCTION`, or `PROCEDURE` when the following object is a table, a stored function, or a stored procedure.

The privileges that a user holds for a database, table, column, or routine are formed additively as the logical `OR` of the account privileges at each of the privilege levels, including the global level. It is not possible to deny a privilege granted at a higher level by absence of that privilege at a lower level. For example, this statement grants the `SELECT` and `INSERT` privileges globally:

```
GRANT SELECT, INSERT ON *.* TO u1;
```

The globally granted privileges apply to all databases, tables, and columns, even though not granted at any of those lower levels.

It is possible to deny explicitly a privilege granted at the global level by revoking it for particular databases, if the `partial_revokes` system variable is enabled:

```
GRANT SELECT, INSERT, UPDATE ON *.* TO u1;
REVOKE INSERT, UPDATE ON db1.* FROM u1;
```

The result of the preceding statements is that `SELECT` applies globally to all tables, whereas `INSERT` and `UPDATE` apply globally except to tables in `db1`. Account access to `db1` is read only.

Details of the privilege-checking procedure are presented in Section 6.2.7, "Access Control, Stage 2: Request Verification".

If you are using table, column, or routine privileges for even one user, the server examines table, column, and routine privileges for all users and this slows down MySQL a bit. Similarly, if you limit the number of queries, updates, or connections for any users, the server must monitor these values.

MySQL enables you to grant privileges on databases or tables that do not exist. For tables, the privileges to be granted must include the `CREATE` privilege. This behavior is by design, and is intended to enable the database administrator to prepare user accounts and privileges for databases or tables that are to be created at a later time.

**Important**

MySQL does not automatically revoke any privileges when you drop a database or table. However, if you drop a routine, any routine-level privileges granted for that routine are revoked.

**Global Privileges**

Global privileges are administrative or apply to all databases on a given server. To assign global privileges, use `ON *.*` syntax:

```
GRANT ALL ON *.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON *.* TO 'someuser'@'somehost';
```

The `CREATE TABLESPACE`, `CREATE USER`, `FILE`, `PROCESS`, `RELOAD`, `REPLICATION CLIENT`, `REPLICATION SLAVE`, `SHOW DATABASES`, `SHUTDOWN`, and `SUPER` static privileges are administrative and can only be granted globally.

Dynamic privileges are all global and can only be granted globally.

Other privileges can be granted globally or at more specific levels.

The effect of `GRANT OPTION` granted at the global level differs for static and dynamic privileges:
Account Management Statements

- **GRANT OPTION** granted for any static global privilege applies to all static global privileges.
- **GRANT OPTION** granted for any dynamic privilege applies only to that dynamic privilege.

**GRANT ALL** at the global level grants all static global privileges and all currently registered dynamic privileges. A dynamic privilege registered subsequent to execution of the **GRANT** statement is not granted retroactively to any account.

MySQL stores global privileges in the `mysql.user` system table.

**Database Privileges**

Database privileges apply to all objects in a given database. To assign database-level privileges, use `ON db_name.*` syntax:

```sql
GRANT ALL ON mydb.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.* TO 'someuser'@'somehost';
```

If you use `ON *` syntax (rather than `ON *.*)`, privileges are assigned at the database level for the default database. An error occurs if there is no default database.

The **CREATE**, **DROP**, **EVENT**, **GRANT OPTION**, **LOCK TABLES**, and **REFERENCES** privileges can be specified at the database level. Table or routine privileges also can be specified at the database level, in which case they apply to all tables or routines in the database.

MySQL stores database privileges in the `mysql.db` system table.

**Table Privileges**

Table privileges apply to all columns in a given table. To assign table-level privileges, use `ON db_name.tbl_name` syntax:

```sql
GRANT ALL ON mydb.mytbl TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.mytbl TO 'someuser'@'somehost';
```

If you specify `tbl_name` rather than `db_name.tbl_name`, the statement applies to `tbl_name` in the default database. An error occurs if there is no default database.

The permissible `priv_type` values at the table level are **ALTER**, **CREATE VIEW**, **CREATE**, **DELETE**, **DROP**, **GRANT OPTION**, **INDEX**, **INSERT**, **REFERENCES**, **SELECT**, **SHOW VIEW**, **TRIGGER**, and **UPDATE**.

Table-level privileges apply to base tables and views. They do not apply to tables created with **CREATE TEMPORARY TABLE**, even if the table names match. For information about **TEMPORARY** table privileges, see Section 13.1.20.2, "CREATE TEMPORARY TABLE Statement".

MySQL stores table privileges in the `mysql.tables_priv` system table.

**Column Privileges**

Column privileges apply to single columns in a given table. Each privilege to be granted at the column level must be followed by the column or columns, enclosed within parentheses.

```sql
GRANT SELECT (col1), INSERT (col1, col2) ON mydb.mytbl TO 'someuser'@'somehost';
```

The permissible `priv_type` values for a column (that is, when you use a `column_list` clause) are **INSERT**, **REFERENCES**, **SELECT**, and **UPDATE**.

MySQL stores column privileges in the `mysql.columns_priv` system table.
Stored Routine Privileges

The ALTER ROUTINE, CREATE ROUTINE, EXECUTE, and GRANT OPTION privileges apply to stored routines (procedures and functions). They can be granted at the global and database levels. Except for CREATE ROUTINE, these privileges can be granted at the routine level for individual routines.

```sql
GRANT CREATE ROUTINE ON mydb.* TO 'someuser'@'somehost';
GRANT EXECUTE ON PROCEDURE mydb.myproc TO 'someuser'@'somehost';
```

The permissible priv_type values at the routine level are ALTER ROUTINE, EXECUTE, and GRANT OPTION. CREATE ROUTINE is not a routine-level privilege because you must have the privilege at the global or database level to create a routine in the first place.

MySQL stores routine-level privileges in the mysql.procs_priv system table.

Proxy User Privileges

The PROXY privilege enables one user to be a proxy for another. The proxy user impersonates or takes the identity of the proxied user; that is, it assumes the privileges of the proxied user.

```sql
GRANT PROXY ON 'localuser'@'localhost' TO 'externaluser'@'somehost';
```

When PROXY is granted, it must be the only privilege named in the GRANT statement, and the only permitted WITH option is WITH GRANT OPTION.

Proxying requires that the proxy user authenticate through a plugin that returns the name of the proxied user to the server when the proxy user connects, and that the proxy user have the PROXY privilege for the proxied user. For details and examples, see Section 6.2.19, “Proxy Users”.

MySQL stores proxy privileges in the mysql.proxies_priv system table.

Granting Roles

GRANT syntax without an ON clause grants roles rather than individual privileges. A role is a named collection of privileges; see Section 6.2.10, “Using Roles”. For example:

```sql
GRANT 'role1', 'role2' TO 'user1'@'localhost', 'user2'@'localhost';
```

Each role to be granted must exist, as well as each user account or role to which it is to be granted. Roles cannot be granted to anonymous users.

Granting a role does not automatically cause the role to be active. For information about role activation and inactivation, see Activating Roles.

These privileges are required to grant roles:

- If you have the ROLE_ADMIN privilege (or the deprecated SUPER privilege), you can grant or revoke any role to users or roles.

- If you were granted a role with a GRANT statement that includes the WITH ADMIN OPTION clause, you become able to grant that role to other users or roles, or revoke it from other users or roles, as long as the role is active at such time as you subsequently grant or revoke it. This includes the ability to use WITH ADMIN OPTION itself.

- To grant a role that has the SYSTEM_USER privilege, you must have the SYSTEM_USER privilege.

It is possible to create circular references with GRANT. For example:
CREATE USER 'u1', 'u2';
CREATE ROLE 'r1', 'r2';
GRANT 'u1' TO 'u1';   -- simple loop: u1 -> u1
GRANT 'r1' TO 'r1';   -- simple loop: r1 -> r1
GRANT 'r2' TO 'u2';
GRANT 'u2' TO 'r2';   -- mixed user/role loop: u2 -> r2 -> u2

Circular grant references are permitted but add no new privileges or roles to the grantee because a user or role already has its privileges and roles.

The **AS** Clause and Privilege Restrictions

**GRANT** can specify additional information about the privilege context to use for statement execution by using an **AS** **user** [WITH ROLE] clause. This syntax is visible at the SQL level, although its primary purpose is to enable uniform replication across all nodes of grantor privilege restrictions imposed by partial revokes, by causing those restrictions to appear in the binary log. For information about partial revokes, see Section 6.2.12, “Privilege Restriction Using Partial Revokes”.

When the **AS user** clause is specified, statement execution takes into account any privilege restrictions associated with the named user, including all roles specified by **WITH ROLE**, if present. The result is that the privileges actually granted by the statement may be reduced relative to those specified.

These conditions apply to the **AS user** clause:

- **AS** has an effect only when the named **user** has privilege restrictions (which implies that the **partial_revokes** system variable is enabled).
- If **WITH ROLE** is given, all roles named must be granted to the named **user**.
- The named **user** should be a MySQL account specified as '"user_name'@'host_name', CURRENT_USER, or CURRENT_USER()'. The current user may be named together with **WITH ROLE** for the case that the executing user wants **GRANT** to execute with a set of roles applied that may differ from the roles active within the current session.
- **AS** cannot be used to gain privileges not possessed by the user who executes the **GRANT** statement. The executing user must have at least the privileges to be granted, but the **AS** clause can only restrict the privileges granted, not escalate them.
- With respect to the privileges to be granted, **AS** cannot specify a user/role combination that has more privileges (fewer restrictions) than the user who executes the **GRANT** statement. The **AS user/role** combination is permitted to have more privileges than the executing user, but only if the statement does not grant those additional privileges.
- **AS** is supported only for granting global privileges (**ON *.*
- **AS** is not supported for **PROXY** grants.

The following example illustrates the effect of the **AS** clause. Create a user **u1** that has some global privileges, as well as restrictions on those privileges:

CREATE USER u1;
GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO u1;
REVOKE INSERT, UPDATE ON schema1.* FROM u1;
REVOKE SELECT ON schema2.* FROM u1;

Also create a role **r1** that lifts some of the privilege restrictions and grant the role to **u1**:
CREATE ROLE r1;
GRANT INSERT ON schema1.* TO r1;
GRANT SELECT ON schema2.* TO r1;
GRANT r1 TO u1;

Now, using an account that has no privilege restrictions of its own, grant to multiple users the same set of
global privileges, but each with different restrictions imposed by the AS clause, and check which privileges
are actually granted.

• The GRANT statement here has no AS clause, so the privileges granted are exactly those specified:

```sql
mysql> CREATE USER u2;
mysql> GRANT SELECT, INSERT, UPDATE ON *.* TO u2;
mysql> SHOW GRANTS FOR u2;
+----------------------------------------------+
| Grants for u2@%                            |
|----------------------------------------------+
| GRANT SELECT, INSERT, UPDATE ON *.* TO `u2`@`%` |
+----------------------------------------------+
```

• The GRANT statement here has an AS clause, so the privileges granted are those specified but with the
restrictions from u1 applied:

```sql
mysql> CREATE USER u3;
mysql> GRANT SELECT, INSERT, UPDATE ON *.* TO u3 AS u1;
mysql> SHOW GRANTS FOR u3;
+------------------------------------------+
| Grants for u3@%                          |
|------------------------------------------+
| GRANT SELECT, INSERT, UPDATE ON *.* TO `u3`@`%` |
| REVOKE INSERT, UPDATE ON `schema1`.* FROM `u3`@`%` |
| REVOKE SELECT ON `schema2`.* FROM `u3`@`%`  |
+------------------------------------------+
```

As mentioned previously, the AS clause can only add privilege restrictions; it cannot escalate privileges.
Thus, although u1 has the DELETE privilege, that is not included in the privileges granted because the
statement does not specify granting DELETE.

• The AS clause for the GRANT statement here makes the role r1 active for u1. That role lifts some of the
restrictions on u1. Consequently, the privileges granted have some restrictions, but not so many as for
the previous GRANT statement:

```sql
mysql> CREATE USER u4;
mysql> GRANT SELECT, INSERT, UPDATE ON *.* TO u4 AS u1 WITH ROLE r1;
mysql> SHOW GRANTS FOR u4;
+----------------------------------------------+
| Grants for u4@%                            |
|----------------------------------------------+
| GRANT SELECT, INSERT, UPDATE ON *.* TO `u4`@`%` |
| REVOKE UPDATE ON `schema1`.* FROM `u4`@`%`  |
+----------------------------------------------+
```

If a GRANT statement includes an AS user clause, privilege restrictions on the user who executes the
statement are ignored (rather than applied as they would be in the absence of an AS clause).

Other Account Characteristics

The optional WITH clause is used to enable a user to grant privileges to other users. The WITH GRANT
OPTION clause gives the user the ability to give to other users any privileges the user has at the specified
privilege level.

To grant the GRANT OPTION privilege to an account without otherwise changing its privileges, do this:
GRANT USAGE ON .* TO 'someuser'@'somehost' WITH GRANT OPTION;

Be careful to whom you give the `GRANT OPTION` privilege because two users with different privileges may be able to combine privileges!

You cannot grant another user a privilege which you yourself do not have; the `GRANT OPTION` privilege enables you to assign only those privileges which you yourself possess.

Be aware that when you grant a user the `GRANT OPTION` privilege at a particular privilege level, any privileges the user possesses (or may be given in the future) at that level can also be granted by that user to other users. Suppose that you grant a user the `INSERT` privilege on a database. If you then grant the `SELECT` privilege on the database and specify `WITH GRANT OPTION`, that user can give to other users not only the `SELECT` privilege, but also `INSERT`. If you then grant the `UPDATE` privilege to the user on the database, the user can grant `INSERT`, `SELECT`, and `UPDATE`.

For a nonadministrative user, you should not grant the `ALTER` privilege globally or for the `mysql` system schema. If you do that, the user can try to subvert the privilege system by renaming tables!

For additional information about security risks associated with particular privileges, see Section 6.2.2, “Privileges Provided by MySQL”.

MySQL and Standard SQL Versions of GRANT

The biggest differences between the MySQL and standard SQL versions of `GRANT` are:

- MySQL associates privileges with the combination of a host name and user name and not with only a user name.
- Standard SQL does not have global or database-level privileges, nor does it support all the privilege types that MySQL supports.
- MySQL does not support the standard SQL `UNDER` privilege.
- Standard SQL privileges are structured in a hierarchical manner. If you remove a user, all privileges the user has been granted are revoked. This is also true in MySQL if you use `DROP USER`. See Section 13.7.1.5, “DROP USER Statement”.
- In standard SQL, when you drop a table, all privileges for the table are revoked. In standard SQL, when you revoke a privilege, all privileges that were granted based on that privilege are also revoked. In MySQL, privileges can be dropped with `DROP USER` or `REVOKE` statements.
- In MySQL, it is possible to have the `INSERT` privilege for only some of the columns in a table. In this case, you can still execute `INSERT` statements on the table, provided that you insert values only for those columns for which you have the `INSERT` privilege. The omitted columns are set to their implicit default values if strict SQL mode is not enabled. In strict mode, the statement is rejected if any of the omitted columns have no default value. (Standard SQL requires you to have the `INSERT` privilege on all columns.) For information about strict SQL mode and implicit default values, see Section 5.1.11, “Server SQL Modes”, and Section 11.6, “Data Type Default Values”.

13.7.1.7 RENAME USER Statement

```
RENAME USER old_user TO new_user
[, old_user TO new_user] ...
```

The `RENAME USER` statement renames existing MySQL accounts. An error occurs for old accounts that do not exist or new accounts that already exist.
To use **RENAME USER**, you must have the global **CREATE USER** privilege, or the **UPDATE** privilege for the **mysql** system schema. When the **read_only** system variable is enabled, **RENAME USER** additionally requires the **CONNECTION_ADMIN** privilege (or the deprecated **SUPER** privilege).

**RENAME USER** fails with an error if any account to be renamed is named as the **DEFINER** attribute for any stored object. (That is, the statement fails if renaming an account would cause a stored object to become orphaned.) To perform the operation anyway, you must have the **SET_USER_ID** privilege; in this case, the statement succeeds with a warning rather than failing with an error. For additional information, including how to identify which objects name a given account as the **DEFINER** attribute, see [Orphan Stored Objects](#).

