
- A keyring service interface for keyring key management. This service is accessible at two levels:

  - SQL interface: In SQL statements, call the functions described in Section 6.4.4.15, “General-Purpose Keyring Key-Management Functions”.

  - C interface: In C-language code, call the keyring service functions described in Section 5.6.9.2, “The Keyring Service”.

- Key metadata access:

  - The Performance Schema **keyring_keys** table exposes metadata for keys in the keyring. Key metadata includes key IDs, key owners, and backend key IDs. The **keyring_keys** table does not
expose any sensitive keyring data such as key contents. See Section 27.12.18.2, “The keyring_keys table”.

- The Performance Schema keyring_component_status table provides status information about the keyring component in use, if one is installed. See Section 27.12.18.1, “The keyring_component_status Table”.

- A key migration capability. MySQL supports migration of keys between keystores, enabling DBAs to switch a MySQL installation from one keystore to another. See Section 6.4.4.14, “Migrating Keys Between Keyring Keystores”.

- The implementation of keyring plugins is revised to use the component infrastructure. This is facilitated using the built-in plugin named daemon_keyring_proxy_plugin that acts as a bridge between the plugin and component service APIs. See Section 5.6.8, “The Keyring Proxy Bridge Plugin”.

Warning

For encryption key management, the component_keyring_file and component_keyring_encrypted_file components, and the keyring_file and keyring_encrypted_file plugins are not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).

Within MySQL, keyring service consumers include:

- The InnoDB storage engine uses the keyring to store its key for tablespace encryption. See Section 15.13, “InnoDB Data-at-Rest Encryption”.

- MySQL Enterprise Audit uses the keyring to store the audit log file encryption password. See Encrypting Audit Log Files.

- Binary log and relay log management supports keyring-based encryption of log files. With log file encryption activated, the keyring stores the keys used to encrypt passwords for the binary log files and relay log files. See Section 17.3.2, “Encrypting Binary Log Files and Relay Log Files”.

- The master key to decrypt the file key that decrypts the persisted values of sensitive system variables is stored in the keyring. A keyring component must be enabled on the MySQL Server instance to support secure storage for persisted system variable values, rather than a keyring plugin, which do not support the function. See Persisting Sensitive System Variables.

For general keyring installation instructions, see Section 6.4.4.2, “Keyring Component Installation”, and Section 6.4.4.3, “Keyring Plugin Installation”. For installation and configuration information specific to a given keyring component or plugin, see the section describing it.

For information about using the keyring functions, see Section 6.4.4.15, “General-Purpose Keyring Key-Management Functions”.

Keyring components, plugins, and functions access a keyring service that provides the interface to the keyring. For information about accessing this service and writing keyring plugins, see Section 5.6.9.2, “The Keyring Service”, and Writing Keyring Plugins.

6.4.4.1 Keyring Components Versus Keyring Plugins

The MySQL Keyring originally implemented keystore capabilities using server plugins, but began transitioning to use the component infrastructure. This section briefly compares keyring components and
plugins to provide an overview of their differences. It may assist you in making the transition from plugins to components, or, if you are just beginning to use the keyring, assist you in choosing whether to use a component versus using a plugin.

- Keyring plugin loading uses the `--early-plugin-load` option. Keyring component loading uses a manifest.
- Keyring plugin configuration is based on plugin-specific system variables. For keyring components, no system variables are used. Instead, each component has its own configuration file.
- Keyring components have fewer restrictions than keyring plugins with respect to key types and lengths. See Section 6.4.4.13, “Supported Keyring Key Types and Lengths”.

Note

(component_keyring_oci (like the keyring_oci plugin) can only generate keys of type AES with a size of 16, 24, or 32 bytes.

- Keyring components support secure storage for persisted system variable values, whereas keyring plugins do not support the function.

A keyring component must be enabled on the MySQL server instance to support secure storage for persisted system variable values. The sensitive data that can be protected in this way includes items such as private keys and passwords that appear in the values of system variables. In the operating system file where persisted system variables are stored, the names and values of sensitive system variables are stored in an encrypted format, along with a generated file key to decrypt them. The generated file key is in turn encrypted using a master key that is stored in a keyring. See Persisting Sensitive System Variables.

6.4.4.2 Keyring Component Installation

Keyring service consumers require that a keyring component or plugin be installed:

- To use a keyring component, begin with the instructions here.
- To use a keyring plugin instead, begin with Section 6.4.4.3, “Keyring Plugin Installation”.
- If you intend to use keyring functions in conjunction with the chosen keyring component or plugin, install the functions after installing that component or plugin, using the instructions in Section 6.4.4.15, “General-Purpose Keyring Key-Management Functions”.

Note

Only one keyring component or plugin should be enabled at a time. Enabling multiple keyring components or plugins is unsupported and results may not be as anticipated.

MySQL provides these keyring component choices:

To be usable by the server, the component library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

A keyring component or plugin must be loaded early during the server startup sequence so that other components can access it as necessary during their own initialization. For example, the InnoDB storage engine uses the keyring for tablespace encryption, so a keyring component or plugin must be loaded and available prior to InnoDB initialization.

**Note**

A keyring component must be enabled on the MySQL server instance if you need to support secure storage for persisted system variable values. The keyring plugin does not support the function. See Persisting Sensitive System Variables.

Unlike keyring plugins, keyring components are not loaded using the `--early-plugin-load` server option or configured using system variables. Instead, the server determines which keyring component to load during startup using a manifest, and the loaded component consults its own configuration file when it initializes. Therefore, to install a keyring component, you must:

1. Write a manifest that tells the server which keyring component to load.
2. Write a configuration file for that keyring component.

The first step in installing a keyring component is writing a manifest that indicates which component to load. During startup, the server reads either a global manifest file, or a global manifest file paired with a local manifest file:

- The server attempts to read its global manifest file from the directory where the server is installed.
- If the global manifest file indicates use of a local manifest file, the server attempts to read its local manifest file from the data directory.
- Although global and local manifest files are located in different directories, the file name is `mysqld.my` in both locations.
- It is not an error for a manifest file not to exist. In this case, the server attempts no component loading associated with the file.

Local manifest files permit setting up component loading for multiple instances of the server, such that loading instructions for each server instance are specific to a given data directory instance. This enables different MySQL instances to use different keyring components.

Server manifest files have these properties:

- A manifest file must be in valid JSON format.
- A manifest file permits these items:
  - "read_local_manifest": This item is permitted only in the global manifest file. If the item is not present, the server uses only the global manifest file. If the item is present, its value is `true` or `false`, indicating whether the server should read component-loading information from the local manifest file.

    If the "read_local_manifest" item is present in the global manifest file along with other items, the server checks the "read_local_manifest" item value first:
    - If the value is `false`, the server processes the other items in the global manifest file and ignores the local manifest file.
• If the value is `true`, the server ignores the other items in the global manifest file and attempts to read the local manifest file.

• "components": This item indicates which component to load. The item value is a string that specifies a valid component URN, such as "file://component_keyring_file". A component URN begins with `file://` and indicates the base name of the library file located in the MySQL plugin directory that implements the component.

• Server access to a manifest file should be read only. For example, a `mysqld.my` server manifest file may be owned by `root` and be read/write to `root`, but should be read only to the account used to run the MySQL server. If the manifest file is found during startup to be read/write to that account, the server writes a warning to the error log suggesting that the file be made read only.

• The database administrator has the responsibility for creating any manifest files to be used, and for ensuring that their access mode and contents are correct. If an error occurs, server startup fails and the administrator must correct any issues indicated by diagnostics in the server error log.

Given the preceding manifest file properties, to configure the server to load `component_keyring_file`, create a global manifest file named `mysqld.my` in the `mysqld` installation directory, and optionally create a local manifest file, also named `mysqld.my`, in the data directory. The following instructions describe how to load `component_keyring_file`. To load a different keyring component, substitute its name for `component_keyring_file`.

• To use a global manifest file only, the file contents look like this:

```
{ "components": "file://component_keyring_file" }
```

Create this file in the directory where `mysqld` is installed.

• Alternatively, to use a global and local manifest file pair, the global file looks like this:

```
{ "read_local_manifest": true }
```

Create this file in the directory where `mysqld` is installed.

The local file looks like this:

```
{ "components": "file://component_keyring_file" }
```

Create this file in the data directory.

With the manifest in place, proceed to configuring the keyring component. To do this, check the notes for your chosen keyring component for configuration instructions specific to that component:

• `component_keyring_file`: Section 6.4.4.4, "Using the component_keyring_file File-Based Keyring Component".

• `component_keyring_encrypted_file`: Section 6.4.4.5, "Using the component_keyring_encrypted_file Encrypted File-Based Keyring Component".

• `component_keyring_oci`: Section 6.4.4.11, "Using the Oracle Cloud Infrastructure Vault Keyring Component".
After performing any component-specific configuration, start the server. Verify component installation by examining the Performance Schema `keyring_component_status` table:

```
mysql> SELECT * FROM performance_schema.keyring_component_status;
+---------------------+-------------------------------------------------+
| STATUS_KEY          | STATUS_VALUE                                    |
| Component_name      | component_keyring_file                          |
| Author              | Oracle Corporation                              |
| License             | GPL                                             |
| Implementation_name | component_keyring_file                          |
| Version             | 1.0                                             |
| Component_status    | Active                                          |
| Data_file           | /usr/local/mysql/keyring/component_keyring_file |
| Read_only           | No                                              |
+---------------------+-------------------------------------------------+
```

A `Component_status` value of `Active` indicates that the component initialized successfully.

If the component cannot be loaded, server startup fails. Check the server error log for diagnostic messages. If the component loads but fails to initialize due to configuration problems, the server starts but the `Component_status` value is `Disabled`. Check the server error log, correct the configuration issues, and use the `ALTER INSTANCE RELOAD KEYRING` statement to reload the configuration.

Keyring components should be loaded only by using a manifest file, not by using the `INSTALL COMPONENT` statement. Keyring components loaded using that statement may be available too late in the server startup sequence for certain components that use the keyring, such as InnoDB, because they are registered in the `mysql.component` system table and loaded automatically for subsequent server restarts. But `mysql.component` is an InnoDB table, so any components named in it can be loaded during startup only after InnoDB initialization.

If no keyring component or plugin is available when a component tries to access the keyring service, the service cannot be used by that component. As a result, the component may fail to initialize or may initialize with limited functionality. For example, if InnoDB finds that there are encrypted tablespaces when it initializes, it attempts to access the keyring. If the keyring is unavailable, InnoDB can access only unencrypted tablespaces.

### 6.4.4.3 Keyring Plugin Installation

Keyring service consumers require that a keyring component or plugin be installed:

- To use a keyring plugin, begin with the instructions here. (Also, for general information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.)

- To use a keyring component instead, begin with Section 6.4.4.2, “Keyring Component Installation”.

- If you intend to use keyring functions in conjunction with the chosen keyring component or plugin, install the functions after installing that component or plugin, using the instructions in Section 6.4.4.15, “General-Purpose Keyring Key-Management Functions”.

**Note**

Only one keyring component or plugin should be enabled at a time. Enabling multiple keyring components or plugins is unsupported and results may not be as anticipated.

A keyring component must be enabled on the MySQL Server instance if you need to support secure storage for persisted system variable values, rather than a keyring plugin, which do not support the function. See Persisting Sensitive System Variables.
MySQL provides these keyring plugin choices:

- **keyring_file** (deprecated): Stores keyring data in a file local to the server host. Available in MySQL Community Edition and MySQL Enterprise Edition distributions. For instructions about installing the component that replaces this plugin, see Section 6.4.4.2, “Keyring Component Installation”.

- **keyring_encrypted_file** (deprecated): Stores keyring data in an encrypted, password-protected file local to the server host. Available in MySQL Enterprise Edition distributions. For instructions about installing the component that replaces this plugin, see Section 6.4.4.2, “Keyring Component Installation”.

- **keyring_okv**: A KMIP 1.1 plugin for use with KMIP-compatible back end keyring storage products such as Oracle Key Vault and Gemalto SafeNet KeySecure Appliance. Available in MySQL Enterprise Edition distributions.

- **keyring_aws**: Communicates with the Amazon Web Services Key Management Service as a back end for key generation and uses a local file for key storage. Available in MySQL Enterprise Edition distributions.

- **keyring_hashicorp**: Communicates with HashiCorp Vault for back end storage. Available in MySQL Enterprise Edition distributions.

- **keyring_oci** (deprecated): Communicates with Oracle Cloud Infrastructure Vault for back end storage. See Section 6.4.4.12, “Using the Oracle Cloud Infrastructure Vault Keyring Plugin”.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

A keyring component or plugin must be loaded early during the server startup sequence so that other components can access it as necessary during their own initialization. For example, the InnoDB storage engine uses the keyring for tablespace encryption, so a keyring component or plugin must be loaded and available prior to InnoDB initialization.

Installation for each keyring plugin is similar. The following instructions describe how to install keyring_file. To use a different keyring plugin, substitute its name for keyring_file.

The keyring_file plugin library file base name is keyring_file. The file name suffix differs per platform (for example, .so for Unix and Unix-like systems, .dll for Windows).

To load the plugin, use the `--early-plugin-load` option to name the plugin library file that contains it. For example, on platforms where the plugin library file suffix is .so, use these lines in the server `my.cnf` file, adjusting the .so suffix for your platform as necessary:

```plaintext
[mysqld]
early-plugin-load=keyring_file.so
```

Before starting the server, check the notes for your chosen keyring plugin for configuration instructions specific to that plugin:

- **keyring_file**: Section 6.4.4.6, “Using the keyring_file File-Based Keyring Plugin”.

- **keyring_encrypted_file**: Section 6.4.4.7, “Using the keyring_encrypted_file Encrypted File-Based Keyring Plugin”.

- **keyring_okv**: Section 6.4.4.8, “Using the keyring_okv KMIP Plugin”.

- **keyring_aws**: Section 6.4.4.9, “Using the keyring_aws Amazon Web Services Keyring Plugin”

- **keyring_hashicorp**: Section 6.4.4.10, “Using the HashiCorp Vault Keyring Plugin”
The MySQL Keyring

- **keyring oci**: Section 6.4.4.12, “Using the Oracle Cloud Infrastructure Vault Keyring Plugin”

After performing any plugin-specific configuration, start the server. Verify plugin installation by examining the Information Schema **PLUGINS** table or use the **SHOW PLUGINS** statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE 'keyring%';
+--------------+---------------+
| PLUGIN_NAME  | PLUGIN_STATUS |
|--------------|---------------+
| keyring_file | ACTIVE        |
+--------------+---------------+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

Plugins can be loaded by methods other than **--early-plugin-load**, such as the **--plugin-load** or **--plugin-load-add** option or the **INSTALL PLUGIN** statement. However, keyring plugins loaded using those methods may be available too late in the server startup sequence for certain components that use the keyring, such as **InnoDB**:

- Plugin loading using **--plugin-load** or **--plugin-load-add** occurs after **InnoDB** initialization.
- Plugins installed using **INSTALL PLUGIN** are registered in the **mysql.plugin** system table and loaded automatically for subsequent server restarts. However, because **mysql.plugin** is an **InnoDB** table, any plugins named in it can be loaded during startup only after **InnoDB** initialization.

If no keyring component or plugin is available when a component tries to access the keyring service, the service cannot be used by that component. As a result, the component may fail to initialize or may initialize with limited functionality. For example, if **InnoDB** finds that there are encrypted tablespaces when it initializes, it attempts to access the keyring. If the keyring is unavailable, **InnoDB** can access only unencrypted tablespaces. To ensure that **InnoDB** can access encrypted tablespaces as well, use **--early-plugin-load** to load the keyring plugin.

### 6.4.4.4 Using the component_keyring_file File-Based Keyring Component

The **component_keyring_file** keyring component stores keyring data in a file local to the server host.

**Warning**

For encryption key management, the **component_keyring_file** and **component_keyring_encrypted_file** components, and the **keyring_file** and **keyring_encrypted_file** plugins are not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).

To use **component_keyring_file** for keystore management, you must:

1. Write a manifest that tells the server to load **component_keyring_file**, as described in Section 6.4.4.2, “Keyring Component Installation”.

2. Write a configuration file for **component_keyring_file**, as described here.

When it initializes, **component_keyring_file** reads either a global configuration file, or a global configuration file paired with a local configuration file:

- The component attempts to read its global configuration file from the directory where the component library file is installed (that is, the server plugin directory).
The MySQL Keyring

- If the global configuration file indicates use of a local configuration file, the component attempts to read its local configuration file from the data directory.

- Although global and local configuration files are located in different directories, the file name is `component_keyring_file.cnf` in both locations.

- It is an error for no configuration file to exist. `component_keyring_file` cannot initialize without a valid configuration.

Local configuration files permit setting up multiple server instances to use `component_keyring_file`, such that component configuration for each server instance is specific to a given data directory instance. This enables the same keyring component to be used with a distinct data file for each instance.

`component_keyring_file` configuration files have these properties:

- A configuration file must be in valid JSON format.

- A configuration file permits these configuration items:
  
  - "read_local_config": This item is permitted only in the global configuration file. If the item is not present, the component uses only the global configuration file. If the item is present, its value is `true` or `false`, indicating whether the component should read configuration information from the local configuration file.

    If the "read_local_config" item is present in the global configuration file along with other items, the component checks the "read_local_config" item value first:

    - If the value is `false`, the component processes the other items in the global configuration file and ignores the local configuration file.

    - If the value is `true`, the component ignores the other items in the global configuration file and attempts to read the local configuration file.

  - "path": The item value is a string that names the file to use for storing keyring data. The file should be named using an absolute path, not a relative path. This item is mandatory in the configuration. If not specified, `component_keyring_file` initialization fails.

  - "read_only": The item value indicates whether the keyring data file is read only. The item value is `true` (read only) or `false` (read/write). This item is mandatory in the configuration. If not specified, `component_keyring_file` initialization fails.

- The database administrator has the responsibility for creating any configuration files to be used, and for ensuring that their contents are correct. If an error occurs, server startup fails and the administrator must correct any issues indicated by diagnostics in the server error log.

Given the preceding configuration file properties, to configure `component_keyring_file`, create a global configuration file named `component_keyring_file.cnf` in the directory where the `component_keyring_file` library file is installed, and optionally create a local configuration file, also named `component_keyring_file.cnf`, in the data directory. The following instructions assume that a keyring data file named `/usr/local/mysql/keyring/component_keyring_file` is to be used in read/write fashion.

- To use a global configuration file only, the file contents look like this:

```json
{
  "path": "/usr/local/mysql/keyring/component_keyring_file",
  "read_only": false
}
```
Create this file in the directory where the `component_keyring_file` library file is installed.

- Alternatively, to use a global and local configuration file pair, the global file looks like this:

```json
{
    "read_local_config": true
}
```

Create this file in the directory where the `component_keyring_file` library file is installed.

The local file looks like this:

```json
{
    "path": "/usr/local/mysql/keyring/component_keyring_file",
    "read_only": false
}
```

Create this file in the data directory.

Keyring operations are transactional: `component_keyring_file` uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has the same name as the data file with a suffix of `.backup`.

`component_keyring_file` supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by those functions are accessible at two levels:

- SQL interface: In SQL statements, call the functions described in Section 6.4.4.15, “General-Purpose Keyring Key-Management Functions”.
- C interface: In C-language code, call the keyring service functions described in Section 5.6.9.2, “The Keyring Service”.

Example (using the SQL interface):

```sql
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

For information about the characteristics of key values permitted by `component_keyring_file`, see Section 6.4.13, “Supported Keyring Key Types and Lengths”.

### 6.4.4.5 Using the `component_keyring_encrypted_file` Encrypted File-Based Keyring Component

**Note**

`component_keyring_encrypted_file` is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see [https://www.mysql.com/products/](https://www.mysql.com/products/).

The `component_keyring_encrypted_file` keyring component stores keyring data in an encrypted, password-protected file local to the server host.

**Warning**

For encryption key management, the `component_keyring_file` and `component_keyring_encrypted_file` components, and the `keyring_file` and `keyring_encrypted_file` plugins are not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use
The MySQL Keyring

of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).

To use `component_keyring_encrypted_file` for keystore management, you must:

1. Write a manifest that tells the server to load `component_keyring_encrypted_file`, as described in Section 6.4.4.2, "Keyring Component Installation".

2. Write a configuration file for `component_keyring_encrypted_file`, as described here.

When it initializes, `component_keyring_encrypted_file` reads either a global configuration file, or a global configuration file paired with a local configuration file:

• The component attempts to read its global configuration file from the directory where the component library file is installed (that is, the server plugin directory).

• If the global configuration file indicates use of a local configuration file, the component attempts to read its local configuration file from the data directory.

• Although global and local configuration files are located in different directories, the file name is `component_keyring_encrypted_file.cnf` in both locations.

• It is an error for no Preconfiguration file to exist. `component_keyring_encrypted_file` cannot initialize without a valid configuration.

Local configuration files permit setting up multiple server instances to use `component_keyring_encrypted_file`, such that component configuration for each server instance is specific to a given data directory instance. This enables the same keyring component to be used with a distinct data file for each instance.

`component_keyring_encrypted_file` configuration files have these properties:

• A configuration file must be in valid JSON format.

• A configuration file permits these configuration items:

  • "read_local_config": This item is permitted only in the global configuration file. If the item is not present, the component uses only the global configuration file. If the item is present, its value is `true` or `false`, indicating whether the component should read configuration information from the local configuration file.

  If the "read_local_config" item is present in the global configuration file along with other items, the component checks the "read_local_config" item value first:

  • If the value is `false`, the component processes the other items in the global configuration file and ignores the local configuration file.

  • If the value is `true`, the component ignores the other items in the global configuration file and attempts to read the local configuration file.

  • "path": The item value is a string that names the file to use for storing keyring data. The file should be named using an absolute path, not a relative path. This item is mandatory in the configuration. If not specified, `component_keyring_encrypted_file` initialization fails.

  • "password": The item value is a string that specifies the password for accessing the data file. This item is mandatory in the configuration. If not specified, `component_keyring_encrypted_file` initialization fails.
• "read_only": The item value indicates whether the keyring data file is read only. The item value is `true` (read only) or `false` (read/write). This item is mandatory in the configuration. If not specified, `component_keyring_encrypted_file` initialization fails.

• The database administrator has the responsibility for creating any configuration files to be used, and for ensuring that their contents are correct. If an error occurs, server startup fails and the administrator must correct any issues indicated by diagnostics in the server error log.

• Any configuration file that stores a password should have a restrictive mode and be accessible only to the account used to run the MySQL server.

Given the preceding configuration file properties, to configure `component_keyring_encrypted_file`, create a global configuration file named `component_keyring_encrypted_file.cnf` in the directory where the `component_keyring_encrypted_file` library file is installed, and optionally create a local configuration file, also named `component_keyring_encrypted_file.cnf`, in the data directory. The following instructions assume that a keyring data file named `/usr/local/mysql/keyring/component_keyring_encrypted_file` is to be used in read/write fashion. You must also choose a password.

• To use a global configuration file only, the file contents look like this:

```json
{
    "path": "/usr/local/mysql/keyring/component_keyring_encrypted_file",
    "password": "password",
    "read_only": false
}
```

Create this file in the directory where the `component_keyring_encrypted_file` library file is installed.

• Alternatively, to use a global and local configuration file pair, the global file looks like this:

```json
{
    "read_local_config": true
}
```

Create this file in the directory where the `component_keyring_encrypted_file` library file is installed.

The local file looks like this:

```json
{
    "path": "/usr/local/mysql/keyring/component_keyring_encrypted_file",
    "password": "password",
    "read_only": false
}
```

Create this file in the data directory.

Keyring operations are transactional: `component_keyring_encrypted_file` uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has the same name as the data file with a suffix of `.backup`.

`component_keyring_encrypted_file` supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by those functions are accessible at two levels:

• SQL interface: In SQL statements, call the functions described in Section 6.4.4.15, “General-Purpose Keyring Key-Management Functions”.
The MySQL Keyring

- C interface: In C-language code, call the keyring service functions described in Section 5.6.9.2, “The Keyring Service”.

Example (using the SQL interface):

```sql
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

For information about the characteristics of key values permitted by `component_keyring_encrypted_file`, see Section 6.4.4.13, “Supported Keyring Key Types and Lengths”.

### 6.4.4.6 Using the keyring_file File-Based Keyring Plugin

The `keyring_file` keyring plugin stores keyring data in a file local to the server host.

This plugin is deprecated and subject to removal in a future release of MySQL. Instead, consider using the `component_keyring_file` component for storing keyring data (see Section 6.4.4.4, “Using the component_keyring_file File-Based Keyring Component”).

**Warning**

For encryption key management, the `keyring_file` plugin is not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).

To install `keyring_file`, use the general instructions found in Section 6.4.4.3, “Keyring Plugin Installation”, together with the configuration information specific to `keyring_file` found here.

To be usable during the server startup process, `keyring_file` must be loaded using the `--early-plugin-load` option. The `keyring_file_data` system variable optionally configures the location of the file used by the `keyring_file` plugin for data storage. The default value is platform specific. To configure the file location explicitly, set the variable value at startup. For example, use these lines in the server `my.cnf` file, adjusting the `.so` suffix and file location for your platform as necessary:

```ini
[mysqld]
early-plugin-load=keyring_file.so
keyring_file_data=/usr/local/mysql/mysql-keyring/keyring
```

Keyring operations are transactional: The `keyring_file` plugin uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has the same name as the value of the `keyring_file_data` system variable with a suffix of `.backup`.

For additional information about `keyring_file_data`, see Section 6.4.4.19, “Keyring System Variables”.

To ensure that keys are flushed only when the correct keyring storage file exists, `keyring_file` stores a SHA-256 checksum of the keyring in the file. Before updating the file, the plugin verifies that it contains the expected checksum.

The `keyring_file` plugin supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by those functions are accessible at two levels:

- SQL interface: In SQL statements, call the functions described in Section 6.4.4.15, “General-Purpose Keyring Key-Management Functions”.
- C interface: In C-language code, call the keyring service functions described in Section 5.6.9.2, “The Keyring Service”.

Example (using the SQL interface):
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');

For information about the characteristics of key values permitted by keyring_file, see Section 6.4.4.13, “Supported Keyring Key Types and Lengths”.

6.4.4.7 Using the keyring_encrypted_file Encrypted File-Based Keyring Plugin

Note

The keyring_encrypted_file plugin is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see https://www.mysql.com/products/.

The keyring_encrypted_file keyring plugin stores keyring data in an encrypted, password-protected file local to the server host.

This plugin is deprecated and subject to removal in a future release of MySQL. Instead, consider using the component_keyring_encrypted_file component for storing keyring data (see Section 6.4.4.5, “Using the component_keyring_encrypted_file Encrypted File-Based Keyring Component”).

Warning

For encryption key management, the keyring_encrypted_file plugin is not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).

To install keyring_encrypted_file, use the general instructions found in Section 6.4.4.3, “Keyring Plugin Installation”, together with the configuration information specific to keyring_encrypted_file found here.

To be usable during the server startup process, keyring_encrypted_file must be loaded using the --early-plugin-load option. To specify the password for encrypting the keyring data file, set the keyring_encrypted_file_password system variable. (The password is mandatory; if not specified at server startup, keyring_encrypted_file initialization fails.) The keyring_encrypted_file_data system variable optionally configures the location of the file used by the keyring_encrypted_file plugin for data storage. The default value is platform specific. To configure the file location explicitly, set the variable value at startup. For example, use these lines in the server my.cnf file, adjusting the .so suffix and file location for your platform as necessary and substituting your chosen password:

```
[mysqld]
early-plugin-load=keyring_encrypted_file.so
keyring_encrypted_file_data=/usr/local/mysql/mysql-keyring/keyring-encrypted
keyring_encrypted_file_password=password
```

Because the my.cnf file stores a password when written as shown, it should have a restrictive mode and be accessible only to the account used to run the MySQL server.

Keyring operations are transactional: The keyring_encrypted_file plugin uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has the same name as the value of the keyring_encrypted_file_data system variable with a suffix of .backup.

For additional information about the system variables used to configure the keyring_encrypted_file plugin, see Section 6.4.4.19, “Keyring System Variables”.

To ensure that keys are flushed only when the correct keyring storage file exists, keyring_encrypted_file stores a SHA-256 checksum of the keyring in the file. Before updating the

The MySQL Keyring

file, the plugin verifies that it contains the expected checksum. In addition, \texttt{keyring\_encrypted\_file}
encrypts file contents using AES before writing the file, and decrypts file contents after reading the file.

The \texttt{keyring\_encrypted\_file} plugin supports the functions that comprise the standard MySQL
Keyring service interface. Keyring operations performed by those functions are accessible at two levels:

- SQL interface: In SQL statements, call the functions described in Section 6.4.4.15, “General-Purpose
  Keyring Key-Management Functions”.

- C interface: In C-language code, call the keyring service functions described in Section 5.6.9.2, “The
  Keyring Service”.

Example (using the SQL interface):

\begin{verbatim}
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
\end{verbatim}

For information about the characteristics of key values permitted by \texttt{keyring\_encrypted\_file}, see
Section 6.4.4.13, “Supported Keyring Key Types and Lengths”.

\section*{6.4.4.8 Using the keyring\_okv KMIP Plugin}

\begin{warning}

The \texttt{keyring\_okv} plugin is an extension included in MySQL Enterprise Edition,
a commercial product. To learn more about commercial products, see https://
www.mysql.com/products/.

\end{warning}

The Key Management Interoperability Protocol (KMIP) enables communication of cryptographic keys
between a key management server and its clients. The \texttt{keyring\_okv} keyring plugin uses the KMIP 1.1
protocol to communicate securely as a client of a KMIP back end. Keyring material is generated exclusively
by the back end, not by \texttt{keyring\_okv}. The plugin works with these KMIP-compatible products:

- Oracle Key Vault
- Gemalto SafeNet KeySecure Appliance
- Townsend Alliance Key Manager
- Entrust KeyControl

Each MySQL Server instance must be registered separately as a client for KMIP. If two or more MySQL
Server instances use the same set of credentials, they can interfere with each other’s functioning.

The \texttt{keyring\_okv} plugin supports the functions that comprise the standard MySQL Keyring service
interface. Keyring operations performed by those functions are accessible at two levels:

- SQL interface: In SQL statements, call the functions described in Section 6.4.4.15, “General-Purpose
  Keyring Key-Management Functions”.

- C interface: In C-language code, call the keyring service functions described in Section 5.6.9.2, “The
  Keyring Service”.

Example (using the SQL interface):

\begin{verbatim}
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
\end{verbatim}

For information about the characteristics of key values permitted by \texttt{keyring\_okv}, Section 6.4.4.13,
“Supported Keyring Key Types and Lengths”.
To install `keyring_okv`, use the general instructions found in Section 6.4.4.3, “Keyring Plugin Installation”, together with the configuration information specific to `keyring_okv` found here.

- General `keyring_okv` Configuration
- Configuring `keyring_okv` for Oracle Key Vault
- Configuring `keyring_okv` for Gemalto SafeNet KeySecure Appliance
- Configuring `keyring_okv` for Townsend Alliance Key Manager
- Configuring `keyring_okv` for Entrust KeyControl
- Password-Protecting the `keyring_okv` Key File

**General `keyring_okv` Configuration**

Regardless of which KMIP back end the `keyring_okv` plugin uses for keyring storage, the `keyring_okv_conf_dir` system variable configures the location of the directory used by `keyring_okv` for its support files. The default value is empty, so you must set the variable to name a properly configured directory before the plugin can communicate with the KMIP back end. Unless you do so, `keyring_okv` writes a message to the error log during server startup that it cannot communicate:

```plaintext
[Warning] Plugin keyring_okv reported: 'For keyring_okv to be initialized, please point the keyring_okv_conf_dir variable to a directory containing Oracle Key Vault configuration file and ssl materials'
```

The `keyring_okv_conf_dir` variable must name a directory that contains the following items:

- `okvclient.ora`: A file that contains details of the KMIP back end with which `keyring_okv` communicates.
- `ssl`: A directory that contains the certificate and key files required to establish a secure connection with the KMIP back end: `CA.pem`, `cert.pem`, and `key.pem`. If the key file is password-protected, the `ssl` directory can contain a single-line text file named `password.txt` containing the password needed to decrypt the key file.

Both the `okvclient.ora` file and `ssl` directory with the certificate and key files are required for `keyring_okv` to work properly. The procedure used to populate the configuration directory with these files depends on the KMIP back end used with `keyring_okv`, as described elsewhere.

The configuration directory used by `keyring_okv` as the location for its support files should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use the `/usr/local/mysql/mysql-keyring-okv` directory, the following commands (executed as root) create the directory and set its mode and ownership:

```bash
cd /usr/local/mysql
mkdir mysql-keyring-okv
chown mysql mysql-keyring-okv
chgrp mysql mysql-keyring-okv
```

To be usable during the server startup process, `keyring_okv` must be loaded using the `--early-plugin-load` option. Also, set the `keyring_okv_conf_dir` system variable to tell `keyring_okv` where to find its configuration directory. For example, use these lines in the server `my.cnf` file, adjusting the `.so` suffix and directory location for your platform as necessary:

```plaintext
[mysqld]
early-plugin-load=keyring_okv.so
keyring_okv_conf_dir=/usr/local/mysql/mysql-keyring-okv
```
For additional information about `keyring_okv_conf_dir`, see Section 6.4.19, “Keyring System Variables”.

Configuring `keyring_okv` for Oracle Key Vault

The discussion here assumes that you are familiar with Oracle Key Vault. Some pertinent information sources:

- Oracle Key Vault site
- Oracle Key Vault documentation

In Oracle Key Vault terminology, clients that use Oracle Key Vault to store and retrieve security objects are called endpoints. To communicate with Oracle Key Vault, it is necessary to register as an endpoint and enroll by downloading and installing endpoint support files. Note that you must register a separate endpoint for each MySQL Server instance. If two or more MySQL Server instances use the same endpoint, they can interfere with each other’s functioning.

The following procedure briefly summarizes the process of setting up `keyring_okv` for use with Oracle Key Vault:

1. Create the configuration directory for the `keyring_okv` plugin to use.
2. Register an endpoint with Oracle Key Vault to obtain an enrollment token.
3. Use the enrollment token to obtain the `okvclient.jar` client software download.
4. Install the client software to populate the `keyring_okv` configuration directory that contains the Oracle Key Vault support files.

Use the following procedure to configure `keyring_okv` and Oracle Key Vault to work together. This description only summarizes how to interact with Oracle Key Vault. For details, visit the Oracle Key Vault site and consult the Oracle Key Vault Administrator's Guide.

1. Create the configuration directory that contains the Oracle Key Vault support files, and make sure that the `keyring_okv_conf_dir` system variable is set to name that directory (for details, see General `keyring_okv` Configuration).
2. Log in to the Oracle Key Vault management console as a user who has the System Administrator role.
4. Provide the required endpoint information and click Register. The endpoint type should be Other. Successful registration results in an enrollment token.
5. Log out from the Oracle Key Vault server.
6. Connect again to the Oracle Key Vault server, this time without logging in. Use the endpoint enrollment token to enroll and request the `okvclient.jar` software download. Save this file to your system.
7. Install the `okvclient.jar` file using the following command (you must have JDK 1.4 or higher):

   ```
   java -jar okvclient.jar -d dir_name [-v]
   ```

   The directory name following the `-d` option is the location in which to install extracted files. The `-v` option, if given, causes log information to be produced that may be useful if the command fails.

   When the command asks for an Oracle Key Vault endpoint password, do not provide one. Instead, press Enter. (The result is that no password is required when the endpoint connects to Oracle Key Vault.)
The MySQL Keyring

The preceding command produces an `okvclient.ora` file, which should be in this location under the directory named by the `-d` option in the preceding `java -jar` command:

```
install_dir/conf/okvclient.ora
```

The expected file contents include lines that look like this:

```
SERVER=host_ip:port_num
STANDBY_SERVER=host_ip:port_num
```

The `SERVER` variable is mandatory, and the `STANDBY_SERVER` variable is optional. The `keyring_okv` plugin attempts to communicate with the server running on the host named by the `SERVER` variable and falls back to `STANDBY_SERVER` if that fails.

**Note**

If the existing file is not in this format, then create a new file with the lines shown in the previous example. Also, consider backing up the `okvclient.ora` file before you run the `okvutil` command. Restore the file as needed.

You can specify more than one standby server (up to a maximum of 64). If you do, the `keyring_okv` plugin iterates over them until it can establish a connection, and fails if it cannot. To add extra standby servers, edit the `okvclient.ora` file to specify the IP addresses and port numbers of the servers as a comma-separated list in the value of the `STANDBY_SERVER` variable. For example:

```
STANDBY_SERVER=host_ip:port_num, host_ip:port_num, host_ip:port_num, host_ip:port_num
```

Ensure that the list of standby servers is kept short, accurate, and up to date, and servers that are no longer valid are removed. There is a 20-second wait for each connection attempt, so the presence of a long list of invalid servers can significantly affect the `keyring_okv` plugin’s connection time and therefore the server startup time.

8. Go to the Oracle Key Vault installer directory and test the setup by running this command:

```
okvutil/bin/okvutil list
```

The output should look something like this:

<table>
<thead>
<tr>
<th>Unique ID</th>
<th>Type</th>
<th>Identifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>255AB8DE-C97F-482C-E053-0100007F28B9</td>
<td>Symmetric Key</td>
<td></td>
</tr>
<tr>
<td>264BF6E0-A20E-7C42-E053-0100007FB29C</td>
<td>Symmetric Key</td>
<td></td>
</tr>
</tbody>
</table>

For a fresh Oracle Key Vault server (a server without any key in it), the output looks like this instead, to indicate that there are no keys in the vault:

```
no objects found
```

9. Use this command to extract the `ssl` directory containing SSL materials from the `okvclient.jar` file:

```
jar xf okvclient.jar ssl
```

10. Copy the Oracle Key Vault support files (the `okvclient.ora` file and the `ssl` directory) into the configuration directory.

11. (Optional) If you wish to password-protect the key file, use the instructions in Password-Protecting the `keyring_okv` Key File.

After completing the preceding procedure, restart the MySQL server. It loads the `keyring_okv` plugin and `keyring_okv` uses the files in its configuration directory to communicate with Oracle Key Vault.
Configuring keyring_okv for Gemalto SafeNet KeySecure Appliance

Gemalto SafeNet KeySecure Appliance uses the KMIP protocol (version 1.1 or 1.2). The keyring_okv keyring plugin (which supports KMIP 1.1) can use KeySecure as its KMIP back end for keyring storage.

Use the following procedure to configure keyring_okv and KeySecure to work together. The description only summarizes how to interact with KeySecure. For details, consult the section named Add a KMIP Server in the KeySecure User Guide.

1. Create the configuration directory that contains the KeySecure support files, and make sure that the keyring_okv_conf_dir system variable is set to name that directory (for details, see General keyring_okv Configuration).

2. In the configuration directory, create a subdirectory named ssl to use for storing the required SSL certificate and key files.

3. In the configuration directory, create a file named okvclient.ora. It should have following format:
   
   `SERVER=host_ip:port_num
   STANDBY_SERVER=host_ip:port_num`

   For example, if KeySecure is running on host 198.51.100.20 and listening on port 9002, and also running on alternative host 203.0.113.125 and listening on port 8041, the okvclient.ora file looks like this:

   `SERVER=198.51.100.20:9002
   STANDBY_SERVER=203.0.113.125:8041`

   You can specify more than one standby server (up to a maximum of 64). If you do, the keyring_okv plugin iterates over them until it can establish a connection, and fails if it cannot. To add extra standby servers, edit the okvclient.ora file to specify the IP addresses and port numbers of the servers as a comma-separated list in the value of the STANDBY_SERVER variable. For example:

   `STANDBY_SERVER=host_ip:port_num,host_ip:port_num,host_ip:port_num,host_ip:port_num`

   Ensure that the list of standby servers is kept short, accurate, and up to date, and servers that are no longer valid are removed. There is a 20-second wait for each connection attempt, so the presence of a long list of invalid servers can significantly affect the keyring_okv plugin’s connection time and therefore the server startup time.

4. Connect to the KeySecure Management Console as an administrator with credentials for Certificate Authorities access.

5. Navigate to Security >> Local CAs and create a local certificate authority (CA).

6. Go to Trusted CA Lists. Select Default and click on Properties. Then select Edit for Trusted Certificate Authority List and add the CA just created.

7. Download the CA and save it in the ssl directory as a file named CA.pem.

8. Navigate to Security >> Certificate Requests and create a certificate. Then you can download a compressed tar file containing certificate PEM files.

9. Extract the PEM files from in the downloaded file. For example, if the file name is csr_w_pk_pkcs8.gz, decompress and unpack it using this command:

   `tar zxfv csr_w_pk_pkcs8.gz`

   Two files result from the extraction operation: certificate_request.pem and private_key_pkcs8.pem.
10. Use this `openssl` command to decrypt the private key and create a file named `key.pem`:

   ```bash
   openssl pkcs8 -in private_key_pkcs8.pem -out key.pem
   ```

11. Copy the `key.pem` file into the `ssl` directory.

12. Copy the certificate request in `certificate_request.pem` into the clipboard.

13. Navigate to Security >> Local CAs. Select the same CA that you created earlier (the one you downloaded to create the `CA.pem` file), and click Sign Request. Paste the Certificate Request from the clipboard, choose a certificate purpose of Client (the keyring is a client of KeySecure), and click Sign Request. The result is a certificate signed with the selected CA in a new page.

14. Copy the signed certificate to the clipboard, then save the clipboard contents as a file named `cert.pem` in the `ssl` directory.

15. (Optional) If you wish to password-protect the key file, use the instructions in Password-Protecting the keyring_okv Key File.

After completing the preceding procedure, restart the MySQL server. It loads the `keyring_okv` plugin and `keyring_okv` uses the files in its configuration directory to communicate with KeySecure.

**Configuring keyring_okv for Townsend Alliance Key Manager**

Townsend Alliance Key Manager uses the KMIP protocol. The `keyring_okv` keyring plugin can use Alliance Key Manager as its KMIP back end for keyring storage. For additional information, see Alliance Key Manager for MySQL.

**Configuring keyring_okv for Entrust KeyControl**

Entrust KeyControl uses the KMIP protocol. The `keyring_okv` keyring plugin can use Entrust KeyControl as its KMIP back end for keyring storage. For additional information, see the Oracle MySQL and Entrust KeyControl with nShield HSM Integration Guide.

**Password-Protecting the keyring_okv Key File**

You can optionally protect the key file with a password and supply a file containing the password to enable the key file to be decrypted. To so do, change location to the `ssl` directory and perform these steps:

1. Encrypt the `key.pem` key file. For example, use a command like this, and enter the encryption password at the prompts:

   ```bash
   $> openssl rsa -des3 -in key.pem -out key.pem.new
   Enter PEM pass phrase:
   Verifying - Enter PEM pass phrase:
   ```

2. Save the encryption password in a single-line text file named `password.txt` in the `ssl` directory.

3. Verify that the encrypted key file can be decrypted using the following command. The decrypted file should display on the console:

   ```bash
   $> openssl rsa -in key.pem.new -passin file:password.txt
   ```

4. Remove the original `key.pem` file and rename `key.pem.new` to `key.pem`.

5. Change the ownership and access mode of new `key.pem` file and `password.txt` file as necessary to ensure that they have the same restrictions as other files in the `ssl` directory.

**6.4.4.9 Using the keyring_aws Amazon Web Services Keyring Plugin**
The MySQL Keyring

**Note**

The `keyring_aws` plugin is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see https://www.mysql.com/products/.

The `keyring_aws` keyring plugin communicates with the Amazon Web Services Key Management Service (AWS KMS) as a back end for key generation and uses a local file for key storage. All keyring material is generated exclusively by the AWS server, not by `keyring_aws`.

MySQL Enterprise Edition can work with `keyring_aws` on Red Hat Enterprise Linux, SUSE Linux Enterprise Server, Debian, Ubuntu, macOS, and Windows. MySQL Enterprise Edition does not support the use of `keyring_aws` on these platforms:

- EL6
- Generic Linux (glibc2.12)
- SLES 12 (with versions after MySQL Server 5.7)
- Solaris

The discussion here assumes that you are familiar with AWS in general and KMS in particular. Some pertinent information sources:

- AWS site
- KMS documentation

The following sections provide configuration and usage information for the `keyring_aws` keyring plugin:

- `keyring_aws Configuration`
- `keyring_aws Operation`
- `keyring_aws Credential Changes`

**keyring_aws Configuration**

To install `keyring_aws`, use the general instructions found in Section 6.4.4.3, "Keyring Plugin Installation", together with the plugin-specific configuration information found here.

The plugin library file contains the `keyring_aws` plugin and two loadable functions, `keyring_aws_rotate_cmk()` and `keyring_aws_rotate_keys()`.

To configure `keyring_aws`, you must obtain a secret access key that provides credentials for communicating with AWS KMS and write it to a configuration file:

1. Create an AWS KMS account.

2. Use AWS KMS to create a secret access key ID and secret access key. The access key serves to verify your identity and that of your applications.

3. Use the AWS KMS account to create a KMS key ID. At MySQL startup, set the `keyring_aws_cmk_id` system variable to the CMK ID value. This variable is mandatory and there is no default. (Its value can be changed at runtime if desired using `SET GLOBAL`.)
4. If necessary, create the directory in which the configuration file should be located. The directory should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use /usr/local/mysql/mysql-keyring/keyring_aws_conf as the file name, the following commands (executed as root) create its parent directory and set the directory mode and ownership:

```bash
$> cd /usr/local/mysql
$> mkdir mysql-keyring
$> chmod 750 mysql-keyring
$> chown mysql mysql-keyring
$> chgrp mysql mysql-keyring
```

At MySQL startup, set the `keyring_aws_conf_file` system variable to `/usr/local/mysql/mysql-keyring/keyring_aws_conf` to indicate the configuration file location to the server.

5. Prepare the `keyring_aws` configuration file, which should contain two lines:

   - Line 1: The secret access key ID
   - Line 2: The secret access key

   For example, if the key ID is `wwwwwwwwwwwwwEXAMPLE` and the key is `xxxxxxxxxxxxx/yyyyyyy/zzzzzzzzEXAMPLEKEY`, the configuration file looks like this:

```
wwwwwwwwwwwwwEXAMPLE
xxxxxxxxxxxxx/yyyyyyy/zzzzzzzzEXAMPLEKEY
```

To be usable during the server startup process, `keyring_aws` must be loaded using the `--early-plugin-load` option. The `keyring_aws_cmk_id` system variable is mandatory and configures the KMS key ID obtained from the AWS KMS server. The `keyring_aws_conf_file` and `keyring_aws_data_file` system variables optionally configure the locations of the files used by the `keyring_aws` plugin for configuration information and data storage. The file location variable default values are platform specific. To configure the locations explicitly, set the variable values at startup. For example, use these lines in the server `my.cnf` file, adjusting the `.so` suffix and file locations for your platform as necessary:

```
[mysqld]
early-plugin-load=keyring_aws.so
keyring_aws_cmk_id='arn:aws:kms:us-west-2:111122223333:key/abcd1234-ef56-ab12-cd34-ef56abcd1234'
keyring_aws_conf_file=/usr/local/mysql/mysql-keyring/keyring_aws_conf
keyring_aws_data_file=/usr/local/mysql/mysql-keyring/keyring_aws_data
```

For the `keyring_aws` plugin to start successfully, the configuration file must exist and contain valid secret access key information, initialized as described previously. The storage file need not exist. If it does not, `keyring_aws` attempts to create it (as well as its parent directory, if necessary).

For additional information about the system variables used to configure the `keyring_aws` plugin, see Section 6.4.4.19, “Keyring System Variables”.

Start the MySQL server and install the functions associated with the `keyring_aws` plugin. This is a one-time operation, performed by executing the following statements, adjusting the `.so` suffix for your platform as necessary:

```
CREATE FUNCTION keyring_aws_rotate_cmk RETURNS INTEGER SONAME 'keyring_aws.so';
CREATE FUNCTION keyring_aws_rotate_keys RETURNS INTEGER SONAME 'keyring_aws.so';
```

For additional information about the `keyring_aws` functions, see Section 6.4.4.16, “Plugin-Specific Keyring Key-Management Functions”.
The MySQL Keyring

**keyring/aws Operation**

At plugin startup, the `keyring/aws` plugin reads the AWS secret access key ID and key from its configuration file. It also reads any encrypted keys contained in its storage file into its in-memory cache.

During operation, `keyring/aws` maintains encrypted keys in the in-memory cache and uses the storage file as local persistent storage. Each keyring operation is transactional: `keyring/aws` either successfully changes both the in-memory key cache and the keyring storage file, or the operation fails and the keyring state remains unchanged.

To ensure that keys are flushed only when the correct keyring storage file exists, `keyring/aws` stores a SHA-256 checksum of the keyring in the file. Before updating the file, the plugin verifies that it contains the expected checksum.

The `keyring/aws` plugin supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by these functions are accessible at two levels:

- **SQL interface**: In SQL statements, call the functions described in Section 6.4.4.15, “General-Purpose Keyring Key-Management Functions”.
- **C interface**: In C-language code, call the keyring service functions described in Section 5.6.9.2, “The Keyring Service”.

Example (using the SQL interface):

```sql
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

In addition, the `keyring/aws_rotate_cmk()` and `keyring/aws_rotate_keys()` functions “extend” the keyring plugin interface to provide AWS-related capabilities not covered by the standard keyring service interface. These capabilities are accessible only by calling these functions using SQL. There are no corresponding C-language key service functions.

For information about the characteristics of key values permitted by `keyring/aws`, see Section 6.4.4.13, “Supported Keyring Key Types and Lengths”.

**keyring/aws Credential Changes**

Assuming that the `keyring/aws` plugin has initialized properly at server startup, it is possible to change the credentials used for communicating with AWS KMS:

1. Use AWS KMS to create a new secret access key ID and secret access key.

2. Store the new credentials in the configuration file (the file named by the `keyring/aws_conf_file` system variable). The file format is as described previously.

3. Reinitialize the `keyring/aws` plugin so that it re-reads the configuration file. Assuming that the new credentials are valid, the plugin should initialize successfully.

There are two ways to reinitialize the plugin:

- **Restart the server.** This is simpler and has no side effects, but is not suitable for installations that require minimal server downtime with as few restarts as possible.

- **Reinitialize the plugin without restarting the server** by executing the following statements, adjusting the `.so` suffix for your platform as necessary:

  ```sql
  UNINSTALL PLUGIN keyring/aws;
  INSTALL PLUGIN keyring/aws SONAME 'keyring/aws.so';
  ```
6.4.4.10 Using the HashiCorp Vault Keyring Plugin

Note

The keyring_hashicorp plugin is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see https://www.mysql.com/products/.

The keyring_hashicorp keyring plugin communicates with HashiCorp Vault for back end storage. The plugin supports HashiCorp Vault AppRole authentication. No key information is permanently stored in MySQL server local storage. (An optional in-memory key cache may be used as intermediate storage.) Random key generation is performed on the MySQL server side, with the keys subsequently stored to Hashicorp Vault.

The keyring_hashicorp plugin supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by those functions are accessible at two levels:

• SQL interface: In SQL statements, call the functions described in Section 6.4.4.15, “General-Purpose Keyring Key-Management Functions”.

• C interface: In C-language code, call the keyring service functions described in Section 5.6.9.2, “The Keyring Service”.

Example (using the SQL interface):

```
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

For information about the characteristics of key values permitted by keyring_hashicorp, see Section 6.4.4.13, “Supported Keyring Key Types and Lengths”.

To install keyring_hashicorp, use the general instructions found in Section 6.4.4.3, “Keyring Plugin Installation”, together with the configuration information specific to keyring_hashicorp found here. Plugin-specific configuration includes preparation of the certificate and key files needed for connecting to HashiCorp Vault, as well as configuring HashiCorp Vault itself. The following sections provide the necessary instructions.

• Certificate and Key Preparation

• HashiCorp Vault Setup

• keyring_hashicorp Configuration
Certificate and Key Preparation

The MySQL `keyring_hashicorp` plugin requires a secure connection to the HashiCorp Vault server, employing the HTTPS protocol. A typical setup includes a set of certificate and key files:

- **company.crt**: A custom CA certificate belonging to the organization. This file is used both by HashiCorp Vault server and the `keyring_hashicorp` plugin.
- **vault.key**: The private key of the HashiCorp Vault server instance. This file is used by HashiCorp Vault server.
- **vault.crt**: The certificate of the HashiCorp Vault server instance. This file must be signed by the organization CA certificate.

The following instructions describe how to create the certificate and key files using OpenSSL. (If you already have those files, proceed to HashiCorp Vault Setup.) The instructions as shown apply to Linux platforms and may require adjustment for other platforms.

### Important

Certificates generated by these instructions are self-signed, which may not be very secure. After you gain experience using such files, consider obtaining certificate/key material from a registered certificate authority.

1. Prepare the company and HashiCorp Vault server keys.

   Use the following commands to generate the key files:
   ```bash
   openssl genrsa -aes256 -out company.key 4096
   openssl genrsa -aes256 -out vault.key 2048
   ```

   The commands produce files holding the company private key (`company.key`) and the Vault server private key (`vault.key`). The keys are randomly generated RSA keys of 4,096 and 2,048 bits, respectively.

   Each command prompts for a password. For testing purposes, the password is not required. To disable it, omit the `-aes256` argument.

   The key files hold sensitive information and should be stored in a secure location. The password (also sensitive) is required later, so write it down and store it in a secure location.

   (Optional) To check key file content and validity, use the following commands:
   ```bash
   openssl rsa -in company.key -check
   openssl rsa -in vault.key -check
   ```

2. Create the company CA certificate.

   Use the following command to create a company CA certificate file named `company.crt` that is valid for 365 days (enter the command on a single line):
   ```bash
   openssl req -x509 -new -nodes -key company.key
   -sha256 -days 365 -out company.crt
   ```

   If you used the `-aes256` argument to perform key encryption during key generation, you are prompted for the company key password during CA certificate creation. You are also prompted for information about the certificate holder (that is, you or your company), as shown here:

   ```
   Country Name (2 letter code) [AU]:
   State or Province Name (full name) [Some-State]:
   ```
Answer the prompts with appropriate values.

3. Create a certificate signing request.

To create a HashiCorp Vault server certificate, a Certificate Signing Request (CSR) must be prepared for the newly created server key. Create a configuration file named `request.conf` containing the following lines. If the HashiCorp Vault server does not run on the local host, substitute appropriate CN and IP values, and make any other changes required.

```
[req]
distinguished_name = vault
x509_extensions = v3_req
prompt = no

[vault]
C = US
ST = CA
L = RWC
O = Company
CN = 127.0.0.1

[v3_req]
subjectAltName = @alternatives
authorityKeyIdentifier = keyid,issuer
basicConstraints = CA:TRUE

[alternatives]
IP = 127.0.0.1
```

Use this command to create the signing request:

```
openssl req -new -key vault.key -config request.conf -out request.csr
```

The output file (`request.csr`) is an intermediate file that serves as input for creation of the server certificate.

4. Create the HashiCorp Vault server certificate.

Sign the combined information from the HashiCorp Vault server key (`vault.key`) and the CSR (`request.csr`) with the company certificate (`company.crt`) to create the HashiCorp Vault server certificate (`vault.crt`). Use the following command to do this (enter the command on a single line):

```
openssl x509 -req -in request.csr
-CA company.crt -CAkey company.key -CAcreateserial
-out vault.crt -days 365 -sha256
```

To make the `vault.crt` server certificate useful, append the contents of the `company.crt` company certificate to it. This is required so that the company certificate is delivered along with the server certificate in requests.

```
cat company.crt >> vault.crt
```

If you display the contents of the `vault.crt` file, it should look like this:

```
-----BEGIN CERTIFICATE-----
... content of HashiCorp Vault server certificate ...
-----END CERTIFICATE-----
```
HashiCorp Vault Setup

The following instructions describe how to create a HashiCorp Vault setup that facilitates testing the keyring_hashicorp plugin.

**Important**

A test setup is similar to a production setup, but production use of HashiCorp Vault entails additional security considerations such as use of non-self-signed certificates and storing the company certificate in the system trust store. You must implement whatever additional security steps are needed to satisfy your operational requirements.

These instructions assume availability of the certificate and key files created in Certificate and Key Preparation. See that section if you do not have those files.

1. Fetch the HashiCorp Vault binary.

   Download the HashiCorp Vault binary appropriate for your platform from [https://www.vaultproject.io/downloads.html](https://www.vaultproject.io/downloads.html).

   Extract the content of the archive to produce the executable `vault` command, which is used to perform HashiCorp Vault operations. If necessary, add the directory where you install the command to the system path.

   (Optional) HashiCorp Vault supports autocomplete options that make it easier to use. For more information, see [https://learn.hashicorp.com/vault/getting-started/install#command-completion](https://learn.hashicorp.com/vault/getting-started/install#command-completion).

2. Create the HashiCorp Vault server configuration file.

   Prepare a configuration file named `config.hcl` with the following content. For the `tls_cert_file`, `tls_key_file`, and `path` values, substitute path names appropriate for your system.

   ```hcl
   listener "tcp" {
     address="127.0.0.1:8200"
     tls_cert_file="/home/username/certificates/vault.crt"
     tls_key_file="/home/username/certificates/vault.key"
   }
   storage "file" {
     path = "/home/username/vaultstorage/storage"
   }
   ui = true
   ```

3. Start the HashiCorp Vault server.

   To start the Vault server, use the following command, where the `-config` option specifies the path to the configuration file just created:

   ```bash
   vault server -config=config.hcl
   ```

   During this step, you may be prompted for a password for the Vault server private key stored in the `vault.key` file.

   The server should start, displaying some information on the console (IP, port, and so forth).
So that you can enter the remaining commands, put the `vault server` command in the background or open another terminal before continuing.

4. Initialize the HashiCorp Vault server.

   ![Note]
   
   The operations described in this step are required only when starting Vault the first time, to obtain the unseal key and root token. Subsequent Vault instance restarts require only unsealing using the unseal key.

   Issue the following commands (assuming Bourne shell syntax):

   ```
   export VAULT_SKIP_VERIFY=1
   vault operator init -n 1 -t 1
   ```

   The first command enables the `vault` command to temporarily ignore the fact that no company certificate has been added to the system trust store. It compensates for the fact that our self-signed CA is not added to that store. (For production use, such a certificate should be added.)

   The second command creates a single unseal key with a requirement for a single unseal key to be present for unsealing. (For production use, an instance would have multiple unseal keys with up to that many keys required to be entered to unseal it. The unseal keys should be delivered to key custodians within the company. Use of a single key might be considered a security issue because that permits the vault to be unsealed by a single key custodian.)

   Vault should reply with information about the unseal key and root token, plus some additional text (the actual unseal key and root token values differ from those shown here):

   ```
   ...
   Unseal Key 1: I2xwcFQc892O0Nt2pBiRN1nkHzTUrWS+JybL39BjcOE=
   Initial Root Token: s.vTvXeo3tPEYehfc9WH7oUKz
   ...
   ```

   Store the unseal key and root token in a secure location.

5. Unseal the HashiCorp Vault server.

   Use this command to unseal the Vault server:

   ```
   vault operator unseal
   ```

   When prompted to enter the unseal key, use the key obtained previously during Vault initialization.

   Vault should produce output indicating that setup is complete and the vault is unsealed.
6. Log in to the HashiCorp Vault server and verify its status.

   Prepare the environment variables required for logging in as root:

   ```bash
   vault login s.vTvXeo3tPEYehfcd9WH7oUKz
   ```

   For the token value in that command, substitute the content of the root token obtained previously during Vault initialization.

   Verify the Vault server status:

   ```bash
   vault status
   ```

   The output should contain these lines (among others):

   ```
   ...  
   Initialized     true
   Sealed          false
   ...
   ```

7. Set up HashiCorp Vault authentication and storage.

   **Note**

   The operations described in this step are needed only the first time the Vault instance is run. They need not be repeated afterward.

   Enable the AppRole authentication method and verify that it is in the authentication method list:

   ```bash
   vault auth enable approle
   vault auth list
   ```

   Enable the Vault KeyValue storage engine:

   ```bash
   vault secrets enable -version=1 kv
   ```

   Create and set up a role for use with the keyring_hashicorp plugin (enter the command on a single line):

   ```bash
   vault write auth/approle/role/mysql token_num_uses=0
ten_token_ttl=20m token_max_ttl=30m secret_id_num_uses=0
   ```

8. Add an AppRole security policy.

   **Note**

   The operations described in this step are needed only the first time the Vault instance is run. They need not be repeated afterward.

   Prepare a policy that to permit the previously created role to access appropriate secrets. Create a new file named mysql.hcl with the following content:

   ```hcl
   path "kv/mysql/" {
     capabilities = ["create", "read", "update", "delete", "list"]
   }
   ```
The MySQL Keyring

Note

(kv/mysql/ in this example may need adjustment per your local installation policies and security requirements. If so, make the same adjustment wherever else kv/mysql/ appears in these instructions.

Import the policy file to the Vault server to create a policy named mysql-policy, then assign the policy to the new role:

```
vault policy write mysql-policy mysql.hcl
vault write auth/approle/role/mysql policies=mysql-policy
```

Obtain the ID of the newly created role and store it in a secure location:

```
vault read auth/approle/role/mysql/role-id
```

Generate a secret ID for the role and store it in a secure location:

```
vault write -f auth/approle/role/mysql/secret-id
```

After these AppRole role ID and secret ID credentials are generated, they are expected to remain valid indefinitely. They need not be generated again and the keyring_hashicorp plugin can be configured with them for use on an ongoing basis. For more information about AuthRole authentication, visit https://www.vaultproject.io/docs/auth/approle.html.

keyring_hashicorp Configuration

The plugin library file contains the keyring_hashicorp plugin and a loadable function, keyring_hashicorp_update_config(). When the plugin initializes and terminates, it automatically loads and unloads the function. There is no need to load and unload the function manually.

The keyring_hashicorp plugin supports the configuration parameters shown in the following table. To specify these parameters, assign values to the corresponding system variables.

<table>
<thead>
<tr>
<th>Configuration Parameter</th>
<th>System Variable</th>
<th>Mandatory</th>
</tr>
</thead>
<tbody>
<tr>
<td>HashiCorp Server URL</td>
<td>keyring_hashicorp_server_url</td>
<td>No</td>
</tr>
<tr>
<td>AppRole role ID</td>
<td>keyring_hashicorp_role_id</td>
<td>Yes</td>
</tr>
<tr>
<td>AppRole secret ID</td>
<td>keyring_hashicorp_secret_id</td>
<td>Yes</td>
</tr>
<tr>
<td>Store path</td>
<td>keyring_hashicorp_store_path</td>
<td>Yes</td>
</tr>
<tr>
<td>Authorization Path</td>
<td>keyring_hashicorp_auth_path</td>
<td>No</td>
</tr>
<tr>
<td>CA certificate file path</td>
<td>keyring_hashicorp_ca_path</td>
<td>No</td>
</tr>
<tr>
<td>Cache control</td>
<td>keyring_hashicorp_caching</td>
<td>No</td>
</tr>
</tbody>
</table>

To be usable during the server startup process, keyring_hashicorp must be loaded using the --early-plugin-load option. As indicated by the preceding table, several plugin-related system variables are mandatory and must also be set. For example, use these lines in the server my.cnf file, adjusting the .so suffix and file locations for your platform as necessary:

```
[mysqld]
early-plugin-load=keyring_hashicorp.so
keyring_hashicorp_role_id='ee3b495c-d0c9-11e9-8881-8444c71c32aa'
keyring_hashicorp_secret_id='0512af29-d0ca-11e9-95ee-0010e00dd718'
keyring_hashicorp_store_path='/v1/kv/mysql'
keyring_hashicorp_auth_path='/v1/auth/approle/login'
```
MySQL Server authenticates against HashiCorp Vault using AppRole authentication. Successful authentication requires that two secrets be provided to Vault, a role ID and a secret ID, which are similar in concept to user name and password. The role ID and secret ID values to use are those obtained during the HashiCorp Vault setup procedure performed previously. To specify the two IDs, assign their respective values to the `keyring_hashicorp_role_id` and `keyring_hashicorp_secret_id` system variables.

The setup procedure also results in a store path of `/v1/kv/mysql`, which is the value to assign to `keyring_hashicorp_commit_store_path`.

At plugin initialization time, `keyring_hashicorp` attempts to connect to the HashiCorp Vault server using the configuration values. If the connection is successful, the plugin stores the values in corresponding system variables that have `_commit_` in their name. For example, upon successful connection, the plugin stores the values of `keyring_hashicorp_role_id` and `keyring_hashicorp_store_path` in `keyring_hashicorp_commit_role_id` and `keyring_hashicorp_commit_store_path`.

Reconfiguration at runtime can be performed with the assistance of the `keyring_hashicorp_update_config()` function:

1. Use `SET` statements to assign the desired new values to the configuration system variables shown in the preceding table. These assignments in themselves have no effect on ongoing plugin operation.

2. Invoke `keyring_hashicorp_update_config()` to cause the plugin to reconfigure and reconnect to the HashiCorp Vault server using the new variable values.

3. If the connection is successful, the plugin stores the updated configuration values in corresponding system variables that have `_commit_` in their name.

For example, if you have reconfigured HashiCorp Vault to listen on port 8201 rather than the default 8200, reconfigure `keyring_hashicorp` like this:

```sql
mysql> SET GLOBAL keyring_hashicorp_server_url = 'https://127.0.0.1:8201';
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT keyring_hashicorp_update_config();
```

```
+--------------------------------------+
| keyring_hashicorp_update_config()    |
+--------------------------------------+
| Configuration update was successful. |
+--------------------------------------+
1 row in set (0.03 sec)
```

If the plugin is not able to connect to HashiCorp Vault during initialization or reconfiguration and there was no existing connection, the `_commit_` system variables are set to 'Not committed' for string-valued variables, and `OFF` for Boolean-valued variables. If the plugin is not able to connect but there was an existing connection, that connection remains active and the `_commit_` variables reflect the values used for it.

If you do not set the mandatory system variables at server startup, or if some other plugin initialization error occurs, initialization fails. In this case, you can use the
runtime reconfiguration procedure to initialize the plugin without restarting the server.

For additional information about the keyring_hashicorp plugin-specific system variables and function, see Section 6.4.4.19, “Keyring System Variables”, and Section 6.4.4.16, “Plugin-Specific Keyring Key-Management Functions”.

6.4.4.11 Using the Oracle Cloud Infrastructure Vault Keyring Component

Note

The Oracle Cloud Infrastructure Vault keyring component is included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see https://www.mysql.com/products/.

cOMPONENT_KEYRING_OCI is part of the component infrastructure that communicates with Oracle Cloud Infrastructure Vault for back end storage. No key information is permanently stored in MySQL server local storage. All keys are stored in Oracle Cloud Infrastructure Vault, making this component well suited for Oracle Cloud Infrastructure MySQL customers for management of their MySQL Enterprise Edition keys.

MySQL Keyring began transitioning from plugins to use the component infrastructure. The introduction of component_keyring_oci is a continuation of that effort. For more information, see Keyring Components Versus Keyring Plugins.

Note

Only one keyring component or plugin should be enabled at a time. Enabling multiple keyring components or plugins is unsupported and results may not be as anticipated.

To use component_keyring_oci for keystore management, you must:

1. Write a manifest that tells the server to load component_keyring_oci, as described in Section 6.4.4.2, “Keyring Component Installation”.

2. Write a configuration file for component_keyring_oci, as described here.

After writing a manifest and configuration file, you should be able to access keys that were created using the keyring_oci plugin, provided that you specify the same set of configuration options to initialize the keyring component. The built-in backward compatibility of component_keyring_oci simplifies migrating from the keyring plugin to the component.

• Configuration Notes
• Verify the Component Installation
• Vault Keyring Component Usage

Configuration Notes

When it initializes, component_keyring_oci reads either a global configuration file, or a global configuration file paired with a local configuration file:

• The component attempts to read its global configuration file from the directory where the component library file is installed (that is, the server plugin directory).

• If the global configuration file indicates use of a local configuration file, the component attempts to read its local configuration file from the data directory.
The MySQL Keyring

- Although global and local configuration files are located in different directories, the file name is `component_keyring_oci.cnf` in both locations.

- It is an error for no configuration file to exist. `component_keyring_oci` cannot initialize without a valid configuration.

Local configuration files permit setting up multiple server instances to use `component_keyring_oci`, such that component configuration for each server instance is specific to a given data directory instance. This enables the same keyring component to be used with a distinct Oracle Cloud Infrastructure Vault for each instance.

You are assumed to be familiar with Oracle Cloud Infrastructure concepts, but the following documentation may be helpful when setting up resources to be used by `component_keyring_oci`:

- Overview of Vault
- Required Keys and OCIDs
- Managing Keys
- Managing Compartments
- Managing Vaults
- Managing Secrets

`component_keyring_oci` configuration files have these properties:

- A configuration file must be in valid JSON format.
- A configuration file permits these configuration items:
  - `"read_local_config"`: This item is permitted only in the global configuration file. If the item is not present, the component uses only the global configuration file. If the item is present, its value is `true` or `false`, indicating whether the component should read configuration information from the local configuration file.
    
    If the `"read_local_config"` item is present in the global configuration file along with other items, the component checks the `"read_local_config"` item value first:
    
    - If the value is `false`, the component processes the other items in the global configuration file and ignores the local configuration file.
    
    - If the value is `true`, the component ignores the other items in the global configuration file and attempts to read the local configuration file.
  
  - "user": The OCID of the Oracle Cloud Infrastructure user that `component_keyring_oci` uses for connections. Prior to using `component_keyring_oci`, the user account must exist and be granted access to use the configured Oracle Cloud Infrastructure tenancy, compartment, and vault resources. To obtain the user OCID from the Console, use the instructions at Required Keys and OCIDs.
    
    This value is mandatory.
  
  - "tenancy": The OCID of the Oracle Cloud Infrastructure tenancy that `component_keyring_oci` uses as the location of the MySQL compartment. Prior to using `component_keyring_oci`, you must create a tenancy if it does not exist. To obtain the tenancy OCID from the Console, use the instructions at Required Keys and OCIDs.
    
    This value is mandatory.
The MySQL Keyring

• “compartment”: The OCID of the tenancy compartment that component_keyring oci uses as the location of the MySQL keys. Prior to using component_keyring oci, you must create a MySQL compartment or subcompartment if it does not exist. This compartment should contain no vault keys or vault secrets. It should not be used by systems other than MySQL Keyring. For information about managing compartments and obtaining the OCID, see Managing Compartments.

This value is mandatory.

• “virtual_vault”: The OCID of the Oracle Cloud Infrastructure Vault that component_keyring oci uses for encryption operations. Prior to using component_keyring oci, you must create a new vault in the MySQL compartment if it does not exist. (Alternatively, you can reuse an existing vault that is in a parent compartment of the MySQL compartment.) Compartment users can see and use only the keys in their respective compartments. For information about creating a vault and obtaining the vault OCID, see Managing Vaults.

This value is mandatory.

• “encryption_endpoint”: The endpoint of the Oracle Cloud Infrastructure encryption server that component_keyring oci uses for generating encrypted or encoded information (ciphertext) for new keys. The encryption endpoint is vault specific and Oracle Cloud Infrastructure assigns it at vault-creation time. To obtain the endpoint OCID, view the configuration details for your keyring oci vault, using the instructions at Managing Vaults.

This value is mandatory.

• “management_endpoint”: The endpoint of the Oracle Cloud Infrastructure key management server that component_keyring oci uses for listing existing keys. The key management endpoint is vault specific and Oracle Cloud Infrastructure assigns it at vault-creation time. To obtain the endpoint OCID, view the configuration details for your keyring oci vault, using the instructions at Managing Vaults.

This value is mandatory.

• “vaults_endpoint”: The endpoint of the Oracle Cloud Infrastructure vaults server that component_keyring oci uses for obtaining the value of secrets. The vaults endpoint is vault specific and Oracle Cloud Infrastructure assigns it at vault-creation time. To obtain the endpoint OCID, view the configuration details for your keyring oci vault, using the instructions at Managing Vaults.

This value is mandatory.

• “secrets_endpoint”: The endpoint of the Oracle Cloud Infrastructure secrets server that component_keyring oci uses for listing, creating, and retiring secrets. The secrets endpoint is vault specific and Oracle Cloud Infrastructure assigns it at vault-creation time. To obtain the endpoint OCID, view the configuration details for your keyring oci vault, using the instructions at Managing Vaults.

This value is mandatory.

• “master_key”: The OCID of the Oracle Cloud Infrastructure master encryption key that component_keyring oci uses for encryption of secrets. Prior to using component_keyring oci, you must create a cryptographic key for the Oracle Cloud Infrastructure
The MySQL Keyring

compartment if it does not exist. Provide a MySQL-specific name for the generated key and do not use it for other purposes. For information about key creation, see Managing Keys.

This value is mandatory.

• “key_file”: The path name of the file containing the RSA private key that component_keyring_oci uses for Oracle Cloud Infrastructure authentication. You must also upload the corresponding RSA public key using the Console. The Console displays the key fingerprint value, which you can use to set the "key_fingerprint" value. For information about generating and uploading API keys, see Required Keys and OCIDs.

This value is mandatory.

• “key_fingerprint”: The fingerprint of the RSA private key that component_keyring_oci uses for Oracle Cloud Infrastructure authentication. To obtain the key fingerprint while creating the API keys, execute this command:

```bash
openssl rsa -pubout -outform DER -in ~/.oci/oci_api_key.pem | openssl md5 -c
```

Alternatively, obtain the fingerprint from the Console, which automatically displays the fingerprint when you upload the RSA public key. For information about obtaining key fingerprints, see Required Keys and OCIDs.

This value is mandatory.

• “ca_certificate”: The path name of the CA certificate bundle file that component_keyring_oci component uses for Oracle Cloud Infrastructure certificate verification. The file contains one or more certificates for peer verification. If no file is specified, the default CA bundle installed on the system is used. If the value is set to disabled (case-sensitive), component_keyring_oci performs no certificate verification.

Given the preceding configuration file properties, to configure component_keyring_oci, create a global configuration file named component_keyring_oci.cnf in the directory where the component_keyring_oci library file is installed, and optionally create a local configuration file, also named component_keyring_oci.cnf, in the data directory.

Verify the Component Installation

After performing any component-specific configuration, start the server. Verify component installation by examining the Performance Schema keyring_component_status table:

```sql
mysql> SELECT * FROM performance_schema.keyring_component_status;
```

<table>
<thead>
<tr>
<th>STATUS_KEY</th>
<th>STATUS_VALUE</th>
</tr>
</thead>
<tbody>

</table>

1504
A **Component_status** value of **Active** indicates that the component initialized successfully.

If the component cannot be loaded, server startup fails. Check the server error log for diagnostic messages. If the component loads but fails to initialize due to configuration problems, the server starts but the **Component_status** value is **Disabled**. Check the server error log, correct the configuration issues, and use the `ALTER INSTANCE RELOAD KEYRING` statement to reload the configuration.

It is possible to query MySQL server for the list of existing keys. To see which keys exist, examine the Performance Schema **keyring_keys** table.

```sql
mysql> SELECT * FROM performance_schema.keyring_keys;
```

<table>
<thead>
<tr>
<th>KEY_ID</th>

<td></td>
</tr>
<tr>
<td>YourKey</td>
<td>me@localhost</td>
<td></td>
</tr>
</tbody>
</table>

**Vault Keyring Component Usage**

**component_keyring_oci** supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by those functions are accessible at two levels:

- **SQL interface**: In SQL statements, call the functions described in Section 6.4.4.15, “General-Purpose Keyring Key-Management Functions”.

- **C interface**: In C-language code, call the keyring service functions described in Section 5.6.9.2, “The Keyring Service”.

Example (using the SQL interface):

```sql
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

For information about the characteristics of key values permitted by **component_keyring_oci**, see Section 6.4.4.13, “Supported Keyring Key Types and Lengths”.

**6.4.4.12 Using the Oracle Cloud Infrastructure Vault Keyring Plugin**

**Note**

The **keyring_oci** plugin is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see [https://www.mysql.com/products/](https://www.mysql.com/products/).

The **keyring_oci** plugin is a keyring plugin that communicates with Oracle Cloud Infrastructure Vault for back end storage. No key information is permanently stored in MySQL server local storage. All keys are stored in Oracle Cloud Infrastructure Vault, making this plugin well suited for Oracle Cloud Infrastructure MySQL customers for management of their MySQL Enterprise Edition keys.

This plugin is deprecated and subject to removal in a future release of MySQL. Instead, consider using the **component_keyring_oci** component for storing keyring data (see Section 6.4.4.11, “Using the Oracle Cloud Infrastructure Vault Keyring Component”).
The keyring_oci plugin supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by those functions are accessible at two levels:

- SQL interface: In SQL statements, call the functions described in Section 6.4.4.15, “General-Purpose Keyring Key-Management Functions”.
- C interface: In C-language code, call the keyring service functions described in Section 5.6.9.2, “The Keyring Service”.

Example (using the SQL interface):

```
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

For information about the characteristics of key values permitted by keyring_oci, see Section 6.4.4.13, “Supported Keyring Key Types and Lengths”.

To install keyring_oci, use the general instructions found in Section 6.4.4.3, “Keyring Plugin Installation”, together with the configuration information specific to keyring_oci found here. Plugin-specific configuration involves setting a number of system variables to indicate the names or values of Oracle Cloud Infrastructure resources.

You are assumed to be familiar with Oracle Cloud Infrastructure concepts, but the following documentation may be helpful when setting up resources to be used by the keyring_oci plugin:

- Overview of Vault
- Resource Identifiers
- Required Keys and OCIDs
- Managing Keys
- Managing Compartments
- Managing Vaults
- Managing Secrets

The keyring_oci plugin supports the configuration parameters shown in the following table. To specify these parameters, assign values to the corresponding system variables.

<table>
<thead>
<tr>
<th>Configuration Parameter</th>
<th>System Variable</th>
<th>Mandatory</th>
</tr>
</thead>
<tbody>
<tr>
<td>User OCID</td>
<td>keyring_oci_user</td>
<td>Yes</td>
</tr>
<tr>
<td>Tenancy OCID</td>
<td>keyring_oci_tenancy</td>
<td>Yes</td>
</tr>
<tr>
<td>Compartment OCID</td>
<td>keyring_oci_compartment</td>
<td>Yes</td>
</tr>
<tr>
<td>Vault OCID</td>
<td>keyring_oci_virtual_vault</td>
<td>Yes</td>
</tr>
<tr>
<td>Master key OCID</td>
<td>keyring_oci_master_key</td>
<td>Yes</td>
</tr>
<tr>
<td>Encryption server endpoint</td>
<td>keyring_oci_encryption_endpoint</td>
<td>Yes</td>
</tr>
<tr>
<td>Key management server endpoint</td>
<td>keyring_oci_management_endpoint</td>
<td>Yes</td>
</tr>
<tr>
<td>Vaults server endpoint</td>
<td>keyring_oci_vaults_endpoint</td>
<td>Yes</td>
</tr>
<tr>
<td>Secrets server endpoint</td>
<td>keyring_oci_secrets_endpoint</td>
<td>Yes</td>
</tr>
<tr>
<td>RSA private key file</td>
<td>keyring_oci_key_file</td>
<td>Yes</td>
</tr>
<tr>
<td>RSA private key fingerprint</td>
<td>keyring_oci_key_fingerprint</td>
<td>Yes</td>
</tr>
<tr>
<td>CA certificate bundle file</td>
<td>keyring_oci_ca_certificate</td>
<td>No</td>
</tr>
</tbody>
</table>
To be usable during the server startup process, `keyring_oci` must be loaded using the `--early-plugin-load` option. As indicated by the preceding table, several plugin-related system variables are mandatory and must also be set:

- Oracle Cloud Infrastructure uses Oracle Cloud IDs (OCIDs) extensively to designate resources, and several `keyring_oci` parameters specify OCID values of the resources to use. Consequently, prior to using the `keyring_oci` plugin, these prerequisites must be satisfied:

  - A user for connecting to Oracle Cloud Infrastructure must exist. Create the user if necessary and assign the user OCID to the `keyring_oci_user` system variable.

  - The Oracle Cloud Infrastructure tenancy to be used must exist, as well as the MySQL compartment within the tenancy, and the vault within the compartment. Create these resources if necessary and make sure the user is enabled to use them. Assign the OCIDs for the tenancy, compartment and vault to the `keyring_oci_tenancy`, `keyring_oci_compartment`, and `keyring_oci_virtual_vault` system variables.

  - A master key for encryption must exist. Create it if necessary and assign its OCID to the `keyring_oci_master_key` system variable.

  - Several server endpoints must be specified. These endpoints are vault specific and Oracle Cloud Infrastructure assigns them at vault-creation time. Obtain their values from the vault details page and assign them to the `keyring_oci_encryption_endpoint`, `keyring_oci_management_endpoint`, `keyring_oci_vaults_endpoint`, and `keyring_oci_secrets_endpoint` system variables.

  - The Oracle Cloud Infrastructure API uses an RSA private/public key pair for authentication. To create this key pair and obtain the key fingerprint, use the instructions at Required Keys and OCIDs. Assign the private key file name and key fingerprint to the `keyring_oci_key_file` and `keyring_oci_key_fingerprint` system variables.

In addition to the mandatory system variables, `keyring_oci_ca_certificate` optionally may be set to specify a certificate authority (CA) certificate bundle file for peer authentication.

### Important

If you copy a parameter from the Oracle Cloud Infrastructure Console, the copied value may include an initial `https://` part. Omit that part when setting the corresponding `keyring_oci` system variable.

For example, to load and configure `keyring_oci`, use these lines in the server `my.cnf` file (adjust the `.so` suffix and file location for your platform as necessary):

```sql
[mysqld]
early-plugin-load=keyring_oci.so
keyring_oci_user=ocid1.user.oc1..longAlphaNumericString
keyring_oci_tenancy=ocid1.tenancy.oc1..longAlphaNumericString
keyring_oci_compartment=ocid1.compartment.oc1..longAlphaNumericString
keyring_oci_virtual_vault=ocid1.vault.oc1.iad..shortAlphaNumericString..longAlphaNumericString
keyring_oci_master_key=ocid1.key.oc1.iad..shortAlphaNumericString..longAlphaNumericString
keyring_oci_encryption_endpoint=shortAlphaNumericString-crypto.kms.us-ashburn-1.oraclecloud.com
keyring_oci_management_endpoint=shortAlphaNumericString-management.kms.us-ashburn-1.oraclecloud.com
keyring_oci_vaults_endpoint=vaults.us-ashburn-1.oci.oraclecloud.com
keyring_oci_secrets_endpoint=secrets.vaults.us-ashburn-1.oci.oraclecloud.com
keyring_oci_key_file=file_name
```

For additional information about the `keyring_oci` plugin-specific system variables, see Section 6.4.19, "Keyring System Variables".
The `keyring_oci` plugin does not support runtime reconfiguration and none of its system variables can be modified at runtime. To change configuration parameters, do this:

- Modify parameter settings in the `my.cnf` file, or use `SET PERSIST_ONLY` for parameters that are persisted to `mysqld-auto.conf`.
- Restart the server.

### 6.4.4.13 Supported Keyring Key Types and Lengths

MySQL Keyring supports keys of different types (encryption algorithms) and lengths:

- The available key types depend on which keyring plugin is installed.
- The permitted key lengths are subject to multiple factors:
  - General keyring loadable-function interface limits (for keys managed using one of the keyring functions described in Section 6.4.4.15, “General-Purpose Keyring Key-Management Functions”), or limits from backend implementations. These length limits can vary by key operation type.
  - In addition to the general limits, individual keyring plugins may impose restrictions on key lengths per key type.

Table 6.34, “General Keyring Key Length Limits” shows the general key-length limits. (The lower limits for `keyring_aws` are imposed by the AWS KMS interface, not the keyring functions.) For keyring plugins, Table 6.35, “Keyring Plugin Key Types and Lengths” shows the key types each keyring plugin permits, as well as any plugin-specific key-length restrictions. For most keyring components, the general key-length limits apply and there are no key-type restrictions.

**Table 6.34 General Keyring Key Length Limits**

<table>
<thead>
<tr>
<th>Key Operation</th>
<th>Maximum Key Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>Generate key</td>
<td>16,384 bytes (2,048 previously); 1,024 for <code>keyring_aws</code></td>
</tr>

</tr>
</tbody>
</table>

The **SECRET** key type is intended for general-purpose storage of sensitive data using the MySQL keyring, and is supported by most keyring components and keyring plugins. The keyring encrypts and decrypts **SECRET** data as a byte stream upon storage and retrieval.

Example keyring operations involving the **SECRET** key type:

```sql
SELECT keyring_key_generate('MySecret1', 'SECRET', 20);
SELECT keyring_key_remove('MySecret1');
SELECT keyring_key_store('MySecret2', 'SECRET', 'MySecretData');
SELECT keyring_key_fetch('MySecret2');
SELECT keyring_key_length_fetch('MySecret2');
SELECT keyring_key_type_fetch('MySecret2');
SELECT keyring_key_remove('MySecret2');
```

### 6.4.4.14 Migrating Keys Between Keyring Keystores

A keyring migration copies keys from one keystore to another, enabling a DBA to switch a MySQL installation to a different keystore. A successful migration operation has this result:

- The destination keystore contains the keys it had prior to the migration, plus the keys from the source keystore.
- The source keystore remains the same before and after the migration (because keys are copied, not moved).

If a key to be copied already exists in the destination keystore, an error occurs and the destination keystore is restored to its premigration state.

The keyring manages keystores using keyring components and keyring plugins. This pertains to migration strategy because the way in which the source and destination keystores are managed determines whether a particular type of key migration is possible and the procedure for performing it:

- Migration from one keyring plugin to another: The MySQL server has an operational mode that provides this capability.
• Migration from a keyring plugin to a keyring component: The MySQL server has an operational mode that provides this capability.

• Migration from one keyring component to another: The `mysql_migrate_keyring` utility provides this capability.

• Migration from a keyring component to a keyring plugin: There is no provision for this capability.

The following sections discuss the characteristics of offline and online migrations and describe how to perform migrations.

• Offline and Online Key Migrations

• Key Migration Using a Migration Server

• Key Migration Using the `mysql_migrate_keyring` Utility

• Key Migration Involving Multiple Running Servers

Offline and Online Key Migrations

A key migration is either offline or online:

• Offline migration: For use when you are sure that no running server on the local host is using the source or destination keystore. In this case, the migration operation can copy keys from the source keystore to the destination without the possibility of a running server modifying keystore content during the operation.

• Online migration: For use when a running server on the local host is using the source keystore. In this case, care must be taken to prevent that server from updating keystores during the migration. This involves connecting to the running server and instructing it to pause keyring operations so that keys can be copied safely from the source keystore to the destination. When key copying is complete, the running server is permitted to resume keyring operations.

When you plan a key migration, use these points to decide whether it should be offline or online:

• Do not perform offline migration involving a keystore that is in use by a running server.

• Pausing keyring operations during an online migration is accomplished by connecting to the running server and setting its global `keyring_operations` system variable to `OFF` before key copying and `ON` after key copying. This has several implications:

  • `keyring_operations` was introduced in MySQL 5.7.21, so online migration is possible only if the running server is from MySQL 5.7.21 or higher. If the running server is older, you must stop it, perform an offline migration, and restart it. All migration instructions elsewhere that refer to `keyring_operations` are subject to this condition.

  • The account used to connect to the running server must have the privileges required to modify `keyring_operations`. These privileges are `ENCRYPTION_KEY_ADMIN` in addition to either `SYSTEM_VARIABLES_ADMIN` or the deprecated `SUPER` privilege.

  • If an online migration operation exits abnormally (for example, if it is forcibly terminated), it is possible for `keyring_operations` to remain disabled on the running server, leaving it unable to perform keyring operations. In this case, it may be necessary to connect to the running server and enable `keyring_operations` manually using this statement:

    ```sql
    SET GLOBAL keyring_operations = ON;
    ```
Online key migration provides for pausing keyring operations on a single running server. To perform a migration if multiple running servers are using the keystores involved, use the procedure described at Key Migration Involving Multiple Running Servers.

Key Migration Using a Migration Server

Note

Online key migration using a migration server is only supported if the running server allows socket connections or TCP/IP connections using TLS; it is not supported when, for example, the server is running on a Windows platform and only allows shared memory connections.

A MySQL server becomes a migration server if invoked in a special operational mode that supports key migration. A migration server does not accept client connections. Instead, it runs only long enough to migrate keys, then exits. A migration server reports errors to the console (the standard error output).

A migration server supports these migration types:

- Migration from one keyring plugin to another.

- Migration from a keyring plugin to a keyring component. Older servers support only migration from one keyring plugin to another, in which case the parts of these instructions that refer to keyring components do not apply.

A migration server does not support migration from one keyring component to another. For that type of migration, see Key Migration Using the mysql\_migrate\_keyring Utility.

To perform a key migration operation using a migration server, determine the key migration options required to specify which keyring plugins or components are involved, and whether the migration is offline or online:

- To indicate the source keyring plugin and the destination keyring plugin or component, specify these options:
  
  - \texttt{--keyring-migration-source}: The source keyring plugin that manages the keys to be migrated.
  
  - \texttt{--keyring-migration-destination}: The destination keyring plugin or component to which the migrated keys are to be copied.
  
  - \texttt{--keyring-migration-to-component}: This option is required if the destination is a keyring component rather than a keyring plugin.

  The \texttt{--keyring-migration-source} and \texttt{--keyring-migration-destination} options signify to the server that it should run in key migration mode. For key migration operations, both options are mandatory. Each plugin or component is specified using the name of its library file, including any platform-specific extension such as \texttt{.so} or \texttt{.dll}. The source and destination must differ, and the migration server must support them both.

- For an offline migration, no additional key migration options are needed.

- For an online migration, some running server currently is using the source or destination keystore. To invoke the migration server, specify additional key migration options that indicate how to connect to the running server. This is necessary so that the migration server can connect to the running server and tell it to pause keyring use during the migration operation.

Use of any of the following options signifies an online migration:
The MySQL Keyring

• **--keyring-migration-host**: The host where the running server is located. This is always the local host because the migration server can migrate keys only between keystores managed by local plugins and components.

• **--keyring-migration-user, --keyring-migration-password**: The account credentials to use to connect to the running server.

• **--keyring-migration-port**: For TCP/IP connections, the port number to connect to on the running server.

• **--keyring-migration-socket**: For Unix socket file or Windows named pipe connections, the socket file or named pipe to connect to on the running server.

For additional details about the key migration options, see Section 6.4.4.18, “Keyring Command Options”.

Start the migration server with key migration options indicating the source and destination keystores and whether the migration is offline or online, possibly with other options. Keep the following considerations in mind:

• Other server options might be required, such as configuration parameters for the two keyring plugins. For example, if `keyring_file` is the source or destination, you must set the `keyring_file_data` system variable if the keyring data file location is not the default location. Other non-keyring options may be required as well. One way to specify these options is by using **--defaults-file** to name an option file that contains the required options.

• The migration server expects path name option values to be full paths. Relative path names may not be resolved as you expect.

• The user who invokes a server in key-migration mode must not be the `root` operating system user, unless the **--user** option is specified with a non-`root` user name to run the server as that user.

• The user a server in key-migration mode runs as must have permission to read and write any local keyring files, such as the data file for a file-based plugin.

If you invoke the migration server from a system account different from that normally used to run MySQL, it might create keyring directories or files that are inaccessible to the server during normal operation. Suppose that `mysqld` normally runs as the `mysql` operating system user, but you invoke the migration server while logged in as `isabel`. Any new directories or files created by the migration server are owned by `isabel`. Subsequent startup fails when a server run as the `mysql` operating system user attempts to access file system objects owned by `isabel`.

To avoid this issue, start the migration server as the `root` operating system user and provide a **--user=user_name** option, where `user_name` is the system account normally used to run MySQL. Alternatively, after the migration, examine the keyring-related file system objects and change their ownership and permissions if necessary using `chown`, `chmod`, or similar commands, so that the objects are accessible to the running server.

Example command line for offline migration between two keyring plugins (enter the command on a single line):

```
mysqld --defaults-file=/usr/local/mysql/etc/my.cnf
    --keyring-migration-source=keyring_file.so
    --keyring-migration-destination=keyring_encrypted_file.so
    --keyring_encrypted_file_password=password
```

Example command line for online migration between two keyring plugins:
mysqld --defaults-file=/usr/local/mysql/etc/my.cnf
   --keyring-migration-source=keyring_file.so
   --keyring-migration-destination=keyring_encrypted_file.so
   --keyring_encrypted_file_password=password
   --keyring-migration-host=127.0.0.1
   --keyring-migration-user=root
   --keyring-migration-password=root_password

To perform a migration when the destination is a keyring component rather than a keyring plugin, specify the `--keyring-migration-to-component` option, and name the component as the value of the `--keyring-migration-destination` option.

Example command line for offline migration from a keyring plugin to a keyring component:

```
mysqld --defaults-file=/usr/local/mysql/etc/my.cnf
   --keyring-migration-to-component
   --keyring-migration-source=keyring_file.so
   --keyring-migration-destination=component_keyring_encrypted_file.so
```

Notice that in this case, no `keyring_encrypted_file_password` value is specified. The password for the component data file is listed in the component configuration file.

Example command line for online migration from a keyring plugin to a keyring component:

```
mysqld --defaults-file=/usr/local/mysql/etc/my.cnf
   --keyring-migration-to-component
   --keyring-migration-source=keyring_file.so
   --keyring-migration-destination=component_keyring_encrypted_file.so
   --keyring-migration-host=127.0.0.1
   --keyring-migration-user=root
   --keyring-migration-password=root_password
```

The key migration server performs a migration operation as follows:

1. (Online migration only) Connect to the running server using the connection options.
2. (Online migration only) Disable `keyring_operations` on the running server.
3. Load the keyring plugin/component libraries for the source and destination keystores.
4. Copy keys from the source keystore to the destination.
5. Unload the keyring plugin/component libraries for the source and destination keystores.
6. (Online migration only) Enable `keyring_operations` on the running server.
7. (Online migration only) Disconnect from the running server.

If an error occurs during key migration, the destination keystore is restored to its premigration state.

After a successful online key migration operation, the running server might need to be restarted:

- If the running server was using the source keystore before the migration and should continue to use it after the migration, it need not be restarted after the migration.
- If the running server was using the destination keystore before the migration and should continue to use it after the migration, it should be restarted after the migration to load all keys migrated into the destination keystore.
- If the running server was using the source keystore before the migration but should use the destination keystore after the migration, it must be reconfigured to use the destination keystore and restarted. In this
case, be aware that although the running server is paused from modifying the source keystore during the migration itself, it is not paused during the interval between the migration and the subsequent restart. Care should be taken that the server does not modify the source keystore during this interval because any such changes will not be reflected in the destination keystore.

Key Migration Using the mysql_migrate_keyring Utility

The `mysql_migrate_keyring` utility migrates keys from one keyring component to another. It does not support migrations involving keyring plugins. For that type of migration, use a MySQL server operating in key migration mode; see Key Migration Using a Migration Server.

To perform a key migration operation using `mysql_migrate_keyring`, determine the key migration options required to specify which keyring components are involved, and whether the migration is offline or online:

- To indicate the source and destination keyring components and their location, specify these options:
  - `--source-keyring`: The source keyring component that manages the keys to be migrated.
  - `--destination-keyring`: The destination keyring component to which the migrated keys are to be copied.
  - `--component-dir`: The directory containing keyring component library files. This is typically the value of the `plugin_dir` system variable for the local MySQL server.

All three options are mandatory. Each keyring component name is a component library file name specified without any platform-specific extension such as `.so` or `.dll`. For example, to use the component for which the library file is `component_keyring_file.so`, specify the option as `--source-keyring=component_keyring_file`. The source and destination must differ, and `mysql_migrate_keyring` must support them both.

- For an offline migration, no additional options are needed.
- For an online migration, some running server currently is using the source or destination keystore. In this case, specify the `--online-migration` option to signify an online migration. In addition, specify connection options indicating how to connect to the running server, so that `mysql_migrate_keyring` can connect to it and tell it to pause keyring use during the migration operation.

The `--online-migration` option is commonly used in conjunction with connection options such as these:

- `--host`: The host where the running server is located. This is always the local host because `mysql_migrate_keyring` can migrate keys only between keystores managed by local components.
- `--user, --password`: The account credentials to use to connect to the running server.
- `--port`: For TCP/IP connections, the port number to connect to on the running server.
- `--socket`: For Unix socket file or Windows named pipe connections, the socket file or named pipe to connect to on the running server.

For descriptions of all available options, see Section 4.6.8, “mysql_migrate_keyring — Keyring Key Migration Utility”.

Start `mysql_migrate_keyring` with options indicating the source and destination keystores and whether the migration is offline or online, possibly with other options. Keep the following considerations in mind:
• The user who invokes `mysql_migrate_keyring` must not be the `root` operating system user.

• The user who invokes `mysql_migrate_keyring` must have permission to read and write any local keyring files, such as the data file for a file-based plugin.

If you invoke `mysql_migrate_keyring` from a system account different from that normally used to run MySQL, it might create keyring directories or files that are inaccessible to the server during normal operation. Suppose that `mysqld` normally runs as the `mysql` operating system user, but you invoke `mysql_migrate_keyring` while logged in as `isabel`. Any new directories or files created by `mysql_migrate_keyring` are owned by `isabel`. Subsequent startup fails when a server run as the `mysql` operating system user attempts to access file system objects owned by `isabel`.

To avoid this issue, invoke `mysql_migrate_keyring` as the `mysql` operating system user. Alternatively, after the migration, examine the keyring-related file system objects and change their ownership and permissions if necessary using `chown`, `chmod`, or similar commands, so that the objects are accessible to the running server.

Suppose that you want to migrate keys from `component_keyring_file` to `component_keyring_encrypted_file`, and that the local server stores its keyring component library files in `/usr/local/mysql/lib/plugin`.

If no running server is using the keyring, an offline migration is permitted. Invoke `mysql_migrate_keyring` like this (enter the command on a single line):

```
mysql_migrate_keyring
    --component-dir=/usr/local/mysql/lib/plugin
    --source-keyring=component_keyring_file
    --destination-keyring=component_keyring_encrypted_file
```

If a running server is using the keyring, you must perform an online migration instead. In this case, the `--online-migration` option must be given, along with any connection options required to specify which server to connect to and the MySQL account to use.

The following command performs an online migration. It connects to the local server using a TCP/IP connection and the `admin` account. The command prompts for a password, which you should enter when prompted:

```
mysql_migrate_keyring
    --component-dir=/usr/local/mysql/lib/plugin
    --source-keyring=component_keyring_file
    --destination-keyring=component_keyring_encrypted_file
    --online-migration --host=127.0.0.1 --user=admin --password
```

`mysql_migrate_keyring` performs a migration operation as follows:

1. (Online migration only) Connect to the running server using the connection options.
2. (Online migration only) Disable `keyring_operations` on the running server.
3. Load the keyring component libraries for the source and destination keystores.
4. Copy keys from the source keystore to the destination.
5. Unload the keyring component libraries for the source and destination keystores.
6. (Online migration only) Enable `keyring_operations` on the running server.
7. (Online migration only) Disconnect from the running server.
The MySQL Keyring

If an error occurs during key migration, the destination keystore is restored to its premigration state.

After a successful online key migration operation, the running server might need to be restarted:

• If the running server was using the source keystore before the migration and should continue to use it after the migration, it need not be restarted after the migration.

• If the running server was using the destination keystore before the migration and should continue to use it after the migration, it should be restarted after the migration to load all keys migrated into the destination keystore.

• If the running server was using the source keystore before the migration but should use the destination keystore after the migration, it must be reconfigured to use the destination keystore and restarted. In this case, be aware that although the running server is paused from modifying the source keystore during the migration itself, it is not paused during the interval between the migration and the subsequent restart. Care should be taken that the server does not modify the source keystore during this interval because any such changes will not be reflected in the destination keystore.

Key Migration Involving Multiple Running Servers

Online key migration provides for pausing keyring operations on a single running server. To perform a migration if multiple running servers are using the keystores involved, use this procedure:

1. Connect to each running server manually and set keyring_operations=OFF. This ensures that no running server is using the source or destination keystore and satisfies the required condition for offline migration.

2. Use a migration server or mysql_migrate_keyring to perform an offline key migration for each paused server.

3. Connect to each running server manually and set keyring_operations=ON.

All running servers must support the keyring_operations system variable. Any server that does not must be stopped before the migration and restarted after.

6.4.4.15 General-Purpose Keyring Key-Management Functions

MySQL Server supports a keyring service that enables internal components and plugins to securely store sensitive information for later retrieval.

MySQL Server also includes an SQL interface for keyring key management, implemented as a set of general-purpose functions that access the capabilities provided by the internal keyring service. The keyring functions are contained in a plugin library file, which also contains a keyring_udf plugin that must be enabled prior to function invocation. For these functions to be used, a keyring plugin such as keyring_file or keyring_okv must be enabled.

The functions described here are general purpose and intended for use with any keyring plugin. A given keyring plugin might have functions of its own that are intended for use only with that plugin; see Section 6.4.4.16, “Plugin-Specific Keyring Key-Management Functions”.

The following sections provide installation instructions for the keyring functions and demonstrate how to use them. For information about the keyring service functions invoked by these functions, see Section 5.6.9.2, “The Keyring Service”. For general keyring information, see Section 6.4.4, “The MySQL Keyring”.

• Installing or Uninstalling General-Purpose Keyring Functions
Installing or Uninstalling General-Purpose Keyring Functions

This section describes how to install or uninstall the keyring functions, which are implemented in a plugin library file that also contains a `keyring_udf` plugin. For general information about installing or uninstalling plugins and loadable functions, see Section 5.6.1, "Installing and Uninstalling Plugins", and Section 5.7.1, "Installing and Uninstalling Loadable Functions".

The keyring functions enable keyring key management operations, but the `keyring_udf` plugin must also be installed because the functions do not work correctly without it. Attempts to use the functions without the `keyring_udf` plugin result in an error.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `keyring_udf`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To install the `keyring_udf` plugin and the keyring functions, use the `INSTALL PLUGIN` and `CREATE FUNCTION` statements, adjusting the `.so` suffix for your platform as necessary:

```sql
INSTALL PLUGIN keyring_udf SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_generate RETURNS INTEGER SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_fetch RETURNS STRING SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_length_fetch RETURNS INTEGER SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_type_fetch RETURNS STRING SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_store RETURNS INTEGER SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_remove RETURNS INTEGER SONAME 'keyring_udf.so';
```

If the plugin and functions are used on a source replication server, install them on all replicas as well to avoid replication issues.

Once installed as just described, the plugin and functions remain installed until uninstalled. To remove them, use the `UNINSTALL PLUGIN` and `DROP FUNCTION` statements:

```sql
UNINSTALL PLUGIN keyring_udf;
DROP FUNCTION keyring_key_generate;
DROP FUNCTION keyring_key_fetch;
DROP FUNCTION keyring_key_length_fetch;
DROP FUNCTION keyring_key_type_fetch;
DROP FUNCTION keyring_key_store;
DROP FUNCTION keyring_key_remove;
```

Using General-Purpose Keyring Functions

Before using the keyring general-purpose functions, install them according to the instructions provided in Installing or Uninstalling General-Purpose Keyring Functions.

The keyring functions are subject to these constraints:
• To use any keyring function, the `keyring_udf` plugin must be enabled. Otherwise, an error occurs:

```
ERROR 1123 (HY000): Can't initialize function 'keyring_key_generate';
This function requires keyring_udf plugin which is not installed.
Please install
```

To install the `keyring_udf` plugin, see Installing or Uninstalling General-Purpose Keyring Functions.

• The keyring functions invoke keyring service functions (see Section 5.6.9.2, “The Keyring Service”). The service functions in turn use whatever keyring plugin is installed (for example, `keyring_file` or `keyring_okv`). Therefore, to use any keyring function, some underlying keyring plugin must be enabled. Otherwise, an error occurs:

```
ERROR 3188 (HY000): Function 'keyring_key_generate' failed because underlying keyring service returned an error. Please check if a keyring plugin is installed and that provided arguments are valid for the keyring you are using.
```

To install a keyring plugin, see Section 6.4.4.3, “Keyring Plugin Installation”.

• A user must possess the global `EXECUTE` privilege to use any keyring function. Otherwise, an error occurs:

```
ERROR 1123 (HY000): Can't initialize function 'keyring_key_generate';
The user is not privileged to execute this function. User needs to have EXECUTE
```

To grant the global `EXECUTE` privilege to a user, use this statement:

```
GRANT EXECUTE ON *.* TO user;
```

Alternatively, should you prefer to avoid granting the global `EXECUTE` privilege while still permitting users to access specific key-management operations, “wrapper” stored programs can be defined (a technique described later in this section).

• A key stored in the keyring by a given user can be manipulated later only by the same user. That is, the value of the `CURRENT_USER()` function at the time of key manipulation must have the same value as when the key was stored in the keyring. (This constraint rules out the use of the keyring functions for manipulation of instance-wide keys, such as those created by InnoDB to support tablespace encryption.)

To enable multiple users to perform operations on the same key, “wrapper” stored programs can be defined (a technique described later in this section).

• Keyring functions support the key types and lengths supported by the underlying keyring plugin. For information about keys specific to a particular keyring plugin, see Section 6.4.4.13, “Supported Keyring Key Types and Lengths”.

To create a new random key and store it in the keyring, call `keyring_key_generate()`, passing to it an ID for the key, along with the key type (encryption method) and its length in bytes. The following call creates a 2,048-bit DSA-encrypted key named `MyKey`:

```
mysql> SELECT keyring_key_generate('MyKey', 'DSA', 256);
+-------------------------------------------+
| keyring_key_generate('MyKey', 'DSA', 256) |
| +-------------------------------------------+
| 1 |
+-------------------------------------------+
```

A return value of 1 indicates success. If the key cannot be created, the return value is `NULL` and an error occurs. One reason this might be is that the underlying keyring plugin does not support the specified
The MySQL Keyring

combination of key type and key length; see Section 6.4.4.13, “Supported Keyring Key Types and Lengths”.

To be able to check the return type regardless of whether an error occurs, use `SELECT ... INTO @var_name` and test the variable value:

```
mysql> SELECT keyring_key_generate('', '', -1) INTO @x;
ERROR 3188 (HY000): Function 'keyring_key_generate' failed because underlying keyring service returned an error. Please check if a keyring plugin is installed and that provided arguments are valid for the keyring you are using.
mysql> SELECT @x;
+------+
| @x   |
+------+
| NULL |
+------+
mysql> SELECT keyring_key_generate('x', 'AES', 16) INTO @x;
```

This technique also applies to other keyring functions that for failure return a value and an error.

The ID passed to `keyring_key_generate()` provides a means by which to refer to the key in subsequent functions calls. For example, use the key ID to retrieve its type as a string or its length in bytes as an integer:

```
mysql> SELECT keyring_key_type_fetch('MyKey');
+---------------------------------+
| keyring_key_type_fetch('MyKey') |
| DSA                             |
+---------------------------------+
mysql> SELECT keyring_key_length_fetch('MyKey');
+-----------------------------------+
| keyring_key_length_fetch('MyKey') |
|                               256 |
+-----------------------------------+
```

To retrieve a key value, pass the key ID to `keyring_key_fetch()`. The following example uses `HEX()` to display the key value because it may contain nonprintable characters. The example also uses a short key for brevity, but be aware that longer keys provide better security:

```
mysql> SELECT keyring_key_generate('MyShortKey', 'DSA', 8);
+----------------------------------------------+
| keyring_key_generate('MyShortKey', 'DSA', 8) |
|                                            1 |
+----------------------------------------------+
mysql> SELECT HEX(keyring_key_fetch('MyShortKey'));
+--------------------------------------+
| HEX(keyring_key_fetch('MyShortKey'))    |
| 1DB3B0FC3328A24C                      |
+--------------------------------------+
```

Keyring functions treat key IDs, types, and values as binary strings, so comparisons are case-sensitive. For example, IDs of `MyKey` and `mykey` refer to different keys.
To remove a key, pass the key ID to `keyring_key_remove()`:

```sql
mysql> SELECT keyring_key_remove('MyKey');
+-----------------------------+
| keyring_key_remove('MyKey') |
+-----------------------------+
|                           1 |
+-----------------------------+
```

To obfuscate and store a key that you provide, pass the key ID, type, and value to `keyring_key_store()`:

```sql
mysql> SELECT keyring_key_store('AES_key', 'AES', 'Secret string');
+------------------------------------------------------+
| keyring_key_store('AES_key', 'AES', 'Secret string') |
+------------------------------------------------------+
|                                                    1 |
+------------------------------------------------------+
```

As indicated previously, a user must have the global `EXECUTE` privilege to call keyring functions, and the user who stores a key in the keyring initially must be the same user who performs subsequent operations on the key later, as determined from the `CURRENT_USER()` value in effect for each function call. To permit key operations to users who do not have the global `EXECUTE` privilege or who may not be the key “owner,” use this technique:

1. Define “wrapper” stored programs that encapsulate the required key operations and have a `DEFINER` value equal to the key owner.
2. Grant the `EXECUTE` privilege for specific stored programs to the individual users who should be able to invoke them.
3. If the operations implemented by the wrapper stored programs do not include key creation, create any necessary keys in advance, using the account named as the `DEFINER` in the stored program definitions.

This technique enables keys to be shared among users and provides to DBAs more fine-grained control over who can do what with keys, without having to grant global privileges.

The following example shows how to set up a shared key named `SharedKey` that is owned by the DBA, and a `get_shared_key()` stored function that provides access to the current key value. The value can be retrieved by any user with the `EXECUTE` privilege for that function, which is created in the `key_schema` schema.

From a MySQL administrative account ("root"@'localhost' in this example), create the administrative schema and the stored function to access the key:

```sql
mysql> CREATE SCHEMA key_schema;

mysql> CREATE DEFINER = 'root'@'localhost'
    > FUNCTION key_schema.get_shared_key()
    > RETURNS BLOB READS SQL DATA
    > RETURN keyring_key_fetch('SharedKey');
```

From the administrative account, ensure that the shared key exists:

```sql
mysql> SELECT keyring_key_generate('SharedKey', 'DSA', 8);
+---------------------------------------------+
<table>
<thead>
<tr>
<th>keyring_key_generate('SharedKey', 'DSA', 8)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1520</td>
</tr>
</tbody>
</table>
+---------------------------------------------+
```
From the administrative account, create an ordinary user account to which key access is to be granted:

```
mysql> CREATE USER 'key_user'@'localhost'
    \> IDENTIFIED BY 'key_user_pwd';
```

From the `key_user` account, verify that, without the proper `EXECUTE` privilege, the new account cannot access the shared key:

```
mysql> SELECT HEX(key_schema.get_shared_key());
ERROR 1370 (42000): execute command denied to user 'key_user'@'localhost'
for routine 'key_schema.get_shared_key'
```

From the administrative account, grant `EXECUTE` to `key_user` for the stored function:

```
mysql> GRANT EXECUTE ON FUNCTION key_schema.get_shared_key
    \> TO 'key_user'@'localhost';
```

From the `key_user` account, verify that the key is now accessible:

```
mysql> SELECT HEX(key_schema.get_shared_key());
+----------------------------------+
| HEX(key_schema.get_shared_key()) |
+----------------------------------+
| 9BAFB9E75CEEB013                 |
```

### General-Purpose Keyring Function Reference

For each general-purpose keyring function, this section describes its purpose, calling sequence, and return value. For information about the conditions under which these functions can be invoked, see Using General-Purpose Keyring Functions.

- `keyring_key_fetch(key_id)`

  Given a key ID, deobfuscates and returns the key value.

  Arguments:

  - `key_id`: A string that specifies the key ID.

  Return value:

  Returns the key value as a string for success, `NULL` if the key does not exist, or `NULL` and an error for failure.

  **Note**

  Key values retrieved using `keyring_key_fetch()` are subject to the general keyring function limits described in Section 6.4.4.13, “Supported Keyring Key Types and Lengths”. A key value longer than that length can be stored using a keyring service function (see Section 5.6.9.2, “The Keyring Service”), but if retrieved using `keyring_key_fetch()` is truncated to the general keyring function limit.

  Example:
The example uses `HEX()` to display the key value because it may contain nonprintable characters. The example also uses a short key for brevity, but be aware that longer keys provide better security.

- **keyring_key_generate(key_id, key_type, key_length)**

  Generates a new random key with a given ID, type, and length, and stores it in the keyring. The type and length values must be consistent with the values supported by the underlying keyring plugin. See Section 6.4.4.13, “Supported Keyring Key Types and Lengths”.

  **Arguments:**
  - **key_id**: A string that specifies the key ID.
  - **key_type**: A string that specifies the key type.
  - **key_length**: An integer that specifies the key length in bytes.

  **Return value:**

  Returns 1 for success, or `NULL` and an error for failure.

  **Example:**

  ```
  mysql> SELECT keyring_key_generate('RSA_key', 'RSA', 384);
  +---------------------------------------------+
  | keyring_key_generate('RSA_key', 'RSA', 384) |
  +---------------------------------------------+
  |                                           1 |
  +---------------------------------------------+
  ```

- **keyring_key_length_fetch(key_id)**

  Given a key ID, returns the key length.

  **Arguments:**
  - **key_id**: A string that specifies the key ID.
Return value:
Returns the key length in bytes as an integer for success, NULL if the key does not exist, or NULL and an error for failure.

Example:
See the description of `keyring_key_fetch()`.

- **keyring_key_remove(key_id)**

Removes the key with a given ID from the keyring.

Arguments:
- **key_id**: A string that specifies the key ID.

Return value:
Returns 1 for success, or NULL for failure.

Example:
```
mysql> SELECT keyring_key_remove('AES_key');
+-------------------------------+
| keyring_key_remove('AES_key') |
+-------------------------------+
|                             1 |
+-------------------------------+
```

- **keyring_key_store(key_id, key_type, key)**

Obfuscates and stores a key in the keyring.

Arguments:
- **key_id**: A string that specifies the key ID.
- **key_type**: A string that specifies the key type.
- **key**: A string that specifies the key value.

Return value:
Returns 1 for success, or NULL and an error for failure.

Example:
```
mysql> SELECT keyring_key_store('new key', 'DSA', 'My key value');
+-----------------------------------------------------+
| keyring_key_store('new key', 'DSA', 'My key value') |
+-----------------------------------------------------+
|                                                   1 |
+-----------------------------------------------------+
```

- **keyring_key_type_fetch(key_id)**

Given a key ID, returns the key type.

Arguments:
The MySQL Keyring

- **key_id**: A string that specifies the key ID.

Return value:

Returns the key type as a string for success, **NULL** if the key does not exist, or **NULL** and an error for failure.

Example:

See the description of `keyring_key_fetch()`.

### 6.4.4.16 Plugin-Specific Keyring Key-Management Functions

For each keyring plugin-specific function, this section describes its purpose, calling sequence, and return value. For information about general-purpose keyring functions, see Section 6.4.4.15, “General-Purpose Keyring Key-Management Functions”.

- **keyring_aws_rotate_cmk()**

  Associated keyring plugin: **keyring_aws**

  `keyring_aws_rotate_cmk()` rotates the AWS KMS key. Rotation changes only the key that AWS KMS uses for subsequent data key-encryption operations. AWS KMS maintains previous CMK versions, so keys generated using previous CMKs remain decryptable after rotation.

  Rotation changes the CMK value used inside AWS KMS but does not change the ID used to refer to it, so there is no need to change the `keyring_aws_cmk_id` system variable after calling `keyring_aws_rotate_cmk()`.

  This function requires the **SUPER** privilege.

  Arguments:

  None.

  Return value:

  Returns 1 for success, or **NULL** and an error for failure.

- **keyring_aws_rotate_keys()**

  Associated keyring plugin: **keyring_aws**

  `keyring_aws_rotate_keys()` rotates keys stored in the `keyring_aws` storage file named by the `keyring_aws_data_file` system variable. Rotation sends each key stored in the file to AWS KMS for re-encryption using the value of the `keyring_aws_cmk_id` system variable as the CMK value, and stores the new encrypted keys in the file.

  `keyring_aws_rotate_keys()` is useful for key re-encryption under these circumstances:

  - After rotating the CMK; that is, after invoking the `keyring_aws_rotate_cmk()` function.
  - After changing the `keyring_aws_cmk_id` system variable to a different key value.

  This function requires the **SUPER** privilege.

  Arguments:
None.

Return value:

Returns 1 for success, or NULL and an error for failure.

- keyring_hashicorp_update_config()

Associated keyring plugin: keyring_hashicorp

When invoked, the keyring_hashicorp_update_config() function causes keyring_hashicorp to perform a runtime reconfiguration, as described in keyring_hashicorp Configuration.

This function requires the SYSTEM_VARIABLES_ADMIN privilege because it modifies global system variables.

Arguments:

None.

Return value:

Returns the string 'Configuration update was successful.' for success, or 'Configuration update failed.' for failure.

6.4.4.17 Keyring Metadata

This section describes sources of information about keyring use.

To see whether a keyring plugin is loaded, check the Information Schema PLUGINS table or use the SHOW PLUGINS statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
    FROM INFORMATION_SCHEMA.PLUGINS
    WHERE PLUGIN_NAME LIKE 'keyring%';
```

```
+--------------+---------------+
<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>PLUGIN_STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>keyring_file</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>
+--------------+---------------+
```

To see which keys exist, check the Performance Schema keyring_keys table:

```
mysql> SELECT * FROM performance_schema.keyring_keys;
```

```
+-----------------------------+--------------+----------------+
| KEY_ID                      | KEY_OWNER    | BACKEND_KEY_ID |
|-----------------------------+--------------+----------------+
| audit_log-20210322T130749-1 |              |                |
| MyKey                       | me@localhost |                |
| YourKey                     | me@localhost |                |
+-----------------------------+--------------+----------------+
```

To see whether a keyring component is loaded, check the Performance Schema keyring_component_status table. For example:

```
mysql> SELECT * FROM performance_schema.keyring_component_status;
```

```
+---------------------+-------------------------------------------------+
<table>
<thead>
<tr>
<th>STATUS_KEY</th>
<th>STATUS_VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component_name</td>
<td>component_keyring_file</td>
</tr>
<tr>
<td>Author</td>
<td>Oracle Corporation</td>
</tr>
</tbody>
</table>
```

1525
A Component_status value of Active indicates that the component initialized successfully. If the component loaded but failed to initialize, the value is Disabled.

6.4.4.18 Keyring Command Options

MySQL supports the following keyring-related command-line options:

- **--keyring-migration-destination=plugin**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-migration-destination=plugin_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The destination keyring plugin for key migration. See Section 6.4.4.14, “Migrating Keys Between Keyring Keystores”. The option value interpretation depends on whether --keyring-migration-to-component is specified:

- If no, the option value is a keyring plugin, interpreted the same way as for --keyring-migration-source.

- If yes, the option value is a keyring component, specified as the component library name in the plugin directory, including any platform-specific extension such as .so or .dll.

Note

--keyring-migration-source and --keyring-migration-destination are mandatory for all keyring migration operations. The source and destination plugins must differ, and the migration server must support both plugins.

- **--keyring-migration-host=host_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-migration-host=host_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>localhost</td>
</tr>
</tbody>
</table>

The host location of the running server that is currently using one of the key migration keystores. See Section 6.4.4.14, “Migrating Keys Between Keyring Keystores”. Migration always occurs on the local host, so the option always specifies a value for connecting to a local server, such as localhost, 127.0.0.1, ::1, or the local host IP address or host name.

- **--keyring-migration-password[=password]**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-migration-password[=password]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
The password of the MySQL account used for connecting to the running server that is currently using one of the key migration keystores. See Section 6.4.4.14, “Migrating Keys Between Keyring Keystores”.

The password value is optional. If not given, the server prompts for one. If given, there must be no space between `--keyring-migration-password=` and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. See Section 6.1.2.1, “End-User Guidelines for Password Security”. You can use an option file to avoid giving the password on the command line. In this case, the file should have a restrictive mode and be accessible only to the account used to run the migration server.

• `--keyring-migration-port=port_num`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-migration-port=port_num</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>3306</td>
</tr>
</tbody>
</table>

For TCP/IP connections, the port number for connecting to the running server that is currently using one of the key migration keystores. See Section 6.4.4.14, “Migrating Keys Between Keyring Keystores”.

• `--keyring-migration-socket=path`

| Command-Line Format | --keyring-migration-socket={file_name|pipe_name} |
|---------------------|-----------------------------------------------|
| Type                | String                                        |

For Unix socket file or Windows named pipe connections, the socket file or named pipe for connecting to the running server that is currently using one of the key migration keystores. See Section 6.4.4.14, “Migrating Keys Between Keyring Keystores”.

• `--keyring-migration-source=plugin`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-migration-source=plugin_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The source keyring plugin for key migration. See Section 6.4.4.14, “Migrating Keys Between Keyring Keystores”.

The option value is similar to that for `--plugin-load`, except that only one plugin library can be specified. The value is given as `plugin_library` or `name=plugin_library`, where `plugin_library` is the name of a library file that contains plugin code, and `name` is the name of a plugin to load. If a plugin library is named without any preceding plugin name, the server loads all plugins in the library. With a preceding plugin name, the server loads only the named plugin from the library. The server looks for plugin library files in the directory named by the `plugin_dir` system variable.

**Note**

`--keyring-migration-source` and `--keyring-migration-destination` are mandatory for all keyring migration operations. The source and destination plugins must differ, and the migration server must support both plugins.
• `--keyring-migration-to-component`

| Command-Line Format | `--keyring-migration-to-component[{OFF|ON}]` |
|---------------------|------------------------------------------|
| Type                | Boolean                                  |
| Default Value       | OFF                                      |

Indicates that a key migration is from a keyring plugin to a keyring component. This option makes it possible to migrate keys from any keyring plugin to any keyring component, which facilitates transitioning a MySQL installation from keyring plugins to keyring components.

For key migration from one keyring component to another, use the `mysql_migrate_keyring` utility. Migration from a keyring component to a keyring plugin is not supported. See Section 6.4.4.14, “Migrating Keys Between Keyring Keystores”.

• `--keyring-migration-user=user_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--keyring-migration-user=user_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The user name of the MySQL account used for connecting to the running server that is currently using one of the key migration keystores. See Section 6.4.4.14, “Migrating Keys Between Keyring Keystores”.

6.4.4.19 Keyring System Variables

MySQL Keyring plugins support the following system variables. Use them to configure keyring plugin operation. These variables are unavailable unless the appropriate keyring plugin is installed (see Section 6.4.4.3, “Keyring Plugin Installation”).

• `keyring_aws_cmk_id`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--keyring-aws-cmk-id=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>keyring_aws_cmk_id</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The KMS key ID obtained from the AWS KMS server and used by the `keyring_aws` plugin. This variable is unavailable unless that plugin is installed.

This variable is mandatory. If not specified, `keyring_aws` initialization fails.

• `keyring_aws_conf_file`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--keyring-aws-conf-file=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>keyring_aws_conf_file</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>

If not specified, this plugin cannot be initialized.
The location of the configuration file for the `keyring_aws` plugin. This variable is unavailable unless that plugin is installed.

At plugin startup, `keyring_aws` reads the AWS secret access key ID and key from the configuration file. For the `keyring_aws` plugin to start successfully, the configuration file must exist and contain valid secret access key information, initialized as described in Section 6.4.4.9, “Using the keyring_aws Amazon Web Services Keyring Plugin”.

The default file name is `keyring_aws_conf`, located in the default keyring file directory. The location of this default directory is the same as for the `keyring_file_data` system variable. See the description of that variable for details, as well as for considerations to take into account if you create the directory manually.

- **keyring_aws_data_file**

  The location of the storage file for the `keyring_aws` plugin. This variable is unavailable unless that plugin is installed.

  At plugin startup, if the value assigned to `keyring_aws_data_file` specifies a file that does not exist, the `keyring_aws` plugin attempts to create it (as well as its parent directory, if necessary). If the file does exist, `keyring_aws` reads any encrypted keys contained in the file into its in-memory cache. `keyring_aws` does not cache unencrypted keys in memory.

  The default file name is `keyring_aws_data`, located in the default keyring file directory. The location of this default directory is the same as for the `keyring_file_data` system variable. See the description of that variable for details, as well as for considerations to take into account if you create the directory manually.

- **keyring_aws_region**

  
<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--keyring-aws-region=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>keyring_aws_region</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>us-east-1</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>af-south-1</code></td>
</tr>
</tbody>
</table>
The AWS region for the `keyring_aws` plugin. This variable is unavailable unless that plugin is installed.
The MySQL Keyring

- **keyring_encrypted_file_data**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-encrypted-file-data=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>keyring_encrypted_file_data</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>platform specific</td>
</tr>
</tbody>
</table>

**Note**

The **keyring_encrypted_file** plugin is deprecated and subject to removal in a future version of MySQL. Consider using **component_keyring_encrypted_file** instead; the **component_keyring_encrypted_file** component supersedes the **keyring_encrypted_file** plugin.

The path name of the data file used for secure data storage by the **keyring_encrypted_file** plugin. This variable is unavailable unless that plugin is installed. The file location should be in a directory considered for use only by keyring plugins. For example, do not locate the file under the data directory.

Keyring operations are transactional: The **keyring_encrypted_file** plugin uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has the same name as the value of the **keyring_encrypted_file_data** variable with a suffix of .backup.

Do not use the same **keyring_encrypted_file** data file for multiple MySQL instances. Each instance should have its own unique data file.

The default file name is **keyring_encrypted**, located in a directory that is platform specific and depends on the value of the **INSTALL_LAYOUT CMake** option, as shown in the following table. To specify the default directory for the file explicitly if you are building from source, use the **INSTALL_MYSQLKEYRINGDIR CMake** option.

<table>
<thead>
<tr>
<th>INSTALL_LAYOUT Value</th>
<th>Default <strong>keyring_encrypted_file_data</strong> Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEB, RPM, SVR4</td>
<td>/var/lib/mysql-keyring/keyring_encrypted</td>
</tr>
<tr>
<td>Otherwise</td>
<td>keyring/keyring_encrypted under the CMAKE_INSTALL_PREFIX value</td>
</tr>
</tbody>
</table>

At plugin startup, if the value assigned to **keyring_encrypted_file_data** specifies a file that does not exist, the **keyring_encrypted_file** plugin attempts to create it (as well as its parent directory, if necessary).

If you create the directory manually, it should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use the /usr/
local/mysql/mysql-keyring directory, the following commands (executed as root) create the directory and set its mode and ownership:

```
cd /usr/local/mysql
mkdir mysql-keyring
chmod 750 mysql-keyring
chown mysql mysql-keyring
chgrp mysql mysql-keyring
```

If the `keyring_encrypted_file` plugin cannot create or access its data file, it writes an error message to the error log. If an attempted runtime assignment to `keyring_encrypted_file_data` results in an error, the variable value remains unchanged.

---

**Important**

Once the `keyring_encrypted_file` plugin has created its data file and started to use it, it is important not to remove the file. Loss of the file causes data encrypted using its keys to become inaccessible. (It is permissible to rename or move the file, as long as you change the value of `keyring_encrypted_file_data` to match.)

- `keyring_encrypted_file_password`

---

### Command-Line Format

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--keyring-encrypted-file-password=password</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>keyring_encrypted_file_password</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

---

**Note**

The `keyring_encrypted_file` plugin is deprecated and subject to removal in a future version of MySQL. Consider using `component_keyring_encrypted_file` instead; the `component_keyring_encrypted_file` component supersedes the `keyring_encrypted_file` plugin.

The password used by the `keyring_encrypted_file` plugin. This variable is unavailable unless that plugin is installed.

This variable is mandatory. If not specified, `keyring_encrypted_file` initialization fails.

If this variable is specified in an option file, the file should have a restrictive mode and be accessible only to the account used to run the MySQL server.

---

**Important**

Once the `keyring_encrypted_file_password` value has been set, changing it does not rotate the keyring password and could make the server inaccessible. If an incorrect password is provided, the
**keyring_encrypted_file** plugin cannot load keys from the encrypted keyring file.

The password value cannot be displayed at runtime with `SHOW VARIABLES` or the Performance Schema `global_variables` table because the display value is obfuscated.

- **keyring_file_data**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--keyring-file-data=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>keyring_file_data</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>platform specific</td>
</tr>
</tbody>
</table>

**Note**

The **keyring_file** plugin is deprecated and subject to removal in a future version of MySQL. Consider using **component_keyring_file** instead; the **component_keyring_file** component supersedes the **keyring_file** plugin.

The path name of the data file used for secure data storage by the **keyring_file** plugin. This variable is unavailable unless that plugin is installed. The file location should be in a directory considered for use only by keyring plugins. For example, do not locate the file under the data directory.

Keyring operations are transactional: The **keyring_file** plugin uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has the same name as the value of the **keyring_file_data** system variable with a suffix of `.backup`.

Do not use the same **keyring_file** data file for multiple MySQL instances. Each instance should have its own unique data file.

The default file name is **keyring**, located in a directory that is platform specific and depends on the value of the **INSTALL_LAYOUT** CMake option, as shown in the following table. To specify the default directory for the file explicitly if you are building from source, use the **INSTALLMYSQLKEYRINGDIR** CMake option.

<table>
<thead>
<tr>
<th><strong>INSTALL_LAYOUT</strong> Value</th>
<th>Default <code>keyring_file_data</code> Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEB, RPM, SVR4</td>
<td><code>/var/lib/mysql-keyring/keyring</code></td>
</tr>
<tr>
<td>Otherwise</td>
<td><code>keyring/keyring</code> under the <code>CMAKE_INSTALL_PREFIX</code> value</td>
</tr>
</tbody>
</table>

At plugin startup, if the value assigned to `keyring_file_data` specifies a file that does not exist, the **keyring_file** plugin attempts to create it (as well as its parent directory, if necessary).

If you create the directory manually, it should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use the `/usr/local/mysql/mysql-keyring` directory, the following commands (executed as root) create the directory and set its mode and ownership:
cd /usr/local/mysql
mkdir mysql-keyring
chmod 750 mysql-keyring
chown mysql mysql-keyring
chgrp mysql mysql-keyring

If the `keyring_file` plugin cannot create or access its data file, it writes an error message to the error log. If an attempted runtime assignment to `keyring_file_data` results in an error, the variable value remains unchanged.

---

**Important**

Once the `keyring_file` plugin has created its data file and started to use it, it is important not to remove the file. For example, InnoDB uses the file to store the master key used to decrypt the data in tables that use InnoDB tablespace encryption; see Section 15.13, “InnoDB Data-at-Rest Encryption”. Loss of the file causes data in such tables to become inaccessible. (It is permissible to rename or move the file, as long as you change the value of `keyring_file_data` to match.) It is recommended that you create a separate backup of the keyring data file immediately after you create the first encrypted table and before and after master key rotation.

- `keyring_hashicorp_auth_path`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--keyring-hashicorp-auth-path=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>keyring_hashicorp_auth_path</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>/v1/auth/approle/login</code></td>
</tr>
</tbody>
</table>

The authentication path where AppRole authentication is enabled within the HashiCorp Vault server, for use by the `keyring_hashicorp` plugin. This variable is unavailable unless that plugin is installed.

- `keyring_hashicorp_ca_path`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--keyring-hashicorp-ca-path=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>keyring_hashicorp_ca_path</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>
The absolute path name of a local file accessible to the MySQL server that contains a properly formatted TLS certificate authority for use by the `keyring_hashicorp` plugin. This variable is unavailable unless that plugin is installed.

If this variable is not set, the `keyring_hashicorp` plugin opens an HTTPS connection without using server certificate verification, and trusts any certificate delivered by the HashiCorp Vault server. For this to be safe, it must be assumed that the Vault server is not malicious and that no man-in-the-middle attack is possible. If those assumptions are invalid, set `keyring_hashicorp_ca_path` to the path of a trusted CA certificate. (For example, for the instructions in Certificate and Key Preparation, this is the `company.crt` file.)

- `keyring_hashicorp_caching`

| Command-Line Format | `--keyring-hashicorp-caching[{=OFF|ON}]` |
|---------------------|-----------------------------------------|
| System Variable     | `keyring_hashicorp_caching`             |
| Scope               | Global                                  |
| Dynamic             | Yes                                     |
| *SET_VAR* Hint Applies | No                                        |
| Type                | Boolean                                 |
| Default Value       | OFF                                     |

Whether to enable the optional in-memory key cache used by the `keyring_hashicorp` plugin to cache keys from the HashiCorp Vault server. This variable is unavailable unless that plugin is installed. If the cache is enabled, the plugin populates it during initialization. Otherwise, the plugin populates only the key list during initialization.

Enabling the cache is a compromise: It improves performance, but maintains a copy of sensitive key information in memory, which may be undesirable for security purposes.

- `keyring_hashicorp_commit_auth_path`

<table>
<thead>
<tr>
<th>System Variable</th>
<th><code>keyring_hashicorp_commit_auth_path</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><em>SET_VAR</em> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

This variable is associated with `keyring_hashicorp_auth_path`, from which it takes its value during `keyring_hashicorp` plugin initialization. This variable is unavailable unless that plugin is installed. It reflects the “committed” value actually used for plugin operation if initialization succeeds. For additional information, see `keyring_hashicorp Configuration`.

- `keyring_hashicorp_commit_ca_path`

<table>
<thead>
<tr>
<th>System Variable</th>
<th><code>keyring_hashicorp_commit_ca_path</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
</tbody>
</table>
This variable is associated with `keyring_hashicorp_ca_path`, from which it takes its value during `keyring_hashicorp` plugin initialization. This variable is unavailable unless that plugin is installed. It reflects the “committed” value actually used for plugin operation if initialization succeeds. For additional information, see `keyring_hashicorp` Configuration.

- **keyring_hashicorp_commit_caching**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>keyring_hashicorp_commit_caching</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

This variable is associated with `keyring_hashicorp_caching`, from which it takes its value during `keyring_hashicorp` plugin initialization. This variable is unavailable unless that plugin is installed. It reflects the “committed” value actually used for plugin operation if initialization succeeds. For additional information, see `keyring_hashicorp` Configuration.

- **keyring_hashicorp_commit_role_id**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>keyring_hashicorp_commit_role_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

This variable is associated with `keyring_hashicorp_role_id`, from which it takes its value during `keyring_hashicorp` plugin initialization. This variable is unavailable unless that plugin is installed. It reflects the “committed” value actually used for plugin operation if initialization succeeds. For additional information, see `keyring_hashicorp` Configuration.

- **keyring_hashicorp_commit_server_url**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>keyring_hashicorp_commit_server_url</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

This variable is associated with `keyring_hashicorp_server_url`, from which it takes its value during `keyring_hashicorp` plugin initialization. This variable is unavailable unless that plugin is installed. It reflects the “committed” value actually used for plugin operation if initialization succeeds. For additional information, see `keyring_hashicorp` Configuration.
The MySQL Keyring

- **keyring_hashicorp_commit_store_path**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>keyring_hashicorp_commit_store_path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR</td>
<td>Hint Applies</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

This variable is associated with `keyring_hashicorp_store_path`, from which it takes its value during `keyring_hashicorp` plugin initialization. This variable is unavailable unless that plugin is installed. It reflects the “committed” value actually used for plugin operation if initialization succeeds. For additional information, see `keyring_hashicorp Configuration`.

- **keyring_hashicorp_role_id**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-hashicorp-role-id=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>keyring_hashicorp_role_id</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR</td>
<td>Hint Applies</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>empty string</td>
</tr>
</tbody>
</table>

The HashiCorp Vault AppRole authentication role ID, for use by the `keyring_hashicorp` plugin. This variable is unavailable unless that plugin is installed. The value must be in UUID format.

This variable is mandatory. If not specified, `keyring_hashicorp` initialization fails.

- **keyring_hashicorp_secret_id**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-hashicorp-secret-id=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>keyring_hashicorp_secret_id</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR</td>
<td>Hint Applies</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>empty string</td>
</tr>
</tbody>
</table>

The HashiCorp Vault AppRole authentication secret ID, for use by the `keyring_hashicorp` plugin. This variable is unavailable unless that plugin is installed. The value must be in UUID format.

This variable is mandatory. If not specified, `keyring_hashicorp` initialization fails.

The value of this variable is sensitive, so its value is masked by * characters when displayed.

- **keyring_hashicorp_server_url**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-hashicorp-server-url=value</th>
</tr>
</thead>
</table>

The value of this variable is sensitive, so its value is masked by * characters when displayed.
The MySQL Keyring System Variable

<table>
<thead>
<tr>
<th>System Variable</th>
<th>keyring_hashicorp_server_url</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><a href="https://127.0.0.1:8200">https://127.0.0.1:8200</a></td>
</tr>
</tbody>
</table>

The HashiCorp Vault server URL, for use by the keyring_hashicorp plugin. This variable is unavailable unless that plugin is installed. The value must begin with https://.

- **keyring_hashicorp_store_path**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-hashicorp-store-path=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>keyring_hashicorp_store_path</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>empty string</td>
</tr>
</tbody>
</table>

A store path within the HashiCorp Vault server that is writeable when appropriate AppRole credentials are provided by the keyring_hashicorp plugin. This variable is unavailable unless that plugin is installed. To specify the credentials, set the keyring_hashicorp_role_id and keyring_hashicorp_secret_id system variables (for example, as shown in keyring_hashicorp Configuration).

This variable is mandatory. If not specified, keyring_hashicorp initialization fails.

- **keyring_oci_ca_certificate**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-oci-ca-certificate=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>keyring_oci_ca_certificate</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>empty string</td>
</tr>
</tbody>
</table>

The path name of the CA certificate bundle file that the keyring_oci plugin uses for Oracle Cloud Infrastructure certificate verification. This variable is unavailable unless that plugin is installed.

The file contains one or more certificates for peer verification. If no file is specified, the default CA bundle installed on the system is used. If the value is disabled (case-sensitive), keyring_oci performs no certificate verification.

- **keyring_oci_compartment**
### The MySQL Keyring

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--keyring-oci-compartment=ocid</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>keyring_oci_compartment</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The OCID of the tenancy compartment that the `keyring_oci` plugin uses as the location of the MySQL keys. This variable is unavailable unless that plugin is installed.

Prior to using `keyring_oci`, you must create a MySQL compartment or subcompartment if it does not exist. This compartment should contain no vault keys or vault secrets. It should not be used by systems other than MySQL Keyring.

For information about managing compartments and obtaining the OCID, see [Managing Compartments](#).

This variable is mandatory. If not specified, `keyring_oci` initialization fails.

- `keyring_oci_encryption_endpoint`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--keyring-oci-encryption-endpoint=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>keyring_oci_encryption_endpoint</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The endpoint of the Oracle Cloud Infrastructure encryption server that the `keyring_oci` plugin uses for generating ciphertext for new keys. This variable is unavailable unless that plugin is installed.

The encryption endpoint is vault specific and Oracle Cloud Infrastructure assigns it at vault-creation time. To obtain the endpoint OCID, view the configuration details for your `keyring_oci` vault, using the instructions at [Managing Vaults](#).

This variable is mandatory. If not specified, `keyring_oci` initialization fails.

- `keyring_oci_key_file`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--keyring-oci-key-file=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>keyring_oci_key_file</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td></td>
</tr>
</tbody>
</table>
The MySQL Keyring

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
</table>

The path name of the file containing the RSA private key that the `keyring_oci` plugin uses for Oracle Cloud Infrastructure authentication. This variable is unavailable unless that plugin is installed.

You must also upload the corresponding RSA public key using the Console. The Console displays the key fingerprint value, which you can use to set the `keyring_oci_key_fingerprint` system variable.

For information about generating and uploading API keys, see Required Keys and OCIDs.

This variable is mandatory. If not specified, `keyring_oci` initialization fails.

- `keyring_oci_key_fingerprint`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--keyring-oci-key-fingerprint=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>keyring_oci_key_fingerprint</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The fingerprint of the RSA private key that the `keyring_oci` plugin uses for Oracle Cloud Infrastructure authentication. This variable is unavailable unless that plugin is installed.

To obtain the key fingerprint while creating the API keys, execute this command:

```
openssl rsa -pubout -outform DER -in ~/.oci/oci_api_key.pem | openssl md5 -c
```

Alternatively, obtain the fingerprint from the Console, which automatically displays the fingerprint when you upload the RSA public key.

For information about obtaining key fingerprints, see Required Keys and OCIDs.

This variable is mandatory. If not specified, `keyring_oci` initialization fails.

- `keyring_oci_management_endpoint`

<table>
<thead>
<tr>

</tbody>
</table>
The MySQL Keyring

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
</table>

The endpoint of the Oracle Cloud Infrastructure key management server that the `keyring_oci` plugin uses for listing existing keys. This variable is unavailable unless that plugin is installed.

The key management endpoint is vault specific and Oracle Cloud Infrastructure assigns it at vault-creation time. To obtain the endpoint OCID, view the configuration details for your `keyring_oci` vault, using the instructions at Managing Vaults.

This variable is mandatory. If not specified, `keyring_oci` initialization fails.

• `keyring_oci_master_key`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--keyring-oci-master-key=ocid</code></th>

</tr>
</tbody>
</table>

The OCID of the Oracle Cloud Infrastructure master encryption key that the `keyring_oci` plugin uses for encryption of secrets. This variable is unavailable unless that plugin is installed.

Prior to using `keyring_oci`, you must create a cryptographic key for the Oracle Cloud Infrastructure compartment if it does not exist. Provide a MySQL-specific name for the generated key, and do not use it for other purposes.

For information about key creation, see Managing Keys.

This variable is mandatory. If not specified, `keyring_oci` initialization fails.

• `keyring_oci_secrets_endpoint`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--keyring-oci-secrets-endpoint=value</code></th>

</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The OCID of the Oracle Cloud Infrastructure Vault that the `keyring_oci` plugin uses for encryption operations. This variable is unavailable unless that plugin is installed.

Prior to using `keyring_oci`, you must create a new vault in the MySQL compartment if it does not exist. (Alternatively, you can reuse an existing vault that is in a parent compartment of the MySQL compartment.) Compartment users can see and use only the keys in their respective compartments.

For information about creating a vault and obtaining the vault OCID, see Managing Vaults.

This variable is mandatory. If not specified, `keyring_oci` initialization fails.

- `keyring_okv_conf_dir`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--keyring-okv-conf-dir=dir_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>keyring_okv_conf_dir</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td>empty string</td>
</tr>
</tbody>
</table>

The path name of the directory that stores configuration information used by the `keyring_okv` plugin. This variable is unavailable unless that plugin is installed. The location should be a directory considered for use only by the `keyring_okv` plugin. For example, do not locate the directory under the data directory.

The default `keyring_okv_conf_dir` value is empty. For the `keyring_okv` plugin to be able to access Oracle Key Vault, the value must be set to a directory that contains Oracle Key Vault.
configuration and SSL materials. For instructions on setting up this directory, see Section 6.4.4.8, “Using the keyring_okv KMIP Plugin”.

The directory should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use the /usr/local/mysql/mysql-keyring-okv directory, the following commands (executed as root) create the directory and set its mode and ownership:

```
cd /usr/local/mysql
mkdir mysql-keyring-okv
chmod 750 mysql-keyring-okv
chown mysql mysql-keyring-okv
chgrp mysql mysql-keyring-okv
```

If the value assigned to keyring_okv_conf_dir specifies a directory that does not exist, or that does not contain configuration information that enables a connection to Oracle Key Vault to be established, keyring_okv writes an error message to the error log. If an attempted runtime assignment to keyring_okv_conf_dir results in an error, the variable value and keyring operation remain unchanged.

- **keyring_operations**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>keyring_operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

Whether keyring operations are enabled. This variable is used during key migration operations. See Section 6.4.4.14, “Migrating Keys Between Keyring Keystores”. The privileges required to modify this variable are ENCRYPTION_KEY_ADMIN in addition to either SYSTEM_VARIABLES_ADMIN or the deprecated SUPER privilege.

### 6.4.5 MySQL Enterprise Audit

MySQL Enterprise Audit is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see [https://www.mysql.com/products/](https://www.mysql.com/products/).

MySQL Enterprise Edition includes MySQL Enterprise Audit, implemented using a server plugin named audit_log. MySQL Enterprise Audit uses the open MySQL Audit API to enable standard, policy-based monitoring, logging, and blocking of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines.

When installed, the audit plugin enables MySQL Server to produce a log file containing an audit record of server activity. The log contents include when clients connect and disconnect, and what actions they perform while connected, such as which databases and tables they access. You can add statistics for the time and size of each query to detect outliers.
By default, MySQL Enterprise Audit uses tables in the mysql system database for persistent storage of filter and user account data. To use a different database, set the audit_log_database system variable at server startup.

After you install the audit plugin (see Section 6.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”), it writes an audit log file. By default, the file is named audit.log in the server data directory. To change the name of the file, set the audit_log_file system variable at server startup.

By default, audit log file contents are written in new-style XML format, without compression or encryption. To select the file format, set the audit_log_format system variable at server startup. For details on file format and contents, see Section 6.4.5.4, “Audit Log File Formats”.

For more information about controlling how logging occurs, including audit log file naming and format selection, see Section 6.4.5.5, “Configuring Audit Logging Characteristics”. To perform filtering of audited events, see Section 6.4.5.7, “Audit Log Filtering”. For descriptions of the parameters used to configure the audit log plugin, see Audit Log Options and Variables.

If the audit log plugin is enabled, the Performance Schema (see Chapter 27, MySQL Performance Schema) has instrumentation for it. To identify the relevant instruments, use this query:

```
SELECT NAME FROM performance_schema.setup_instruments
WHERE NAME LIKE '*/alog/*';
```

## 6.4.5.1 Elements of MySQL Enterprise Audit

MySQL Enterprise Audit is based on the audit log plugin and related elements:

- A server-side plugin named audit_log examines auditable events and determines whether to write them to the audit log.

- A set of functions enables manipulation of filtering definitions that control logging behavior, the encryption password, and log file reading.

- Tables in the mysql system database provide persistent storage of filter and user account data, unless you set the audit_log_database system variable at server startup to specify a different database.

- System variables enable audit log configuration and status variables provide runtime operational information.

- The AUDIT_ADMIN privilege enable users to administer the audit log, and the AUDIT_ABORT_EXEMPT privilege enables system users to execute queries that would otherwise be blocked by an “abort” item in the audit log filter.

## 6.4.5.2 Installing or Uninstalling MySQL Enterprise Audit

This section describes how to install or uninstall MySQL Enterprise Audit, which is implemented using the audit log plugin and related elements described in Section 6.4.5.1, “Elements of MySQL Enterprise Audit”. For general information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

Plugin upgrades are not automatic when you upgrade a MySQL installation and some plugin loadable functions must be loaded manually (see Installing Loadable Functions). Alternatively, you can reinstall the plugin after upgrading MySQL to load new functions.

---

**Important**

Read this entire section before following its instructions. Parts of the procedure differ depending on your environment.
If installed, the audit_log plugin involves some minimal overhead even when disabled. To avoid this overhead, do not install MySQL Enterprise Audit unless you plan to use it.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the plugin_dir system variable). If necessary, configure the plugin directory location by setting the value of plugin_dir at server startup.

To install MySQL Enterprise Audit, look in the share directory of your MySQL installation and choose the script that is appropriate for your platform. The available scripts differ in the file name used to refer to the script:

- audit_log_filter_win_install.sql
- audit_log_filter_linux_install.sql

Run the script as follows. The example here uses the Linux installation script and the default mysql system database. Make the appropriate substitution for your system.

```bash
$> mysql -u root -p -D mysql < audit_log_filter_linux_install.sql
Enter password: (enter root password here)
```

It is possible to specify a custom database for storing JSON filter tables when you run the installation script. Create the database first; its name should not exceed 64 characters. For example:

```sql
mysql> CREATE DATABASE IF NOT EXISTS database-name;
```

Next, run the script using the alternative database name.

```bash
$> mysql -u root -p -D database-name < audit_log_filter_linux_install.sql
Enter password: (enter root password here)
```

Some MySQL versions have introduced changes to the structure of the MySQL Enterprise Audit tables. To ensure that your tables are up to date for upgrades from earlier versions of MySQL, perform the MySQL upgrade procedure, making sure to use the option that forces an update (see Section 2.10, “Upgrading MySQL”). If you prefer to run the update statements only for the MySQL Enterprise Audit tables, see the following discussion.

For new MySQL installations, the USER and HOST columns in the audit_log_user table used by MySQL Enterprise Audit have definitions that better correspond to the definitions of the User and Host columns in the mysql.user system table. For upgrades to an installation for which MySQL Enterprise Audit is already installed, it is recommended that you alter the table definitions as follows:

```sql
ALTER TABLE mysql.audit_log_user
    DROP FOREIGN KEY audit_log_user_ibfk_1;
ALTER TABLE mysql.audit_log_filter
    CONVERT TO CHARACTER SET utf8mb4 COLLATE utf8mb4_0900_as_ci;
ALTER TABLE mysql.audit_log_user
    CONVERT TO CHARACTER SET utf8mb4 COLLATE utf8mb4_0900_as_ci;
ALTER TABLE mysql.audit_log_user
    MODIFY COLUMN USER VARCHAR(32);
ALTER TABLE mysql.audit_log_user
```
ADD FOREIGN KEY (FILTERNAME) REFERENCES mysql.audit_log_filter(NAME);

### Note

To use MySQL Enterprise Audit in the context of source/replica replication, Group Replication, or InnoDB Cluster, you must prepare the replica nodes prior to running the installation script on the source node. This is necessary because the `INSTALL PLUGIN` statement in the script is not replicated.

1. On each replica node, extract the `INSTALL PLUGIN` statement from the installation script and execute it manually.
2. On the source node, run the installation script as described previously.

To verify plugin installation, examine the Information Schema `PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE 'audit%';
```

<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>PLUGIN_STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>audit_log</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>

If the plugin fails to initialize, check the server error log for diagnostic messages.

After MySQL Enterprise Audit is installed, you can use the `--audit-log` option for subsequent server startups to control `audit_log` plugin activation. For example, to prevent the plugin from being removed at runtime, use this option:

```
[mysqld]
audit-log=FORCE_PLUS_PERMANENT
```

If it is desired to prevent the server from running without the audit plugin, use `--audit-log` with a value of `FORCE` or `FORCE_PLUS_PERMANENT` to force server startup to fail if the plugin does not initialize successfully.

### Important

By default, rule-based audit log filtering logs no auditable events for any users. This differs from legacy audit log behavior, which logs all auditable events for all users (see Section 6.4.5.10, “Legacy Mode Audit Log Filtering”). Should you wish to produce log-everything behavior with rule-based filtering, create a simple filter to enable logging and assign it to the default account:

```
SELECT audit_log_filter_set_filter('log_all', '{ "filter": { "log": true } });
SELECT audit_log_filter_set_user('%', 'log_all');
```

The filter assigned to `%` is used for connections from any account that has no explicitly assigned filter (which initially is true for all accounts).

When installed as just described, MySQL Enterprise Audit remains installed until uninstalled. To remove it, run the uninstall script located in the `share` directory of your MySQL installation. The example here specifies the default system database, `mysql`. Make the appropriate substitution for your system.

```
$> mysql -u root -p -D mysql < audit_log_filter_uninstall.sql
Enter password: (enter root password here)
```

1547
6.4.5.3 MySQL Enterprise Audit Security Considerations

By default, contents of audit log files produced by the audit log plugin are not encrypted and may contain sensitive information, such as the text of SQL statements. For security reasons, audit log files should be written to a directory accessible only to the MySQL server and to users with a legitimate reason to view the log. The default file name is `audit.log` in the data directory. This can be changed by setting the `audit_log_file` system variable at server startup. Other audit log files may exist due to log rotation.

For additional security, enable audit log file encryption. See Encrypting Audit Log Files.

6.4.5.4 Audit Log File Formats

The MySQL server calls the audit log plugin to write an audit record to its log file whenever an auditable event occurs. Typically the first audit record written after plugin startup contains the server description and startup options. Elements following that one represent events such as client connect and disconnect events, executed SQL statements, and so forth. Only top-level statements are logged, not statements within stored programs such as triggers or stored procedures. Contents of files referenced by statements such as `LOAD DATA` are not logged.

To select the log format that the audit log plugin uses to write its log file, set the `audit_log_format` system variable at server startup. These formats are available:

- **New-style XML format** (`audit_log_format=NEW`): An XML format that has better compatibility with Oracle Audit Vault than old-style XML format. MySQL 8.2 uses new-style XML format by default.
- **Old-style XML format** (`audit_log_format=OLD`): The original audit log format used by default in older MySQL series.
- **JSON format** (`audit_log_format=JSON`): Writes the audit log as a JSON array. Only this format supports the optional query time and size statistics.

By default, audit log file contents are written in new-style XML format, without compression or encryption.

If you change `audit_log_format`, it is recommended that you also change `audit_log_file`. For example, if you set `audit_log_format` to JSON, set `audit_log_file` to `audit.json`. Otherwise, newer log files will have a different format than older files, but they will all have the same base name with nothing to indicate when the format changed.