Each account name uses the format described in [Section 6.2.4, “Specifying Account Names”](#). For example:

```sql
RENAME USER 'jeffrey'@'localhost' TO 'jeff'@'127.0.0.1';
```

The host name part of the account name, if omitted, defaults to '%'.

**RENAME USER** causes the privileges held by the old user to be those held by the new user. However, **RENAME USER** does not automatically drop or invalidate databases or objects within them that the old user created. This includes stored programs or views for which the **DEFINER** attribute names the old user. Attempts to access such objects may produce an error if they execute in definer security context. (For information about security context, see [Section 25.6, “Stored Object Access Control”](#).)

The privilege changes take effect as indicated in [Section 6.2.13, “When Privilege Changes Take Effect”](#).

### 13.7.1.8 REVOKE Statement

```sql
REVOKE [IF EXISTS] priv_type [(column_list)] [,..., priv_type [(column_list)]] ...
ON [object_type] priv_level
FROM user_or_role [, user_or_role] ...
[IGNORE UNKNOWN USER]
REVOKE [IF EXISTS] ALL [PRIVILEGES], GRANT OPTION
FROM user_or_role [, user_or_role] ...
[IGNORE UNKNOWN USER]
REVOKE [IF EXISTS] PROXY ON user_or_role
FROM user_or_role [, user_or_role] ...
[IGNORE UNKNOWN USER]
REVOKE [IF EXISTS] role [,..., role ] ...
FROM user_or_role [, user_or_role ] ...
[IGNORE UNKNOWN USER]

user_or_role: {
user (see [Section 6.2.4, “Specifying Account Names”](#))
| role (see [Section 6.2.5, “Specifying Role Names”](#))
}
```

The **REVOKE** statement enables system administrators to revoke privileges and roles, which can be revoked from user accounts and roles.

For details on the levels at which privileges exist, the permissible **priv_type**, **priv_level**, and **object_type** values, and the syntax for specifying users and passwords, see [Section 13.7.1.6, “GRANT Statement”](#).

For information about roles, see [Section 6.2.10, “Using Roles”](#).

When the **read_only** system variable is enabled, **REVOKE** requires the **CONNECTION_ADMIN** or privilege (or the deprecated **SUPER** privilege), in addition to any other required privileges described in the following discussion.
All the forms shown for `REVOKE` support an `IF EXISTS` option as well as an `IGNORE UNKNOWN USER` option. With neither of these modifications, `REVOKE` either succeeds for all named users and roles, or rolls back and has no effect if any error occurs; the statement is written to the binary log only if it succeeds for all named users and roles. The precise effects of `IF EXISTS` and `IGNORE UNKNOWN USER` are discussed later in this section.

Each account name uses the format described in Section 6.2.4, “Specifying Account Names”. Each role name uses the format described in Section 6.2.5, “Specifying Role Names”. For example:

```sql
REVOKE INSERT ON *.* FROM 'jeffrey'@'localhost';
REVOKE 'role1', 'role2' FROM 'user1'@'localhost', 'user2'@'localhost';
REVOKE SELECT ON world.* FROM 'role3';
```

The host name part of the account or role name, if omitted, defaults to '%'.

To use the first `REVOKE` syntax, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are revoking.

To revoke all privileges, use the second syntax, which drops all global, database, table, column, and routine privileges for the named users or roles:

```sql
REVOKE ALL PRIVILEGES, GRANT OPTION
FROM user_or_role [, user_or_role] ...
```

`REVOKE ALL PRIVILEGES, GRANT OPTION` does not revoke any roles.

To use this `REVOKE` syntax, you must have the global `CREATE USER` privilege, or the `UPDATE` privilege for the `mysql` system schema.

The syntax for which the `REVOKE` keyword is followed by one or more role names takes a `FROM` clause indicating one or more users or roles from which to revoke the roles.

The `IF EXISTS` and `IGNORE UNKNOWN USER` options have the effects listed here:

- **IF EXISTS** means that, if the target user or role exists but no such privilege or role is found assigned to the target for any reason, a warning is raised, instead of an error; if no privilege or role named by the statement is assigned to the target, the statement has no (other) effect. Otherwise, `REVOKE` executes normally; if the user does not exist, the statement raises an error.

  **Example:** Given table `t1` in database `test`, we execute the following statements, with the results shown.

```sql
mysql> CREATE USER jerry@localhost;
Query OK, 0 rows affected (0.01 sec)

mysql> REVOKE SELECT ON test.t1 FROM jerry@localhost;
ERROR 1147 (42000): There is no such grant defined for user 'jerry' on host 'localhost' on table 't1'

mysql> REVOKE IF EXISTS SELECT ON test.t1 FROM jerry@localhost;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Warning
Code: 1147
Message: There is no such grant defined for user 'jerry' on host 'localhost' on table 't1'
1 row in set (0.00 sec)
```

`IF EXISTS` causes an error to be demoted to a warning even if the privilege or role named does not exist, or the statement attempts to assign it at the wrong level.
Account Management Statements

- If the `REVOKE` statement includes `IGNORE UNKNOWN USER`, the statement raises a warning for any target user or role named in the statement but not found; if no target named by the statement exists, `REVOKE` succeeds but has no actual effect. Otherwise, the statement executes as usual, and attempting to revoke a privilege not assigned to the target for whatever reason raises an error, as expected.

*Example* (continuing from the previous example):

```sql
mysql> DROP USER IF EXISTS jerry@localhost;
Query OK, 0 rows affected (0.01 sec)

mysql> REVOKE SELECT ON test.t1 FROM jerry@localhost;
ERROR 1147 (42000): There is no such grant defined for user 'jerry' on host 'localhost' on table 't1'

mysql> REVOKE SELECT ON test.t1 FROM jerry@localhost IGNORE UNKNOWN USER;
Query OK, 0 rows affected, 1 warning (0.01 sec)

mysql> SHOW WARNINGS;
*************************** 1. row ***************************
Level: Warning
Code: 3162
Message: Authorization ID jerry does not exist.
1 row in set (0.00 sec)
```

- The combination of `IF EXISTS` and `IGNORE UNKNOWN USER` means that `REVOKE` never raises an error for an unknown target user or role or for an unassigned or unavailable privilege, and the statement as whole in such cases succeeds; roles or privileges are removed from existing target users or roles whenever possible, and any revocation which is not possible raises a warning and executes as a `NOOP`.

*Example* (again continuing from example in the previous item):

```sql
# No such user, no such role
mysql> DROP ROLE IF EXISTS Bogus;
Query OK, 0 rows affected, 1 warning (0.02 sec)

mysql> SHOW WARNINGS;
+-------+------+----------------------------------------------+
| Level | Code | Message                                      |
+-------+------+----------------------------------------------+
| Note  | 3162 | Authorization ID 'Bogus'@'%' does not exist. |
+-------+------+----------------------------------------------+
1 row in set (0.00 sec)

# This statement attempts to revoke a nonexistent role from a nonexistent user
mysql> REVOKE Bogus ON test FROM jerry@localhost;
ERROR 3619 (HY000): Illegal privilege level specified for test

# The same, with IF EXISTS
mysql> REVOKE IF EXISTS Bogus ON test FROM jerry@localhost;
ERROR 1147 (42000): There is no such grant defined for user 'jerry' on host 'localhost' on table 'test'

# The same, with IGNORE UNKNOWN USER
mysql> REVOKE Bogus ON test FROM jerry@localhost IGNORE UNKNOWN USER;
ERROR 3619 (HY000): Illegal privilege level specified for test

# The same, with both options
mysql> REVOKE IF EXISTS Bogus ON test FROM jerry@localhost IGNORE UNKNOWN USER;
Query OK, 0 rows affected, 2 warnings (0.01 sec)

mysql> SHOW WARNINGS;
<table>
<thead>
<tr>
<th>Level</th>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Warning</td>
<td>3619</td>
<td>Illegal privilege level specified for test</td>
</tr>
<tr>
<td>Warning</td>
<td>3162</td>
<td>Authorization ID jerry does not exist.</td>
</tr>
</tbody>
</table>
Roles named in the mandatory_roles system variable value cannot be revoked. When IF EXISTS and IGNORE UNKNOWN USER are used together in a statement that tries to remove a mandatory privilege, the error normally raised by attempting to do this is demoted to a warning; the statement executes successfully, but does not make any changes.

A revoked role immediately affects any user account from which it was revoked, such that within any current session for the account, its privileges are adjusted for the next statement executed.

Revoking a role revokes the role itself, not the privileges that it represents. Suppose that an account is granted a role that includes a given privilege, and is also granted the privilege explicitly or another role that includes the privilege. In this case, the account still possesses that privilege if the first role is revoked. For example, if an account is granted two roles that each include SELECT, the account still can select after either role is revoked.

REVOKE ALL ON *.* (at the global level) revokes all granted static global privileges and all granted dynamic privileges.

A revoked privilege that is granted but not known to the server is revoked with a warning. This situation can occur for dynamic privileges. For example, a dynamic privilege can be granted while the component that registers it is installed, but if that component is subsequently uninstalled, the privilege becomes unregistered, although accounts that possess the privilege still possess it and it can be revoked from them.

REVOKE removes privileges, but does not remove rows from the mysql.user system table. To remove a user account entirely, use DROP USER. See Section 13.7.1.5, “DROP USER Statement”.

If the grant tables hold privilege rows that contain mixed-case database or table names and the lower_case_table_names system variable is set to a nonzero value, REVOKE cannot be used to revoke these privileges. It is necessary in such cases to manipulate the grant tables directly. (GRANT does not create such rows when lower_case_table_names is set, but such rows might have been created prior to setting the variable. The lower_case_table_names setting can only be configured when initializing the server.)

When successfully executed from the mysql program, REVOKE responds with Query OK, 0 rows affected. To determine what privileges remain after the operation, use SHOW GRANTS. See Section 13.7.7.22, “SHOW GRANTS Statement”.

13.7.1.9 SET DEFAULT ROLE Statement

SET DEFAULT ROLE

{NONE | ALL | role [, role ] ...}
TO user [, user ] ...

For each user named immediately after the TO keyword, this statement defines which roles become active when the user connects to the server and authenticates, or when the user executes the SET ROLE DEFAULT statement during a session.

SET DEFAULT ROLE is alternative syntax for ALTER USER ... DEFAULT ROLE (see Section 13.7.1.1, “ALTER USER Statement”). However, ALTER USER can set the default for only a single user, whereas SET DEFAULT ROLE can set the default for multiple users. On the other hand, you can specify CURRENT_USER as the user name for the ALTER USER statement, whereas you cannot for SET DEFAULT ROLE.

SET DEFAULT ROLE requires these privileges:

• Setting the default roles for another user requires the global CREATE USER privilege, or the UPDATE privilege for the mysql.default_roles system table.
• Setting the default roles for yourself requires no special privileges, as long as the roles you want as the default have been granted to you.

Each role name uses the format described in Section 6.2.5, “Specifying Role Names”. For example:

```
SET DEFAULT ROLE 'admin', 'developer' TO 'joe'@'10.0.0.1';
```

The host name part of the role name, if omitted, defaults to '%'.

The clause following the `DEFAULT ROLE` keywords permits these values:

- **NONE**: Set the default to **NONE** (no roles).
- **ALL**: Set the default to all roles granted to the account.
- **role [, role ] ...**: Set the default to the named roles, which must exist and be granted to the account at the time `SET DEFAULT ROLE` is executed.

**Note**

`SET DEFAULT ROLE` and `SET ROLE DEFAULT` are different statements:

- **SET DEFAULT ROLE** defines which account roles to activate by default within account sessions.
- **SET ROLE DEFAULT** sets the active roles within the current session to the current account default roles.

For role usage examples, see Section 6.2.10, “Using Roles”.

### 13.7.1.10 SET PASSWORD Statement

```
SET PASSWORD [FOR user] auth_option
   [REPLACE 'current_auth_string']
   [RETAIN CURRENT PASSWORD]
```

*auth_option*:

```
{ = 'auth_string'
 | TO RANDOM
}
```

The `SET PASSWORD` statement assigns a password to a MySQL user account. The password may be either explicitly specified in the statement or randomly generated by MySQL. The statement may also include a password-verification clause that specifies the account current password to be replaced, and a clause that manages whether an account has a secondary password. `'auth_string'` and `'current_auth_string'` each represent a cleartext (unencrypted) password.

**Note**

Rather than using `SET PASSWORD` to assign passwords, `ALTER USER` is the preferred statement for account alterations, including assigning passwords. For example:

```
ALTER USER user IDENTIFIED BY 'auth_string';
```

**Note**

Clauses for random password generation, password verification, and secondary passwords apply only to accounts that use an authentication plugin that stores credentials internally to MySQL. For accounts that use a plugin that performs
authentication against a credentials system that is external to MySQL, password management must be handled externally against that system as well. For more information about internal credentials storage, see Section 6.2.15, “Password Management”.

The REPLACE 'current_auth_string' clause performs password verification. If given:

- REPLACE specifies the account current password to be replaced, as a cleartext (unencrypted) string.
- The clause must be given if password changes for the account are required to specify the current password, as verification that the user attempting to make the change actually knows the current password.
- The clause is optional if password changes for the account may but need not specify the current password.
- The statement fails if the clause is given but does not match the current password, even if the clause is optional.
- REPLACE can be specified only when changing the account password for the current user.

For more information about password verification by specifying the current password, see Section 6.2.15, “Password Management”.

The RETAIN CURRENT PASSWORD clause implements dual-password capability. If given:

- RETAIN CURRENT PASSWORD retains an account current password as its secondary password, replacing any existing secondary password. The new password becomes the primary password, but clients can use the account to connect to the server using either the primary or secondary password. (Exception: If the new password specified by the SET PASSWORD statement is empty, the secondary password becomes empty as well, even if RETAIN CURRENT PASSWORD is given.)
- If you specify RETAIN CURRENT PASSWORD for an account that has an empty primary password, the statement fails.
- If an account has a secondary password and you change its primary password without specifying RETAIN CURRENT PASSWORD, the secondary password remains unchanged.

For more information about use of dual passwords, see Section 6.2.15, “Password Management”.

SET PASSWORD permits these auth_option syntaxes:

- = 'auth_string'
  Assigns the account the given literal password.

- TO RANDOM
  Assigns the account a password randomly generated by MySQL. The statement also returns the cleartext password in a result set to make it available to the user or application executing the statement.

For details about the result set and characteristics of randomly generated passwords, see Random Password Generation.

Important

Under some circumstances, SET PASSWORD may be recorded in server logs or on the client side in a history file such as ~/.mysql_history, which means that
cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see Section 6.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 4.5.1.3, “mysql Client Logging”.

**SET PASSWORD** can be used with or without a **FOR** clause that explicitly names a user account:

- With a **FOR** user clause, the statement sets the password for the named account, which must exist:

  ```sql
  SET PASSWORD FOR 'jeffrey'@'localhost' = 'auth_string';
  ```

- With no **FOR** user clause, the statement sets the password for the current user:

  ```sql
  SET PASSWORD = 'auth_string';
  ```

Any client who connects to the server using a nonanonymous account can change the password for that account. (In particular, you can change your own password.) To see which account the server authenticated you as, invoke the **CURRENT_USER()** function:

```sql
SELECT CURRENT_USER();
```

If a **FOR** user clause is given, the account name uses the format described in Section 6.2.4, “Specifying Account Names”. For example:

```sql
SET PASSWORD FOR 'bob'@'%.example.org' = 'auth_string';
```

The host name part of the account name, if omitted, defaults to '%'.

**SET PASSWORD** interprets the string as a cleartext string, passes it to the authentication plugin associated with the account, and stores the result returned by the plugin in the account row in the `mysql.user` system table. (The plugin is given the opportunity to hash the value into the encryption format it expects. The plugin may use the value as specified, in which case no hashing occurs.)

Setting the password for a named account (with a **FOR** clause) requires the **UPDATE** privilege for the `mysql` system schema. Setting the password for yourself (for a nonanonymous account with no **FOR** clause) requires no special privileges.

Statements that modify secondary passwords require these privileges:

- The **APPLICATION_PASSWORD_ADMIN** privilege is required to use the **RETAIN CURRENT PASSWORD** clause for **SET PASSWORD** statements that apply to your own account. The privilege is required to manipulate your own secondary password because most users require only one password.

- If an account is to be permitted to manipulate secondary passwords for all accounts, it should be granted the **CREATE_USER** privilege rather than **APPLICATION_PASSWORD_ADMIN**.

When the **read_only** system variable is enabled, **SET PASSWORD** requires the **CONNECTION_ADMIN** privilege (or the deprecated **SUPER** privilege), in addition to any other required privileges.

For additional information about setting passwords and authentication plugins, see Section 6.2.14, “Assigning Account Passwords”, and Section 6.2.17, “Pluggable Authentication”.

### 13.7.11 SET ROLE Statement

```
SET ROLE {DEFAULT | NONE | ALL}
```
SET ROLE modifies the current user's effective privileges within the current session by specifying which of its granted roles are active. Granted roles include those granted explicitly to the user and those named in the mandatory_roles system variable value.

Examples:

```
SET ROLE DEFAULT;
SET ROLE 'role1', 'role2';
SET ROLE ALL;
SET ROLE ALL EXCEPT 'role1', 'role2';
```

Each role name uses the format described in Section 6.2.5, "Specifying Role Names". The host name part of the role name, if omitted, defaults to '%'.

Privileges that the user has been granted directly (rather than through roles) remain unaffected by changes to the active roles.

The statement permits these role specifiers:

- **DEFAULT**: Activate the account default roles. Default roles are those specified with SET DEFAULT ROLE.

  When a user connects to the server and authenticates successfully, the server determines which roles to activate as the default roles. If the activate_all_roles_on_login system variable is enabled, the server activates all granted roles. Otherwise, the server executes SET ROLE DEFAULT implicitly. The server activates only default roles that can be activated. The server writes warnings to its error log for default roles that cannot be activated, but the client receives no warnings.

  If a user executes SET ROLE DEFAULT during a session, an error occurs if any default role cannot be activated (for example, if it does not exist or is not granted to the user). In this case, the current active roles are not changed.

- **NONE**: Set the active roles to NONE (no active roles).

- **ALL**: Activate all roles granted to the account.

- **ALL EXCEPT role [, role ] ...**: Activate all roles granted to the account except those named. The named roles need not exist or be granted to the account.

- **role [, role ] ...**: Activate the named roles, which must be granted to the account.

Note

**SET DEFAULT ROLE** and **SET ROLE DEFAULT** are different statements:

- **SET DEFAULT ROLE** defines which account roles to activate by default within account sessions.

- **SET ROLE DEFAULT** sets the active roles within the current session to the current account default roles.

For role usage examples, see Section 6.2.10, "Using Roles".

**13.7.2 Resource Group Management Statements**

| ALL EXCEPT role [, role ] ... |
| role [, role ] ... |

```
MySQL supports creation and management of resource groups, and permits assigning threads running within the server to particular groups so that threads execute according to the resources available to the group. This section describes the SQL statements available for resource group management. For general discussion of the resource group capability, see Section 5.1.16, “Resource Groups”.

13.7.2.1 ALTER RESOURCE GROUP Statement

**ALTER RESOURCE GROUP** is used for resource group management (see Section 5.1.16, “Resource Groups”). This statement alters modifiable attributes of an existing resource group. It requires the **RESOURCE_GROUP_ADMIN** privilege.

*group_name* identifies which resource group to alter. If the group does not exist, an error occurs.

The attributes for CPU affinity, priority, and whether the group is enabled can be modified with **ALTER RESOURCE GROUP**. These attributes are specified the same way as described for **CREATE RESOURCE GROUP** (see Section 13.7.2.2, “CREATE RESOURCE GROUP Statement”). Only the attributes specified are altered. Unspecified attributes retain their current values.

The **FORCE** modifier is used with **DISABLE**. It determines statement behavior if the resource group has any threads assigned to it:

- If **FORCE** is not given, existing threads in the group continue to run until they terminate, but new threads cannot be assigned to the group.
- If **FORCE** is given, existing threads in the group are moved to their respective default group (system threads to **SYS_default**, user threads to **USR_default**).

The name and type attributes are set at group creation time and cannot be modified thereafter with **ALTER RESOURCE GROUP**.

Examples:

- Alter a group CPU affinity:
  ```sql
  ALTER RESOURCE GROUP rg1 VCPU = 0-63;
  ```

- Alter a group thread priority:
  ```sql
  ALTER RESOURCE GROUP rg2 THREAD_PRIORITY = 5;
  ```

- Disable a group, moving any threads assigned to it to the default groups:
  ```sql
  ALTER RESOURCE GROUP rg3 DISABLE FORCE;
  ```

Resource group management is local to the server on which it occurs. **ALTER RESOURCE GROUP** statements are not written to the binary log and are not replicated.

13.7.2.2 CREATE RESOURCE GROUP Statement

**CREATE RESOURCE GROUP** is used for resource group management (see Section 5.1.16, “Resource Groups”). This statement alters modifiable attributes of an existing resource group. It requires the **RESOURCE_GROUP_ADMIN** privilege.

*group_name* identifies which resource group to alter. If the group does not exist, an error occurs.

The attributes for CPU affinity, priority, and whether the group is enabled can be modified with **CREATE RESOURCE GROUP**. These attributes are specified the same way as described for **ALTER RESOURCE GROUP** (see Section 13.7.2.2, “CREATE RESOURCE GROUP Statement”). Only the attributes specified are altered. Unspecified attributes retain their current values.

The **FORCE** modifier is used with **DISABLE**. It determines statement behavior if the resource group has any threads assigned to it:

- If **FORCE** is not given, existing threads in the group continue to run until they terminate, but new threads cannot be assigned to the group.
- If **FORCE** is given, existing threads in the group are moved to their respective default group (system threads to **SYS_default**, user threads to **USR_default**).

The name and type attributes are set at group creation time and cannot be modified thereafter with **CREATE RESOURCE GROUP**.

Examples:

- Create a group CPU affinity:
  ```sql
  CREATE RESOURCE GROUP rg1 VCPU = 0-63;
  ```

- Create a group thread priority:
  ```sql
  CREATE RESOURCE GROUP rg2 THREAD_PRIORITY = 5;
  ```

- Create a group, moving any threads assigned to it to the default groups:
  ```sql
  CREATE RESOURCE GROUP rg3 DISABLE FORCE;
  ```

Resource group management is local to the server on which it occurs. **CREATE RESOURCE GROUP** statements are not written to the binary log and are not replicated.
CREATE RESOURCE GROUP is used for resource group management (see Section 5.1.16, “Resource Groups”). This statement creates a new resource group and assigns its initial attribute values. It requires the RESOURCE_GROUP_ADMIN privilege.

**group_name** identifies which resource group to create. If the group already exists, an error occurs.

The **TYPE** attribute is required. It should be **SYSTEM** for a system resource group, **USER** for a user resource group. The group type affects permitted **THREAD_PRIORITY** values, as described later.

The **VCPU** attribute indicates the CPU affinity; that is, the set of virtual CPUs the group can use:

- If **VCPU** is not given, the resource group has no CPU affinity and can use all available CPUs.
- If **VCPU** is given, the attribute value is a list of comma-separated CPU numbers or ranges:
  - Each number must be an integer in the range from 0 to the number of CPUs – 1. For example, on a system with 64 CPUs, the number can range from 0 to 63.
  - A range is given in the form \( M - N \), where \( M \) is less than or equal to \( N \) and both numbers are in the CPU range.
  - If a CPU number is an integer outside the permitted range or is not an integer, an error occurs.

Example **VCPU** specifiers (these are all equivalent):

```
VCPU = 0,1,2,3,9,10
VCPU = 0-3,9-10
VCPU = 9,10,0-3
VCPU = 0,10,1,9,3,2
```

The **THREAD_PRIORITY** attribute indicates the priority for threads assigned to the group:

- If **THREAD_PRIORITY** is not given, the default priority is 0.
- If **THREAD_PRIORITY** is given, the attribute value must be in the range from -20 (highest priority) to 19 (lowest priority). The priority for system resource groups must be in the range from -20 to 0. The priority for user resource groups must be in the range from 0 to 19. Use of different ranges for system and user groups ensures that user threads never have a higher priority than system threads.

**ENABLE** and **DISABLE** specify that the resource group is initially enabled or disabled. If neither is specified, the group is enabled by default. A disabled group cannot have threads assigned to it.

Examples:

- Create an enabled user group that has a single CPU and the lowest priority:

  ```
  CREATE RESOURCE GROUP rg1
  TYPE = USER
  VCPU = 0
  THREAD_PRIORITY = 19;
  ```

- Create a disabled system group that has no CPU affinity (can use all CPUs) and the highest priority:

  ```
  CREATE RESOURCE GROUP rg2
  TYPE = SYSTEM
  ```
Resource group management is local to the server on which it occurs. CREATE RESOURCE GROUP statements are not written to the binary log and are not replicated.

## 13.7.2.3 DROP RESOURCE GROUP Statement

```sql
DROP RESOURCE GROUP group_name [FORCE]
```

DROP RESOURCE GROUP is used for resource group management (see Section 5.1.16, “Resource Groups”). This statement drops a resource group. It requires the RESOURCE_GROUP_ADMIN privilege.

*group_name* identifies which resource group to drop. If the group does not exist, an error occurs.

The **FORCE** modifier determines statement behavior if the resource group has any threads assigned to it:

- If **FORCE** is not given and any threads are assigned to the group, an error occurs.
- If **FORCE** is given, existing threads in the group are moved to their respective default group (system threads to SYS_default, user threads to USR_default).

Examples:

- Drop a group, failing if the group contains any threads:
  ```sql
  DROP RESOURCE GROUP rg1;
  ```
- Drop a group and move existing threads to the default groups:
  ```sql
  DROP RESOURCE GROUP rg2 FORCE;
  ```

Resource group management is local to the server on which it occurs. DROP RESOURCE GROUP statements are not written to the binary log and are not replicated.

## 13.7.2.4 SET RESOURCE GROUP Statement

```sql
SET RESOURCE GROUP group_name [FOR thread_id [, thread_id] ...]
```

SET RESOURCE GROUP is used for resource group management (see Section 5.1.16, “Resource Groups”). This statement assigns threads to a resource group. It requires the RESOURCE_GROUP_ADMIN or RESOURCE_GROUP_USER privilege.

*group_name* identifies which resource group to be assigned. Any *thread_id* values indicate threads to assign to the group. Thread IDs can be determined from the Performance Schema threads table. If the resource group or any named thread ID does not exist, an error occurs.

With no **FOR** clause, the statement assigns the current thread for the session to the resource group.

With a **FOR** clause that names thread IDs, the statement assigns those threads to the resource group.

For attempts to assign a system thread to a user resource group or a user thread to a system resource group, a warning occurs.

Examples:

- Assign the current session thread to a group:
SET RESOURCE GROUP rg1;

• Assign the named threads to a group:

SET RESOURCE GROUP rg2 FOR 14, 78, 4;

Resource group management is local to the server on which it occurs. SET RESOURCE GROUP statements are not written to the binary log and are not replicated.

An alternative to SET RESOURCE GROUP is the RESOURCE_GROUP optimizer hint, which assigns individual statements to a resource group. See Section 8.9.3, “Optimizer Hints”.

13.7.3 Table Maintenance Statements

13.7.3.1 ANALYZE TABLE Statement

ANALYZE [NO_WRITE_TO_BINLOG | LOCAL]
  TABLE tbl_name [, tbl_name] ...

ANALYZE [NO_WRITE_TO_BINLOG | LOCAL]
  TABLE tbl_name
  UPDATE HISTOGRAM ON col_name [, col_name] ...
  [WITH N BUCKETS]

ANALYZE [NO_WRITE_TO_BINLOG | LOCAL]
  TABLE tbl_name
  UPDATE HISTOGRAM ON col_name [USING DATA 'json_data']

ANALYZE [NO_WRITE_TO_BINLOG | LOCAL]
  TABLE tbl_name
  DROP HISTOGRAM ON col_name [, col_name] ...

ANALYZE TABLE generates table statistics:

• ANALYZE TABLE without either HISTOGRAM clause performs a key distribution analysis and stores the distribution for the named table or tables. For MyISAM tables, ANALYZE TABLE for key distribution analysis is equivalent to using myisamchk --analyze.

• ANALYZE TABLE with the UPDATE HISTOGRAM clause generates histogram statistics for the named table columns and stores them in the data dictionary. Only one table name is permitted with this syntax. MySQL also supports setting the histogram of a single column to a user-defined JSON value.

• ANALYZE TABLE with the DROP HISTOGRAM clause removes histogram statistics for the named table columns from the data dictionary. Only one table name is permitted for this syntax.

This statement requires SELECT and INSERT privileges for the table.

ANALYZE TABLE works with InnoDB, NDB, and MyISAM tables. It does not work with views.

If the innodb_read_only system variable is enabled, ANALYZE TABLE may fail because it cannot update statistics tables in the data dictionary, which use InnoDB. For ANALYZE TABLE operations that update the key distribution, failure may occur even if the operation updates the table itself (for example, if it is a MyISAM table). To obtain the updated distribution statistics, set information_schema_stats_expiry=0.

ANALYZE TABLE is supported for partitioned tables, and you can use ALTER TABLE ... ANALYZE PARTITION to analyze one or more partitions; for more information, see Section 13.1.9, “ALTER TABLE Statement”, and Section 24.3.4, “Maintenance of Partitions”.

3025
During the analysis, the table is locked with a read lock for InnoDB and MyISAM.

`ANALYZE TABLE` removes the table from the table definition cache, which requires a flush lock. If there are long running statements or transactions still using the table, subsequent statements and transactions must wait for those operations to finish before the flush lock is released. Because `ANALYZE TABLE` itself typically finishes quickly, it may not be apparent that delayed transactions or statements involving the same table are due to the remaining flush lock.

By default, the server writes `ANALYZE TABLE` statements to the binary log so that they replicate to replicas. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias LOCAL.

- **ANALYZE TABLE Output**
- **Key Distribution Analysis**
- **Histogram Statistics Analysis**
- **Other Considerations**

**ANALYZE TABLE Output**

`ANALYZE TABLE` returns a result set with the columns shown in the following table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td><code>analyze</code> or <code>histogram</code></td>
</tr>
<tr>
<td>Msg_type</td>
<td><code>status</code>, <code>error</code>, <code>info</code>, <code>note</code>, or <code>warning</code></td>
</tr>
<tr>
<td>Msg_text</td>
<td>An informational message</td>
</tr>
</tbody>
</table>

**Key Distribution Analysis**

`ANALYZE TABLE` without either `HISTOGRAM` clause performs a key distribution analysis and stores the distribution for the table or tables. Any existing histogram statistics remain unaffected.

If the table has not changed since the last key distribution analysis, the table is not analyzed again.

MySQL uses the stored key distribution to decide the order in which tables should be joined for joins on something other than a constant. In addition, key distributions can be used when deciding which indexes to use for a specific table within a query.

To check the stored key distribution cardinality, use the `SHOW INDEX` statement or the `INFORMATION_SCHEMA STATISTICS` table. See Section 13.7.7.23, “SHOW INDEX Statement”, and Section 26.3.34, “The INFORMATION_SCHEMA STATISTICS Table”.

For InnoDB tables, `ANALYZE TABLE` determines index cardinality by performing random dives on each of the index trees and updating index cardinality estimates accordingly. Because these are only estimates, repeated runs of `ANALYZE TABLE` could produce different numbers. This makes `ANALYZE TABLE` fast on InnoDB tables but not 100% accurate because it does not take all rows into account.

You can make the statistics collected by `ANALYZE TABLE` more precise and more stable by enabling `innodb_stats_persistent`, as explained in Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”. When `innodb_stats_persistent` is enabled, it is important to run `ANALYZE TABLE` after major changes to index column data, as statistics are not recalculated periodically (such as after a server restart).
If `innodb_stats_persistent` is enabled, you can change the number of random dives by modifying the `innodb_stats_persistent_sample_pages` system variable. If `innodb_stats_persistent` is disabled, modify `innodb_stats_transient_sample_pages` instead.

For more information about key distribution analysis in InnoDB, see Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”, and Section 15.8.10.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”.

MySQL uses index cardinality estimates in join optimization. If a join is not optimized in the right way, try running `ANALYZE TABLE`. In the few cases that `ANALYZE TABLE` does not produce values good enough for your particular tables, you can use `FORCE INDEX` with your queries to force the use of a particular index, or set the `max_seeks_for_key` system variable to ensure that MySQL prefers index lookups over table scans. See Section B.3.5, “Optimizer-Related Issues”.

### Histogram Statistics Analysis

`ANALYZE TABLE` with the `HISTOGRAM` clause enables management of histogram statistics for table column values. For information about histogram statistics, see Section 8.9.6, “Optimizer Statistics”.

These histogram operations are available:

- `ANALYZE TABLE` with an `UPDATE HISTOGRAM` clause generates histogram statistics for the named table columns and stores them in the data dictionary. Only one table name is permitted for this syntax.

  The optional `WITH N BUCKETS` clauses specifies the number of buckets for the histogram. The value of `N` must be an integer in the range from 1 to 1024. If this clause is omitted, the number of buckets is 100.

- `ANALYZE TABLE` with a `DROP HISTOGRAM` clause removes histogram statistics for the named table columns from the data dictionary. Only one table name is permitted for this syntax.

Stored histogram management statements affect only the named columns. Consider these statements:

```sql
ANALYZE TABLE t UPDATE HISTOGRAM ON c1, c2, c3 WITH 10 BUCKETS;
ANALYZE TABLE t UPDATE HISTOGRAM ON c1, c3 WITH 10 BUCKETS;
ANALYZE TABLE t DROP HISTOGRAM ON c2;
```

The first statement updates the histograms for columns `c1`, `c2`, and `c3`, replacing any existing histograms for those columns. The second statement updates the histograms for `c1` and `c3`, leaving the `c2` histogram unaffected. The third statement removes the histogram for `c2`, leaving those for `c1` and `c3` unaffected.

When sampling user data as part of building a histogram, not all values are read; this may lead to missing some values considered important. In such cases, it might be useful to modify the histogram, or to set your own histogram explicitly based on your own criteria, such as the complete data set. `ANALYZE TABLE tbl_name UPDATE HISTOGRAM ON col_name USING DATA 'json_data'` updates a column of the histogram table with data supplied in the same JSON format used to display `HISTOGRAM` column values from the Information Schema `COLUMN_STATISTICS` table. Only one column can be modified when updating the histogram with JSON data.

We can illustrate the use of `USING DATA` by first generating a histogram on column `c1` of table `t`, like this:

```sql
mysql> ANALYZE TABLE t UPDATE HISTOGRAM ON c1;
```

```
+--------+-----------+----------+-----------------------------------------------+
| Table  | Op        | Msg_type | Msg_text                                      |
+--------+-----------+----------+-----------------------------------------------+
| mydb.t | histogram | status   | Histogram statistics created for column 'c1'.  |
+--------+-----------+----------+-----------------------------------------------+
```

We can see the histogram generated in the `COLUMN_STATISTICS` table:
### Table Maintenance Statements

```
mysql> TABLE information_schema.column_statistics\G
*************************** 1. row ***************************
SCHEMA_NAME: mydb
TABLE_NAME: t
COLUMN_NAME: c1
HISTOGRAM: {
  "buckets": [[206, 0.0625], [456, 0.125], [608, 0.1875]],
  "data-type": "int",
  "null-values": 0.0,
  "collation-id": 8,
  "sampling-rate": 1.0,
  "histogram-type": "singleton",
  "number-of-buckets-specified": 100
}
```

Now we drop the histogram, and when we check `COLUMN_STATISTICS`, it is now empty:

```
mysql> ANALYZE TABLE t DROP HISTOGRAM ON c1;
```

```
+--------+-----------+----------+-----------------------------------------------+
| Table  | Op        | Msg_type | Msg_text                                      |
+--------+-----------+----------+-----------------------------------------------+
| mydb.t | histogram | status   | Histogram statistics removed for column 'c1'. |
+--------+-----------+----------+-----------------------------------------------+
```

```
mysql> TABLE information_schema.column_statistics\G
Empty set (0.00 sec)
```

We can restore the dropped histogram by inserting its JSON representation obtained previously from the `HISTOGRAM` column of the `COLUMN_STATISTICS` table, and when we query that table again, we can see that the histogram has been restored to its previous state:

```
mysql> ANALYZE TABLE t UPDATE HISTOGRAM ON c1
->   USING DATA '{
    "buckets": [[206, 0.0625], [456, 0.125], [608, 0.1875]],
    "data-type": "int",
    "null-values": 0.0,
    "collation-id": 8,
    "sampling-rate": 1.0,
    "histogram-type": "singleton",
    "number-of-buckets-specified": 100
}';
```

```
+--------+-----------+----------+-----------------------------------------------+
| Table  | Op        | Msg_type | Msg_text                                      |
+--------+-----------+----------+-----------------------------------------------+
| mydb.t | histogram | status   | Histogram statistics created for column 'c1'. |
+--------+-----------+----------+-----------------------------------------------+
```

```
mysql> TABLE information_schema.column_statistics\G
*************************** 1. row ***************************
SCHEMA_NAME: mydb
TABLE_NAME: t
COLUMN_NAME: c1
HISTOGRAM: {
  "buckets": [[206, 0.0625], [456, 0.125], [608, 0.1875]],
  "data-type": "int",
  "null-values": 0.0,
  "collation-id": 8,
  "sampling-rate": 1.0,
  "histogram-type": "singleton",
  "number-of-buckets-specified": 100
}
```

Histogram generation is not supported for encrypted tables (to avoid exposing data in the statistics) or **TEMPORARY** tables.

Histogram generation applies to columns of all data types except geometry types (spatial data) and **JSON**.

Histograms can be generated for stored and virtual generated columns.

Histograms cannot be generated for columns that are covered by single-column unique indexes.

Histogram management statements attempt to perform as much of the requested operation as possible, and report diagnostic messages for the remainder. For example, if an `UPDATE HISTOGRAM` statement names multiple columns, but some of them do not exist or have an unsupported data type, histograms are generated for the other columns, and messages are produced for the invalid columns.

Histograms are affected by these DDL statements:
Table Maintenance Statements

- **DROP TABLE** removes histograms for columns in the dropped table.
- **DROP DATABASE** removes histograms for any table in the dropped database because the statement drops all tables in the database.
- **RENAME TABLE** does not remove histograms. Instead, it renames histograms for the renamed table to be associated with the new table name.
- **ALTER TABLE** statements that remove or modify a column remove histograms for that column.
- **ALTER TABLE ... CONVERT TO CHARACTER SET** removes histograms for character columns because they are affected by the change of character set. Histograms for noncharacter columns remain unaffected.

The **histogram_generation_max_mem_size** system variable controls the maximum amount of memory available for histogram generation. The global and session values may be set at runtime.

Changing the global **histogram_generation_max_mem_size** value requires privileges sufficient to set global system variables. Changing the session **histogram_generation_max_mem_size** value requires privileges sufficient to set restricted session system variables. See Section 5.1.9.1, “System Variable Privileges”.

If the estimated amount of data to be read into memory for histogram generation exceeds the limit defined by **histogram_generation_max_mem_size**, MySQL samples the data rather than reading all of it into memory. Sampling is evenly distributed over the entire table. MySQL uses **SYSTEM** sampling, which is a page-level sampling method.

The **sampling-rate** value in the HISTOGRAM column of the Information Schema **COLUMN_STATISTICS** table can be queried to determine the fraction of data that was sampled to create the histogram. The **sampling-rate** is a number between 0.0 and 1.0. A value of 1 means that all of the data was read (no sampling).

The following example demonstrates sampling. To ensure that the amount of data exceeds the **histogram_generation_max_mem_size** limit for the purpose of the example, the limit is set to a low value (2000000 bytes) prior to generating histogram statistics for the **birth_date** column of the **employees** table.

```sql
mysql> SET histogram_generation_max_mem_size = 2000000;
mysql> USE employees;
mysql> ANALYZE TABLE employees UPDATE HISTOGRAM ON birth_date WITH 16 BUCKETS;
```

![Output of ANALYZE TABLE](image)

```sql
mysql> SELECT HISTOGRAM->>'$."sampling-rate"'
FROM INFORMATION_SCHEMA.COLUMN_STATISTICS
WHERE TABLE_NAME = "employees"
AND COLUMN_NAME = "birth_date";
```

![Output of SELECT HISTOGRAM->>'$."sampling-rate"'](image)

A **sampling-rate** value of 0.0491431208869665 means that approximately 4.9% of the data from the **birth_date** column was read into memory for generating histogram statistics.
Table Maintenance Statements

The InnoDB storage engine provides its own sampling implementation for data stored in InnoDB tables. The default sampling implementation used by MySQL when storage engines do not provide their own requires a full table scan, which is costly for large tables. The InnoDB sampling implementation improves sampling performance by avoiding full table scans.

The sampled_pages_read and sampled_pages_skipped INNODB_METRICS counters can be used to monitor sampling of InnoDB data pages. (For general INNODB_METRICS counter usage information, see Section 26.4.21, "The INFORMATION_SCHEMA INNODB_METRICS Table").

The following example demonstrates sampling counter usage, which requires enabling the counters prior to generating histogram statistics.

```sql
mysql> SET GLOBAL innodb_monitor_enable = 'sampled%';

mysql> USE employees;

mysql> ANALYZE TABLE employees UPDATE HISTOGRAM ON birth_date WITH 16 BUCKETS
G
*************************** 1. row ***************************
Table: employees.employees
  Op: histogram
Msg_type: status
Msg_text: Histogram statistics created for column 'birth_date'.

mysql> USE INFORMATION_SCHEMA;

mysql> SELECT NAME, COUNT FROM INNODB_METRICS WHERE NAME LIKE 'sampled%'
G
*************************** 1. row ***************************
NAME: sampled_pages_read
COUNT: 43
*************************** 2. row ***************************
NAME: sampled_pages_skipped
COUNT: 843
```

This formula approximates a sampling rate based on the sampling counter data:

```
sampling rate = sampled_page_read / (sampled_pages_read + sampled_pages_skipped)
```

A sampling rate based on sampling counter data is roughly the same as the sampling-rate value in the HISTOGRAM column of the Information Schema COLUMN_STATISTICS table.

For information about memory allocations performed for histogram generation, monitor the Performance Schema memory/sql/histograms instrument. See Section 27.12.20.10, "Memory Summary Tables".

Other Considerations

ANALYZE TABLE clears table statistics from the Information Schema INNODB_TABLESTATS table and sets the STATS_INITIALIZED column to Uninitialized. Statistics are collected again the next time the table is accessed.

13.7.3.2 CHECK TABLE Statement

```
CHECK TABLE tbl_name [, tbl_name] ... [option] ...
```

```
option: {
    FOR UPGRADE
    | QUICK
    | FAST
    | MEDIUM
    | EXTENDED
    | CHANGED
}
```
CHECK TABLE checks a table or tables for errors. CHECK TABLE can also check views for problems, such as tables that are referenced in the view definition that no longer exist.

To check a table, you must have some privilege for it.

CHECK TABLE works for InnoDB, MyISAM, ARCHIVE, and CSV tables.

Before running CHECK TABLE on InnoDB tables, see CHECK TABLE Usage Notes for InnoDB Tables.

CHECK TABLE is supported for partitioned tables, and you can use ALTER TABLE ... CHECK PARTITION to check one or more partitions; for more information, see Section 13.1.9, "ALTER TABLE Statement", and Section 24.3.4, "Maintenance of Partitions".

CHECK TABLE ignores virtual generated columns that are not indexed.

- CHECK TABLE Output
- Checking Version Compatibility
- Checking Data Consistency
- CHECK TABLE Usage Notes for InnoDB Tables
- CHECK TABLE Usage Notes for MyISAM Tables

**CHECK TABLE Output**

CHECK TABLE returns a result set with the columns shown in the following table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td>Always check</td>
</tr>
<tr>
<td>Msg_type</td>
<td>status, error, info, note, or warning</td>
</tr>
<tr>
<td>Msg_text</td>
<td>An informational message</td>
</tr>
</tbody>
</table>

The statement might produce many rows of information for each checked table. The last row has a **Msg_type** value of **status** and the **Msg_text** normally should be **OK**. **Table is already up to date** means that the storage engine for the table indicated that there was no need to check the table.

**Checking Version Compatibility**

The **FOR UPGRADE** option checks whether the named tables are compatible with the current version of MySQL. With **FOR UPGRADE**, the server checks each table to determine whether there have been any incompatible changes in any of the table's data types or indexes since the table was created. If not, the check succeeds. Otherwise, if there is a possible incompatibility, the server runs a full check on the table (which might take some time).

Incompatibilities might occur because the storage format for a data type has changed or because its sort order has changed. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases.

**FOR UPGRADE** discovers these incompatibilities:

- The indexing order for end-space in **TEXT** columns for InnoDB and MyISAM tables changed between MySQL 4.1 and 5.0.
The storage method of the new DECIMAL data type changed between MySQL 5.0.3 and 5.0.5.

Changes are sometimes made to character sets or collations that require table indexes to be rebuilt. For details about such changes, see Section 2.10.4, “Changes in MySQL 8.2”. For information about rebuilding tables, see Section 2.10.13, “Rebuilding or Repairing Tables or Indexes”.

MySQL 8.2 does not support the 2-digit YEAR(2) data type permitted in older versions of MySQL. For tables containing YEAR(2) columns, CHECK TABLE recommends REPAIR TABLE, which converts 2-digit YEAR(2) columns to 4-digit YEAR columns.

Trigger creation time is maintained.

A table is reported as needing a rebuild if it contains old temporal columns in pre-5.6.4 format (TIME, DATETIME, and TIMESTAMP columns without support for fractional seconds precision) and the avoid_temporal_upgrade system variable is disabled. This helps the MySQL upgrade procedure detect and upgrade tables containing old temporal columns. If avoid_temporal_upgrade is enabled, FOR UPGRADE ignores the old temporal columns present in the table; consequently, the upgrade procedure does not upgrade them.

To check for tables that contain such temporal columns and need a rebuild, disable avoid_temporal_upgrade before executing CHECK TABLE ... FOR UPGRADE.

Warnings are issued for tables that use nonnative partitioning because nonnative partitioning is removed in MySQL 8.2. See Chapter 24, Partitioning.

### Checking Data Consistency

The following table shows the other check options that can be given. These options are passed to the storage engine, which may use or ignore them.

<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUICK</td>
<td>Do not scan the rows to check for incorrect links. Applies to InnoDB and MyISAM tables and views.</td>
</tr>
<tr>
<td>FAST</td>
<td>Check only tables that have not been closed properly. Ignored for InnoDB; applies only to MyISAM tables and views.</td>
</tr>
<tr>
<td>CHANGED</td>
<td>Check only tables that have been changed since the last check or that have not been closed properly. Ignored for InnoDB; applies only to MyISAM tables and views.</td>
</tr>
<tr>
<td>MEDIUM</td>
<td>Scan rows to verify that deleted links are valid. This also calculates a key checksum for the rows and verifies this with a calculated checksum for the keys. Ignored for InnoDB; applies only to MyISAM tables and views.</td>
</tr>
<tr>
<td>EXTENDED</td>
<td>Do a full key lookup for all keys for each row. This ensures that the table is 100% consistent, but takes a long time. Ignored for InnoDB; applies only to MyISAM tables and views.</td>
</tr>
</tbody>
</table>

You can combine check options, as in the following example that does a quick check on the table to determine whether it was closed properly:

```sql
CHECK TABLE test_table FAST QUICK;
```
Table Maintenance Statements

Note

If **CHECK TABLE** finds no problems with a table that is marked as “corrupted” or “not closed properly”, **CHECK TABLE** may remove the mark.