- **New-Style XML Audit Log File Format**
- **Old-Style XML Audit Log File Format**
- **JSON Audit Log File Format**

**New-Style XML Audit Log File Format**

Here is a sample log file in new-style XML format (`audit_log_format=NEW`), reformatted slightly for readability:

```xml
<?xml version="1.0" encoding="utf-8"?>
<AUDIT>
  <AUDIT_RECORD>
    <TIMESTAMP>2019-10-03T14:06:33 UTC</TIMESTAMP>
    <RECORD_ID>1_2019-10-03T14:06:33</RECORD_ID>
    <NAME>Audit</NAME>
    <SERVER_ID>1</SERVER_ID>
    <VERSION>1</VERSION>
    <STARTUP_OPTIONS>/usr/local/mysql/bin/mysqld
                    --socket=/usr/local/mysql/mysql.sock
                    --port=3306</STARTUP_OPTIONS>
    <OS_VERSION>i686-Linux</OS_VERSION>
</AUDIT>```
<AUDIT_RECORD>
  <TIMESTAMP>2019-10-03T14:09:38 UTC</TIMESTAMP>
  <RECORD_ID>2_2019-10-03T14:06:33</RECORD_ID>

  <SQLTEXT>DROP TABLE IF EXISTS t</SQLTEXT>
</AUDIT_RECORD>

<AUDIT_RECORD>
  <TIMESTAMP>2019-10-03T14:09:39 UTC</TIMESTAMP>
  <RECORD_ID>8_2019-10-03T14:06:33</RECORD_ID>
  <NAME>Quit</NAME>
  <CONNECTION_ID>5</CONNECTION_ID>
  <STATUS>0</STATUS>
  <STATUS_CODE>0</STATUS_CODE>
  <USER>root</USER>
  <OS_LOGIN/>
  <HOST>localhost</HOST>
  <IP>127.0.0.1</IP>
  <COMMAND_CLASS>connect</COMMAND_CLASS>
  <CONNECTION_TYPE>SSL/TLS</CONNECTION_TYPE>
</AUDIT_RECORD>

...
The audit log file is written as XML, using UTF-8 (up to 4 bytes per character). The root element is `<AUDIT>`. The root element contains `<AUDIT_RECORD>` elements, each of which provides information about an audited event. When the audit log plugin begins writing a new log file, it writes the XML declaration and opening `<AUDIT>` root element tag. When the plugin closes a log file, it writes the closing `</AUDIT>` root element tag. The closing tag is not present while the file is open.

Elements within `<AUDIT_RECORD>` elements have these characteristics:

- Some elements appear in every `<AUDIT_RECORD>` element. Others are optional and may appear depending on the audit record type.
- Order of elements within an `<AUDIT_RECORD>` element is not guaranteed.
- Element values are not fixed length. Long values may be truncated as indicated in the element descriptions given later.
- The `<`, `>`, `"`, and `&` characters are encoded as `&lt;`, `&gt;`, `&quot;`, and `&amp;`, respectively. NUL bytes (U+00) are encoded as the `?` character.
- Characters not valid as XML characters are encoded using numeric character references. Valid XML characters are:

```
#x9 | #xA | #xD | [#x20-#xD7FF] | [#xE000-#xFFFD] | [#x10000-#x10FFFF]
```

The following elements are mandatory in every `<AUDIT_RECORD>` element:

- `<NAME>`

A string representing the type of instruction that generated the audit event, such as a command that the server received from a client.

Example:

```
<NAME>Query</NAME>
```

Some common `<NAME>` values:

- **Audit** When auditing starts, which may be server startup time
- **Connect** When a client connects, also known as logging in
MySQL Enterprise Audit

<table>
<thead>
<tr>
<th>Event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Query</td>
<td>An SQL statement (executed directly)</td>
</tr>
<tr>
<td>Prepare</td>
<td>Preparation of an SQL statement; usually followed by Execute</td>
</tr>
<tr>
<td>Execute</td>
<td>Execution of an SQL statement; usually follows Prepare</td>
</tr>
<tr>
<td>Shutdown</td>
<td>Server shutdown</td>
</tr>
<tr>
<td>Quit</td>
<td>When a client disconnects</td>
</tr>
<tr>
<td>NoAudit</td>
<td>Auditing has been turned off</td>
</tr>
</tbody>
</table>

The possible values are Audit, Binlog Dump, Change user, Close stmt, Connect Out, Connect, Create DB, Daemon, Debug, Delayed insert, Drop DB, Execute, Fetch, Field List, Init DB, Kill, Long Data, NoAudit, Ping, Prepare, Processlist, Query, Quit, Refresh, Register Slave, Reset stmt, Set option, Shutdown, Sleep, Statistics, Table Dump, TableDelete, TableInsert, TableRead, TableUpdate, Time.

Many of these values correspond to the COM_xxx command values listed in the my_command.h header file. For example, Create DB and Change user correspond to COM_CREATE_DB and COM_CHANGE_USER, respectively.

Events having <NAME> values of TableXXX accompany Query events. For example, the following statement generates one Query event, two TableRead events, and a TableInsert events:

```
INSERT INTO t3 SELECT t1.* FROM t1 JOIN t2;
```

Each TableXXX event contains <TABLE> and <DB> elements to identify the table to which the event refers and the database that contains the table.

- **<RECORD_ID>**
  
  A unique identifier for the audit record. The value is composed from a sequence number and timestamp, in the format SEQ_TIMESTAMP. When the audit log plugin opens the audit log file, it initializes the sequence number to the size of the audit log file, then increments the sequence by 1 for each record logged. The timestamp is a UTC value in YYYY-MM-DDThh:mm:ss format indicating the date and time when the audit log plugin opened the file.

  Example:

  `<RECORD_ID>12_2019-10-03T14:06:33</RECORD_ID>`

- **<TIMESTAMP>**
  
  A string representing a UTC value in YYYY-MM-DDThh:mm:ss UTC format indicating the date and time when the audit event was generated. For example, the event corresponding to execution of an SQL statement received from a client has a <TIMESTAMP> value occurring after the statement finishes, not when it was received.

  Example:

  `<TIMESTAMP>2019-10-03T14:09:45 UTC</TIMESTAMP>`

The following elements are optional in <AUDIT_RECORD> elements. Many of them occur only with specific <NAME> element values.

- **<COMMAND_CLASS>**
  
  A string that indicates the type of action performed.

  Example:

  `<COMMAND_CLASS>drop_table</COMMAND_CLASS>`
The values correspond to the `statement/sql/xxx` command counters. For example, `xxx` is `drop_table` and `select` for `DROP TABLE` and `SELECT` statements, respectively. The following statement displays the possible names:

```
SELECT REPLACE(EVENT_NAME, 'statement/sql/', '') AS name
FROM performance_schema.events_statements_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'statement/sql/%'
ORDER BY name;
```

• **<CONNECTION_ATTRIBUTES>**

Events with a `<COMMAND_CLASS>` value of `connect` may include a `<CONNECTION_ATTRIBUTES>` element to display the connection attributes passed by the client at connect time. (For information about these attributes, which are also exposed in Performance Schema tables, see Section 27.12.9, “Performance Schema Connection Attribute Tables”.)

The `<CONNECTION_ATTRIBUTES>` element contains one `<ATTRIBUTE>` element per attribute, each of which contains `<NAME>` and `<VALUE>` elements to indicate the attribute name and value, respectively.

Example:

```
<CONNECTION_ATTRIBUTES>
ATTRIBUTE
  NAME_pid
  VALUE 42794
ATTRIBUTE
  NAME_os
  VALUE macos0.14
ATTRIBUTE
  NAME_platform
  VALUE x86_64
ATTRIBUTE
  NAME_client_version
  VALUE 8.1.0
ATTRIBUTE
  NAME_client_name
  VALUE libmysql
ATTRIBUTE
  NAME_program_name
  VALUE mysqladmin
</CONNECTION_ATTRIBUTES>
```

If no connection attributes are present in the event, none are logged and no `<CONNECTION_ATTRIBUTES>` element appears. This can occur if the connection attempt is unsuccessful, the client passes no attributes, or the connection occurs internally such as during server startup or when initiated by a plugin.

• **<CONNECTION_ID>**

An unsigned integer representing the client connection identifier. This is the same as the value returned by the `CONNECTION_ID()` function within the session.

Example:

```
<CONNECTION_ID>123</CONNECTION_ID>
```
• `<CONNECTION_TYPE>`

The security state of the connection to the server. Permitted values are TCP/IP (TCP/IP connection established without encryption), SSL/TLS (TCP/IP connection established with encryption), Socket (Unix socket file connection), Named Pipe (Windows named pipe connection), and Shared Memory (Windows shared memory connection).

Example:

```xml
<CONNECTION_TYPE>SSL/TLS</CONNECTION_TYPE>
```

• `<DB>`

A string representing a database name.

Example:

```xml
<DB>test</DB>
```

For connect events, this element indicates the default database; the element is empty if there is no default database. For table-access events, the element indicates the database to which the accessed table belongs.

• `<HOST>`

A string representing the client host name.

Example:

```xml
<HOST>localhost</HOST>
```

• `<IP>`

A string representing the client IP address.

Example:

```xml
<IP>127.0.0.1</IP>
```

• `<MYSQL_VERSION>`

A string representing the MySQL server version. This is the same as the value of the `VERSION()` function or `version` system variable.

Example:

```xml
<MYSOL_VERSION>5.7.21-log</MYSQL_VERSION>
```

• `<OS_LOGIN>`

A string representing the external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this element is empty. The value is the same as that of the `external_user` system variable (see Section 6.2.19, “Proxy Users”).

Example:

```xml
<OS_LOGIN>jeffrey</OS_LOGIN>
```

• `<OS_VERSION>`
A string representing the operating system on which the server was built or is running.

Example:

```
<OS_VERSION>x86_64-Linux</OS_VERSION>
```

- `<PRIV_USER>`

A string representing the user that the server authenticated the client as. This is the user name that the server uses for privilege checking, and may differ from the `<USER>` value.

Example:

```
<PRIV_USER>jeffrey</PRIV_USER>
```

- `<PROXY_USER>`

A string representing the proxy user (see Section 6.2.19, “Proxy Users”). The value is empty if user proxying is not in effect.

Example:

```
<PROXY_USER>developer</PROXY_USER>
```

- `<SERVER_ID>`

An unsigned integer representing the server ID. This is the same as the value of the `server_id` system variable.

Example:

```
.SERVER_ID>1</SERVER_ID>
```

- `<SQLTEXT>`

A string representing the text of an SQL statement. The value can be empty. Long values may be truncated. The string, like the audit log file itself, is written using UTF-8 (up to 4 bytes per character), so the value may be the result of conversion. For example, the original statement might have been received from the client as an SJIS string.

Example:

```
<SQLTEXT>DELETE FROM t1</SQLTEXT>
```

- `<STARTUP_OPTIONS>`

A string representing the options that were given on the command line or in option files when the MySQL server was started. The first option is the path to the server executable.

Example:

```
<STARTUP_OPTIONS>/usr/local/mysql/bin/mysqld
--port=3306 --log_output=FILE</STARTUP_OPTIONS>
```

- `<STATUS>`

An unsigned integer representing the command status: 0 for success, nonzero if an error occurred. This is the same as the value of the `mysql_errno()` C API function. See the description for `<STATUS_CODE>` for information about how it differs from `<STATUS>`. 
The audit log does not contain the SQLSTATE value or error message. To see the associations between error codes, SQLSTATE values, and messages, see Server Error Message Reference.

Warnings are not logged.

Example:

```xml
<STATUS>1051</STATUS>
```

- **<STATUS_CODE>**

  An unsigned integer representing the command status: 0 for success, 1 if an error occurred.

  The STATUS_CODE value differs from the STATUS value: STATUS_CODE is 0 for success and 1 for error, which is compatible with the EZ_collector consumer for Audit Vault. STATUS is the value of the mysql_errno() C API function. This is 0 for success and nonzero for error, and thus is not necessarily 1 for error.

  Example:

  ```xml
  <STATUS_CODE>0</STATUS_CODE>
  ```

- **<TABLE>**

  A string representing a table name.

  Example:

  ```xml
  <TABLE>t3</TABLE>
  ```

- **<USER>**

  A string representing the user name sent by the client. This may differ from the <PRIV_USER> value.

  Example:

  ```xml
  <USER>root[root] @ localhost [127.0.0.1]</USER>
  ```

- **<VERSION>**

  An unsigned integer representing the version of the audit log file format.

  Example:

  ```xml
  <VERSION>1</VERSION>
  ```

### Old-Style XML Audit Log File Format

Here is a sample log file in old-style XML format (audit_log_format=OLD), reformatted slightly for readability:

```xml
<?xml version="1.0" encoding="utf-8"?>
<AUDIT>
  <AUDIT_RECORD
    TIMESTAMP="2019-10-03T14:25:00 UTC"
    RECORD_ID="1_2019-10-03T14:25:00"
    NAME="Audit"
    SERVER_ID="1"
    VERSION="1"
    STARTUP_OPTIONS="--port=3306"
  
```

```xml
</AUDIT>
```
The audit log file is written as XML, using UTF-8 (up to 4 bytes per character). The root element is <AUDIT>. The root element contains <AUDIT_RECORD> elements, each of which provides information about an audited event. When the audit log plugin begins writing a new log file, it writes the XML declaration and opening <AUDIT> root element tag. When the plugin closes a log file, it writes the closing </AUDIT> root element tag. The closing tag is not present while the file is open.

Attributes of <AUDIT_RECORD> elements have these characteristics:
Some attributes appear in every `<AUDIT_RECORD>` element. Others are optional and may appear depending on the audit record type.

Order of attributes within an `<AUDIT_RECORD>` element is not guaranteed.

Attribute values are not fixed length. Long values may be truncated as indicated in the attribute descriptions given later.

The `<`, `>`, `"`, and `&` characters are encoded as `<`, `>`, `"`, and `&`, respectively. NUL bytes (U+00) are encoded as the `?` character.

Characters not valid as XML characters are encoded using numeric character references. Valid XML characters are:

<table>
<thead>
<tr>
<th>Hex</th>
<th>Decimal</th>
</tr>
</thead>
<tbody>
<tr>
<td>#x9</td>
<td>9</td>
</tr>
<tr>
<td>#xA</td>
<td>10</td>
</tr>
<tr>
<td>#xD</td>
<td>13</td>
</tr>
<tr>
<td>[#x20-#xD7FF]</td>
<td></td>
</tr>
<tr>
<td>[#x10000-#x10FFFF]</td>
<td></td>
</tr>
</tbody>
</table>

The following attributes are mandatory in every `<AUDIT_RECORD>` element:

- **NAME**
  
  A string representing the type of instruction that generated the audit event, such as a command that the server received from a client.

  Example: `NAME="Query"

Some common `NAME` values:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Audit</td>
<td>When auditing starts, which may be server startup time</td>
</tr>
<tr>
<td>Connect</td>
<td>When a client connects, also known as logging in</td>
</tr>
<tr>
<td>Query</td>
<td>An SQL statement (executed directly)</td>
</tr>
<tr>
<td>Prepare</td>
<td>Preparation of an SQL statement; usually followed by Prepare</td>
</tr>
<tr>
<td>Execute</td>
<td>Execution of an SQL statement; usually follows Prepare</td>
</tr>
<tr>
<td>Shutdown</td>
<td>Server shutdown</td>
</tr>
<tr>
<td>Quit</td>
<td>When a client disconnects</td>
</tr>
<tr>
<td>NoAudit</td>
<td>Auditing has been turned off</td>
</tr>
</tbody>
</table>

The possible values are Audit, Binlog Dump, Change user, Close stmt, Connect Out, Connect, Create DB, Daemon, Debug, Delayed insert, Drop DB, Execute, Fetch, Field List, Init DB, Kill, Long Data, NoAudit, Ping, Prepare, Processlist, Query, Quit, Refresh, Register Slave, Reset stmt, Set option, Shutdown, Sleep, Statistics, Table Dump, TableDelete, TableInsert, TableRead, TableUpdate, Time.

Many of these values correspond to the COM_xxx command values listed in the my_command.h header file. For example, "Create DB" and "Change user" correspond to COM_CREATE_DB and COM_CHANGE_USER, respectively.

Events having `NAME` values of `TableXXX` accompany `Query` events. For example, the following statement generates one `Query` event, two `TableRead` events, and a `TableInsert` events:

```sql
INSERT INTO t3 SELECT t1.* FROM t1 JOIN t2;
```

Each `TableXXX` event has `TABLE` and `DB` attributes to identify the table to which the event refers and the database that contains the table.

`Connect` events for old-style XML audit log format do not include connection attributes.

- **RECORD_ID**
  
  A unique identifier for the audit record. The value is composed from a sequence number and timestamp, in the format `SEQ_TIMESTAMP`. When the audit log plugin opens the audit log file, it initializes the
sequence number to the size of the audit log file, then increments the sequence by 1 for each record logged. The timestamp is a UTC value in \texttt{YYYY-MM-DDThh:mm:ss} format indicating the date and time when the audit log plugin opened the file.

Example: \texttt{RECORD_ID="12_2019-10-03T14:25:00"}

- \textbf{TIMESTAMP}

A string representing a UTC value in \texttt{YYYY-MM-DDThh:mm:ss} UTC format indicating the date and time when the audit event was generated. For example, the event corresponding to execution of an SQL statement received from a client has a \texttt{TIMESTAMP} value occurring after the statement finishes, not when it was received.

Example: \texttt{TIMESTAMP="2019-10-03T14:25:32 UTC"}

The following attributes are optional in \texttt{<AUDIT_RECORD>} elements. Many of them occur only for elements with specific values of the \texttt{NAME} attribute.

- \textbf{COMMAND_CLASS}

A string that indicates the type of action performed.

Example: \texttt{COMMAND_CLASS="drop_table"}

The values correspond to the \texttt{statement/sql/xxx} command counters. For example, \texttt{xxx} is \texttt{drop_table} and \texttt{select} for \texttt{DROP TABLE} and \texttt{SELECT} statements, respectively. The following statement displays the possible names:

\begin{verbatim}
SELECT REPLACE(EVENT_NAME, 'statement/sql/', '') AS name
FROM performance_schema.events_statements_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'statement/sql/%'
ORDER BY name;
\end{verbatim}

- \textbf{CONNECTION_ID}

An unsigned integer representing the client connection identifier. This is the same as the value returned by the \texttt{CONNECTION_ID()} function within the session.

Example: \texttt{CONNECTION_ID="127"}

- \textbf{CONNECTION_TYPE}

The security state of the connection to the server. Permitted values are \texttt{TCP/IP} (TCP/IP connection established without encryption), \texttt{SSL/TLS} (TCP/IP connection established with encryption), \texttt{Socket} (Unix socket file connection), \texttt{Named Pipe} (Windows named pipe connection), and \texttt{Shared Memory} (Windows shared memory connection).

Example: \texttt{CONNECTION_TYPE="SSL/TLS"}

- \textbf{DB}

A string representing a database name.

Example: \texttt{DB="test"}

For connect events, this attribute indicates the default database; the attribute is empty if there is no default database. For table-access events, the attribute indicates the database to which the accessed table belongs.
• **HOST**
  A string representing the client host name.
  Example: `HOST="localhost"`

• **IP**
  A string representing the client IP address.
  Example: `IP="127.0.0.1"`

• **MYSQL_VERSION**
  A string representing the MySQL server version. This is the same as the value of the `VERSION()` function or `version` system variable.
  Example: `MYSQL_VERSION="5.7.21-log"`

• **OS_LOGIN**
  A string representing the external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this attribute is empty. The value is the same as that of the `external_user` system variable (see Section 6.2.19, “Proxy Users”).
  Example: `OS_LOGIN="jeffrey"`

• **OS_VERSION**
  A string representing the operating system on which the server was built or is running.
  Example: `OS_VERSION="x86_64-Linux"`

• **PRIV_USER**
  A string representing the user that the server authenticated the client as. This is the user name that the server uses for privilege checking, and it may differ from the `USER` value.
  Example: `PRIV_USER="jeffrey"`

• **PROXY_USER**
  A string representing the proxy user (see Section 6.2.19, “Proxy Users”). The value is empty if user proxying is not in effect.
  Example: `PROXY_USER="developer"`

• **SERVER_ID**
  An unsigned integer representing the server ID. This is the same as the value of the `server_id` system variable.
  Example: `SERVER_ID="1"`

• **SQLTEXT**
  A string representing the text of an SQL statement. The value can be empty. Long values may be truncated. The string, like the audit log file itself, is written using UTF-8 (up to 4 bytes per character), so
the value may be the result of conversion. For example, the original statement might have been received from the client as an SJIS string.

Example: SQLTEXT="DELETE FROM t1"

- **STARTUP_OPTIONS**

A string representing the options that were given on the command line or in option files when the MySQL server was started.

Example: STARTUP_OPTIONS="--port=3306 --log_output=FILE"

- **STATUS**

An unsigned integer representing the command status: 0 for success, nonzero if an error occurred. This is the same as the value of the mysql_errno() C API function. See the description for STATUS_CODE for information about how it differs from STATUS.

The audit log does not contain the SQLSTATE value or error message. To see the associations between error codes, SQLSTATE values, and messages, see Server Error Message Reference.

Warnings are not logged.

Example: STATUS="1051"

- **STATUS_CODE**

An unsigned integer representing the command status: 0 for success, 1 if an error occurred.

The STATUS_CODE value differs from the STATUS value: STATUS_CODE is 0 for success and 1 for error, which is compatible with the EZ_collector consumer for Audit Vault. STATUS is the value of the mysql_errno() C API function. This is 0 for success and nonzero for error, and thus is not necessarily 1 for error.

Example: STATUS_CODE="0"

- **TABLE**

A string representing a table name.

Example: TABLE="t3"

- **USER**

A string representing the user name sent by the client. This may differ from the PRIV_USER value.

- **VERSION**

An unsigned integer representing the version of the audit log file format.

Example: VERSION="1"

### JSON Audit Log File Format

For JSON-format audit logging (audit_log_format=JSON), the log file contents form a JSON array with each array element representing an audited event as a JSON hash of key-value pairs. Examples of complete event records appear later in this section. The following is an excerpt of partial events:

```json
[...
```
The audit log file is written using UTF-8 (up to 4 bytes per character). When the audit log plugin begins writing a new log file, it writes the opening [array marker. When the plugin closes a log file, it writes the closing ] array marker. The closing marker is not present while the file is open.

Items within audit records have these characteristics:

• Some items appear in every audit record. Others are optional and may appear depending on the audit record type.

• Order of items within an audit record is not guaranteed.

• Item values are not fixed length. Long values may be truncated as indicated in the item descriptions given later.

• The " and \ characters are encoded as \" and \, respectively.

JSON format is the only audit log file format that supports the optional query time and size statistics. This data is available in the slow query log for qualifying queries, and in the context of the audit log it similarly helps to detect outliers for activity analysis.

To add the query statistics to the log file, you must set them up as a filter using the
\audit_log_filter_set_filter()\ audit log function as the service element of the JSON filtering syntax. For instructions to do this, see \Adding Query Statistics for Outlier Detection\. For the \bytes_sent\ and \bytes_received\ fields to be populated, the system variable \log_slow_extra\ must be set to ON.

The following examples show the JSON object formats for different event types (as indicated by the \class\ and \event\ items), reformatted slightly for readability:

Auditing startup event:

```
{ 
  "timestamp": "2019-10-03 14:21:56",
  "id": 0,
  "class": "audit",
  "event": "startup",
  "startup_data": { 
    "server_id": 1,
    "os_version": "i686-Linux",
    "mysql_version": "5.7.21-log",
    "args": ["/usr/local/mysql/bin/mysqld",
```
When the audit log plugin starts as a result of server startup (as opposed to being enabled at runtime), connection_id is set to 0, and account and login are not present.

Auditing shutdown event:

```
{ "timestamp": "2019-10-03 14:28:20",
  "id": 3,
  "class": "audit",
  "event": "shutdown",
  "connection_id": 0,
  "shutdown_data": { "server_id": 1 } }
```

When the audit log plugin is uninstalled as a result of server shutdown (as opposed to being disabled at runtime), connection_id is set to 0, and account and login are not present.

Connect or change-user event:

```
{ "timestamp": "2019-10-03 14:23:18",
  "id": 1,
  "class": "connection",
  "event": "connect",
  "connection_id": 5,
  "account": { "user": "root", "host": "localhost" },
  "login": { "user": "root", "os": "", "ip": ":1", "proxy": "" },
  "connection_data": { "connection_type": "ssl",
    "status": 0,
    "db": "test",
    "connection_attributes": {
      "_pid": "43236",
      ...
      "program_name": "mysqladmin"
    } }
}
```

Disconnect event:

```
{ "timestamp": "2019-10-03 14:24:45",
  "id": 3,
  "class": "connection",
  "event": "disconnect",
  "connection_id": 5,
  "account": { "user": "root", "host": "localhost" },
  "login": { "user": "root", "os": "", "ip": ":1", "proxy": "" },
  "connection_data": { "connection_type": "ssl" } }
```

Query event:

```
{ "timestamp": "2019-10-03 14:23:35",
  "id": 2,
  "class": "general",
  "event": "status",
  "connection_id": 5,
  "account": { "user": "root", "host": "localhost" },
  "login": { "user": "root", "os": "", "ip": ":1", "proxy": "" },
  "general_data": { "command": "Query",
    "sql_command": "show_variables",
    "query": "SHOW VARIABLES",
    "status": 0 } }
```

Query event with optional query statistics for outlier detection:

```
{ "timestamp": "2022-01-28 13:09:30",

The items in the following list appear at the top level of JSON-format audit records: Each item value is either a scalar or a JSON hash. For items that have a hash value, the description lists only the item names within that hash. For more complete descriptions of second-level hash items, see later in this section.

- **account**

  The MySQL account associated with the event. The value is a hash containing these items equivalent to the value of the `CURRENT_USER()` function within the section: `user, host`.

  Example:

  ```json
  "account": { "user": "user", "host": "localhost" }
  ```

- **class**

  A string representing the event class. The class defines the type of event, when taken together with the `event` item that specifies the event subclass.

  Example:

  ```json
  "class": "table_access"
  ```

The following table shows the permitted combinations of class and event values.

<table>
<thead>
<tr>
<th>Class Value</th>
<th>Permitted Event Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>audit</td>
<td>startup, shutdown</td>
</tr>
<tr>
<td>connection</td>
<td>connect, change_user, disconnect</td>
</tr>
<tr>
<td>general</td>
<td>status</td>
</tr>
<tr>
<td>table_access_data</td>
<td>read, delete, insert, update</td>
</tr>
</tbody>
</table>
MySQL Enterprise Audit

- **connection_data**

  Information about a client connection. The value is a hash containing these items: *connection_type*, *status*, *db*, and possibly *connection_attributes*. This item occurs only for audit records with a *class* value of *connection*.

  **Example:**

  ```json
  "connection_data": { "connection_type": "ssl", "status": 0, "db": "test" }
  ```

  Events with a *class* value of *connection* and *event* value of *connect* may include a *connection_attributes* item to display the connection attributes passed by the client at connect time. (For information about these attributes, which are also exposed in Performance Schema tables, see Section 27.12.9, “Performance Schema Connection Attribute Tables”.)

  The *connection_attributes* value is a hash that represents each attribute by its name and value.

  **Example:**

  ```json
  "connection_attributes": { 
  "_pid": "43236", 
  "_os": "macos0.14", 
  "_platform": "x86_64", 
  "_client_version": "8.1.0", 
  "_client_name": "libmysql",  
  "program_name": "mysqladmin"
  }
  ```

  If no connection attributes are present in the event, none are logged and no *connection_attributes* item appears. This can occur if the connection attempt is unsuccessful, the client passes no attributes, or the connection occurs internally such as during server startup or when initiated by a plugin.

- **connection_id**

  An unsigned integer representing the client connection identifier. This is the same as the value returned by the `CONNECTION_ID()` function within the session.

  **Example:**

  ```json
  "connection_id": 5
  ```

- **event**

  A string representing the subclass of the event class. The subclass defines the type of event, when taken together with the *class* item that specifies the event class. For more information, see the *class* item description.

  **Example:**

  ```json
  "event": "connect"
  ```

- **general_data**

  Information about an executed statement or command. The value is a hash containing these items: *command*, *sql_command*, *query*, *status*. This item occurs only for audit records with a *class* value of *general*.

  **Example:**

  ```json
MySQL Enterprise Audit

"general_data": { "command": "Query", "sql_command": "show_variables", "query": "SHOW VARIABLES", "status": 0 }

• id

An unsigned integer representing an event ID.

Example:

"id": 2

For audit records that have the same timestamp value, their id values distinguish them and form a sequence. Within the audit log, timestamp/id pairs are unique. These pairs are bookmarks that identify event locations within the log.

• login

Information indicating how a client connected to the server. The value is a hash containing these items: user, os, ip, proxy.

Example:

"login": { "user": "root", "os": ",", "ip": ":\:1", "proxy": "" }

• query_statistics

Optional query statistics for outlier detection. The value is a hash containing these items: query_time, rows_sent, rows_examined, bytes_received, bytes_sent. For instructions to set up the query statistics, see Adding Query Statistics for Outlier Detection.

Example:

"query_statistics": { "query_time": 0.116250, "bytes_sent": 18384, "bytes_received": 78858, "rows_sent": 3, "rows_examined": 20878 }

• shutdown_data

Information pertaining to audit log plugin termination. The value is a hash containing these items: server_id. This item occurs only for audit records with class and event values of audit and shutdown, respectively.

Example:

"shutdown_data": { "server_id": 1 }

• startup_data

Information pertaining to audit log plugin initialization. The value is a hash containing these items: server_id, os_version, mysql_version, args. This item occurs only for audit records with class and event values of audit and startup, respectively.

Example:

"startup_data": { "server_id": 1, "os_version": "i686-Linux", "args": "" }
MySQL Enterprise Audit

```
"mysql_version": "5.7.21-log",
"args": ["/usr/local/mysql/bin/mysqld",
         "--loose-audit-log-format=JSON",
         "--log-error=log.err",
         "--pid-file=mysqld.pid",
         "--port=3306" ]
```

- **table_access_data**

  Information about an access to a table. The value is a hash containing these items: `db`, `table`, `query`, `sql_command`, This item occurs only for audit records with a `class` value of `table_access`.

  **Example:**

  ```json
  "table_access_data": { "db": "test",
                       "table": "t1",
                       "query": "INSERT INTO t1 (i) VALUES(1),(2),(3)",
                       "sql_command": "insert" }
  ```

- **time**

  This field is similar to that in the `timestamp` field, but the value is an integer and represents the UNIX timestamp value indicating the date and time when the audit event was generated.

  **Example:**

  ```json
  "time": 1618498687
  ```

  The `time` field occurs in JSON-format log files only if the `audit_log_format_unix_timestamp` system variable is enabled.

- **timestamp**

  A string representing a UTC value in `YYYY-MM-DD hh:mm:ss` format indicating the date and time when the audit event was generated. For example, the event corresponding to execution of an SQL statement received from a client has a `timestamp` value occurring after the statement finishes, not when it was received.

  **Example:**

  ```json
  "timestamp": "2019-10-03 13:50:01"
  ```

  For audit records that have the same `timestamp` value, their `id` values distinguish them and form a sequence. Within the audit log, `timestamp/id` pairs are unique. These pairs are bookmarks that identify event locations within the log.

  These items appear within hash values associated with top-level items of JSON-format audit records:

- **args**

  An array of options that were given on the command line or in option files when the MySQL server was started. The first option is the path to the server executable.

  **Example:**

  ```json
  "args": ["/usr/local/mysql/bin/mysqld",
           "--loose-audit-log-format=JSON",
           "--log-error=log.err",
           "--pid-file=mysqld.pid",
           "--port=3306" ]
  ```
• bytes_received

The number of bytes received from the client. This item is part of the optional query statistics. For this field to be populated, the system variable `log_slow_extra` must be set to ON.

Example:
```
"bytes_received": 78858
```

• bytes_sent

The number of bytes sent to the client. This item is part of the optional query statistics. For this field to be populated, the system variable `log_slow_extra` must be set to ON.

Example:
```
"bytes_sent": 18384
```

• command

A string representing the type of instruction that generated the audit event, such as a command that the server received from a client.

Example:
```
"command": "Query"
```

• connection_type

The security state of the connection to the server. Permitted values are `tcp/ip` (TCP/IP connection established without encryption), `ssl` (TCP/IP connection established with encryption), `socket` (Unix socket file connection), `named_pipe` (Windows named pipe connection), and `shared_memory` (Windows shared memory connection).

Example:
```
"connection_type": "tcp/tcp"
```

• db

A string representing a database name. For `connection_data`, it is the default database. For `table_access_data`, it is the table database.

Example:
```
"db": "test"
```

• host

A string representing the client host name.

Example:
```
"host": "localhost"
```

• ip

A string representing the client IP address.

Example:
MySQL Enterprise Audit

- **ip**: ::1

- **mysql_version**

  A string representing the MySQL server version. This is the same as the value of the `VERSION()` function or `version` system variable.

  Example:

  "mysql_version": "5.7.21-log"

- **os**

  A string representing the external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this attribute is empty. The value is the same as that of the `external_user` system variable. See Section 6.2.19, “Proxy Users”.

  Example:

  "os": "jeffrey"

- **os_version**

  A string representing the operating system on which the server was built or is running.

  Example:

  "os_version": "i686-Linux"

- **proxy**

  A string representing the proxy user (see Section 6.2.19, “Proxy Users”). The value is empty if user proxying is not in effect.

  Example:

  "proxy": "developer"

- **query**

  A string representing the text of an SQL statement. The value can be empty. Long values may be truncated. The string, like the audit log file itself, is written using UTF-8 (up to 4 bytes per character), so the value may be the result of conversion. For example, the original statement might have been received from the client as an SJIS string.

  Example:

  "query": "DELETE FROM t1"

- **query_time**

  The query execution time in microseconds (if the `longlong` data type is selected) or seconds (if the `double` data type is selected). This item is part of the optional query statistics.

  Example:

  "query_time": 0.116250
- **rows_examined**
  The number of rows accessed during the query. This item is part of the optional query statistics.

  **Example:**
  
  ```json
  "rows_examined": 20878
  ```

- **rows_sent**
  The number of rows sent to the client as a result. This item is part of the optional query statistics.

  **Example:**
  
  ```json
  "rows_sent": 3
  ```

- **server_id**
  An unsigned integer representing the server ID. This is the same as the value of the `server_id` system variable.

  **Example:**
  
  ```json
  "server_id": 1
  ```

- **sql_command**
  A string that indicates the SQL statement type.

  **Example:**
  
  ```json
  "sql_command": "insert"
  ```

  The values correspond to the `statement/sql/xxx` command counters. For example, `xxx` is `drop_table` and `select` for `DROP_TABLE` and `SELECT` statements, respectively. The following statement displays the possible names:

  ```sql
  SELECT REPLACE(EVENT_NAME, 'statement/sql/', '') AS name
  FROM performance_schema.events_statements_summary_global_by_event_name
  WHERE EVENT_NAME LIKE 'statement/sql/%'
  ORDER BY name;
  ```

- **status**
  An unsigned integer representing the command status: 0 for success, nonzero if an error occurred. This is the same as the value of the `mysql_errno()` C API function.

  The audit log does not contain the SQLSTATE value or error message. To see the associations between error codes, SQLSTATE values, and messages, see [Server Error Message Reference](#).

  Warnings are not logged.

  **Example:**
  
  ```json
  "status": 1051
  ```
• **table**

A string representing a table name.

Example:
```
"table": "t1"
```

• **user**

A string representing a user name. The meaning differs depending on the item within which `user` occurs:

• Within `account` items, `user` is a string representing the user that the server authenticated the client as. This is the user name that the server uses for privilege checking.

• Within `login` items, `user` is a string representing the user name sent by the client.

Example:
```
"user": "root"
```

### 6.4.5.5 Configuring Audit Logging Characteristics

This section describes how to configure audit logging characteristics, such as the file to which the audit log plugin writes events, the format of written events, whether to enable log file compression and encryption, and space management.

• [Naming Conventions for Audit Log Files](#)
• [Selecting Audit Log File Format](#)
• [Enabling the Audit Log Flush Task](#)
• [Adding Query Statistics for Outlier Detection](#)
• [Compressing Audit Log Files](#)
• [Encrypting Audit Log Files](#)
• [Manually Uncompressing and Decrypting Audit Log Files](#)
• [Audit Log File Encryption Prior to MySQL 8.0.17](#)
• [Space Management of Audit Log Files](#)
• [Write Strategies for Audit Logging](#)

For additional information about the functions and system variables that affect audit logging, see [Audit Log Functions](#), and [Audit Log Options and Variables](#).

The audit log plugin can also control which audited events are written to the audit log file, based on event content or the account from which events originate. See [Section 6.4.5.7, “Audit Log Filtering”](#).

### Naming Conventions for Audit Log Files

To configure the audit log file name, set the `audit_log_file` system variable at server startup. The default name is `audit.log` in the server data directory. For best security, write the audit log to a directory accessible only to the MySQL server and to users with a legitimate reason to view the log.
The plugin interprets the `audit_log_file` value as composed of an optional leading directory name, a base name, and an optional suffix. If compression or encryption are enabled, the effective file name (the name actually used to create the log file) differs from the configured file name because it has additional suffixes:

- If compression is enabled, the plugin adds a suffix of `.gz`.
- If encryption is enabled, the plugin adds a suffix of `.pwd_id.enc`, where `pwd_id` indicates which encryption password to use for log file operations. The audit log plugin stores encryption passwords in the keyring; see Encrypting Audit Log Files.

The effective audit log file name is the name resulting from the addition of applicable compression and encryption suffixes to the configured file name. For example, if the configured `audit_log_file` value is `audit.log`, the effective file name is one of the values shown in the following table:

<table>
<thead>
<tr>
<th>Enabled Features</th>
<th>Effective File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>No compression or encryption</td>
<td><code>audit.log</code></td>
</tr>
<tr>
<td>Compression</td>
<td><code>audit.log.gz</code></td>
</tr>
<tr>
<td>Encryption</td>
<td><code>audit.log.pwd_id.enc</code></td>
</tr>
<tr>
<td>Compression, encryption</td>
<td><code>audit.log.gz.pwd_id.enc</code></td>
</tr>
</tbody>
</table>

`pwd_id` indicates the ID of the password used to encrypt or decrypt a file. `pwd_id` format is `pwd_timestamp-seq`, where:

- `pwd_timestamp` is a UTC value in `YYYYMMDDThhmmss` format indicating when the password was created.
- `seq` is a sequence number. Sequence numbers start at 1 and increase for passwords that have the same `pwd_timestamp` value.

Here are some example `pwd_id` password ID values:

```
20190403T142359-1
20190403T142400-1
20190403T142400-2
```

To construct the corresponding keyring IDs for storing passwords in the keyring, the audit log plugin adds a prefix of `audit_log-` to the `pwd_id` values. For the example password IDs just shown, the corresponding keyring IDs are:

```
audit_log-20190403T142359-1
audit_log-20190403T142400-1
audit_log-20190403T142400-2
```

The ID of the password currently used for encryption by the audit log plugin is the one having the largest `pwd_timestamp` value. If multiple passwords have that `pwd_timestamp` value, the current password ID is the one with the largest sequence number. For example, in the preceding set of password IDs, two of them have the largest timestamp, `20190403T142400`, so the current password ID is the one with the largest sequence number (2).

The audit log plugin performs certain actions during initialization and termination based on the effective audit log file name:

- During initialization, the plugin checks whether a file with the audit log file name already exists and renames it if so. (In this case, the plugin assumes that the previous server invocation exited unexpectedly with the audit log plugin running.) The plugin then writes to a new empty audit log file.
- During termination, the plugin renames the audit log file.
MySQL Enterprise Audit

• File renaming (whether during plugin initialization or termination) occurs according to the usual rules for automatic size-based log file rotation; see Manual Audit Log File Rotation (Before MySQL 8.0.31).

Selecting Audit Log File Format

To configure the audit log file format, set the `audit_log_format` system variable at server startup. These formats are available:

• NEW: New-style XML format. This is the default.
• OLD: Old-style XML format.
• JSON: JSON format. Writes the audit log as a JSON array. Only this format supports the optional query time and size statistics.

For details about each format, see Section 6.4.5.4, “Audit Log File Formats”.

Enabling the Audit Log Flush Task

MySQL Enterprise Audit provides the capability of setting a refresh interval to dispose of the in-memory cache automatically. A flush task configured using the `audit_log_flush_interval_seconds` system variable has a value of zero by default, which means the task is not scheduled to run.

When the task is configured to run (the value is non-zero), MySQL Enterprise Audit attempts to call the `scheduler` component at its initialization and configure a regular, recurring flush of its memory cache:

• If the audit log cannot find an implementation of the scheduler registration service, it does not schedule the flush and continue loading.
• Audit log implements the `dynamic_loader_services_loaded_notification` service and listens for new registrations of `mysql_scheduler` so that audit log can register its scheduled task into the newly loaded scheduler.
• Audit log only registers itself into the first scheduler implementation loaded.

Similarly, MySQL Enterprise Audit calls the `scheduler` component at its deinitialization and unconfigures the recurring flush that it has scheduled. It keeps an active reference to the scheduler registration service until the scheduled task is unregistered, ensuring that the `scheduler` component cannot be unloaded while there are active scheduled jobs. All of the results from executing the scheduler and its tasks are written to the server error log.

To schedule an audit log flush task:

1. Confirm that the `scheduler` component is loaded and enabled. The component is enabled (ON) by default (see `component_scheduler.enabled`).

```sql
SELECT * FROM mysql.components;
```

```
+--------------+--------------------+----------------------------+
<table>
<thead>
<tr>
<th>component_id</th>
<th>component_group_id</th>
<th>component_urn</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>file://component_scheduler</td>
</tr>
</tbody>
</table>
+--------------+--------------------+----------------------------+
```

2. Install the `audit_log` plugin, if it is not installed already (see Section 6.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”).

3. Start the server using `audit_log_flush_interval_seconds` and set the value to a number greater than 59. The upper limit of the value varies by platform. For example, to configure the flush task to recur every two minutes:

```
$> mysqld --audit_log_flush_interval_seconds=120
```
For more information, see the `audit_log_flush_interval_seconds` system variable.

### Adding Query Statistics for Outlier Detection

In MySQL 8.2, you can extend log files in JSON format with optional data fields to show the query time, the number of bytes sent and received, the number of rows returned to the client, and the number of rows examined. This data is available in the slow query log for qualifying queries, and in the context of the audit log it similarly helps to detect outliers for activity analysis. The extended data fields can be added only when the audit log is in JSON format (`audit_log_format=JSON`), which is not the default setting.

The query statistics are delivered to the audit log through component services that you set up as an audit log filtering function. The services are named `mysql_audit_print_service_longlong_data_source` and `mysql_audit_print_service_double_data_source`. You can choose either data type for each output item. For the query time, `longlong` outputs the value in microseconds, and `double` outputs the value in seconds.

You add the query statistics using the `audit_log_filter_set_filter()` audit log function, as the `service` element of the JSON filtering syntax, as follows:

```sql
SELECT audit_log_filter_set_filter('QueryStatistics',
   '{
   "filter": {
   "class": {
   "name": "general",
   "event": {
   "name": "status",
   "service": {
   "implementation": "mysql_server",
   "tag": "query_statistics",
   "name": "query_time",
   "type": "double",
   "name": "bytes_sent",
   "type": "longlong",
   "name": "bytes_received",
   "type": "longlong",
   "name": "rows_sent",
   "type": "longlong",
   "name": "rows_examined",
   "type": "longlong"
   }
   }
   }
   }
   }');
```

For the `bytes_sent` and `bytes_received` fields to be populated, the system variable `log_slow_extra` must be set to `ON`. If the system variable is value is `OFF`, a null value is written to the log file for these fields.

If you want to stop collecting the query statistics, use the `audit_log_filter_set_filter()` audit log function to remove the filter, for example:

```sql
SELECT audit_log_filter_remove_filter('QueryStatistics');
```

### Compressing Audit Log Files

Audit log file compression can be enabled for any logging format.

To configure audit log file compression, set the `audit_log_compression` system variable at server startup. Permitted values are `NONE` (no compression; the default) and `GZIP` (GNU Zip compression).

If both compression and encryption are enabled, compression occurs before encryption. To recover the original file manually, first decrypt it, then uncompress it. See Manually Uncompressing and Decrypting Audit Log Files.

### Encrypting Audit Log Files

Audit log file encryption can be enabled for any logging format. Encryption is based on user-defined passwords (with the exception of the initial password that the audit log plugin generates). To use this feature, the MySQL keyring must be enabled because audit logging uses it for password storage. Any keyring component or plugin can be used; for instructions, see `Section 6.4.4, “The MySQL Keyring”`.

To configure audit log file encryption, set the `audit_log_encryption` system variable at server startup. Permitted values are `NONE` (no encryption; the default) and `AES` (AES-256-CBC cipher encryption).
To set or get an encryption password at runtime, use these audit log functions:

• To set the current encryption password, invoke `audit_log_encryption_password_set()`. This function stores the new password in the keyring. If encryption is enabled, it also performs a log file rotation operation that renames the current log file, and begins a new log file encrypted with the password. File renaming occurs according to the usual rules for automatic size-based log file rotation; see Manual Audit Log File Rotation (Before MySQL 8.0.31).

If the `audit_log_password_history_keep_days` system variable is nonzero, invoking `audit_log_encryption_password_set()` also causes expiration of old archived audit log encryption passwords. For information about audit log password history, including password archiving and expiration, see the description of that variable.

• To get the current encryption password, invoke `audit_log_encryption_password_get()` with no argument. To get a password by ID, pass an argument that specifies the keyring ID of the current password or an archived password.

To determine which audit log keyring IDs exist, query the Performance Schema `keyring_keys` table:

```
mysql> SELECT KEY_ID FROM performance_schema.keyring_keys
    > WHERE KEY_ID LIKE 'audit_log%'
    > ORDER BY KEY_ID;
+-----------------------------+
| KEY_ID                      |
+-----------------------------+
| audit_log-20190415T152248-1 |
| audit_log-20190415T153507-1 |
| audit_log-20190416T125122-1 |
| audit_log-20190416T141608-1 |
+-----------------------------+
```

For additional information about audit log encryption functions, see Audit Log Functions.

When the audit log plugin initializes, if it finds that log file encryption is enabled, it checks whether the keyring contains an audit log encryption password. If not, the plugin automatically generates a random initial encryption password and stores it in the keyring. To discover this password, invoke `audit_log_encryption_password_get()`.

If both compression and encryption are enabled, compression occurs before encryption. To recover the original file manually, first decrypt it, then uncompress it. See Manually Uncompressing and Decrypting Audit Log Files.

**Manually Uncompressing and Decrypting Audit Log Files**

Audit log files can be uncompressed and decrypted using standard tools. This should be done only for log files that have been closed (archived) and are no longer in use, not for the log file that the audit log plugin is currently writing. You can recognize archived log files because they have been renamed by the audit log plugin to include a timestamp in the file name just after the base name.

For this discussion, assume that `audit_log_file` is set to `audit.log`. In that case, an archived audit log file has one of the names shown in the following table.

<table>
<thead>
<tr>
<th>Enabled Features</th>
<th>Archived File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>No compression or encryption</td>
<td><code>audit.timestamp.log</code></td>
</tr>
<tr>
<td>Compression</td>
<td><code>audit.timestamp.log.gz</code></td>
</tr>
<tr>
<td>Encryption</td>
<td><code>audit.timestamp.log.pwd_id.enc</code></td>
</tr>
<tr>
<td>Compression, encryption</td>
<td><code>audit.timestamp.log.gz.pwd_id.enc</code></td>
</tr>
</tbody>
</table>
As discussed in Naming Conventions for Audit Log Files, £pwd_id£ format is £pwd_timestamp-seq$. Thus, the names of archived encrypted log files actually contain two timestamps. The first indicates file rotation time, and the second indicates when the encryption password was created.

Consider the following set of archived encrypted log file names:

<table>
<thead>
<tr>
<th>File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>audit.20190410T205827.log.20190403T185337-1.enc</td>
</tr>
<tr>
<td>audit.20190410T210243.log.20190403T185337-1.enc</td>
</tr>
<tr>
<td>audit.20190415T145309.log.20190414T223342-1.enc</td>
</tr>
<tr>
<td>audit.20190415T151322.log.20190414T223342-2.enc</td>
</tr>
</tbody>
</table>

Each file name has a unique rotation-time timestamp. By contrast, the password timestamps are not unique:

- The first two files have the same password ID and sequence number (20190403T185337-1). They have the same encryption password.
- The second two files have the same password ID (20190414T223342) but different sequence numbers (1, 2). These files have different encryption passwords.

To uncompress a compressed log file manually, use `gunzip, gzip -d`, or equivalent command. For example:

```bash
gunzip -c audit.timestamp.log.gz > audit.timestamp.log
```

To decrypt an encrypted log file manually, use the `openssl` command. For example:

```bash
openssl enc -d -aes-256-cbc -pass pass:password -md sha256
  -in audit.timestamp.log.pwd_id.enc
  -out audit.timestamp.log
```

To execute that command, you must obtain `password`, the encryption password. To do this, use `audit_log_encryption_password_get()`. For example, if the audit log file name is `audit.20190415T151322.log.20190414T223342-2.enc`, the password ID is 20190414T223342-2 and the keyring ID is `audit-log-20190414T223342-2`. Retrieve the keyring password like this:

```sql
SELECT audit_log_encryption_password_get('audit-log-20190414T223342-2');
```

If both compression and encryption are enabled for audit logging, compression occurs before encryption. In this case, the file name has `.gz` and `.pwd_id.enc` suffixes added, corresponding to the order in which those operations occur. To recover the original file manually, perform the operations in reverse. That is, first decrypt the file, then uncompress it:

```bash
openssl enc -d -aes-256-cbc -pass pass:password -md sha256
  -in audit.timestamp.log.gz.pwd_id.enc
  -out audit.timestamp.log.gz

gunzip -c audit.timestamp.log.gz > audit.timestamp.log
```

### Audit Log File Encryption Prior to MySQL 8.0.17

This section covers the differences in audit log file encryption capabilities prior to and as of MySQL 8.0.17, which is when password history was implemented (which includes password archiving and expiration). It also indicates how the audit log plugin handles upgrades to MySQL 8.0.17 or higher from versions lower than 8.0.17.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Prior to MySQL 8.0.17</th>
<th>As of MySQL 8.0.17</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of passwords</td>
<td>Single password only</td>
<td>Multiple passwords permitted</td>
</tr>
<tr>
<td>Encrypted log file names</td>
<td><code>.enc</code> suffix</td>
<td><code>.pwd_id.enc</code> suffix</td>
</tr>
<tr>
<td>Password keyring ID</td>
<td><code>audit_log</code></td>
<td><code>audit_log-pwd_id</code></td>
</tr>
</tbody>
</table>
Prior to MySQL 8.0.17, there is no password history, so setting a new password makes the old password inaccessible, rendering MySQL Enterprise Audit unable to read log files encrypted with the old password. Should you anticipate a need to decrypt those files manually, you must maintain a record of previous passwords.

If audit log file encryption is enabled when you upgrade to MySQL 8.0.17 or higher from a lower version, the audit log plugin performs these upgrade actions:

- During plugin initialization, the plugin checks for an encryption password with a keyring ID of `audit_log`. If it finds one, the plugin duplicates the password using a keyring ID in `audit_log-pwd_id` format and uses it as the current encryption password. (For details about `pwd_id` syntax, see Naming Conventions for Audit Log Files.)
- Existing encrypted log files have a suffix of `.enc`. The plugin does not rename these to have a suffix of `pwd_id.enc`, but can read them as long as the key with the ID of `audit_log` remains in the keyring.
- When password cleanup occurs, if the plugin expires any password with a keyring ID in `audit_log-pwd_id` format, it also expires the password with a keyring ID of `audit_log`, if it exists. (At this point, encrypted log files that have a suffix of `.enc` rather than `pwd_id.enc` become unreadable by the plugin, so it is assumed that you no longer need them.)

### Space Management of Audit Log Files

The audit log file has the potential to grow quite large and consume a great deal of disk space. If you are collecting the optional query time and size statistics, this increases the space requirements. The query statistics are only supported with JSON format.

To manage the space used, employ these methods:

- Log file rotation. This involves rotating the current log file by renaming it, then opening a new current log file using the original name. Rotation can be performed manually, or configured to occur automatically.
- Pruning of rotated JSON-format log files, if automatic rotation is enabled. Pruning can be performed based on log file age or combined log file size.

To configure audit log file space management, use the following system variables:

- If `audit_log_rotate_on_size` is 0 (the default), automatic log file rotation is disabled.
- No rotation occurs unless performed manually.
- To rotate the current file, use one of the following methods:
  - Before MySQL 8.0.31, manually rename the file, then enable `audit_log_flush` to close it and open a new current log file using the original name. This file rotation method and the `audit_log_flush` variable are deprecated in MySQL 8.0.31.
  - From MySQL 8.0.31, run `SELECT audit_log_rotate();` to rename the file and open a new audit log file using the original name.

With this file rotation method, pruning of rotated JSON-format log files does not occur; `audit_log_max_size` and `audit_log_prune_seconds` have no effect.

- From MySQL 8.0.31, run `SELECT audit_log_rotate();` to rename the file and open a new audit log file using the original name.

With this file rotation method, pruning of rotated JSON-format log files occurs if `audit_log_max_size` or `audit_log_prune_seconds` has a value greater than 0.
See Manual Audit Log File Rotation (Before MySQL 8.0.31).

- If `audit_log_rotate_on_size` is greater than 0, automatic audit log file rotation is enabled:
  - Automatic rotation occurs when a write to the current log file causes its size to exceed the `audit_log_rotate_on_size` value, as well as under certain other conditions; see Automatic Audit Log File Rotation. When automatic rotation occurs, the audit log plugin renames the current log file and opens a new current log file using the original name.
  - Pruning of rotated JSON-format log files occurs if `audit_log_max_size` or `audit_log_prune_seconds` has a value greater than 0.
  - `audit_log_flush` has no effect.

  **Note**
  For JSON-format log files, rotation also occurs when the value of the `audit_log_format_unix_timestamp` system variable is changed at runtime. However, this does not occur for space-management purposes, but rather so that, for a given JSON-format log file, all records in the file either do or do not include the `time` field.

  **Note**
  Rotated (renamed) log files are not removed automatically. For example, with size-based log file rotation, renamed log files have unique names and accumulate indefinitely. They do not rotate off the end of the name sequence. To avoid excessive use of space:
  - For JSON-format log files: Enable log file pruning as described in Audit Log File Pruning.
  - Otherwise (for non-JSON files, or prior to MySQL 8.0.24 for all log formats): Remove old files periodically, backing them up first as necessary. If backed-up log files are encrypted, also back up the corresponding encryption passwords to a safe place, should you need to decrypt the files later.

The following sections describe log file rotation and pruning in greater detail.

- Manual Audit Log File Rotation (Before MySQL 8.0.31)
- Manual Audit Log File Rotation (From MySQL 8.0.31)
- Automatic Audit Log File Rotation
- Audit Log File Pruning

**Manual Audit Log File Rotation (Before MySQL 8.0.31)**

  **Note**
  From MySQL 8.0.31, the `audit_log_flush` variable and this method of audit log file rotation are deprecated; expect support to be removed in a future version of MySQL.

  If `audit_log_rotate_on_size` is 0 (the default), no log rotation occurs unless performed manually. In this case, the audit log plugin closes and reopens the log file when the `audit_log_flush` value changes.
from disabled to enabled. Log file renaming must be done externally to the server. Suppose that the log file name is `audit.log` and you want to maintain the three most recent log files, cycling through the names `audit.log.1` through `audit.log.3`. On Unix, perform rotation manually like this:

1. From the command line, rename the current log files:

   ```bash
   mv audit.log.2 audit.log.3
   mv audit.log.1 audit.log.2
   mv audit.log audit.log.1
   ```

   This strategy overwrites the current `audit.log.3` contents, placing a bound on the number of archived log files and the space they use.

2. At this point, the plugin is still writing to the current log file, which has been renamed to `audit.log.1`. Connect to the server and flush the log file so the plugin closes it and reopens a new `audit.log` file:

   ```sql
   SET GLOBAL audit_log_flush = ON;
   ```

   `audit_log_flush` is special in that its value remains OFF so that you need not disable it explicitly before enabling it again to perform another flush.

   **Note**

   If compression or encryption are enabled, log file names include suffixes that signify the enabled features, as well as a password ID if encryption is enabled. If file names include a password ID, be sure to retain the ID in the name of any files you rename manually so that the password to use for decryption operations can be determined.

   **Note**

   For JSON-format logging, renaming audit log files manually makes them unavailable to the log-reading functions because the audit log plugin can no longer determine that they are part of the log file sequence (see Section 6.4.5.6, “Reading Audit Log Files”). Consider setting `audit_log_rotate_on_size` greater than 0 to use size-based rotation instead.

**Manual Audit Log File Rotation (From MySQL 8.0.31)**

If `audit_log_rotate_on_size` is 0 (the default), no log rotation occurs unless performed manually.

To rotate the audit log file manually, run `SELECT audit_log_rotate();` to rename the current audit log file and open a new audit log file. Files are renamed according to the conventions described in Naming Conventions for Audit Log Files.

The `AUDIT_ADMIN` privilege is required to use the `audit_log_rotate()` function.

Managing the number of archived log files (the files that have been renamed) and the space they use is a manual task that involves removing archived audit log files that are no longer needed from your file system.

The content of audit log files that are renamed using the `audit_log_rotate()` function can be read by `audit_log_read()` function.

**Automatic Audit Log File Rotation**

If `audit_log_rotate_on_size` is greater than 0, setting `audit_log_flush` has no effect. Instead, whenever a write to the current log file causes its size to exceed the `audit_log_rotate_on_size` value, the audit log plugin automatically renames the current log file and opens a new current log file using the original name.
Automatic size-based rotation also occurs under these conditions:

- During plugin initialization, if a file with the audit log file name already exists (see Naming Conventions for Audit Log Files).
- During plugin termination.
- When the `audit_log_encryption_password_set()` function is called to set the encryption password, if encryption is enabled. (Rotation does not occur if encryption is disabled.)

The plugin renames the original file by inserting a timestamp just after its base name. For example, if the file name is `audit.log`, the plugin renames it to a value such as `audit.20210115T140633.log`. The timestamp is a UTC value in `YYYYMMDDThhmmss` format. For XML logging, the timestamp indicates rotation time. For JSON logging, the timestamp is that of the last event written to the file.

If log files are encrypted, the original file name already contains a timestamp indicating the encryption password creation time (see Naming Conventions for Audit Log Files). In this case, the file name after rotation contains two timestamps. For example, an encrypted log file named `audit.log.20210110T130749-1.enc` is renamed to a value such as `audit.20210115T140633.log.20210110T130749-1.enc`.

Audit Log File Pruning

The audit log plugin supports pruning of rotated JSON-format audit log files, if automatic log file rotation is enabled. To use this capability:

- Set `audit_log_format` to `JSON`. (In addition, consider also changing `audit_log_file`; see Selecting Audit Log File Format.)
- Set `audit_log_rotate_on_size` greater than 0 to specify the size in bytes at which automatic log file rotation occurs.
- By default, no pruning of automatically rotated JSON-format log files occurs. To enable pruning, set one of these system variables to a value greater than 0:
  - Set `audit_log_max_size` greater than 0 to specify the limit in bytes on the combined size of rotated log files above which the files become subject to pruning.
  - Set `audit_log_prune_seconds` greater than 0 to specify the number of seconds after which rotated log files become subject to pruning.

Nonzero values of `audit_log_max_size` take precedence over nonzero values of `audit_log_prune_seconds`. If both are set greater than 0 at plugin initialization, a warning is written to the server error log. If a client sets both greater than 0 at runtime, a warning is returned to the client.

Note

Warnings to the error log are written as Notes, which are information messages. To ensure that such messages appear in the error log and are not discarded, make sure that error-logging verbosity is sufficient to include information messages. For example, if you are using priority-based log filtering, as described in Section 5.4.2.5, “Priority-Based Error Log Filtering (log_filter_internal)”, set the `log_errorverbosity` system variable to a value of 3.

Pruning of JSON-format log files, if enabled, occurs as follows:

- When automatic rotation takes place; for the conditions under which this happens, see Automatic Audit Log File Rotation.
• When the global `audit_log_max_size` or `audit_log_prune_seconds` system variable is set at runtime.

For pruning based on combined rotated log file size, if the combined size is greater than the limit specified by `audit_log_max_size`, the audit log plugin removes the oldest files until their combined size does not exceed the limit.

For pruning based on rotated log file age, the pruning point is the current time minus the value of `audit_log_prune_seconds`. In rotated JSON-format log files, the timestamp part of each file name indicates the timestamp of the last event written to the file. The audit log plugin uses file name timestamps to determine which files contain only events older than the pruning point, and removes them.

**Write Strategies for Audit Logging**

The audit log plugin can use any of several strategies for log writes. Regardless of strategy, logging occurs on a best-effort basis, with no guarantee of consistency.

To specify a write strategy, set the `audit_log_strategy` system variable at server startup. By default, the strategy value is `ASYNCHRONOUS` and the plugin logs asynchronously to a buffer, waiting if the buffer is full. It's possible to tell the plugin not to wait (PERFORMANCE) or to log synchronously, either using file system caching (SEMISYNCHRONOUS) or forcing output with a `sync()` call after each write request (SYNCHRONOUS).

In many cases, the plugin writes directly to a JSON-format audit log if the current query is too large for the buffer. The write strategy determines how the plugin increments the direct write count. You can track the number direct writes with the `Audit_log_direct_writes` status variable.

For asynchronous write strategy, the `audit_log_buffer_size` system variable is the buffer size in bytes. Set this variable at server startup to change the buffer size. The plugin uses a single buffer, which it allocates when it initializes and removes when it terminates. The plugin does not allocate this buffer for nonasynchronous write strategies.

Asynchronous logging strategy has these characteristics:

• Minimal impact on server performance and scalability.

• Blocking of threads that generate audit events for the shortest possible time; that is, time to allocate the buffer plus time to copy the event to the buffer.

• Output goes to the buffer. A separate thread handles writes from the buffer to the log file.

With asynchronous logging, the integrity of the log file may be compromised if a problem occurs during a write to the file or if the plugin does not shut down cleanly (for example, in the event that the server host exits unexpectedly). To reduce this risk, set `audit_log_strategy` to use synchronous logging.

A disadvantage of PERFORMANCE strategy is that it drops events when the buffer is full. For a heavily loaded server, the audit log may have events missing.

**6.4.5.6 Reading Audit Log Files**

The audit log plugin supports functions that provide an SQL interface for reading JSON-format audit log files. (This capability does not apply to log files written in other formats.)

When the audit log plugin initializes and is configured for JSON logging, it uses the directory containing the current audit log file as the location to search for readable audit log files. The plugin determines the file location, base name, and suffix from the value of the `audit_log_file` system variable, then looks for files with names that match the following pattern, where `[...]` indicates optional file name parts:

```
basename[.timestamp].suffix[.gz][.pwd_id].enc
```

1580
If a file name ends with `.enc`, the file is encrypted and reading its unencrypted contents requires a decryption password obtained from the keyring. The audit log plugin determines the keyring ID of the decryption password as follows:

- If `.enc` is preceded by `pwd_id`, the keyring ID is `audit_log-pwd_id`.
- If `.enc` is not preceded by `pwd_id`, the file has an old name from before audit log encryption password history was implemented. The keyring ID is `audit_log`.

For more information about encrypted audit log files, see Encrypting Audit Log Files.

The plugin ignores files that have been renamed manually and do not match the pattern, and files that were encrypted with a password no longer available in the keyring. The plugin opens each remaining candidate file, verifies that the file actually contains JSON audit events, and sorts the files using the timestamps from the first event of each file. The result is a sequence of files that are subject to access using the log-reading functions:

- `audit_log_read()` reads events from the audit log or closes the reading process.
- `audit_log_read_bookmark()` returns a bookmark for the most recently written audit log event. This bookmark is suitable for passing to `audit_log_read()` to indicate where to begin reading.
- `audit_log_read()` takes an optional JSON string argument, and the result returned from a successful call to either function is a JSON string.

To use the functions to read the audit log, follow these principles:

- Call `audit_log_read()` to read events beginning from a given position or the current position, or to close reading:
  - To initialize an audit log read sequence, pass an argument that indicates the position at which to begin. One way to do so is to pass the bookmark returned by `audit_log_read_bookmark()`:
    ```sql
    SELECT audit_log_read(audit_log_read_bookmark());
    ```
  - To continue reading from the current position in the sequence, call `audit_log_read()` with no position specified:
    ```sql
    SELECT audit_log_read();
    ```
  - To explicitly close the read sequence, pass a JSON `null` argument:
    ```sql
    SELECT audit_log_read('null');
    ```
    It is unnecessary to close reading explicitly. Reading is closed implicitly when the session ends or a new read sequence is initialized by calling `audit_log_read()` with an argument that indicates the position at which to begin.

- A successful call to `audit_log_read()` to read events returns a JSON string containing an array of audit events:
  - If the final value of the returned array is not a JSON `null` value, there are more events following those just read and `audit_log_read()` can be called again to read more of them.
  - If the final value of the returned array is a JSON `null` value, there are no more events left to be read in the current read sequence.

Each non-null array element is an event represented as a JSON hash. For example:

```json
{
...
```

For more information about the content of JSON-format audit events, see JSON Audit Log File Format.

- An `audit_log_read()` call to read events that does not specify a position produces an error under any of these conditions:
  - A read sequence has not yet been initialized by passing a position to `audit_log_read()`.
  - There are no more events left to be read in the current read sequence; that is, `audit_log_read()` previously returned an array ending with a JSON null value.
  - The most recent read sequence has been closed by passing a JSON null value to `audit_log_read()`.

To read events under those conditions, it is necessary to first initialize a read sequence by calling `audit_log_read()` with an argument that specifies a position.

To specify a position to `audit_log_read()`, include an argument that indicates where to begin reading. For example, pass a bookmark, which is a JSON hash containing `timestamp` and `id` elements that uniquely identify a particular event. Here is an example bookmark, obtained by calling the `audit_log_read_bookmark()` function:

```sql
mysql> SELECT audit_log_read_bookmark();
+-------------------------------------------------+
| audit_log_read_bookmark()                       |
+-------------------------------------------------+
| { "timestamp": "2020-05-18 21:03:44", "id": 0 } |
+-------------------------------------------------+
```

Passing the current bookmark to `audit_log_read()` initializes event reading beginning at the bookmark position:

```sql
mysql> SELECT audit_log_read(audit_log_read_bookmark());
+-----------------------------------------------------------------------+
| audit_log_read(audit_log_read_bookmark())                             |
+-----------------------------------------------------------------------+
| [ { "timestamp": "2020-05-18 22:41:24", "id": 0, "class": "connection", "event": "connect", ... } ] |
```

The argument to `audit_log_read()` is optional. If present, it can be a JSON null value to close the read sequence, or a JSON hash.

Within a hash argument to `audit_log_read()`, items are optional and control aspects of the read operation such as the position at which to begin reading or how many events to read. The following items are significant (other items are ignored):

```json
{ "timestamp": "2020-05-18 13:39:33", "id": 0,
  "class": "connection", "event": "connect",
  ...
},
{ "timestamp": "2020-05-18 13:39:33", "id": 1,
  "class": "general", "event": "status",
  ...
},
{ "timestamp": "2020-05-18 13:39:33", "id": 2,
  "class": "connection", "event": "disconnect",
  ...
},
null
]```
• **start**: The position within the audit log of the first event to read. The position is given as a timestamp and the read starts from the first event that occurs on or after the timestamp value. The `start` item has this format, where `value` is a literal timestamp value:

    "start": { "timestamp": "value" }

• **timestamp, id**: The position within the audit log of the first event to read. The `timestamp` and `id` items together comprise a bookmark that uniquely identify a particular event. If an `audit_log_read()` argument includes either item, it must include both to completely specify a position or an error occurs.

• **max_array_length**: The maximum number of events to read from the log. If this item is omitted, the default is to read to the end of the log or until the read buffer is full, whichever comes first.

To specify a starting position to `audit_log_read()`, pass a hash argument that includes either a `start` item or a bookmark consisting of `timestamp` and `id` items. If a hash argument includes both a `start` item and a bookmark, an error occurs.

If a hash argument specifies no starting position, reading continues from the current position.

If a timestamp value includes no time part, a time part of `00:00:00` is assumed.

Example arguments accepted by `audit_log_read()`:

• Read events starting with the first event that occurs on or after the given timestamp:

    ```json
    audit_log_read('{ "start": { "timestamp": "2020-05-24 12:30:00" } }')
    ```

• Like the previous example, but read at most 3 events:

    ```json
    audit_log_read('{ "start": { "timestamp": "2020-05-24 12:30:00" }, "max_array_length": 3 }')
    ```

• Read events starting with the first event that occurs on or after `2020-05-24 00:00:00` (the timestamp includes no time part, so `00:00:00` is assumed):

    ```json
    audit_log_read('{ "start": { "timestamp": "2020-05-24" } }')
    ```

• Read events starting with the event that has the exact timestamp and event ID:

    ```json
    audit_log_read('{ "timestamp": "2020-05-24 12:30:00", "id": 0 }')
    ```

• Like the previous example, but read at most 3 events:

    ```json
    audit_log_read('{ "timestamp": "2020-05-24 12:30:00", "id": 0, "max_array_length": 3 }')
    ```

• Read events from the current position in the read sequence:

    ```json
    audit_log_read()
    ```

• Read at most 5 events beginning at the current position in the read sequence:

    ```json
    audit_log_read('{ "max_array_length": 5 }')
    ```

• Close the current read sequence:

    ```json
    audit_log_read('null')
    ```

A JSON string returned from either log-reading function can be manipulated as necessary. Suppose that a call to obtain a bookmark produces this value:

    ```sql
    mysql> SET @mark := audit_log_read_bookmark();
    mysql> SELECT @mark;
    +------------------------------------------+
    | @mark |
    +------------------------------------------+
    | 1583  |
    ```
Calling `audit_log_read()` with that argument can return multiple events. To limit `audit_log_read()` to reading at most $N$ events, add to the string a `max_array_length` item with that value. For example, to read a single event, modify the string as follows:

```sql
mysql> SET @mark := JSON_SET(@mark, '$.max_array_length', 1);
mysql> SELECT @mark;
```

The modified string, when passed to `audit_log_read()`, produces a result containing at most one event, no matter how many are available.

Prior to MySQL 8.0.19, string return values from audit log functions are binary strings. To use a binary string with functions that require a nonbinary string (such as functions that manipulate `JSON` values), convert it to a nonbinary string. For example, before passing a bookmark to `JSON_SET()`, convert it to `utf8mb4` as follows:

```sql
SET @mark = CONVERT(@mark USING utf8mb4);
```

That statement can be used even for MySQL 8.2 for those versions, it is essentially a no-op and is harmless.

If an audit log function is invoked from within the `mysql` client, binary string results display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 4.5.1, "mysql — The MySQL Command-Line Client".

To set a limit on the number of bytes that `audit_log_read()` reads, set the `audit_log_read_buffer_size` system variable. This variable has a default of 32KB and can be set at runtime. Each client should set its session value of `audit_log_read_buffer_size` appropriately for its use of `audit_log_read()`.

Each call to `audit_log_read()` returns as many available events as fit within the buffer size. Events that do not fit within the buffer size are skipped and generate warnings. Given this behavior, consider these factors when assessing the proper buffer size for an application:

- There is a tradeoff between number of calls to `audit_log_read()` and events returned per call:
  - With a smaller buffer size, calls return fewer events, so more calls are needed.
  - With a larger buffer size, calls return more events, so fewer calls are needed.
  - With a smaller buffer size, such as the default size of 32KB, there is a greater chance for events to exceed the buffer size and thus to be skipped.

For additional information about audit log-reading functions, see Audit Log Functions.

### 6.4.5.7 Audit Log Filtering

**Note**

For audit log filtering to work as described here, the audit log plugin and the accompanying audit tables and functions must be installed. If the plugin is installed without the accompanying audit tables and functions needed for rule-based filtering,
the plugin operates in legacy filtering mode, described in Section 6.4.5.10, “Legacy Mode Audit Log Filtering”. Legacy mode (deprecated) is filtering behavior as it was prior to MySQL 5.7.13; that is, before the introduction of rule-based filtering.

- Properties of Audit Log Filtering
- Constraints on Audit Log Filtering Functions
- Using Audit Log Filtering Functions

**Properties of Audit Log Filtering**

The audit log plugin has the capability of controlling logging of audited events by filtering them:

- Audited events can be filtered using these characteristics:
  - User account
  - Audit event class
  - Audit event subclass
  - Audit event fields such as those that indicate operation status or SQL statement executed
- Audit filtering is rule based:
  - A filter definition creates a set of auditing rules. Definitions can be configured to include or exclude events for logging based on the characteristics just described.
  - Filter rules have the capability of blocking (aborting) execution of qualifying events, in addition to existing capabilities for event logging.
  - Multiple filters can be defined, and any given filter can be assigned to any number of user accounts.
  - It is possible to define a default filter to use with any user account that has no explicitly assigned filter.

Audit log filtering is used to implement component services. To get the optional query statistics available from that release, you set them up as a filter using the service component, which implements the services that write the statistics to the audit log. For instructions to set this filter up, see Adding Query Statistics for Outlier Detection.

For information about writing filtering rules, see Section 6.4.5.8, “Writing Audit Log Filter Definitions”.

- Audit filters can be defined and modified using an SQL interface based on function calls. To display audit filters, query the `mysql.audit_log_filter` table.
- Audit filter definitions are stored in the tables in the `mysql` system database.
- Within a given session, the value of the read-only `audit_log_filter_id` system variable indicates whether a filter is assigned to the session.

**Note**

By default, rule-based audit log filtering logs no auditable events for any users. To log all auditable events for all users, use the following statements, which create a simple filter to enable logging and assign it to the default account:

```sql
SELECT audit_log_filter_set_filter('log_all', '{ "filter": { "log": true } }');
SELECT audit_log_filter_set_user('%', 'log_all');
```
The filter assigned to % is used for connections from any account that has no explicitly assigned filter (which initially is true for all accounts).

As previously mentioned, the SQL interface for audit filtering control is function based. The following list briefly summarizes these functions:

- `audit_log_filter_set_filter()`: Define a filter.
- `audit_log_filter_remove_filter()`: Remove a filter.
- `audit_log_filter_set_user()`: Start filtering a user account.
- `audit_log_filter_remove_user()`: Stop filtering a user account.
- `audit_log_filter_flush()`: Flush manual changes to the filter tables to affect ongoing filtering.

For usage examples and complete details about the filtering functions, see Using Audit Log Filtering Functions, and Audit Log Functions.

Constraints on Audit Log Filtering Functions

Audit log filtering functions are subject to these constraints:

- To use any filtering function, the `audit_log` plugin must be enabled or an error occurs. In addition, the audit tables must exist or an error occurs. To install the `audit_log` plugin and its accompanying functions and tables, see Section 6.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”.

- To use any filtering function, a user must possess the AUDIT_ADMIN privilege or an error occurs. To grant one of these privileges to a user account, use this statement:

```
GRANT privilege ON *.* TO user;
```

Alternatively, should you prefer to avoid granting the AUDIT_ADMIN or SUPER privilege while still permitting users to access specific filtering functions, “wrapper” stored programs can be defined. This technique is described in the context of keyring functions in Using General-Purpose Keyring Functions; it can be adapted for use with filtering functions.

- The `audit_log` plugin operates in legacy mode if it is installed but the accompanying audit tables and functions are not created. The plugin writes these messages to the error log at server startup:

```
[Warning] Plugin audit_log reported: 'Failed to open the audit log filter tables.'
[Warning] Plugin audit_log reported: 'Audit Log plugin supports a filtering, which has not been installed yet. Audit Log plugin will run in the legacy mode, which will be disabled in the next release.'
```

In legacy mode, which is deprecated, filtering can be done based only on event account or status. For details, see Section 6.4.5.10, “Legacy Mode Audit Log Filtering”.

- It is theoretically possible for a user with sufficient permissions to mistakenly create an “abort” item in the audit log filter that prevents themselves and other administrators from accessing the system. The AUDIT_ABORT_EXEMPT privilege is available to permit a user account’s queries to always be executed even if an “abort” item would block them. Accounts with this privilege can therefore be used to regain access to a system following an audit misconfiguration. The query is still logged in the audit log, but instead of being rejected, it is permitted due to the privilege.

Accounts created with the SYSTEM_USER privilege have the AUDIT_ABORT_EXEMPT privilege assigned automatically when they are created. The AUDIT_ABORT_EXEMPT privilege is also assigned to existing accounts with the SYSTEM_USER privilege when you carry out an upgrade procedure, if no existing accounts have that privilege assigned.
Using Audit Log Filtering Functions

Before using the audit log functions, install them according to the instructions provided in Section 6.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”. The AUDIT_ADMIN or SUPER privilege is required to use any of these functions.