If a table is corrupted, the problem is most likely in the indexes and not in the data part. All of the preceding check types check the indexes thoroughly and should thus find most errors.

To check a table that you assume is okay, use no check options or the **QUICK** option. The latter should be used when you are in a hurry and can take the very small risk that **QUICK** does not find an error in the data file. (In most cases, under normal usage, MySQL should find any error in the data file. If this happens, the table is marked as “corrupted” and cannot be used until it is repaired.)

**FAST** and **CHANGED** are mostly intended to be used from a script (for example, to be executed from **cron**) to check tables periodically. In most cases, **FAST** is to be preferred over **CHANGED**. (The only case when it is not preferred is when you suspect that you have found a bug in the **MyISAM** code.)

**EXTENDED** is to be used only after you have run a normal check but still get errors from a table when MySQL tries to update a row or find a row by key. This is very unlikely if a normal check has succeeded.

Use of **CHECK TABLE ... EXTENDED** might influence execution plans generated by the query optimizer.

Some problems reported by **CHECK TABLE** cannot be corrected automatically:

• **Found row where the auto_increment column has the value 0.**

  This means that you have a row in the table where the **AUTO_INCREMENT** index column contains the value 0. (It is possible to create a row where the **AUTO_INCREMENT** column is 0 by explicitly setting the column to 0 with an **UPDATE** statement.)

  This is not an error in itself, but could cause trouble if you decide to dump the table and restore it or do an **ALTER TABLE** on the table. In this case, the **AUTO_INCREMENT** column changes value according to the rules of **AUTO_INCREMENT** columns, which could cause problems such as a duplicate-key error.

  To get rid of the warning, execute an **UPDATE** statement to set the column to some value other than 0.

**CHECK TABLE Usage Notes for InnoDB Tables**

The following notes apply to **InnoDB** tables:

• If **CHECK TABLE** encounters a corrupt page, the server exits to prevent error propagation (Bug #10132). If the corruption occurs in a secondary index but table data is readable, running **CHECK TABLE** can still cause a server exit.

• If **CHECK TABLE** encounters a corrupted **DB_TRX_ID** or **DB_ROLL_PTR** field in a clustered index, **CHECK TABLE** can cause **InnoDB** to access an invalid undo log record, resulting in an **MVCC**-related server exit.

• If **CHECK TABLE** encounters errors in **InnoDB** tables or indexes, it reports an error, and usually marks the index and sometimes marks the table as corrupted, preventing further use of the index or table. Such errors include an incorrect number of entries in a secondary index or incorrect links.

• If **CHECK TABLE** finds an incorrect number of entries in a secondary index, it reports an error but does not cause a server exit or prevent access to the file.

• **CHECK TABLE** surveys the index page structure, then surveys each key entry. It does not validate the key pointer to a clustered record or follow the path for **BLOB** pointers.
Table Maintenance Statements

- When an InnoDB table is stored in its own .ibd file, the first 3 pages of the .ibd file contain header information rather than table or index data. The CHECK TABLE statement does not detect inconsistencies that affect only the header data. To verify the entire contents of an InnoDB .ibd file, use the innochecksum command.

- When running CHECK TABLE on large InnoDB tables, other threads may be blocked during CHECK TABLE execution. To avoid timeouts, the semaphore wait threshold (600 seconds) is extended by 2 hours (7200 seconds) for CHECK TABLE operations. If InnoDB detects semaphore waits of 240 seconds or more, it starts printing InnoDB monitor output to the error log. If a lock request extends beyond the semaphore wait threshold, InnoDB aborts the process. To avoid the possibility of a semaphore wait timeout entirely, run CHECK TABLE QUICK instead of CHECK TABLE.

- CHECK TABLE functionality for InnoDB SPATIAL indexes includes an R-tree validity check and a check to ensure that the R-tree row count matches the clustered index.

- CHECK TABLE supports secondary indexes on virtual generated columns, which are supported by InnoDB.

- InnoDB supports parallel clustered index reads, which can improve CHECK TABLE performance. InnoDB reads the clustered index twice during a CHECK TABLE operation. The second read can be performed in parallel. The innodb_parallel_read_threads session variable must be set to a value greater than 1 for parallel clustered index reads to occur. The default value is 4. The actual number of threads used to perform a parallel clustered index read is determined by the innodb_parallel_read_threads setting or the number of index subtrees to scan, whichever is smaller.

CHECK TABLE Usage Notes for MyISAM Tables

The following notes apply to MyISAM tables:

- CHECK TABLE updates key statistics for MyISAM tables.

- If CHECK TABLE output does not return OK or Table is already up to date, you should normally run a repair of the table. See Section 7.6, “MyISAM Table Maintenance and Crash Recovery”.

- If none of the CHECK TABLE options QUICK, MEDIUM, or EXTENDED are specified, the default check type for dynamic-format MyISAM tables is MEDIUM. This has the same result as running myisamchk --medium-check tbl_name on the table. The default check type also is MEDIUM for static-format MyISAM tables, unless CHANGED or FAST is specified. In that case, the default is QUICK. The row scan is skipped for CHANGED and FAST because the rows are very seldom corrupted.

13.7.3.3 CHECKSUM TABLE Statement

| CHECKSUM TABLE tbl_name [, tbl_name] ... [QUICK | EXTENDED] |

CHECKSUM TABLE reports a checksum for the contents of a table. You can use this statement to verify that the contents are the same before and after a backup, rollback, or other operation that is intended to put the data back to a known state.

This statement requires the SELECT privilege for the table.

This statement is not supported for views. If you run CHECKSUM TABLE against a view, the Checksum value is always NULL, and a warning is returned.

For a nonexistent table, CHECKSUM TABLE returns NULL and generates a warning.

During the checksum operation, the table is locked with a read lock for InnoDB and MyISAM.
Performance Considerations

By default, the entire table is read row by row and the checksum is calculated. For large tables, this could take a long time, thus you would only perform this operation occasionally. This row-by-row calculation is what you get with the EXTENDED clause, with InnoDB and all other storage engines other than MyISAM, and with MyISAM tables not created with the CHECKSUM=1 clause.

For MyISAM tables created with the CHECKSUM=1 clause, CHECKSUM TABLE or CHECKSUM TABLE ... QUICK returns the “live” table checksum that can be returned very fast. If the table does not meet all these conditions, the QUICK method returns NULL. The QUICK method is not supported with InnoDB tables. See Section 13.1.20, “CREATE TABLE Statement” for the syntax of the CHECKSUM clause.

The checksum value depends on the table row format. If the row format changes, the checksum also changes. For example, the storage format for temporal types such as TIME, DATETIME, and TIMESTAMP changed in MySQL 5.6 prior to MySQL 5.6.5, so if a 5.5 table is upgraded to MySQL 5.6, the checksum value may change.

Important

If the checksums for two tables are different, then it is almost certain that the tables are different in some way. However, because the hashing function used by CHECKSUM TABLE is not guaranteed to be collision-free, there is a slight chance that two tables which are not identical can produce the same checksum.

13.7.3.4 OPTIMIZE TABLE Statement

OPTIMIZE [NO_WRITE_TO_BINLOG | LOCAL]
   TABLE tbl_name [, tbl_name] ...

OPTIMIZE TABLE reorganizes the physical storage of table data and associated index data, to reduce storage space and improve I/O efficiency when accessing the table. The exact changes made to each table depend on the storage engine used by that table.

Use OPTIMIZE TABLE in these cases, depending on the type of table:

- After doing substantial insert, update, or delete operations on an InnoDB table that has its own .ibd file because it was created with the innodb_file_per_table option enabled. The table and indexes are reorganized, and disk space can be reclaimed for use by the operating system.

- After doing substantial insert, update, or delete operations on columns that are part of a FULLTEXT index in an InnoDB table. Set the configuration option innodb_optimize_fulltext_only=1 first. To keep the index maintenance period to a reasonable time, set the innodb_ft_num_word_optimize option to specify how many words to update in the search index, and run a sequence of OPTIMIZE TABLE statements until the search index is fully updated.

- After deleting a large part of a MyISAM or ARCHIVE table, or making many changes to a MyISAM or ARCHIVE table with variable-length rows (tables that have VARCHAR, VARBINARY, BLOB, or TEXT columns). Deleted rows are maintained in a linked list and subsequent INSERT operations reuse old row positions. You can use OPTIMIZE TABLE to reclaim the unused space and to defragment the data file. After extensive changes to a table, this statement may also improve performance of statements that use the table, sometimes significantly.

This statement requires SELECT and INSERT privileges for the table.

OPTIMIZE TABLE works for InnoDB, MyISAM, and ARCHIVE tables. OPTIMIZE TABLE is also supported for dynamic columns of in-memory NDB tables. It does not work for fixed-width columns of in-memory
Table Maintenance Statements

tables, nor does it work for Disk Data tables. The performance of \texttt{OPTIMIZE} on NDB Cluster tables can be tuned using \texttt{--ndb-optimization-delay}, which controls the length of time to wait between processing batches of rows by \texttt{OPTIMIZE TABLE}. For more information, see Section 23.2.7.11, “Previous NDB Cluster Issues Resolved in NDB Cluster 8.0”.

For NDB Cluster tables, \texttt{OPTIMIZE TABLE} can be interrupted by (for example) killing the SQL thread performing the \texttt{OPTIMIZE} operation.

By default, \texttt{OPTIMIZE TABLE} does \textit{not} work for tables created using any other storage engine and returns a result indicating this lack of support. You can make \texttt{OPTIMIZE TABLE} work for other storage engines by starting \texttt{mysqld} with the \texttt{--skip-new} option. In this case, \texttt{OPTIMIZE TABLE} is just mapped to \texttt{ALTER TABLE}.

This statement does not work with views.

\texttt{OPTIMIZE TABLE} is supported for partitioned tables. For information about using this statement with partitioned tables and table partitions, see Section 24.3.4, “Maintenance of Partitions”.

By default, the server writes \texttt{OPTIMIZE TABLE} statements to the binary log so that they replicate to replicas. To suppress logging, specify the optional \texttt{NO_WRITE_TO_BINLOG} keyword or its alias \texttt{LOCAL}.

- \texttt{OPTIMIZE TABLE} Output
- InnoDB Details
- MyISAM Details
- Other Considerations

\textbf{OPTIMIZE TABLE} Output

\texttt{OPTIMIZE TABLE} returns a result set with the columns shown in the following table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td>Always \texttt{optimize}</td>
</tr>
<tr>
<td>\texttt{Msg_type}</td>
<td>\texttt{status, error, info, note, or warning}</td>
</tr>
<tr>
<td>\texttt{Msg_text}</td>
<td>An informational message</td>
</tr>
</tbody>
</table>

\texttt{OPTIMIZE TABLE} table catches and throws any errors that occur while copying table statistics from the old file to the newly created file. For example, if the user ID of the owner of the \texttt{.MYD} or \texttt{.MYI} file is different from the user ID of the \texttt{mysqld} process, \texttt{OPTIMIZE TABLE} generates a “cannot change ownership of the file” error unless \texttt{mysqld} is started by the \texttt{root} user.

\textbf{InnoDB Details}

For InnoDB tables, \texttt{OPTIMIZE TABLE} is mapped to \texttt{ALTER TABLE ... FORCE}, which rebuilds the table to update index statistics and free unused space in the clustered index. This is displayed in the output of \texttt{OPTIMIZE TABLE} when you run it on an InnoDB table, as shown here:

```sql
mysql> OPTIMIZE TABLE foo;
```

<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>\texttt{Msg_type}</th>
<th>\texttt{Msg_text}</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.foo</td>
<td>optimize</td>
<td>note</td>
<td>Table does not support optimize, doing recreate + analyze instead</td>
</tr>
</tbody>
</table>

3036
OPTIMIZE TABLE uses online DDL for regular and partitioned InnoDB tables, which reduces downtime for concurrent DML operations. The table rebuild triggered by OPTIMIZE TABLE is completed in place. An exclusive table lock is only taken briefly during the prepare phase and the commit phase of the operation. During the prepare phase, metadata is updated and an intermediate table is created. During the commit phase, table metadata changes are committed.

OPTIMIZE TABLE rebuilds the table using the table copy method under the following conditions:

- When the `old_alter_table` system variable is enabled.
- When the server is started with the `--skip-new` option.

OPTIMIZE TABLE using online DDL is not supported for InnoDB tables that contain FULLTEXT indexes. The table copy method is used instead.

InnoDB stores data using a page-allocation method and does not suffer from fragmentation in the same way that legacy storage engines (such as MyISAM) do. When considering whether or not to run optimize, consider the workload of transactions that your server is expected to process:

- Some level of fragmentation is expected. InnoDB only fills pages 93% full, to leave room for updates without having to split pages.
- Delete operations might leave gaps that leave pages less filled than desired, which could make it worthwhile to optimize the table.
- Updates to rows usually rewrite the data within the same page, depending on the data type and row format, when sufficient space is available. See Section 15.9.1.5, “How Compression Works for InnoDB Tables” and Section 15.10, “InnoDB Row Formats”.
- High-concurrency workloads might leave gaps in indexes over time, as InnoDB retains multiple versions of the same data due through its MVCC mechanism. See Section 15.3, “InnoDB Multi-Versioning”.

MyISAM Details

For MyISAM tables, OPTIMIZE TABLE works as follows:

1. If the table has deleted or split rows, repair the table.
2. If the index pages are not sorted, sort them.
3. If the table’s statistics are not up to date (and the repair could not be accomplished by sorting the index), update them.

Other Considerations

OPTIMIZE TABLE is performed online for regular and partitioned InnoDB tables. Otherwise, MySQL locks the table during the time OPTIMIZE TABLE is running.

OPTIMIZE TABLE does not sort R-tree indexes, such as spatial indexes on POINT columns. (Bug #23578)

13.7.3.5 REPAIR TABLE Statement

```
REPAIR [NO_WRITE_TO_BINLOG | LOCAL]
```
REPAIR TABLE repairs a possibly corrupted table, for certain storage engines only.

This statement requires `SELECT` and `INSERT` privileges for the table.

Although normally you should never have to run `REPAIR TABLE`, if disaster strikes, this statement is very likely to get back all your data from a `MyISAM` table. If your tables become corrupted often, try to find the reason for it, to eliminate the need to use `REPAIR TABLE`. See Section B.3.3.3, “What to Do If MySQL Keeps Crashing”, and Section 16.2.4, “MyISAM Table Problems”.

`REPAIR TABLE` checks the table to see whether an upgrade is required. If so, it performs the upgrade, following the same rules as `CHECK TABLE ... FOR UPGRADE`. See Section 13.7.3.2, “CHECK TABLE Statement”, for more information.

**Important**

- Make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors. See Chapter 7, *Backup and Recovery*.

- If the server exits during a `REPAIR TABLE` operation, it is essential after restarting it that you immediately execute another `REPAIR TABLE` statement for the table before performing any other operations on it. In the worst case, you might have a new clean index file without information about the data file, and then the next operation you perform could overwrite the data file. This is an unlikely but possible scenario that underscores the value of making a backup first.

- In the event that a table on the source becomes corrupted and you run `REPAIR TABLE` on it, any resulting changes to the original table are *not* propagated to replicas.

**REPAIR TABLE Storage Engine and Partitioning Support**

`REPAIR TABLE` works for `MyISAM`, `ARCHIVE`, and `CSV` tables. For `MyISAM` tables, it has the same effect as `mysqldump --recover tbl_name` by default. This statement does not work with views.

`REPAIR TABLE` is supported for partitioned tables. However, the `USE_FRM` option cannot be used with this statement on a partitioned table.

You can use `ALTER TABLE ... REPAIR PARTITION` to repair one or more partitions; for more information, see Section 13.1.9, “ALTER TABLE Statement”, and Section 24.3.4, “Maintenance of Partitions”.

**REPAIR TABLE Options**

- `NO_WRITE_TO_BINLOG` or `LOCAL`
By default, the server writes `REPAIR TABLE` statements to the binary log so that they replicate to replicas. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

- **QUICK**

  If you use the `QUICK` option, `REPAIR TABLE` tries to repair only the index file, and not the data file. This type of repair is like that done by `myisamchk --recover --quick`.

- **EXTENDED**

  If you use the `EXTENDED` option, MySQL creates the index row by row instead of creating one index at a time with sorting. This type of repair is like that done by `myisamchk --safe-recover`.

- **USE_FRM**

  The `USE_FRM` option is available for use if the `.MYI` index file is missing or if its header is corrupted. This option tells MySQL not to trust the information in the `.MYI` file header and to re-create it using information from the data dictionary. This kind of repair cannot be done with `myisamchk`.

  **Caution**

  Use the `USE_FRM` option *only* if you cannot use regular `REPAIR` modes. Telling the server to ignore the `.MYI` file makes important table metadata stored in the `.MYI` unavailable to the repair process, which can have deleterious consequences:

  - The current `AUTO_INCREMENT` value is lost.
  - The link to deleted records in the table is lost, which means that free space for deleted records remains unoccupied thereafter.
  - The `.MYI` header indicates whether the table is compressed. If the server ignores this information, it cannot tell that a table is compressed and repair can cause change or loss of table contents. This means that `USE_FRM` should not be used with compressed tables. That should not be necessary, anyway: Compressed tables are read only, so they should not become corrupt.

  If you use `USE_FRM` for a table that was created by a different version of the MySQL server than the one you are currently running, `REPAIR TABLE` does not attempt to repair the table. In this case, the result set returned by `REPAIR TABLE` contains a line with a `Msg_type` value of `error` and a `Msg_text` value of `Failed repairing incompatible .FRM file`.

  If `USE_FRM` is used, `REPAIR TABLE` does not check the table to see whether an upgrade is required.

**REPAIR TABLE Output**

`REPAIR TABLE` returns a result set with the columns shown in the following table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td>Always repair</td>
</tr>
<tr>
<td>Msg_type</td>
<td><code>status</code>, <code>error</code>, <code>info</code>, <code>note</code>, or <code>warning</code></td>
</tr>
</tbody>
</table>
The `REPAIR TABLE` statement might produce many rows of information for each repaired table. The last row has a `Msg_type` value of `status` and `Msg_test` normally should be `OK`. For a `MyISAM` table, if you do not get `OK`, you should try repairing it with `myisamchk --safe-recover`. (`REPAIR TABLE` does not implement all the options of `myisamchk`. With `myisamchk --safe-recover`, you can also use options that `REPAIR TABLE` does not support, such as `--max-record-length`.)

`REPAIR TABLE` catches and throws any errors that occur while copying table statistics from the old corrupted file to the newly created file. For example, if the user ID of the owner of the `.MYD` or `.MYI` file is different from the user ID of the `mysqld` process, `REPAIR TABLE` generates a "cannot change ownership of the file" error unless `mysqld` is started by the `root` user.

Table Repair Considerations

`REPAIR TABLE` upgrades a table if it contains old temporal columns in pre-5.6.4 format (`TIME`, `DATETIME`, and `TIMESTAMP` columns without support for fractional seconds precision) and the `avoid_temporal_upgrade` system variable is disabled. If `avoid_temporal_upgrade` is enabled, `REPAIR TABLE` ignores the old temporal columns present in the table and does not upgrade them.

To upgrade tables that contain such temporal columns, disable `avoid_temporal_upgrade` before executing `REPAIR TABLE`.

You may be able to increase `REPAIR TABLE` performance by setting certain system variables. See Section 8.6.3, “Optimizing REPAIR TABLE Statements”.

13.7.4 Component, Plugin, and Loadable Function Statements

13.7.4.1 CREATE FUNCTION Statement for Loadable Functions

```
CREATE [AGGREGATE] FUNCTION [IF NOT EXISTS] function_name
  RETURNS {STRING|INTEGER|REAL|DECIMAL}
  SONAME shared_library_name
```

This statement loads the loadable function named `function_name`. (`CREATE FUNCTION` is also used to created stored functions; see Section 13.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”.)

A loadable function is a way to extend MySQL with a new function that works like a native (built-in) MySQL function such as `ABS()` or `CONCAT()`. See Adding a Loadable Function.

`function_name` is the name that should be used in SQL statements to invoke the function. The `RETURNS` clause indicates the type of the function's return value. `DECIMAL` is a legal value after `RETURNS`, but currently `DECIMAL` functions return string values and should be written like `STRING` functions.

`IF NOT EXISTS` prevents an error from occurring if there already exists a loadable function with the same name. It does not prevent an error from occurring if there already exists a built-in function having the same name. `IF NOT EXISTS` is also supported for `CREATE FUNCTION` statements. See Function Name Resolution.

The `AGGREGATE` keyword, if given, signifies that the function is an aggregate (group) function. An aggregate function works exactly like a native MySQL aggregate function such as `SUM()` or `COUNT()`.

`shared_library_name` is the base name of the shared library file containing the code that implements the function. The file must be located in the plugin directory. This directory is given by the value of the
plugin_dir system variable. For more information, see Section 5.7.1, “Installing and Uninstalling Loadable Functions”.

**CREATE FUNCTION** requires the **INSERT** privilege for the **mysql** system schema because it adds a row to the **mysql.func** system table to register the function.

**CREATE FUNCTION** also adds the function to the Performance Schema **user_defined_functions** table that provides runtime information about installed loadable functions. See Section 27.12.22.10, “The **user_defined_functions** Table”.

**Note**

Like the **mysql.func** system table, the Performance Schema **user_defined_functions** table lists loadable functions installed using **CREATE FUNCTION**. Unlike the **mysql.func** table, the **user_defined_functions** table also lists loadable functions installed automatically by server components or plugins. This difference makes **user_defined_functions** preferable to **mysql.func** for checking which loadable functions are installed.

During the normal startup sequence, the server loads functions registered in the **mysql.func** table. If the server is started with the **--skip-grant-tables** option, functions registered in the table are not loaded and are unavailable.

**Note**

To upgrade the shared library associated with a loadable function, issue a **DROP FUNCTION** statement, upgrade the shared library, and then issue a **CREATE FUNCTION** statement. If you upgrade the shared library first and then use **DROP FUNCTION**, the server may unexpectedly shut down.

### 13.7.4.2 DROP FUNCTION Statement for Loadable Functions

**DROP FUNCTION [IF EXISTS] function_name**

This statement drops the loadable function named **function_name**. (**DROP FUNCTION** is also used to drop stored functions; see Section 13.1.29, “**DROP PROCEDURE and DROP FUNCTION Statements**”.)

**DROP FUNCTION** is the complement of **CREATE FUNCTION**. It requires the **DELETE** privilege for the **mysql** system schema because it removes the row from the **mysql.func** system table that registers the function.

**DROP FUNCTION** also removes the function from the Performance Schema **user_defined_functions** table that provides runtime information about installed loadable functions. See Section 27.12.22.10, “The **user_defined_functions** Table”.

During the normal startup sequence, the server loads functions registered in the **mysql.func** table. Because **DROP FUNCTION** removes the **mysql.func** row for the dropped function, the server does not load the function during subsequent restarts.

**DROP FUNCTION** cannot be used to drop a loadable function that is installed automatically by components or plugins rather than by using **CREATE FUNCTION**. Such a function is also dropped automatically, when the component or plugin that installed it is uninstalled.

**Note**

To upgrade the shared library associated with a loadable function, issue a **DROP FUNCTION** statement, upgrade the shared library, and then issue a **CREATE**
The `FUNCTION` statement. If you upgrade the shared library first and then use `DROP FUNCTION`, the server may unexpectedly shut down.

13.7.4.3 INSTALL COMPONENT Statement

```
INSTALL COMPONENT  component_name  [, component_name  ...  
                            [SET  variable  =  expr  [, variable  =  expr  ...  ]] 
```

`variable`: {
  `{GLOBAL | @@GLOBAL.}  [component_prefix.]system_var_name 
  | {PERSIST | @@PERSIST.}  [component_prefix.]system_var_name 
}

This statement installs one or more components, which become active immediately. A component provides services that are available to the server and other components; see Section 5.5. "MySQL Components". `INSTALL COMPONENT` requires the `INSERT` privilege for the `mysql.component` system table because it adds a row to that table to register the component.

Example:

```
INSTALL COMPONENT 'file://component1', 'file://component2';
```

A component is named using a URN that begins with `file://` and indicates the base name of the library file that implements the component, located in the directory named by the `plugin_dir` system variable. Component names do not include any platform-dependent file name suffix such as `.so` or `.dll`. (These naming details are subject to change because component name interpretation is itself performed by a service and the component infrastructure makes it possible to replace the default service implementation with alternative implementations.)

`INSTALL COMPONENT` permits setting the values of component system variables when you install one or more components. The `SET` clause enables you to specify variable values precisely when they are needed, without the inconvenience or limitations associated with other forms of assignment. Specifically, you can also set component variables with these alternatives:

- At server startup using options on the command line or in an option file, but doing so involves a server restart. The values do not take effect until you install the component. You can specify an invalid variable name for a component on the command line without triggering an error.

- Dynamically while the server is running by means of the `SET` statement, which enables you to modify operation of the server without having to stop and restart it. Setting a read-only variable is not permitted.

The optional `SET` clause applies a value, or values, only to the component specified in the `INSTALL COMPONENT` statement, rather than to all subsequent installations of that component. `SET GLOBAL` or `PERSIST` works for all types of variables, including read-only variables, without having to restart the server. A component system variable that you set using `INSTALL COMPONENT` takes precedence over any conflicting value coming from the command line or an option file.

Example:

```
INSTALL COMPONENT 'file://component1', 'file://component2'
  SET GLOBAL component1.var1 = 12 + 3, PERSIST component2.var2 = 'strings';
```

Omitting `PERSIST` or `GLOBAL` is equivalent to specifying `GLOBAL`.

Specifying `PERSIST` for any variable in `SET` silently executes `SET PERSIST_ONLY` immediately after `INSTALL COMPONENT` loads the components, but before updating the `mysql.component` table. If `SET PERSIST_ONLY` fails, then the server unloads all of the previously loaded new components without persisting anything to `mysql.component`.
The `SET` clause accepts only valid variable names of the component being installed and emits an error message for all invalid names. Subqueries, stored functions, and aggregate functions are not permitted as part of the value expression. If you install a single component, it is not necessary to prefix the variable name with the component name.

**Note**

While specifying a variable value using the `SET` clause is similar to that of the command line—it is available immediately at variable registration—there is a distinct difference in how the `SET` clause handles invalid numerical values for boolean variables. For example, if you set a boolean variable to 11 (`component1.boolvar = 11`), you see the following behavior:

- `SET` clause yields true
- Command line yields false (11 is neither ON nor 1)

If any error occurs, the statement fails and has no effect. For example, this happens if a component name is erroneous, a named component does not exist or is already installed, or component initialization fails.

A loader service handles component loading, which includes adding installed components to the `mysql.component` system table that serves as a registry. For subsequent server restarts, any components listed in `mysql.component` are loaded by the loader service during the startup sequence. This occurs even if the server is started with the `--skip-grant-tables` option.

If a component depends on services not present in the registry and you attempt to install the component without also installing the component or components that provide the services on which it depends, an error occurs:

```
ERROR 3527 (HY000): Cannot satisfy dependency for service 'component_a'
required by component 'component_b'.
```

To avoid this problem, either install all components in the same statement, or install the dependent component after installing any components on which it depends.

**Note**

For keyring components, do not use `INSTALL COMPONENT`. Instead, configure keyring component loading using a manifest file. See Section 6.4.4.2, "Keyring Component Installation".

### 13.7.4.4 INSTALL PLUGIN Statement

```
INSTALL PLUGIN plugin_name SONAME 'shared_library_name'
```

This statement installs a server plugin. It requires the `INSERT` privilege for the `mysql.plugin` system table because it adds a row to that table to register the plugin.

`plugin_name` is the name of the plugin as defined in the plugin descriptor structure contained in the library file (see Plugin Data Structures). Plugin names are not case-sensitive. For maximal compatibility, plugin names should be limited to ASCII letters, digits, and underscore because they are used in C source files, shell command lines, M4 and Bourne shell scripts, and SQL environments.

`shared_library_name` is the name of the shared library that contains the plugin code. The name includes the file name extension (for example, `libmyplugin.so`, `libmyplugin.dll`, or `libmyplugin.dylib`).
The shared library must be located in the plugin directory (the directory named by the `plugin_dir` system variable). The library must be in the plugin directory itself, not in a subdirectory. By default, `plugin_dir` is the plugin directory under the directory named by the `pkglibdir` configuration variable, but it can be changed by setting the value of `plugin_dir` at server startup. For example, set its value in a `my.cnf` file:

```
[mysqld]
plugin_dir=/path/to/plugin/directory
```

If the value of `plugin_dir` is a relative path name, it is taken to be relative to the MySQL base directory (the value of the `basedir` system variable).

`INSTALL PLUGIN` loads and initializes the plugin code to make the plugin available for use. A plugin is initialized by executing its initialization function, which handles any setup that the plugin must perform before it can be used. When the server shuts down, it executes the deinitialization function for each plugin that is loaded so that the plugin has a chance to perform any final cleanup.

`INSTALL PLUGIN` also registers the plugin by adding a line that indicates the plugin name and library file name to the `mysql.plugin` system table. During the normal startup sequence, the server loads and initializes plugins registered in `mysql.plugin`. This means that a plugin is installed with `INSTALL PLUGIN` only once, not every time the server starts. If the server is started with the `--skip-grant-tables` option, plugins registered in the `mysql.plugin` table are not loaded and are unavailable.

A plugin library can contain multiple plugins. For each of them to be installed, use a separate `INSTALL PLUGIN` statement. Each statement names a different plugin, but all of them specify the same library name.

`INSTALL PLUGIN` causes the server to read option (`my.cnf`) files just as during server startup. This enables the plugin to pick up any relevant options from those files. It is possible to add plugin options to an option file even before loading a plugin (if the `loose` prefix is used). It is also possible to uninstall a plugin, edit `my.cnf`, and install the plugin again. Restarting the plugin this way enables it to the new option values without a server restart.

For options that control individual plugin loading at server startup, see Section 5.6.1, “Installing and Uninstalling Plugins”. If you need to load plugins for a single server startup when the `--skip-grant-tables` option is given (which tells the server not to read system tables), use the `--plugin-load` option. See Section 5.1.7, “Server Command Options”.

To remove a plugin, use the `UNINSTALL PLUGIN` statement.

For additional information about plugin loading, see Section 5.6.1, “Installing and Uninstalling Plugins”.

To see what plugins are installed, use the `SHOW PLUGINS` statement or query the `INFORMATION_SCHEMA.PLUGINS` table.

If you recompile a plugin library and need to reinstall it, you can use either of the following methods:

- Use `UNINSTALL PLUGIN` to uninstall all plugins in the library, install the new plugin library file in the plugin directory, and then use `INSTALL PLUGIN` to install all plugins in the library. This procedure has the advantage that it can be used without stopping the server. However, if the plugin library contains many plugins, you must issue many `INSTALL PLUGIN` and `UNINSTALL PLUGIN` statements.

- Stop the server, install the new plugin library file in the plugin directory, and restart the server.

### 13.7.4.5 UNINSTALL COMPONENT Statement

```
UNINSTALL COMPONENT component_name [, component_name ] ...
```

This statement deactivates and uninstalls one or more components. A component provides services that are available to the server and other components; see Section 5.5, “MySQL Components”. UNINSTALL
**CLONE Statement**

**COMPONENT** is the complement of **INSTALL COMPONENT**. It requires the **DELETE** privilege for the **mysql.component** system table because it removes the row from that table that registers the component. **UNINSTALL COMPONENT** does not undo persisted variables, including the variables persisted using **INSTALL COMPONENT ... SET PERSIST**.

Example:

```sql
UNINSTALL COMPONENT 'file://component1', 'file://component2';
```

For information about component naming, see Section 13.7.4.3, "INSTALL COMPONENT Statement".