The audit log filtering functions enable filtering control by providing an interface to create, modify, and remove filter definitions and assign filters to user accounts.

Filter definitions are JSON values. For information about using JSON data in MySQL, see Section 11.5, “The JSON Data Type”. This section shows some simple filter definitions. For more information about filter definitions, see Section 6.4.5.8, “Writing Audit Log Filter Definitions”.

When a connection arrives, the audit log plugin determines which filter to use for the new session by searching for the user account name in the current filter assignments:

- If a filter is assigned to the user, the audit log uses that filter.
- Otherwise, if no user-specific filter assignment exists, but there is a filter assigned to the default account (%), the audit log uses the default filter.
- Otherwise, the audit log selects no audit events from the session for processing.

If a change-user operation occurs during a session (see mysql_change_user()), filter assignment for the session is updated using the same rules but for the new user.

By default, no accounts have a filter assigned, so no processing of auditable events occurs for any account.

Suppose that you want to change the default to be to log only connection-related activity (for example, to see connect, change-user, and disconnect events, but not the SQL statements users execute while connected). To achieve this, define a filter (shown here named log_conn_events) that enables logging only of events in the connection class, and assign that filter to the default account, represented by the % account name:

```sql
SET @f = '{ "filter": { "class": { "name": "connection" } } }';
SELECT audit_log_filter_set_filter('log_conn_events', @f);
SELECT audit_log_filter_set_user('%', 'log_conn_events');
```

Now the audit log uses this default account filter for connections from any account that has no explicitly defined filter.

To assign a filter explicitly to a particular user account or accounts, define the filter, then assign it to the relevant accounts:

```sql
SELECT audit_log_filter_set_filter('log_all', '{ "filter": { "log": true } }');
SELECT audit_log_filter_set_user('user1@localhost', 'log_all');
SELECT audit_log_filter_set_user('user2@localhost', 'log_all');
```

Now full logging is enabled for user1@localhost and user2@localhost. Connections from other accounts continue to be filtered using the default account filter.

To disassociate a user account from its current filter, either unassign the filter or assign a different filter:

- To unassign the filter from the user account:

  ```sql
  SELECT audit_log_filter_remove_user('user1@localhost');
  ```

  Filtering of current sessions for the account remains unaffected. Subsequent connections from the account are filtered using the default account filter if there is one, and are not logged otherwise.
To assign a different filter to the user account:

```sql
SELECT audit_log_filter_set_filter('log_nothing', '{ "filter": { "log": false } }');
SELECT audit_log_filter_set_user('user1@localhost', 'log_nothing');
```

Filtering of current sessions for the account remains unaffected. Subsequent connections from the account are filtered using the new filter. For the filter shown here, that means no logging for new connections from `user1@localhost`.

For audit log filtering, user name and host name comparisons are case-sensitive. This differs from comparisons for privilege checking, for which host name comparisons are not case-sensitive.

To remove a filter, do this:

```sql
SELECT audit_log_filter_remove_filter('log_nothing');
```

Removing a filter also unassigns it from any users to whom it is assigned, including any current sessions for those users.

The filtering functions just described affect audit filtering immediately and update the audit log tables in the `mysql` system database that store filters and user accounts (see Audit Log Tables). It is also possible to modify the audit log tables directly using statements such as INSERT, UPDATE, and DELETE, but such changes do not affect filtering immediately. To flush your changes and make them operational, call `audit_log_filter_flush()`:

```sql
SELECT audit_log_filter_flush();
```

```
6.4.5.8 Writing Audit Log Filter Definitions

Filter definitions are JSON values. For information about using JSON data in MySQL, see Section 11.5, “The JSON Data Type”.

Filter definitions have this form, where `actions` indicates how filtering takes place:

```json
{ "filter": actions }
```

The following discussion describes permitted constructs in filter definitions.

- Logging All Events
• Logging Specific Event Classes
• Logging Specific Event Subclasses
• Inclusive and Exclusive Logging
• Testing Event Field Values
• Blocking Execution of Specific Events
• Logical Operators
• Referencing Predefined Variables
• Referencing Predefined Functions
• Replacement of Event Field Values
• Replacing a User Filter

Logging All Events
To explicitly enable or disable logging of all events, use a `log` item in the filter:

```json
{  "filter": { "log": true }
}
```

The `log` value can be either `true` or `false`.

The preceding filter enables logging of all events. It is equivalent to:

```json
{  "filter": { }
}
```

Logging behavior depends on the `log` value and whether `class` or `event` items are specified:

• With `log` specified, its given value is used.

• Without `log` specified, logging is `true` if no `class` or `event` item is specified, and `false` otherwise (in which case, `class` or `event` can include their own `log` item).

Logging Specific Event Classes
To log events of a specific class, use a `class` item in the filter, with its `name` field denoting the name of the class to log:

```json
{  "filter": {  
    "class": { "name": "connection" }
  }
}
```

The `name` value can be `connection`, `general`, or `table_access` to log connection, general, or table-access events, respectively.

The preceding filter enables logging of events in the `connection` class. It is equivalent to the following filter with `log` items made explicit:

```json
{  "filter": {  
    "log": false,
    "class": { "name": "connection" }  
  }
}
```
To enable logging of multiple classes, define the `class` value as a JSON array element that names the classes:

```json
{  "filter": {    "class": [      { "name": "connection" },      { "name": "general" },      { "name": "table_access" }    ]  }
}
```

**Note**

When multiple instances of a given item appear at the same level within a filter definition, the item values can be combined into a single instance of that item within an array value. The preceding definition can be written like this:

```json
{  "filter": {    "class": [      { "name": [ "connection", "general", "table_access" ] }    ]  }
}
```

### Logging Specific Event Subclasses

To select specific event subclasses, use an `event` item containing a `name` item that names the subclasses. The default action for events selected by an `event` item is to log them. For example, this filter enables logging for the named event subclasses:

```json
{  "filter": {    "class": [      { "name": "connection",      "event": [        { "name": "connect" },        { "name": "disconnect" }      ]    },      { "name": "general" },      { "name": "table_access",      "event": [        { "name": "insert" },        { "name": "delete" },        { "name": "update" }      ]    }    ]  }
}
```

The `event` item can also contain explicit `log` items to indicate whether to log qualifying events. This `event` item selects multiple events and explicitly indicates logging behavior for them:

```json
"event": [  "log": true,  "name": "connection" ]
```
The `event` item can also indicate whether to block qualifying events, if it contains an `abort` item. For details, see Blocking Execution of Specific Events.

**Table 6.37, “Event Class and Subclass Combinations”** describes the permitted subclass values for each event class.

**Table 6.37 Event Class and Subclass Combinations**

<table>
<thead>
<tr>
<th>Event Class</th>
<th>Event Subclass</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>connection</td>
<td>connect</td>
<td>Connection initiation (successful or unsuccessful)</td>
</tr>
<tr>

</tbody>
</table>
Inclusive and Exclusive Logging

A filter can be defined in inclusive or exclusive mode:

- Inclusive mode logs only explicitly specified items.
- Exclusive mode logs everything but explicitly specified items.

To perform inclusive logging, disable logging globally and enable logging for specific classes. This filter logs `connect` and `disconnect` events in the `connection` class, and events in the `general` class:

```
{  
  "filter": {  
    "log": false,  
    "class": [  
      {  
        "name": "connection",  
        "event": [  
          { "name": "connect", "log": true },  
          { "name": "disconnect", "log": true }  
        ]  
      },  
      { "name": "general", "log": true }  
    ]  
  }  
}
```

To perform exclusive logging, enable logging globally and disable logging for specific classes. This filter logs everything except events in the `general` class:

```
{  
  "filter": {  
    "log": true,  
    "class": {  
      "name": "general", "log": false }  
  }  
}
```

This filter logs `change_user` events in the `connection` class, `message` events, and `table_access` events, by virtue of not logging everything else:

```
{  
  "filter": {  
    "log": true,  
    "class": [  
      {  
        "name": "connection",  
        "event": [  
          { "name": "connect", "log": false },  
          { "name": "disconnect", "log": false }  
        ]  
      },  
      { "name": "general", "log": false }  
    ]  
  }  
}
```

Testing Event Field Values

To enable logging based on specific event field values, specify a `field` item within the `log` item that indicates the field name and its expected value:
Each event contains event class-specific fields that can be accessed from within a filter to perform custom filtering.

An event in the `connection` class indicates when a connection-related activity occurs during a session, such as a user connecting to or disconnecting from the server. Table 6.39, “Connection Event Fields” indicates the permitted fields for `connection` events.

### Table 6.39 Connection Event Fields

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Field Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>status</td>
<td>integer</td>
<td>Event status: 0: OK Otherwise: Failed</td>
</tr>
<tr>
<td>connection_id</td>
<td>unsigned int</td>
<td>Connection ID</td>
</tr>
<tr>
<td>user.str</td>
<td>string</td>
<td>User name specified during authentication</td>
</tr>
<tr>
<td>user.length</td>
<td>unsigned int</td>
<td>User name length</td>
</tr>
<tr>
<td>priv_user.str</td>
<td>string</td>
<td>Authenticated user name (account user name)</td>
</tr>
<tr>
<td>priv_user.length</td>
<td>unsigned int</td>
<td>Authenticated user name length</td>
</tr>
<tr>
<td>external_user.str</td>
<td>string</td>
<td>External user name (provided by third-party authentication plugin)</td>
</tr>
<tr>
<td>external_user.length</td>
<td>unsigned int</td>
<td>External user name length</td>
</tr>
<tr>
<td>proxy_user.str</td>
<td>string</td>
<td>Proxy user name</td>
</tr>
<tr>
<td>proxy_user.length</td>
<td>unsigned int</td>
<td>Proxy user name length</td>
</tr>
<tr>
<td>host.str</td>
<td>string</td>
<td>Connected user host</td>
</tr>
<tr>
<td>host.length</td>
<td>unsigned int</td>
<td>Connected user host length</td>
</tr>
<tr>
<td>ip.str</td>
<td>string</td>
<td>Connected user IP address</td>
</tr>
<tr>
<td>ip.length</td>
<td>unsigned int</td>
<td>Connected user IP address length</td>
</tr>
<tr>
<td>database.str</td>
<td>string</td>
<td>Database name specified at connect time</td>
</tr>
<tr>
<td>database.length</td>
<td>unsigned int</td>
<td>Database name length</td>
</tr>
<tr>
<td>connection_type</td>
<td>integer</td>
<td>Connection type: 0 or &quot;::undefined&quot;: Undefined</td>
</tr>
</tbody>
</table>
The "::xxx" values are symbolic pseudo-constants that may be given instead of the literal numeric values. They must be quoted as strings and are case-sensitive.

An event in the `general` class indicates the status code of an operation and its details. Table 6.40, “General Event Fields” indicates the permitted fields for `general` events.

### Table 6.40 General Event Fields

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Field Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>general_error_code</td>
<td>integer</td>
<td>Event status:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0: OK</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Otherwise: Failed</td>
</tr>
<tr>
<td>general_thread_id</td>
<td>unsigned integer</td>
<td>Connection/thread ID</td>
</tr>
<tr>
<td>general_user.str</td>
<td>string</td>
<td>User name specified during authentication</td>
</tr>
<tr>
<td>general_user.length</td>
<td>unsigned integer</td>
<td>User name length</td>
</tr>
<tr>
<td>general_command.str</td>
<td>string</td>
<td>Command name</td>
</tr>
<tr>
<td>general_command.length</td>
<td>unsigned integer</td>
<td>Command name length</td>
</tr>
<tr>
<td>general_query.str</td>
<td>string</td>
<td>SQL statement text</td>
</tr>
<tr>
<td>general_query.length</td>
<td>unsigned integer</td>
<td>SQL statement text length</td>
</tr>
<tr>
<td>general_host.str</td>
<td>string</td>
<td>Host name</td>
</tr>
<tr>
<td>general_host.length</td>
<td>unsigned integer</td>
<td>Host name length</td>
</tr>
<tr>
<td>general_sql_command.str</td>
<td>string</td>
<td>SQL command type name</td>
</tr>
<tr>
<td>general_sql_command.length</td>
<td>unsigned integer</td>
<td>SQL command type name length</td>
</tr>
<tr>
<td>general_external_user.str</td>
<td>string</td>
<td>External user name (provided by third-party authentication plugin)</td>
</tr>
<tr>
<td>general_external_user.length</td>
<td>unsigned integer</td>
<td>External user name length</td>
</tr>
<tr>
<td>general_ip.str</td>
<td>string</td>
<td>Connected user IP address</td>
</tr>
<tr>
<td>general_ip.length</td>
<td>unsigned integer</td>
<td>Connection user IP address</td>
</tr>
</tbody>
</table>

`general_command.str` indicates a command name: Query, Execute, Quit, or Change user.

A `general` event with the `general_command.str` field set to Query or Execute contains `general_sql_command.str` set to a value that specifies the type of SQL command: alter_db,
alter_db_upgrade, admin_commands, and so forth. The available general_sql_command.str values can be seen as the last components of the Performance Schema instruments displayed by this statement:

```
mysql> SELECT NAME FROM performance_schema.setup_instruments WHERE NAME LIKE 'statement/sql/%' ORDER BY NAME;
+---------------------------------------+
| NAME                                  |
+---------------------------------------+
| statement/sql/alter_db                |
| statement/sql/alter_db_upgrade        |
| statement/sql/alter_event             |
| statement/sql/alter_function          |
| statement/sql/alter_instance          |
| statement/sql/alter_procedure         |
| statement/sql/alter_server            |
| ...                                   |
```

An event in the table_access class provides information about a specific type of access to a table. Table 6.41, “Table-Access Event Fields” indicates the permitted fields for table_access events.

### Table 6.41 Table-Access Event Fields

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Field Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>connection_id</td>
<td>unsigned integer</td>
<td>Event connection ID</td>
</tr>
<tr>
<td>sql_command_id</td>
<td>integer</td>
<td>SQL command ID</td>
</tr>
<tr>
<td>query.str</td>
<td>string</td>
<td>SQL statement text</td>
</tr>
<tr>
<td>query.length</td>
<td>unsigned integer</td>
<td>SQL statement text length</td>
</tr>
<tr>
<td>table_database.str</td>
<td>string</td>
<td>Database name associated with event</td>
</tr>
<tr>
<td>table_database.length</td>
<td>unsigned integer</td>
<td>Database name length</td>
</tr>
<tr>
<td>table_name.str</td>
<td>string</td>
<td>Table name associated with event</td>
</tr>
<tr>
<td>table_name.length</td>
<td>unsigned integer</td>
<td>Table name length</td>
</tr>
</tbody>
</table>

The following list shows which statements produce which table-access events:

- **read event**:
  - SELECT
  - INSERT ... SELECT (for tables referenced in SELECT clause)
  - REPLACE ... SELECT (for tables referenced in SELECT clause)
  - UPDATE ... WHERE (for tables referenced in WHERE clause)
  - HANDLER ... READ
- **delete event**:
  - DELETE
  - TRUNCATE TABLE
- **insert event**:
  - INSERT
• **INSERT ... SELECT** (for table referenced in **INSERT** clause)
• **REPLACE**
• **REPLACE ... SELECT** (for table referenced in **REPLACE** clause)
• **LOAD DATA**
• **LOAD XML**
• **update** event:
  • **UPDATE**
  • **UPDATE ... WHERE** (for tables referenced in **UPDATE** clause)

### Blocking Execution of Specific Events

**event** items can include an **abort** item that indicates whether to prevent qualifying events from executing. **abort** enables rules to be written that block execution of specific SQL statements.

---

**Important**

It is theoretically possible for a user with sufficient permissions to mistakenly create an **abort** item in the audit log filter that prevents themselves and other administrators from accessing the system. The **AUDIT_ABORT_EXEMPT** privilege is available to permit a user account’s queries to always be executed even if an **abort** item would block them. Accounts with this privilege can therefore be used to regain access to a system following an audit misconfiguration. The query is still logged in the audit log, but instead of being rejected, it is permitted due to the privilege.

Accounts created with the **SYSTEM_USER** privilege have the **AUDIT_ABORT_EXEMPT** privilege assigned automatically when they are created. The **AUDIT_ABORT_EXEMPT** privilege is also assigned to existing accounts with the **SYSTEM_USER** privilege when you carry out an upgrade procedure, if no existing accounts have that privilege assigned.

The **abort** item must appear within an **event** item. For example:

```json
"event": {
  "name": "qualifying event subclass names",
  "abort": "condition"
}
```

For event subclasses selected by the **name** item, the **abort** action is true or false, depending on **condition** evaluation. If the condition evaluates to true, the event is blocked. Otherwise, the event continues executing.

The **condition** specification can be as simple as **true** or **false**, or it can be more complex such that evaluation depends on event characteristics.

This filter blocks **INSERT, UPDATE, and DELETE** statements:

```json
{
  "filter": {
    "class": {
      "name": "table_access",
      "event": {
        "name": "table_access",
        "condition": "true"
      }
    }
  }
}
```
This more complex filter blocks the same statements, but only for a specific table (finances.bank_account):

```
{
    "filter": {
        "class": {
            "name": "table_access",
            "event": {
                "name": [ "insert", "update", "delete" ],
                "abort": { "and": [
                        { "field": { "name": "table_database.str", "value": "finances" } },
                        { "field": { "name": "table_name.str", "value": "bank_account" } }
                    ],
                    "and": []
                }
            }
        }
    }
}
```

Statements matched and blocked by the filter return an error to the client:

```
ERROR 1045 (28000): Statement was aborted by an audit log filter
```

Not all events can be blocked (see Table 6.38, “Log and Abort Characteristics Per Event Class and Subclass Combination”). For an event that cannot be blocked, the audit log writes a warning to the error log rather than blocking it.

For attempts to define a filter in which the `abort` item appears elsewhere than in an `event` item, an error occurs.

**Logical Operators**

Logical operators (`and`, `or`, `not`) permit construction of complex conditions, enabling more advanced filtering configurations to be written. The following `log` item logs only `general` events with `general_command` fields having a specific value and length:

```
{
    "filter": {
        "class": {
            "name": "general",
            "event": {
                "name": "status",
                "log": {
                    "or": [
                        { "and": [
                            { "field": { "name": "general_command.str", "value": "Query" } },
                            { "field": { "name": "general_command.length", "value": 5 } }
                        ],
                        { "and": [
                            { "field": { "name": "general_command.str", "value": "Execute" } },
                            { "field": { "name": "general_command.length", "value": 7 } }
                        ]
                    ]
                }
            }
        }
    }
}
```
Referencing Predefined Variables

To refer to a predefined variable in a log condition, use a variable item, which takes name and value items and tests equality of the named variable against a given value:

```json
"variable": {
  "name": "variable_name",
  "value": comparison_value
}
```

This is true if variable_name has the value comparison_value, false otherwise.

Example:

```json
{
  "filter": {
    "class": {
      "name": "general",
      "event": {
        "name": "status",
        "log": {
          "variable": {
            "name": "audit_log_connection_policy_value",
            "value": "::none"
          }
        }
      }
    }
  }
}
```

Each predefined variable corresponds to a system variable. By writing a filter that tests a predefined variable, you can modify filter operation by setting the corresponding system variable, without having to redefine the filter. For example, by writing a filter that tests the value of the audit_log_connection_policy_value predefined variable, you can modify filter operation by changing the value of the audit_log_connection_policy system variable.

The audit_log_***_policy system variables are used for the deprecated legacy mode audit log (see Section 6.4.5.10, “Legacy Mode Audit Log Filtering”). With rule-based audit log filtering, those variables remain visible (for example, using SHOW VARIABLES), but changes to them have no effect unless you write filters containing constructs that refer to them.

The following list describes the permitted predefined variables for variable items:

- **audit_log_connection_policy_value**

  This variable corresponds to the value of the audit_log_connection_policy system variable. The value is an unsigned integer. Table 6.42, “audit_log_connection_policy_value Values” shows the permitted values and the corresponding audit_log_connection_policy values.

**Table 6.42 audit_log_connection_policy_value Values**

<table>
<thead>
<tr>
<th>Value</th>
<th>Corresponding audit_log_connection_policy Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 or &quot;::none&quot;</td>
<td>NONE</td>
</tr>
</tbody>
</table>
### MySQL Enterprise Audit

<table>
<thead>
<tr>
<th>Value</th>
<th>Corresponding <code>audit_log_connection_policy</code> Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 or &quot;::errors&quot;</td>
<td>ERRORS</td>
</tr>
<tr>
<td>2 or &quot;::all&quot;</td>
<td>ALL</td>
</tr>
</tbody>
</table>

The "::xxx" values are symbolic pseudo-constants that may be given instead of the literal numeric values. They must be quoted as strings and are case-sensitive.

- **audit_log_policy_value**

  This variable corresponds to the value of the `audit_log_policy` system variable. The value is an unsigned integer. Table 6.43, “audit_log_policy_value Values” shows the permitted values and the corresponding `audit_log_policy` values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Corresponding <code>audit_log_policy</code> Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 or &quot;::none&quot;</td>
<td>NONE</td>
</tr>
<tr>
<td>1 or &quot;::logins&quot;</td>
<td>LOGINS</td>
</tr>
<tr>
<td>2 or &quot;::all&quot;</td>
<td>ALL</td>
</tr>
<tr>
<td>3 or &quot;::queries&quot;</td>
<td>QUERIES</td>
</tr>
</tbody>
</table>

The "::xxx" values are symbolic pseudo-constants that may be given instead of the literal numeric values. They must be quoted as strings and are case-sensitive.

- **audit_log_statement_policy_value**

  This variable corresponds to the value of the `audit_log_statement_policy` system variable. The value is an unsigned integer. Table 6.44, “audit_log_statement_policy_value Values” shows the permitted values and the corresponding `audit_log_statement_policy` values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Corresponding <code>audit_log_statement_policy</code> Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 or &quot;::none&quot;</td>
<td>NONE</td>
</tr>
<tr>
<td>1 or &quot;::errors&quot;</td>
<td>ERRORS</td>
</tr>
<tr>
<td>2 or &quot;::all&quot;</td>
<td>ALL</td>
</tr>
</tbody>
</table>

The "::xxx" values are symbolic pseudo-constants that may be given instead of the literal numeric values. They must be quoted as strings and are case-sensitive.

### Referencing Predefined Functions

To refer to a predefined function in a log condition, use a `function` item, which takes `name` and `args` items to specify the function name and its arguments, respectively:

```
"function": {
  "name": "function_name",
  "args": arguments
}
```

The `name` item should specify the function name only, without parentheses or the argument list.
The `args` item must satisfy these conditions:

- If the function takes no arguments, no `args` item should be given.
- If the function does take arguments, an `args` item is needed, and the arguments must be given in the order listed in the function description. Arguments can refer to predefined variables, event fields, or string or numeric constants.

If the number of arguments is incorrect or the arguments are not of the correct data types required by the function an error occurs.

Example:

```json
{
    "filter": {
        "class": {
            "name": "general",
            "event": {
                "name": "status",
                "log": {
                    "function": {
                        "name": "find_in_include_list",
                        "args": [
                            { "string": [ { "field": "user.str" },
                                          { "string": "@"},
                                          { "field": "host.str" } ] }
                        ]
                    }
                }
            }
        }
    }
}
```

The preceding filter determines whether to log `general` class `status` events depending on whether the current user is found in the `audit_log_include_accounts` system variable. That user is constructed using fields in the event.

The following list describes the permitted predefined functions for `function` items:

- `audit_log_exclude_accounts_is_null()`
  Checks whether the `audit_log_exclude_accounts` system variable is NULL. This function can be helpful when defining filters that correspond to the legacy audit log implementation.
  Arguments:
  None.
  
- `audit_log_include_accounts_is_null()`
  Checks whether the `audit_log_include_accounts` system variable is NULL. This function can be helpful when defining filters that correspond to the legacy audit log implementation.
  Arguments:
  None.

- `debug_sleep(millisec)`
  Sleeps for the given number of milliseconds. This function is used during performance measurement.
  `debug_sleep()` is available for debug builds only.
Arguments:

- **millisec**: An unsigned integer that specifies the number of milliseconds to sleep.

- **find_in_exclude_list(account)**
  Checks whether an account string exists in the audit log exclude list (the value of the `audit_log_exclude_accounts` system variable).
  
  Arguments:
  - **account**: A string that specifies the user account name.

- **find_in_include_list(account)**
  Checks whether an account string exists in the audit log include list (the value of the `audit_log_include_accounts` system variable).
  
  Arguments:
  - **account**: A string that specifies the user account name.

- **query_digest([str])**
  This function has differing behavior depending on whether an argument is given:
  
  - With no argument, `query_digest` returns the statement digest value corresponding to the statement literal text in the current event.
  
  - With an argument, `query_digest` returns a Boolean indicating whether the argument is equal to the current statement digest.

  Arguments:
  - **str**: This argument is optional. If given, it specifies a statement digest to be compared against the digest for the statement in the current event.

Examples:

This function item includes no argument, so `query_digest` returns the current statement digest as a string:

```
"function": {
  "name": "query_digest"
}
```

This function item includes an argument, so `query_digest` returns a Boolean indicating whether the argument equals the current statement digest:

```
"function": {
  "name": "query_digest",
  "args": "SELECT ?"
}
```

- **string_find(text, substr)**
  Checks whether the `substr` value is contained in the `text` value. This search is case-sensitive.

  Arguments:
Replacement of Event Field Values

Audit filter definitions support replacement of certain audit event fields, so that logged events contain the replacement value rather than the original value. This capability enables logged audit records to include statement digests rather than literal statements, which can be useful for MySQL deployments for which statements may expose sensitive values.

Field replacement in audit events works like this:

- Field replacements are specified in audit filter definitions, so audit log filtering must be enabled as described in Section 6.4.5.7, “Audit Log Filtering”.
- Not all fields can be replaced. Table 6.45, “Event Fields Subject to Replacement” shows which fields are replaceable in which event classes.

### Table 6.45 Event Fields Subject to Replacement

<table>
<thead>
<tr>
<th>Event Class</th>
<th>Field Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>general</td>
<td>general_query.str</td>
</tr>
<tr>
<td>table_access</td>
<td>query.str</td>
</tr>
</tbody>
</table>

- Replacement is conditional. Each replacement specification in a filter definition includes a condition, enabling a replaceable field to be changed, or left unchanged, depending on the condition result.
- If replacement occurs, the replacement specification indicates the replacement value using a function that is permitted for that purpose.

As Table 6.45, “Event Fields Subject to Replacement” shows, currently the only replaceable fields are those that contain statement text (which occurs in events of the `general` and `table_access` classes). In addition, the only function permitted for specifying the replacement value is `query_digest`. This means that the only permitted replacement operation is to replace statement literal text by its corresponding digest.

Because field replacement occurs at an early auditing stage (during filtering), the choice of whether to write statement literal text or digest values applies regardless of log format written later (that is, whether the audit log plugin produces XML or JSON output).

Field replacement can take place at differing levels of event granularity:

- To perform field replacement for all events in a class, filter events at the class level.
- To perform replacement on a more fine-grained basis, include additional event-selection items. For example, you can perform field replacement only for specific subclasses of a given event class, or only in events for which fields have certain characteristics.

Within a filter definition, specify field replacement by including a `print` item, which has this syntax:

```
"print": {
  "field": {
    "name": "field_name",
    "print": condition,
    "replace": replacement_value
  }
}
```
Within the `print` item, its `field` item takes these three items to indicate how whether and how replacement occurs:

- **name**: The field for which replacement (potentially) occurs. `field_name` must be one of those shown in Table 6.45, “Event Fields Subject to Replacement”.

- **print**: The condition that determines whether to retain the original field value or replace it:
  - If `condition` evaluates to `true`, the field remains unchanged.
  - If `condition` evaluates to `false`, replacement occurs, using the value of the `replace` item.

To unconditionally replace a field, specify the condition like this:

```json
"print": false
```

- **replace**: The replacement value to use when the `print` condition evaluates to `false`. Specify `replacement_value` using a `function` item.

For example, this filter definition applies to all events in the `general` class, replacing the statement literal text with its digest:

```json
{
  "filter": {
    "class": {
      "name": "general",
      "print": {
        "field": {
          "name": "general_query.str",
          "print": false,
          "replace": {
            "function": {
              "name": "query_digest"
            }
          }
        }
      }
    }
  }
}
```

The preceding filter uses this `print` item to unconditionally replace the statement literal text contained in `general_query.str` by its digest value:

```json
"print": {
  "field": {
    "name": "general_query.str",
    "print": false,
    "replace": {
      "function": {
        "name": "query_digest"
      }
    }
  }
}
```

`print` items can be written different ways to implement different replacement strategies. The `replace` item just shown specifies the replacement text using this `function` construct to return a string representing the current statement digest:
The `query_digest` function can also be used in another way, as a comparator that returns a Boolean, which enables its use in the `print` condition. To do this, provide an argument that specifies a comparison statement digest:

```
"function": {
  "name": "query_digest",
  "args": "digest"
}
```

In this case, `query_digest` returns `true` or `false` depending on whether the current statement digest is the same as the comparison digest. Using `query_digest` this way enables filter definitions to detect statements that match particular digests. The condition in the following construct is true only for statements that have a digest equal to `SELECT ?`, thus effecting replacement only for statements that do not match the digest:

```
"print": {
  "field": {
    "name": "general_query.str",
    "print": {
      "function": {
        "name": "query_digest",
        "args": "SELECT ?"
      }
    },
    "replace": {
      "function": {
        "name": "query_digest"
      }
    }
  }
}
```

To perform replacement only for statements that do match the digest, use `not` to invert the condition:

```
"print": {
  "field": {
    "name": "general_query.str",
    "print": {
      "not": {
        "function": {
          "name": "query_digest",
          "args": "SELECT ?"
        }
      },
      "replace": {
        "function": {
          "name": "query_digest"
        }
      }
    }
  }
}
```

Suppose that you want the audit log to contain only statement digests and not literal statements. To achieve this, you must perform replacement on all events that contain statement text; that is, events in the `general` and `table_access` classes. An earlier filter definition showed how to unconditionally replace statement text for `general` events. To do the same for `table_access` events, use a filter that is similar but changes the class from `general` to `table_access` and the field name from `general_query.str` to `query.str`:
Combining the `general` and `table_access` filters results in a single filter that performs replacement for all statement text-containing events:

```json
{
  "filter": {
    "class": [
      {
        "name": "general",
        "print": {
          "field": {
            "name": "general_query.str",
            "print": false,
            "replace": {
              "function": {
                "name": "query_digest"
              }
            }
          }
        }
      }
    ,
      {
        "name": "table_access",
        "print": {
          "field": {
            "name": "query.str",
            "print": false,
            "replace": {
              "function": {
                "name": "query_digest"
              }
            }
          }
        }
      }
    ]
  }
}
```

To perform replacement on only some events within a class, add items to the filter that indicate more specifically when replacement occurs. The following filter applies to events in the `table_access` class, but performs replacement only for `insert` and `update` events (leaving `read` and `delete` events unchanged):

```json
{
  "filter": {
    "class": {
      "name": "table_access",
      "print": {
        "field": {
          "name": "query.str",
          "print": false,
          "replace": {
            "function": {
              "name": "query_digest"
            }
          }
        }
      }
    }
  }
}
```
This filter performs replacement for general class events corresponding to the listed account-management statements (the effect being to hide credential and data values in the statements):

```json
{
    "filter": {
        "class": {
            "name": "general",
            "event": {
                "name": "status",
                "print": {
                    "field": {
                        "name": "general_query.str",
                        "print": false,
                        "replace": {
                            "function": {
                                "name": "query_digest"
                            }
                        }
                    }
                }
            }
        },
        "log": {
            "or": [
                {
                    "field": {
                        "name": "general_sql_command.str",
                        "value": "alter_user"
                    }
                },
                {
                    "field": {
                        "name": "general_sql_command.str",
                        "value": "alter_user_default_role"
                    }
                },
                {
                    "field": {
                        "name": "general_sql_command.str",
                        "value": "create_role"
                    }
                },
                {
                    "field": {
                        "name": "general_sql_command.str",
                        "value": "create_user"
                    }
                }
            ]
        }
    }
}
```
Replacing a User Filter

In some cases, the filter definition can be changed dynamically. To do this, define a filter configuration within an existing filter. For example:

```json
{
  "filter": {
    "id": "main",
    "class": {
      "name": "table_access",
      "event": {
        "name": [ "update", "delete" ],
        "log": false,
        "filter": {
          "class": {
            "name": "general",
            "event": { "name": "status",
            "filter": { "ref": "main" } }
          },
          "activate": {
            "or": {
              "field": { "name": "table_name.str", "value": "temp_1" } },
              "field": { "name": "table_name.str", "value": "temp_2" } }
          }
        }
      }
    }
  }
}
```

A new filter is activated when the activate item within a subfilter evaluates to true. Using activate in a top-level filter is not permitted.

A new filter can be replaced with the original one by using a ref item inside the subfilter to refer to the original filter id.

The filter shown operates like this:

- The main filter waits for table_access events, either update or delete.
- If the update or delete table_access event occurs on the temp_1 or temp_2 table, the filter is replaced with the internal one (without an id, since there is no need to refer to it explicitly).
- If the end of the command is signalled (general / status event), an entry is written to the audit log file and the filter is replaced with the main filter.

The filter is useful to log statements that update or delete anything from the temp_1 or temp_2 tables, such as this one:

```
UPDATE temp_1, temp_3 SET temp_1.a=21, temp_3.a=23;
```
The statement generates multiple `table_access` events, but the audit log file contains only `general / status` entries.

Note

Any `id` values used in the definition are evaluated with respect only to that definition. They have nothing to do with the value of the `audit_log_filter_id` system variable.

### 6.4.5.9 Disabling Audit Logging

The `audit_log_disable` variable permits disabling audit logging for all connecting and connected sessions. The `audit_log_disable` variable can be set in a MySQL Server option file, in a command-line startup string, or at runtime using a `SET` statement; for example:

```sql
SET GLOBAL audit_log_disable = true;
```

Setting `audit_log_disable` to true disables the audit log plugin. The plugin is re-enabled when `audit_log_disable` is set back to `false`, which is the default setting.

Starting the audit log plugin with `audit_log_disable = true` generates a warning (`ER_WARN_AUDIT_LOG_DISABLED`) with the following message: Audit Log is disabled. Enable it with `audit_log_disable = false`. Setting `audit_log_disable` to false also generates warning. When `audit_log_disable` is set to true, audit log function calls and variable changes generate a session warning.

Setting the runtime value of `audit_log_disable` requires the `AUDIT_ADMIN` privilege, in addition to the `SYSTEM_VARIABLES_ADMIN` privilege (or the deprecated `SUPER` privilege) normally required to set a global system variable runtime value.

### 6.4.5.10 Legacy Mode Audit Log Filtering

Note

This section describes legacy audit log filtering, which applies if the `audit_log` plugin is installed without the accompanying audit tables and functions needed for rule-based filtering.

Legacy Mode Audit Log Filtering is deprecated.

The audit log plugin can filter audited events. This enables you to control whether audited events are written to the audit log file based on the account from which events originate or event status. Status filtering occurs separately for connection events and statement events.

- Legacy Event Filtering by Account
- Legacy Event Filtering by Status

### Legacy Event Filtering by Account

To filter audited events based on the originating account, set one (not both) of the following system variables at server startup or runtime. These deprecated variables apply only for legacy audit log filtering.

- `audit_log_include_accounts`: The accounts to include in audit logging. If this variable is set, only these accounts are audited.
• **audit_log_exclude_accounts**: The accounts to exclude from audit logging. If this variable is set, all but these accounts are audited.

The value for either variable can be `NULL` or a string containing one or more comma-separated account names, each in `user_name@host_name` format. By default, both variables are `NULL`, in which case, no account filtering is done and auditing occurs for all accounts.

Modifications to `audit_log_include_accounts` or `audit_log_exclude_accounts` affect only connections created subsequent to the modification, not existing connections.

Example: To enable audit logging only for the `user1` and `user2` local host accounts, set the `audit_log_include_accounts` system variable like this:

```
SET GLOBAL audit_log_include_accounts = 'user1@localhost,user2@localhost';
```

Only one of `audit_log_include_accounts` or `audit_log_exclude_accounts` can be non-NULL at a time:

- If you set `audit_log_include_accounts`, the server sets `audit_log_exclude_accounts` to `NULL`.
- If you attempt to set `audit_log_exclude_accounts`, an error occurs unless `audit_log_include_accounts` is `NULL`. In this case, you must first clear `audit_log_include_accounts` by setting it to `NULL`.

```
-- This sets audit_log_exclude_accounts to NULL
SET GLOBAL audit_log_include_accounts = value;

-- This fails because audit_log_include_accounts is not NULL
SET GLOBAL audit_log_exclude_accounts = value;

-- To set audit_log_exclude_accounts, first set
-- audit_log_include_accounts to NULL
SET GLOBAL audit_log_include_accounts = NULL;
SET GLOBAL audit_log_exclude_accounts = value;
```

If you inspect the value of either variable, be aware that `SHOW VARIABLES` displays `NULL` as an empty string. To display `NULL` as `NULL`, use `SELECT` instead:

```
mysql> SHOW VARIABLES LIKE 'audit_log_include_accounts';
+---------------------------------+---------+
| Variable_name                    | Value   |
+---------------------------------+---------+
| audit_log_include_accounts       |        |
+---------------------------------+---------+
mysql> SELECT @@audit_log_include_accounts;
+--------------------------------------+
| @@audit_log_include_accounts        |
| NULL                                |
+--------------------------------------+
```

If a user name or host name requires quoting because it contains a comma, space, or other special character, quote it using single quotes. If the variable value itself is quoted with single quotes, double each inner single quote or escape it with a backslash. The following statements each enable audit logging for the local `root` account and are equivalent, even though the quoting styles differ:

```
SET GLOBAL audit_log_include_accounts = 'root@localhost';
SET GLOBAL audit_log_include_accounts = '''root''@'''localhost'''';
SET GLOBAL audit_log_include_accounts = '\root\'@\'localhost\'';
SET GLOBAL audit_log_include_accounts = '''root''@''localhost''';
```
The last statement does not work if the ANSI_QUOTES SQL mode is enabled because in that mode double quotes signify identifier quoting, not string quoting.

Legacy Event Filtering by Status

To filter audited events based on status, set the following system variables at server startup or runtime. These deprecated variables apply only for legacy audit log filtering. For JSON audit log filtering, different status variables apply; see Audit Log Options and Variables.

- `audit_log_connection_policy`: Logging policy for connection events
- `audit_log_statement_policy`: Logging policy for statement events

Each variable takes a value of ALL (log all associated events; this is the default), ERRORS (log only failed events), or NONE (do not log events). For example, to log all statement events but only failed connection events, use these settings:

```sql
SET GLOBAL audit_log_statement_policy = ALL;
SET GLOBAL audit_log_connection_policy = ERRORS;
```

Another policy system variable, `audit_log_policy`, is available but does not afford as much control as `audit_log_connection_policy` and `audit_log_statement_policy`. It can be set only at server startup.

![Note](image)

The `audit_log_policy` legacy-mode system variable is deprecated.

At runtime, it is a read-only variable. It takes a value of ALL (log all events; this is the default), LOGINS (log connection events), QUERIES (log statement events), or NONE (do not log events). For any of those values, the audit log plugin logs all selected events without distinction as to success or failure. Use of `audit_log_policy` at startup works as follows:

- If you do not set `audit_log_policy` or set it to its default of ALL, any explicit settings for `audit_log_connection_policy` or `audit_log_statement_policy` apply as specified. If not specified, they default to ALL.
- If you set `audit_log_policy` to a non-ALL value, that value takes precedence over and is used to set `audit_log_connection_policy` and `audit_log_statement_policy`, as indicated in the following table. If you also set either of those variables to a value other than their default of ALL, the server writes a message to the error log to indicate that their values are being overridden.

<table>
<thead>
<tr>
<th>Startup audit_log_policy Value</th>
<th>Resulting audit_log_connection_policy Value</th>
<th>Resulting audit_log_statement_policy Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOGINS</td>
<td>ALL</td>
<td>NONE</td>
</tr>
<tr>
<td>QUERIES</td>
<td>NONE</td>
<td>ALL</td>
</tr>
<tr>
<td>NONE</td>
<td>NONE</td>
<td>NONE</td>
</tr>
</tbody>
</table>

6.4.5.11 Audit Log Reference

The following sections provide a reference to MySQL Enterprise Audit elements:

- Audit Log Tables
- Audit Log Functions
• Audit Log Option and Variable Reference
• Audit Log Options and Variables
• Audit Log Status Variables

To install the audit log tables and functions, use the instructions provided in Section 6.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”. Unless those objects are installed, the audit_log plugin operates in (deprecated) legacy mode. See Section 6.4.5.10, “Legacy Mode Audit Log Filtering”.

Audit Log Tables

MySQL Enterprise Audit uses tables in the mysql system database for persistent storage of filter and user account data. The tables can be accessed only by users who have privileges for that database. To use a different database, set the audit_log_database system variable at server startup. The tables use the InnoDB storage engine.

If these tables are missing, the audit_log plugin operates in (deprecated) legacy mode. See Section 6.4.5.10, “Legacy Mode Audit Log Filtering”.

The audit_log_filter table stores filter definitions. The table has these columns:

• NAME
  The filter name.

• FILTER
  The filter definition associated with the filter name. Definitions are stored as JSON values.

The audit_log_user table stores user account information. The table has these columns:

• USER
  The user name part of an account. For an account user1@localhost, the USER part is user1.

• HOST
  The host name part of an account. For an account user1@localhost, the HOST part is localhost.

• FILTERNAME
  The name of the filter assigned to the account. The filter name associates the account with a filter defined in the audit_log_filter table.

Audit Log Functions

This section describes, for each audit log function, its purpose, calling sequence, and return value. For information about the conditions under which these functions can be invoked, see Section 6.4.5.7, “Audit Log Filtering”.

Each audit log function returns a string that indicates whether the operation succeeded. OK indicates success. ERROR: message indicates failure.

Audit log functions convert string arguments to utf8mb4 and string return values are utf8mb4 strings. Previously, audit log functions treated string arguments as binary strings (which means they did not distinguish lettercase), and string return values were binary strings.
If an audit log function is invoked from within the mysql client, binary string results display using hexadecimal notation, depending on the value of the --binary-as-hex. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

These audit log functions are available:

- **audit_log_encryption_password_get([keyring_id])**

  This function fetches an audit log encryption password from the MySQL keyring, which must be enabled or an error occurs. Any keyring component or plugin can be used; for instructions, see Section 6.4.4, “The MySQL Keyring”.

  With no argument, the function retrieves the current encryption password as a binary string. An argument may be given to specify which audit log encryption password to retrieve. The argument must be the keyring ID of the current password or an archived password.

  For additional information about audit log encryption, see Encrypting Audit Log Files.

  Arguments:

  - **keyring_id**: This optional argument indicates the keyring ID of the password to retrieve. The maximum permitted length is 766 bytes. If omitted, the function retrieves the current password.

  Return value:

  The password string for success (up to 766 bytes), or NULL and an error for failure.

  Example:

  Retrieve the current password:

  ```
  mysql> SELECT audit_log_encryption_password_get();
  +-------------------------------------+
  | audit_log_encryption_password_get() |
  +-------------------------------------+
  | secret                              |
  +-------------------------------------+
  ```

  To retrieve a password by ID, you can determine which audit log keyring IDs exist by querying the Performance Schema keyring_keys table:

  ```
  mysql> SELECT KEY_ID FROM performance_schema.keyring_keys WHERE KEY_ID LIKE 'audit_log%'
  ORDER BY KEY_ID;
  +-----------------------------+
  | KEY_ID                      |
  +-----------------------------+
  | audit_log-20190415T152248-1 |
  | audit_log-20190415T153507-1 |
  | audit_log-20190416T125122-1 |
  | audit_log-20190416T141608-1 |
  +-----------------------------+
  mysql> SELECT audit_log_encryption_password_get('audit_log-20190416T125122-1');
  +------------------------------------------------------------------+
  | audit_log_encryption_password_get('audit_log-20190416T125122-1') |
  +------------------------------------------------------------------+
  | segreto                                                          |
  +------------------------------------------------------------------+
  ```

- **audit_log_encryption_password_set(password)**
Sets the current audit log encryption password to the argument and stores the password in the MySQL keyring. The password is stored as a `utf8mb4` string. Previously, the password was stored in binary form.

If encryption is enabled, this function performs a log file rotation operation that renames the current log file, and begins a new log file encrypted with the password. The keyring must be enabled or an error occurs. Any keyring component or plugin can be used; for instructions, see Section 6.4.4, “The MySQL Keyring”.

For additional information about audit log encryption, see Encrypting Audit Log Files.

Arguments:

`password`: The password string. The maximum permitted length is 766 bytes.

Return value:

1 for success, 0 for failure.

Example:

```
mysql> SELECT audit_log_encryption_password_set(password);
+---------------------------------------------+
| audit_log_encryption_password_set(password) |
| 1                                           |
+---------------------------------------------+
```

• `audit_log_filter_flush()`

Calling any of the other filtering functions affects operational audit log filtering immediately and updates the audit log tables. If instead you modify the contents of those tables directly using statements such as `INSERT`, `UPDATE`, and `DELETE`, the changes do not affect filtering immediately. To flush your changes and make them operational, call `audit_log_filter_flush()`.

**Warning**

`audit_log_filter_flush()` should be used only after modifying the audit tables directly, to force reloading all filters. Otherwise, this function should
be avoided. It is, in effect, a simplified version of unloading and reloading the `audit_log` plugin with `UNINSTALL PLUGIN` plus `INSTALL PLUGIN`.

`audit_log_filter_flush()` affects all current sessions and detaches them from their previous filters. Current sessions are no longer logged unless they disconnect and reconnect, or execute a change-user operation.

If this function fails, an error message is returned and the audit log is disabled until the next successful call to `audit_log_filter_flush()`.

Arguments:

None.

Return value:

A string that indicates whether the operation succeeded. `OK` indicates success. `ERROR: message` indicates failure.

Example:

```sql
mysql> SELECT audit_log_filter_flush();
+--------------------------+
| audit_log_filter_flush() |
| OK                       |
+--------------------------+
```

- `audit_log_filter_remove_filter(filter_name)`

Given a filter name, removes the filter from the current set of filters. It is not an error for the filter not to exist.

If a removed filter is assigned to any user accounts, those users stop being filtered (they are removed from the `audit_log_user` table). Termination of filtering includes any current sessions for those users: They are detached from the filter and no longer logged.

Arguments:

- `filter_name`: A string that specifies the filter name.

Return value:

A string that indicates whether the operation succeeded. `OK` indicates success. `ERROR: message` indicates failure.

Example:

```sql
mysql> SELECT audit_log_filter_remove_filter('SomeFilter');
+----------------------------------------------+
| audit_log_filter_remove_filter('SomeFilter') |
| OK                                           |
+----------------------------------------------+
```

- `audit_log_filter_remove_user(user_name)`

Given a user account name, cause the user to be no longer assigned to a filter. It is not an error if the user has no filter assigned. Filtering of current sessions for the user remains unaffected. New
connections for the user are filtered using the default account filter if there is one, and are not logged otherwise.

If the name is %, the function removes the default account filter that is used for any user account that has no explicitly assigned filter.

Arguments:

• **user_name**: The user account name as a string in `user_name@host_name` format, or % to represent the default account.

Return value:

A string that indicates whether the operation succeeded. **OK** indicates success. **ERROR: message** indicates failure.

Example:

```sql
mysql> SELECT audit_log_filter_remove_user('user1@localhost');
+-----------------------------------------------+
| audit_log_filter_remove_user('user1@localhost') |
| OK                                              |
+-----------------------------------------------+
```

• **audit_log_filter_set_filter(filter_name, definition)**

Given a filter name and definition, adds the filter to the current set of filters. If the filter already exists and is used by any current sessions, those sessions are detached from the filter and are no longer logged. This occurs because the new filter definition has a new filter ID that differs from its previous ID.

Arguments:

• **filter_name**: A string that specifies the filter name.

• **definition**: A JSON value that specifies the filter definition.

Return value:

A string that indicates whether the operation succeeded. **OK** indicates success. **ERROR: message** indicates failure.

Example:

```sql
mysql> SET @f = '{ "filter": { "log": false } }';
mysql> SELECT audit_log_filter_set_filter('SomeFilter', @f);
+-----------------------------------------------+
| audit_log_filter_set_filter('SomeFilter', @f) |
| OK                                            |
+-----------------------------------------------+
```

• **audit_log_filter_set_user(user_name, filter_name)**

Given a user account name and a filter name, assigns the filter to the user. A user can be assigned only one filter, so if the user was already assigned a filter, the assignment is replaced. Filtering of current sessions for the user remains unaffected. New connections are filtered using the new filter.

As a special case, the name % represents the default account. The filter is used for connections from any user account that has no explicitly assigned filter.
Arguments:

- **user_name**: The user account name as a string in `user_name@host_name` format, or % to represent the default account.

- **filter_name**: A string that specifies the filter name.

Return value:

A string that indicates whether the operation succeeded. **OK** indicates success. **ERROR**: **message** indicates failure.

Example:

```sql
mysql> SELECT audit_log_filter_set_user('user1@localhost', 'SomeFilter');
+------------------------------------------------------------+
| audit_log_filter_set_user('user1@localhost', 'SomeFilter') |
+------------------------------------------------------------+
| OK                                                         |
+------------------------------------------------------------+
```

**audit_log_read([arg])**

Reads the audit log and returns a **JSON** string result. If the audit log format is not **JSON**, an error occurs.

With no argument or a **JSON** hash argument, `audit_log_read()` reads events from the audit log and returns a **JSON** string containing an array of audit events. Items in the hash argument influence how reading occurs, as described later. Each element in the returned array is an event represented as a **JSON** hash, with the exception that the last element may be a **JSON null** value to indicate no following events are available to read.

With an argument consisting of a **JSON null** value, `audit_log_read()` closes the current read sequence.

For additional details about the audit log-reading process, see Section 6.4.5.6, “Reading Audit Log Files”.

Arguments:

To obtain a bookmark for the most recently written event, call `audit_log_read_bookmark()`.

**arg**: The argument is optional. If omitted, the function reads events from the current position. If present, the argument can be a **JSON null** value to close the read sequence, or a **JSON** hash. Within a hash argument, items are optional and control aspects of the read operation such as the position at which to begin reading or how many events to read. The following items are significant (other items are ignored):

- **start**: The position within the audit log of the first event to read. The position is given as a timestamp and the read starts from the first event that occurs on or after the timestamp value. The **start** item has this format, where **value** is a literal timestamp value:

  ```json
  "start": { "timestamp": "value" }
  ```

- **timestamp, id**: The position within the audit log of the first event to read. The **timestamp** and **id** items together comprise a bookmark that uniquely identify a particular event. If an
MySQL Enterprise Audit

audit_log_read() argument includes either item, it must include both to completely specify a
position or an error occurs.
• max_array_length: The maximum number of events to read from the log. If this item is omitted, the
default is to read to the end of the log or until the read buffer is full, whichever comes first.
To specify a starting position to audit_log_read(), pass a hash argument that includes either a
start item or a bookmark consisting of timestamp and id items. If a hash argument includes both a
start item and a bookmark, an error occurs.
If a hash argument specifies no starting position, reading continues from the current position.
If a timestamp value includes no time part, a time part of 00:00:00 is assumed.
Return value:
If the call succeeds, the return value is a JSON string containing an array of audit events, or a JSON
null value if that was passed as the argument to close the read sequence. If the call fails, the return
value is NULL and an error occurs.
Example:
mysql> SELECT audit_log_read(audit_log_read_bookmark());
+-----------------------------------------------------------------------+
| audit_log_read(audit_log_read_bookmark())
|
+-----------------------------------------------------------------------+
| [ {"timestamp":"2020-05-18 22:41:24","id":0,"class":"connection", ... |
+-----------------------------------------------------------------------+
mysql> SELECT audit_log_read('null');
+------------------------+
| audit_log_read('null') |
+------------------------+
| null
|
+------------------------+

Notes:
Prior to MySQL 8.2, string return values could be binary JSON strings. For information about converting
such values to nonbinary strings, see Section 6.4.5.6, “Reading Audit Log Files”.

1617


• `audit_log_read_bookmark()`

Returns a **JSON** string representing a bookmark for the most recently written audit log event. If the audit log format is not **JSON**, an error occurs.

The bookmark is a **JSON** hash with `timestamp` and `id` items that uniquely identify the position of an event within the audit log. It is suitable for passing to `audit_log_read()` to indicate to that function the position at which to begin reading.

For additional details about the audit log-reading process, see Section 6.4.5.6, “Reading Audit Log Files”.

Arguments:
None.

Return value:
A **JSON** string containing a bookmark for success, or **NULL** and an error for failure.

Example:
```
mysql> SELECT audit_log_read_bookmark();
+-------------------------------------------------+
| audit_log_read_bookmark()                       |
+-------------------------------------------------+
| { "timestamp": "2019-10-03 21:03:44", "id": 0 } |
+-------------------------------------------------+
```

Notes:
Prior to MySQL 8.2, string return values could be binary **JSON** strings. For information about converting such values to nonbinary strings, see Section 6.4.5.6, “Reading Audit Log Files”.

• `audit_log_rotate()`

Arguments:
None.

Return value:
The renamed file name.

Example:
```
mysql> SELECT audit_log_rotate();
```

Using `audit_log_rotate()` requires the `AUDIT_ADMIN` privilege.

### Audit Log Option and Variable Reference

Audit Log Options and Variables

This section describes the command options and system variables that configure operation of MySQL Enterprise Audit. If values specified at startup time are incorrect, the `audit_log` plugin may fail to initialize properly and the server does not load it. In this case, the server may also produce error messages for other audit log settings because it does not recognize them.

To configure activation of the audit log plugin, use this option:

- `--audit-log[=value]`

<table>

Command-Line Format | `--audit-log[=value]`
Type                  | Enumeration
This option controls how the server loads the `audit_log` plugin at startup. It is available only if the plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load` or `--plugin-load-add`. See Section 6.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”.

The option value should be one of those available for plugin-loading options, as described in Section 5.6.1, “Installing and Uninstalling Plugins”. For example, `--audit-log=FORCE_PLUS_PERMANENT` tells the server to load the plugin and prevent it from being removed while the server is running.

If the audit log plugin is enabled, it exposes several system variables that permit control over logging:

```sql
mysql> SHOW VARIABLES LIKE 'audit_log%';
+--------------------------------------+--------------+
| Variable_name                        | Value        |
+--------------------------------------+--------------+
| audit_log_buffer_size                | 1048576      |
| audit_log_compression                | NONE         |
| audit_log_connection_policy          | ALL          |
| audit_log_current_session            | OFF          |
| audit_log_database                   | mysql        |
| audit_log_disable                    | OFF          |
| audit_log_encryption                 | NONE         |
| audit_log_exclude_accounts           |              |
| audit_log_file                       | audit.log    |
| audit_log_filter_id                  | 0            |
| audit_log_flush                      | OFF          |
| audit_log_flush_interval_seconds     | 0            |
| audit_log_format                     | NEW          |
| audit_log_format_unix_timestamp      | OFF          |
| audit_log_include_accounts           |              |
| audit_log_max_size                   | 0            |
| audit_log_password_history_keep_days | 0            |
| audit_log_policy                     | ALL          |
| audit_log_prune_seconds              | 0            |
| audit_log_read_buffer_size           | 32768        |
| audit_log_rotate_on_size             | 0            |
| audit_log_statement_policy           | ALL          |
| audit_log_strategy                   | ASYNCHRONOUS |
+--------------------------------------+--------------+
```

You can set any of these variables at server startup, and some of them at runtime. Those that are available only for legacy mode audit log filtering are so noted.

- **audit_log_buffer_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--audit-log-buffer-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>audit_log_buffer_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>
When the audit log plugin writes events to the log asynchronously, it uses a buffer to store event contents prior to writing them. This variable controls the size of that buffer, in bytes. The server adjusts the value to a multiple of 4096. The plugin uses a single buffer, which it allocates when it initializes and removes when it terminates. The plugin allocates this buffer only if logging is asynchronous.

- **audit_log_compression**

Command-Line Format  
--audit-log-compression=value

System Variable  
audit_log_compression

Scope  
Global

Dynamic  
No

SET_VAR Hint Applies  
No

Type  
Enumeration

Default Value  
NONE

Valid Values  
NONE

GZIP

The type of compression for the audit log file. Permitted values are NONE (no compression; the default) and GZIP (GNU Zip compression). For more information, see Compressing Audit Log Files.

- **audit_log_connection_policy**

Command-Line Format  
--audit-log-connection-policy=value

Deprecated  
Yes

System Variable  
audit_log_connection_policy

Scope  
Global

Dynamic  
Yes

SET_VAR Hint Applies  
No

Type  
Enumeration

Default Value  
ALL

Valid Values  
ALL

ERRORS
Note

This deprecated variable applies only to legacy mode audit log filtering (see Section 6.4.5.10, “Legacy Mode Audit Log Filtering”).

The policy controlling how the audit log plugin writes connection events to its log file. The following table shows the permitted values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>Log all connection events</td>
</tr>
<tr>
<td>ERRORS</td>
<td>Log only failed connection events</td>
</tr>
<tr>
<td>NONE</td>
<td>Do not log connection events</td>
</tr>
</tbody>
</table>

Note

At server startup, any explicit value given for audit_log_connection_policy may be overridden if audit_log_policy is also specified, as described in Section 6.4.5.5, “Configuring Audit Logging Characteristics”.

• audit_log_current_session

<table>
<thead>
<tr>
<th>System Variable</th>
<th>audit_log_current_session</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>depends on filtering policy</td>
</tr>
</tbody>
</table>

Whether audit logging is enabled for the current session. The session value of this variable is read only. It is set when the session begins based on the values of the audit_log_include_accounts and audit_log_exclude_accounts system variables. The audit log plugin uses the session value to determine whether to audit events for the session. (There is a global value, but the plugin does not use it.)

• audit_log_database

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--audit-log-database=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>audit_log_database</td>
</tr>
<tr>
<td>Scope</td>

<th>Yes</th>
</tr>
</thead>
</table>

SET_VAR Hint Applies

<table>
<thead>
<tr>
<th>SET_VAR Hint Applies</th>
<th>No</th>
</tr>
</thead>
</table>

Type

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
</table>
The accounts for which events should not be logged. The value should be NULL or a string containing a list of one or more comma-separated account names. For more information, see Section 6.4.5.7, “Audit Log Filtering”.

Modifications to `audit_log_exclude_accounts` affect only connections created subsequent to the modification, not existing connections.

### audit_log_file

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--audit-log-file=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>audit_log_file</code></td>
</tr>

<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>audit.log</code></td>
</tr>
</tbody>
</table>

The base name and suffix of the file to which the audit log plugin writes events. The default value is `audit.log`, regardless of logging format. To have the name suffix correspond to the format, set the name explicitly, choosing a different suffix (for example, `audit.xml` for XML format, `audit.json` for JSON format).

If the value of `audit_log_file` is a relative path name, the plugin interprets it relative to the data directory. If the value is a full path name, the plugin uses the value as is. A full path name may be useful if it is desirable to locate audit files on a separate file system or directory. For security reasons, write the audit log file to a directory accessible only to the MySQL server and to users with a legitimate reason to view the log.

For details about how the audit log plugin interprets the `audit_log_file` value and the rules for file renaming that occurs at plugin initialization and termination, see Naming Conventions for Audit Log Files.

The audit log plugin uses the directory containing the audit log file (determined from the `audit_log_file` value) as the location to search for readable audit log files. From these log files and the current file, the plugin constructs a list of the ones that are subject to use with the audit log bookmarking and reading functions. See Section 6.4.5.6, “Reading Audit Log Files”.

### audit_log_filter_id

<table>
<thead>
<tr>
<th>System Variable</th>
<th><code>audit_log_filter_id</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
</tbody>
</table>
The session value of this variable indicates the internally maintained ID of the audit filter for the current session. A value of 0 means that the session has no filter assigned.

- **audit_log_flush**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>audit_log_flush</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

  **Note**

  The `audit_log_flush` variable is deprecated as of MySQL 8.0.31; expect support for it to be removed in a future version of MySQL. It is superseded by the `audit_log_rotate()` function.

  If `audit_log_rotate_on_size` is 0, automatic audit log file rotation is disabled and rotation occurs only when performed manually. In that case, enabling `audit_log_flush` by setting it to 1 or ON causes the audit log plugin to close and reopen its log file to flush it. (The variable value remains OFF so that you need not disable it explicitly before enabling it again to perform another flush.) For more information, see Section 6.4.5.5, “Configuring Audit Logging Characteristics”.

- **audit_log_flush_interval_seconds**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--audit-log-flush-interval-seconds[=value]</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>audit_log_flush_interval_seconds</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Unsigned Long</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value (Windows)</td>
<td>4294967295</td>
</tr>
<tr>
<td>Maximum Value (Other)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Unit</td>
<td>seconds</td>
</tr>
</tbody>
</table>

  This system variable depends on the `scheduler` component, which must be installed and enabled (see Section 5.5.5, “Scheduler Component”). To check the status of the component:
When `audit_log_flush_interval_seconds` has a value of zero (the default), no automatic refresh of the privileges occurs, even if the `scheduler` component is enabled (ON).

Values between 0 and 60 (1 to 59) are not acknowledged; instead, these values adjust to 60 automatically and the server emits a warning. Values greater than 60 define the number of seconds the `scheduler` component waits from startup, or from the beginning of the previous execution, until it attempts to schedule another execution.

To persist this global system variable to the `mysqld-auto.cnf` file without setting the global variable runtime value, precede the variable name by the `PERSIST_ONLY` keyword or the `@@PERSIST_ONLY.` qualifier.

- `audit_log_format`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--audit-log-format=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>audit_log_format</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>NEW</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>OLD</code></td>
</tr>
<tr>
<td></td>
<td><code>NEW</code></td>
</tr>
<tr>
<td></td>
<td><code>JSON</code></td>
</tr>
</tbody>
</table>

The audit log file format. Permitted values are `OLD` (old-style XML), `NEW` (new-style XML; the default), and `JSON`. For details about each format, see Section 6.4.5.4, “Audit Log File Formats”.

- `audit_log_format_unix_timestamp`

| Command-Line Format | `--audit-log-format-unix-timestamp[={OFF|ON}]` |
|---------------------|---------------------------------------------|
| System Variable     | `audit_log_format_unix_timestamp`         |
| Scope               | Global                                    |
| Dynamic             | Yes                                        |
| `SET_VAR` Hint Applies | No                              |
| Type                | Boolean                                   |
MySQL Enterprise Audit

<table>
<thead>
<tr>
<th>Default Value</th>
<th>OFF</th>
</tr>
</thead>
</table>

This variable applies only for JSON-format audit log output. When that is true, enabling this variable causes each log file record to include a `time` field. The field value is an integer that represents the UNIX timestamp value indicating the date and time when the audit event was generated.

Changing the value of this variable at runtime causes log file rotation so that, for a given JSON-format log file, all records in the file either do or do not include the `time` field.

Setting the runtime value of `audit_log_format_unix_timestamp` requires the `AUDIT_ADMIN` privilege, in addition to the `SYSTEM_VARIABLES_ADMIN` privilege (or the deprecated `SUPER` privilege) normally required to set a global system variable runtime value.

• **audit_log_include_accounts**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--audit-log-include-accounts=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>audit_log_include_accounts</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>NULL</code></td>
</tr>
</tbody>
</table>

**Note**

This deprecated variable applies only to legacy mode audit log filtering (see Section 6.4.5.10, “Legacy Mode Audit Log Filtering”).

The accounts for which events should be logged. The value should be `NULL` or a string containing a list of one or more comma-separated account names. For more information, see Section 6.4.5.7, “Audit Log Filtering”.

Modifications to `audit_log_include_accounts` affect only connections created subsequent to the modification, not existing connections.

• **audit_log_max_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--audit-log-max-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>audit_log_max_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value (Windows)</td>
<td>4294967295</td>
</tr>
<tr>
<td>Maximum Value (Other)</td>
<td>18446744073709551615</td>
</tr>
</tbody>
</table>
audit_log_max_size pertains to audit log file pruning, which is supported for JSON-format log files only. It controls pruning based on combined log file size:

- A value of 0 (the default) disables size-based pruning. No size limit is enforced.
- A value greater than 0 enables size-based pruning. The value is the combined size above which audit log files become subject to pruning.

If you set audit_log_max_size to a value that is not a multiple of 4096, it is truncated to the nearest multiple. In particular, setting it to a value less than 4096 sets it to 0 and no size-based pruning occurs.

If both audit_log_max_size and audit_log_rotate_on_size are greater than 0, audit_log_max_size should be more than 7 times the value of audit_log_rotate_on_size. Otherwise, a warning is written to the server error log because in this case the “granularity” of size-based pruning may be insufficient to prevent removal of all or most rotated log files each time it occurs.

**Note**

Setting audit_log_max_size by itself is not sufficient to cause log file pruning to occur because the pruning algorithm uses audit_log_rotate_on_size, audit_log_max_size, and audit_log_prune_seconds in conjunction. For details, see Space Management of Audit Log Files.

- audit_log_password_history_keep_days

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--audit-log-password-history-keep-days=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>audit_log_password_history_keep_days</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
<tr>
<td>Unit</td>
<td>days</td>
</tr>
</tbody>
</table>

The audit log plugin implements log file encryption using encryption passwords stored in the MySQL keyring (see Encrypting Audit Log Files). The plugin also implements password history, which includes password archiving and expiration (removal).

When the audit log plugin creates a new encryption password, it archives the previous password, if one exists, for later use. The audit_log_password_history_keep_days variable controls automatic removal of expired archived passwords. Its value indicates the number of days after which archived audit
log encryption passwords are removed. The default of 0 disables password expiration: the password retention period is forever.

New audit log encryption passwords are created under these circumstances:

- During plugin initialization, if the plugin finds that log file encryption is enabled, it checks whether the keyring contains an audit log encryption password. If not, the plugin automatically generates a random initial encryption password.
- When the `audit_log_encryption_password_set()` function is called to set a specific password.

In each case, the plugin stores the new password in the key ring and uses it to encrypt new log files.

Removal of expired audit log encryption passwords occurs under these circumstances:

- During plugin initialization.
- When the `audit_log_encryption_password_set()` function is called.
- When the runtime value of `audit_log_password_history_keep_days` is changed from its current value to a value greater than 0. Runtime value changes occur for `SET` statements that use the `GLOBAL` or `PERSIST` keyword, but not the `PERSIST_ONLY` keyword. `PERSIST_ONLY` writes the variable setting to `mysqld-auto.cnf`, but has no effect on the runtime value.

When password removal occurs, the current value of `audit_log_password_history_keep_days` determines which passwords to remove:

- If the value is 0, the plugin removes no passwords.
- If the value is $N > 0$, the plugin removes passwords more than $N$ days old.

\[\text{Note}\]

Take care not to expire old passwords that are still needed to read archived encrypted log files.

If you normally leave password expiration disabled (that is, `audit_log_password_history_keep_days` has a value of 0), it is possible to perform an on-demand cleanup operation by temporarily assigning the variable a value greater than zero. For example, to expire passwords older than 365 days, do this:

```sql
SET GLOBAL audit_log_password_history_keep_days = 365;
SET GLOBAL audit_log_password_history_keep_days = 0;
```

Setting the runtime value of `audit_log_password_history_keep_days` requires the `AUDIT_ADMIN` privilege, in addition to the `SYSTEM_VARIABLES_ADMIN` privilege (or the deprecated `SUPER` privilege) normally required to set a global system variable runtime value.

- **audit_log_policy**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--audit-log-policy=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>audit_log_policy</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
</tbody>
</table>
The policy controlling how the audit log plugin writes events to its log file. The following table shows the permitted values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>Log all events</td>
</tr>
<tr>
<td>LOGINS</td>
<td>Log only login events</td>
</tr>
<tr>
<td>QUERIES</td>
<td>Log only query events</td>
</tr>
<tr>
<td>NONE</td>
<td>Log nothing (disable the audit stream)</td>
</tr>
</tbody>
</table>

**audit_log_policy** can be set only at server startup. At runtime, it is a read-only variable. Two other system variables, **audit_log_connection_policy** and **audit_log_statement_policy**, provide finer control over logging policy and can be set either at startup or at runtime. If you use **audit_log_policy** at startup instead of the other two variables, the server uses its value to set those variables. For more information about the policy variables and their interaction, see Section 6.4.5.5, “Configuring Audit Logging Characteristics”.

- **audit_log_prune_seconds**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--audit-log-prune-seconds=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>audit_log_prune_seconds</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value (Windows)</td>
<td>4294967295</td>
</tr>
<tr>
<td>Maximum Value (Other)</td>
<td>18446744073709551615</td>
</tr>
</tbody>
</table>
**audit_log_prune_seconds** pertains to audit log file pruning, which is supported for JSON-format log files only. It controls pruning based on log file age:

- A value of 0 (the default) disables age-based pruning. No age limit is enforced.
- A value greater than 0 enables age-based pruning. The value is the number of seconds after which audit log files become subject to pruning.

**Note**

Setting `audit_log_prune_seconds` by itself is not sufficient to cause log file pruning to occur because the pruning algorithm uses `audit_log_rotate_on_size`, `audit_log_max_size`, and `audit_log_prune_seconds` in conjunction. For details, see [Space Management of Audit Log Files](#).

**• audit_log_read_buffer_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--audit-log-read-buffer-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>audit_log_read_buffer_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code></td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>32768</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>32768</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4194304</td>
</tr>
<tr>
<td>Unit</td>
<td>bytes</td>
</tr>
</tbody>
</table>

The buffer size for reading from the audit log file, in bytes. The `audit_log_read()` function reads no more than this many bytes. Log file reading is supported only for JSON log format. For more information, see [Section 6.4.5.6, “Reading Audit Log Files”](#).

This variable has a default of 32KB and can be set at runtime. Each client should set its session value of `audit_log_read_buffer_size` appropriately for its use of `audit_log_read()`.

**• audit_log_rotate_on_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--audit-log-rotate-on-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>audit_log_rotate_on_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code></td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------------</td>
</tr>
<tr>
<td>Unit</td>
<td>bytes</td>
</tr>
<tr>
<td>Block Size</td>
<td>4096</td>
</tr>
</tbody>
</table>

If `audit_log_rotate_on_size` is 0, the audit log plugin does not perform automatic size-based log file rotation. If rotation is to occur, you must perform it manually; see Manual Audit Log File Rotation (Before MySQL 8.0.31).

If `audit_log_rotate_on_size` is greater than 0, automatic size-based log file rotation occurs. Whenever a write to the log file causes its size to exceed the `audit_log_rotate_on_size` value, the audit log plugin renames the current log file and opens a new current log file using the original name.

If you set `audit_log_rotate_on_size` to a value that is not a multiple of 4096, it is truncated to the nearest multiple. In particular, setting it to a value less than 4096 sets it to 0 and no rotation occurs, except manually.

**Note**

`audit_log_rotate_on_size` controls whether audit log file rotation occurs. It can also be used in conjunction with `audit_log_max_size` and `audit_log_prune_seconds` to configure pruning of rotated JSON-format log files. For details, see Space Management of Audit Log Files.

- `audit_log_statement_policy`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--audit-log-statement-policy=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>audit_log_statement_policy</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ALL</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ALL, ERRORS, NONE</td>
</tr>
</tbody>
</table>

**Note**

This deprecated variable applies only to legacy mode audit log filtering (see Section 6.4.5.10, “Legacy Mode Audit Log Filtering”).

The policy controlling how the audit log plugin writes statement events to its log file. The following table shows the permitted values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>Log all statement events</td>
</tr>
<tr>
<td>ERRORS</td>
<td>Log only failed statement events</td>
</tr>
</tbody>
</table>
MySQL Enterprise Audit

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NONE</td>
<td>Do not log statement events</td>
</tr>
</tbody>
</table>

**Note**

At server startup, any explicit value given for `audit_log_statement_policy` may be overridden if `audit_log_policy` is also specified, as described in Section 6.4.5.5, “Configuring Audit Logging Characteristics”.

- `audit_log_strategy`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--audit-log-strategy=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>audit_log_strategy</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>ASYNCHRONOUS</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>ASYNCHRONOUS</code></td>
</tr>
<tr>
<td></td>
<td><code>PERFORMANCE</code></td>
</tr>
<tr>
<td></td>
<td><code>SEMISYNCHRONOUS</code></td>
</tr>
<tr>
<td></td>
<td><code>SYNCHRONOUS</code></td>
</tr>
</tbody>
</table>

The logging method used by the audit log plugin. These strategy values are permitted:

- **ASYNCHRONOUS**: Log asynchronously. Wait for space in the output buffer.
- **PERFORMANCE**: Log asynchronously. Drop requests for which there is insufficient space in the output buffer.
- **SEMISYNCHRONOUS**: Log synchronously. Permit caching by the operating system.
- **SYNCHRONOUS**: Log synchronously. Call `sync()` after each request.

**Audit Log Status Variables**

If the audit log plugin is enabled, it exposes several status variables that provide operational information. These variables are available for legacy mode audit filtering (deprecated) and JSON mode audit filtering.

- **Audit_log_current_size**

  The size of the current audit log file. The value increases when an event is written to the log and is reset to 0 when the log is rotated.

- **Audit_log_direct_writes**

  When the audit log plugin writes events to the JSON-format audit log, it uses a buffer to store event contents prior to writing them. If the query length is greater than the size of the buffer, then the plugin writes the event directly to the log, bypassing the buffer. This variable shows the number
of direct writes. The plugin determines the count based on the current write strategy in use (see `audit_log_strategy`).

**Table 6.47 Write-Strategy Effect on the Direct Write Count**

<table>
<thead>
<tr>
<th>Write Strategy</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASYNCHRONOUS</td>
<td>Incremented if the event size does not fit into the internal buffer.</td>
</tr>
<tr>
<td></td>
<td>(audit_log_buffer_size server system variable).</td>
</tr>
<tr>
<td>PERFORMANCE</td>
<td>Not incremented. The plugin discards events larger than internal buffer.</td>
</tr>
<tr>
<td>SEMISYNCHRONOUS</td>
<td>Always incremented.</td>
</tr>
<tr>
<td>SYNCHRONOUS</td>
<td>Always incremented.</td>
</tr>
</tbody>
</table>

- **Audit_log_event_max_drop_size**
  
  The size of the largest dropped event in performance logging mode. For a description of logging modes, see Section 6.4.5.5, “Configuring Audit Logging Characteristics”.

- **Audit_log_events**
  
  The number of events handled by the audit log plugin, whether or not they were written to the log based on filtering policy (see Section 6.4.5.5, “Configuring Audit Logging Characteristics”).

- **Audit_log_events_filtered**
  
  The number of events handled by the audit log plugin that were filtered (not written to the log) based on filtering policy (see Section 6.4.5.5, “Configuring Audit Logging Characteristics”).

- **Audit_log_events_lost**
  
  The number of events lost in performance logging mode because an event was larger than the available audit log buffer space. This value may be useful for assessing how to set `audit_log_buffer_size` to size the buffer for performance mode. For a description of logging modes, see Section 6.4.5.5, “Configuring Audit Logging Characteristics”.

- **Audit_log_events_written**
  
  The number of events written to the audit log.

- **Audit_log_total_size**
  
  The total size of events written to all audit log files. Unlike `Audit_log_current_size`, the value of `Audit_log_total_size` increases even when the log is rotated.

- **Audit_log_write_waits**
  
  The number of times an event had to wait for space in the audit log buffer in asynchronous logging mode. For a description of logging modes, see Section 6.4.5.5, “Configuring Audit Logging Characteristics”.

### 6.4.5.12 Audit Log Restrictions

MySQL Enterprise Audit is subject to these general restrictions:

- Only SQL statements are logged. Changes made by no-SQL APIs, such as memcached, Node.JS, and the NDB API, are not logged.
The Audit Message Component

- Only top-level statements are logged, not statements within stored programs such as triggers or stored procedures.

- Contents of files referenced by statements such as `LOAD DATA` are not logged.

**NDB Cluster.** It is possible to use MySQL Enterprise Audit with MySQL NDB Cluster, subject to the following conditions:

- All changes to be logged must be done using the SQL interface. Changes using no-SQL interfaces, such as those provided by the NDB API, memcached, or ClusterJ, are not logged.

- The plugin must be installed on each MySQL server that is used to execute SQL on the cluster.

- Audit plugin data must be aggregated amongst all MySQL servers used with the cluster. This aggregation is the responsibility of the application or user.

### 6.4.6 The Audit Message Component

The `audit_api_message_emit` component enables applications to add their own message events to the audit log, using the `audit_api_message_emit_udf()` function.

The `audit_api_message_emit` component cooperates with all plugins of audit type. For concreteness, examples use the `audit_log` plugin described in Section 6.4.5, “MySQL Enterprise Audit”.

#### Installing or Uninstalling the Audit Message Component

**Installing or Uninstalling the Audit Message Component**

To be usable by the server, the component library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

To install the `audit_api_message_emit` component, use this statement:

```
INSTALL COMPONENT "file://component_audit_api_message_emit";
```

Component installation is a one-time operation that need not be done per server startup. `INSTALL COMPONENT` loads the component, and also registers it in the `mysql.component` system table to cause it to be loaded during subsequent server startups.

To uninstall the `audit_api_message_emit` component, use this statement:

```
UNINSTALL COMPONENT "file://component_audit_api_message_emit";
```

`UNINSTALL COMPONENT` unloads the component, and unregisters it from the `mysql.component` system table to cause it not to be loaded during subsequent server startups.

Because installing and uninstalling the `audit_api_message_emit` component installs and uninstalls the `audit_api_message_emit_udf()` function that the component implements, it is not necessary to use `CREATE FUNCTION` or `DROP FUNCTION` to do so.

**Audit Message Function**

This section describes the `audit_api_message_emit_udf()` function implemented by the `audit_api_message_emit` component.
Before using the audit message function, install the audit message component according to the instructions provided at Installing or Uninstalling the Audit Message Component.

- `audit_api_message_emit_udf(component, producer, message[, key, value] ...)`

Adds a message event to the audit log. Message events include component, producer, and message strings of the caller's choosing, and optionally a set of key-value pairs.

An event posted by this function is sent to all enabled plugins of audit type, each of which handles the event according to its own rules. If no plugin of audit type is enabled, posting the event has no effect.

Arguments:
- `component`: A string that specifies a component name.
- `producer`: A string that specifies a producer name.
- `message`: A string that specifies the event message.
- `key`, `value`: Events may include 0 or more key-value pairs that specify an arbitrary application-provided data map. Each `key` argument is a string that specifies a name for its immediately following `value` argument. Each `value` argument specifies a value for its immediately following `key` argument. Each `value` can be a string or numeric value, or `NULL`.

Return value:

The string `OK` to indicate success. An error occurs if the function fails.

Example:

```
mysql> SELECT audit_api_message_emit_udf('component_text',
                                       'producer_text',
                                       'message_text',
                                       'key1', 'value1',
                                       'key2', 123,
                                       'key3', NULL) AS 'Message';

+---------+
<table>
<thead>
<tr>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>OK</td>
</tr>
</tbody>
</table>
+---------+
```

Additional information:

Each audit plugin that receives an event posted by `audit_api_message_emit_udf()` logs the event in plugin-specific format. For example, the `audit_log` plugin (see Section 6.4.5, "MySQL Enterprise Audit") logs message values as follows, depending on the log format configured by the `audit_log_format` system variable:

- **JSON format (audit_log_format=JSON):**

```json
{
  ...
  "class": "message",
  "event": "user",
  ...
  "message_data": {
    "component": "component_text",
    "producer": "producer_text",
    "message": "message_text",
    "map": {
```
• New-style XML format \texttt{(audit\_log\_format=NEW)}:

\begin{verbatim}
<AUDIT_RECORD>
  ...
  <NAME>Message</NAME>
  ...
  <COMMAND_CLASS>user</COMMAND_CLASS>
  <COMPONENT>component_text</COMPONENT>
  <PRODUCER>producer_text</PRODUCER>
  <MESSAGE>message_text</MESSAGE>
  <MAP>
    <ELEMENT>
      <KEY>key1</KEY>
      <VALUE>value1</VALUE>
    </ELEMENT>
    <ELEMENT>
      <KEY>key2</KEY>
      <VALUE>123</VALUE>
    </ELEMENT>
    <ELEMENT>
      <KEY>key3</KEY>
      <VALUE/>
    </ELEMENT>
  </MAP>
</AUDIT_RECORD>
\end{verbatim}

• Old-style XML format \texttt{(audit\_log\_format=OLD)}:

\begin{verbatim}
<AUDIT_RECORD
  ...
  NAME="Message"
  ...
  COMMAND_CLASS="user"
  COMPONENT="component_text"
  PRODUCER="producer_text"
  MESSAGE="message_text"/>
\end{verbatim}

\begin{quote}
\textbf{Note}

Message events logged in old-style XML format do not include the key-value map due to representational constraints imposed by this format.
\end{quote}

Messages posted by \texttt{audit\_api\_message\_emit\_udf()} have an event class of \texttt{MYSQL\_AUDIT\_MESSAGE\_CLASS} and a subclass of \texttt{MYSQL\_AUDIT\_MESSAGE\_USER}. (Internally generated audit messages have the same class and a subclass of \texttt{MYSQL\_AUDIT\_MESSAGE\_INTERNAL}; this subclass currently is unused.) To refer to such events in \texttt{audit\_log} filtering rules, use a \texttt{class} element with a \texttt{name} value of \texttt{message}. For example:

\begin{verbatim}
{
  "filter": {
    "class": {
      "name": "message"
    }
  }
\end{verbatim}
Should it be necessary to distinguish user-generated and internally generated message events, test the subclass value against user or internal.

Filtering based on the contents of the key-value map is not supported.

For information about writing filtering rules, see Section 6.4.5.7, “Audit Log Filtering”.

### 6.4.7 MySQL Enterprise Firewall

MySQL Enterprise Firewall is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see https://www.mysql.com/products/.

MySQL Enterprise Edition includes MySQL Enterprise Firewall, an application-level firewall that enables database administrators to permit or deny SQL statement execution based on matching against lists of accepted statement patterns. This helps harden MySQL Server against attacks such as SQL injection or attempts to exploit applications by using them outside of their legitimate query workload characteristics.

Each MySQL account registered with the firewall has its own statement allowlist, enabling protection to be tailored per account. For a given account, the firewall can operate in recording, protecting, or detecting mode, for training in the accepted statement patterns, active protection against unacceptable statements, or passive detection of unacceptable statements. The diagram illustrates how the firewall processes incoming statements in each mode.
The following sections describe the elements of MySQL Enterprise Firewall, discuss how to install and use it, and provide reference information for its elements.

6.4.7.1 Elements of MySQL Enterprise Firewall

MySQL Enterprise Firewall is based on a plugin library that includes these elements:

- A server-side plugin named `MYSQL_FIREWALL` examines SQL statements before they execute and, based on the registered firewall profiles, renders a decision whether to execute or reject each statement.

- The `MYSQL_FIREWALL` plugin, along with server-side plugins named `MYSQL_FIREWALL_USERS` and `MYSQL_FIREWALL_WHITELIST` implement Performance Schema and `INFORMATION_SCHEMA` tables that provide views into the registered profiles.
MySQL Enterprise Firewall

• Profiles are cached in memory for better performance. Tables in the firewall database provide backing storage of firewall data for persistence of profiles across server restarts. The firewall database can be the mysql system database or a custom schema (see Installing MySQL Enterprise Firewall).

• Stored procedures perform tasks such as registering firewall profiles, establishing their operational mode, and managing transfer of firewall data between the cache and persistent storage.

• Administrative functions provide an API for lower-level tasks such as synchronizing the cache with persistent storage.

• System variables enable firewall configuration and status variables provide runtime operational information.

• The FIREWALL_ADMIN and FIREWALL_USER privileges enable users to administer firewall rules for any user, and their own firewall rules, respectively.

• The FIREWALL_EXEMPT privilege exempts a user from firewall restrictions. This is useful, for example, for any database administrator who configures the firewall, to avoid the possibility of a misconfiguration causing even the administrator to be locked out and unable to execute statements.

6.4.7.2 Installing or Uninstalling MySQL Enterprise Firewall

MySQL Enterprise Firewall installation is a one-time operation that installs the elements described in Section 6.4.7.1, “Elements of MySQL Enterprise Firewall”. Installation can be performed using a graphical interface or manually:

• On Windows, MySQL Configurator includes an option to enable MySQL Enterprise Firewall for you.

• MySQL Workbench 6.3.4 or higher can install MySQL Enterprise Firewall, enable or disable an installed firewall, or uninstall the firewall.

• Manual MySQL Enterprise Firewall installation involves running a script located in the share directory of your MySQL installation.

Important
Read this entire section before following its instructions. Parts of the procedure differ depending on your environment.

Note
If installed, MySQL Enterprise Firewall involves some minimal overhead even when disabled. To avoid this overhead, do not install the firewall unless you plan to use it.

For usage instructions, see Section 6.4.7.3, “Using MySQL Enterprise Firewall”. For reference information, see Section 6.4.7.4, “MySQL Enterprise Firewall Reference”.

• Installing MySQL Enterprise Firewall

• Uninstalling MySQL Enterprise Firewall

Installing MySQL Enterprise Firewall

If MySQL Enterprise Firewall is already installed from an older version of MySQL, uninstall it using the instructions given later in this section and then restart your server before installing the current version. In this case, it is also necessary to register your configuration again.

On Windows, you can use Section 2.3.2, “Configuration: Using MySQL Configurator” to install MySQL Enterprise Firewall by checking the Enable MySQL Enterprise Firewall check box from the
**Networking** tab. *(Open Firewall port for network access)* has a different purpose. It refers to Windows Firewall and controls whether Windows blocks the TCP/IP port on which the MySQL server listens for client connections.

To install MySQL Enterprise Firewall using MySQL Workbench, see MySQL Enterprise Firewall Interface.

To install MySQL Enterprise Firewall manually, look in the *share* directory of your MySQL installation and choose the script that is appropriate for your platform. The available scripts differ in the file name used to refer to the script:

- `win_install_firewall.sql`
- `linux_install_firewall.sql`

The installation script creates stored procedures and tables in the firewall database you specify when you run the script. The *mysql* system database is the traditional storage option, however, it is preferred that you create and use a custom schema for this purpose.

To use the *mysql* system database, run the script as follows from the command line. The example here uses the Linux installation script. Make the appropriate substitutions for your system.