If any error occurs, the statement fails and has no effect. For example, this happens if a component name is erroneous, a named component is not installed, or cannot be uninstalled because other installed components depend on it.

A loader service handles component unloading, which includes removing uninstalled components from the **mysql.component** system table that serves as a registry. As a result, unloaded components are not loaded during the startup sequence for subsequent server restarts.

**Note**

This statement has no effect for keyring components, which are loaded using a manifest file and cannot be uninstalled. See Section 6.4.4.2, "Keyring Component Installation".

### 13.7.4.6 UNINSTALL PLUGIN Statement

**UNINSTALL PLUGIN**  

This statement removes an installed server plugin. **UNINSTALL PLUGIN** is the complement of **INSTALL PLUGIN**. It requires the **DELETE** privilege for the **mysql.plugin** system table because it removes the row from that table that registers the plugin.

**plugin_name** must be the name of some plugin that is listed in the **mysql.plugin** table. The server executes the plugin’s deinitialization function and removes the row for the plugin from the **mysql.plugin** system table, so that subsequent server restarts do not load and initialize the plugin. **UNINSTALL PLUGIN** does not remove the plugin’s shared library file.

You cannot uninstall a plugin if any table that uses it is open.

Plugin removal has implications for the use of associated tables. For example, if a full-text parser plugin is associated with a **FULLTEXT** index on the table, uninstalling the plugin makes the table unusable. Any attempt to access the table results in an error. The table cannot even be opened, so you cannot drop an index for which the plugin is used. This means that uninstalling a plugin is something to do with care unless you do not care about the table contents. If you are uninstalling a plugin with no intention of reinstalling it later and you care about the table contents, you should dump the table with **mysqldump** and remove the **WITH PARSER** clause from the dumped **CREATE TABLE** statement so that you can reload the table later. If you do not care about the table, **DROP TABLE** can be used even if any plugins associated with the table are missing.

For additional information about plugin loading, see Section 5.6.1, “Installing and Uninstalling Plugins”.

### 13.7.5 CLONE Statement

**CLONE**  

**clone_action**

```sql
clone_action: {  
    LOCAL DATA DIRECTORY ['clone_dir'];
}
```
The **CLONE** statement is used to clone data locally or from a remote MySQL server instance. To use **CLONE** syntax, the clone plugin must be installed. See Section 5.6.7, “The Clone Plugin”.

**CLONE LOCAL DATA DIRECTORY** syntax clones data from the local MySQL data directory to a directory on the same server or node where the MySQL server instance runs. The 'clone_dir' directory is the full path of the local directory that data is cloned to. An absolute path is required. The specified directory must not exist, but the specified path must be an existent path. The MySQL server requires the necessary write access to create the specified directory. For more information, see Section 5.6.7.2, “Cloning Data Locally”.

**CLONE INSTANCE** syntax clones data from a remote MySQL server instance (the donor) and transfers it to the MySQL instance where the cloning operation was initiated (the recipient).

- **user** is the clone user on the donor MySQL server instance.
- **host** is the hostname address of the donor MySQL server instance. Internet Protocol version 6 (IPv6) address format is not supported. An alias to the IPv6 address can be used instead. An IPv4 address can be used as is.
- **port** is the port number of the donor MySQL server instance. (The X Protocol port specified by mysqlx_port is not supported. Connecting to the donor MySQL server instance through MySQL Router is also not supported.)
- **IDENTIFIED BY 'password'** specifies the password of the clone user on the donor MySQL server instance.
- **DATA DIRECTORY [ = ] 'clone_dir'** is an optional clause used to specify a directory on the recipient for the data you are cloning. Use this option if you do not want to remove existing data in the recipient data directory. An absolute path is required, and the directory must not exist. The MySQL server must have the necessary write access to create the directory.

When the optional **DATA DIRECTORY [ = ] 'clone_dir'** clause is not used, a cloning operation removes existing data in the recipient data directory, replaces it with the cloned data, and automatically restarts the server afterward.

- **[REQUIRE [NO] SSL]** explicitly specifies whether an encrypted connection is to be used or not when transferring cloned data over the network. An error is returned if the explicit specification cannot be satisfied. If an SSL clause is not specified, clone attempts to establish an encrypted connection by default, falling back to an insecure connection if the secure connection attempt fails. A secure connection is required when cloning encrypted data regardless of whether this clause is specified. For more information, see Configuring an Encrypted Connection for Cloning.

For additional information about cloning data from a remote MySQL server instance, see Section 5.6.7.3, “Cloning Remote Data”.

### 13.7.6 SET Statements

The **SET** statement has several forms. Descriptions for those forms that are not associated with a specific server capability appear in subsections of this section:

- **SET var_name = value** enables you to assign values to variables that affect the operation of the server or clients. See Section 13.7.6.1, “SET Syntax for Variable Assignment”.

---

<table>
<thead>
<tr>
<th>INSTANCE FROM 'user'@'host':port</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDENTIFIED BY 'password'</td>
</tr>
<tr>
<td>[DATA DIRECTORY [ = ] 'clone_dir']</td>
</tr>
<tr>
<td>[REQUIRE [NO] SSL]</td>
</tr>
</tbody>
</table>
• **SET CHARACTER SET** and **SET NAMES** assign values to character set and collation variables associated with the current connection to the server. See [Section 13.7.6.2, “SET CHARACTER SET Statement”](#) and [Section 13.7.6.3, “SET NAMES Statement”](#).

Descriptions for the other forms appear elsewhere, grouped with other statements related to the capability they help implement:

• **SET DEFAULT ROLE** and **SET ROLE** set the default role and current role for user accounts. See [Section 13.7.1.9, “SET DEFAULT ROLE Statement”](#) and [Section 13.7.1.11, “SET ROLE Statement”](#).

• **SET PASSWORD** assigns account passwords. See [Section 13.7.1.10, “SET PASSWORD Statement”](#).

• **SET RESOURCE GROUP** assigns threads to a resource group. See [Section 13.7.2.4, “SET RESOURCE GROUP Statement”](#).

• **SET TRANSACTION ISOLATION LEVEL** sets the isolation level for transaction processing. See [Section 13.3.7, “SET TRANSACTION Statement”](#).

### 13.7.6.1 SET Syntax for Variable Assignment

```sql
SET variable = expr [, variable = expr] ...
```

**variable**: 

- `user_var_name`
- `param_name`
- `local_var_name`
- `GLOBAL | @@GLOBAL. system_var_name`
- `{PERSIST | @@PERSIST.} system_var_name`
- `{PERSIST_ONLY | @@PERSIST_ONLY.} system_var_name`
- `{SESSION | @@SESSION. | @@} system_var_name`

**SET** syntax for variable assignment enables you to assign values to different types of variables that affect the operation of the server or clients:

• User-defined variables. See [Section 9.4, “User-Defined Variables”](#).

• Stored procedure and function parameters, and stored program local variables. See [Section 13.6.4, “Variables in Stored Programs”](#).

• System variables. See [Section 5.1.8, “Server System Variables”](#). System variables also can be set at server startup, as described in [Section 5.1.9, “Using System Variables”](#).

A **SET** statement that assigns variable values is not written to the binary log, so in replication scenarios it affects only the host on which you execute it. To affect all replication hosts, execute the statement on each host.

The following sections describe **SET** syntax for setting variables. They use the `=` assignment operator, but the `:=` assignment operator is also permitted for this purpose.

• **User-Defined Variable Assignment**

• **Parameter and Local Variable Assignment**

• **System Variable Assignment**

• **SET Error Handling**

• **Multiple Variable Assignment**
• System Variable References in Expressions

User-Defined Variable Assignment

User-defined variables are created locally within a session and exist only within the context of that session; see Section 9.4, “User-Defined Variables”.

A user-defined variable is written as `@var_name` and is assigned an expression value as follows:

```sql
SET @var_name = expr;
```

Examples:

```sql
SET @name = 43;
SET @total_tax = (SELECT SUM(tax) FROM taxable_transactions);
```

As demonstrated by those statements, `expr` can range from simple (a literal value) to more complex (the value returned by a scalar subquery).

The Performance Schema `user_variables_by_thread` table contains information about user-defined variables. See Section 27.12.10, “Performance Schema User-Defined Variable Tables”.

Parameter and Local Variable Assignment

`SET` applies to parameters and local variables in the context of the stored object within which they are defined. The following procedure uses the `increment` procedure parameter and `counter` local variable:

```sql
CREATE PROCEDURE p(increment INT)
BEGIN
    DECLARE counter INT DEFAULT 0;
    WHILE counter < 10 DO
        -- ... do work ...
        SET counter = counter + increment;
    END WHILE;
END;
```

System Variable Assignment

The MySQL server maintains system variables that configure its operation. A system variable can have a global value that affects server operation as a whole, a session value that affects the current session, or both. Many system variables are dynamic and can be changed at runtime using the `SET` statement to affect operation of the current server instance. `SET` can also be used to persist certain system variables to the `mysqld-auto.cnf` file in the data directory, to affect server operation for subsequent startups.

If a `SET` statement is issued for a sensitive system variable, the query is rewritten to replace the value with "<redacted>" before it is logged to the general log and audit log. This takes place even if secure storage through a keyring component is not available on the server instance.

If you change a session system variable, the value remains in effect within your session until you change the variable to a different value or the session ends. The change has no effect on other sessions.

If you change a global system variable, the value is remembered and used to initialize the session value for new sessions until you change the variable to a different value or the server exits. The change is visible to any client that accesses the global value. However, the change affects the corresponding session value only for clients that connect after the change. The global variable change does not affect the session value for any current client sessions (not even the session within which the global value change occurs).

To make a global system variable setting permanent so that it applies across server restarts, you can persist it to the `mysqld-auto.cnf` file in the data directory. It is also possible to make persistent configuration changes by manually modifying a `my.cnf` option file, but that is more cumbersome, and an
error in a manually entered setting might not be discovered until much later. \textit{SET} statements that persist system variables are more convenient and avoid the possibility of malformed settings because settings with syntax errors do not succeed and do not change server configuration. For more information about persisting system variables and the \texttt{mysqld-auto.cnf} file, see Section 5.1.9.3, “Persisted System Variables”.

\begin{note}
Setting or persisting a global system variable value always requires special privileges. Setting a session system variable value normally requires no special privileges and can be done by any user, although there are exceptions. For more information, see Section 5.1.9.1, “System Variable Privileges”.
\end{note}

The following discussion describes the syntax options for setting and persisting system variables:

- To assign a value to a global system variable, precede the variable name by the \texttt{GLOBAL} keyword or the \texttt{@@GLOBAL.} qualifier:

  \begin{verbatim}
  SET GLOBAL max_connections = 1000;
  SET @@GLOBAL.max_connections = 1000;
  \end{verbatim}

- To assign a value to a session system variable, precede the variable name by the \texttt{SESSION} or \texttt{LOCAL} keyword, by the \texttt{@@SESSION., @@LOCAL., or @@} qualifier, or by no keyword or no modifier at all:

  \begin{verbatim}
  SET SESSION sql_mode = 'TRADITIONAL';
  SET LOCAL sql_mode = 'TRADITIONAL';
  SET @@SESSION.sql_mode = 'TRADITIONAL';
  SET @@LOCAL.sql_mode = 'TRADITIONAL';
  SET @sql_mode = 'TRADITIONAL';
  SET sql_mode = 'TRADITIONAL';
  \end{verbatim}

A client can change its own session variables, but not those of any other client.

- To persist a global system variable to the \texttt{mysqld-auto.cnf} option file in the data directory, precede the variable name by the \texttt{PERSIST} keyword or the \texttt{@@PERSIST.} qualifier:

  \begin{verbatim}
  SET PERSIST max_connections = 1000;
  SET @@PERSIST.max_connections = 1000;
  \end{verbatim}

This \texttt{SET} syntax enables you to make configuration changes at runtime that also persist across server restarts. Like \texttt{SET GLOBAL}, \texttt{SET PERSIST} sets the global variable runtime value, but also writes the variable setting to the \texttt{mysqld-auto.cnf} file (replacing any existing variable setting if there is one).

- To persist a global system variable to the \texttt{mysqld-auto.cnf} file without setting the global variable runtime value, precede the variable name by the \texttt{PERSIST_ONLY} keyword or the \texttt{@@PERSIST_ONLY.} qualifier:

  \begin{verbatim}
  SET PERSIST_ONLY back_log = 100;
  SET @@PERSIST_ONLY.back_log = 100;
  \end{verbatim}

Like \texttt{PERSIST}, \texttt{PERSISTONLY} writes the variable setting to \texttt{mysqld-auto.cnf}. However, unlike \texttt{PERSIST}, \texttt{PERSIST_ONLY} does not modify the global variable runtime value. This makes \texttt{PERSIST_ONLY} suitable for configuring read-only system variables that can be set only at server startup.

To set a global system variable value to the compiled-in MySQL default value or a session system variable to the current corresponding global value, set the variable to the value \texttt{DEFAULT}. For example, the following two statements are identical in setting the session value of \texttt{max_join_size} to the current global value:

\begin{verbatim}
3049
\end{verbatim}
Using **SET** to persist a global system variable to a value of **DEFAULT** or to its literal default value assigns the variable its default value and adds a setting for the variable to **mysql-auto.cnf**. To remove the variable from the file, use **RESET PERSIST**.

Some system variables cannot be persisted or are persist-restricted. See **Section 5.1.9.4, “Nonpersistible and Persist-Restricted System Variables”**.

A system variable implemented by a plugin can be persisted if the plugin is installed when the **SET** statement is executed. Assignment of the persisted plugin variable takes effect for subsequent server restarts if the plugin is still installed. If the plugin is no longer installed, the plugin variable no longer exists when the server reads the **mysql-auto.cnf** file. In this case, the server writes a warning to the error log and continues:

```
currently unknown variable 'var_name'
was read from the persisted config file
```

To display system variable names and values:

- Use the **SHOW VARIABLES** statement; see **Section 13.7.7.43, “SHOW VARIABLES Statement”**.
- Several Performance Schema tables provide system variable information. See **Section 27.12.14, “Performance Schema System Variable Tables”**.
- The Performance Schema **variables_info** table contains information showing when and by which user each system variable was most recently set. See **Section 27.12.14.2, “Performance Schema variables_info Table”**.
- The Performance Schema **persisted_variables** table provides an SQL interface to the **mysql-auto.cnf** file, enabling its contents to be inspected at runtime using **SELECT** statements. See **Section 27.12.14.1, “Performance Schema persisted_variables Table”**.

**SET Error Handling**

If any variable assignment in a **SET** statement fails, the entire statement fails and no variables are changed, nor is the **mysql-auto.cnf** file changed.

**SET** produces an error under the circumstances described here. Most of the examples show **SET** statements that use keyword syntax (for example, **GLOBAL** or **SESSION**), but the principles are also true for statements that use the corresponding modifiers (for example, @@GLOBAL. or @@SESSION.).

- **Use of SET** (any variant) to set a read-only variable:

```
mysql> SET GLOBAL version = 'abc';
ERROR 1238 (HY000): Variable 'version' is a read only variable
```

- **Use of GLOBAL, PERSIST, or PERSIST_ONLY** to set a variable that has only a session value:

```
mysql> SET GLOBAL sql_log_bin = ON;
ERROR 1228 (HY000): Variable 'sql_log_bin' is a SESSION variable and can't be used with SET GLOBAL
```

- **Use of SESSION** to set a variable that has only a global value:

```
mysql> SET SESSION max_connections = 1000;
ERROR 1229 (HY000): Variable 'max_connections' is a GLOBAL variable and should be set with SET GLOBAL
```
SET Statements

- Omission of `GLOBAL`, `PERSIST`, or `PERSIST_ONLY` to set a variable that has only a global value:

  ```
  mysql> SET max_connections = 1000;
  ERROR 1229 (HY000): Variable 'max_connections' is a GLOBAL variable and should be set with SET GLOBAL
  ```

- Use of `PERSIST` or `PERSIST_ONLY` to set a variable that cannot be persisted:

  ```
  mysql> SET PERSIST port = 3307;
  ERROR 1238 (HY000): Variable 'port' is a read only variable
  mysql> SET PERSIST_ONLY port = 3307;
  ERROR 1238 (HY000): Variable 'port' is a non persistent read only variable
  ```

- The `@@GLOBAL`, `@@PERSIST`, `@@PERSIST_ONLY`, `@@SESSION`, and `@@` modifiers apply only to system variables. An error occurs for attempts to apply them to user-defined variables, stored procedure or function parameters, or stored program local variables.

- Not all system variables can be set to `DEFAULT`. In such cases, assigning `DEFAULT` results in an error.

  ```
  • An error occurs for attempts to assign `DEFAULT` to user-defined variables, stored procedure or function parameters, or stored program local variables.
  ```

Multiple Variable Assignment

A `SET` statement can contain multiple variable assignments, separated by commas. This statement assigns values to a user-defined variable and a system variable:

  ```
  SET @x = 1, SESSION sql_mode = '';
  ```

If you set multiple system variables in a single statement, the most recent `GLOBAL`, `PERSIST`, `PERSIST_ONLY`, or `SESSION` keyword in the statement is used for following assignments that have no keyword specified.

Examples of multiple-variable assignment:

  ```
  SET GLOBAL sort_buffer_size = 1000000, SESSION sort_buffer_size = 1000000;
  SET @@GLOBAL.sort_buffer_size = 1000000, @@LOCAL.sort_buffer_size = 1000000;
  SET GLOBAL max_connections = 1000, sort_buffer_size = 1000000;
  ```

The `@@GLOBAL`, `@@PERSIST`, `@@PERSIST_ONLY`, `@@SESSION`, and `@@` modifiers apply only to the immediately following system variable, not any remaining system variables. This statement sets the `sort_buffer_size` global value to 50000 and the session value to 1000000:

  ```
  SET @@GLOBAL.sort_buffer_size = 50000, sort_buffer_size = 1000000;
  ```

System Variable References in Expressions

To refer to the value of a system variable in expressions, use one of the `@@`-modifiers (except `@@PERSIST` and `@@PERSIST_ONLY`, which are not permitted in expressions). For example, you can retrieve system variable values in a `SELECT` statement like this:

  ```
  SELECT @@GLOBAL.sql_mode, @@SESSION.sql_mode, @@sql_mode;
  ```

Note

A reference to a system variable in an expression as `@@var_name` (with `@@` rather than `@@GLOBAL`, or `@@SESSION`) returns the session value if it exists and the global value otherwise. This differs from `SET @@var_name = expr`, which always refers to the session value.
### 13.7.6.2 SET CHARACTER SET Statement

```sql
SET {CHARACTER SET | CHARSET}
{'charset_name' | DEFAULT}
```

This statement maps all strings sent between the server and the current client with the given mapping. `SET CHARACTER SET` sets three session system variables: `character_set_client` and `character_set_results` are set to the given character set, and `character_set_connection` to the value of `character_set_database`. See Section 10.4, "Connection Character Sets and Collations".

`charset_name` may be quoted or unquoted.

The default character set mapping can be restored by using the value `DEFAULT`. The default depends on the server configuration.

Some character sets cannot be used as the client character set. Attempting to use them with `SET CHARACTER SET` produces an error. See Impermissible Client Character Sets.

### 13.7.6.3 SET NAMES Statement

```sql
SET NAMES {'charset_name'
[COLLATE 'collation_name'] | DEFAULT}
```

This statement sets the three session system variables `character_set_client`, `character_set_connection`, and `character_set_results` to the given character set. Setting `character_set_connection` to `charset_name` also sets `collation_connection` to the default collation for `charset_name`. See Section 10.4, "Connection Character Sets and Collations".

The optional `COLLATE` clause may be used to specify a collation explicitly. If given, the collation must one of the permitted collations for `charset_name`.

`charset_name` and `collation_name` may be quoted or unquoted.

The default mapping can be restored by using a value of `DEFAULT`. The default depends on the server configuration.

Some character sets cannot be used as the client character set. Attempting to use them with `SET NAMES` produces an error. See Impermissible Client Character Sets.

### 13.7.7 SHOW Statements

`SHOW` has many forms that provide information about databases, tables, columns, or status information about the server. This section describes those following:

- `SHOW {BINARY | MASTER} LOGS`
- `SHOW BINLOG EVENTS [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]`
- `SHOW [CHARACTER SET | CHARSET] [like_or_where]`
- `SHOW COLLATION [like_or_where]`
- `SHOW [FULL] COLUMNS FROM tbl_name [FROM db_name] [like_or_where]`
- `SHOW CREATE DATABASE db_name`
- `SHOW CREATE EVENT event_name`
- `SHOW CREATE FUNCTION func_name`
- `SHOW CREATE PROCEDURE proc_name`
- `SHOW CREATE TABLE tbl_name`
- `SHOW CREATE TRIGGER trigger_name`
- `SHOW CREATE VIEW view_name`
- `SHOW DATABASES [like_or_where]`
- `SHOW ENGINE engine_name [STATUS | MUTEX]`
- `SHOW [STORAGE] ENGINES`
- `SHOW ERRORS [LIMIT [offset,] row_count]`
- `SHOW EVENTS`
SHOW FUNCTION CODE `func_name`
SHOW FUNCTION STATUS [like_or_where]
SHOW GRANTS FOR user
SHOW (MASTER | BINARY LOG) STATUS
SHOW OPEN TABLES [FROM db_name] [like_or_where]
SHOW PLUGINS
SHOW PROCEDURE CODE proc_name
SHOW PROCEDURE STATUS [like_or_where]
SHOW PRIVILEGES
SHOW [FULL] PROCESSLIST
SHOW PROFILE [types] [FOR QUERY n] [OFFSET n] [LIMIT n]
SHOW PROFILES
SHOW RELAYLOG EVENTS [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
SHOW (REPLICAS | SLAVE HOSTS)
SHOW (REPLICA | SLAVE) STATUS [FOR CHANNEL channel]
SHOW [GLOBAL | SESSION] STATUS [like_or_where]
SHOW TABLE STATUS [FROM db_name] [like_or_where]
SHOW TRIGGERS [FROM db_name] [like_or_where]
SHOW [GLOBAL | SESSION] VARIABLES [like_or_where]
SHOW WARNINGS [LIMIT [offset,] row_count]

like_or_where: {
  LIKE 'pattern'
  | WHERE expr
}

If the syntax for a given SHOW statement includes a LIKE 'pattern' part, 'pattern' is a string that can contain the SQL % and _ wildcard characters. The pattern is useful for restricting statement output to matching values.

Several SHOW statements also accept a WHERE clause that provides more flexibility in specifying which rows to display. See Section 26.8, "Extensions to SHOW Statements".

In SHOW statement results, user names and host names are quoted using backticks (`).

Many MySQL APIs (such as PHP) enable you to treat the result returned from a SHOW statement as you would a result set from a SELECT; see Chapter 29, Connectors and APIs, or your API documentation for more information. In addition, you can work in SQL with results from queries on tables in the INFORMATION_SCHEMA database, which you cannot easily do with results from SHOW statements. See Chapter 26, INFORMATION_SCHEMA Tables.

13.7.7.1 SHOW BINARY LOGS Statement

SHOW BINARY LOGS
SHOW MASTER LOGS

Lists the binary log files on the server. This statement is used as part of the procedure described in Section 13.4.1.1, "PURGE BINARY LOGS Statement", that shows how to determine which logs can be purged. SHOW BINARY LOGS requires the REPLICATION CLIENT privilege (or the deprecated SUPER privilege).

Encrypted binary log files have a 512-byte file header that stores information required for encryption and decryption of the file. This is included in the file size displayed by SHOW BINARY LOGS. The Encrypted column shows whether or not the binary log file is encrypted. Binary log encryption is active if binlog_encryption=ON is set for the server. Existing binary log files are not encrypted or decrypted if binary log encryption is activated or deactivated while the server is running.

mysql> SHOW BINARY LOGS;
+---------------+-----------+-----------+
| Log_name      | File_size | Encrypted |
+---------------+-----------+-----------+
SHOW Statements

+---------------+-----------+-----------+
| binlog.000015 | 724935    | Yes       |
| binlog.000016 | 733481    | Yes       |
+---------------+-----------+-----------+

SHOW MASTER LOGS is equivalent to SHOW BINARY LOGS.

13.7.7.2 SHOW BINARY LOG STATUS Statement

SHOW BINARY LOG STATUS

This statement is added in MySQL 8.2.0 as a replacement for SHOW MASTER STATUS, which is now deprecated. It provides status information about the binary log files of the source server, and requires the REPLICATION CLIENT privilege (or the deprecated SUPER privilege).

Example:

```
mysql> SHOW BINARY LOG STATUS\G
*************************** 1. row ***************************
File: source-bin.000002
Position: 1307
Binlog_Do_DB: test
Binlog_Ignore_DB: manual, mysql
Executed_Gtid_Set: 3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5
1 row in set (0.00 sec)
```

When global transaction IDs are in use, Executed_Gtid_Set shows the set of GTIDs for transactions that have been executed on the source. This is the same as the value for the gtid_executed system variable on this server, as well as the value for Executed_Gtid_Set in the output of SHOW REPLICA STATUS on this server.

13.7.7.3 SHOW BINLOG EVENTS Statement

SHOW BINLOG EVENTS
```
[IN 'log_name']
[FROM pos]
[LIMIT [offset,,] row_count]
```

Shows the events in the binary log. If you do not specify 'log_name', the first binary log is displayed. SHOW BINLOG EVENTS requires the REPLICATION SLAVE privilege.

The LIMIT clause has the same syntax as for the SELECT statement. See Section 13.2.13, “SELECT Statement”.

Note

Issuing a SHOW BINLOG EVENTS with no LIMIT clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the binary log (which includes all statements executed by the server that modify data). As an alternative to SHOW BINLOG EVENTS, use the mysqlbinlog utility to save the binary log to a text file for later examination and analysis. See Section 4.6.9, "mysqlbinlog — Utility for Processing Binary Log Files".

SHOW BINLOG EVENTS displays the following fields for each event in the binary log:

- **Log_name**
  
  The name of the file that is being listed.

- **Pos**
SHOW Statements

The position at which the event occurs.

• **Event_type**
  
  An identifier that describes the event type.

• **Server_id**
  
  The server ID of the server on which the event originated.

• **End_log_pos**
  
  The position at which the next event begins, which is equal to Pos plus the size of the event.

• **Info**
  
  More detailed information about the event type. The format of this information depends on the event type.

For compressed transaction payloads, the `Transaction_payload_event` is first printed as a single unit, then it is unpacked and each event inside it is printed.

Some events relating to the setting of user and system variables are not included in the output from `SHOW BINLOG EVENTS`. To get complete coverage of events within a binary log, use `mysqlbinlog`.

`SHOW BINLOG EVENTS` does not work with relay log files. You can use `SHOW RELAYLOG EVENTS` for this purpose.

### 13.7.7.4 SHOW CHARACTER SET Statement

```
SHOW {CHARACTER SET | CHARSET} [LIKE 'pattern' | WHERE expr]
```

The `SHOW CHARACTER SET` statement shows all available character sets. The `LIKE` clause, if present, indicates which character set names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 26.8, “Extensions to SHOW Statements”. For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin%';
+---------+-----------------------------+-------------------+--------+
| Charset | Description                 | Default collation | Maxlen |
|---------+-----------------------------+-------------------+--------+
| latin1  | cp1252 West European        | latin1_swedish_ci |      1 |
| latin2  | ISO 8859-2 Central European | latin2_general_ci |      1 |
| latin5  | ISO 8859-9 Turkish          | latin5_turkish_ci |      1 |
| latin7  | ISO 8859-13 Baltic          | latin7_general_ci |      1 |
```

`SHOW CHARACTER SET` output has these columns:

• **Charset**
  
  The character set name.

• **Description**
  
  A description of the character set.

• **Default collation**
  
  The default collation for the character set.
SHOW Statements

- **Maxlen**
  The maximum number of bytes required to store one character.

The `filename` character set is for internal use only; consequently, `SHOW CHARACTER SET` does not display it.

Character set information is also available from the `INFORMATION_SCHEMA CHARACTER_SETS` table.

### 13.7.7.5 SHOW COLLATION Statement

```sql
SHOW COLLATION [LIKE 'pattern' | WHERE expr]
```

This statement lists collations supported by the server. By default, the output from `SHOW COLLATION` includes all available collations. The `LIKE` clause, if present, indicates which collation names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 26.8, “Extensions to SHOW Statements”. For example:

```
mysql> SHOW COLLATION WHERE Charset = 'latin1';
```

<table>
<thead>
<tr>
<th>Collation</th>
<th>Charset</th>
<th>Id</th>
<th>Default</th>
<th>Compiled</th>
<th>Sortlen</th>
</tr>
</thead>
<tbody>
<tr>
<td>latin1_german1_ci</td>
<td>latin1</td>
<td>5</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_swedish_ci</td>
<td>latin1</td>
<td>8</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_danish_ci</td>
<td>latin1</td>
<td>15</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_german2_ci</td>
<td>latin1</td>
<td>31</td>
<td></td>
<td>Yes</td>
<td>2</td>
</tr>
<tr>
<td>latin1_bin</td>
<td>latin1</td>
<td>47</td>
<td></td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_general_ci</td>
<td>latin1</td>
<td>48</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_general_cs</td>
<td>latin1</td>
<td>49</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_spanish_ci</td>
<td>latin1</td>
<td>94</td>
<td></td>
<td>Yes</td>
<td>1</td>
</tr>
</tbody>
</table>
```

`SHOW COLLATION` output has these columns:

- **Collation**
  The collation name.

- **Charset**
  The name of the character set with which the collation is associated.

- **Id**
  The collation ID.

- **Default**
  Whether the collation is the default for its character set.

- **Compiled**
  Whether the character set is compiled into the server.

- **Sortlen**
  This is related to the amount of memory required to sort strings expressed in the character set.

To see the default collation for each character set, use the following statement. `Default` is a reserved word, so to use it as an identifier, it must be quoted as such:
Collation information is also available from the INFORMATION_SCHEMA COLLATIONS table. See Section 26.3.6, “The INFORMATION_SCHEMA COLLATIONS Table”.

### 13.7.7.6 SHOW COLUMNS Statement

SHOW [EXTENDED] [FULL] {COLUMNS | FIELDS}

[(FROM | IN) tbl_name]

[{{FROM | IN} db_name]}

[LIKE 'pattern' | WHERE expr]

SHOW COLUMNS displays information about the columns in a given table. It also works for views. SHOW COLUMNS displays information only for those columns for which you have some privilege.

An alternative to `tbl_name FROM db_name` syntax is `db_name.tbl_name`. These two statements are equivalent:

SHOW COLUMNS FROM mytable FROM mydb;
SHOW COLUMNS FROM mydb.mytable;

The optional `EXTENDED` keyword causes the output to include information about hidden columns that MySQL uses internally and are not accessible by users.

The optional `FULL` keyword causes the output to include the column collation and comments, as well as the privileges you have for each column.

The `LIKE` clause, if present, indicates which column names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 26.8, “Extensions to SHOW Statements”.

The data types may differ from what you expect them to be based on a `CREATE TABLE` statement because MySQL sometimes changes data types when you create or alter a table. The conditions under which this occurs are described in Section 13.1.20.7, “Silent Column Specification Changes”.

SHOW COLUMNS displays the following values for each table column:

- **Field**
  - The name of the column.
SHOW Statements

• **Type**
  The column data type.

• **Collation**
  The collation for nonbinary string columns, or **NULL** for other columns. This value is displayed only if you use the **FULL** keyword.

• **Null**
  The column nullability. The value is **YES** if **NULL** values can be stored in the column, **NO** if not.

• **Key**
  Whether the column is indexed:
  • If **Key** is empty, the column either is not indexed or is indexed only as a secondary column in a multiple-column, nonunique index.
  • If **Key** is **PRI**, the column is a **PRIMARY KEY** or is one of the columns in a multiple-column **PRIMARY KEY**.