```
$> mysql -u root -p -D mysql < linux_install_firewall.sql
```

To create and use a custom schema with the script, do the following:

1. Start the server with the `--loose-mysql-firewall-database=database-name` option. Insert the name of the custom schema to be used as the firewall database.

   By prefixing the option with `--loose`, the program does not emit an error and exit, but instead issues only a warning.

2. Invoke the MySQL client program and create the custom schema on the server.

   ```
   mysql> CREATE DATABASE IF NOT EXISTS database-name;
   ```

3. Run the script, naming the custom schema as the database for MySQL Enterprise Firewall.

```
$> mysql -u root -p -D database-name < linux_install_firewall.sql
```

Installing MySQL Enterprise Firewall either using a graphical interface or manually should enable the firewall. To verify that, connect to the server and execute this statement:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'mysql_firewall_mode';
+---------------------+-------+
| Variable_name       | Value |
+---------------------+-------+
| mysql_firewall_mode | ON    |
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

**Note**

To use MySQL Enterprise Firewall in the context of source/replica replication, Group Replication, or InnoDB Cluster, you must prepare the replica nodes prior to running the installation script on the source node. This is necessary because the `INSTALL PLUGIN` statements in the script are not replicated.
1. On each replica node, extract the INSTALL PLUGIN statements from the installation script and execute them manually.

2. On the source node, run the installation script as described previously.

### Uninstalling MySQL Enterprise Firewall

MySQL Enterprise Firewall can be uninstalled using MySQL Workbench or manually.

To uninstall MySQL Enterprise Firewall using MySQL Workbench 6.3.4 or higher, see MySQL Enterprise Firewall Interface, in Chapter 31, MySQL Workbench.

To uninstall MySQL Enterprise Firewall at the command line, run the uninstall script located in the share directory of your MySQL installation. The example here specifies the system database, mysql.

```bash
$> mysql -u root -p -D mysql < uninstall_firewall.sql
Enter password: (enter root password here)
```

If you created a custom schema when you installed MySQL Enterprise Firewall, make the appropriate substitution for your system.

```bash
$> mysql -u root -p -D database-name < uninstall_firewall.sql
Enter password: (enter root password here)
```

This script removes the plugins, tables, functions, and stored procedures for MySQL Enterprise Firewall.

### 6.4.7.3 Using MySQL Enterprise Firewall

Before using MySQL Enterprise Firewall, install it according to the instructions provided in Section 6.4.7.2, “Installing or Uninstalling MySQL Enterprise Firewall”.

This section describes how to configure MySQL Enterprise Firewall using SQL statements. Alternatively, MySQL Workbench 6.3.4 or higher provides a graphical interface for firewall control. See MySQL Enterprise Firewall Interface.

- Enabling or Disabling the Firewall
- Scheduling Firewall Cache Reloads
- Assigning Firewall Privileges
- Firewall Concepts
- Registering Firewall Group Profiles
- Registering Firewall Account Profiles
- Monitoring the Firewall
- Migrating Account Profiles to Group Profiles

### Enabling or Disabling the Firewall

To enable or disable the firewall, set the mysql_firewall_mode system variable. By default, this variable is enabled when the firewall is installed. To control the initial firewall state explicitly, you can set the variable at server startup. For example, to enable the firewall in an option file, use these lines:

```
[mysqld]
mysql_firewall_mode=ON
```
After modifying `my.cnf`, restart the server to cause the new setting to take effect.

Alternatively, to set and persist the firewall setting at runtime:

```sql
SET PERSIST mysql_firewall_mode = OFF;
SET PERSIST mysql_firewall_mode = ON;
```

**SET PERSIST** sets a value for the running MySQL instance. It also saves the value, causing it to carry over to subsequent server restarts. To change a value for the running MySQL instance without having it carry over to subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`. See Section 13.7.6.1, “SET Syntax for Variable Assignment”.

### Scheduling Firewall Cache Reloads

Each time the `MYSQL_FIREWALL` server-side plugin initializes, it loads data from these tables to its internal cache:

- `firewall_whitelist`
- `firewall_group_allowlist`
- `firewall_users`
- `firewall_groups`
- `firewall_membership`

Without restarting the server or reinstalling the server-side plugin, modification of data outside of the plugin is not reflected internally. The `mysql_firewall_reload_interval_seconds` system variable makes it possible to force memory cache reloads from tables at specified intervals. By default, the periodic interval value is set to zero, which disables reloads.

To schedule regular cache reloads, first ensure that the scheduler component is installed and enabled (see Section 5.5.5, “Scheduler Component”). To check the status of the component:

```sql
SHOW VARIABLES LIKE 'component_scheduler%';
```

```
+-----------------------------+-------+
| Variable_name               | Value |
|-----------------------------+-------|
| component_scheduler.enabled | On    |
```

With the firewall installed, set the `mysql_firewall_reload_interval_seconds` global system variable at server startup to a number between 60 and the `INT_MAX` macro value of the platform hosting the server. Values between zero and 60 (1 through 59) reset to 60. For example:

```
$> mysqld [server-options] --mysql-firewall-reload-interval-seconds=40
...
2023-08-31T17:46:35.043468Z 0 [Warning] [MY-015031] [Server] Plugin MYSQL_FIREWALL reported: 'Invalid reload interval specified: 40. Valid values are 0 (off) or greater than or equal to 60. Adjusting to 60.'
...
```

Alternatively, to set and persist the firewall setting at startup, precede the read-only variable name by the `PERSIST_ONLY` keyword or the `@@PERSIST_ONLY` qualifier:

```sql
SET PERSIST_ONLY mysql_firewall_reload_interval_seconds = 120;
SET @@PERSIST_ONLY.mysql_firewall_reload_interval_seconds = 120;
```

After modifying the variable, restart the server to cause the new setting to take effect.
Assigning Firewall Privileges

With the firewall installed, grant the appropriate privileges to the MySQL account or accounts to be used for administering it. The privileges depend on which firewall operations an account should be permitted to perform:

- Grant the `FIREWALL_EXEMPT` privilege to any account that should be exempt from firewall restrictions. This is useful, for example, for a database administrator who configures the firewall, to avoid the possibility of a misconfiguration causing even the administrator to be locked out and unable to execute statements.

- Grant the `FIREWALL_ADMIN` privilege to any account that should have full administrative firewall access. (Some administrative firewall functions can be invoked by accounts that have `FIREWALL_ADMIN` or the deprecated `SUPER` privilege, as indicated in the individual function descriptions.)

- Grant the `FIREWALL_USER` privilege to any account that should have administrative access only for its own firewall rules.

- Grant the `EXECUTE` privilege for the firewall stored procedures in the firewall database. These may invoke administrative functions, so stored procedure access also requires the privileges indicated earlier that are needed for those functions. The firewall database can be the `mysql` system database or a custom schema (see Installing MySQL Enterprise Firewall).

Note

The `FIREWALL_EXEMPT`, `FIREWALL_ADMIN`, and `FIREWALL_USER` privileges can be granted only while the firewall is installed because the `MYSQL_FIREWALL` plugin defines those privileges.

Firewall Concepts

The MySQL server permits clients to connect and receives from them SQL statements to be executed. If the firewall is enabled, the server passes to it each incoming statement that does not immediately fail with a syntax error. Based on whether the firewall accepts the statement, the server executes it or returns an error to the client. This section describes how the firewall accomplishes the task of accepting or rejecting statements.

- Firewall Profiles
- Firewall Statement Matching
- Profile Operational Modes
- Firewall Statement Handling When Multiple Profiles Apply

Firewall Profiles

The firewall uses a registry of profiles that determine whether to permit statement execution. Profiles have these attributes:

- An allowlist. The allowlist is the set of rules that defines which statements are acceptable to the profile.

- A current operational mode. The mode enables the profile to be used in different ways. For example: the profile can be placed in training mode to establish the allowlist; the allowlist can be used for restricting statement execution or intrusion detection; the profile can be disabled entirely.

- A scope of applicability. The scope indicates which client connections the profile applies to:
• The firewall supports account-based profiles such that each profile matches a particular client account (client user name and host name combination). For example, you can register one account profile for which the allowlist applies to connections originating from admin@localhost and another account profile for which the allowlist applies to connections originating from myapp@apphost.example.com.

• The firewall supports group profiles that can have multiple accounts as members, with the profile allowlist applying equally to all members. Group profiles enable easier administration and greater flexibility for deployments that require applying a given set of allowlist rules to multiple accounts.

Initially, no profiles exist, so by default, the firewall accepts all statements and has no effect on which statements MySQL accounts can execute. To apply firewall protective capabilities, explicit action is required:

• Register one or more profiles with the firewall.

• Train the firewall by establishing the allowlist for each profile; that is, the types of statements the profile permits clients to execute.

• Place the trained profiles in protecting mode to harden MySQL against unauthorized statement execution:

  • MySQL associates each client session with a specific user name and host name combination. This combination is the session account.

  • For each client connection, the firewall uses the session account to determine which profiles apply to handling incoming statements from the client.

    The firewall accepts only statements permitted by the applicable profile allowlists.

Most firewall principles apply identically to group profiles and account profiles. The two types of profiles differ in these respects:

• An account profile allowlist applies only to a single account. A group profile allowlist applies when the session account matches any account that is a member of the group.

• To apply an allowlist to multiple accounts using account profiles, it is necessary to register one profile per account and duplicate the allowlist across each profile. This entails training each account profile individually because each one must be trained using the single account to which it applies.

  A group profile allowlist applies to multiple accounts, with no need to duplicate it for each account. A group profile can be trained using any or all of the group member accounts, or training can be limited to any single member. Either way, the allowlist applies to all members.

• Account profile names are based on specific user name and host name combinations that depend on which clients connect to the MySQL server. Group profile names are chosen by the firewall administrator with no constraints other than that their length must be from 1 to 288 characters.

Note

Due to the advantages of group profiles over account profiles, and because a group profile with a single member account is logically equivalent to an account profile for that account, it is recommended that all new firewall profiles be created as group profiles. Account profiles are deprecated as of MySQL 8.0.26 and subject to removal in a future MySQL version. For assistance converting existing account profiles, see Migrating Account Profiles to Group Profiles.

The profile-based protection afforded by the firewall enables implementation of strategies such as these:
MySQL Enterprise Firewall

- If an application has unique protection requirements, configure it to use an account not used for any other purpose and set up a group profile or account profile for that account.

- If related applications share protection requirements, associate each application with its own account, then add these application accounts as members of the same group profile. Alternatively, configure all the applications to use the same account and associate them with an account profile for that account.

Firewall Statement Matching

Statement matching performed by the firewall does not use SQL statements as received from clients. Instead, the server converts incoming statements to normalized digest form and firewall operation uses these digests. The benefit of statement normalization is that it enables similar statements to be grouped and recognized using a single pattern. For example, these statements are distinct from each other:

```
SELECT first_name, last_name FROM customer WHERE customer_id = 1;\nselect first_name, last_name from customer where customer_id = 99;
SELECT first_name, last_name FROM customer WHERE customer_id = 143;
```

But all of them have the same normalized digest form:

```
SELECT `first_name` , `last_name` FROM `customer` WHERE `customer_id` = ?
```

By using normalization, firewall allowlists can store digests that each match many different statements received from clients. For more information about normalization and digests, see Section 27.10, “Performance Schema Statement Digests and Sampling”.

Warning

Setting the `max_digest_length` system variable to zero disables digest production, which also disables server functionality that requires digests, such as MySQL Enterprise Firewall.

Profile Operational Modes

Each profile registered with the firewall has its own operational mode, chosen from these values:

- **OFF**: This mode disables the profile. The firewall considers it inactive and ignores it.

- **RECORDING**: This is the firewall training mode. Incoming statements received from a client that matches the profile are considered acceptable for the profile and become part of its “fingerprint.” The firewall records the normalized digest form of each statement to learn the acceptable statement patterns for the profile. Each pattern is a rule, and the union of the rules is the profile allowlist.

  A difference between group and account profiles is that statement recording for a group profile can be limited to statements received from a single group member (the training member).

- **PROTECTING**: In this mode, the profile allows or prevents statement execution. The firewall matches incoming statements against the profile allowlist, accepting only statements that match and rejecting those that do not. After training a profile in RECORDING mode, switch it to PROTECTING mode to harden MySQL against access by statements that deviate from the allowlist. If the `mysql_firewall_trace` system variable is enabled, the firewall also writes rejected statements to the error log.

- **DETECTING**: This mode detects but does not block intrusions (statements that are suspicious because they match nothing in the profile allowlist). In DETECTING mode, the firewall writes suspicious statements to the error log but accepts them without denying access.

When a profile is assigned any of the preceding mode values, the firewall stores the mode in the profile. Firewall mode-setting operations also permit a mode value of RESET, but this value is not stored: setting a profile to RESET mode causes the firewall to delete all rules for the profile and set its mode to OFF.
MySQL Enterprise Firewall

**Note**

Messages written to the error log in **DETECTING** mode or because `mysql_firewall_trace` is enabled are written as Notes, which are information messages. To ensure that such messages appear in the error log and are not discarded, make sure that error-logging verbosity is sufficient to include information messages. For example, if you are using priority-based log filtering, as described in Section 5.4.2.5, “Priority-Based Error Log Filtering (log_filter_internal)”, set the `log_error_verbosity` system variable to a value of 3.

**Firewall Statement Handling When Multiple Profiles Apply**

For simplicity, later sections that describe how to set up profiles take the perspective that the firewall matches incoming statements from a client against only a single profile, either a group profile or account profile. But firewall operation can be more complex:

- A group profile can include multiple accounts as members.
- An account can be a member of multiple group profiles.
- Multiple profiles can match a given client.

The following description covers the general case of how the firewall operates, when potentially multiple profiles apply to incoming statements.

As previously mentioned, MySQL associates each client session with a specific user name and host name combination known as the **session account**. The firewall matches the session account against registered profiles to determine which profiles apply to handling incoming statements from the session:

- The firewall ignores inactive profiles (profiles with a mode of **OFF**).
- The session account matches every active group profile that includes a member having the same user and host. There can be more than one such group profile.
- The session account matches an active account profile having the same user and host, if there is one. There is at most one such account profile.

In other words, the session account can match 0 or more active group profiles, and 0 or 1 active account profiles. This means that 0, 1, or multiple firewall profiles are applicable to a given session, for which the firewall handles each incoming statement as follows:

- If there is no applicable profile, the firewall imposes no restrictions and accepts the statement.
- If there are applicable profiles, their modes determine statement handling:
  - The firewall records the statement in the allowlist of each applicable profile that is in **RECORDING** mode.
  - The firewall writes the statement to the error log for each applicable profile in **DETECTING** mode for which the statement is suspicious (does not match the profile allowlist).
  - The firewall accepts the statement if at least one applicable profile is in **RECORDING** or **DETECTING** mode (those modes accept all statements), or if the statement matches the allowlist of at least one applicable profile in **PROTECTING** mode. Otherwise, the firewall rejects the statement (and writes it to the error log if the `mysql_firewall_trace` system variable is enabled).

With that description in mind, the next sections revert to the simplicity of the situations when a single group profile or a single account profile apply, and cover how to set up each type of profile.
Registering Firewall Group Profiles

MySQL Enterprise Firewall supports registration of group profiles. A group profile can have multiple accounts as its members. To use a firewall group profile to protect MySQL against incoming statements from a given account, follow these steps:

1. Register the group profile and put it in **RECORDING** mode.

2. Add a member account to the group profile.

3. Connect to the MySQL server using the member account and execute statements to be learned. This trains the group profile and establishes the rules that form the profile allowlist.

4. Add to the group profile any other accounts that are to be group members.

5. Switch the group profile to **PROTECTING** mode. When a client connects to the server using any account that is a member of the group profile, the profile allowlist restricts statement execution.

6. Should additional training be necessary, switch the group profile to **RECORDING** mode again, update its allowlist with new statement patterns, then switch it back to **PROTECTING** mode.

Observe these guidelines for firewall-related account references:

- Take note of the context in which account references occur. To name an account for firewall operations, specify it as a single quoted string ("user_name@host_name"). This differs from the usual MySQL convention for statements such as `CREATE USER` and `GRANT`, for which you quote the user and host parts of an account name separately ('user_name'@'host_name').

  The requirement for naming accounts as a single quoted string for firewall operations means that you cannot use accounts that have embedded @@ characters in the user name.

- The firewall assesses statements against accounts represented by actual user and host names as authenticated by the server. When registering accounts in profiles, do not use wildcard characters or netmasks:

  - Suppose that an account named me@%.example.org exists and a client uses it to connect to the server from the host abc.example.org.

  - The account name contains a % wildcard character, but the server authenticates the client as having a user name of me and host name of abc.example.com, and that is what the firewall sees.

  - Consequently, the account name to use for firewall operations is me@abc.example.org rather than me@%.example.org.

The following procedure shows how to register a group profile with the firewall, train the firewall to know the acceptable statements for that profile (its allowlist), use the profile to protect MySQL against execution of unacceptable statements, and add and remove group members. The example uses a group profile name of `fwgrp`. The example profile is presumed for use by clients of an application that accesses tables in the `sakila` database (available at https://dev.mysql.com/doc/index-other.html).

Use an administrative MySQL account to perform the steps in this procedure, except those steps designated for execution by member accounts of the firewall group profile. For statements executed by member accounts, the default database should be `sakila`. (You can use a different database by adjusting the instructions accordingly.)

1. If necessary, create the accounts that are to be members of the `fwgrp` group profile and grant them appropriate access privileges. Statements for one member are shown here (choose an appropriate password):

```sql
CREATE USER 'user_name'@'host_name'
GRANT ALL PRIVILEGES ON `sakila`.* TO 'user_name'@'host_name'
```
CREATE USER 'member1'@'localhost' IDENTIFIED BY 'password';
GRANT ALL ON sakila.* TO 'member1'@'localhost';

2. Use the `sp_set_firewall_group_mode()` stored procedure to register the group profile with the
firewall and place the profile in **RECORDING** (training) mode:

```sql
CALL mysql.sp_set_firewall_group_mode('fwgrp', 'RECORDING');
```

**Note**

If you have installed MySQL Enterprise Firewall in a custom schema, then make
appropriate substitution for your system. For example, if the firewall is installed
in the `fwdb` schema, then execute the stored procedures like this:

```sql
CALL fwdb.sp_set_firewall_group_mode('fwgrp', 'RECORDING');
```

3. Use the `sp_firewall_group_enlist()` stored procedure to add an initial member account for use
in training the group profile allowlist:

```sql
CALL mysql.sp_firewall_group_enlist('fwgrp', 'member1@localhost');
```

4. To train the group profile using the initial member account, connect to the server as `member1`
from the server host so that the firewall sees a session account of `member1@localhost`. Then execute some
statements to be considered legitimate for the profile. For example:

```sql
SELECT title, release_year FROM film WHERE film_id = 1;
UPDATE actor SET last_update = NOW() WHERE actor_id = 1;
SELECT store_id, COUNT(*) FROM inventory GROUP BY store_id;
```

The firewall receives the statements from the `member1@localhost` account. Because that account
is a member of the `fwgrp` profile, which is in **RECORDING** mode, the firewall interprets the statements
as applicable to `fwgrp` and records the normalized digest form of the statements as rules in the `fwgrp`
allowlist. Those rules then apply to all accounts that are members of `fwgrp`.

**Note**

Until the `fwgrp` group profile receives statements in **RECORDING** mode, its
allowlist is empty, which is equivalent to “deny all.” No statement can match an
empty allowlist, which has these implications:

- The group profile cannot be switched to **PROTECTING** mode. It would reject
every statement, effectively prohibiting the accounts that are group members
from executing any statement.

- The group profile can be switched to **DETECTING** mode. In this case, the
profile accepts every statement but logs it as suspicious.

5. At this point, the group profile information is cached, including its name, membership, and allowlist. To
see this information, query the Performance Schema firewall tables:

```sql
mysql> SELECT MODE FROM performance_schema.firewall_groups
WHERE NAME = 'fwgrp';
+-----------+
<table>
<thead>
<tr>
<th>MODE</th>
</tr>
</thead>
<tbody>
<tr>

mysql> SELECT RULE FROM performance_schema.firewall_group_allowlist
WHERE NAME = 'fwgrp';

+----------------------------------------------------------------------+
| RULE                                                                 |
+----------------------------------------------------------------------+
| SELECT @@"version_comment" LIMIT ?                                  |
| UPDATE `actor` SET `last_update` = NOW ( ) WHERE `actor_id` = ?      |
| SELECT `title` , `release_year` FROM `film` WHERE `film_id` = ?      |
| SELECT `store_id` , COUNT (*) FROM `inventory` GROUP BY `store_id` |

---

Note

The `@version_comment` rule comes from a statement sent automatically by the `mysql` client when you connect to the server.

Important

Train the firewall under conditions matching application use. For example, to determine server characteristics and capabilities, a given MySQL connector might send statements to the server at the beginning of each session. If an application normally is used through that connector, train the firewall using the connector, too. That enables those initial statements to become part of the allowlist for the group profile associated with the application.

6. Invoke `sp_set_firewall_group_mode()` again to switch the group profile to PROTECTING mode:

```
CALL mysql.sp_set_firewall_group_mode('fwgrp', 'PROTECTING');
```

Important

Switching the group profile out of RECORDING mode synchronizes its cached data to the firewall database tables that provide persistent underlying storage. If you do not switch the mode for a profile that is being recorded, the cached data is not written to persistent storage and is lost when the server is restarted. The firewall database can be the `mysql` system database or a custom schema (see Installing MySQL Enterprise Firewall).

7. Add to the group profile any other accounts that should be members:

```
CALL mysql.sp_firewall_group_enlist('fwgrp', 'member2@localhost');
CALL mysql.sp_firewall_group_enlist('fwgrp', 'member3@localhost');
CALL mysql.sp_firewall_group_enlist('fwgrp', 'member4@localhost');
```

The profile allowlist trained using the `member1@localhost` account now also applies to the additional accounts.

8. To verify the updated group membership, query the `firewall_membership` table again:

```
mysql> SELECT * FROM performance_schema.firewall_membership
WHERE GROUP_ID = 'fwgrp' ORDER BY MEMBER_ID;
+----------+-------------------+
<table>
<thead>
<tr>
<th>GROUP_ID</th>
<th>MEMBER_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>fwgrp</td>
<td>member1@localhost</td>
</tr>
<tr>
<td>fwgrp</td>
<td>member2@localhost</td>
</tr>
<tr>
<td>fwgrp</td>
<td>member3@localhost</td>
</tr>
<tr>
<td>fwgrp</td>
<td>member4@localhost</td>
</tr>
</tbody>
</table>
```
9. Test the group profile against the firewall by using any account in the group to execute some acceptable and unacceptable statements. The firewall matches each statement from the account against the profile allowlist and accepts or rejects it:

- This statement is not identical to a training statement but produces the same normalized statement as one of them, so the firewall accepts it:

```
mysql> SELECT title, release_year FROM film WHERE film_id = 98;
```

```
+-------------------+--------------+
| title             | release_year |
|-------------------+--------------+
| BRIGHT ENCOUNTERS | 2006         |
```

- These statements match nothing in the allowlist, so the firewall rejects each with an error:

```
mysql> SELECT title, release_year FROM film WHERE film_id = 98 OR TRUE;
ERROR 1045 (28000): Statement was blocked by Firewall
```

```
mysql> SHOW TABLES LIKE 'customer%';
ERROR 1045 (28000): Statement was blocked by Firewall
```

```
mysql> TRUNCATE TABLE mysql.slow_log;
ERROR 1045 (28000): Statement was blocked by Firewall
```

- If the `mysql_firewall_trace` system variable is enabled, the firewall also writes rejected statements to the error log. For example:

```
[Note] Plugin MYSQL_FIREWALL reported:
'ACCESS DENIED for 'member1@localhost'. Reason: No match in allowlist.
Statement: TRUNCATE TABLE `mysql`. `slow_log''
```

These log messages may be helpful in identifying the source of attacks, should that be necessary.

10. Should members need to be removed from the group profile, use the `sp_firewall_group_delist()` stored procedure rather than `sp_firewall_group_enlist()`:

```
CALL mysql.sp_firewall_group_delist('fwgrp', 'member3@localhost');
```

The firewall group profile now is trained for member accounts. When clients connect using any account in the group and attempt to execute statements, the profile protects MySQL against statements not matched by the profile allowlist.

The procedure just shown added only one member to the group profile before training its allowlist. Doing so provides better control over the training period by limiting which accounts can add new acceptable statements to the allowlist. Should additional training be necessary, you can switch the profile back to **RECORDING** mode:

```
CALL mysql.sp_set_firewall_group_mode('fwgrp', 'RECORDING');
```

However, that enables any member of the group to execute statements and add them to the allowlist. To limit the additional training to a single group member, call `sp_set_firewall_group_mode_and_user()`, which is like `sp_set_firewall_group_mode()` but takes one more argument specifying which account is permitted to train the profile in **RECORDING** mode. For example, to enable training only by `member4@localhost`, do this:

```
CALL mysql.sp_set_firewall_group_mode_and_user('fwgrp', 'RECORDING', 'member4@localhost');
```

That enables additional training by the specified account without having to remove the other group members. They can execute statements, but the statements are not added to the allowlist. (Remember, however, that in **RECORDING** mode the other members can execute any statement.)
Note
To avoid unexpected behavior when a particular account is specified as the training account for a group profile, always ensure that account is a member of the group.

After the additional training, set the group profile back to **PROTECTING** mode:

```sql
CALL mysql.sp_set_firewall_group_mode('fwgrp', 'PROTECTING');
```

The training account established by `sp_set_firewall_group_mode_and_user()` is saved in the group profile, so the firewall remembers it in case more training is needed later. Thus, if you call `sp_set_firewall_group_mode()` (which takes no training account argument), the current profile training account, `member4@localhost`, remains unchanged.

To clear the training account if it actually is desired to enable all group members to perform training in **RECORDING** mode, call `sp_set_firewall_group_mode_and_user()` and pass a **NULL** value for the account argument:

```sql
CALL mysql.sp_set_firewall_group_mode_and_user('fwgrp', 'RECORDING', NULL);
```

It is possible to detect intrusions by logging nonmatching statements as suspicious without denying access. First, put the group profile in **DETECTING** mode:

```sql
CALL mysql.sp_set_firewall_group_mode('fwgrp', 'DETECTING');
```

Then, using a member account, execute a statement that does not match the group profile allowlist. In **DETECTING** mode, the firewall permits the nonmatching statement to execute:

```sql
mysql> SHOW TABLES LIKE 'customer%';
+------------------------------+
| Tables_in_sakila (customer%) |
+------------------------------+
| customer                     |
| customer_list                |
+------------------------------+
```

In addition, the firewall writes a message to the error log:

```
[Note] Plugin MYSQL_FIREWALL reported:
'SUSPICIOUS STATEMENT from 'member1@localhost'. Reason: No match in allowlist.
Statement: SHOW TABLES LIKE ?'
```

To disable a group profile, change its mode to **OFF**:

```sql
CALL mysql.sp_set_firewall_group_mode('fwgrp', 'OFF');
```

To forget all training for a profile and disable it, reset it:

```sql
CALL mysql.sp_set_firewall_group_mode('fwgrp', 'RESET');
```

The reset operation causes the firewall to delete all rules for the profile and set its mode to **OFF**.

**Registering Firewall Account Profiles**

MySQL Enterprise Firewall enables profiles to be registered that correspond to individual accounts. To use a firewall account profile to protect MySQL against incoming statements from a given account, follow these steps:

1. Register the account profile and put it in **RECORDING** mode.

2. Connect to the MySQL server using the account and execute statements to be learned. This trains the account profile and establishes the rules that form the profile allowlist.
3. Switch the account profile to **PROTECTING** mode. When a client connects to the server using the account, the account profile allowlist restricts statement execution.

4. Should additional training be necessary, switch the account profile to **RECORDING** mode again, update its allowlist with new statement patterns, then switch it back to **PROTECTING** mode.

Observe these guidelines for firewall-related account references:

- Take note of the context in which account references occur. To name an account for firewall operations, specify it as a single quoted string (`'user_name@host_name'`). This differs from the usual MySQL convention for statements such as **CREATE USER** and **GRANT**, for which you quote the user and host parts of an account name separately (`'user_name'@'host_name'`).

  The requirement for naming accounts as a single quoted string for firewall operations means that you cannot use accounts that have embedded `@` characters in the user name.

- The firewall assesses statements against accounts represented by actual user and host names as authenticated by the server. When registering accounts in profiles, do not use wildcard characters or netmasks:

  - Suppose that an account named `me@%.example.org` exists and a client uses it to connect to the server from the host `abc.example.org`.

  - The account name contains a `%` wildcard character, but the server authenticates the client as having a user name of `me` and host name of `abc.example.com`, and that is what the firewall sees.

  - Consequently, the account name to use for firewall operations is `me@abc.example.org` rather than `me@%.example.org`.

The following procedure shows how to register an account profile with the firewall, train the firewall to know the acceptable statements for that profile (its allowlist), and use the profile to protect MySQL against execution of unacceptable statements by the account. The example account, `fwuser@localhost`, is presumed for use by an application that accesses tables in the **sakila** database (available at [https://dev.mysql.com/doc/index-other.html](https://dev.mysql.com/doc/index-other.html)).

Use an administrative MySQL account to perform the steps in this procedure, except those steps designated for execution by the `fwuser@localhost` account that corresponds to the account profile registered with the firewall. For statements executed using this account, the default database should be **sakila**. (You can use a different database by adjusting the instructions accordingly.)

1. If necessary, create the account to use for executing statements (choose an appropriate password) and grant it privileges for the **sakila** database:

   ```sql
   CREATE USER 'fwuser'@'localhost' IDENTIFIED BY 'password';
   GRANT ALL ON sakila.* TO 'fwuser'@'localhost';
   ```

2. Use the **sp_set_firewall_mode()** stored procedure to register the account profile with the firewall and place the profile in **RECORDING** (training) mode:

   ```sql
   CALL mysql.sp_set_firewall_mode('fwuser@localhost', 'RECORDING');
   ```

   **Note**

   If you have installed MySQL Enterprise Firewall in a custom schema, then make appropriate substitution for your system. For example, if the firewall is installed in the **fwdb** schema, then execute the stored procedures like this:

   ```sql
   CALL fwdb.sp_set_firewall_mode('fwuser@localhost', 'RECORDING');
   ```
3. To train the registered account profile, connect to the server as `fwuser` from the server host so that the firewall sees a session account of `fwuser@localhost`. Then use the account to execute some statements to be considered legitimate for the profile. For example:

```
SELECT first_name, last_name FROM customer WHERE customer_id = 1;
UPDATE rental SET return_date = NOW() WHERE rental_id = 1;
SELECT get_customer_balance(1, NOW());
```

Because the profile is in `RECORDING` mode, the firewall records the normalized digest form of the statements as rules in the profile allowlist.

```
4. At this point, the account profile information is cached. To see this information, query the `INFORMATION_SCHEMA` firewall tables:

```
mysql> SELECT MODE FROM INFORMATION_SCHEMA.MYSQL_FIREWALL_USERS
    WHERE USERHOST = 'fwuser@localhost';
+-----------+
| MODE      |
+-----------+
| RECORDING |
+-----------+
mysql>
```

```
mysql> SELECT RULE FROM INFORMATION_SCHEMA.MYSQL_FIREWALL_WHITELIST
    WHERE USERHOST = 'fwuser@localhost';
+----------------------------------------------------------------------------+
<table>
<thead>
<tr>
<th>RULE</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT <code>first_name</code> , <code>last_name</code> FROM <code>customer</code> WHERE <code>customer_id</code> = ?</td>
</tr>
<tr>
<td>SELECT <code>get_customer_balance</code> ( ? , NOW ( ) )</td>
</tr>
<tr>
<td>UPDATE <code>rental</code> SET <code>return_date</code> = NOW ( ) WHERE <code>rental_id</code> = ?</td>
</tr>
<tr>
<td>SELECT @@<code>version_comment</code> LIMIT ?</td>
</tr>
<tr>
<td>----------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
```

**Note**

Until the `fwuser@localhost` account profile receives statements in `RECORDING` mode, its allowlist is empty, which is equivalent to “deny all.” No statement can match an empty allowlist, which has these implications:

- The account profile cannot be switched to `PROTECTING` mode. It would reject every statement, effectively prohibiting the account from executing any statement.
- The account profile can be switched to `DETECTING` mode. In this case, the profile accepts every statement but logs it as suspicious.

**Important**

Train the firewall under conditions matching application use. For example, to determine server characteristics and capabilities, a given MySQL connector might send statements to the server at the beginning of each session. If an application normally is used through that connector, train the firewall using the connector, too. That enables those initial statements to become part of the allowlist for the account profile associated with the application.
5. Invoke `sp_set_firewall_mode()` again, this time switching the account profile to PROTECTING mode:

```sql
CALL mysql.sp_set_firewall_mode('fwuser@localhost', 'PROTECTING');
```

**Important**

Switching the account profile out of RECORDING mode synchronizes its cached data to the firewall database tables that provide persistent underlying storage. If you do not switch the mode for a profile that is being recorded, the cached data is not written to persistent storage and is lost when the server is restarted. The firewall database can be the `mysql` system database or a custom schema (see Installing MySQL Enterprise Firewall).

6. Test the account profile by using the account to execute some acceptable and unacceptable statements. The firewall matches each statement from the account against the profile allowlist and accepts or rejects it:

- This statement is not identical to a training statement but produces the same normalized statement as one of them, so the firewall accepts it:

```sql
mysql> SELECT first_name, last_name FROM customer WHERE customer_id = '48';
+------------+-----------+
| first_name | last_name |
+------------+-----------+
| ANN        | EVANS     |
```

- These statements match nothing in the allowlist, so the firewall rejects each with an error:

```sql
mysql> SELECT first_name, last_name FROM customer WHERE customer_id = 1 OR TRUE;
ERROR 1045 (28000): Statement was blocked by Firewall
mysql> SHOW TABLES LIKE 'customer%';
ERROR 1045 (28000): Statement was blocked by Firewall
mysql> TRUNCATE TABLE mysql.slow_log;
ERROR 1045 (28000): Statement was blocked by Firewall
```

- If the `mysql_firewall_trace` system variable is enabled, the firewall also writes rejected statements to the error log. For example:

```
[Note] Plugin MYSQL_FIREWALL reported:
'ACCESS DENIED for fwuser@localhost. Reason: No match in allowlist.
Statement: TRUNCATE TABLE `mysql` . `slow_log`'
```

These log messages may be helpful in identifying the source of attacks, should that be necessary.

The firewall account profile now is trained for the `fwuser@localhost` account. When clients connect using that account and attempt to execute statements, the profile protects MySQL against statements not matched by the profile allowlist.

It is possible to detect intrusions by logging nonmatching statements as suspicious without denying access. First, put the account profile in DETECTING mode:

```sql
CALL mysql.sp_set_firewall_mode('fwuser@localhost', 'DETECTING');
```

Then, using the account, execute a statement that does not match the account profile allowlist. In DETECTING mode, the firewall permits the nonmatching statement to execute:

```sql
mysql> SHOW TABLES LIKE 'customer%';
+-------------------------------+
| Tables_in_sakila (customer%) |
```
In addition, the firewall writes a message to the error log:

```
[Note] Plugin MYSQL_FIREWALL reported:
'SUSPICIOUS STATEMENT from 'fwuser@localhost'. Reason: No match in allowlist.
Statement: SHOW TABLES LIKE ?'
```

To disable an account profile, change its mode to **OFF**:

```
CALL mysql.sp_set_firewall_mode('user', 'OFF');
```

To forget all training for a profile and disable it, reset it:

```
CALL mysql.sp_set_firewall_mode('user', 'RESET');
```

The reset operation causes the firewall to delete all rules for the profile and set its mode to **OFF**.

### Monitoring the Firewall

To assess firewall activity, examine its status variables. For example, after performing the procedure shown earlier to train and protect the `fwgrp` group profile, the variables look like this:

```
mysql> SHOW GLOBAL STATUS LIKE 'Firewall%';
+----------------------------+-------+
| Variable_name              | Value |
+----------------------------+-------+
| Firewall_access_denied     | 3     |
| Firewall_access_granted    | 4     |
| Firewall_access_suspicious | 1     |
| Firewall_cached_entries    | 4     |
```

The variables indicate the number of statements rejected, accepted, logged as suspicious, and added to the cache, respectively. The `Firewall_access_granted` count is 4 because of the `@@version_comment` statement sent by the `mysql` client each of the three times you connected using the registered account, plus the `SHOW TABLES` statement that was not blocked in `DETECTING` mode.

### Migrating Account Profiles to Group Profiles

MySQL Enterprise Firewall supports account profiles that each apply to a single account and also group profiles that each can apply to multiple accounts. A group profile enables easier administration when the same allowlist is to be applied to multiple accounts: instead of creating one account profile per account and duplicating the allowlist across all those profiles, create a single group profile and make the accounts members of it. The group allowlist then applies to all the accounts.

A group profile with a single member account is logically equivalent to an account profile for that account, so it is possible to administer the firewall using group profiles exclusively, rather than a mix of account and group profiles. For new firewall installations, that is accomplished by uniformly creating new profiles as group profiles and avoiding account profiles.

Due to the greater flexibility offered by group profiles, it is recommended that all new firewall profiles be created as group profiles. Account profiles are deprecated as of MySQL 8.0.26 and subject to removal in a future MySQL version. For upgrades from firewall installations that already contain account profiles, MySQL Enterprise Firewall includes a stored procedure named `sp_migrate_firewall_user_to_group()` to help you convert account profiles to group profiles. To use it, perform the following procedure as a user who has the `FIREWALL_ADMIN` privilege:
1. Run the `firewall_profile_migration.sql` script to install the `sp_migrate_firewall_user_to_group()` stored procedure. The script is located in the share directory of your MySQL installation.

Specify the same firewall database name on the command line that you previously defined for your firewall installation. The example here specifies the system database, `mysql`.

```
$> mysql -u root -p -D mysql < firewall_profile_migration.sql
Enter password: (enter root password here)
```

If you installed MySQL Enterprise Firewall in a custom schema, make the appropriate substitution for your system.

2. Identify which account profiles exist by querying the Information Schema `MYSQL_FIREWALL_USERS` table. For example:

```
mysql> SELECT USERHOST FROM INFORMATION_SCHEMA.MYSQL_FIREWALL_USERS;
+-------------------------------+
| USERHOST                      |
+-------------------------------+
| admin@localhost               |
| local_client@localhost        |
| remote_client@abc.example.com |
+-------------------------------+
```

3. For each account profile identified by the previous step, convert it to a group profile. Replace the `mysql` prefix with the actual firewall database name, if necessary:

```
CALL mysql.sp_migrate_firewall_user_to_group('admin@localhost', 'admins');
CALL mysql.sp_migrate_firewall_user_to_group('local_client@localhost', 'local_clients');
CALL mysql.sp_migrate_firewall_user_to_group('remote_client@localhost', 'remote_clients');
```

In each case, the account profile must exist and must not currently be in RECORDING mode, and the group profile must not already exist. The resulting group profile has the named account as its single enlisted member, which is also set as the group training account. The group profile operational mode is taken from the account profile operational mode.

4. (Optional) Remove `sp_migrate_firewall_user_to_group()`:

```
DROP PROCEDURE IF EXISTS mysql.sp_migrate_firewall_user_to_group;
```

If you installed MySQL Enterprise Firewall in a custom schema, make the appropriate substitution for your system.

For additional details about `sp_migrate_firewall_user_to_group()`, see Firewall Miscellaneous Stored Procedures.

### 6.4.7.4 MySQL Enterprise Firewall Reference

The following sections provide a reference to MySQL Enterprise Firewall elements:

- MySQL Enterprise Firewall Tables
- MySQL Enterprise Firewall Stored Procedures
- MySQL Enterprise Firewall Administrative Functions
- MySQL Enterprise Firewall System Variables
- MySQL Enterprise Firewall Status Variables
MySQL Enterprise Firewall Tables

MySQL Enterprise Firewall maintains profile information on a per-group and per-account basis. It uses tables in the firewall database for persistent storage and INFORMATION_SCHEMA or Performance Schema tables to provide views into in-memory cached data. When enabled, the firewall bases operational decisions on the cached data. The firewall database can be the mysql system database or a custom schema (see Installing MySQL Enterprise Firewall).

- Firewall Group Profile Tables
- Firewall Account Profile Tables

Firewall Group Profile Tables

MySQL Enterprise Firewall maintains group profile information using tables in the firewall database (mysql or custom) for persistent storage and Performance Schema tables to provide views into in-memory cached data.

Each system and Performance Schema table is accessible only by accounts that have the SELECT privilege for it.

The default-database.firewall_groups table lists names and operational modes of registered firewall group profiles. The table has the following columns (with the corresponding Performance Schema firewall_groups table having similar but not necessarily identical columns):

- NAME
  The group profile name.

- MODE
  The current operational mode for the profile. Permitted mode values are OFF, DETECTING, PROTECTING, and RECORDING. For details about their meanings, see Firewall Concepts.

- USERHOST
  The training account for the group profile, to be used when the profile is in RECORDING mode. The value is NULL, or a non-NULL account that has the format user_name@host_name:
  - If the value is NULL, the firewall records allowlist rules for statements received from any account that is a member of the group.
  - If the value is non-NULL, the firewall records allowlist rules only for statements received from the named account (which should be a member of the group).

The default-database.firewall_group_allowlist table lists allowlist rules of registered firewall group profiles. The table has the following columns (with the corresponding Performance Schema firewall_group_allowlist table having similar but not necessarily identical columns):

- NAME
  The group profile name.

- RULE
  A normalized statement indicating an acceptable statement pattern for the profile. A profile allowlist is the union of its rules.
MySQL Enterprise Firewall

- **ID**
  
  An integer column that is a primary key for the table.

The `default-database.firewall_membership` table lists the members (accounts) of registered firewall group profiles. The table has the following columns (with the corresponding Performance Schema `firewall_membership` table having similar but not necessarily identical columns):

- **GROUP_ID**
  
  The group profile name.

- **MEMBER_ID**
  
  The name of an account that is a member of the profile.

**Firewall Account Profile Tables**

MySQL Enterprise Firewall maintains account profile information using tables in the firewall database for persistent storage and INFORMATION_SCHEMA tables to provide views into in-memory cached data. The firewall database can be the mysql system database or a custom schema (see Installing MySQL Enterprise Firewall).

Each default database table is accessible only by accounts that have the SELECT privilege for it. The INFORMATION_SCHEMA tables are accessible by anyone.

As of MySQL 8.0.26, these tables are deprecated and subject to removal in a future MySQL version. See Migrating Account Profiles to Group Profiles.

The `default-database.firewall_users` table lists names and operational modes of registered firewall account profiles. The table has the following columns (with the corresponding MYSQL_FIREWALL_USERS table having similar but not necessarily identical columns):

- **USERHOST**
  
  The account profile name. Each account name has the format `user_name@host_name`.

- **MODE**
  
  The current operational mode for the profile. Permitted mode values are OFF, DETECTING, PROTECTING, RECORDING, and RESET. For details about their meanings, see Firewall Concepts.

The `firewall-database.firewall_whitelist` table lists allowlist rules of registered firewall account profiles. The table has the following columns (with the corresponding MYSQL_FIREWALL_WHITELIST table having similar but not necessarily identical columns):

- **USERHOST**
  
  The account profile name. Each account name has the format `user_name@host_name`.

- **RULE**
  
  A normalized statement indicating an acceptable statement pattern for the profile. A profile allowlist is the union of its rules.

- **ID**
  
  An integer column that is a primary key for the table.
MySQL Enterprise Firewall Stored Procedures

MySQL Enterprise Firewall stored procedures perform tasks such as registering profiles with the firewall, establishing their operational mode, and managing transfer of firewall data between the cache and persistent storage. These procedures invoke administrative functions that provide an API for lower-level tasks.

Firewall stored procedures are created in the firewall database. The firewall database can be the `mysql` system database or a custom schema (see Installing MySQL Enterprise Firewall).

To invoke a firewall stored procedure, either do so while the specified firewall database is the default database, or qualify the procedure name with the database name. For example, if `mysql` is the firewall database:

```sql
CALL mysql.sp_set_firewall_group_mode('group', 'mode');
```

Note

If you have installed MySQL Enterprise Firewall in a custom schema, then make appropriate substitution for your system. For example, if the firewall is installed in the `fwdb` schema, then execute the stored procedures like this:

```sql
CALL fwdb.sp_set_firewall_group_mode('group', 'mode');
```

- Firewall Group Profile Stored Procedures
- Firewall Account Profile Stored Procedures
- Firewall Miscellaneous Stored Procedures

Firewall Group Profile Stored Procedures

These stored procedures perform management operations on firewall group profiles:

- `sp_firewall_group_delist(group, user)`

  This stored procedure removes an account from a firewall group profile.

  If the call succeeds, the change in group membership is made to both the in-memory cache and persistent storage.

  Arguments:

  - `group`: The name of the affected group profile.
  - `user`: The account to remove, as a string in `user_name@host_name` format.

  Example:

  ```sql
  CALL mysql.sp_firewall_group_delist('g', 'fwuser@localhost');
  ```

- `sp_firewall_group_enlist(group, user)`

  This stored procedure adds an account to a firewall group profile. It is not necessary to register the account itself with the firewall before adding the account to the group.

  If the call succeeds, the change in group membership is made to both the in-memory cache and persistent storage.

  Arguments:
MySQL Enterprise Firewall

• **group**: The name of the affected group profile.

• **user**: The account to add, as a string in `user_name@host_name` format.

Example:

```sql
CALL mysql.sp_firewall_group_enlist('g', 'fwuser@localhost');
```

• **sp_reload_firewall_group_rules(group)**

This stored procedure provides control over firewall operation for individual group profiles. The procedure uses firewall administrative functions to reload the in-memory rules for a group profile from the rules stored in the `firewall-database.firewall_group_allowlist` table.

Arguments:

• **group**: The name of the affected group profile.

Example:

```sql
CALL mysql.sp_reload_firewall_group_rules('myapp');
```

**Warning**

This procedure clears the group profile in-memory allowlist rules before reloading them from persistent storage, and sets the profile mode to OFF. If the profile mode was not OFF prior to the `sp_reload_firewall_group_rules()` call, use `sp_set_firewall_group_mode()` to restore its previous mode after reloading the rules. For example, if the profile was in PROTECTING mode, that is no longer true after calling `sp_reload_firewall_group_rules()` and you must set it to PROTECTING again explicitly.

• **sp_set_firewall_group_mode(group, mode)**

This stored procedure establishes the operational mode for a firewall group profile, after registering the profile with the firewall if it was not already registered. The procedure also invokes firewall administrative functions as necessary to transfer firewall data between the cache and persistent storage. This procedure may be called even if the `mysql_firewall_mode` system variable is OFF, although setting the mode for a profile has no operational effect until the firewall is enabled.

If the profile previously existed, any recording limitation for it remains unchanged. To set or clear the limitation, call `sp_set_firewall_group_mode_and_user()` instead.

Arguments:

• **group**: The name of the affected group profile.

• **mode**: The operational mode for the profile, as a string. Permitted mode values are OFF, DETECTING, PROTECTING, and RECORDING. For details about their meanings, see Firewall Concepts.

Example:

```sql
CALL mysql.sp_set_firewall_group_mode('myapp', 'PROTECTING');
```
• sp_set_firewall_group_mode_and_user(group, mode, user)

This stored procedure registers a group with the firewall and establishes its operational mode, similar to \texttt{sp_set_firewall_group_mode()}, but also specifies the training account to be used when the group is in \textsc{recording} mode.

Arguments:

• \textit{group}: The name of the affected group profile.

• \textit{mode}: The operational mode for the profile, as a string. Permitted mode values are \textsc{off}, \textsc{detecting}, \textsc{protecting}, and \textsc{recording}. For details about their meanings, see \textbf{Firewall Concepts}.

• \textit{user}: The training account for the group profile, to be used when the profile is in \textsc{recording} mode. The value is \textsc{null}, or a non-\textsc{null} account that has the format \texttt{user\_name@host\_name}:

  • If the value is \textsc{null}, the firewall records allowlist rules for statements received from any account that is a member of the group.
  
  • If the value is non-\textsc{null}, the firewall records allowlist rules only for statements received from the named account (which should be a member of the group).

Example:

\begin{verbatim}
CALL mysql.sp_set_firewall_group_mode_and_user('myapp', 'RECORDING', 'myapp_user1@localhost');
\end{verbatim}

\section*{Firewall Account Profile Stored Procedures}

These stored procedures perform management operations on firewall account profiles:

• sp_reload_firewall_rules(user)

This stored procedure provides control over firewall operation for individual account profiles. The procedure uses firewall administrative functions to reload the in-memory rules for an account profile from the rules stored in the \texttt{firewall-database.firewall Whitelist} table.

Arguments:

• \textit{user}: The name of the affected account profile, as a string in \texttt{user\_name@host\_name} format.

Example:

\begin{verbatim}
CALL sp_reload_firewall_rules('fwuser@localhost');
\end{verbatim}

\begin{warning}

This procedure clears the account profile in-memory allowlist rules before reloading them from persistent storage, and sets the profile mode to \textsc{off}. If the profile mode was not \textsc{off} prior to the \texttt{sp_reload_firewall_rules()} call, use \texttt{sp_set_firewall_mode()} to restore its previous mode after reloading the rules. For example, if the profile was in \textsc{protecting} mode, that is no longer true after calling \texttt{sp_reload_firewall_rules()} and you must set it to \textsc{protecting} again explicitly.

As of MySQL 8.0.26, this procedure is deprecated and subject to removal in a future MySQL version. See \textbf{Migrating Account Profiles to Group Profiles}.

\end{warning}

• sp_set_firewall_mode(user, mode)
This stored procedure establishes the operational mode for a firewall account profile, after registering the profile with the firewall if it was not already registered. The procedure also invokes firewall administrative functions as necessary to transfer firewall data between the cache and persistent storage. This procedure may be called even if the `mysql_firewall_mode` system variable is `OFF`, although setting the mode for a profile has no operational effect until the firewall is enabled.

Arguments:

- **user**: The name of the affected account profile, as a string in `user_name@host_name` format.
- **mode**: The operational mode for the profile, as a string. Permitted mode values are `OFF`, `DETECTING`, `PROTECTING`, `RECORDING`, and `RESET`. For details about their meanings, see [Firewall Concepts](#).

Switching an account profile to any mode but `RECORDING` synchronizes its firewall cache data to the firewall database tables that provide persistent underlying storage (`mysql` or custom). Switching the mode from `OFF` to `RECORDING` reloads the allowlist from the `firewall-database.firewall_whitelist` table into the cache.

If an account profile has an empty allowlist, its mode cannot be set to `PROTECTING` because the profile would reject every statement, effectively prohibiting the account from executing statements. In response to such a mode-setting attempt, the firewall produces a diagnostic message that is returned as a result set rather than as an SQL error:

```sql
mysql> CALL sp_set_firewall_mode('a@b','PROTECTING');
+----------------------------------------------------------------------+
| set_firewall_mode(arg_userhost, arg_mode)                            |
+----------------------------------------------------------------------+
| ERROR: PROTECTING mode requested for a@b but the allowlist is empty. |
+----------------------------------------------------------------------+
```

As of MySQL 8.0.26, this procedure is deprecated and subject to removal in a future MySQL version. See [Migrating Account Profiles to Group Profiles](#).

**Firewall Miscellaneous Stored Procedures**

These stored procedures perform miscellaneous firewall management operations.

- **sp_migrate_firewall_user_to_group(user, group)**

As of MySQL 8.0.26, account profiles are deprecated because group profiles can do anything account profiles can do. The `sp_migrate_firewall_user_to_group()` stored procedure converts a firewall account profile to a group profile with the account as its single enlisted member. Run the `firewall_profile_migration.sql` script to install it. The conversion procedure is discussed in [Migrating Account Profiles to Group Profiles](#).

This routine requires the `FIREWALL_ADMIN` privilege.

Arguments:

- **user**: The name of the account profile to convert to a group profile, as a string in `user_name@host_name` format. The account profile must exist, and must not currently be in `RECORDING` mode.

- **group**: The name of the new group profile, which must not already exist. The new group profile has the named account as its single enlisted member, and that member is set as the group training account. The group profile operational mode is taken from the account profile operational mode.
MySQL Enterprise Firewall Administrative Functions

MySQL Enterprise Firewall administrative functions provide an API for lower-level tasks such as synchronizing the firewall cache with the underlying system tables.

Under normal operation, these functions are invoked by the firewall stored procedures, not directly by users. For that reason, these function descriptions do not include details such as information about their arguments and return types.

- Firewall Group Profile Functions
- Firewall Account Profile Functions
- Firewall Miscellaneous Functions

Firewall Group Profile Functions

These functions perform management operations on firewall group profiles:

- `firewall_group_delist(group, user)`

  This function removes an account from a group profile. It requires the FIREWALL_ADMIN privilege.

  Example:

  ```
  SELECT firewall_group_delist('g', 'fwuser@localhost');
  ```

- `firewall_group_enlist(group, user)`

  This function adds an account to a group profile. It requires the FIREWALL_ADMIN privilege.

  It is not necessary to register the account itself with the firewall before adding the account to the group.

  Example:

  ```
  SELECT firewall_group_enlist('g', 'fwuser@localhost');
  ```

- `read_firewall_group_allowlist(group, rule)`

  This aggregate function updates the recorded-statement cache for the named group profile through a `SELECT` statement on the firewall-database.firewall_group_allowlist table. It requires the FIREWALL_ADMIN privilege.

  Example:

  ```
  SELECT read_firewall_group_allowlist('my_fw_group', fgw.rule)
  FROM mysql.firewall_group_allowlist AS fgw
  WHERE NAME = 'my_fw_group';
  ```

- `read_firewall_groups(group, mode, user)`

  This aggregate function updates the firewall group profile cache through a `SELECT` statement on the firewall-database.firewall_groups table. It requires the FIREWALL_ADMIN privilege.

  Example:
MySQL Enterprise Firewall

```
SELECT read_firewall_groups('g', 'RECORDING', 'fwuser@localhost')
FROM mysql.firewall_groups;
```

- **set_firewall_group_mode(group, mode[, user])**

  This function manages the group profile cache, establishes the profile operational mode, and optionally specifies the profile training account. It requires the FIREWALL_ADMIN privilege.

  If the optional `user` argument is not given, any previous `user` setting for the profile remains unchanged. To change the setting, call the function with a third argument.

  If the optional `user` argument is given, it specifies the training account for the group profile, to be used when the profile is in RECORDING mode. The value is NULL, or a non-NULL account that has the format `user_name@host_name`:

  - If the value is NULL, the firewall records allowlist rules for statements received from any account that is a member of the group.
  - If the value is non-NULL, the firewall records allowlist rules only for statements received from the named account (which should be a member of the group).

  Example:

  ```
  SELECT set_firewall_group_mode('g', 'DETECTING');
  ```

Firewall Account Profile Functions

These functions perform management operations on firewall account profiles:

- **read_firewall_users(user, mode)**

  This aggregate function updates the firewall account profile cache through a SELECT statement on the firewall-database.firewall_users table. It requires the FIREWALL_ADMIN privilege or the deprecated SUPER privilege.

  Example:

  ```
  SELECT read_firewall_users('fwuser@localhost', 'RECORDING')
  FROM mysql.firewall_users;
  ```

  As of MySQL 8.0.26, this function is deprecated and subject to removal in a future MySQL version. See Migrating Account Profiles to Group Profiles.

- **read_firewall_whitelist(user, rule)**

  This aggregate function updates the recorded-statement cache for the named account profile through a SELECT statement on the firewall-database.firewall_whitelist table. It requires the FIREWALL_ADMIN privilege or the deprecated SUPER privilege.

  Example:

  ```
  SELECT read_firewall_whitelist('fwuser@localhost', fw.rule)
  FROM mysql.firewall_whitelist AS fw
  WHERE USERHOST = 'fwuser@localhost';
  ```

  As of MySQL 8.0.26, this function is deprecated and subject to removal in a future MySQL version. See Migrating Account Profiles to Group Profiles.

- **set_firewall_mode(user, mode)**
MySQL Enterprise Firewall

This function manages the account profile cache and establishes the profile operational mode. It requires the `FIREWALL_ADMIN` privilege or the deprecated `SUPER` privilege.

Example:

```
SELECT set_firewall_mode('fwuser@localhost', 'RECORDING');
```

As of MySQL 8.0.26, this function is deprecated and subject to removal in a future MySQL version. See [Migrating Account Profiles to Group Profiles](#).

Firewall Miscellaneous Functions

These functions perform miscellaneous firewall operations:

- `mysql_firewall_flush_status()`
  
  This function resets several firewall status variables to 0:
  
  - `Firewall_access_denied`
  
  - `Firewall_access_granted`
  
  - `Firewall_access_suspicious`

  This function requires the `FIREWALL_ADMIN` privilege or the deprecated `SUPER` privilege.

  Example:

  ```
  SELECT mysql_firewall_flush_status();
  ```

- `normalize_statement(stmt)`
  
  This function normalizes an SQL statement into the digest form used for allowlist rules. It requires the `FIREWALL_ADMIN` privilege or the deprecated `SUPER` privilege.

  Example:

  ```
  SELECT normalize_statement('SELECT * FROM t1 WHERE c1 > 2');
  ```

  **Note**

  The same digest functionality is available outside firewall context using the `STATEMENT_DIGEST_TEXT()` SQL function.

MySQL Enterprise Firewall System Variables

MySQL Enterprise Firewall supports the following system variables. Use them to configure firewall operation. These variables are unavailable unless the firewall is installed (see [Section 6.4.7.2, “Installing or Uninstalling MySQL Enterprise Firewall”](#)).

- `mysql_firewall_database`
MySQL Enterprise Firewall

<table>
<thead>
<tr>
<th>SET_VAR</th>
<th>Hint Applies</th>
<th>No</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>Default Value</td>
<td>mysql</td>
<td></td>
</tr>
</tbody>
</table>

Specifies the database from which MySQL Enterprise Firewall reads data. Typically, the MySQL Enterprise Firewall server-side plugin stores its internal data (tables, stored procedures, and functions) in the mysql system database, but you can create and use a custom schema instead (see Installing MySQL Enterprise Firewall). This variable permits specifying an alternative database name at startup.

- **mysql_firewall_mode**

  | Command-Line Format | --mysql-firewall-mode{=OFF|ON} |
  |---------------------|--------------------------------|
  | System Variable     | mysql_firewall_mode            |
  | Scope               | Global                         |
  | Dynamic             | Yes                            |
  | SET_VAR Hint Applies| No                             |
  | Type                | Boolean                        |
  | Default Value       | ON                             |

Whether MySQL Enterprise Firewall is enabled (the default) or disabled.

- **mysql_firewall_reload_interval_seconds**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mysql-firewall-reload-interval-seconds=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>mysql_firewall_reload_interval_seconds</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>60 (unless 0: OFF)</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>INT_MAX</td>
</tr>
<tr>
<td>Unit</td>
<td>seconds</td>
</tr>
</tbody>
</table>

Specifies the interval (in seconds) that the server-side plugin uses to reload its internal cache from firewall tables. When mysql_firewall_reload_interval_seconds has a value of zero (the default), no periodic reloading of data from tables occurs at runtime. Values between 0 and 60 (1 to 59) are not acknowledged by the plugin. Instead, these values adjust to 60 automatically.

This variable requires that the scheduler component be enabled (ON). For more information, see Scheduling Firewall Cache Reloads.

- **mysql_firewall_trace**

  | Command-Line Format | --mysql-firewall-trace{=OFF|ON} |
  |---------------------|--------------------------------|
  | System Variable     | mysql_firewall_trace            |

This variable applies to the server-side plugin console output to display trace messages.
### MySQL Enterprise Firewall Status Variables

MySQL Enterprise Firewall supports the following status variables. Use them to obtain information about firewall operational status. These variables are unavailable unless the firewall is installed (see Section 6.4.7.2, “Installing or Uninstalling MySQL Enterprise Firewall”). Firewall status variables are set to 0 whenever the `MYSQL_FIREWALL` plugin is installed or the server is started. Many of them are reset to zero by the `mysql_firewall_flush_status()` function (see MySQL Enterprise Firewall Administrative Functions).

- **Firewall_access_denied**
  The number of statements rejected by MySQL Enterprise Firewall.

- **Firewall_access_granted**
  The number of statements accepted by MySQL Enterprise Firewall.

- **Firewall_access_suspicious**
  The number of statements logged by MySQL Enterprise Firewall as suspicious for users who are in DETECTING mode.

- **Firewall_cached_entries**
  The number of statements recorded by MySQL Enterprise Firewall, including duplicates.

## 6.5 MySQL Enterprise Data Masking and De-Identification

**Note**

MySQL Enterprise Data Masking and De-Identification is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, [https://www.mysql.com/products/](https://www.mysql.com/products/).

MySQL Enterprise Edition provides data masking and de-identification capabilities:

- Transformation of existing data to mask it and remove identifying characteristics, such as changing all digits of a credit card number but the last four to 'X' characters.

- Generation of random data, such as email addresses and payment card numbers.

- Substitution of data by data from dictionaries stored in the database. The dictionaries are easily replicated in a standard way. Administration is restricted to authorized users who are granted special privileges so that only they can create and modify the dictionaries.
MySQL Enterprise Data Masking and De-Identification was implemented originally in MySQL as a plugin library. As of MySQL 8.2, MySQL Enterprise Edition also provides components to access data masking and de-identification capabilities. For information about the similarities and differences, see Table 6.48, “Comparison Between Data-Masking Components and Plugin Elements”.

If you are using MySQL Enterprise Data Masking and De-Identification for the first time, consider installing the components for access to the ongoing enhancements only available with component infrastructure.

The way that applications use these capabilities depends on the purpose for which the data is used and who accesses it:

• Applications that use sensitive data may protect it by performing data masking and permitting use of partially masked data for client identification. Example: A call center may ask for clients to provide their last four Social Security Number digits.

• Applications that require properly formatted data, but not necessarily the original data, can synthesize sample data. Example: An application developer who is testing data validators but has no access to original data may synthesize random data with the same format.

• Applications that must substitute a real name with a dictionary term to protect sensitive information, but still provide realistic content to application users. Example: A user in training who is restricted from viewing addresses gets a random term from dictionary city names instead of the real city name. A variant of this scenario may be that the real city name is replaced only if it exists in usa_city_names.

Example 1:

Medical research facilities can hold patient data that comprises a mix of personal and medical data. This may include genetic sequences (long strings), test results stored in JSON format, and other data types. Although the data may be used mostly by automated analysis software, access to genome data or test results of particular patients is still possible. In such cases, data masking should be used to render this information not personally identifiable.

Example 2:

A credit card processor company provides a set of services using sensitive data, such as:

• Processing a large number of financial transactions per second.

• Storing a large amount of transaction-related data.

• Protecting transaction-related data with strict requirements for personal data.

• Handling client complaints about transactions using reversible or partially masked data.

A typical transaction may include many types of sensitive information, including:

• Credit card number.

• Transaction type and amount.

• Merchant type.

• Transaction cryptogram (to confirm transaction legitimacy).
Those types of information may then be joined within a bank or other card-issuing financial institution with client personal data, such as:

- Full client name (either person or company).
- Address.
- Date of birth.
- Social Security number.
- Email address.
- Phone number.

Various employee roles within both the card processing company and the financial institution require access to that data. Some of these roles may require access only to masked data. Other roles may require access to the original data on a case-to-case basis, which is recorded in audit logs.

Masking and de-identification are core to regulatory compliance, so MySQL Enterprise Data Masking and De-Identification can help application developers satisfy privacy requirements:

- PCI – DSS: Payment Card Data.
- HIPAA: Privacy of Health Data, Health Information Technology for Economic and Clinical Health Act (HITECH Act).
- Data Protection Act (UK): Protection of Personal Data.
- FERPA – Student Data, NASD, CA SB1386 and AB 1950, State Data Protection Laws, Basel II.

The following sections describe the elements of MySQL Enterprise Data Masking and De-Identification, discuss how to install and use it, and provide reference information for its elements.

### 6.5.1 Data-Masking Components Versus the Data-Masking Plugin

Previously, MySQL enabled masking and de-identification capabilities using a server-side plugin, but transitioned to use the component infrastructure as an alternative implementation. The following table briefly compares MySQL Enterprise Data Masking and De-Identification components and the plugin library to provide an overview of their differences. It may assist you in making the transition from the plugin to components.

#### Note

Only the data-masking components or the plugin should be enabled at a time. Enabling both components and the plugin is unsupported and results may not be as anticipated.

### MySQL Enterprise Data Masking and De-Identification Components

MySQL Enterprise Data Masking and De-Identification implements these elements:

- A table in the `mysql` system database for persistent storage of dictionaries and terms.

- A component named `component_masking` that implements masking functionality and exposes it as service interface for developers.

Developers who wish to incorporate the same service functions used by `component_masking` should consult the `internal\components\masking\component_masking.h` file in a MySQL source distribution or https://dev.mysql.com/doc/dev/mysql-server/latest.

- A component named `component_masking_functions` that provides loadable functions.

The set of loadable functions enables an SQL-level API for performing masking and de-identification operations. Some of the functions require the `MASKING_DICTIONARIES_ADMIN` dynamic privilege.

### 6.5.2.1 MySQL Enterprise Data Masking and De-Identification Component Installation

Components provide expanded access to MySQL Enterprise Data Masking and De-Identification functionality. Previously, MySQL implemented masking and de-identification capabilities as a plugin library file containing a plugin and several loadable functions. Before you begin the component installation, remove the `data_masking` plugin and all of its loadable functions to avoid conflicts. For instructions, see Section 6.5.3.1, “MySQL Enterprise Data Masking and De-Identification Plugin Installation”.

MySQL Enterprise Data Masking and De-Identification database table and components are:

- `masking_dictionaries` table
  
  Purpose: A table in the `mysql` system schema that provides persistent storage of dictionaries and terms.

- `component_masking` component
MySQL Enterprise Data Masking and De-Identification Components

Purpose: The component implements the core of the masking functionality and exposes it as services.

URN: file:///component_masking

• component_masking_functions component

Purpose: The component exposes all functionality of the component_masking component as loadable functions. Some of the functions require the MASKING_DICTIONARIES_ADMIN dynamic privilege.

URN: file:///component_masking_functions

To set up MySQL Enterprise Data Masking and De-Identification, do the following:

1. Create the masking_dictionaries table.

CREATE TABLE IF NOT EXISTS mysql.masking_dictionaries(
  Dictionary VARCHAR(256) NOT NULL,
  Term VARCHAR(256) NOT NULL,
  UNIQUE INDEX dictionary_term_idx (Dictionary, Term),
  INDEX dictionary_idx (Dictionary)
) ENGINE = InnoDB DEFAULT CHARSET=utf8mb4;

2. Use the INSTALL COMPONENT SQL statement to install data masking components.

INSTALL COMPONENT 'file:///component_masking';
INSTALL COMPONENT 'file:///component_masking_functions';

If the components and functions are used on a replication source server, install them on all replica servers as well to avoid replication issues. While the components are loaded, information about them is available as described in Section 5.5.2, “Obtaining Component Information”.

To remove MySQL Enterprise Data Masking and De-Identification, do the following:

1. Use the UNINSTALL COMPONENT SQL statement to uninstall the data masking components.

UNINSTALL COMPONENT 'file:///component_masking';
UNINSTALL COMPONENT 'file:///component_masking_functions';

2. Drop the masking_dictionaries table.

DROP TABLE mysql.masking_dictionaries;

component_masking_functions installs all of the related loadable functions automatically. Similarly, the component when uninstalled also automatically uninstalls those functions. For general information about installing or uninstalling components, see Section 5.5.1, “Installing and Uninstalling Components”.

6.5.2.2 Using MySQL Enterprise Data Masking and De-Identification Components

Before using MySQL Enterprise Data Masking and De-Identification, install it according to the instructions provided at Section 6.5.2.1, “MySQL Enterprise Data Masking and De-Identification Component Installation”.

To use MySQL Enterprise Data Masking and De-Identification in applications, invoke the functions that are appropriate for the operations you wish to perform. For detailed function descriptions, see Section 6.5.2.4, “MySQL Enterprise Data Masking and De-Identification Component Function Descriptions”. This section demonstrates how to use the functions to carry out some representative tasks. It first presents an overview of the available functions, followed by some examples of how the functions might be used in real-world context:
MySQL Enterprise Data Masking and De-Identification Components

- Masking Data to Remove Identifying Characteristics
- Generating Random Data with Specific Characteristics
- Generating Random Data Using Dictionaries
- Using Masked Data for Customer Identification
- Creating Views that Display Masked Data

Masking Data to Remove Identifying Characteristics

MySQL provides general-purpose masking component functions that mask arbitrary strings, and special-purpose masking functions that mask specific types of values.

General-Purpose Masking Component Functions

`mask_inner()` and `mask_outer()` are general-purpose functions that mask parts of arbitrary strings based on position within the string. Both functions support an input string that is encoded in any character set:

- `mask_inner()` masks the interior of its string argument, leaving the ends unmasked. Other arguments specify the sizes of the unmasked ends.

```sql
mysql> SELECT mask_inner('This is a string', 5, 1);
+--------------------------------------+
| mask_inner('This is a string', 5, 1) |
+--------------------------------------+
| This XXXXXXXXg                      |
+--------------------------------------+

mysql> SELECT mask_outer('This is a string', 5, 1);
+--------------------------------------+
| mask_outer('This is a string', 5, 1) |
+--------------------------------------+
| XXXXXXXis a strinX                  |
+--------------------------------------+
```

- `mask_outer()` does the reverse, masking the ends of its string argument, leaving the interior unmasked. Other arguments specify the sizes of the masked ends.

```sql
mysql> SELECT mask_outer('This is a string', 5, 1);
+--------------------------------------+
| mask_outer('This is a string', 5, 1) |
+--------------------------------------+
| XXXXXXXis a strinX                  |
+--------------------------------------+
```

MySQL> SELECT mask_outer('This is a string', 1, 5);
+--------------------------------------+
| mask_outer('This is a string', 1, 5) |
+--------------------------------------+
| Xhis is a sXXXXX                     |
+--------------------------------------+

MySQL> SELECT mask_inner("かすみがうら市", 3, 1);
+----------------------------------+
| mask_inner("かすみがうら市", 3, 1) |
+----------------------------------+
| かすみXXX市                       |
+----------------------------------+

MySQL> SELECT mask_outer("かすみがうら市", 3, 1);
+----------------------------------+
| mask_outer("かすみがうら市", 3, 1) |
| かすみxxx市                       |
+----------------------------------+

MySQL> SELECT mask_outer("かすみがうら市", 1, 3);
+----------------------------------+
| mask_outer("かすみがうら市", 1, 3) |
| かxxxうら市                       |
+----------------------------------+

MySQL> SELECT mask_inner("かすみがうら市", 3, 1);
+----------------------------------+
| mask_inner("かすみがうら市", 3, 1) |
| かすみxxx市                       |
+----------------------------------+

MySQL> SELECT mask_outer("かすみがうら市", 1, 3);
+----------------------------------+
| mask_outer("かすみがうら市", 1, 3) |
| かxxxうら市                       |
+----------------------------------+

By default, `mask_inner()` and `mask_outer()` use 'X' as the masking character, but permit an optional masking-character argument:

```sql
mysql> SELECT mask_inner('This is a string', 5, 1, '*');
+-------------------------------------------+
| mask_inner('This is a string', 5, 1, '*') |
| This **********g                          |
+-------------------------------------------+
mysql> SELECT mask_inner("かすみがうら市", 2, 2, "#");
+---------------------------------------+
| mask_inner("かすみがうら市", 2, 2, "#") |
|かす###ら市                               |
+---------------------------------------+
```

### Special-Purpose Masking Component Functions

Other masking functions expect a string argument representing a specific type of value and mask it to remove identifying characteristics.

**Note**

The examples here supply function arguments using the random value generation functions that return the appropriate type of value. For more information about generation functions, see [Generating Random Data with Specific Characteristics](#).

#### Payment card Primary Account Number masking.

Masking functions provide strict and relaxed masking of Primary Account numbers.

- **mask_pan()** masks all but the last four digits of the number:

  ```sql
  mysql> SELECT mask_pan(gen_rnd_pan());
  +-------------------------+
  | mask_pan(gen_rnd_pan()) |
  | XXXXXXXXXXXX2461        |
  +-------------------------+
  ```

- **mask_pan_relaxed()** is similar but does not mask the first six digits that indicate the payment card issuer unmasked:

  ```sql
  mysql> SELECT mask_pan_relaxed(gen_rnd_pan());
  +---------------------------------+
  | mask_pan_relaxed(gen_rnd_pan()) |
  | 770630XXXXXX0807                |
  +---------------------------------+
  ```

#### International Bank Account Number masking.

`mask_iban()` masks all but the first two letters (denoting the country) of the number:

```sql
mysql> SELECT mask_iban(gen_rnd_iban());
+---------------------------+
| mask_iban(gen_rnd_iban()) |
| ZZ** **** **** ****       |
+---------------------------+
```

#### Universally Unique Identifier masking.

`mask_uuid()` masks all meaningful characters:

```sql
mysql> SELECT mask_uuid(gen_rnd_uuid());
+--------------------------------------+
| mask_uuid(gen_rnd_uuid())            |
| 1674                                 |
+--------------------------------------+
```
US Social Security Number masking.  

`mask_ssn()` masks all but the last four digits of the number:

```sql
mysql> SELECT mask_ssn(gen_rnd_ssn());
+-------------------------+
| mask_ssn(gen_rnd_ssn()) |
| ***-**-1723             |
+-------------------------+
```

Canada Social Insurance Number masking.  

`mask_canada_sin()` masks meaningful digits of the number:

```sql
mysql> SELECT mask_canada_sin(gen_rnd_canada_sin());
+---------------------------------------+
| mask_canada_sin(gen_rnd_canada_sin()) |
| XXX-XXX-XXX                           |
+---------------------------------------+
```

United Kingdom National Insurance Number masking.  

`mask_uk_nin()` masks all but the first two digits of the number:

```sql
mysql> SELECT mask_uk_nin(gen_rnd_uk_nin());
+-------------------------------+
| mask_uk_nin(gen_rnd_uk_nin()) |
| ZH*******                    |
+-------------------------------+
```

Generating Random Data with Specific Characteristics

Several component functions generate random values. These values can be used for testing, simulation, and so forth.

`gen_range()` returns a random integer selected from a given range:

```sql
mysql> SELECT gen_range(1, 10);
+------------------+
| gen_range(1, 10) |
|                 6 |
+------------------+
```

`gen_rnd_canada_sin()` returns a random number chosen from a range not used for legitimate numbers:

```sql
mysql> SELECT gen_rnd_canada_sin();
+---------------------------------------+
| gen_rnd_canada_sin() |
|                      +
+---------------------------------------+
```

(The `gen_rnd_canada_sin()` function result is not shown because its return values should be used only for testing purposes, and not for publication. It cannot be guaranteed the number is not assigned to a legitimate Canada SIN.)

`gen_rnd_email()` returns a random email address with a specified number of digits for the name and surname parts in the specified domain, `mynet.com` in the following example:

```sql
mysql> SELECT gen_rnd_email(6, 8, 'mynet.com');
+------------------------------+
| gen_rnd_email(6, 8, 'mynet') |
|                            1675 |
+------------------------------+
```
MySQL Enterprise Data Masking and De-Identification Components

`gen_rnd_iban()` returns a number chosen from a range not used for legitimate numbers:

```sql
mysql> SELECT gen_rnd_iban('XO', 24);
+-------------------------------+
| gen_rnd_iban('XO', 24)        |
+-------------------------------+
| XO25 SL7A PGQR B9NN 6IVB RFE8 |
+-------------------------------+
```

`gen_rnd_pan()` returns a random payment card Primary Account Number:

```sql
mysql> SELECT gen_rnd_pan();
(The `gen_rnd_pan()` function result is not shown because its return values should be used only for testing purposes, and not for publication. It cannot be guaranteed the number is not assigned to a legitimate payment account.)
```

`gen_rnd_ssn()` returns a random US Social Security Number with the first and second parts each chosen from a range not used for legitimate numbers:

```sql
mysql> SELECT gen_rnd_ssn();
+---------------+
| gen_rnd_ssn() |
+---------------+
| 912-45-1615   |
+---------------+
```

`gen_rnd_uk_nin()` returns a number chosen from a range not used for legitimate numbers:

```sql
mysql> SELECT gen_rnd_uk_nin();
+------------------+
| gen_rnd_uk_nin() |
+------------------+
(The `gen_rnd_uk_nin()` function result is not shown because its return values should be used only for testing purposes, and not for publication. It cannot be guaranteed the number is not assigned to a legitimate NIN.)
```

`gen_rnd_us_phone()` returns a random US phone number in the 555 area code not used for legitimate numbers:

```sql
mysql> SELECT gen_rnd_us_phone();
+--------------------+
| gen_rnd_us_phone() |
+--------------------+
| 1-555-747-5627     |
+--------------------+
```

`gen_rnd_uuid()` returns a number chosen from a range not used for legitimate identifiers:

```sql
mysql> SELECT gen_rnd_uuid();
+--------------------------------------+
| gen_rnd_uuid()                       |
+--------------------------------------+
| 68946384-6880-3150-6889-928076732539 |
+--------------------------------------+
```

**Generating Random Data Using Dictionaries**

MySQL Enterprise Data Masking and De-Identification enables dictionaries to be used as sources of random values called **terms**. To use a dictionary, it must first be added to the `masking_dictionaries`
system table and given a name. The dictionaries are read from the table and loaded to the cache during
initialization of the components (on server startup). Terms then can then be added, removed, and selected
from dictionaries and used as random values or as replacements for other values.

Note

Always edit dictionaries using dictionary administration functions rather than
modifying the table directly. If you manipulate the table manually, the dictionary
cache becomes inconsistent with the table.

A valid masking_dictionaries table has these characteristics:

• An administrator created the masking_dictionaries system table in the mysql schema as follows:

```
CREATE TABLE IF NOT EXISTS masking_dictionaries(
    Dictionary VARCHAR(256) NOT NULL,
    Term VARCHAR(256) NOT NULL,
    UNIQUE INDEX dictionary_term_idx (Dictionary, Term),
    INDEX dictionary_idx (Dictionary)
) ENGINE = InnoDB DEFAULT CHARSET=utf8mb4;
```

• MASKING_DICTIONARY_ADMIN privilege is required to add and remove terms, or to remove an entire
dictionary.

• The table may contain multiple dictionaries and their terms.

• Any user account can view the dictionaries. Given enough queries, all of the terms in dictionaries are
retrievable. Avoid adding sensitive data to the dictionary table.

Suppose that a dictionary named DE_cities includes these city names in Germany:

Berlin
Munich
Bremen

Use masking_dictionary_term_add() to assign a dictionary name and one term:

```sql
mysql> SELECT masking_dictionary_term_add('DE_Cities', 'Berlin');
+----------------------------------------------------+
| masking_dictionary_term_add('DE_Cities', 'Berlin') |
|                                                  1 |
+----------------------------------------------------+
mysql> SELECT masking_dictionary_term_add('DE_Cities', 'Munich');
+----------------------------------------------------+
| masking_dictionary_term_add('DE_Cities', 'Munich') |
|                                                  1 |
+----------------------------------------------------+
mysql> SELECT masking_dictionary_term_add('DE_Cities', 'Bremen');
+----------------------------------------------------+
| masking_dictionary_term_add('DE_Cities', 'Bremen') |
|                                                  1 |
+----------------------------------------------------+
```

Also suppose that a dictionary named US_Cities contains these city names in the United States:

Houston
Phoenix
Detroit

```sql
mysql> SELECT masking_dictionary_term_add('US_Cities', 'Houston');
```
MySQL Enterprise Data Masking and De-Identification Components

```sql
mysql> SELECT masking_dictionary_term_add('US_Cities', 'Phoenix');
| masking_dictionary_term_add('US_Cities', 'Phoenix') |
+-----------------------------------------------------+
|                                                   1 |
+-----------------------------------------------------+

To select a random term from a dictionary, use `gen_dictionary()`:

```sql
mysql> SELECT gen_dictionary('DE_Cities');
+-----------------------------+
| gen_dictionary('DE_Cities') |
+-----------------------------+
| Berlin                      |
+-----------------------------+

mysql> SELECT gen_dictionary('US_Cities');
+-----------------------------+
| gen_dictionary('US_Cities') |
+-----------------------------+
| Phoenix                     |
+-----------------------------+

To select a random term from multiple dictionaries, randomly select one of the dictionaries, then select a term from it:

```sql
mysql> SELECT gen_dictionary(ELT(gen_range(1,2), 'DE_Cities', 'US_Cities'));
+-----------------------------------------------+
| gen_dictionary(ELT(gen_range(1,2), 'DE_Cities', 'US_Cities')) |
+-----------------------------------------------+
| Detroit                                       |
+-----------------------------------------------+

mysql> SELECT gen_dictionary(ELT(gen_range(1,2), 'DE_Cities', 'US_Cities'));
+-----------------------------------------------+
| gen_dictionary(ELT(gen_range(1,2), 'DE_Cities', 'US_Cities')) |
+-----------------------------------------------+
| Bremen                                        |
+-----------------------------------------------+

The `gen_blocklist()` function enables a term from one dictionary to be replaced by a term from another dictionary, which effects masking by substitution. Its arguments are the term to replace, the dictionary in which the term appears, and the dictionary from which to choose a replacement. For example, to substitute a US city for a German city, or vice versa, use `gen_blocklist()` like this:

```sql
mysql> SELECT gen_blocklist('Munich', 'DE_Cities', 'US_Cities');
+-------------------------------+
| gen_blocklist('Munich', 'DE_Cities', 'US_Cities') |
+-------------------------------+
| Houston                       |
+-------------------------------+

mysql> SELECT gen_blocklist('El Paso', 'US_Cities', 'DE_Cities');
+-------------------------------+
| gen_blocklist('El Paso', 'US_Cities', 'DE_Cities') |
+-------------------------------+
| Bremen                         |
+-------------------------------+
```
If the term to replace is not in the first dictionary, `gen_blocklist()` returns it unchanged:

```sql
mysql> SELECT gen_blocklist('Moscow', 'DE_Cities', 'US_Cities');
+---------------------------------------------------------------+
| gen_blocklist('Moscow', 'DE_Cities', 'US_Cities')             |
+---------------------------------------------------------------+
| Moscow                                                         |
+---------------------------------------------------------------+
```

### Using Masked Data for Customer Identification

At customer-service call centers, one common identity verification technique is to ask customers to provide their last four Social Security Number (SSN) digits. For example, a customer might say her name is Joanna Bond and that her last four SSN digits are `0007`.

Suppose that a `customer` table containing customer records has these columns:

- **id**: Customer ID number.
- **first_name**: Customer first name.
- **last_name**: Customer last name.
- **ssn**: Customer Social Security Number.

For example, the table might be defined as follows:

```sql
CREATE TABLE customer
(
    id         BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    first_name VARCHAR(40),
    last_name  VARCHAR(40),
    ssn        VARCHAR(11)
);
```

The application used by customer-service representatives to check the customer SSN might execute a query like this:

```sql
mysql> SELECT id, ssn
mysql> FROM customer
mysql> WHERE first_name = 'Joanna' AND last_name = 'Bond';
+-----+-------------+
| id  | ssn         |
+-----+-------------+
| 786 | 906-39-0007 |
+-----+-------------+
```

However, that exposes the SSN to the customer-service representative, who has no need to see anything but the last four digits. Instead, the application can use this query to display only the masked SSN:

```sql
mysql> SELECT id, mask_ssn(CONVERT(ssn USING binary)) AS masked_ssn
mysql> FROM customer
mysql> WHERE first_name = 'Joanna' AND last_name = 'Bond';
+-----+-------------+
| id  | masked_ssn  |
+-----+-------------+
| 786 | ***-**-0007 |
+-----+-------------+
```

Now the representative sees only what is necessary, and customer privacy is preserved.

Why was the `CONVERT()` function used for the argument to `mask_ssn()`? Because `mask_ssn()` requires an argument of length 11. Thus, even though `ssn` is defined as `VARCHAR(11)`, if the `ssn` column has a multibyte character set, it may appear to be longer than 11 bytes when passed to a loadable
function, and returns `NULL` while logging the error. Converting the value to a binary string ensures that the function sees an argument of length 11.

A similar technique may be needed for other data masking functions when string arguments do not have a single-byte character set.

### Creating Views that Display Masked Data

If masked data from a table is used for multiple queries, it may be convenient to define a view that produces masked data. That way, applications can select from the view without performing masking in individual queries.

For example, a masking view on the `customer` table from the previous section can be defined like this:

```sql
CREATE VIEW masked_customer AS
SELECT id, first_name, last_name,
mask_ssn(CONVERT(ssn USING binary)) AS masked_ssn
FROM customer;
```

Then the query to look up a customer becomes simpler but still returns masked data:

```sql
mysql> SELECT id, masked_ssn
FROM masked_customer
WHERE first_name = 'Joanna' AND last_name = 'Bond';

+-----+-------------+
<table>
<thead>
<tr>
<th>id</th>
<th>masked_ssn</th>
</tr>
</thead>
<tbody>
<tr>
<td>786</td>
<td>*<strong>-</strong>-0007</td>
</tr>
</tbody>
</table>
```

6.5.2.4 MySQL Enterprise Data Masking and De-Identification Component Function Descriptions

The MySQL Enterprise Data Masking and De-Identification components includes several functions, which may be grouped into these categories:

- Data Masking Component Functions
- Random Data Generation Component Functions
- Dictionary Masking Administration Component Functions
- Dictionary Generating Component Functions

Data Masking Component Functions

Each component function in this section performs a masking operation on its string argument and returns the masked result.

- `mask_canada_sin(str [, mask_char])`

  Masks a Canada Social Insurance Number (SIN) and returns the number with all meaningful digits replaced by 'X' characters. An optional masking character can be specified.

  Arguments:
  - `str`: The string to mask. The accepted formats are:
    - Nine non-separated digits.
    - Nine digits grouped in pattern: `xxx-xxx-xxx` (`-` is any separator character).
    This argument is converted to the `utf8mb4` character set.
  - `mask_char`: (Optional) The single character to use for masking. The default is 'X' if `mask_char` is not given.

  Return value:
  The masked Canada SIN as a string encoded in the `utf8mb4` character set, an error if the argument is not the correct length, or `NULL` if `str` is in incorrect format or contains a multibyte character.
Example:

```sql
mysql> SELECT mask_canada_sin('046-454-286'), mask_canada_sin('abcdefijk');
+--------------------------------+------------------------------+
| mask_canada_sin('046-454-286') | mask_canada_sin('abcdefijk') |
|--------------------------------+------------------------------|
| XXX-XXX-XXX                    | XXXXXXXXX                    |
+--------------------------------+------------------------------+
mysql>
```

Example:

```sql
mysql> SELECT mask_canada_sin('046-454-286-909');
ERROR 1123 (HY000): Can't initialize function 'mask_canada_sin'; Argument 0 is too long.
```

Example:

```sql
mysql> SELECT mask_canada_sin('909');
ERROR 1123 (HY000): Can't initialize function 'mask_canada_sin'; Argument 0 is too short.
```

Example:

```sql
mysql> SELECT mask_canada_sin('046-454-286'), mask_canada_sin('abcdefijk');
+--------------------------------+------------------------------+
| mask_canada_sin('046-454-286') | mask_canada_sin('abcdefijk') |
|--------------------------------+------------------------------|
| XXX-XXX-XXX                    | XXXXXXXXX                    |
+--------------------------------+------------------------------+
mysql>
```

Example:

```sql
mysql> SELECT mask_canada_sin('909');
ERROR 1123 (HY000): Can't initialize function 'mask_canada_sin'; Argument 0 is too short.
```

Example:

```sql
mysql> SELECT mask_canada_sin('046-454-286-909');
ERROR 1123 (HY000): Can't initialize function 'mask_canada_sin'; Argument 0 is too long.
```

Example:

```sql
mysql> SELECT mask_iban('IE12 BOFI 9000 0112 3456 78'), mask_iban('abcdefghijk');
+------------------------------------------+--------------------------+
| mask_iban('IE12 BOFI 9000 0112 3456 78') | mask_iban('abcdefghijk') |
|------------------------------------------+--------------------------|
| IE** **** **** **** **** **              | ab*********              |
+------------------------------------------+--------------------------+
mysql>
```

Example:

```sql
mysql> SELECT mask_iban('IE12 BOFI 9000 0112 3456 78 IE12 BOFI 9000 0112 3456 78');
ERROR 1123 (HY000): Can't initialize function 'mask_iban'; Argument 0 is too long.
```

Example:

```sql
mysql> SELECT mask_iban('IE12 BOFI 9000 0112 3456 78');
ERROR 1123 (HY000): Can't initialize function 'mask_iban'; Argument 0 is too short.
```

Example:

```sql
mysql> SELECT mask_iban('IE12 BOFI 9000 0112 3456 78 IE12 BOFI 9000 0112 3456 78');
ERROR 1123 (HY000): Can't initialize function 'mask_iban'; Argument 0 is too long.
```

Example:

```sql
mysql> SELECT mask_iban('IE12 BOFI 9000 0112 3456 78 IE12 BOFI 9000 0112 3456 78');
ERROR 1123 (HY000): Can't initialize function 'mask_iban'; Argument 0 is too long.
```

Example:

```sql
mysql> SELECT mask_iban('IE12 BOFI 9000 0112 3456 78 IE12 BOFI 9000 0112 3456 78');
ERROR 1123 (HY000): Can't initialize function 'mask_iban'; Argument 0 is too long.
```

Example:

```sql
mysql> SELECT mask_iban('IE12 BOFI 9000 0112 3456 78 IE12 BOFI 9000 0112 3456 78');
ERROR 1123 (HY000): Can't initialize function 'mask_iban'; Argument 0 is too long.
```

Example:

```sql
mysql> SELECT mask_iban('IE12 BOFI 9000 0112 3456 78 IE12 BOFI 9000 0112 3456 78');
ERROR 1123 (HY000): Can't initialize function 'mask_iban'; Argument 0 is too long.
```

Example:

```sql
mysql> SELECT mask_iban('IE12 BOFI 9000 0112 3456 78 IE12 BOFI 9000 0112 3456 78');
ERROR 1123 (HY000): Can't initialize function 'mask_iban'; Argument 0 is too long.
```

Example:

```sql
mysql> SELECT mask_iban('IE12 BOFI 9000 0112 3456 78 IE12 BOFI 9000 0112 3456 78');
ERROR 1123 (HY000): Can't initialize function 'mask_iban'; Argument 0 is too long.
```

Example:

```sql
mysql> SELECT mask_iban('IE12 BOFI 9000 0112 3456 78 IE12 BOFI 9000 0112 3456 78');
ERROR 1123 (HY000): Can't initialize function 'mask_iban'; Argument 0 is too long.
```

Example:

```sql
mysql> SELECT mask_iban('IE12 BOFI 9000 0112 3456 78 IE12 BOFI 9000 0112 3456 78');
ERROR 1123 (HY000): Can't initialize function 'mask_iban'; Argument 0 is too long.
```

Example:

```sql
mysql> SELECT mask_iban('IE12 BOFI 9000 0112 3456 78 IE12 BOFI 9000 0112 3456 78');
ERROR 1123 (HY000): Can't initialize function 'mask_iban'; Argument 0 is too long.
```

Example:

```sql
mysql> SELECT mask_iban('IE12 BOFI 9000 0112 3456 78 IE12 BOFI 9000 0112 3456 78');
ERROR 1123 (HY000): Can't initialize function 'mask_iban'; Argument 0 is too long.
```

Example:

```sql
mysql> SELECT mask_iban('IE12 BOFI 9000 0112 3456 78 IE12 BOFI 9000 0112 3456 78');
```
Arguments:

- **str**: The string to mask. This argument is converted to the utf8mb4 character set.
- **margin1**: A nonnegative integer that specifies the number of characters on the left end of the string to remain unmasked. If the value is 0, no left end characters remain unmasked.
- **margin2**: A nonnegative integer that specifies the number of characters on the right end of the string to remain unmasked. If the value is 0, no right end characters remain unmasked.
- **mask_char**: (Optional) The single character to use for masking. The default is 'X' if mask_char is not given.

Return value:

The masked string encoded in the same character set used for str, or an error if either margin is negative.

If the sum of the margin values is larger than the argument length, no masking occurs and the argument is returned unchanged.

**Note**

The function is optimized to work faster for single byte strings (having equal byte length and character length). For example, the utf8mb4 character set uses only one byte for ASCII characters, so the function processes strings containing only ASCII characters as single-byte character strings.

Example:

```sql
mysql> SELECT mask_inner('abcdef', 1, 2), mask_inner('abcdef',0, 5);
+-----------------------------+---------------------------+
| mask_inner('abcdef', 1, 2) | mask_inner('abcdef',0, 5) |
| aXXXef                     | Xbcdef                    |
+-----------------------------+---------------------------+
mysql> SELECT mask_inner('abcdef', 1, 2, '*'), mask_inner('abcdef',0, 5, '#');
+---------------------------------+--------------------------------+
| mask_inner('abcdef', 1, 2, '*') | mask_inner('abcdef',0, 5, '#') |
| a***ef                          | #bcdef                         |
+---------------------------------+--------------------------------+
```
`mask_outer(str, margin1, margin2 [, mask_char])`

Masks the left and right ends of a string, leaving the interior unmasked, and returns the result. An optional masking character can be specified.

`mask_outer` supports all character sets.

Arguments:

- `str`: The string to mask. This argument is converted to the `utf8mb4` character set.
- `margin1`: A nonnegative integer that specifies the number of characters on the left end of the string to mask. If the value is 0, no left end characters are masked.
- `margin2`: A nonnegative integer that specifies the number of characters on the right end of the string to mask. If the value is 0, no right end characters are masked.
- `mask_char`: (Optional) The single character to use for masking. The default is 'X' if `mask_char` is not given.

Return value:

The masked string encoded in the same character set used for `str`, or an error if either margin is negative.

If the sum of the margin values is larger than the argument length, the entire argument is masked.

**Note**

The function is optimized to work faster for single byte strings (having equal byte length and character length). For example, the `utf8mb4` character set uses only one byte for ASCII characters, so the function processes strings containing only ASCII characters as single-byte character strings.

Example:

```sql
mysql> SELECT mask_outer('abcdef', 1, 2), mask_outer('abcdef',0, 5);
+----------------------------+---------------------------+
| mask_outer('abcdef', 1, 2) | mask_outer('abcdef',0, 5) |
+----------------------------+---------------------------+
| XbcdXX                     | aXXXXX                    |
+----------------------------+---------------------------+
mysql> SELECT mask_outer('abcdef', 1, 2, '*'), mask_outer('abcdef',0, 5, '#');
+---------------------------------+--------------------------------+
| mask_outer('abcdef', 1, 2, '*') | mask_outer('abcdef',0, 5, '#') |
+---------------------------------+--------------------------------+
| *bcd**                          | a#####                         |
+---------------------------------+--------------------------------+
```
• **mask_pan** *(str [, mask_char])*

Masks a payment card Primary Account Number (PAN) and returns the number with all but the last four digits replaced by 'X' characters. An optional masking character can be specified.

Arguments:

• **str**: The string to mask. The string must contain a minimum of 14 and a maximum of 19 alphanumeric characters. This argument is converted to the utf8mb4 character set.

• **mask_char**: (Optional) The single character to use for masking. The default is 'X' if mask_char is not given.

Return value:

The masked payment number as a string encoded in the utf8mb4 character set, an error if the argument is not the correct length, or NULL if str is in incorrect format or contains a multibyte character.

Example:

```sql
mysql> SELECT mask_pan(gen_rnd_pan());
+-------------------------+
| mask_pan(gen_rnd_pan()) |
| XXXXXXXXXXXX9102        |
+-------------------------+
mysql>
```

• **mask_pan_relaxed**(str)

Masks a payment card Primary Account Number and returns the number with all but the first six and last four digits replaced by 'X' characters. The first six digits indicate the payment card issuer. An optional masking character can be specified.

Arguments:

• **str**: The string to mask. The string must be a suitable length for the Primary Account Number, but is not otherwise checked. This argument is converted to the utf8mb4 character set.

• **mask_char**: (Optional) The single character to use for masking. The default is 'X' if mask_char is not given.

Return value:

The masked payment number as a string encoded in the utf8mb4 character set, an error if the argument is not the correct length, or NULL if str is in incorrect format or contains a multibyte character.

Example:

```sql
mysql> SELECT mask_pan_relaxed(gen_rnd_pan());
+---------------------------------+
| mask_pan_relaxed(gen_rnd_pan()) |
| XXXXXXXXXXXX8268               |
+---------------------------------+
mysql> SELECT mask_pan_relaxed('a*Z');
ERROR 1123 (HY000): Can't initialize function 'mask_pan'; Argument 0 is too short.
```
MySQL Enterprise Data Masking and De-Identification Components

<table>

</tr>
<tr>
<td>ERROR 1123 (HY000): Can't initialize function 'mask_pan_relaxed'; Argument 0 is too short.</td>
</tr>
</tbody>
</table>

- **mask_ssn**(str [, mask_char])

Masks a US Social Security Number (SSN) and returns the number with all but the last four digits replaced by ‘*’ characters. An optional masking character can be specified.

Arguments:

- **str**: The string to mask. The accepted formats are:
  - Nine non-separated digits.
  - Nine digits grouped in pattern: xxx-xx-xxxx (‘-’ is any separator character).

  This argument is converted to the utf8mb4 character set.

- **mask_char**: (Optional) The single character to use for masking. The default is ‘*’ if **mask_char** is not given.

Return value:

The masked Social Security Number as a string encoded in the utf8mb4 character set, an error if the argument is not the correct length, or **NULL** if **str** is in incorrect format or contains a multibyte character.

Example:

| mysql> SELECT mask_ssn('909-63-6922'), mask_ssn('cdefghijk'); |
| +-------------------------+-------------------------+ |
| | mask_ssn('909-63-6922') | mask_ssn('cdefghijk') | |
| | ***-**-6922 | *******hijk | |
| mysql> SELECT mask_ssn('909'); |
| ERROR 1123 (HY000): Can't initialize function 'mask_ssn'; Argument 0 is too short. |
| mysql> SELECT mask_ssn('123456789123456789'); |
| ERROR 1123 (HY000): Can't initialize function 'mask_ssn'; Argument 0 is too long. |
MySQL Enterprise Data Masking and De-Identification Components

- **mask_uk_nin(str [, mask_char])**

  Masks a United Kingdom National Insurance Number (UK NIN) and returns the number with all but the first two digits replaced by '***' characters. An optional masking character can be specified.

  Arguments:

  - **str**: The string to mask. The accepted formats are:
    - Nine non-separated digits.
    - Nine digits grouped in pattern: xxx-xx-xxxx ('-' is any separator character).
    - Nine digits grouped in pattern: xx-xxxxxx-x ('-' is any separator character).

    This argument is converted to the **utf8mb4** character set.

  - **mask_char**: (Optional) The single character to use for masking. The default is '***' if **mask_char** is not given.

  Return value:

  The masked UK NIN as a string encoded in the **utf8mb4** character set, an error if the argument is not the correct length, or **NULL** if **str** is in incorrect format or contains a multibyte character.

  Example:

  ```sql
  mysql> SELECT mask_uk_nin('QQ 12 34 56 C'), mask_uk_nin('abcdefghi');
  +------------------------------+--------------------------+
  | mask_uk_nin('QQ 12 34 56 C') | mask_uk_nin('abcdefghi') |
  +------------------------------+--------------------------+
  | QQ ** ** ** *                | ab*******                |
  +------------------------------+--------------------------+
  mysql> SELECT mask_uk_nin('909');
  ERROR 1123 (HY000): Can't initialize function 'mask_uk_nin'; Argument 0 is too short.
  mysql> SELECT mask_uk_nin('abcdefghijk');
  ERROR 1123 (HY000): Can't initialize function 'mask_uk_nin'; Argument 0 is too long.
  ```
MySQL Enterprise Data Masking and De-Identification Components

- **mask_uuid(str [, mask_char])**

  Masks a Universally Unique Identifier (UUID) and returns the number with all meaningful characters replaced by '* ' characters. An optional masking character can be specified.

  Arguments:

  - **str**: The string to mask. The accepted format is `xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx` in which 'x' is any digit and '-' is any separator character. This argument is converted to the `utf8mb4` character set.

  - **mask_char**: (Optional) The single character to use for masking. The default is '*' if `mask_char` is not given.

  Return value:

  The masked UUID as a string encoded in the `utf8mb4` character set, an error if the argument is not the correct length, or `NULL` if `str` is in incorrect format or contains a multibyte character.

  **Example**:

  ```
  mysql> SELECT mask_uuid(gen_rnd_uuid());
  +--------------------------------------+
  | mask_uuid(gen_rnd_uid())            |
  +--------------------------------------+
  | ********-****-****-****-************ |
  +--------------------------------------+
  mysql>
  ```

Random Data Generation Component Functions

The component functions in this section generate random values for different types of data. When possible, generated values have characteristics reserved for demonstration or test values, to avoid having them mistaken for legitimate data. For example, `gen_rnd_us_phone()` returns a US phone number that uses the 555 area code, which is not assigned to phone numbers in actual use. Individual function descriptions describe any exceptions to this principle.

- **gen_range(lower, upper)**

  Generates a random number chosen from a specified range.

  Arguments:

  - **lower**: An integer that specifies the lower boundary of the range.

  - **upper**: An integer that specifies the upper boundary of the range, which must not be less than the lower boundary.

  Return value:

  A random integer (encoded in the `utf8mb4` character set) in the range from `lower` to `upper`, inclusive, or `NULL` if the `upper` argument is less than `lower`. 
For better quality of random values, use `RAND()` instead of this function.

Example:

```sql
mysql> SELECT gen_range(100, 200), gen_range(-1000, -800);
+---------------------+------------------------+
<table>
<thead>
<tr>
<th>gen_range(100, 200)</th>
<th>gen_range(-1000, -800)</th>
</tr>
</thead>
<tbody>
<tr>
<td>177</td>
<td>-917</td>
</tr>
</tbody>
</table>
+---------------------+------------------------+

mysql> SELECT gen_range(1, 0);
+-----------------+
| gen_range(1, 0) |
+-----------------+
| NULL            |
```

• `gen_rnd_canada_sin()`

Generates a random Canada Social Insurance Number (SIN) in `AAA-BBB CCC` format. The generated number passes the Luhn check algorithm, which ensures the consistency of this number.

Warning

Values returned from `gen_rnd_canada_sin()` should be used only for test purposes, and are not suitable for publication. There is no way to guarantee that a given return value is not assigned to a legitimate Canada SIN. Should it be necessary to publish a `gen_rnd_canada_sin()` result, consider masking it with `mask_canada_sin()`.

Arguments:

None.

Return value:

A random Canada SIN as a string encoded in the `utf8mb4` character set.

Example:

```sql
mysql> SELECT gen_rnd_canada_sin();
+----------------------+
| gen_rnd_canada_sin()  |
| 046-454-286          |
+----------------------+
```
• `gen_rnd_email(name_size, surname_size, domain)`

Generates a random email address in the form of `random_name.random_surname@domain`.

Arguments:

• `name_size`: (Optional) An integer that specifies the number of characters in the name part of an address. The default is five if `name_size` is not given.

• `surname_size`: (Optional) An integer that specifies the number of characters in the surname part of an address. The default is seven if `surname_size` is not given.

• `domain`: (Optional) A string that specifies the domain part of the address. The default is `example.com` if `domain` is not given.

Return value:

A random email address as a string encoded in the `utf8mb4` character set.

Example:

```sql
mysql> SELECT gen_rnd_email(name_size = 4, surname_size = 5, domain = 'mynet.com');
+----------------------------------------------------------------+
| gen_rnd_email(name_size = 4, surname_size = 5, domain = 'mynet.com') |
| lsoy.qwupp@mynet.com                                               |
+----------------------------------------------------------------+
mysql> SELECT gen_rnd_email();
+---------------------------+
| gen_rnd_email()           |
+---------------------------+
| ijocv.mwvhhuf@example.com |
+---------------------------+
```

• `gen_rnd_iban([country, size])`

Generates a random International Bank Account Number (IBAN) in `AAAA BBBB CCCC DDDD` format. The generated string starts with a two-character country code, two check digits computed according to the IBAN specification and random alphanumeric characters up to the required size.

**Warning**

Values returned from `gen_rnd_iban()` should be used only for test purposes, and are not suitable for publication if used with a valid country code. There is no way to guarantee that a given return value is not assigned to a legitimate bank.
account. Should it be necessary to publish a `gen_rnd_iban()` result, consider masking it with `mask_iban()`.

Arguments:

- `country`: (Optional) Two-character country code; default value is `ZZ`
- `size`: (Optional) Number of meaningful characters; default 16, minimum 15, maximum 34

Return value:

A random IBAN as a string encoded in the `utf8mb4` character set.

Example:

```sql
mysql> SELECT gen_rnd_iban();
+-----------------------------+
| gen_rnd_iban()              |
+-----------------------------+
| ZZ79 3K2J WNH9 1V0DI        |
+-----------------------------+
```

`gen_rnd_pan([size])`

Generates a random payment card Primary Account Number. The number passes the Luhn check (an algorithm that performs a checksum verification against a check digit).

```
Warning
```

Values returned from `gen_rnd_pan()` should be used only for test purposes, and are not suitable for publication. There is no way to guarantee that a given return value is not assigned to a legitimate payment account. Should it be necessary to publish a `gen_rnd_pan()` result, consider masking it with `mask_pan()` or `mask_pan_relaxed()`.

Arguments:

- `size`: (Optional) An integer that specifies the size of the result. The default is 16 if `size` is not given. If given, `size` must be an integer in the range from 12 to 19.

Return value:

A random payment number as a string, or an error if a `size` argument outside the permitted range is given.

Example:

```sql
mysql> SELECT mask_pan(gen_rnd_pan());
+-------------------------+
| mask_pan(gen_rnd_pan()) |
+-------------------------+
| XXXXXXXXXXXX5805        |
+-------------------------+

mysql> SELECT mask_pan(gen_rnd_pan(19));
+---------------------------+
| mask_pan(gen_rnd_pan(19)) |
+---------------------------+
| XXXXXXXXXXXXXXX5067       |
+---------------------------+

mysql> SELECT mask_pan_relaxed(gen_rnd_pan());
```
MySQL Enterprise Data Masking and De-Identification Components

<table>
<thead>
<tr>
<th>mask_pan_relaxed(gen_rnd_pan())</th>
</tr>
</thead>
<tbody>
<tr>
<td>398403XXXXXX9547</td>
</tr>
<tr>
<td>----------------------------------</td>
</tr>
</tbody>
</table>

mysql> SELECT mask_pan_relaxed(gen_rnd_pan(19));
+-----------------------------------+
| mask_pan_relaxed(gen_rnd_pan(19)) |
|-----------------------------------+
<table>
<thead>
<tr>
<th>578416XXXXXXXXX6509</th>
</tr>
</thead>
</table>

mysql> SELECT gen_rnd_pan(20);
ERROR 1123 (HY000): Can't initialize function 'gen_rnd_pan'; Minimal value of argument 0 is 14.

• gen_rnd_ssn()

Generates a random US Social Security Number in AAA–BB–CCCC format. The AAA part is greater than 900, which are characteristics not used for legitimate social security numbers.

Arguments:

None.

Return value:

A random Social Security Number as a string encoded in the utf8mb4 character set.

Example:

```sql
mysql> SELECT gen_rnd_ssn();
+---------------+
| gen_rnd_ssn() |
+---------------+
| 951-26-0058   |
+---------------+
```

• gen_rnd_uk_nin()

Generates a random United Kingdom National Insurance Number (UK NIN) in nine-character format. NIN starts with two character prefix randomly selected from the set of valid prefixes, six random numbers, and one character suffix randomly selected from the set of valid suffixes.

Warning

Values returned from gen_rnd_uk_nin() should be used only for test purposes, and are not suitable for publication. There is no way to guarantee that a given return value is not assigned to a legitimate NIN. Should it be necessary to publish a gen_rnd_uk_nin() result, consider masking it with mask_uk_nin().

Arguments:

None.

Return value:

A random UK NIN as a string encoded in the utf8mb4 character set.

Example:

```sql
mysql> SELECT gen_rnd_uk_nin();
+----------------------+
| gen_rnd_uk_nin()     |
| 1692                 |
+----------------------+
MySQL Enterprise Data Masking and De-Identification Components

```
+----------------------+
| QQ123456C            |
+----------------------+
```

- **gen_rnd_us_phone()**

  Generates a random US phone number in *1-555-AAA-BBBB* format. The 555 area code is not used for legitimate phone numbers.

  **Arguments:**

  None.

  **Return value:**

  A random US phone number as a string encoded in the *utf8mb4* character set.

  **Example:**

  ```sql
  mysql> SELECT gen_rnd_us_phone();
  +--------------------+
  | gen_rnd_us_phone() |
  | 1-555-682-5423     |
  +--------------------+
  ```

- **gen_rnd_uuid()**

  Generates a random Universally Unique Identifier (UUID) segmented with dashes.

  **Arguments:**

  None.

  **Return value:**

  A random UUID as a string encoded in the *utf8mb4* character set.

  **Example:**

  ```sql
  mysql> SELECT gen_rnd_uuid();
  +--------------------------------------+
  | gen_rnd_uuid()                       |
  | 123e4567-e89b-12d3-a456-426614174000 |
  +--------------------------------------+
  ```

**Dictionary Masking Administration Component Functions**

The component functions in this section manipulate dictionaries of terms and perform administrative masking operations based on them. All of these functions require the *MASKING_DICTIONARIES_ADMIN* privilege.

When a dictionary of terms is created, it becomes part of the dictionary registry and is assigned a name to be used by other dictionary functions.

- **masking_dictionary_remove(dictionary_name)**

  Removes a dictionary and all of its terms from the dictionary registry. This function requires the *MASKING_DICTIONARIES_ADMIN* privilege.
Arguments:

- `dictionary_name`: A string that names the dictionary to remove from the dictionary table. This argument is converted to the `utf8mb4` character set.

Return value:

A string that indicates whether the remove operation succeeded. `1` indicates success. `NULL` indicates the dictionary name is not found.

Example:

```sql
mysql> SELECT masking_dictionary_remove('mydict');
+-------------------------------------+
| masking_dictionary_remove('mydict') |
+-------------------------------------+
|                                   1 |
+-------------------------------------+

mysql> SELECT masking_dictionary_remove('no-such-dict');
+-------------------------------------------+
| masking_dictionary_remove('no-such-dict') |
+-------------------------------------------+
|                                      NULL |
+-------------------------------------------+
```

- `masking_dictionary_term_add(dictionary_name, term_name)`

Adds one term to the named dictionary. This function requires the `MASKING_DICTIONARIES_ADMIN` privilege.

⚠️ **Important**

Dictionaries and their terms are persisted to a table in the `mysql` schema. All of the terms in a dictionary are accessible to any user account if that user...
executes `gen_dictionary()` repeatedly. Avoid adding sensitive information to
dictionaries.

Each term is defined by a named dictionary. `masking_dictionary_term_add()` permits you to add
one dictionary term at a time.

Arguments:

- `dictionary_name`: A string that provides a name for the dictionary. This argument is converted to
  the `utf8mb4` character set.

- `term_name`: A string that specifies the term name in the dictionary table. This argument is converted
to the `utf8mb4` character set.

Return value:

A string that indicates whether the add term operation succeeded. 1 indicates success. NULL indicates failure. Term add failure can occur for several reasons, including:

- A term with the given name is already added.
- The dictionary name is not found.

Example:

```
mysql> SELECT masking_dictionary_term_add('mydict','newterm');
+--------------------------------------------------+
| masking_dictionary_term_add('mydict','newterm') |
| 1                                               |
+--------------------------------------------------+

mysql> SELECT masking_dictionary_term_add('mydict','');
+------------------------------------------+
| masking_dictionary_term_add('mydict','')   |
| NULL                                     |
+------------------------------------------+
```
• **masking_dictionary_term_remove(dictionary_name, term_name)**

Removes one term from the named dictionary. This function requires the `MASKING_DICTIONARIES_ADMIN` privilege.

Arguments:

• *dictionary_name*: A string that provides a name for the dictionary. This argument is converted to the `utf8mb4` character set.

• *term_name*: A string that specifies the term name in the dictionary table. This argument is converted to the `utf8mb4` character set.

Return value:

A string that indicates whether the remove term operation succeeded. **`1`** indicates success. **`NULL`** indicates failure. Term remove failure can occur for several reasons, including:

• A term with the given name is not found.

• The dictionary name is not found.

Example:

```sql
mysql> SELECT masking_dictionary_term_add('mydict','newterm');
+-------------------------------------------------+
| masking_dictionary_term_add('mydict','newterm') |
|                                               1 |
+-------------------------------------------------+

mysql> SELECT masking_dictionary_term_remove('mydict','');
+---------------------------------------------+
| masking_dictionary_term_remove('mydict','') |
|                                        NULL |
+---------------------------------------------+
```

**Dictionary Generating Component Functions**

The component functions in this section manipulate dictionaries of terms and perform generating operations based on them.

When a dictionary of terms is created, it becomes part of the dictionary registry and is assigned a name to be used by other dictionary functions.

• **gen_blocklist(str, from_dictionary_name, to_dictionary_name)**

Replaces a term present in one dictionary with a term from a second dictionary and returns the replacement term. This masks the original term by substitution.

Arguments:

• *term*: A string that indicates the term to replace. This argument is converted to the `utf8mb4` character set.

• *from_dictionary_name*: A string that names the dictionary containing the term to replace. This argument is converted to the `utf8mb4` character set.

• *to_dictionary_name*: A string that names the dictionary from which to choose the replacement term. This argument is converted to the `utf8mb4` character set.
MySQL Enterprise Data Masking and De-Identification Plugin

Return value:

A string encoded in the utf8mb4 character set randomly chosen from to_dictionary_name as a replacement for term, or term if it does not appear in from_dictionary_name, or an error if either dictionary name is not in the dictionary registry.

Note

If the term to replace appears in both dictionaries, it is possible for the return value to be the same term.

Example:

```
mysql> SELECT gen_blocklist('Berlin', 'DE_Cities', 'US_Cities');
+---------------------------------------------------+
| gen_blocklist('Berlin', 'DE_Cities', 'US_Cities') |
| Phoenix                                           |
+---------------------------------------------------+
```

• gen_dictionary(dictionary_name)

Returns a random term from a dictionary.

Arguments:

• dictionary_name: A string that names the dictionary from which to choose the term. This argument is converted to the utf8mb4 character set.

Return value:

A random term from the dictionary as a string encoded in the utf8mb4 character set, or NULL if the dictionary name is not in the dictionary registry.

Example:

```
mysql> SELECT gen_dictionary('mydict');
+--------------------------+
| gen_dictionary('mydict') |
| My term                  |
+--------------------------+
```

mysql> SELECT gen_dictionary('no-such-dict');
ERROR 1123 (HY000): Can't initialize function 'gen_dictionary'; Cannot access dictionary, check if dictionary name is valid.

6.5.3 MySQL Enterprise Data Masking and De-Identification Plugin

MySQL Enterprise Data Masking and De-Identification is based on a plugin library that implements these elements:

• A server-side plugin named data_masking.

• A set of loadable functions provides an SQL-level API for performing masking and de-identification operations. Some of these functions require the SUPER privilege.

6.5.3.1 MySQL Enterprise Data Masking and De-Identification Plugin Installation
This section describes how to install or uninstall MySQL Enterprise Data Masking and De-Identification, which is implemented as a plugin library file containing a plugin and several loadable functions. For general information about installing or uninstalling plugins and loadable functions, see Section 5.6.1, "Installing and Uninstalling Plugins", and Section 5.7.1, "Installing and Uninstalling Loadable Functions".

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the plugin_dir system variable). If necessary, configure the plugin directory location by setting the value of plugin_dir at server startup.

The plugin library file base name is data_masking. The file name suffix differs per platform (for example, .so for Unix and Unix-like systems, .dll for Windows).

To install the MySQL Enterprise Data Masking and De-Identification plugin and functions, use the INSTALL PLUGIN and CREATE FUNCTION statements, adjusting the .so suffix for your platform as necessary:

```
INSTALL PLUGIN data_masking SONAME 'data_masking.so';
CREATE FUNCTION gen_blocklist RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_dictionary RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_dictionary_drop RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_dictionary_load RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_range RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_rnd_email RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_rnd_pan RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_rnd_ssn RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_rnd_us_phone RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION mask_inner RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION mask_outer RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION mask_pan RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION mask_pan_relaxed RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION mask_ssn RETURNS STRING
  SONAME 'data_masking.so';
```

If the plugin and functions are used on a replication source server, install them on all replica servers as well to avoid replication issues.

Once installed as just described, the plugin and functions remain installed until uninstalled. To remove them, use the UNINSTALL PLUGIN and DROP FUNCTION statements:

```
UNINSTALL PLUGIN data_masking;
DROP FUNCTION gen_blocklist;
DROP FUNCTION gen_dictionary;
DROP FUNCTION gen_dictionary_drop;
DROP FUNCTION gen_dictionary_load;
DROP FUNCTION gen_range;
DROP FUNCTION gen_rnd_email;
DROP FUNCTION gen_rnd_pan;
DROP FUNCTION gen_rnd_ssn;
DROP FUNCTION gen_rnd_us_phone;
```
6.5.3.2 Using the MySQL Enterprise Data Masking and De-Identification Plugin

Before using MySQL Enterprise Data Masking and De-Identification, install it according to the instructions provided at Section 6.5.3.1, "MySQL Enterprise Data Masking and De-Identification Plugin Installation".

To use MySQL Enterprise Data Masking and De-Identification in applications, invoke the functions that are appropriate for the operations you wish to perform. For detailed function descriptions, see Section 6.5.3.4, "MySQL Enterprise Data Masking and De-Identification Plugin Function Descriptions". This section demonstrates how to use the functions to carry out some representative tasks. It first presents an overview of the available functions, followed by some examples of how the functions might be used in real-world context:

- Masking Data to Remove Identifying Characteristics
- Generating Random Data with Specific Characteristics
- Generating Random Data Using Dictionaries
- Using Masked Data for Customer Identification
- Creating Views that Display Masked Data

Masking Data to Remove Identifying Characteristics

MySQL provides general-purpose masking functions that mask arbitrary strings, and special-purpose masking functions that mask specific types of values.

General-Purpose Masking Functions

`mask_inner()` and `mask_outer()` are general-purpose functions that mask parts of arbitrary strings based on position within the string:

- `mask_inner()` masks the interior of its string argument, leaving the ends unmasked. Other arguments specify the sizes of the unmasked ends.

```sql
mysql> SELECT mask_inner('This is a string', 5, 1);
| mask_inner('This is a string', 5, 1) |
+--------------------------------------+
| This XXXXXXXXg                      |
+--------------------------------------+
mysql> SELECT mask_inner('This is a string', 1, 5);
| mask_inner('This is a string', 1, 5) |
+--------------------------------------+
| TXXXXXXXXXXstring                   |
+--------------------------------------+
```

- `mask_outer()` does the reverse, masking the ends of its string argument, leaving the interior unmasked. Other arguments specify the sizes of the masked ends.

```sql
mysql> SELECT mask_outer('This is a string', 5, 1);
| mask_outer('This is a string', 5, 1) |
+--------------------------------------+
| This XXXXXXXXXXXXg                  |
+--------------------------------------+
```
MySQL Enterprise Data Masking and De-Identification Plugin

`mysql> SELECT mask_outer('This is a string', 1, 5);`  
`+--------------------------------------+`  
`| mask_outer('This is a string', 1, 5) |`  
`+--------------------------------------+`  
`| Xhis is a sXXXXX                     |`  

By default, `mask_inner()` and `mask_outer()` use 'X' as the masking character, but permit an optional masking-character argument:

`mysql> SELECT mask_inner('This is a string', 5, 1, '*');`  
`+-------------------------------------------+`  
`| mask_inner('This is a string', 5, 1, '*') |`  
`+-------------------------------------------+`  
`| This **********g                          |`  

Special-Purpose Masking Functions

Other masking functions expect a string argument representing a specific type of value and mask it to remove identifying characteristics.

**Note**

The examples here supply function arguments using the random value generation functions that return the appropriate type of value. For more information about generation functions, see Generating Random Data with Specific Characteristics.

Payment card Primary Account Number masking.  

Masking functions provide strict and relaxed masking of Primary Account Numbers.

• `mask_pan()` masks all but the last four digits of the number:

`mysql> SELECT mask_pan(gen_rnd_pan());`  
`+-------------------------+`  
`| mask_pan(gen_rnd_pan()) |`  
`+-------------------------+`  
`| XXXXXXXXXXXX2461        |`  

• `mask_pan_relaxed()` is similar but does not mask the first six digits that indicate the payment card issuer unmasked:

`mysql> SELECT mask_pan_relaxed(gen_rnd_pan());`  
`+---------------------------------+`  
`| mask_pan_relaxed(gen_rnd_pan()) |`  
`+---------------------------------+`  
`| 770630XXXXXX0807                |`  

US Social Security number masking.  

`mask_ssn()` masks all but the last four digits of the number:

`mysql> SELECT mask_ssn(gen_rnd_ssn());`
Generating Random Data with Specific Characteristics

Several functions generate random values. These values can be used for testing, simulation, and so forth.

**gen_range()** returns a random integer selected from a given range:

```sql
mysql> SELECT gen_range(1, 10);
+------------------+
| gen_range(1, 10) |
+------------------+
|                6 |
+------------------+
```

**gen_rnd_email()** returns a random email address in the `example.com` domain:

```sql
mysql> SELECT gen_rnd_email();
+---------------------------+
| gen_rnd_email()           |
| ayxnq.xmkpvvy@example.com |
+---------------------------+
```

**gen_rnd_pan()** returns a random payment card Primary Account Number:

```sql
mysql> SELECT gen_rnd_pan();
```

(The `gen_rnd_pan()` function result is not shown because its return values should be used only for testing purposes, and not for publication. It cannot be guaranteed the number is not assigned to a legitimate payment account.)

**gen_rnd_ssn()** returns a random US Social Security number with the first and second parts each chosen from a range not used for legitimate numbers:

```sql
mysql> SELECT gen_rnd_ssn();
+---------------+
| gen_rnd_ssn() |
| 912-45-1615   |
+---------------+
```

**gen_rnd_us_phone()** returns a random US phone number in the 555 area code not used for legitimate numbers:

```sql
mysql> SELECT gen_rnd_us_phone();
+--------------------+
| gen_rnd_us_phone() |
| 1-555-747-5627     |
+--------------------+
```

Generating Random Data Using Dictionaries

MySQL Enterprise Data Masking and De-Identification enables dictionaries to be used as sources of random values. To use a dictionary, it must first be loaded from a file and given a name. Each loaded
A valid dictionary file has these characteristics:

- The file contents are plain text, one term per line.
- Empty lines are ignored.
- The file must contain at least one term.

Suppose that a file named `de_cities.txt` contains these city names in Germany:

```
Berlin
Munich
Bremen
```

Also suppose that a file named `us_cities.txt` contains these city names in the United States:

```
Chicago
Houston
Phoenix
El Paso
Detroit
```

Assume that the `secure_file_priv` system variable is set to `/usr/local/mysql/mysql-files`. In that case, copy the dictionary files to that directory so that the MySQL server can access them. Then use `gen_dictionary_load()` to load the dictionaries into the dictionary registry and assign them names:

```
mysql> SELECT gen_dictionary_load('/usr/local/mysql/mysql-files/de_cities.txt', 'DE_Cities');
+--------------------------------------------------------------------------------+
| gen_dictionary_load('/usr/local/mysql/mysql-files/de_cities.txt', 'DE_Cities') |
+--------------------------------------------------------------------------------+
| Dictionary load success                                                        |
+--------------------------------------------------------------------------------+
mysql> SELECT gen_dictionary_load('/usr/local/mysql/mysql-files/us_cities.txt', 'US_Cities');
+--------------------------------------------------------------------------------+
| gen_dictionary_load('/usr/local/mysql/mysql-files/us_cities.txt', 'US_Cities') |
+--------------------------------------------------------------------------------+
| Dictionary load success                                                        |
+--------------------------------------------------------------------------------+
```

To select a random term from a dictionary, use `gen_dictionary()`:

```
mysql> SELECT gen_dictionary('DE_Cities');
+-----------------------------+
| gen_dictionary('DE_Cities') |
| Berlin                      |
+-----------------------------+
mysql> SELECT gen_dictionary('US_Cities');
+-----------------------------+
| gen_dictionary('US_Cities') |
| Phoenix                     |
+-----------------------------+
```

To select a random term from multiple dictionaries, randomly select one of the dictionaries, then select a term from it:

```
mysql> SELECT gen_dictionary(ELT(gen_range(1,2), 'DE_Cities', 'US_Cities'));
```

```
1702
```
The `gen_dictionary()` function enables a term from one dictionary to be replaced by a term from another dictionary, which effects masking by substitution. Its arguments are the term to replace, the dictionary in which the term appears, and the dictionary from which to choose a replacement. For example, to substitute a US city for a German city, or vice versa, use `gen_dictionary()` like this:

```sql
mysql> SELECT gen_dictionary(ELT(gen_range(1, 2), 'DE_Cities', 'US_Cities'));
+---------------------------------------------------------------+
| Detroit                                                       |
+---------------------------------------------------------------+
```

If the term to replace is not in the first dictionary, `gen_dictionary()` returns it unchanged:

```sql
mysql> SELECT gen_dictionary('Moscow', 'DE_Cities', 'US_Cities');
+---------------------------------------------------+
| gen_dictionary('Moscow', 'DE_Cities', 'US_Cities') |
+---------------------------------------------------+
| Moscow                                           |
+---------------------------------------------------+
```

### Using Masked Data for Customer Identification

At customer-service call centers, one common identity verification technique is to ask customers to provide their last four Social Security number (SSN) digits. For example, a customer might say her name is Joanna Bond and that her last four SSN digits are 0007.

Suppose that a `customer` table containing customer records has these columns:

- **id**: Customer ID number.
- **first_name**: Customer first name.
- **last_name**: Customer last name.
- **ssn**: Customer Social Security number.

For example, the table might be defined as follows:

```sql
CREATE TABLE customer
(
    id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    first_name VARCHAR(40),
    last_name VARCHAR(40),
    ssn VARCHAR(11)
) AUTO_INCREMENT;
```
The application used by customer-service representatives to check the customer SSN might execute a query like this:

```sql
mysql> SELECT id, ssn
      > FROM customer
      > WHERE first_name = 'Joanna' AND last_name = 'Bond';
+-----+-------------+
| id  | ssn         |
+-----+-------------+
| 786 | 906-39-0007 |
+-----+-------------+
```

However, that exposes the SSN to the customer-service representative, who has no need to see anything but the last four digits. Instead, the application can use this query to display only the masked SSN:

```sql
mysql> SELECT id, mask_ssn(CONVERT(ssn USING binary)) AS masked_ssn
      > FROM customer
      > WHERE first_name = 'Joanna' AND last_name = 'Bond';
+-----+-------------+
| id  | masked_ssn  |
+-----+-------------+
| 786 | XXX-XX-0007 |
+-----+-------------+
```

Now the representative sees only what is necessary, and customer privacy is preserved.

Why was the `CONVERT()` function used for the argument to `mask_ssn()`? Because `mask_ssn()` requires an argument of length 11. Thus, even though `ssn` is defined as `VARCHAR(11)`, if the `ssn` column has a multibyte character set, it may appear to be longer than 11 bytes when passed to a loadable function, and an error occurs. Converting the value to a binary string ensures that the function sees an argument of length 11.

A similar technique may be needed for other data masking functions when string arguments do not have a single-byte character set.

### Creating Views that Display Masked Data

If masked data from a table is used for multiple queries, it may be convenient to define a view that produces masked data. That way, applications can select from the view without performing masking in individual queries.

For example, a masking view on the `customer` table from the previous section can be defined like this:

```sql
CREATE VIEW masked_customer AS
SELECT id, first_name, last_name,
     mask_ssn(CONVERT(ssn USING binary)) AS masked_ssn
FROM customer;
```

Then the query to look up a customer becomes simpler but still returns masked data:

```sql
mysql> SELECT id, masked_ssn
      > FROM masked_customer
      > WHERE first_name = 'Joanna' AND last_name = 'Bond';
+-----+-------------+
| id  | masked_ssn  |
+-----+-------------+
| 786 | XXX-XX-0007 |
+-----+-------------+
```

6.5.3.4 MySQL Enterprise Data Masking and De-Identification Plugin Function Descriptions

The MySQL Enterprise Data Masking and De-Identification plugin library includes several functions, which may be grouped into these categories:

- Data Masking Plugin Functions
- Random Data Generation Plugin Functions
- Random Data Dictionary-Based Plugin Functions

These functions support the single-byte `latin1` character set for string arguments and return values. If a string return value should be in a different character set, convert it. The following example shows how to convert the result of `gen_rnd_email()` to the `utf8mb4` character set:

```sql
SET @email = CONVERT(gen_rnd_email() USING utf8mb4);
```

It may also be necessary to convert string arguments, as illustrated in Using Masked Data for Customer Identification.
If a MySQL Enterprise Data Masking and De-Identification function is invoked from within the `mysql` client, binary string results display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

Data Masking Plugin Functions

Each plugin function in this section performs a masking operation on its string argument and returns the masked result.

- **mask_inner**(str, margin1, margin2 [, mask_char])

  Masks the interior part of a string, leaving the ends untouched, and returns the result. An optional masking character can be specified.

  Arguments:
  
  - **str**: The string to mask.
  - **margin1**: A nonnegative integer that specifies the number of characters on the left end of the string to remain unmasked. If the value is 0, no left end characters remain unmasked.
  - **margin2**: A nonnegative integer that specifies the number of characters on the right end of the string to remain unmasked. If the value is 0, no right end characters remain unmasked.
  - **mask_char**: (Optional) The single character to use for masking. The default is 'X' if `mask_char` is not given.

  The masking character must be a single-byte character. Attempts to use a multibyte character produce an error.

  Return value:

  The masked string, or **NULL** if either margin is negative.

  If the sum of the margin values is larger than the argument length, no masking occurs and the argument is returned unchanged.

  Example:

  ```
  mysql> SELECT mask_inner('abcdef', 1, 2), mask_inner('abcdef',0, 5);
  +----------------+---------------------+
  | mask_inner('abcdef', 1, 2) | mask_inner('abcdef',0, 5) |
  +----------------+---------------------+
  | aXXXef         | Xbcdef              |
  +----------------+---------------------+

  mysql> SELECT mask_inner('abcdef', 1, 2, '*'), mask_inner('abcdef',0, 5, '#');
  +---------------------------------+---------------------------------+
  | mask_inner('abcdef', 1, 2, '*') | mask_inner('abcdef',0, 5, '#') |
  +---------------------------------+---------------------------------+
  | a***ef                         | #bcdef                          |
  +---------------------------------+---------------------------------+
  ```

- **mask_outer**(str, margin1, margin2 [, mask_char])

  Masks the left and right ends of a string, leaving the interior unmasked, and returns the result. An optional masking character can be specified.

  Arguments:
• **str**: The string to mask.

• **margin1**: A nonnegative integer that specifies the number of characters on the left end of the string to mask. If the value is 0, no left end characters are masked.

• **margin2**: A nonnegative integer that specifies the number of characters on the right end of the string to mask. If the value is 0, no right end characters are masked.

• **mask_char**: (Optional) The single character to use for masking. The default is 'X' if `mask_char` is not given.

  The masking character must be a single-byte character. Attempts to use a multibyte character produce an error.

Return value:

The masked string, or NULL if either margin is negative.

If the sum of the margin values is larger than the argument length, the entire argument is masked.

Example:

```sql
mysql> SELECT mask_outer('abcdef', 1, 2), mask_outer('abcdef', 0, 5);
+----------------------------+---------------------------+
| mask_outer('abcdef', 1, 2) | mask_outer('abcdef', 0, 5) |
+----------------------------+---------------------------+
| XbcdXX                     | aXXXXX                    |
+----------------------------+---------------------------+
mysql> SELECT mask_outer('abcdef', 1, 2, '*'), mask_outer('abcdef', 0, 5, '#');
+---------------------------------+--------------------------------+
| mask_outer('abcdef', 1, 2, '*') | mask_outer('abcdef', 0, 5, '#') |
+---------------------------------+--------------------------------+
| *bcd**                          | a#####                         |
+---------------------------------+--------------------------------+
```

• **mask_pan(str)**

  Masks a payment card Primary Account Number and returns the number with all but the last four digits replaced by 'X' characters.

Arguments:

• **str**: The string to mask. The string must be a suitable length for the Primary Account Number, but is not otherwise checked.

Return value:

The masked payment number as a string. If the argument is shorter than required, it is returned unchanged.

Example:

```sql
mysql> SELECT mask_pan(gen_rnd_pan());
+-------------------------+
| mask_pan(gen_rnd_pan()) |
+-------------------------+
| XXXXXXXXXXXX9102        |
+-------------------------+
mysql> SELECT mask_pan(gen_rnd_pan(19));
+---------------------------+
| 1707                      |
+---------------------------+
```
MySQL Enterprise Data Masking and De-Identification Plugin

| mask_pan(gen_rnd_pan(19)) | +---------------------------+ | XXXXXXXXXXXXXXXXX8268 | +---------------------------+ mysql> SELECT mask_pan('a*Z'); +-----------------+ | mask_pan('a*Z') | | a*Z | +-----------------+ 

• **mask_pan_relaxed(str)**

Masks a payment card Primary Account Number and returns the number with all but the first six and last four digits replaced by ‘X’ characters. The first six digits indicate the payment card issuer.

**Arguments:**

• **str**: The string to mask. The string must be a suitable length for the Primary Account Number, but is not otherwise checked.

**Return value:**

The masked payment number as a string. If the argument is shorter than required, it is returned unchanged.

**Example:**

```sql
mysql> SELECT mask_pan_relaxed(gen_rnd_pan()); +---------------------------------+ | mask_pan_relaxed(gen_rnd_pan()) | | 551279XXXXXX3108 | +---------------------------------+ 
```

```sql
mysql> SELECT mask_pan_relaxed(gen_rnd_pan(19)); +-----------------------------------+ | mask_pan_relaxed(gen_rnd_pan(19)) | | 462634XXXXXXXXXX6739 | +-----------------------------------+ 
```

```sql
mysql> SELECT mask_pan_relaxed('a*Z'); +-------------------------+ | mask_pan_relaxed('a*Z') | | a*Z | +-------------------------+ 
```
MySQL Enterprise Data Masking and De-Identification Plugin

• `mask_ssn(str)`

Masks a US Social Security number and returns the number with all but the last four digits replaced by 'X' characters.

Arguments:
• `str`: The string to mask. The string must be 11 characters long.

Return value:
The masked Social Security number as a string, or an error if the argument is not the correct length.

Example:
```
mysql> SELECT mask_ssn('909-63-6922'), mask_ssn('abcdefghijk');
+-------------------------+-------------------------+
| mask_ssn('909-63-6922') | mask_ssn('abcdefghijk') |
| XXX-XX-6922             | XXX-XX-hijk             |
+-------------------------+-------------------------+
mysql> SELECT mask_ssn('909');
ERROR 1123 (HY000): Can't initialize function 'mask_ssn'; MASK_SSN: Error: String argument width too small
mysql> SELECT mask_ssn('123456789123456789');
ERROR 1123 (HY000): Can't initialize function 'mask_ssn'; MASK_SSN: Error: String argument width too large
```

Random Data Generation Plugin Functions

The plugin functions in this section generate random values for different types of data. When possible, generated values have characteristics reserved for demonstration or test values, to avoid having them mistaken for legitimate data. For example, `gen_rnd_us_phone()` returns a US phone number that uses the 555 area code, which is not assigned to phone numbers in actual use. Individual function descriptions describe any exceptions to this principle.

• `gen_range(lower, upper)`

Generates a random number chosen from a specified range.

Arguments:
• `lower`: An integer that specifies the lower boundary of the range.
• `upper`: An integer that specifies the upper boundary of the range, which must not be less than the lower boundary.

Return value:
A random integer in the range from `lower` to `upper`, inclusive, or `NULL` if the `upper` argument is less than `lower`.

Example:
```
mysql> SELECT gen_range(100, 200), gen_range(-1000, -800);
+---------------------+------------------------+
| gen_range(100, 200) | gen_range(-1000, -800) |
|                     |                        |
| 177                 | -917                   |
+---------------------+------------------------+
mysql> SELECT gen_range(1, 0);
```
MySQL Enterprise Data Masking and De-Identification Plugin

• **gen_rnd_email()**

  Generates a random email address in the `example.com` domain.

  Arguments:
  None.

  Return value:
  A random email address as a string.

  Example:

  ```
  mysql> SELECT gen_rnd_email();
  +---------------------------+
  | gen_rnd_email()           |
  | ijocv.mwvhuf@example.com  |
  +---------------------------+
  ```

• **gen_rnd_pan([size])**

  Generates a random payment card Primary Account Number. The number passes the Luhn check (an algorithm that performs a checksum verification against a check digit).

  **Warning**

  Values returned from `gen_rnd_pan()` should be used only for test purposes, and are not suitable for publication. There is no way to guarantee that a given return value is not assigned to a legitimate payment account. Should it be necessary to publish a `gen_rnd_pan()` result, consider masking it with `mask_pan()` or `mask_pan_relaxed()`.

  Arguments:
  • `size`: (Optional) An integer that specifies the size of the result. The default is 16 if `size` is not given. If given, `size` must be an integer in the range from 12 to 19.

  Return value:
  A random payment number as a string, or `NULL` if a `size` argument outside the permitted range is given.

  Example:

  ```
  mysql> SELECT mask_pan(gen_rnd_pan());
  +-------------------------+
  | mask_pan(gen_rnd_pan()) |
  | XXXXXXXXXXXX5805        |
  +-------------------------+
  ```

  ```
  mysql> SELECT mask_pan(gen_rnd_pan(19));
  +---------------------------+
  | mask_pan(gen_rnd_pan(19)) |
  +---------------------------+
  ```
MySQL Enterprise Data Masking and De-Identification Plugin

```sql
mysql> SELECT mask_pan_relaxed(gen_rnd_pan());
+--------------------------------------------------+
| mask_pan_relaxed(gen_rnd_pan())                  |
+--------------------------------------------------+
| 398403XXXXXXXXX9547                              |
+--------------------------------------------------+
mysql>
```

```sql
mysql> SELECT mask_pan_relaxed(gen_rnd_pan(19));
+----------------------------------------------------------+
| mask_pan_relaxed(gen_rnd_pan(19))                        |
+----------------------------------------------------------+
| 578416XXXXXXXXX6509                                      |
+----------------------------------------------------------+
mysql>
```

```sql
mysql> SELECT gen_rnd_pan(11), gen_rnd_pan(20);
+-----------------+-----------------+
| gen_rnd_pan(11) | gen_rnd_pan(20) |
+-----------------+-----------------+
| NULL            | NULL            |
+-----------------+-----------------+
```

- **gen_rnd_ssn()**
  
  Generates a random US Social Security number in **AAA-BB-CCCC** format. The **AAA** part is greater than 900 and the **BB** part is less than 70, which are characteristics not used for legitimate Social Security numbers.

  Arguments:
  None.

  Return value:
  A random Social Security number as a string.

  Example:

  ```sql
  mysql> SELECT gen_rnd_ssn();
  +---------------+
  | gen_rnd_ssn() |
  +---------------+
  | 951-26-0058   |
  +---------------+
  ```

- **gen_rnd_us_phone()**
  
  Generates a random US phone number in **1-555-AAA-BBBB** format. The 555 area code is not used for legitimate phone numbers.

  Arguments:
  None.

  Return value:
  A random US phone number as a string.

  Example:

  ```sql
  mysql> SELECT gen_rnd_us_phone();
  +-----------------------------+
  | gen_rnd_us_phone()          |
  +-----------------------------+
  ```
Random Data Dictionary-Based Plugin Functions

The plugin functions in this section manipulate dictionaries of terms and perform generation and masking operations based on them. Some of these functions require the \texttt{SUPER} privilege.

When a dictionary is loaded, it becomes part of the dictionary registry and is assigned a name to be used by other dictionary functions. Dictionaries are loaded from plain text files containing one term per line. Empty lines are ignored. To be valid, a dictionary file must contain at least one nonempty line.

- \texttt{gen\_blacklist(str, dictionary\_name, replacement\_dictionary\_name)}

  Replaces a term present in one dictionary with a term from a second dictionary and returns the replacement term. This masks the original term by substitution. This function is deprecated in MySQL 8.0.23; use \texttt{gen\_blocklist()} instead.

- \texttt{gen\_blocklist(str, dictionary\_name, replacement\_dictionary\_name)}

  Replaces a term present in one dictionary with a term from a second dictionary and returns the replacement term. This masks the original term by substitution. This function was added in MySQL 8.0.23; use it instead of \texttt{gen\_blacklist()}.

Arguments:

- \texttt{str}: A string that indicates the term to replace.
- \texttt{dictionary\_name}: A string that names the dictionary containing the term to replace.
- \texttt{replacement\_dictionary\_name}: A string that names the dictionary from which to choose the replacement term.

Return value:

A string randomly chosen from \texttt{replacement\_dictionary\_name} as a replacement for \texttt{str}, or \texttt{str} if it does not appear in \texttt{dictionary\_name}, or NULL if either dictionary name is not in the dictionary registry.

If the term to replace appears in both dictionaries, it is possible for the return value to be the same term.

Example:

```
mysql> SELECT gen\_blocklist('Berlin', 'DE\_Cities', 'US\_Cities');
+---------------------------------------------------+
| gen\_blocklist('Berlin', 'DE\_Cities', 'US\_Cities') |
| Phoenix                                           |
+---------------------------------------------------+
```

- \texttt{gen\_dictionary(dictionary\_name)}

  Returns a random term from a dictionary.

Arguments:

- \texttt{dictionary\_name}: A string that names the dictionary from which to choose the term.

Return value:
A random term from the dictionary as a string, or `NULL` if the dictionary name is not in the dictionary registry.

Example:

```sql
mysql> SELECT gen_dictionary('mydict');
+--------------------------+
| gen_dictionary('mydict') |
| My term                 |
+--------------------------+
mysql> SELECT gen_dictionary('no-such-dict');
+--------------------------------+
| gen_dictionary('no-such-dict') |
| NULL                           |
+--------------------------------+
```

• `gen_dictionary_drop(dictionary_name)`

Removes a dictionary from the dictionary registry.

This function requires the `SUPER` privilege.

Arguments:

• `dictionary_name`: A string that names the dictionary to remove from the dictionary registry.

Return value:

Example:

```sql
mysql> SELECT gen_dictionary_drop('mydict');
+-------------------------------+
| gen_dictionary_drop('mydict') |
| Dictionary removed            |
+-------------------------------+
mysql> SELECT gen_dictionary_drop('no-such-dict');
+-------------------------------------+
| gen_dictionary_drop('no-such-dict') |
| Dictionary removal error          |
+-------------------------------------+
```
- `gen_dictionary_load(dictionary_path, dictionary_name)`

  Loads a file into the dictionary registry and assigns the dictionary a name to be used with other functions that require a dictionary name argument.

  This function requires the `SUPER` privilege.

  **Important**

  Dictionaries are not persistent. Any dictionary used by applications must be loaded for each server startup.

  Once loaded into the registry, a dictionary is used as is, even if the underlying dictionary file changes. To reload a dictionary, first drop it with `gen_dictionary_drop()`, then load it again with `gen_dictionary_load()`.

  Arguments:
  - `dictionary_path`: A string that specifies the path name of the dictionary file.
  - `dictionary_name`: A string that provides a name for the dictionary.

  Return value:

  A string that indicates whether the load operation succeeded. `Dictionary load success` indicates success. `Dictionary load error` indicates failure. Dictionary load failure can occur for several reasons, including:

  - A dictionary with the given name is already loaded.
  - The dictionary file is not found.
  - The dictionary file contains no terms.
  - The `secure_file_priv` system variable is set and the dictionary file is not located in the directory named by the variable.

  Example:

  ```sql
  mysql> SELECT gen_dictionary_load('/usr/local/mysql/mysql-files/mydict','mydict');
  +---------------------------------------------------------------------+
  | gen_dictionary_load('/usr/local/mysql/mysql-files/mydict','mydict') |
  +---------------------------------------------------------------------+
  | Dictionary load success                                             |
  +---------------------------------------------------------------------+
  mysql>
  mysql> SELECT gen_dictionary_load('/dev/null','null');
  +--------------------------------------------------+
  | gen_dictionary_load('/dev/null','null')          |
  +--------------------------------------------------+
  | Dictionary load error                             |
  +--------------------------------------------------+
  ```

### 6.6 MySQL Enterprise Encryption

**Note**

MySQL Enterprise Encryption is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, [https://www.mysql.com/products/](https://www.mysql.com/products/).
MySQL Enterprise Edition includes a set of encryption functions that expose OpenSSL capabilities at the SQL level. The functions enable Enterprise applications to perform the following operations:

- Implement added data protection using public-key asymmetric cryptography
- Create public and private keys and digital signatures
- Perform asymmetric encryption and decryption
- Use cryptographic hashing for digital signing and data verification and validation

In releases before MySQL 8.0.30, these functions are based on the `openssl_udf` shared library. From MySQL 8.0.30, they are provided by a MySQL component `component_enterprise_encryption`.

### 6.6.1 MySQL Enterprise Encryption Installation and Upgrading

In releases before MySQL 8.0.30, the functions provided by MySQL Enterprise Encryption are installed by creating them individually, based on the `openssl_udf` shared library. From MySQL 8.0.30, the functions are provided by a MySQL component `component_enterprise_encryption`, and installing the component installs all of the functions. The functions from the `openssl_udf` shared library are deprecated from that release, and you should upgrade to the component instead.

- **Installation From MySQL 8.0.30**
- **Installation To MySQL 8.0.29**
- **Upgrading MySQL Enterprise Encryption**

#### Installation From MySQL 8.0.30

From MySQL 8.0.30, MySQL Enterprise Encryption’s functions are provided by a MySQL component `component_enterprise_encryption`, rather than being installed from the `openssl_udf` shared library. If you are upgrading to MySQL 8.0.30 from an earlier release where you used MySQL Enterprise Encryption, the functions you created remain available and are supported. However, these legacy functions are deprecated from this release, and it is recommended that you install the component instead. The component functions are backward compatible. For upgrade information, see [Upgrading MySQL Enterprise Encryption](#).

If you are upgrading, before installing the component, unload the legacy functions using the `DROP FUNCTION` statement:

```
DROP FUNCTION asymmetric_decrypt;
DROP FUNCTION asymmetricderive;
DROP FUNCTION asymmetric_encrypt;
DROP FUNCTION asymmetric_sign;
DROP FUNCTION asymmetric_verify;
DROP FUNCTION create_asymmetric_priv_key;
DROP FUNCTION create_asymmetric_pub_key;
DROP FUNCTION create_dh_parameters;
DROP FUNCTION create_digest;
```

The function names must be specified in lowercase. The statements require the `DROP` privilege for the `mysql` database.

To install the component, issue an `INSTALL COMPONENT` statement:

```
INSTALL COMPONENT "file://component_enterprise_encryption";
```

`INSTALL COMPONENT` requires the `INSERT` privilege for the `mysql.component` system table because it adds a row to that table to register the component. To verify that the component has been installed, issue:
Components listed in `mysql.component` are loaded by the loader service during the startup sequence.

If you need to uninstall the component, issue an `UNINSTALL COMPONENT` statement:

```
UNINSTALL COMPONENT "file://component_enterprise_encryption";
```

For more details, see Section 5.5.1, “Installing and Uninstalling Components”.

Installing the component installs all of the functions, so you do not need to create them using `CREATE FUNCTION` statements as you do before MySQL 8.0.30. Uninstalling the component uninstalls all of the functions.

When you have installed the component, if you want the component functions to support decryption and verification for content produced by the legacy functions before MySQL 8.0.30, set the component’s system variable `enterprise_encryption.rsa_support_legacy_padding` to ON. Also, if you want to change the maximum length allowed for the RSA keys generated by the component functions, use the component’s system variable `enterprise_encryption.maximum_rsa_key_size` to set an appropriate maximum. For configuration information, see Section 6.6.2, “Configuring MySQL Enterprise Encryption”.

**Installation To MySQL 8.0.29**

Before MySQL 8.0.29, MySQL Enterprise Encryption functions are located in a loadable function library file installed in the plugin directory (the directory named by the `plugin_dir` system variable). The function library base name is `openssl_udf` and the suffix is platform dependent. For example, the file name on Linux or Windows is `openssl_udf.so` or `openssl_udf.dll`, respectively.

To install functions from the `openssl_udf` shared library file, use the `CREATE FUNCTION` statement. To load all functions from the library, use this set of statements, adjusting the file name suffix as necessary:

```
CREATE FUNCTION asymmetric_decrypt RETURNS STRING SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_derive RETURNS STRING SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_encrypt RETURNS STRING SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_sign RETURNS STRING SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_verify RETURNS INTEGER SONAME 'openssl_udf.so';
CREATE FUNCTION create_asymmetric_priv_key RETURNS STRING SONAME 'openssl_udf.so';
CREATE FUNCTION create_asymmetric_pub_key RETURNS STRING SONAME 'openssl_udf.so';
CREATE FUNCTION create_dh_parameters RETURNS STRING SONAME 'openssl_udf.so';
CREATE FUNCTION create_digest RETURNS STRING SONAME 'openssl_udf.so';
```

Once installed, the functions remain installed across server restarts. If you need to unload the functions, use the `DROP FUNCTION` statement:

```
DROP FUNCTION asymmetric_decrypt;
DROP FUNCTION asymmetric_derive;
DROP FUNCTION asymmetric_encrypt;
DROP FUNCTION asymmetric_sign;
DROP FUNCTION asymmetric_verify;
DROP FUNCTION create_asymmetric_priv_key;
DROP FUNCTION create_asymmetric_pub_key;
DROP FUNCTION create_dh_parameters;
DROP FUNCTION create_digest;
```
In the `CREATE FUNCTION` and `DROP FUNCTION` statements, the function names must be specified in lowercase. This differs from their use at function invocation time, for which you can use any lettercase.

The `CREATE FUNCTION` and `DROP FUNCTION` statements require the `INSERT` and `DROP` privilege, respectively, for the `mysql` database.

The functions provided by the `openssl_udf` shared library allow a minimum key size of 1024 bits. You can set a maximum key size using the `MYSQL_OPENSSL_UDF_RSA_BITS_THRESHOLD`, `MYSQL_OPENSSL_UDF_DSA_BITS_THRESHOLD`, and `MYSQL_OPENSSL_UDF_DH_BITS_THRESHOLD` environment variables, as described in Section 6.6.2, “Configuring MySQL Enterprise Encryption”. If you do not set a maximum key size, the upper limit is 16384 for the RSA algorithm and 10000 for the DSA algorithm, as specified by OpenSSL.

### Upgrading MySQL Enterprise Encryption

If you upgrade to MySQL 8.0.30 or later from an earlier release where you used the functions provided by the `openssl_udf` shared library, the functions you created remain available and are supported. However, these legacy functions are deprecated from MySQL 8.0.30, and it is recommended that you install the MySQL Enterprise Encryption component instead.

When you are upgrading, before installing the component, you must unload the legacy functions using the `DROP FUNCTION` statement. For instructions to do this, see Installation From MySQL 8.0.30.

The component functions are backward compatible:

- RSA public and private keys generated by the legacy functions can be used with the component functions.
- Data encrypted with the legacy functions can be decrypted by the component functions.
- Signatures created by the legacy functions can be verified with the component functions.

For the component functions to support decryption and verification for content produced by the legacy functions, you must set the system variable `enterprise_encryption.rsa_support_legacy_padding` to `ON` (the default is `OFF`). For configuration information, see Section 6.6.2, “Configuring MySQL Enterprise Encryption”.

The legacy functions cannot handle encrypted data, public keys, and signatures created by the component functions, due to the differences in the padding and key format used by the component functions to meet the current standards.

The new functions provided by the `component_enterprise_encryption` component have some differences in behavior and support from the legacy functions provided by the `openssl_udf` shared library. The most important of these are as follows:

- The legacy functions support the older DSA algorithm and Diffie-Hellman key exchange method. The component functions use only the generally preferred RSA algorithm.
- For the legacy functions, the minimum RSA key size is less than current best practice. The component functions follow current best practice on minimum RSA key size.
- The legacy functions support only SHA2 for digests, and require digests for signatures. The component functions also support SHA3 for digests (provided that OpenSSL 1.1.1 is in use), and do not require digests for signatures, although they support them.
- The `asymmetric_encrypt()` legacy function supports encryption using private keys. The `asymmetric_encrypt()` component function only accepts a public key. It is recommended that you only encrypt using public keys with the legacy function as well.
Configuring MySQL Enterprise Encryption

- The `create_dh_parameters()` and `asymmetric_derive()` legacy functions for the Diffie-Hellman key exchange method are not provided by the `component enterprise encryption` component.

Table 1 summarizes the technical differences in support and operation between the legacy functions provided by the `openssl udf` shared library, and the functions provided by the `component enterprise encryption` component from MySQL 8.0.30.

### Table 6.51 MySQL Enterprise Encryption functions

<table>
<thead>
<tr>

</table>

### 6.6.2 Configuring MySQL Enterprise Encryption

MySQL Enterprise Encryption lets you limit keys to a length that provides adequate security for your requirements while balancing this with resource usage. You can also configure the functions provided by the `component enterprise encryption` component from MySQL 8.0.30, to support decryption and verification for content produced by the legacy `openssl udf` shared library functions.

**Decryption Support By Component Functions For Legacy Functions**

By default, the functions provided by the `component enterprise encryption` component from MySQL 8.0.30 do not decrypt encrypted text, or verify signatures, that were produced by the legacy functions provided in earlier releases by the `openssl udf` shared library. The component functions assume that encrypted text uses the RSAES-OAEP padding scheme, and signatures use the RSASSA-PSS signature scheme. However, encrypted text produced by the legacy functions uses the RSAES-PKCS1-v1_5 padding scheme, and signatures produced by the legacy functions use the RSASSA-PKCS1-v1_5 signature scheme.

If you want the component functions to support content produced by the legacy functions before MySQL 8.0.30, set the component’s system variable `enterprise encryption rsa support legacy padding` to ON. The system variable is available when the component is installed. When you set it to ON, the component functions first attempt to decrypt or verify content assuming it has their normal schemes. If that does not work, they also attempt to decrypt or verify the content assuming it has the schemes used by the legacy functions. This behavior is not the default because it increases the time taken to process content that cannot be decrypted or verified at all. If you are not handling content produced by the legacy functions, leave the system variable to default to OFF.
Key Length Limits

The amount of CPU resources required by MySQL Enterprise Encryption's key generation functions increases as the key length increases. For some installations, this might result in unacceptable CPU usage if applications frequently generate excessively long keys.

OpenSSL specifies a minimum key length of 1024 bits for all keys. OpenSSL also specifies a maximum key length of 16384 bits for RSA keys, 10000 bits for DSA keys, and 10000 bits for DH keys.

From MySQL 8.0.30, the functions provided by the `component_enterprise_encryption` component have a higher minimum key length of 2048 bits for RSA keys, which is in line with current best practice for minimum key lengths. The component's system variable `enterprise_encryption.maximum_rsa_key_size` specifies the maximum key size, and it defaults to 4096 bits. You can change this to allow keys up to the maximum length allowed by OpenSSL, 16384 bits.

For releases before MySQL 8.0.30, the legacy functions provided by the `openssl_udf` shared library default to OpenSSL's minimum and maximum limits. If the maximum values are too high, you can specify a lower maximum key length using the following system variables:

- `MYSQL_OPENSSL_UDF_DSA_BITS_THRESHOLD`: Maximum DSA key length in bits for `create_asymmetric_priv_key()`. The minimum and maximum values for this variable are 1024 and 10000.
- `MYSQL_OPENSSL_UDF_RSA_BITS_THRESHOLD`: Maximum RSA key length in bits for `create_asymmetric_priv_key()`. The minimum and maximum values for this variable are 1024 and 16384.
- `MYSQL_OPENSSL_UDF_DH_BITS_THRESHOLD`: Maximum key length in bits for `create_dh_parameters()`. The minimum and maximum values for this variable are 1024 and 10000.

To use any of these environment variables, set them in the environment of the process that starts the server. If set, their values take precedence over the maximum key lengths imposed by OpenSSL. For example, to set a maximum key length of 4096 bits for DSA and RSA keys for `create_asymmetric_priv_key()`, set these variables:

```
export MYSQL_OPENSSL_UDF_DSA_BITS_THRESHOLD=4096
export MYSQL_OPENSSL_UDF_RSA_BITS_THRESHOLD=4096
```

The example uses Bourne shell syntax. The syntax for other shells may differ.

6.6.3 MySQL Enterprise Encryption Usage and Examples

To use MySQL Enterprise Encryption in applications, invoke the functions that are appropriate for the operations you wish to perform. This section demonstrates how to carry out some representative tasks.

In releases before MySQL 8.0.30, MySQL Enterprise Encryption's functions are based on the `openssl_udf` shared library. From MySQL 8.0.30, the functions are provided by a MySQL component `component_enterprise_encryption`. In some cases, the behavior of the component functions differs from the behavior of the legacy functions provided by the `openssl_udf`. For a list of the differences, see Upgrading MySQL Enterprise Encryption. For full details of the behavior of each component's functions, see Section 6.6.4, “MySQL Enterprise Encryption Function Reference”.

If you install the legacy functions then upgrade to MySQL 8.0.30 or later, the functions you created remain available, are supported, and continue to work in the same way. However, they are deprecated from MySQL 8.0.30, and it is recommended that you install the MySQL Enterprise Encryption component `component_enterprise_encryption` instead. For instructions to upgrade, see Installation From MySQL 8.0.30.
The following general considerations apply when choosing key lengths and encryption algorithms:

- The strength of encryption for private and public keys increases with the key size, but the time for key generation increases as well.

- For the legacy functions, generation of DH keys takes much longer than RSA or DSA keys. The component functions from MySQL 8.0.30 only support RSA keys.

- Asymmetric encryption functions consume more resources compared to symmetric functions. They are good for encrypting small amounts of data and creating and verifying signatures. For encrypting large amounts of data, symmetric encryption functions are faster. MySQL Server provides the `AES_ENCRYPT()` and `AES_DECRYPT()` functions for symmetric encryption.

Key string values can be created at runtime and stored into a variable or table using `SET`, `SELECT`, or `INSERT`. This example works with both the component function and the legacy function:

```sql
SET @priv1 = create_asymmetric_priv_key('RSA', 2048);
SELECT create_asymmetric_priv_key('RSA', 2048) INTO @priv2;
INSERT INTO t (key_col) VALUES(create_asymmetric_priv_key('RSA', 1024));
```

Key string values stored in files can be read using the `LOAD_FILE()` function by users who have the `FILE` privilege. Digest and signature strings can be handled similarly.

- Create a private/public key pair
- Use the public key to encrypt data and the private key to decrypt it
- Generate a digest from a string
- Use the digest with a key pair

### Create a private/public key pair

This example works with both the component functions and the legacy functions:

```sql
-- Encryption algorithm
SET @algo = 'RSA';
-- Key length in bits; make larger for stronger keys
SET @key_len = 2048;

-- Create private key
SET @priv = create_asymmetric_priv_key(@algo, @key_len);
-- Derive corresponding public key from private key, using same algorithm
SET @pub = create_asymmetric_pub_key(@algo, @priv);
```

You can use the key pair to encrypt and decrypt data or to sign and verify data.

### Use the public key to encrypt data and the private key to decrypt it

This example works with both the component functions and the legacy functions. In both cases, the members of the key pair must be RSA keys:

```sql
SET @ciphertext = asymmetric_encrypt(@algo, 'My secret text', @pub);
SET @plaintext = asymmetric_decrypt(@algo, @ciphertext, @priv);
```

### Generate a digest from a string

This example works with both the component functions and the legacy functions:

```sql
-- Digest type
SET @dig_type = 'SHA512';
```
Use the digest with a key pair

The key pair can be used to sign data, then verify that the signature matches the digest. This example works with both the component functions and the legacy functions:

```sql
-- Encryption algorithm; keys must have been created using same algorithm
SET @algo = 'RSA';
-- Digest algorithm to sign the data
SET @dig_type = 'SHA512';

-- Generate signature for digest and verify signature against digest
SET @sig = asymmetric_sign(@algo, @dig, @priv, @dig_type);
-- Verify signature against digest
SET @verf = asymmetric_verify(@algo, @dig, @sig, @pub, @dig_type);
```

For the legacy functions, signatures require a digest. For the component functions, signatures do not require a digest, and can use any data string. The digest type in these functions refers to the algorithm that is used to sign the data, not the algorithm that was used to create the original input for the signature. This example is for the component functions:

```sql
-- Encryption algorithm; keys must have been created using same algorithm
SET @algo = 'RSA';
-- Arbitrary text string for signature
SET @text = repeat('j', 256);
-- Digest algorithm to sign the data
SET @dig_type = 'SHA512';

-- Generate signature for digest and verify signature against digest
SET @sig = asymmetric_sign(@algo, @text, @priv, @dig_type);
-- Verify signature against digest
SET @verf = asymmetric_verify(@algo, @text, @sig, @pub, @dig_type);
```

### 6.6.4 MySQL Enterprise Encryption Function Reference

In releases from MySQL 8.0.30, MySQL Enterprise Encryption's functions are provided by the MySQL component `component_enterprise_encryption`. For their descriptions, see Section 6.6.5, "MySQL Enterprise Encryption Component Function Descriptions".

In releases before MySQL 8.0.30, MySQL Enterprise Encryption's functions are based on the `openssl_udf` shared library. The functions continue to be available in later releases if they have been installed, but they are deprecated. For their descriptions, see Section 6.6.6, "MySQL Enterprise Encryption Legacy Function Descriptions".

For information on upgrading to the new component functions provided by the MySQL component `component_enterprise_encryption`, and a list of the behavior differences between the legacy functions and the component functions, see Upgrading MySQL Enterprise Encryption.

### 6.6.5 MySQL Enterprise Encryption Component Function Descriptions

In releases from MySQL 8.0.30, MySQL Enterprise Encryption's functions are provided by the MySQL component `component_enterprise_encryption`. This reference describes those functions.

For information on upgrading to the new component functions provided by the MySQL component `component_enterprise_encryption`, and a list of the behavior differences between the legacy functions and the component functions, see Upgrading MySQL Enterprise Encryption.
MySQL Enterprise Encryption Component Function Descriptions

The reference for the legacy functions in releases before MySQL 8.0.30 based on the openssl_udf shared library is Section 6.6.6, “MySQL Enterprise Encryption Legacy Function Descriptions”.

MySQL Enterprise Encryption functions have these general characteristics:

• For arguments of the wrong type or an incorrect number of arguments, each function returns an error.

• If the arguments are not suitable to permit a function to perform the requested operation, it returns NULL or 0 as appropriate. This occurs, for example, if a function does not support a specified algorithm, a key length is too short or long, or a string expected to be a key string in PEM format is not a valid key.

• The underlying SSL library takes care of randomness initialization.

The component functions only support the RSA encryption algorithm.

For additional examples and discussion, see Section 6.6.3, “MySQL Enterprise Encryption Usage and Examples”.

• **asymmetric_decrypt(algorithm, data_str, priv_key_str)**

Decrypts an encrypted string using the given algorithm and key string, and returns the resulting plaintext as a binary string. If decryption fails, the result is NULL.

For the legacy version of this function in use before MySQL 8.0.29, see Section 6.6.6, “MySQL Enterprise Encryption Legacy Function Descriptions”.

By default, the component_enterprise_encryption function assumes that encrypted text uses the RSAES-OAEP padding scheme. The function supports decryption for content encrypted by the legacy openssl_udf shared library functions if the system variable enterprise_encryption.rsa_support_legacy_padding is set to ON (the default is OFF). When ON is set, the function also supports the RSAES-PKCS1-v1_5 padding scheme, as used by the legacy openssl_udf shared library functions. When OFF is set, content encrypted by the legacy functions cannot be decrypted, and the function returns null output for such content.

**algorithm** is the encryption algorithm used to create the key. The supported algorithm value is 'RSA'.

**data_str** is the encrypted string to decrypt, which was encrypted with asymmetric_encrypt().

**priv_key_str** is a valid PEM encoded RSA private key. For successful decryption, the key string must correspond to the public key string used with asymmetric_encrypt() to produce the encrypted string. The asymmetric_encrypt() component function only supports encryption using a public key, so decryption takes place with the corresponding private key.

For a usage example, see the description of asymmetric_encrypt().

• **asymmetric_encrypt(algorithm, data_str, pub_key_str)**

Encrypts a string using the given algorithm and key string, and returns the resulting ciphertext as a binary string. If encryption fails, the result is NULL.

For the legacy version of this function in use before MySQL 8.0.29, see Section 6.6.6, “MySQL Enterprise Encryption Legacy Function Descriptions”.

**algorithm** is the encryption algorithm used to create the key. The supported algorithm value is 'RSA'.

**data_str** is the string to encrypt. The length of this string cannot be greater than the key string length in bytes, minus 42 (to account for the padding).
pub_key_str is a valid PEM encoded RSA public key. The asymmetric_encrypt() component function only supports encryption using a public key.

To recover the original unencrypted string, pass the encrypted string to asymmetric_decrypt(), along with the other part of the key pair used for encryption, as in the following example:

```sql
-- Generate private/public key pair
SET @priv = create_asymmetric_priv_key('RSA', 2048);
SET @pub = create_asymmetric_pub_key('RSA', @priv);

-- Encrypt using public key, decrypt using private key
SET @ciphertext = asymmetric_encrypt('RSA', 'The quick brown fox', @pub);
SET @plaintext = asymmetric_decrypt('RSA', @ciphertext, @priv);
```

Suppose that:

```sql
SET @s = a string to be encrypted
SET @priv = a valid private RSA key string in PEM format
SET @pub = the corresponding public RSA key string in PEM format
```

Then these identity relationships hold:

```
asymmetric_decrypt('RSA', asymmetric_encrypt('RSA', @s, @pub), @priv) = @s
```

• asymmetric_sign(algorithm, text, priv_key_str, digest_type)

  Signs a digest string or data string using a private key, and returns the signature as a binary string. If signing fails, the result is NULL.

  For the legacy version of this function in use before MySQL 8.0.29, see Section 6.6.6, “MySQL Enterprise Encryption Legacy Function Descriptions”.

algorithm is the encryption algorithm used to create the key. The supported algorithm value is 'RSA'.

text is a data string or digest string. The function accepts digests but does not require them, as it is also capable of handling data strings of an arbitrary length. A digest string can be generated by calling create_digest().

priv_key_str is the private key string to use for signing the digest string. It must be a valid PEM encoded RSA private key.

digest_type is the algorithm to be used to sign the data. The supported digest_type values are 'SHA224', 'SHA256', 'SHA384', and 'SHA512' when OpenSSL 1.0.1 is in use. If OpenSSL 1.1.1 is in use, the additional digest_type values 'SHA3-224', 'SHA3-256', 'SHA3-384', and 'SHA3-512' are available.

For a usage example, see the description of asymmetric_verify().

• asymmetric_verify(algorithm, text, sig_str, pub_key_str, digest_type)

  Verifies whether the signature string matches the digest string, and returns 1 or 0 to indicate whether verification succeeded or failed. If verification fails, the result is NULL.

  For the legacy version of this function in use before MySQL 8.0.29, see Section 6.6.6, “MySQL Enterprise Encryption Legacy Function Descriptions”.

By default, the componentEnterpriseEncryption function assumes that signatures use the RSASSA-PSS signature scheme. The function supports verification for signatures
produced by the legacy openssl_udf shared library functions if the system variable
enterprise_encryption.rsa_support_legacy_padding is set to ON (the default is OFF). When
ON is set, the function also supports the RSASSA-PKCS1-v1_5 signature scheme, as used by the legacy
openssl_udf shared library functions. When OFF is set, signatures produced by the legacy functions
cannot be verified, and the function returns null output for such content.

_algorithm_ is the encryption algorithm used to create the key. The supported algorithm value is 'RSA'.

text is a data string or digest string. The component function accepts digests but does not require
them, as it is also capable of handling data strings of an arbitrary length. A digest string can be
generated by calling _create_digest()._

_sig_str_ is the signature string to be verified. A signature string can be generated by calling
asymmetric_sign().

_pub_key_str_ is the public key string of the signer. It corresponds to the private key passed to
asymmetric_sign() to generate the signature string. It must be a valid PEM encoded RSA public key.

digest_type_ is the algorithm that was used to sign the data. The supported _digest_type_ values
are 'SHA224', 'SHA256', 'SHA384', and 'SHA512' when OpenSSL 1.0.1 is in use. If OpenSSL
1.1.1 is in use, the additional _digest_type_ values 'SHA3-224', 'SHA3-256', 'SHA3-384', and
'SHA3-512' are available.

```sql
SET @algo = 'RSA';
SET @dig_type = 'SHA512';

SET @priv = create_asymmetric_priv_key(@algo, 2048);
SET @pub = create_asymmetric_pub_key(@algo, @priv);

SET @dig = create_digest(@dig_type, 'The quick brown fox');

SET @sig = asymmetric_sign(@algo, @dig, @priv, @dig_type);
SET @verf = asymmetric_verify(@algo, @dig, @sig, @pub, @dig_type);
```

• _create_asymmetric_priv_key(_algorithm_, _key_length_)_

Creates a private key using the given algorithm and key length, and returns the key as a binary string in
PEM format. The key is in PKCS #8 format. If key generation fails, the result is NULL.

For the legacy version of this function in use before MySQL 8.0.29, see Section 6.6.6, "MySQL
Enterprise Encryption Legacy Function Descriptions".

_algorithm_ is the encryption algorithm used to create the key. The supported algorithm value is 'RSA'.

_key_length_ is the key length in bits. If you exceed the maximum allowed key length or
specify less than the minimum, key generation fails and the result is null output. The minimum
allowed key length in bits is 2048. The maximum allowed key length is the value of the
enterprise_encryption.maximum_rsa_key_size system variable, which defaults to 4096. It
has a maximum setting of 16384, which is the maximum key length allowed for the RSA algorithm. See
Section 6.6.2, "Configuring MySQL Enterprise Encryption".

**Note**

Generating longer keys can consume significant CPU resources. Limiting the key
length using the _enterprise_encryption.maximum_rsa_key_size_ system variable
This example creates a 2048-bit RSA private key, then derives a public key from the private key:

```sql
SET @priv = create_asymmetric_priv_key('RSA', 2048);
SET @pub = create_asymmetric_pub_key('RSA', @priv);
```

Derives a public key from the given private key using the given algorithm, and returns the key as a binary string in PEM format. The key is in PKCS #8 format. If key derivation fails, the result is `NULL`.

For the legacy version of this function in use before MySQL 8.0.29, see Section 6.6.6, “MySQL Enterprise Encryption Legacy Function Descriptions”.

`algorithm` is the encryption algorithm used to create the key. The supported algorithm value is `'RSA'`.

`priv_key_str` is a valid PEM encoded RSA private key.

For a usage example, see the description of `create_asymmetric_priv_key()`.

```sql
SET @dig = create_digest('SHA512', 'The quick brown fox');
```

```sql
6.6.6 MySQL Enterprise Encryption Legacy Function Descriptions

In releases before MySQL 8.0.30, MySQL Enterprise Encryption's functions are based on the `openssl_udf` shared library. This reference describes those functions. The functions continue to be available in later releases if they have been installed, but they are deprecated.

For information on upgrading to the new component functions provided by the MySQL component `component_enterprise_encryption`, and a list of the behavior differences between the legacy functions and the component functions, see Upgrading MySQL Enterprise Encryption.

The reference for the component functions is Section 6.6.5, “MySQL Enterprise Encryption Component Function Descriptions”.

MySQL Enterprise Encryption functions have these general characteristics:
• For arguments of the wrong type or an incorrect number of arguments, each function returns an error.

• If the arguments are not suitable to permit a function to perform the requested operation, it returns NULL or 0 as appropriate. This occurs, for example, if a function does not support a specified algorithm, a key length is too short or long, or a string expected to be a key string in PEM format is not a valid key.

• The underlying SSL library takes care of randomness initialization.

Several of the legacy functions take an encryption algorithm argument. The following table summarizes the supported algorithms by function.

**Table 6.52 Supported Algorithms by Function**

<table>
<thead>
<tr>
<th>Function</th>
<th>Supported Algorithms</th>
</tr>
</thead>
<tbody>
<tr>
<td>asymmetric_decrypt()</td>
<td>RSA</td>
</tr>
<tr>
<td>asymmetric_derive()</td>
<td>DH</td>
</tr>
<tr>
<td>asymmetric_encrypt()</td>
<td>RSA</td>
</tr>
<tr>
<td>asymmetric_sign()</td>
<td>RSA, DSA</td>
</tr>
<tr>
<td>asymmetric_verify()</td>
<td>RSA, DSA</td>
</tr>
<tr>
<td>create_asymmetric_priv_key()</td>
<td>RSA, DSA, DH</td>
</tr>
<tr>
<td>create_asymmetric_pub_key()</td>
<td>RSA, DSA, DH</td>
</tr>
<tr>
<td>create_dh_parameters()</td>
<td>DH</td>
</tr>
</tbody>
</table>

**Note**

Although you can create keys using any of the RSA, DSA, or DH encryption algorithms, other legacy functions that take key arguments might accept only certain types of keys. For example, asymmetric_encrypt() and asymmetric_decrypt() accept only RSA keys.

For additional examples and discussion, see Section 6.6.3, “MySQL Enterprise Encryption Usage and Examples”.

• **asymmetric_decrypt(algorithm, crypt_str, key_str)**

Decrypts an encrypted string using the given algorithm and key string, and returns the resulting plaintext as a binary string. If decryption fails, the result is NULL.

The openssl_udf shared library function cannot decrypt content produced by the component_enterprise_encryption functions that are available from MySQL 8.0.30.

*algorithm* is the encryption algorithm used to create the key. The supported algorithm value is 'RSA'.

*crypt_str* is the encrypted string to decrypt, which was encrypted with asymmetric_encrypt().

*key_str* is a valid PEM encoded RSA public or private key. For successful decryption, the key string must correspond to the public or private key string used with asymmetric_encrypt() to produce the encrypted string.

For a usage example, see the description of asymmetric_encrypt().

• **asymmetric_derive(pub_key_str, priv_key_str)**

Derives a symmetric key using the private key of one party and the public key of another, and returns the resulting key as a binary string. If key derivation fails, the result is NULL.
pub_key_str and priv_key_str are valid PEM encoded key strings that were created using the DH algorithm.

Suppose that you have two pairs of public and private keys:

```sql
SET @dhp = create_dh_parameters(1024);
SET @priv1 = create_asymmetric_priv_key('DH', @dhp);
SET @pub1 = create_asymmetric_pub_key('DH', @priv1);
SET @priv2 = create_asymmetric_priv_key('DH', @dhp);
SET @pub2 = create_asymmetric_pub_key('DH', @priv2);
```

Suppose further that you use the private key from one pair and the public key from the other pair to create a symmetric key string. Then this symmetric key identity relationship holds:

```sql
asymmetric_derive(@pub1, @priv2) = asymmetric_derive(@pub2, @priv1)
```

This example requires DH private/public keys as inputs, created using a shared symmetric secret. Create the secret by passing the key length to `create_dh_parameters()`, then pass the secret as the "key length" to `create_asymmetric_priv_key()`.

```sql
-- Generate DH shared symmetric secret
SET @dhp = create_dh_parameters(1024);

-- Generate DH key pairs
SET @algo = 'DH';
SET @priv1 = create_asymmetric_priv_key(@algo, @dhp);
SET @pub1 = create_asymmetric_pub_key(@algo, @priv1);
SET @priv2 = create_asymmetric_priv_key(@algo, @dhp);
SET @pub2 = create_asymmetric_pub_key(@algo, @priv2);

-- Generate symmetric key using public key of first party, private key of second party
SET @sym1 = asymmetric_derive(@pub1, @priv2);

-- Or use public key of second party, private key of first party
SET @sym2 = asymmetric_derive(@pub2, @priv1);
```

- **asymmetric_encrypt(algorithm, str, key_str)**

Encrypts a string using the given algorithm and key string, and returns the resulting ciphertext as a binary string. If encryption fails, the result is NULL.

algorithm is the encryption algorithm used to create the key. The supported algorithm value is 'RSA'.

str is the string to encrypt. The length of this string cannot be greater than the key string length in bytes, minus 11 (to account for the padding).

key_str is a valid PEM encoded RSA public or private key.

To recover the original unencrypted string, pass the encrypted string to `asymmetric_decrypt()`, along with the other part of the key pair used for encryption, as in the following example:

```sql
-- Generate private/public key pair
SET @priv = create_asymmetric_priv_key('RSA', 1024);
SET @pub = create_asymmetric_pub_key('RSA', @priv);

-- Encrypt using private key, decrypt using public key
SET @ciphertext = asymmetric_encrypt('RSA', 'The quick brown fox', @priv);
SET @plaintext = asymmetric_decrypt('RSA', @ciphertext, @pub);

-- Encrypt using public key, decrypt using private key
SET @ciphertext = asymmetric_encrypt('RSA', 'The quick brown fox', @pub);
```
SET @plaintext = asymmetric_decrypt('RSA', @ciphertext, @priv);

Suppose that:

SET @s = a string to be encrypted
SET @priv = a valid private RSA key string in PEM format
SET @pub = the corresponding public RSA key string in PEM format

Then these identity relationships hold:

\[
\text{asymmetric_decrypt('RSA', asymmetric_encrypt('RSA', @s, @priv), @pub)} = @s
\]
\[
\text{asymmetric_decrypt('RSA', asymmetric_encrypt('RSA', @s, @pub), @priv)} = @s
\]

- **asymmetric_sign(algorithm, digest_str, priv_key_str, digest_type)**

Signs a digest string using a private key string, and returns the signature as a binary string. If signing fails, the result is NULL.

**algorithm** is the encryption algorithm used to create the key. The supported algorithm values are 'RSA' and 'DSA'.

**digest_str** is a digest string. A digest string can be generated by calling create_digest().

**priv_key_str** is the private key string to use for signing the digest string. It can be a valid PEM encoded RSA private key or DSA private key.

**digest_type** is the algorithm to be used to sign the data. The supported digest_type values are 'SHA224', 'SHA256', 'SHA384', and 'SHA512'.

For a usage example, see the description of asymmetric_verify().

- **asymmetric_verify(algorithm, digest_str, sig_str, pub_key_str, digest_type)**

Verifies whether the signature string matches the digest string, and returns 1 or 0 to indicate whether verification succeeded or failed. If verification fails, the result is NULL.

The openssl_udf shared library function cannot verify content produced by the component_enterprise_encryption functions that are available from MySQL 8.0.30.

**algorithm** is the encryption algorithm used to create the key. The supported algorithm values are 'RSA' and 'DSA'.

**digest_str** is the digest string. A digest string is required, and can be generated by calling create_digest().

**sig_str** is the signature string to be verified. A signature string can be generated by calling asymmetric_sign().

**pub_key_str** is the public key string of the signer. It corresponds to the private key passed to asymmetric_sign() to generate the signature string. It must be a valid PEM encoded RSA public key or DSA public key.

**digest_type** is the algorithm that was used to sign the data. The supported digest_type values are 'SHA224', 'SHA256', 'SHA384', and 'SHA512'.

-- Set the encryption algorithm and digest type
SET @algo = 'RSA';
SET @dig_type = 'SHA224';
-- Create private/public key pair
SET @priv = create_asymmetric_priv_key(@algo, 1024);
SET @pub = create_asymmetric_pub_key(@algo, @priv);

-- Generate digest from string
SET @dig = create_digest(@dig_type, 'The quick brown fox');

-- Generate signature for digest and verify signature against digest
SET @sig = asymmetric_sign(@algo, @dig, @priv, @dig_type);
SET @verf = asymmetric_verify(@algo, @dig, @sig, @pub, @dig_type);

• create_asymmetric_priv_key(algorithm, {key_len|dh_secret})

Creates a private key using the given algorithm and key length or DH secret, and returns the key as a binary string in PEM format. The key is in PKCS #1 format. If key generation fails, the result is NULL.

**algorithm** is the encryption algorithm used to create the key. The supported algorithm values are 'RSA', 'DSA', and 'DH'.

**key_len** is the key length in bits for RSA and DSA keys. If you exceed the maximum allowed key length or specify less than the minimum, key generation fails and the result is null output. The minimum allowed key length in bits is 1,024, and the maximum allowed key length is 16,384 for the RSA algorithm or 10,000 for the DSA algorithm. These key-length limits are constraints imposed by OpenSSL. Server administrators can impose additional limits on maximum key length by setting the MYSQL_OPENSSL_UDF_RSA_BITS_THRESHOLD, MYSQL_OPENSSL_UDF_DSA_BITS_THRESHOLD, and MYSQL_OPENSSL_UDF_DH_BITS_THRESHOLD environment variables. See Section 6.6.2, "Configuring MySQL Enterprise Encryption".

**Note**
Generating longer keys can consume significant CPU resources. Limiting the key length using the environment variables lets you provide adequate security for your requirements while balancing this with resource usage.

**dh_secret** is a shared DH secret, which must be passed instead of a key length for DH keys. To create the secret, pass the key length to create_dh_parameters().

This example creates a 2,048-bit DSA private key, then derives a public key from the private key:

```sql
SET @priv = create_asymmetric_priv_key('DSA', 2048);
SET @pub = create_asymmetric_pub_key('DSA', @priv);
```

For an example showing DH key generation, see the description of asymmetricderive().

• create_asymmetric_pub_key(algorithm, priv_key_str)

Derives a public key from the given private key using the given algorithm, and returns the key as a binary string in PEM format. The key is in PKCS #1 format. If key derivation fails, the result is NULL.

**algorithm** is the encryption algorithm used to create the key. The supported algorithm values are 'RSA', 'DSA', and 'DH'.

**priv_key_str** is a valid PEM encoded RSA, DSA, or DH private key.

For a usage example, see the description of create_asymmetric_priv_key().
• `create_dh_parameters(key_len)`

Creates a shared secret for generating a DH private/public key pair and returns a binary string that can be passed to `create_asymmetric_priv_key()`. If secret generation fails, the result is `NULL`.

`key_len` is the key length. The minimum and maximum key lengths in bits are 1,024 and 10,000. These key-length limits are constraints imposed by OpenSSL. Server administrators can impose additional limits on maximum key length by setting the `MYSQL_OPENSSL_UDF_RSA_BITS_THRESHOLD`, `MYSQL_OPENSSL_UDF_DSA_BITS_THRESHOLD`, and `MYSQL_OPENSSL_UDF_DH_BITS_THRESHOLD` environment variables. See Section 6.6.2, “Configuring MySQL Enterprise Encryption”.

For an example showing how to use the return value for generating symmetric keys, see the description of `asymmetric_derive()`.

```sql
SET @dhp = create_dh_parameters(1024);
```

• `create_digest(digest_type, str)`

Creates a digest from the given string using the given digest type, and returns the digest as a binary string. If digest generation fails, the result is `NULL`.

The resulting digest string is suitable for use with `asymmetric_sign()` and `asymmetric_verify()`. A digest is required for these functions.

`digest_type` is the digest algorithm to be used to generate the digest string. The supported `digest_type` values are 'SHA224', 'SHA256', 'SHA384', and 'SHA512'.

`str` is the non-null data string for which the digest is to be generated.

```sql
SET @dig = create_digest('SHA512', 'The quick brown fox');
```

### 6.7 SELinux

Security-Enhanced Linux (SELinux) is a mandatory access control (MAC) system that implements access rights by applying a security label referred to as a SELinux context to each system object. SELinux policy modules use SELinux contexts to define rules for how processes, files, ports, and other system objects interact with each other. Interaction between system objects is only permitted if a policy rule allows it.

An SELinux context (the label applied to a system object) has the following fields: `user`, `role`, `type`, and `security level`. Type information rather than the entire SELinux context is used most commonly to define rules for how processes interact with other system objects. MySQL SELinux policy modules, for example, define policy rules using `type` information.

You can view SELinux contexts using operating system commands such as `ls` and `ps` with the `-Z` option. Assuming that SELinux is enabled and a MySQL Server is running, the following commands show the SELinux context for the `mysqld` process and MySQL data directory:

**mysqld process:**

```bash
$> ps -eZ | grep mysqld
system_u:system_r:mysqld_t:s0 5924 ? 00:00:03 mysqld
```

**MySQL data directory:**

```bash
$> cd /var/lib
$> ls -Z | grep mysql
system_u:object_r:mysqld_db_t:s0 mysql
```
where:

- `system_u` is an SELinux user identity for system processes and objects.
- `system_r` is an SELinux role used for system processes.
- `objects_r` is an SELinux role used for system objects.
- `mysql_t` is the type associated with the mysql process.
- `mysql_db_t` is the type associated with the MySQL data directory and its files.
- `s0` is the security level.

For more information about interpreting SELinux contexts, refer to your distribution’s SELinux documentation.

### 6.7.1 Check if SELinux is Enabled

SELinux is enabled by default on some Linux distributions including Oracle Linux, RHEL, CentOS, and Fedora. Use the `sestatus` command to determine if SELinux is enabled on your distribution:

```bash
$> sestatus
SELinux status:                 enabled
SELinuxfs mount:                /sys/fs/selinux
SELinux root directory:         /etc/selinux
Loaded policy name:             targeted
Current mode:                   enforcing
Mode from config file:          enforcing
Policy MLS status:              enabled
Policy deny_unknown status:     allowed
Memory protection checking:     actual (secure)
Max kernel policy version:      31
```

If SELinux is disabled or the `sestatus` command is not found, refer to your distribution’s SELinux documentation for guidance before enabling SELinux.

### 6.7.2 Changing the SELinux Mode

SELinux supports enforcing, permissive, and disabled modes. Enforcing mode is the default. Permissive mode allows operations that are not permitted in enforcing mode and logs those operations to the SELinux audit log. Permissive mode is typically used when developing policies or troubleshooting. In disabled mode, policies are not enforced, and contexts are not applied to system objects, which makes it difficult to enable SELinux later.

To view the current SELinux mode, use the `sestatus` command mentioned previously or the `getenforce` utility:

```bash
$> getenforce
Enforcing
```

To change the SELinux mode, use the `setenforce` utility:

```bash
$> setenforce 0
$> getenforce
Permissive

$> setenforce 1
$> getenforce
Enforcing
```
Changes made with `setenforce` are lost when you restart the system. To permanently change the SELinux mode, edit the `/etc/selinux/config` file and restart the system.

### 6.7.3 MySQL Server SELinux Policies

MySQL Server SELinux policy modules are typically installed by default. You can view installed modules using the `semodule -l` command. MySQL Server SELinux policy modules include:

- `mysqld_selinux`
- `mysqld_safe_selinux`

For information about MySQL Server SELinux policy modules, refer to the SELinux manual pages. The manual pages provide information about types and Booleans associated with the MySQL service. Manual pages are named in the `service-name_selinux` format.

```
man mysqld_selinux
```

If SELinux manual pages are not available, refer to your distribution's SELinux documentation for information about how to generate manual pages using the `sepolicy manpage` utility.

### 6.7.4 SELinux File Context

The MySQL Server reads from and writes to many files. If the SELinux context is not set correctly for these files, access to the files could be denied.

The instructions that follow use the `semanage` binary to manage file context; on RHEL, it's part of the `policycoreutils-python-utils` package:

```
yum install -y policycoreutils-python-utils
```

After installing the `semanage` binary, you can list MySQL file contexts using `semanage` with the `fcontext` option.

```
semanage fcontext -l | grep -i mysql
```

#### Setting the MySQL Data Directory Context

The default data directory location is `/var/lib/mysql/`; and the SELinux context used is `mysqld_db_t`.

If you edit the configuration file to use a different location for the data directory, or for any of the files normally in the data directory (such as the binary logs), you may need to set the context for the new location. For example:

```
semanage fcontext -a -t mysqld_db_t "/path/to/my/custom/datadir(/.*)?"  
restorecon -Rv /path/to/my/custom/datadir

semanage fcontext -a -t mysqld_db_t "/path/to/my/custom/logdir(/.*)?"  
restorecon -Rv /path/to/my/custom/logdir
```

#### Setting the MySQL Error Log File Context

The default location for RedHat RPMs is `/var/log/mysqld.log`; and the SELinux context type used is `mysqld_log_t`.

If you edit the configuration file to use a different location, you may need to set the context for the new location. For example:
Setting the PID File Context

The default location for the PID file is `/var/run/mysqld/mysqld.pid`; and the SELinux context type used is `mysqld_var_run_t`.

If you edit the configuration file to use a different location, you may need to set the context for the new location. For example:

```bash
semanage fcontext -a -t mysqld_var_run_t "/path/to/my/custom/pidfile/directory/.*?"
restorecon -Rv /path/to/my/custom/pidfile/directory
```

Setting the Unix Domain Socket Context

The default location for the Unix domain socket is `/var/lib/mysql/mysql.sock`; and the SELinux context type used is `mysqld_var_run_t`.

If you edit the configuration file to use a different location, you may need to set the context for the new location. For example:

```bash
semanage fcontext -a -t mysqld_var_run_t "/path/to/my/custom/mysql\sock"
restorecon -Rv /path/to/my/custom/mysql.sock
```

Setting the `secure_file_priv` Directory Context

For MySQL versions since 5.6.34, 5.7.16, and 8.0.11.

Installing the MySQL Server RPM creates a `/var/lib/mysql-files/` directory but does not set the SELinux context for it. The `/var/lib/mysql-files/` directory is intended to be used for operations such as `SELECT ... INTO OUTFILE`.

If you enabled the use of this directory by setting `secure_file_priv`, you may need to set the context like so:

```bash
semanage fcontext -a -t mysqld_db_t "/var/lib/mysql-files/(/.*)?"
restorecon -Rv /var/lib/mysql-files
```

Edit this path if you used a different location. For security purposes, this directory should never be within the data directory.

For more information about this variable, see the `secure_file_priv` documentation.

6.7.5 SELinux TCP Port Context

The instructions that follow use the `semanage` binary to manage port context; on RHEL, it's part of the `policycoreutils-python-utils` package:

```bash
yum install -y policycoreutils-python-utils
```

After installing the `semanage` binary, you can list ports defined with the `mysqld_port_t` context using `semanage` with the `port` option.

```bash
$> semanage port -l | grep mysqld
mysqld_port_t tcp 1186, 3306, 63132-63164
```

6.7.5.1 Setting the TCP Port Context for mysqld
The default TCP port for `mysqld` is **3306**; and the SELinux context type used is `mysqld_port_t`.

If you configure `mysqld` to use a different TCP port, you may need to set the context for the new port. For example to define the SELinux context for a non-default port such as port 3307:

```bash
semanage port -a -t mysqld_port_t -p tcp 3307
```

To confirm that the port is added:

```bash
$> semanage port -l | grep mysqld
mysqld_port_t                  tcp      3307, 1186, 3306, 63132-63164
```

### 6.7.5.2 Setting the TCP Port Context for MySQL Features

If you enable certain MySQL features, you might need to set the SELinux TCP port context for additional ports used by those features. If ports used by MySQL features do not have the correct SELinux context, the features might not function correctly.

The following sections describe how to set port contexts for MySQL features. Generally, the same method can be used to set the port context for any MySQL features. For information about ports used by MySQL features, refer to the [MySQL Port Reference](#).

From MySQL 8.0.14 to MySQL 8.0.17, the `mysql_connect_any` SELinux boolean must be set to **ON**. As of MySQL 8.0.18, enabling `mysql_connect_any` is not required or recommended.

```bash
setsebool -P mysql_connect_any=ON
```

#### Setting the TCP Port Context for Group Replication

If SELinux is enabled, you must set the port context for the Group Replication communication port, which is defined by the `group_replication_local_address` variable. `mysqld` must be able to bind to the Group Replication communication port and listen there. InnoDB Cluster relies on Group Replication so this applies equally to instances used in a cluster. To view ports currently used by MySQL, issue:

```bash
semanage port -l | grep mysqld
```

Assuming the Group Replication communication port is 33061, set the port context by issuing:

```bash
semanage port -a -t mysqld_port_t -p tcp 33061
```

#### Setting the TCP Port Context for Document Store

If SELinux is enabled, you must set the port context for the communication port used by X Plugin, which is defined by the `mysqlx_port` variable. `mysqld` must be able to bind to the X Plugin communication port and listen there.

Assuming the X Plugin communication port is 33060, set the port context by issuing:

```bash
semanage port -a -t mysqld_port_t -p tcp 33060
```

#### Setting the TCP Port Context for MySQL Router

If SELinux is enabled, you must set the port context for the communication ports used by MySQL Router. Assuming the additional communication ports used by MySQL Router are the default 6446, 6447, 64460 and 64470, on each instance set the port context by issuing:

```bash
semanage port -a -t mysqld_port_t -p tcp 6446
semanage port -a -t mysqld_port_t -p tcp 6447
semanage port -a -t mysqld_port_t -p tcp 64460
```
6.7.6 Troubleshooting SELinux

Troubleshooting SELinux typically involves placing SELinux into permissive mode, rerunning problematic operations, checking for access denial messages in the SELinux audit log, and placing SELinux back into enforcing mode after problems are resolved.

To avoid placing the entire system into permissive mode using `setenforce`, you can permit only the MySQL service to run permissively by placing its SELinux domain (`mysqld_t`) into permissive mode using the `semanage` command:

```
semanage permissive -a mysqld_t
```

When you are finished troubleshooting, use this command to place the `mysqld_t` domain back into enforcing mode:

```
semanage permissive -d mysqld_t
```

SELinux writes logs for denied operations to `/var/log/audit/audit.log`. You can check for denials by searching for “denied” messages.

```
grep "denied" /var/log/audit/audit.log
```

The following sections describes a few common areas where SELinux-related issues may be encountered.

### File Contexts

If a MySQL directory or file has an incorrect SELinux context, access may be denied. This issue can occur if MySQL is configured to read from or write to a non-default directory or file. For example, if you configure MySQL to use a non-default data directory, the directory may not have the expected SELinux context.

Attempting to start the MySQL service on a non-default data directory with an invalid SELinux context causes the following startup failure.

```
$> systemctl start mysql.service
Job for mysql.service failed because the control process exited with error code.
See "systemctl status mysql.service" and "journalctl -xe" for details.
```

In this case, a “denial” message is logged to `/var/log/audit/audit.log`:

```
$> grep "denied" /var/log/audit/audit.log
```

For information about setting the proper SELinux context for MySQL directories and files, see Section 6.7.4, “SELinux File Context”.

### Port Access

SELinux expects services such as MySQL Server to use specific ports. Changing ports without updating the SELinux policies may cause a service failure.

The `mysql_port_t` port type defines the ports that the MySQL listens on. If you configure the MySQL Server to use a non-default port, such as port 3307, and do not update the policy to reflect the change, the MySQL service fails to start:

```
$> systemctl start mysqld.service
```

FIPS Support

Job for mysqld.service failed because the control process exited with error code. See "systemctl status mysqld.service" and "journalctl -xe" for details.

In this case, a denial message is logged to /var/log/audit/audit.log:

```bash
$> grep "denied" /var/log/audit/audit.log
```

```bash
type=AVC msg=audit(1587134375.845:198): avc: denied { name_bind } for pid=7340
comm="mysqld" src=3307 scontext=system_u:system_r:mysqld_t:s0
tcontext=system_u:system_r:unreserved_port_t:s0 tclass=tcp_socket permissive=0
```

For information about setting the proper SELinux port context for MySQL, see Section 6.7.5, “SELinux TCP Port Context”. Similar port access issues can occur when enabling MySQL features that use ports that are not defined with the required context. For more information, see Section 6.7.5.2, “Setting the TCP Port Context for MySQL Features”.

### Application Changes

SELinux may not be aware of application changes. For example, a new release, an application extension, or a new feature may access system resources in a way that is not permitted by SELinux, resulting in access denials. In such cases, you can use the `audit2allow` utility to create custom policies to permit access where it is required. The typical method for creating custom policies is to change the SELinux mode to permissive, identify access denial messages in the SELinux audit log, and use the `audit2allow` utility to create custom policies to permit access.

For information about using the `audit2allow` utility, refer to your distribution’s SELinux documentation.

If you encounter access issues for MySQL that you believe should be handled by standard MySQL SELinux policy modules, please open a bug report in your distribution’s bug tracking system.

### 6.8 FIPS Support

MySQL supports FIPS mode, if compiled using OpenSSL 3.0 or OpenSSL 1.0.2, and an OpenSSL library and FIPS Object Module are available at runtime.

FIPS mode on the server side applies to cryptographic operations performed by the server. This includes replication (source/replica and Group Replication) and X Plugin, which run within the server. FIPS mode also applies to attempts by clients to connect to the server.

The following sections describe FIPS mode and how to take advantage of it within MySQL:

- **FIPS Overview**
- **System Requirements for FIPS Mode in MySQL**
- **Configuring FIPS Mode in MySQL**

#### FIPS Overview

Federal Information Processing Standards 140-2 (FIPS 140-2) describes a security standard that can be required by Federal (US Government) agencies for cryptographic modules used to protect sensitive or valuable information. To be considered acceptable for such Federal use, a cryptographic module must be certified for FIPS 140-2. If a system intended to protect sensitive data lacks the proper FIPS 140-2 certificate, Federal agencies cannot purchase it.

Products such as OpenSSL can be used in FIPS mode, although the OpenSSL library itself is not validated for FIPS. Instead, the OpenSSL library is used with the OpenSSL FIPS Object Module to enable OpenSSL-based applications to operate in FIPS mode.
For general information about FIPS and its implementation in OpenSSL, these references may be helpful:

- National Institute of Standards and Technology FIPS PUB 140-2
- OpenSSL FIPS 140-2 Security Policy
- fips_module manual page

**Important**

FIPS mode imposes conditions on cryptographic operations such as restrictions on acceptable encryption algorithms or requirements for longer key lengths. For OpenSSL, the exact FIPS behavior depends on the OpenSSL version.

**System Requirements for FIPS Mode in MySQL**

For MySQL to support FIPS mode, these system requirements must be satisfied:

- At build time, MySQL must be compiled using OpenSSL. FIPS mode cannot be used in MySQL if compilation uses an SSL library different from OpenSSL.

In addition, MySQL must be compiled with an OpenSSL version that is certified for use with FIPS. OpenSSL 1.0.2 and OpenSSL 3.0 are certified, but OpenSSL 1.1.1 is not. Binary distributions for recent versions of MySQL are compiled using OpenSSL 1.1.1 on some platforms, which means they are not certified for FIPS. This leads to tradeoffs in available MySQL features, depending on system and MySQL configuration:

- Use a system that has OpenSSL 1.0.2 and the required FIPS Object Module. In this case, you can enable FIPS mode for MySQL if you use a binary distribution compiled using OpenSSL 1.0.2, or compile MySQL from source using OpenSSL 1.0.2. However, in this case, you cannot use the TLSv1.3 protocol or ciphersuites (which require OpenSSL 1.1.1). In addition, you are using an OpenSSL version that reached End of Life status at the end of 2019.

- Use a system that has OpenSSL 1.1.1 or higher. In this case, you can install MySQL using binary packages, and you can use the TLSv1.3 protocol and ciphersuites, in addition to other already supported TLS protocols. However, you cannot enable FIPS mode for MySQL.

- Use a system that has OpenSSL 3.0 and the required FIPS Object Module. In this case, you can enable FIPS mode for MySQL if you use a binary distribution compiled using OpenSSL 3.0, or compile MySQL from source using OpenSSL 3.0. It is possible to handle FIPS mode directly through OpenSSL 3.0 configuration files rather than using the server-side system variable and client-side options (deprecated as of MySQL 8.0.34). When MySQL is compiled using OpenSSL 3.0, and an OpenSSL library and FIPS Object Module are available at runtime, the server reads the OpenSSL configuration file and respects the preference to use a FIPS provider, if one is set.

For general information about upgrading to OpenSSL 3.0, see [OpenSSL 3.0 Migration Guide](#).

- At runtime, the OpenSSL library and OpenSSL FIPS Object Module must be available as shared (dynamically linked) objects. It is possible to build statically linked OpenSSL objects, but MySQL cannot use them.

FIPS mode has been tested for MySQL on EL7, but may work on other systems.

If your platform or operating system provides the OpenSSL FIPS Object Module, you can use it. Otherwise, you can build the OpenSSL library and FIPS Object Module from source. Use the instructions in the fips_module manpage (see [FIPS Overview](#)).
Configuring FIPS Mode in MySQL

Note
The server-side and client-side options described in this section are deprecated.

MySQL enables control of FIPS mode on the server side and the client side:

- The `ssl_fips_mode` system variable controls whether the server operates in FIPS mode.
- The `--ssl-fips-mode` client option controls whether a given MySQL client operates in FIPS mode.

The `ssl_fips_mode` system variable and `--ssl-fips-mode` client option permit these values:

- **OFF**: Disable FIPS mode.
- **ON**: Enable FIPS mode.
- **STRICT**: Enable “strict” FIPS mode.

On the server side, numeric `ssl_fips_mode` values of 0, 1, and 2 are equivalent to OFF, ON, and STRICT, respectively.

Important
In general, STRICT imposes more restrictions than ON, but MySQL itself has no FIPS-specific code other than to specify to OpenSSL the FIPS mode value. The exact behavior of FIPS mode for ON or STRICT depends on the OpenSSL version. For details, refer to the `fips_module` manpage (see FIPS Overview).

Note
If the OpenSSL FIPS Object Module is not available, the only permitted value for `ssl_fips_mode` and `--ssl-fips-mode` is OFF. An error occurs for attempts to set the FIPS mode to a different value.

FIPS mode on the server side applies to cryptographic operations performed by the server. This includes replication (source/replica and Group Replication) and X Plugin, which run within the server.

FIPS mode also applies to attempts by clients to connect to the server. When enabled, on either the client or server side, it restricts which of the supported encryption ciphers can be chosen. However, enabling FIPS mode does not require that an encrypted connection must be used, or that user credentials must be encrypted. For example, if FIPS mode is enabled, stronger cryptographic algorithms are required. In particular, MD5 is restricted, so trying to establish an encrypted connection using an encryption cipher such as `RC4-MD5` does not work. But there is nothing about FIPS mode that prevents establishing an unencrypted connection. (To do that, you can use the REQUIRE clause for `CREATE USER` or `ALTER USER` for specific user accounts, or set the `require_secure_transport` system variable to affect all accounts.)

  7.6.5 Setting Up a MyISAM Table Maintenance Schedule .................... 1763

It is important to back up your databases so that you can recover your data and be up and running again in case problems occur, such as system crashes, hardware failures, or users deleting data by mistake. Backups are also essential as a safeguard before upgrading a MySQL installation, and they can be used to transfer a MySQL installation to another system or to set up replica servers.

MySQL offers a variety of backup strategies from which you can choose the methods that best suit the requirements for your installation. This chapter discusses several backup and recovery topics with which you should be familiar:

• Types of backups: Logical versus physical, full versus incremental, and so forth.
• Methods for creating backups.
• Recovery methods, including point-in-time recovery.
• Backup scheduling, compression, and encryption.
• Table maintenance, to enable recovery of corrupt tables.

Additional Resources

Resources related to backup or to maintaining data availability include the following:

• Customers of MySQL Enterprise Edition can use the MySQL Enterprise Backup product for backups. For an overview of the MySQL Enterprise Backup product, see Section 30.2, “MySQL Enterprise Backup Overview”.

1739
• A forum dedicated to backup issues is available at https://forums.mysql.com/list.php?28.

• Details for mysqldump can be found in Chapter 4, MySQL Programs.

• The syntax of the SQL statements described here is given in Chapter 13, SQL Statements.

• For additional information about InnoDB backup procedures, see Section 15.18.1, “InnoDB Backup”.

• Replication enables you to maintain identical data on multiple servers. This has several benefits, such as enabling client query load to be distributed over servers, availability of data even if a given server is taken offline or fails, and the ability to make backups with no impact on the source by using a replica. See Chapter 17, Replication.

• MySQL InnoDB Cluster is a collection of products that work together to provide a high availability solution. A group of MySQL servers can be configured to create a cluster using MySQL Shell. The cluster of servers has a single source, called the primary, which acts as the read-write source. Multiple secondary servers are replicas of the source. A minimum of three servers are required to create a high availability cluster. A client application is connected to the primary via MySQL Router. If the primary fails, a secondary is automatically promoted to the role of primary, and MySQL Router routes requests to the new primary.

• NDB Cluster provides a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. See Chapter 23, MySQL NDB Cluster 8.2, which provides information about MySQL NDB Cluster 8.1.0.

### 7.1 Backup and Recovery Types

This section describes the characteristics of different types of backups.

#### Physical (Raw) Versus Logical Backups

Physical backups consist of raw copies of the directories and files that store database contents. This type of backup is suitable for large, important databases that need to be recovered quickly when problems occur.

Logical backups save information represented as logical database structure (CREATE DATABASE, CREATE TABLE statements) and content (INSERT statements or delimited-text files). This type of backup is suitable for smaller amounts of data where you might edit the data values or table structure, or recreate the data on a different machine architecture.

Physical backup methods have these characteristics:

• The backup consists of exact copies of database directories and files. Typically this is a copy of all or part of the MySQL data directory.

• Physical backup methods are faster than logical because they involve only file copying without conversion.

• Output is more compact than for logical backup.

• Because backup speed and compactness are important for busy, important databases, the MySQL Enterprise Backup product performs physical backups. For an overview of the MySQL Enterprise Backup product, see Section 30.2, “MySQL Enterprise Backup Overview”.

• Backup and restore granularity ranges from the level of the entire data directory down to the level of individual files. This may or may not provide for table-level granularity, depending on storage engine. For
example, InnoDB tables can each be in a separate file, or share file storage with other InnoDB tables; each MyISAM table corresponds uniquely to a set of files.

• In addition to databases, the backup can include any related files such as log or configuration files.

• Data from MEMORY tables is tricky to back up this way because their contents are not stored on disk.  
  (The MySQL Enterprise Backup product has a feature where you can retrieve data from MEMORY tables during a backup.)

• Backups are portable only to other machines that have identical or similar hardware characteristics.

• Backups can be performed while the MySQL server is not running. If the server is running, it is necessary to perform appropriate locking so that the server does not change database contents during the backup. MySQL Enterprise Backup does this locking automatically for tables that require it.

• Physical backup tools include the mysqlbackup of MySQL Enterprise Backup for InnoDB or any other tables, or file system-level commands (such as cp, scp, tar, rsync) for MyISAM tables.

• For restore:
  • MySQL Enterprise Backup restores InnoDB and other tables that it backed up.
  • ndb_restore restores NDB tables.
  • Files copied at the file system level can be copied back to their original locations with file system commands.

Logical backup methods have these characteristics:

• The backup is done by querying the MySQL server to obtain database structure and content information.

• Backup is slower than physical methods because the server must access database information and convert it to logical format. If the output is written on the client side, the server must also send it to the backup program.

• Output is larger than for physical backup, particularly when saved in text format.

• Backup and restore granularity is available at the server level (all databases), database level (all tables in a particular database), or table level. This is true regardless of storage engine.

• The backup does not include log or configuration files, or other database-related files that are not part of databases.

• Backups stored in logical format are machine independent and highly portable.

• Logical backups are performed with the MySQL server running. The server is not taken offline.

• Logical backup tools include the mysqldump program and the SELECT ... INTO OUTFILE statement. These work for any storage engine, even MEMORY.

• To restore logical backups, SQL-format dump files can be processed using the mysql client. To load delimited-text files, use the LOAD DATA statement or the mysqlimport client.

Online Versus Offline Backups

Online backups take place while the MySQL server is running so that the database information can be obtained from the server. Offline backups take place while the server is stopped. This distinction can also
be described as “hot” versus “cold” backups; a “warm” backup is one where the server remains running but locked against modifying data while you access database files externally.

Online backup methods have these characteristics:

• The backup is less intrusive to other clients, which can connect to the MySQL server during the backup and may be able to access data depending on what operations they need to perform.

• Care must be taken to impose appropriate locking so that data modifications do not take place that would compromise backup integrity. The MySQL Enterprise Backup product does such locking automatically.

Offline backup methods have these characteristics:

• Clients can be affected adversely because the server is unavailable during backup. For that reason, such backups are often taken from a replica that can be taken offline without harming availability.

• The backup procedure is simpler because there is no possibility of interference from client activity.

A similar distinction between online and offline applies for recovery operations, and similar characteristics apply. However, it is more likely for clients to be affected by online recovery than by online backup because recovery requires stronger locking. During backup, clients might be able to read data while it is being backed up. Recovery modifies data and does not just read it, so clients must be prevented from accessing data while it is being restored.

Local Versus Remote Backups

A local backup is performed on the same host where the MySQL server runs, whereas a remote backup is done from a different host. For some types of backups, the backup can be initiated from a remote host even if the output is written locally on the server host.

• mysqldump can connect to local or remote servers. For SQL output (CREATE and INSERT statements), local or remote dumps can be done and generate output on the client. For delimited-text output (with the --tab option), data files are created on the server host.

• SELECT ... INTO OUTFILE can be initiated from a local or remote client host, but the output file is created on the server host.

• Physical backup methods typically are initiated locally on the MySQL server host so that the server can be taken offline, although the destination for copied files might be remote.

Snapshot Backups

Some file system implementations enable “snapshots” to be taken. These provide logical copies of the file system at a given point in time, without requiring a physical copy of the entire file system. (For example, the implementation may use copy-on-write techniques so that only parts of the file system modified after the snapshot time need be copied.) MySQL itself does not provide the capability for taking file system snapshots. It is available through third-party solutions such as Veritas, LVM, or ZFS.

Full Versus Incremental Backups

A full backup includes all data managed by a MySQL server at a given point in time. An incremental backup consists of the changes made to the data during a given time span (from one point in time to another). MySQL has different ways to perform full backups, such as those described earlier in this section. Incremental backups are made possible by enabling the server's binary log, which the server uses to record data changes.
Full Versus Point-in-Time (Incremental) Recovery

A full recovery restores all data from a full backup. This restores the server instance to the state that it had when the backup was made. If that state is not sufficiently current, a full recovery can be followed by recovery of incremental backups made since the full backup, to bring the server to a more up-to-date state.

Incremental recovery is recovery of changes made during a given time span. This is also called point-in-time recovery because it makes a server’s state current up to a given time. Point-in-time recovery is based on the binary log and typically follows a full recovery from the backup files that restores the server to its state when the backup was made. Then the data changes written in the binary log files are applied as incremental recovery to redo data modifications and bring the server up to the desired point in time.

Table Maintenance

Data integrity can be compromised if tables become corrupt. For InnoDB tables, this is not a typical issue. For programs to check MyISAM tables and repair them if problems are found, see Section 7.6, “MyISAM Table Maintenance and Crash Recovery”.

Backup Scheduling, Compression, and Encryption

Backup scheduling is valuable for automating backup procedures. Compression of backup output reduces space requirements, and encryption of the output provides better security against unauthorized access of backed-up data. MySQL itself does not provide these capabilities. The MySQL Enterprise Backup product can compress InnoDB backups, and compression or encryption of backup output can be achieved using file system utilities. Other third-party solutions may be available.

7.2 Database Backup Methods

This section summarizes some general methods for making backups.

Making a Hot Backup with MySQL Enterprise Backup

Customers of MySQL Enterprise Edition can use the MySQL Enterprise Backup product to do physical backups of entire instances or selected databases, tables, or both. This product includes features for incremental and compressed backups. Backing up the physical database files makes restore much faster than logical techniques such as the mysqldump command. InnoDB tables are copied using a hot backup mechanism. (Ideally, the InnoDB tables should represent a substantial majority of the data.) Tables from other storage engines are copied using a warm backup mechanism. For an overview of the MySQL Enterprise Backup product, see Section 30.2, “MySQL Enterprise Backup Overview”.

Making Backups with mysqldump

The mysqldump program can make backups. It can back up all kinds of tables. (See Section 7.4, “Using mysqldump for Backups”.

For InnoDB tables, it is possible to perform an online backup that takes no locks on tables using the --single-transaction option to mysqldump. See Section 7.3.1, “Establishing a Backup Policy”.

Making Backups by Copying Table Files

MyISAM tables can be backed up by copying table files (*.MYD, *.MYI files, and associated *.sdi files). To get a consistent backup, stop the server or lock and flush the relevant tables:

```
FLUSH TABLES tbl_list WITH READ LOCK;
```
Making Delimited-Text File Backups

You need only a read lock; this enables other clients to continue to query the tables while you are making a copy of the files in the database directory. The flush is needed to ensure that the all active index pages are written to disk before you start the backup. See Section 13.3.6, “LOCK TABLES and UNLOCK TABLES Statements”, and Section 13.7.8.3, “FLUSH Statement”.

You can also create a binary backup simply by copying the table files, as long as the server isn't updating anything. (But note that table file copying methods do not work if your database contains InnoDB tables. Also, even if the server is not actively updating data, InnoDB may still have modified data cached in memory and not flushed to disk.)

For an example of this backup method, refer to the export and import example in Section 13.2.6, “IMPORT TABLE Statement”.

Making Delimited-Text File Backups

To create a text file containing a table's data, you can use SELECT * INTO OUTFILE 'file_name' FROM tbl_name. The file is created on the MySQL server host, not the client host. For this statement, the output file cannot already exist because permitting files to be overwritten constitutes a security risk. See Section 13.2.13, “SELECT Statement”. This method works for any kind of data file, but saves only table data, not the table structure.

Another way to create text data files (along with files containing CREATE TABLE statements for the backed up tables) is to use mysqldump with the --tab option. See Section 7.4.3, “Dumping Data in Delimited-Text Format with mysqldump”.

To reload a delimited-text data file, use LOAD DATA or mysqlimport.

Making Incremental Backups by Enabling the Binary Log

MySQL supports incremental backups using the binary log. The binary log files provide you with the information you need to replicate changes to the database that are made subsequent to the point at which you performed a backup. Therefore, to allow a server to be restored to a point-in-time, binary logging must be enabled on it, which is the default setting for MySQL 8.2; see Section 5.4.4, “The Binary Log”.

At the moment you want to make an incremental backup (containing all changes that happened since the last full or incremental backup), you should rotate the binary log by using FLUSH LOGS. This done, you need to copy to the backup location all binary logs which range from the one of the moment of the last full or incremental backup to the last but one. These binary logs are the incremental backup; at restore time, you apply them as explained in Section 7.5, “Point-in-Time (Incremental) Recovery”. The next time you do a full backup, you should also rotate the binary log using FLUSH LOGS or mysqldump --flush-logs. See Section 4.5.4, “mysqldump — A Database Backup Program”.

Making Backups Using Replicas

If you have performance problems with a server while making backups, one strategy that can help is to set up replication and perform backups on the replica rather than on the source. See Section 17.4.1, “Using Replication for Backups”.

If you are backing up a replica, you should back up its connection metadata repository and applier metadata repository (see Section 17.2.4, “Relay Log and Replication Metadata Repositories”) when you back up the replica’s databases, regardless of the backup method you choose. This information is always needed to resume replication after you restore the replica’s data. If your replica is replicating LOAD DATA statements, you should also back up any SQL_LOAD-* files that exist in the directory that the replica uses for this purpose. The replica needs these files to resume replication of any interrupted LOAD DATA
Recovering Corrupt Tables

operations. The location of this directory is the value of the system variable `replica_load_tmpdir`. If the server was not started with that variable set, the directory location is the value of the `tmpdir` system variable.

Recovering Corrupt Tables

If you have to restore MyISAM tables that have become corrupt, try to recover them using `REPAIR TABLE` or `mysamchk -r` first. That should work in 99.9% of all cases. If `mysamchk` fails, see Section 7.6, “MyISAM Table Maintenance and Crash Recovery”.

Making Backups Using a File System Snapshot

If you are using a Veritas file system, you can make a backup like this:

1. From a client program, execute `FLUSH TABLES WITH READ LOCK`.
2. From another shell, execute `mount vxfs snapshot`.
3. From the first client, execute `UNLOCK TABLES`.
4. Copy files from the snapshot.
5. Unmount the snapshot.

Similar snapshot capabilities may be available in other file systems, such as LVM or ZFS.

7.3 Example Backup and Recovery Strategy

This section discusses a procedure for performing backups that enables you to recover data after several types of crashes:

- Operating system crash
- Power failure
- File system crash
- Hardware problem (hard drive, motherboard, and so forth)

The example commands do not include options such as `--user` and `--password` for the `mysqldump` and `mysql` client programs. You should include such options as necessary to enable client programs to connect to the MySQL server.

Assume that data is stored in the InnoDB storage engine, which has support for transactions and automatic crash recovery. Assume also that the MySQL server is under load at the time of the crash. If it were not, no recovery would ever be needed.

For cases of operating system crashes or power failures, we can assume that MySQL’s disk data is available after a restart. The InnoDB data files might not contain consistent data due to the crash, but InnoDB reads its logs and finds in them the list of pending committed and noncommitted transactions that have not been flushed to the data files. InnoDB automatically rolls back those transactions that were not committed, and flushes to its data files those that were committed. Information about this recovery process is conveyed to the user through the MySQL error log. The following is an example log excerpt:

```
InnoDB: Database was not shut down normally.
InnoDB: Starting recovery from log files...
```
Establishing a Backup Policy

For the cases of file system crashes or hardware problems, we can assume that the MySQL disk data is not available after a restart. This means that MySQL fails to start successfully because some blocks of disk data are no longer readable. In this case, it is necessary to reformat the disk, install a new one, or otherwise correct the underlying problem. Then it is necessary to recover our MySQL data from backups, which means that backups must already have been made. To make sure that is the case, design and implement a backup policy.

### 7.3.1 Establishing a Backup Policy

To be useful, backups must be scheduled regularly. A full backup (a snapshot of the data at a point in time) can be done in MySQL with several tools. For example, MySQL Enterprise Backup can perform a physical backup of an entire instance, with optimizations to minimize overhead and avoid disruption when backing up InnoDB data files; mysqldump provides online logical backup. This discussion uses mysqldump.

Assume that we make a full backup of all our InnoDB tables in all databases using the following command on Sunday at 1 p.m., when load is low:

```
$> mysqldump --all-databases --source-data --single-transaction > backup_sunday_1_PM.sql
```

The resulting .sql file produced by mysqldump contains a set of SQL INSERT statements that can be used to reload the dumped tables at a later time.

This backup operation acquires a global read lock on all tables at the beginning of the dump (using FLUSH TABLES WITH READ LOCK). As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If long updating statements are running when the FLUSH statement is issued, the backup operation may stall until those statements finish. After that, the dump becomes lock-free and does not disturb reads and writes on the tables.

It was assumed earlier that the tables to back up are InnoDB tables, so --single-transaction uses a consistent read and guarantees that data seen by mysqldump does not change. (Changes made by other clients to InnoDB tables are not seen by the mysqldump process.) If the backup operation includes nontransactional tables, consistency requires that they do not change during the backup. For example, for the MyISAM tables in the mysql database, there must be no administrative changes to MySQL accounts during the backup.

Full backups are necessary, but it is not always convenient to create them. They produce large backup files and take time to generate. They are not optimal in the sense that each successive full backup includes all data, even that part that has not changed since the previous full backup. It is more efficient to make an initial full backup, and then to make incremental backups. The incremental backups are smaller and take
less time to produce. The tradeoff is that, at recovery time, you cannot restore your data just by reloading the full backup. You must also process the incremental backups to recover the incremental changes.

To make incremental backups, we need to save the incremental changes. In MySQL, these changes are represented in the binary log, so the MySQL server should always be started with the --log-bin option to enable that log. With binary logging enabled, the server writes each data change into a file while it updates data. Looking at the data directory of a MySQL server that has been running for some days, we find these MySQL binary log files:

- rw-rw---- 1 guilhem guilhem  1277324 Nov 10 23:59 gbichot2-bin.000001
- rw-rw---- 1 guilhem guilhem   4 Nov 10 23:59 gbichot2-bin.000002
- rw-rw---- 1 guilhem guilhem    79 Nov 11 11:06 gbichot2-bin.000003
- rw-rw---- 1 guilhem guilhem   508 Nov 11 11:08 gbichot2-bin.000004
- rw-rw---- 1 guilhem guilhem 220047446 Nov 12 16:47 gbichot2-bin.000005
- rw-rw---- 1 guilhem guilhem  998412 Nov 14 10:08 gbichot2-bin.000006
- rw-rw---- 1 guilhem guilhem    361 Nov 14 10:07 gbichot2-bin.index

Each time it restarts, the MySQL server creates a new binary log file using the next number in the sequence. While the server is running, you can also tell it to close the current binary log file and begin a new one manually by issuing a FLUSH LOGS SQL statement or with a mysqladmin flush-logs command. mysqldump also has an option to flush the logs. The .index file in the data directory contains the list of all MySQL binary logs in the directory.

The MySQL binary logs are important for recovery because they form the set of incremental backups. If you make sure to flush the logs when you make your full backup, the binary log files created afterward contain all the data changes made since the backup. Let's modify the previous mysqldump command a bit so that it flushes the MySQL binary logs at the moment of the full backup, and so that the dump file contains the name of the new current binary log:

```
$> mysqldump --single-transaction --flush-logs --source-data=2 --all-databases > backup_sunday_1_PM.sql
```

After executing this command, the data directory contains a new binary log file, gbichot2-bin.000007, because the --flush-logs option causes the server to flush its logs. The --source-data option causes mysqldump to write binary log information to its output, so the resulting .sql dump file includes these lines:

```
-- Position to start replication or point-in-time recovery from
-- CHANGE REPLICATION SOURCE TO SOURCE_LOG_FILE='gbichot2-bin.000007',SOURCE_LOG_POS=4;
```

Because the mysqldump command made a full backup, those lines mean two things:

- The dump file contains all changes made before any changes written to the gbichot2-bin.000007 binary log file or higher.
- All data changes logged after the backup are not present in the dump file, but are present in the gbichot2-bin.000007 binary log file or higher.

On Monday at 1 p.m., we can create an incremental backup by flushing the logs to begin a new binary log file. For example, executing a mysqladmin flush-logs command creates gbichot2-bin.000008. All changes between the Sunday 1 p.m. full backup and Monday 1 p.m. are written in gbichot2-bin.000007. This incremental backup is important, so it is a good idea to copy it to a safe place. (For example, back it up on tape or DVD, or copy it to another machine.) On Tuesday at 1 p.m., execute another mysqladmin flush-logs command. All changes between Monday 1 p.m. and Tuesday 1 p.m. are written in gbichot2-bin.000008 (which also should be copied somewhere safe).

The MySQL binary logs take up disk space. To free up space, purge them from time to time. One way to do this is by deleting the binary logs that are no longer needed, such as when we make a full backup:
Using Backups for Recovery

```
$> mysqldump --single-transaction --flush-logs --source-data=2 --all-databases --delete-source-logs > backup_sunday_1_PM.sql
```

**Note**

Deleting the MySQL binary logs with `mysqldump --delete-source-logs` can be dangerous if your server is a replication source server, because replicas might not yet fully have processed the contents of the binary log. The description for the `PURGE BINARY LOGS` statement explains what should be verified before deleting the MySQL binary logs. See Section 13.4.1.1, “PURGE BINARY LOGS Statement”.

7.3.2 Using Backups for Recovery

Now, suppose that we have a catastrophic unexpected exit on Wednesday at 8 a.m. that requires recovery from backups. To recover, first we restore the last full backup we have (the one from Sunday 1 p.m.). The full backup file is just a set of SQL statements, so restoring it is very easy:

```
$> mysql < backup_sunday_1_PM.sql
```

At this point, the data is restored to its state as of Sunday 1 p.m.. To restore the changes made since then, we must use the incremental backups; that is, the `gbichot2-bin.000007` and `gbichot2-bin.000008` binary log files. Fetch the files if necessary from where they were backed up, and then process their contents like this:

```
$> mysqlbinlog gbichot2-bin.000007 gbichot2-bin.000008 | mysql
```

We now have recovered the data to its state as of Tuesday 1 p.m., but still are missing the changes from that date to the date of the crash. To not lose them, we would have needed to have the MySQL server store its MySQL binary logs into a safe location (RAID disks, SAN, ...) different from the place where it stores its data files, so that these logs were not on the destroyed disk. (That is, we can start the server with a `--log-bin` option that specifies a location on a different physical device from the one on which the data directory resides. That way, the logs are safe even if the device containing the directory is lost.) If we had done this, we would have the `gbichot2-bin.000009` file (and any subsequent files) at hand, and we could apply them using `mysqlbinlog` and `mysql` to restore the most recent data changes with no loss up to the moment of the crash:

```
$> mysqlbinlog gbichot2-bin.000009 ... | mysql
```

For more information about using `mysqlbinlog` to process binary log files, see Section 7.5, “Point-in-Time (Incremental) Recovery”.

7.3.3 Backup Strategy Summary

In case of an operating system crash or power failure, InnoDB itself does all the job of recovering data. But to make sure that you can sleep well, observe the following guidelines:

- Always turn the MySQL server with binary logging enabled (that is the default setting for MySQL 8.2). If you have such safe media, this technique can also be good for disk load balancing (which results in a performance improvement).
- Make periodic full backups, using the `mysqldump` command shown earlier in Section 7.3.1, “Establishing a Backup Policy”, that makes an online, nonblocking backup.
- Make periodic incremental backups by flushing the logs with `FLUSH LOGS` or `mysqladmin flush-logs`.

7.4 Using mysqldump for Backups
This section describes how to use `mysqldump` to produce dump files, and how to reload dump files. A dump file can be used in several ways:

- As a backup to enable data recovery in case of data loss.
- As a source of data for setting up replicas.
- As a source of data for experimentation:
  - To make a copy of a database that you can use without changing the original data.
  - To test potential upgrade incompatibilities.

`mysqldump` produces two types of output, depending on whether the `--tab` option is given:

- Without `--tab`, `mysqldump` writes SQL statements to the standard output. This output consists of `CREATE` statements to create dumped objects (databases, tables, stored routines, and so forth), and `INSERT` statements to load data into tables. The output can be saved in a file and reloaded later using `mysql` to recreate the dumped objects. Options are available to modify the format of the SQL statements, and to control which objects are dumped.

- With `--tab`, `mysqldump` produces two output files for each dumped table. The server writes one file as tab-delimited text, one line per table row. This file is named `tbl_name.txt` in the output directory. The server also sends a `CREATE TABLE` statement for the table to `mysqldump`, which writes it as a file named `tbl_name.sql` in the output directory.

### 7.4.1 Dumping Data in SQL Format with mysqldump

This section describes how to use `mysqldump` to create SQL-format dump files. For information about reloading such dump files, see Section 7.4.2, “Reloading SQL-Format Backups”.

By default, `mysqldump` writes information as SQL statements to the standard output. You can save the output in a file:

```
$> mysqldump [arguments] > file_name
```

To dump all databases, invoke `mysqldump` with the `--all-databases` option:

```
$> mysqldump --all-databases > dump.sql
```

To dump only specific databases, name them on the command line and use the `--databases` option:

```
$> mysqldump --databases db1 db2 db3 > dump.sql
```

The `--databases` option causes all names on the command line to be treated as database names. Without this option, `mysqldump` treats the first name as a database name and those following as table names.
Reloading SQL-Format Backups

With `--all-databases` or `--databases`, `mysqldump` writes `CREATE DATABASE` and `USE` statements prior to the dump output for each database. This ensures that when the dump file is reloaded, it creates each database if it does not exist and makes it the default database so database contents are loaded into the same database from which they came. If you want to cause the dump file to force a drop of each database before recreating it, use the `--add-drop-database` option as well. In this case, `mysqldump` writes a `DROP DATABASE` statement preceding each `CREATE DATABASE` statement.

To dump a single database, name it on the command line:

```
$> mysqldump --databases test > dump.sql
```

In the single-database case, it is permissible to omit the `--databases` option:

```
$> mysqldump test > dump.sql
```

The difference between the two preceding commands is that without `--databases`, the dump output contains no `CREATE DATABASE` or `USE` statements. This has several implications:

- When you reload the dump file, you must specify a default database name so that the server knows which database to reload.
- For reloading, you can specify a database name different from the original name, which enables you to reload the data into a different database.
- If the database to be reloaded does not exist, you must create it first.
- Because the output contains no `CREATE DATABASE` statement, the `--add-drop-database` option has no effect. If you use it, it produces no `DROP DATABASE` statement.

To dump only specific tables from a database, name them on the command line following the database name:

```
$> mysqldump test t1 t3 t7 > dump.sql
```

By default, if GTIDs are in use on the server where you create the dump file (`gtid_mode=ON`), `mysqldump` includes a `SET @@GLOBAL.gtid_purged` statement in the output to add the GTIDs from the `gtid_executed` set on the source server to the `gtid_purged` set on the target server. If you are dumping only specific databases or tables, it is important to note that the value that is included by `mysqldump` includes the GTIDs of all transactions in the `gtid_executed` set on the source server, even those that changed suppressed parts of the database, or other databases on the server that were not included in the partial dump. If you only replay one partial dump file on the target server, the extra GTIDs do not cause any problems with the future operation of that server. However, if you replay a second dump file on the target server that contains the same GTIDs (for example, another partial dump from the same source server), any `SET @@GLOBAL.gtid_purged` statement in the second dump file fails. To avoid this issue, either set the `mysqldump` option `--set-gtid-purged` to `OFF` or `COMMENTED` to output the second dump file without an active `SET @@GLOBAL.gtid_purged` statement, or remove the statement manually before replaying the dump file.

### 7.4.2 Reloading SQL-Format Backups

To reload a dump file written by `mysqldump` that consists of SQL statements, use it as input to the `mysql` client. If the dump file was created by `mysqldump` with the `--all-databases` or `--databases` option, it contains `CREATE DATABASE` and `USE` statements and it is not necessary to specify a default database into which to load the data:

```
$> mysql < dump.sql
```

Alternatively, from within `mysql`, use a `source` command:
Dumping Data in Delimited-Text Format with mysqldump

If the file is a single-database dump not containing `CREATE DATABASE` and `USE` statements, create the database first (if necessary):

```
$> mysqladmin create db1
```

Then specify the database name when you load the dump file:

```
$> mysql db1 < dump.sql
```

Alternatively, from within `mysql`, create the database, select it as the default database, and load the dump file:

```
mysql> CREATE DATABASE IF NOT EXISTS db1;
mysql> USE db1;
mysql> source dump.sql
```

Note
For Windows PowerShell users: Because the "<" character is reserved for future use in PowerShell, an alternative approach is required, such as using quotes `cmd.exe /c "mysql < dump.sql"`.

7.4.3 Dumping Data in Delimited-Text Format with mysqldump

This section describes how to use `mysqldump` to create delimited-text dump files. For information about reloading such dump files, see Section 7.4.4, "Reloading Delimited-Text Format Backups".

If you invoke `mysqldump` with the `--tab=dir_name` option, it uses `dir_name` as the output directory and dumps tables individually in that directory using two files for each table. The table name is the base name for these files. For a table named `t1`, the files are named `t1.sql` and `t1.txt`. The `.sql` file contains a `CREATE TABLE` statement for the table. The `.txt` file contains the table data, one line per table row.

The following command dumps the contents of the `db1` database to files in the `/tmp` database:

```
$> mysqldump --tab=/tmp db1
```

The `.txt` files containing table data are written by the server, so they are owned by the system account used for running the server. The server uses `SELECT ... INTO OUTFILE` to write the files, so you must have the `FILE` privilege to perform this operation, and an error occurs if a given `.txt` file already exists.

The server sends the `CREATE` definitions for dumped tables to `mysqldump`, which writes them to `.sql` files. These files therefore are owned by the user who executes `mysqldump`.

It is best that `--tab` be used only for dumping a local server. If you use it with a remote server, the `--tab` directory must exist on both the local and remote hosts, and the `.txt` files are written by the server in the remote directory (on the server host), whereas the `.sql` files are written by `mysqldump` in the local directory (on the client host).

For `mysqldump --tab`, the server by default writes table data to `.txt` files one line per row with tabs between column values, no quotation marks around column values, and newline as the line terminator. (These are the same defaults as for `SELECT ... INTO OUTFILE`.)

To enable data files to be written using a different format, `mysqldump` supports these options:

- `--fields-terminated-by=str`
  The string for separating column values (default: tab).
• `--fields-enclosed-by=char`
  The character within which to enclose column values (default: no character).

• `--fields-optionally-enclosed-by=char`
  The character within which to enclose non-numeric column values (default: no character).

• `--fields-escaped-by=char`
  The character for escaping special characters (default: no escaping).

• `--lines-terminated-by=str`
  The line-termination string (default: newline).

Depending on the value you specify for any of these options, it might be necessary on the command line to quote or escape the value appropriately for your command interpreter. Alternatively, specify the value using hex notation. Suppose that you want `mysqldump` to quote column values within double quotation marks. To do so, specify double quote as the value for the `--fields-enclosed-by` option. But this character is often special to command interpreters and must be treated specially. For example, on Unix, you can quote the double quote like this:

```
--fields-enclosed-by='"'
```

On any platform, you can specify the value in hex:

```
--fields-enclosed-by=0x22
```

It is common to use several of the data-formatting options together. For example, to dump tables in comma-separated values format with lines terminated by carriage-return/newline pairs (`\r\n`), use this command (enter it on a single line):

```
$> mysqldump --tab=/tmp --fields-terminated-by=,
               --fields-enclosed-by='"' --lines-terminated-by=0x0d0a db1
```

Should you use any of the data-formatting options to dump table data, you need to specify the same format when you reload data files later, to ensure proper interpretation of the file contents.

### 7.4.4 Reloading Delimited-Text Format Backups

For backups produced with `mysqldump --tab`, each table is represented in the output directory by a `.sql` file containing the `CREATE TABLE` statement for the table, and a `.txt` file containing the table data. To reload a table, first change location into the output directory. Then process the `.sql` file with `mysql` to create an empty table and process the `.txt` file to load the data into the table:

```
$> mysql db1 < t1.sql
$> mysqlimport db1 t1.txt
```

An alternative to using `mysqlimport` to load the data file is to use the `LOAD DATA` statement from within the `mysql` client:

```
mysql> USE db1;
mysql> LOAD DATA INFILE 't1.txt' INTO TABLE t1;
```

If you used any data-formatting options with `mysqldump` when you initially dumped the table, you must use the same options with `mysqlimport` or `LOAD DATA` to ensure proper interpretation of the data file contents:
mysqlimport --fields-terminated-by=, --fields-enclosed-by="" --lines-terminated-by=0x0d0a db1 t1.txt

Or:

mysql> USE db1;
mysql> LOAD DATA INFILE 't1.txt' INTO TABLE t1
FIELDS TERMINATED BY ',' FIELDS ENCLOSED BY '"'
LINES TERMINED BY '\r\n';

7.4.5 mysqldump Tips

This section surveys techniques that enable you to use `mysqldump` to solve specific problems:

- How to make a copy a database
- How to copy a database from one server to another
- How to dump stored programs (stored procedures and functions, triggers, and events)
- How to dump definitions and data separately

7.4.5.1 Making a Copy of a Database

```
$> mysqldump db1 > dump.sql
$> mysqladmin create db2
$> mysql db2 < dump.sql
```

Do not use `--databases` on the `mysqldump` command line because that causes `USE db1` to be included in the dump file, which overrides the effect of naming `db2` on the `mysql` command line.

7.4.5.2 Copy a Database from one Server to Another

On Server 1:

```
$> mysqldump --databases db1 > dump.sql
```

Copy the dump file from Server 1 to Server 2.

On Server 2:

```
$> mysql < dump.sql
```

Use of `--databases` with the `mysqldump` command line causes the dump file to include `CREATE DATABASE` and `USE` statements that create the database if it does exist and make it the default database for the reloaded data.

Alternatively, you can omit `--databases` from the `mysqldump` command. Then you need to create the database on Server 2 (if necessary) and specify it as the default database when you reload the dump file.

On Server 1:

```
$> mysqldump db1 > dump.sql
```

On Server 2:

```
$> mysqladmin create db1
$> mysql db1 < dump.sql
```

You can specify a different database name in this case, so omitting `--databases` from the `mysqldump` command enables you to dump data from one database and load it into another.
7.4.5.3 Dumping Stored Programs

Several options control how `mysqldump` handles stored programs (stored procedures and functions, triggers, and events):

- `--events`: Dump Event Scheduler events
- `--routines`: Dump stored procedures and functions
- `--triggers`: Dump triggers for tables

The `--triggers` option is enabled by default so that when tables are dumped, they are accompanied by any triggers they have. The other options are disabled by default and must be specified explicitly to dump the corresponding objects. To disable any of these options explicitly, use its skip form: `--skip-events`, `--skip-routines`, or `--skip-triggers`.

7.4.5.4 Dumping Table Definitions and Content Separately

The `--no-data` option tells `mysqldump` not to dump table data, resulting in the dump file containing only statements to create the tables. Conversely, the `--no-create-info` option tells `mysqldump` to suppress `CREATE` statements from the output, so that the dump file contains only table data.

For example, to dump table definitions and data separately for the `test` database, use these commands:

```sh
$> mysqldump --no-data test > dump-defs.sql
$> mysqldump --no-create-info test > dump-data.sql
```

For a definition-only dump, add the `--routines` and `--events` options to also include stored routine and event definitions:

```sh
$> mysqldump --no-data --routines --events test > dump-defs.sql
```

7.4.5.5 Using mysqldump to Test for Upgrade Incompatibilities

When contemplating a MySQL upgrade, it is prudent to install the newer version separately from your current production version. Then you can dump the database and database object definitions from the production server and load them into the new server to verify that they are handled properly. (This is also useful for testing downgrades.)

On the production server:

```sh
$> mysqldump --all-databases --no-data --routines --events > dump-defs.sql
```

On the upgraded server:

```sh
$> mysql < dump-defs.sql
```

Because the dump file does not contain table data, it can be processed quickly. This enables you to spot potential incompatibilities without waiting for lengthy data-loading operations. Look for warnings or errors while the dump file is being processed.

After you have verified that the definitions are handled properly, dump the data and try to load it into the upgraded server.

On the production server:

```sh
$> mysqldump --all-databases --no-create-info > dump-data.sql
```
On the upgraded server:

```bash
$ mysql < dump-data.sql
```

Now check the table contents and run some test queries.

### 7.5 Point-in-Time (Incremental) Recovery

Point-in-time recovery refers to recovery of data changes up to a given point in time. Typically, this type of recovery is performed after restoring a full backup that brings the server to its state as of the time the backup was made. (The full backup can be made in several ways, such as those listed in Section 7.2, “Database Backup Methods”.) Point-in-time recovery then brings the server up to date incrementally from the time of the full backup to a more recent time.

#### 7.5.1 Point-in-Time Recovery Using Binary Log

This section explains the general idea of using the binary log to perform a point-in-time-recovery. The next section, Section 7.5.2, “Point-in-Time Recovery Using Event Positions”, explains the operation in details with an example.

---

**Note**

Many of the examples in this and the next section use the `mysql` client to process binary log output produced by `mysqlbinlog`. If your binary log contains `\0` (null) characters, that output cannot be parsed by `mysql` unless you invoke it with the `--binary-mode` option.

---

The source of information for point-in-time recovery is the set of binary log files generated subsequent to the full backup operation. Therefore, to allow a server to be restored to a point-in-time, binary logging must be enabled on it, which is the default setting for MySQL 8.2 (see Section 5.4.4, “The Binary Log”).

To restore data from the binary log, you must know the name and location of the current binary log files. By default, the server creates binary log files in the data directory, but a path name can be specified with the `--log-bin` option to place the files in a different location. To see a listing of all binary log files, use this statement:

```sql
mysql> SHOW BINARY LOGS;
```

To determine the name of the current binary log file, issue the following statement:

```sql
mysql> SHOW BINARY LOG STATUS;
```

The `mysqlbinlog` utility converts the events in the binary log files from binary format to text so that they can be viewed or applied. `mysqlbinlog` has options for selecting sections of the binary log based on event times or position of events within the log. See Section 4.6.9, “mysqlbinlog — Utility for Processing Binary Log Files”.

Applying events from the binary log causes the data modifications they represent to be reexecuted. This enables recovery of data changes for a given span of time. To apply events from the binary log, process `mysqlbinlog` output using the `mysql` client:

```bash
$ mysqlbinlog binlog_files | mysql -u root -p
```

If binary log files have been encrypted, `mysqlbinlog` cannot read them directly as in the above example, but can read them from the server using the `--read-from-remote-server (-R)` option. For example:

```bash
$ mysqlbinlog --read-from-remote-server --host=host_name --port=3306 --user=root --password --ssl-mode=required binlog_files | mysql -u root -p
```
Here, the option `--ssl-mode=required` has been used to ensure that the data from the binary log files is protected in transit, because it is sent to `mysqlbinlog` in an unencrypted format.

**Important**

`VERIFY_CA` and `VERIFY_IDENTITY` are better choices than `REQUIRED` for the SSL mode, because they help prevent man-in-the-middle attacks. To implement one of these settings, you must first ensure that the CA certificate for the server is reliably available to all the clients that use it in your environment, otherwise availability issues will result. See [Command Options for Encrypted Connections](#).

Viewing log contents can be useful when you need to determine event times or positions to select partial log contents prior to executing events. To view events from the log, send `mysqlbinlog` output into a paging program:

```
$> mysqlbinlog binlog_files | more
```

Alternatively, save the output in a file and view the file in a text editor:

```
$> mysqlbinlog binlog_files > tmpfile
$> ... edit tmpfile ...
```

After editing the file, apply the contents as follows:

```
$> mysql -u root -p < tmpfile
```

If you have more than one binary log to apply on the MySQL server, use a single connection to apply the contents of all binary log files that you want to process. Here is one way to do so:

```
$> mysqlbinlog binlog.000001 binlog.000002 | mysql -u root -p
```

Another approach is to write the whole log to a single file and then process the file:

```
$> mysqlbinlog binlog.000001 > /tmp/statements.sql
$> mysqlbinlog binlog.000002 >> /tmp/statements.sql
$> mysql -u root -p -e "source /tmp/statements.sql"
```

### 7.5.2 Point-in-Time Recovery Using Event Positions

The last section, *Section 7.5.1, “Point-in-Time Recovery Using Binary Log”*, explains the general idea of using the binary log to perform a point-in-time-recovery. The section explains the operation in details with an example.

As an example, suppose that around 20:06:00 on March 11, 2020, an SQL statement was executed that deleted a table. You can perform a point-in-time recovery to restore the server up to its state right before the table deletion. These are some sample steps to achieve that:

1. Restore the last full backup created before the point-in-time of interest (call it $t_p$, which is 20:06:00 on March 11, 2020 in our example). When finished, note the binary log position up to which you have restored the server for later use, and restart the server.

**Note**

While the last binary log position recovered is also displayed by InnoDB after the restore and server restart, that is *not* a reliable means for obtaining the ending log position of your restore, as there could be DDL events and non-InnoDB changes that have taken place after the time reflected by the displayed position. Your backup and restore tool should provide you with the last binary...
Point-in-Time Recovery Using Event Positions

log position for your recovery: for example, if you are using `mysqlbinlog` for the task, check the stop position of the binary log replay; if you are using MySQL Enterprise Backup, the last binary log position has been saved in your backup. See Point-in-Time Recovery.

2. Find the precise binary log event position corresponding to the point in time up to which you want to restore your database. In our example, given that we know the rough time where the table deletion took place ($t_p$), we can find the log position by checking the log contents around that time using the `mysqlbinlog` utility. Use the `--start-datetime` and `--stop-datetime` options to specify a short time period around $t_p$, and then look for the event in the output. For example:

```
$> mysqlbinlog --start-datetime="2020-03-11 20:05:00" \
    --stop-datetime="2020-03-11 20:08:00" --verbose \
    /var/lib/mysql/bin.123456 | grep 'DROP TABLE'
```

```

```

From the output of `mysqlbinlog`, the `DROP TABLE `pets`.'cats'` statement can be found in the segment of the binary log between the line # at 232 and # at 355, which means the statement takes place after the log position 232, and the log is at position 355 after the `DROP TABLE` statement.

Note

Only use the `--start-datetime` and `--stop-datetime` options to help you find the actual event positions of interest. Using the two options to specify the range of binary log segment to apply is not recommended: there is a higher risk of missing binary log events when using the options. Use `--start-position` and `--stop-position` instead.

3. Apply the events in binary log file to the server, starting with the log position you found in step 1 (assume it is 155) and ending at the position you have found in step 2 that is before your point-in-time of interest (which is 232):
MyISAM Table Maintenance and Crash Recovery

```
$> mysqlbinlog --start-position=155 --stop-position=232 /var/lib/mysql/bin.123456 \\
| mysql -u root -p
```

The command recovers all the transactions from the starting position until just before the stop position. Because the output of `mysqlbinlog` includes `SET TIMESTAMP` statements before each SQL statement recorded, the recovered data and related MySQL logs reflect the original times at which the transactions were executed.

Your database has now been restored to the point-in-time of interest, \( t_p \), right before the table `pets.cats` was dropped.

4. Beyond the point-in-time recovery that has been finished, if you also want to reexecute all the statements after your point-in-time of interest, use `mysqlbinlog` again to apply all the events after \( t_p \) to the server. We noted in step 2 that after the statement we wanted to skip, the log is at position 355; we can use it for the `--start-position` option, so that any statements after the position are included:

```
$> mysqlbinlog --start-position=355 /var/lib/mysql/bin.123456 \\
| mysql -u root -p
```

Your database has been restored the latest statement recorded in the binary log file, but with the selected event skipped.

#### 7.6 MyISAM Table Maintenance and Crash Recovery

This section discusses how to use `myisamchk` to check or repair MyISAM tables (tables that have `.MYD` and `.MYI` files for storing data and indexes). For general `myisamchk` background, see Section 4.6.4, “myisamchk — MyISAM Table-Maintenance Utility”. Other table-repair information can be found at Section 2.10.13, “Rebuilding or Repairing Tables or Indexes”.

You can use `myisamchk` to check, repair, or optimize database tables. The following sections describe how to perform these operations and how to set up a table maintenance schedule. For information about using `myisamchk` to get information about your tables, see Section 4.6.4.5, “Obtaining Table Information with `myisamchk`”.

Even though table repair with `myisamchk` is quite secure, it is always a good idea to make a backup before doing a repair or any maintenance operation that could make a lot of changes to a table.

`myisamchk` operations that affect indexes can cause MyISAM FULLTEXT indexes to be rebuilt with full-text parameters that are incompatible with the values used by the MySQL server. To avoid this problem, follow the guidelines in Section 4.6.4.1, “myisamchk General Options”.

MyISAM table maintenance can also be done using the SQL statements that perform operations similar to what `myisamchk` can do:

- To check MyISAM tables, use `CHECK TABLE`.
- To repair MyISAM tables, use `REPAIR TABLE`.
- To optimize MyISAM tables, use `OPTIMIZE TABLE`.
- To analyze MyISAM tables, use `ANALYZE TABLE`.

For additional information about these statements, see Section 13.7.3, “Table Maintenance Statements”.

These statements can be used directly or by means of the `mysqlcheck` client program. One advantage of these statements over `myisamchk` is that the server does all the work. With `myisamchk`, you must
make sure that the server does not use the tables at the same time so that there is no unwanted interaction between `myisamchk` and the server.

### 7.6.1 Using myisamchk for Crash Recovery

This section describes how to check for and deal with data corruption in MySQL databases. If your tables become corrupted frequently, you should try to find the reason why. See Section B.3.3.3, “What to Do If MySQL Keeps Crashing”.

For an explanation of how MyISAM tables can become corrupted, see Section 16.2.4, “MyISAM Table Problems”.

If you run `mysqld` with external locking disabled (which is the default), you cannot reliably use `myisamchk` to check a table when `mysqld` is using the same table. If you can be certain that no one can access the tables using `mysqld` while you run `myisamchk`, you only have to execute `mysqladmin flush-tables` before you start checking the tables. If you cannot guarantee this, you must stop `mysqld` while you check the tables. If you run `myisamchk` to check tables that `mysqld` is updating at the same time, you may get a warning that a table is corrupt even when it is not.

If the server is run with external locking enabled, you can use `myisamchk` to check tables at any time. In this case, if the server tries to update a table that `myisamchk` is using, the server waits for `myisamchk` to finish before it continues.

If you use `myisamchk` to repair or optimize tables, you must always ensure that the `mysqld` server is not using the table (this also applies if external locking is disabled). If you do not stop `mysqld`, you should at least do a `mysqladmin flush-tables` before you run `myisamchk`. Your tables may become corrupted if the server and `myisamchk` access the tables simultaneously.

When performing crash recovery, it is important to understand that each MyISAM table `tbl_name` in a database corresponds to the three files in the database directory shown in the following table.

<table>
<thead>
<tr>
<th>File</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>tbl_name.MYD</code></td>
<td>Data file</td>
</tr>
<tr>
<td><code>tbl_name.MYI</code></td>
<td>Index file</td>
</tr>
</tbody>
</table>

Each of these three file types is subject to corruption in various ways, but problems occur most often in data files and index files.

`myisamchk` works by creating a copy of the `.MYD` data file row by row. It ends the repair stage by removing the old `.MYD` file and renaming the new file to the original file name. If you use `--quick`, `myisamchk` does not create a temporary `.MYD` file, but instead assumes that the `.MYD` file is correct and generates only a new index file without touching the `.MYD` file. This is safe, because `myisamchk` automatically detects whether the `.MYD` file is corrupt and aborts the repair if it is. You can also specify the `--quick` option twice to `myisamchk`. In this case, `myisamchk` does not abort on some errors (such as duplicate-key errors) but instead tries to resolve them by modifying the `.MYD` file. Normally the use of two `--quick` options is useful only if you have too little free disk space to perform a normal repair. In this case, you should at least make a backup of the table before running `myisamchk`.

### 7.6.2 How to Check MyISAM Tables for Errors

To check a MyISAM table, use the following commands:

- `mysqldump tbl_name`

```bash
mysqldump tbl_name
```
How to Repair MyISAM Tables

This finds 99.99% of all errors. What it cannot find is corruption that involves only the data file (which is very unusual). If you want to check a table, you should normally run `myisamchk` without options or with the `–s` (silent) option.

- `myisamchk -m tbl_name`
  This finds 99.999% of all errors. It first checks all index entries for errors and then reads through all rows. It calculates a checksum for all key values in the rows and verifies that the checksum matches the checksum for the keys in the index tree.

- `myisamchk -e tbl_name`
  This does a complete and thorough check of all data (`-e` means "extended check"). It does a check-read of every key for each row to verify that they indeed point to the correct row. This may take a long time for a large table that has many indexes. Normally, `myisamchk` stops after the first error it finds. If you want to obtain more information, you can add the `–v` (verbose) option. This causes `myisamchk` to keep going, up through a maximum of 20 errors.

- `myisamchk -e -i tbl_name`
  This is like the previous command, but the `–i` option tells `myisamchk` to print additional statistical information.

In most cases, a simple `myisamchk` command with no arguments other than the table name is sufficient to check a table.

### 7.6.3 How to Repair MyISAM Tables

The discussion in this section describes how to use `myisamchk` on MyISAM tables (extensions `.MYI` and `.MYD`).

You can also use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair MyISAM tables. See Section 13.7.3.2, "CHECK TABLE Statement", and Section 13.7.3.5, "REPAIR TABLE Statement".

Symptoms of corrupted tables include queries that abort unexpectedly and observable errors such as these:

- Can't find file `tbl_name.MYI` (Errcode: `nnn`)
- Unexpected end of file
- Record file is crashed
- Got error `nnn` from table handler

To get more information about the error, run `perror nnn`, where `nnn` is the error number. The following example shows how to use `perror` to find the meanings for the most common error numbers that indicate a problem with a table:

```
$> perror 126 127 132 134 135 136 141 144 145
MySQL error code 126 = Index file is crashed
MySQL error code 127 = Record-file is crashed
MySQL error code 132 = Old database file
MySQL error code 134 = Record was already deleted (or record file crashed)
MySQL error code 135 = No more room in record file
MySQL error code 136 = No more room in index file
MySQL error code 141 = Duplicate unique key or constraint on write or update
MySQL error code 144 = Table is crashed and last repair failed
```
How to Repair MyISAM Tables

MySQL error code 145 = Table was marked as crashed and should be repaired

Note that error 135 (no more room in record file) and error 136 (no more room in index file) are not errors that can be fixed by a simple repair. In this case, you must use ALTER TABLE to increase the MAX_ROWS and AVG_ROW_LENGTH table option values:

```
ALTER TABLE tbl_name MAX_ROWS=xxx AVG_ROW_LENGTH=yyy;
```

If you do not know the current table option values, use SHOW CREATE TABLE.

For the other errors, you must repair your tables. myisamchk can usually detect and fix most problems that occur.

The repair process involves up to three stages, described here. Before you begin, you should change location to the database directory and check the permissions of the table files. On Unix, make sure that they are readable by the user that mysqld runs as (and to you, because you need to access the files you are checking). If it turns out you need to modify files, they must also be writable by you.

This section is for the cases where a table check fails (such as those described in Section 7.6.2, “How to Check MyISAM Tables for Errors”), or you want to use the extended features that myisamchk provides.

The myisamchk options used for table maintenance with are described in Section 4.6.4, “myisamchk — MyISAM Table-Maintenance Utility”. myisamchk also has variables that you can set to control memory allocation that may improve performance. See Section 4.6.4.6, “myisamchk Memory Usage”.

If you are going to repair a table from the command line, you must first stop the mysqld server. Note that when you do mysqladmin shutdown on a remote server, the mysqld server is still available for a while after mysqladmin returns, until all statement-processing has stopped and all index changes have been flushed to disk.

**Stage 1: Checking your tables**

Run myisamchk *.MYI or myisamchk -e *.MYI if you have more time. Use the -s (silent) option to suppress unnecessary information.

If the mysqld server is stopped, you should use the --update-state option to tell myisamchk to mark the table as “checked.”

You have to repair only those tables for which myisamchk announces an error. For such tables, proceed to Stage 2.

If you get unexpected errors when checking (such as out of memory errors), or if myisamchk crashes, go to Stage 3.

**Stage 2: Easy safe repair**

First, try myisamchk -r -q tbl_name (-r -q means “quick recovery mode”). This attempts to repair the index file without touching the data file. If the data file contains everything that it should and the delete links point at the correct locations within the data file, this should work, and the table is fixed. Start repairing the next table. Otherwise, use the following procedure:

1. Make a backup of the data file before continuing.
2. Use myisamchk -r tbl_name (-r means “recovery mode”). This removes incorrect rows and deleted rows from the data file and reconstructs the index file.
3. If the preceding step fails, use myisamchk --safe-recover tbl_name. Safe recovery mode uses an old recovery method that handles a few cases that regular recovery mode does not (but is slower).
### 7.6.4 MyISAM Table Optimization

To coalesce fragmented rows and eliminate wasted space that results from deleting or updating rows, run `myisamchk` in recovery mode:

```
$> myisamchk -r tbl_name
```

You can optimize a table in the same way by using the `OPTIMIZE TABLE` SQL statement. `OPTIMIZE TABLE` does a table repair and a key analysis, and also sorts the index tree so that key lookups are faster. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use `OPTIMIZE TABLE`. See Section 13.7.3.4, “OPTIMIZE TABLE Statement”.

`myisamchk` has a number of other options that you can use to improve the performance of a table:

- `--analyze` or `-a`: Perform key distribution analysis. This improves join performance by enabling the join optimizer to better choose the order in which to join the tables and which indexes it should use.
• \texttt{--sort-index} or \texttt{-S}: Sort the index blocks. This optimizes seeks and makes table scans that use indexes faster.

• \texttt{--sort-records=index\_num} or \texttt{-R index\_num}: Sort data rows according to a given index. This makes your data much more localized and may speed up range-based \texttt{SELECT} and \texttt{ORDER BY} operations that use this index.

For a full description of all available options, see Section 4.6.4, “myisamchk — MyISAM Table-Maintenance Utility”.

### 7.6.5 Setting Up a MyISAM Table Maintenance Schedule

It is a good idea to perform table checks on a regular basis rather than waiting for problems to occur. One way to check and repair MyISAM tables is with the \texttt{CHECK TABLE} and \texttt{REPAIR TABLE} statements. See Section 13.7.3, “Table Maintenance Statements”.

Another way to check tables is to use \texttt{myisamchk}. For maintenance purposes, you can use \texttt{myisamchk \texttt{-s}}. The \texttt{-s} option (short for \texttt{--silent}) causes \texttt{myisamchk} to run in silent mode, printing messages only when errors occur.

It is also a good idea to enable automatic MyISAM table checking. For example, whenever the machine has done a restart in the middle of an update, you usually need to check each table that could have been affected before it is used further. (These are “expected crashed tables.”) To cause the server to check MyISAM tables automatically, start it with the \texttt{myisam\_recover\_options} system variable set. See Section 5.1.8, “Server System Variables”.

You should also check your tables regularly during normal system operation. For example, you can run a \texttt{cron} job to check important tables once a week, using a line like this in a \texttt{crontab} file:

```
35 0 * * 0 /path/to/myisamchk --fast --silent /path/to/datadir/*//*.MYI
```

This prints out information about crashed tables so that you can examine and repair them as necessary.

To start with, execute \texttt{myisamchk \texttt{-s}} each night on all tables that have been updated during the last 24 hours. As you see that problems occur infrequently, you can back off the checking frequency to once a week or so.

Normally, MySQL tables need little maintenance. If you are performing many updates to MyISAM tables with dynamic-sized rows (tables with \texttt{VARCHAR}, \texttt{BLOB}, or \texttt{TEXT} columns) or have tables with many deleted rows you may want to defragment/reclaim space from the tables from time to time. You can do this by using \texttt{OPTIMIZE TABLE} on the tables in question. Alternatively, if you can stop the \texttt{mysqld} server for a while, change location into the data directory and use this command while the server is stopped:

```
$> myisamchk \texttt{-r \texttt{-s \texttt{-sort-index \texttt{-myisam\_sort\_buffer\_size=16M}}}} */*.MYI
```

This chapter explains how to optimize MySQL performance and provides examples. Optimization involves configuring, tuning, and measuring performance, at several levels. Depending on your job role (developer, DBA, or a combination of both), you might optimize at the level of individual SQL statements, entire applications, a single database server, or multiple networked database servers. Sometimes you can be proactive and plan in advance for performance, while other times you might troubleshoot a configuration or code issue after a problem occurs. Optimizing CPU and memory usage can also improve scalability, allowing the database to handle more load without slowing down.
8.1 Optimization Overview

Database performance depends on several factors at the database level, such as tables, queries, and configuration settings. These software constructs result in CPU and I/O operations at the hardware level, which you must minimize and make as efficient as possible. As you work on database performance, you start by learning the high-level rules and guidelines for the software side, and measuring performance using wall-clock time. As you become an expert, you learn more about what happens internally, and start measuring things such as CPU cycles and I/O operations.

Typical users aim to get the best database performance out of their existing software and hardware configurations. Advanced users look for opportunities to improve the MySQL software itself, or develop their own storage engines and hardware appliances to expand the MySQL ecosystem.

- Optimizing at the Database Level
- Optimizing at the Hardware Level
- Balancing Portability and Performance

Optimizing at the Database Level

The most important factor in making a database application fast is its basic design:

- Are the tables structured properly? In particular, do the columns have the right data types, and does each table have the appropriate columns for the type of work? For example, applications that perform frequent updates often have many tables with few columns, while applications that analyze large amounts of data often have few tables with many columns.

- Are the right indexes in place to make queries efficient?

- Are you using the appropriate storage engine for each table, and taking advantage of the strengths and features of each storage engine you use? In particular, the choice of a transactional storage engine such as InnoDB or a nontransactional one such as MyISAM can be very important for performance and scalability.

  **Note**

  InnoDB is the default storage engine for new tables. In practice, the advanced InnoDB performance features mean that InnoDB tables often outperform the simpler MyISAM tables, especially for a busy database.

- Does each table use an appropriate row format? This choice also depends on the storage engine used for the table. In particular, compressed tables use less disk space and so require less disk I/O to read and write the data. Compression is available for all kinds of workloads with InnoDB tables, and for read-only MyISAM tables.

- Does the application use an appropriate locking strategy? For example, by allowing shared access when possible so that database operations can run concurrently, and requesting exclusive access when appropriate so that critical operations get top priority. Again, the choice of storage engine is significant. The InnoDB storage engine handles most locking issues without involvement from you, allowing for better concurrency in the database and reducing the amount of experimentation and tuning for your code.

- Are all memory areas used for caching sized correctly? That is, large enough to hold frequently accessed data, but not so large that they overload physical memory and cause paging. The main memory areas to configure are the InnoDB buffer pool and the MyISAM key cache.
Optimizing at the Hardware Level

Any database application eventually hits hardware limits as the database becomes more and more busy. A DBA must evaluate whether it is possible to tune the application or reconfigure the server to avoid these bottlenecks, or whether more hardware resources are required. System bottlenecks typically arise from these sources:

- Disk seeks. It takes time for the disk to find a piece of data. With modern disks, the mean time for this is usually lower than 10ms, so we can in theory do about 100 seeks a second. This time improves slowly with new disks and is very hard to optimize for a single table. The way to optimize seek time is to distribute the data onto more than one disk.

- Disk reading and writing. When the disk is at the correct position, we need to read or write the data. With modern disks, one disk delivers at least 10–20MB/s throughput. This is easier to optimize than seeks because you can read in parallel from multiple disks.

- CPU cycles. When the data is in main memory, we must process it to get our result. Having large tables compared to the amount of memory is the most common limiting factor. But with small tables, speed is usually not the problem.

- Memory bandwidth. When the CPU needs more data than can fit in the CPU cache, main memory bandwidth becomes a bottleneck. This is an uncommon bottleneck for most systems, but one to be aware of.

Balancing Portability and Performance

To use performance-oriented SQL extensions in a portable MySQL program, you can wrap MySQL-specific keywords in a statement within /*! */ comment delimiters. Other SQL servers ignore the commented keywords. For information about writing comments, see Section 9.7, “Comments”.

8.2 Optimizing SQL Statements

The core logic of a database application is performed through SQL statements, whether issued directly through an interpreter or submitted behind the scenes through an API. The tuning guidelines in this section help to speed up all kinds of MySQL applications. The guidelines cover SQL operations that read and write data, the behind-the-scenes overhead for SQL operations in general, and operations used in specific scenarios such as database monitoring.

8.2.1 Optimizing SELECT Statements

Queries, in the form of SELECT statements, perform all the lookup operations in the database. Tuning these statements is a top priority, whether to achieve sub-second response times for dynamic web pages, or to chop hours off the time to generate huge overnight reports.

Besides SELECT statements, the tuning techniques for queries also apply to constructs such as CREATE TABLE...AS SELECT, INSERT INTO...SELECT, and WHERE clauses in DELETE statements. Those statements have additional performance considerations because they combine write operations with the read-oriented query operations.

NDB Cluster supports a join pushdown optimization whereby a qualifying join is sent in its entirety to NDB Cluster data nodes, where it can be distributed among them and executed in parallel. For more information about this optimization, see Conditions for NDB pushdown joins.

The main considerations for optimizing queries are:
• To make a slow `SELECT ... WHERE` query faster, the first thing to check is whether you can add an index. Set up indexes on columns used in the `WHERE` clause, to speed up evaluation, filtering, and the final retrieval of results. To avoid wasted disk space, construct a small set of indexes that speed up many related queries used in your application.

Indexes are especially important for queries that reference different tables, using features such as joins and foreign keys. You can use the `EXPLAIN` statement to determine which indexes are used for a `SELECT`. See Section 8.3.1, “How MySQL Uses Indexes” and Section 8.8.1, “Optimizing Queries with `EXPLAIN`”.

• Isolate and tune any part of the query, such as a function call, that takes excessive time. Depending on how the query is structured, a function could be called once for every row in the result set, or even once for every row in the table, greatly magnifying any inefficiency.

• Minimize the number of full table scans in your queries, particularly for big tables.

• Keep table statistics up to date by using the `ANALYZE TABLE` statement periodically, so the optimizer has the information needed to construct an efficient execution plan.

• Learn the tuning techniques, indexing techniques, and configuration parameters that are specific to the storage engine for each table. Both `InnoDB` and `MyISAM` have sets of guidelines for enabling and sustaining high performance in queries. For details, see Section 8.5.6, “Optimizing InnoDB Queries” and Section 8.6.1, “Optimizing MyISAM Queries”.

• You can optimize single-query transactions for `InnoDB` tables, using the technique in Section 8.5.3, “Optimizing InnoDB Read-Only Transactions”.

• Avoid transforming the query in ways that make it hard to understand, especially if the optimizer does some of the same transformations automatically.

• If a performance issue is not easily solved by one of the basic guidelines, investigate the internal details of the specific query by reading the `EXPLAIN` plan and adjusting your indexes, `WHERE` clauses, join clauses, and so on. (When you reach a certain level of expertise, reading the `EXPLAIN` plan might be your first step for every query.)

• Adjust the size and properties of the memory areas that MySQL uses for caching. With efficient use of the `InnoDB buffer pool`, `MyISAM` key cache, and the MySQL query cache, repeated queries run faster because the results are retrieved from memory the second and subsequent times.

• Even for a query that runs fast using the cache memory areas, you might still optimize further so that they require less cache memory, making your application more scalable. Scalability means that your application can handle more simultaneous users, larger requests, and so on without experiencing a big drop in performance.

• Deal with locking issues, where the speed of your query might be affected by other sessions accessing the tables at the same time.

### 8.2.1.1 WHERE Clause Optimization

This section discusses optimizations that can be made for processing `WHERE` clauses. The examples use `SELECT` statements, but the same optimizations apply for `WHERE` clauses in `DELETE` and `UPDATE` statements.

**Note**

Because work on the MySQL optimizer is ongoing, not all of the optimizations that MySQL performs are documented here.
You might be tempted to rewrite your queries to make arithmetic operations faster, while sacrificing readability. Because MySQL does similar optimizations automatically, you can often avoid this work, and leave the query in a more understandable and maintainable form. Some of the optimizations performed by MySQL follow:

- **Removal of unnecessary parentheses:**

  
  
  ```sql
  ((a AND b) AND c OR (((a AND b) AND (c AND d))))
  ```

  
  
  ```sql
  (a AND b AND c) OR (a AND b AND c AND d)
  ```

- **Constant folding:**

  
  
  ```sql
  (a<b AND b=c) AND a=5
  ```

  
  
  ```sql
  b>5 AND b=c AND a=5
  ```

- **Constant condition removal:**

  
  
  ```sql
  (b>=5 AND b=5) OR (b=6 AND 5=5) OR (b=7 AND 5=6)
  ```

  
  
  ```sql
  b=5 OR b=6
  ```

This takes place during preparation rather than during the optimization phase, which helps in simplification of joins. See Section 8.2.1.9, “Outer Join Optimization”, for further information and examples.

- **Constant expressions used by indexes are evaluated only once.**

- **Comparisons of columns of numeric types with constant values are checked and folded or removed for invalid or out-of-range values:**

  
  
  ```sql
  # CREATE TABLE t (c TINYINT UNSIGNED NOT NULL);
  SELECT * FROM t WHERE c < 256;
  ```

  
  
  ```sql
  SELECT * FROM t WHERE 1;
  ```

  See Section 8.2.1.14, “Constant-Folding Optimization”, for more information.

- **COUNT(∗) on a single table without a WHERE is retrieved directly from the table information for MyISAM and MEMORY tables. This is also done for any NOT NULL expression when used with only one table.**

- **Early detection of invalid constant expressions. MySQL quickly detects that some SELECT statements are impossible and returns no rows.**

- **HAVING is merged with WHERE if you do not use GROUP BY or aggregate functions (COUNT(), MIN(), and so on).**

- For each table in a join, a simpler WHERE is constructed to get a fast WHERE evaluation for the table and also to skip rows as soon as possible.

- All constant tables are read first before any other tables in the query. A constant table is any of the following:

  - An empty table or a table with one row.
  
  - A table that is used with a WHERE clause on a PRIMARY KEY or a UNIQUE index, where all index parts are compared to constant expressions and are defined as NOT NULL.

All of the following tables are used as constant tables:

```sql
SELECT * FROM t WHERE primary_key=1;
SELECT * FROM t1,t2
WHERE t1.primary_key=1 AND t2.primary_key=t1.id;
```
Optimizing SELECT Statements

• The best join combination for joining the tables is found by trying all possibilities. If all columns in ORDER
BY and GROUP BY clauses come from the same table, that table is preferred first when joining.

• If there is an ORDER BY clause and a different GROUP BY clause, or if the ORDER BY or GROUP BY
contains columns from tables other than the first table in the join queue, a temporary table is created.

• If you use the SQL_SMALL_RESULT modifier, MySQL uses an in-memory temporary table.

• Each table index is queried, and the best index is used unless the optimizer believes that it is more
efficient to use a table scan. At one time, a scan was used based on whether the best index spanned
more than 30% of the table, but a fixed percentage no longer determines the choice between using an
index or a scan. The optimizer now is more complex and bases its estimate on additional factors such as
table size, number of rows, and I/O block size.

• In some cases, MySQL can read rows from the index without even consulting the data file. If all columns
used from the index are numeric, only the index tree is used to resolve the query.

• Before each row is output, those that do not match the HAVING clause are skipped.

Some examples of queries that are very fast:

```sql
SELECT COUNT(*) FROM tbl_name;
SELECT MIN(key_part1), MAX(key_part1) FROM tbl_name;
SELECT MAX(key_part2) FROM tbl_name
  WHERE key_part1 = constant;
SELECT ... FROM tbl_name
  ORDER BY key_part1, key_part2, ... LIMIT 10;
SELECT ... FROM tbl_name
  ORDER BY key_part1 DESC, key_part2 DESC, ... LIMIT 10;
```

MySQL resolves the following queries using only the index tree, assuming that the indexed columns are
numeric:

```sql
SELECT key_part1, key_part2 FROM tbl_name WHERE key_part1 = val;
SELECT COUNT(*) FROM tbl_name
  WHERE key_part1 = val1 AND key_part2 = val2;
SELECT MAX(key_part2) FROM tbl_name GROUP BY key_part1;
```

The following queries use indexing to retrieve the rows in sorted order without a separate sorting pass:

```sql
SELECT ... FROM tbl_name
  ORDER BY key_part1, key_part2, ... ;
SELECT ... FROM tbl_name
  ORDER BY key_part1 DESC, key_part2 DESC, ... ;
```

### 8.2.1.2 Range Optimization

The range access method uses a single index to retrieve a subset of table rows that are contained within
one or several index value intervals. It can be used for a single-part or multiple-part index. The following
sections describe conditions under which the optimizer uses range access.

• Range Access Method for Single-Part Indexes

• Range Access Method for Multiple-Part Indexes
Optimizing SELECT Statements

- Equality Range Optimization of Many-Valued Comparisons
- Skip Scan Range Access Method
- Range Optimization of Row Constructor Expressions
- Limiting Memory Use for Range Optimization

Range Access Method for Single-Part Indexes

For a single-part index, index value intervals can be conveniently represented by corresponding conditions in the \texttt{WHERE} clause, denoted as \textit{range conditions} rather than “intervals.”

The definition of a range condition for a single-part index is as follows:

- For both \texttt{BTREE} and \texttt{HASH} indexes, comparison of a key part with a constant value is a range condition when using the \texttt{=}, \texttt{<>}, \texttt{IN()}, \texttt{IS NULL}, or \texttt{IS NOT NULL} operators.

- Additionally, for \texttt{BTREE} indexes, comparison of a key part with a constant value is a range condition when using the \texttt{>}, \texttt{<}, \texttt{>=}, \texttt{<=}, \texttt{BETWEEN}, \texttt{! =}, or \texttt{<>} operators, or \texttt{LIKE} comparisons if the argument to \texttt{LIKE} is a constant string that does not start with a wildcard character.

- For all index types, multiple range conditions combined with \texttt{OR} or \texttt{AND} form a range condition.

“Constant value” in the preceding descriptions means one of the following:

- A constant from the query string
- A column of a \texttt{const} or \texttt{system} table from the same join
- The result of an uncorrelated subquery
- Any expression composed entirely from subexpressions of the preceding types

Here are some examples of queries with range conditions in the \texttt{WHERE} clause:

```sql
SELECT * FROM t1
   WHERE key_col > 1
   AND key_col < 10;
SELECT * FROM t1
   WHERE key_col = 1
   OR key_col IN (15,18,20);
SELECT * FROM t1
   WHERE key_col LIKE 'ab%' 
   OR key_col BETWEEN 'bar' AND 'foo';
```

Some nonconstant values may be converted to constants during the optimizer constant propagation phase.

MySQL tries to extract range conditions from the \texttt{WHERE} clause for each of the possible indexes. During the extraction process, conditions that cannot be used for constructing the range condition are dropped, conditions that produce overlapping ranges are combined, and conditions that produce empty ranges are removed.

Consider the following statement, where \texttt{key1} is an indexed column and \texttt{nonkey} is not indexed:

```sql
SELECT * FROM t1 WHERE
  (key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
  (key1 < 'bar' AND nonkey = 4) OR
  (key1 < 'uux' AND key1 > 'z');
```
Optimizing SELECT Statements

The extraction process for key `key1` is as follows:

1. Start with original `WHERE` clause:
   ```sql
   (key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%$b')) OR
   (key1 < 'bar' AND nonkey = 4) OR
   (key1 < 'uux' AND key1 > 'z')
   ```

2. Remove `nonkey = 4` and `key1 LIKE '%$b'` because they cannot be used for a range scan. The correct way to remove them is to replace them with `TRUE`, so that we do not miss any matching rows when doing the range scan. Replacing them with `TRUE` yields:
   ```sql
   (key1 < 'abc' AND (key1 LIKE 'abcde%' OR TRUE)) OR
   (key1 < 'bar' AND TRUE) OR
   (key1 < 'uux' AND key1 > 'z')
   ```

3. Collapse conditions that are always true or false:
   - `(key1 LIKE 'abcde%' OR TRUE)` is always true
   - `(key1 < 'uux' AND key1 > 'z')` is always false
   
   Replacing these conditions with constants yields:
   ```sql
   (key1 < 'abc' AND TRUE) OR (key1 < 'bar' AND TRUE) OR (FALSE)
   ```

   Removing unnecessary `TRUE` and `FALSE` constants yields:
   ```sql
   (key1 < 'abc') OR (key1 < 'bar')
   ```

4. Combining overlapping intervals into one yields the final condition to be used for the range scan:
   ```sql
   (key1 < 'bar')
   ```

In general (and as demonstrated by the preceding example), the condition used for a range scan is less restrictive than the `WHERE` clause. MySQL performs an additional check to filter out rows that satisfy the range condition but not the full `WHERE` clause.

The range condition extraction algorithm can handle nested AND/OR constructs of arbitrary depth, and its output does not depend on the order in which conditions appear in `WHERE` clause.

MySQL does not support merging multiple ranges for the range access method for spatial indexes. To work around this limitation, you can use a `UNION` with identical `SELECT` statements, except that you put each spatial predicate in a different `SELECT`.

Range Access Method for Multiple-Part Indexes

Range conditions on a multiple-part index are an extension of range conditions for a single-part index. A range condition on a multiple-part index restricts index rows to lie within one or several key tuple intervals. Key tuple intervals are defined over a set of key tuples, using ordering from the index.

For example, consider a multiple-part index defined as `key1(key_part1, key_part2, key_part3)`, and the following set of key tuples listed in key order:

<table>
<thead>
<tr>
<th>key_part1</th>
<th>key_part2</th>
<th>key_part3</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>1</td>
<td>'abc'</td>
</tr>
<tr>
<td>NULL</td>
<td>1</td>
<td>'xyz'</td>
</tr>
<tr>
<td>NULL</td>
<td>2</td>
<td>'foo'</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>'abc'</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>'xyz'</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>'abc'</td>
</tr>
</tbody>
</table>
The condition `key_part1 = 1` defines this interval:

\[(1, -\infty, -\infty) \leq (key\_part1, key\_part2, key\_part3) < (1, +\infty, +\infty)\]

The interval covers the 4th, 5th, and 6th tuples in the preceding data set and can be used by the range access method.

By contrast, the condition `key_part3 = 'abc'` does not define a single interval and cannot be used by the range access method.

The following descriptions indicate how range conditions work for multiple-part indexes in greater detail.

- For **HASH** indexes, each interval containing identical values can be used. This means that the interval can be produced only for conditions in the following form:

\[
key\_part1 \ cmp \ const1 \\
AND \ key\_part2 \ cmp \ const2 \\
AND \ ... \\
AND \ key\_partN \ cmp \ constN;
\]

Here, `const1, const2, ...` are constants, `cmp` is one of the `=, \leq, \geq, IS\ NULL` comparison operators, and the conditions cover all index parts. (That is, there are `N` conditions, one for each part of an `N`-part index.) For example, the following is a range condition for a three-part **HASH** index:

`key\_part1 = 1 \ AND \ key\_part2 \ IS\ NULL \ AND \ key\_part3 = 'foo'`

For the definition of what is considered to be a constant, see [Range Access Method for Single-Part Indexes](#).

- For a **BTREE** index, an interval might be usable for conditions combined with **AND**, where each condition compares a key part with a constant value using `=, \leq, \geq, IS\ NULL, >, <, >=, <=, !=, <>, BETWEEN, or LIKE 'pattern'` (where 'pattern' does not start with a wildcard). An interval can be used as long as it is possible to determine a single key tuple containing all rows that match the condition (or two intervals if `<>` or `!=` is used).

The optimizer attempts to use additional key parts to determine the interval as long as the comparison operator is `=, \leq, \geq, IS\ NULL`. If the operator is `>`, `<`, `>=`, `<=`, `!=`, `<>`, `BETWEEN`, or `LIKE`, the optimizer uses it but considers no more key parts. For the following expression, the optimizer uses `=` from the first comparison. It also uses `>=` from the second comparison but considers no further key parts and does not use the third comparison for interval construction:

`key\_part1 = 'foo' \ AND \ key\_part2 >= 10 \ AND \ key\_part3 > 10`

The single interval is:

\[('foo', 10, -\infty) < (key\_part1, key\_part2, key\_part3) < ('foo', +\infty, +\infty)\]

It is possible that the created interval contains more rows than the initial condition. For example, the preceding interval includes the value `('foo', 11, 0)`, which does not satisfy the original condition.

- If conditions that cover sets of rows contained within intervals are combined with **OR**, they form a condition that covers a set of rows contained within the union of their intervals. If the conditions are combined with **AND**, they form a condition that covers a set of rows contained within the intersection of their intervals. For example, for this condition on a two-part index:

\[\{(key\_part1 = 1 \ AND \ key\_part2 < 2) \ OR \ (key\_part1 > 5)\}\]

The intervals are:
In this example, the interval on the first line uses one key part for the left bound and two key parts for the right bound. The interval on the second line uses only one key part. The key_len column in the EXPLAIN output indicates the maximum length of the key prefix used.

In some cases, key_len may indicate that a key part was used, but that might be not what you would expect. Suppose that key_part1 and key_part2 can be NULL. Then the key_len column displays two key part lengths for the following condition:

key_part1 >= 1 AND key_part2 < 2

But, in fact, the condition is converted to this:

key_part1 >= 1 AND key_part2 IS NOT NULL

For a description of how optimizations are performed to combine or eliminate intervals for range conditions on a single-part index, see Range Access Method for Single-Part Indexes. Analogous steps are performed for range conditions on multiple-part indexes.

Equality Range Optimization of Many-Valued Comparisons

Consider these expressions, where col_name is an indexed column:

col_name IN(val1, ..., valN)
col_name = val1 OR ... OR col_name = valN

Each expression is true if col_name is equal to any of several values. These comparisons are equality range comparisons (where the “range” is a single value). The optimizer estimates the cost of reading qualifying rows for equality range comparisons as follows:

• If there is a unique index on col_name, the row estimate for each range is 1 because at most one row can have the given value.

• Otherwise, any index on col_name is nonunique and the optimizer can estimate the row count for each range using dives into the index or index statistics.

With index dives, the optimizer makes a dive at each end of a range and uses the number of rows in the range as the estimate. For example, the expression col_name IN (10, 20, 30) has three equality ranges and the optimizer makes two dives per range to generate a row estimate. Each pair of dives yields an estimate of the number of rows that have the given value.

Index dives provide accurate row estimates, but as the number of comparison values in the expression increases, the optimizer takes longer to generate a row estimate. Use of index statistics is less accurate than index dives but permits faster row estimation for large value lists.

The eq_range_index_dive_limit system variable enables you to configure the number of values at which the optimizer switches from one row estimation strategy to the other. To permit use of index dives for comparisons of up to N equality ranges, set eq_range_index_dive_limit to N + 1. To disable use of statistics and always use index dives regardless of N, set eq_range_index_dive_limit to 0.

To update table index statistics for best estimates, use ANALYZE TABLE.

Prior to MySQL 8.2, there is no way of skipping the use of index dives to estimate index usefulness, except by using the eq_range_index_dive_limit system variable. In MySQL 8.2, index dive skipping is possible for queries that satisfy all these conditions:
Optimizing SELECT Statements

- The query is for a single table, not a join on multiple tables.
- A single-index `FORCE INDEX` index hint is present. The idea is that if index use is forced, there is nothing to be gained from the additional overhead of performing dives into the index.
- The index is nonunique and not a `FULLTEXT` index.
- No subquery is present.
- No `DISTINCT`, `GROUP BY`, or `ORDER BY` clause is present.

For `EXPLAIN FOR CONNECTION`, the output changes as follows if index dives are skipped:

- For traditional output, the `rows` and `filtered` values are `NULL`.
- For JSON output, `rows_examined_per_scan` and `rows_produced_per_join` do not appear, `skip_index_dive_due_to_force` is `true`, and cost calculations are not accurate.

Without `FOR CONNECTION`, `EXPLAIN` output does not change when index dives are skipped.

After execution of a query for which index dives are skipped, the corresponding row in the Information Schema `OPTIMIZER_TRACE` table contains an `index_dives_for_range_access` value of `skipped_due_to_force_index`.

Skip Scan Range Access Method

Consider the following scenario:

```sql
CREATE TABLE t1 (f1 INT NOT NULL, f2 INT NOT NULL, PRIMARY KEY(f1, f2));
INSERT INTO t1 VALUES
  (1,1), (1,2), (1,3), (1,4), (1,5),
  (2,1), (2,2), (2,3), (2,4), (2,5);
INSERT INTO t1 SELECT f1, f2 + 5 FROM t1;
INSERT INTO t1 SELECT f1, f2 + 10 FROM t1;
INSERT INTO t1 SELECT f1, f2 + 20 FROM t1;
INSERT INTO t1 SELECT f1, f2 + 40 FROM t1;
ANALYZE TABLE t1;
EXPLAIN SELECT f1, f2 FROM t1 WHERE f2 > 40;
```

To execute this query, MySQL can choose an index scan to fetch all rows (the index includes all columns to be selected), then apply the `f2 > 40` condition from the `WHERE` clause to produce the final result set.

A range scan is more efficient than a full index scan, but cannot be used in this case because there is no condition on `f1`, the first index column. The optimizer can perform multiple range scans, one for each value of `f1`, using a method called Skip Scan that is similar to Loose Index Scan (see Section 8.2.1.17, “GROUP BY Optimization”):

1. Skip between distinct values of the first index part, `f1` (the index prefix).
2. Perform a subrange scan on each distinct prefix value for the `f2 > 40` condition on the remaining index part.

For the data set shown earlier, the algorithm operates like this:

1. Get the first distinct value of the first key part (`f1 = 1`).
2. Construct the range based on the first and second key parts (`f1 = 1 AND f2 > 40`).
3. Perform a range scan.
4. Get the next distinct value of the first key part (`f1 = 2`).
5. Construct the range based on the first and second key parts (\(f_1 = 2 \text{ AND } f_2 > 40\)).

6. Perform a range scan.

Using this strategy decreases the number of accessed rows because MySQL skips the rows that do not qualify for each constructed range. This Skip Scan access method is applicable under the following conditions:

- Table T has at least one compound index with key parts of the form \([A_1, \ldots, A_k, B_1, \ldots, B_m, C, D_1, \ldots, D_n]\). Key parts A and D may be empty, but B and C must be nonempty.
- The query references only one table.
- The query does not use \textsc{group by} or \textsc{distinct}.
- The query references only columns in the index.
- The predicates on \(A_1, \ldots, A_k\) must be equality predicates and they must be constants. This includes the \textsc{in()} operator.
- The query must be a conjunctive query; that is, an AND of OR conditions: \((\text{cond1}(\text{key_part1}) \text{ OR cond2(\text{key_part1})) AND (\text{cond1}(\text{key_part2}) \text{ OR } \ldots) AND ...}\)
- There must be a range condition on C.
- Conditions on D columns are permitted. Conditions on D must be in conjunction with the range condition on C.

Use of Skip Scan is indicated in \textsc{explain} output as follows:

- \textit{Using index for skip scan} in the \textit{Extra} column indicates that the loose index Skip Scan access method is used.

- If the index can be used for Skip Scan, the index should be visible in the \textit{possible_keys} column.

Use of Skip Scan is indicated in optimizer trace output by a \texttt{"skip_scan"} element of this form:

```json
"skip_scan_range": {
  "type": "skip_scan",
  "index": "index_used_for_skip_scan",
  "key_parts_used_for_access": [key_parts_used_for_access],
  "range": [range]
}
```

You may also see a \texttt{"best_skip_scan_summary"} element. If Skip Scan is chosen as the best range access variant, a \texttt{"chosen_range_access_summary"} is written. If Skip Scan is chosen as the overall best access method, a \texttt{"best_access_path"} element is present.

Use of Skip Scan is subject to the value of the \texttt{skip_scan} flag of the \texttt{optimizer_switch} system variable. See Section 8.9.2, “Switchable Optimizations”. By default, this flag is \texttt{on}. To disable it, set \texttt{skip_scan} to \texttt{off}.

In addition to using the \texttt{optimizer_switch} system variable to control optimizer use of Skip Scan session-wide, MySQL supports optimizer hints to influence the optimizer on a per-statement basis. See Section 8.9.3, “Optimizer Hints”.

### Range Optimization of Row Constructor Expressions

The optimizer is able to apply the range scan access method to queries of this form:
Optimizing SELECT Statements

Previously, for range scans to be used, it was necessary to write the query as:

```sql
SELECT ... FROM t1 WHERE ( col_1, col_2 ) IN (( 'a', 'b' ), ( 'c', 'd' ));
```

For the optimizer to use a range scan, queries must satisfy these conditions:

- Only **IN()** predicates are used, not **NOT IN()**.
- On the left side of the **IN()** predicate, the row constructor contains only column references.
- On the right side of the **IN()** predicate, row constructors contain only runtime constants, which are either literals or local column references that are bound to constants during execution.
- On the right side of the **IN()** predicate, there is more than one row constructor.

For more information about the optimizer and row constructors, see Section 8.2.1.22, “Row Constructor Expression Optimization”

Limiting Memory Use for Range Optimization

To control the memory available to the range optimizer, use the `range_optimizer_max_mem_size` system variable:

- A value of 0 means “no limit.”
- With a value greater than 0, the optimizer tracks the memory consumed when considering the range access method. If the specified limit is about to be exceeded, the range access method is abandoned and other methods, including a full table scan, are considered instead. This could be less optimal. If this happens, the following warning occurs (where `N` is the current `range_optimizer_max_mem_size` value):
  ```
  Warning 3170 Memory capacity of N bytes for
  'range_optimizer_max_mem_size' exceeded. Range
  optimization was not done for this query.
  ```
- For **UPDATE** and **DELETE** statements, if the optimizer falls back to a full table scan and the `sql_safe_updates` system variable is enabled, an error occurs rather than a warning because, in effect, no key is used to determine which rows to modify. For more information, see Using Safe-Updates Mode (--safe-updates).

For individual queries that exceed the available range optimization memory and for which the optimizer falls back to less optimal plans, increasing the `range_optimizer_max_mem_size` value may improve performance.

To estimate the amount of memory needed to process a range expression, use these guidelines:

- For a simple query such as the following, where there is one candidate key for the range access method, each predicate combined with **OR** uses approximately 230 bytes:
  ```sql
  SELECT COUNT(*) FROM t
  WHERE a=1 OR a=2 OR a=3 OR ... a=N;
  ```
- Similarly for a query such as the following, each predicate combined with **AND** uses approximately 125 bytes:
  ```sql
  SELECT COUNT(*) FROM t
  WHERE a=1 AND b=1 AND c=1 ... N;
  ```
• For a query with \texttt{IN()} predicates:

\begin{verbatim}
SELECT COUNT(*) FROM t
    WHERE a IN (1,2, ..., M) AND b IN (1,2, ..., N);
\end{verbatim}

Each literal value in an \texttt{IN()} list counts as a predicate combined with \texttt{OR}. If there are two \texttt{IN()} lists, the number of predicates combined with \texttt{OR} is the product of the number of literal values in each list. Thus, the number of predicates combined with \texttt{OR} in the preceding case is $M \times N$.

### 8.2.1.3 Index Merge Optimization

The \textit{Index Merge} access method retrieves rows with multiple range scans and merges their results into one. This access method merges index scans from a single table only, not scans across multiple tables. The merge can produce unions, intersections, or unions-of-intersections of its underlying scans.

Example queries for which Index Merge may be used:

\begin{verbatim}
SELECT * FROM tbl_name WHERE key1 = 10 OR key2 = 20;
SELECT * FROM tbl_name
    WHERE (key1 = 10 OR key2 = 20) AND non_key = 30;
SELECT * FROM t1, t2
    WHERE (t1.key1 IN (1,2) OR t1.key2 LIKE 'value%')
        AND t2.key1 = t1.some_col;
SELECT * FROM t1, t2
    WHERE t1.key1 = 1
        AND (t2.key1 = t1.some_col OR t2.key2 = t1.some_col2);
\end{verbatim}

\begin{note}
The Index Merge optimization algorithm has the following known limitations:

- If your query has a complex \texttt{WHERE} clause with deep \texttt{AND/OR} nesting and MySQL does not choose the optimal plan, try distributing terms using the following identity transformations:

\begin{verbatim}
(x AND y) OR z \Rightarrow (x OR z) AND (y OR z)
(x OR y) AND z \Rightarrow (x AND z) OR (y AND z)
\end{verbatim}

- Index Merge is not applicable to full-text indexes.
\end{note}

In \texttt{EXPLAIN} output, the Index Merge method appears as \texttt{index_merge} in the \texttt{type} column. In this case, the \texttt{key} column contains a list of indexes used, and \texttt{key_len} contains a list of the longest key parts for those indexes.

The Index Merge access method has several algorithms, which are displayed in the \texttt{Extra} field of \texttt{EXPLAIN} output:

- Using \texttt{intersect(...)}
- Using \texttt{union(...)}
- Using \texttt{sort_union(...)}

The following sections describe these algorithms in greater detail. The optimizer chooses between different possible Index Merge algorithms and other access methods based on cost estimates of the various available options.

- \textit{Index Merge Intersection Access Algorithm}
Index Merge Intersection Access Algorithm

This access algorithm is applicable when a \texttt{WHERE} clause is converted to several range conditions on different keys combined with \texttt{AND}, and each condition is one of the following:

- An $N$-part expression of this form, where the index has exactly $N$ parts (that is, all index parts are covered):
  \[
  \text{key}_1\text{part1} = \text{const}_1 \text{ AND key}_2\text{part2} = \text{const}_2 \text{ ... AND key}_N\text{partN} = \text{const}_N
  \]

- Any range condition over the primary key of an \texttt{InnoDB} table.

Examples:

```
SELECT * FROM innodb_table
  WHERE primary_key < 10 AND key_col1 = 20;
```

```
SELECT * FROM tbl_name
  WHERE key1\text{part1} = 1 AND key1\text{part2} = 2 AND key2 = 2;
```

The Index Merge intersection algorithm performs simultaneous scans on all used indexes and produces the intersection of row sequences that it receives from the merged index scans.

If all columns used in the query are covered by the used indexes, full table rows are not retrieved (\texttt{EXPLAIN} output contains \texttt{Using index} in \texttt{Extra} field in this case). Here is an example of such a query:

```
SELECT COUNT(*) FROM t1 WHERE key1 = 1 AND key2 = 1;
```

If the used indexes do not cover all columns used in the query, full rows are retrieved only when the range conditions for all used keys are satisfied.

If one of the merged conditions is a condition over the primary key of an \texttt{InnoDB} table, it is not used for row retrieval, but is used to filter out rows retrieved using other conditions.

Index Merge Union Access Algorithm

The criteria for this algorithm are similar to those for the Index Merge intersection algorithm. The algorithm is applicable when the table’s \texttt{WHERE} clause is converted to several range conditions on different keys combined with \texttt{OR}, and each condition is one of the following:

- An $N$-part expression of this form, where the index has exactly $N$ parts (that is, all index parts are covered):
  \[
  \text{key}_1\text{part1} = \text{const}_1 \text{ OR key}_2\text{part2} = \text{const}_2 \text{ ... OR key}_N\text{partN} = \text{const}_N
  \]

- Any range condition over a primary key of an \texttt{InnoDB} table.

- A condition for which the Index Merge intersection algorithm is applicable.

Examples:

```
SELECT * FROM t1
  WHERE key1 = 1 OR key2 = 2 OR key3 = 3;
```

```
SELECT * FROM innodb_table
```
Optimizing SELECT Statements

WHERE (key1 = 1 AND key2 = 2)
   OR (key3 = 'foo' AND key4 = 'bar') AND key5 = 5;

Index Merge Sort-Union Access Algorithm

This access algorithm is applicable when the WHERE clause is converted to several range conditions combined by OR, but the Index Merge union algorithm is not applicable.

Examples:

```
SELECT * FROM tbl_name
   WHERE key_col1 < 10 OR key_col2 < 20;
```

```
SELECT * FROM tbl_name
   WHERE (key_col1 > 10 OR key_col2 = 20) AND nonkey_col = 30;
```

The difference between the sort-union algorithm and the union algorithm is that the sort-union algorithm must first fetch row IDs for all rows and sort them before returning any rows.

Influencing Index Merge Optimization

Use of Index Merge is subject to the value of the index_merge, index_merge_intersection, index_merge_union, and index_merge_sort_union flags of the optimizer_switch system variable. See Section 8.9.2, “Switchable Optimizations”. By default, all those flags are on. To enable only certain algorithms, set index_merge to off, and enable only such of the others as should be permitted.

In addition to using the optimizer_switch system variable to control optimizer use of the Index Merge algorithms session-wide, MySQL supports optimizer hints to influence the optimizer on a per-statement basis. See Section 8.9.3, “Optimizer Hints”.

8.2.1.4 Hash Join Optimization

By default, MySQL employs hash joins whenever possible. It is possible to control whether hash joins are employed using one of the BNL and NO_BNL optimizer hints, or by setting block_nested_loop=on or block_nested_loop=off as part of the setting for the optimizer_switch server system variable.

MySQL employs a hash join for any query for which each join has an equi-join condition, and in which there are no indexes that can be applied to any join conditions, such as this one:

```
SELECT *
   FROM t1
   JOIN t2
   ON t1.c1=t2.c1;
```

A hash join can also be used when there are one or more indexes that can be used for single-table predicates.

A hash join is usually faster than and is intended to be used in such cases instead of the block nested loop algorithm (see Block Nested-Loop Join Algorithm) employed in previous versions of MySQL. Support for block nested loop was removed in MySQL 8.0, and the MySQL 8.2 server employs a hash join wherever a block nested loop would have been used previously.

In the example just shown and the remaining examples in this section, we assume that the three tables t1, t2, and t3 have been created using the following statements:

```
CREATE TABLE t1 (c1 INT, c2 INT);
CREATE TABLE t2 (c1 INT, c2 INT);
CREATE TABLE t3 (c1 INT, c2 INT);
```

You can see that a hash join is being employed by using EXPLAIN, like this:
Optimizing SELECT Statements

mysql> EXPLAIN
    
    -> SELECT * FROM t1
    
    -> JOIN t2 ON t1.c1=t2.c1
    
    ********************************* 1. row *********************************

    id: 1
    select_type: SIMPLE
    table: t1
    partitions: NULL
    type: ALL
    possible_keys: NULL
    key: NULL
    key_len: NULL
    ref: NULL
    rows: 1
    filtered: 100.00
    Extra: NULL

    ********************************* 2. row *********************************

    id: 1
    select_type: SIMPLE
    table: t2
    partitions: NULL
    type: ALL
    possible_keys: NULL
    key: NULL
    key_len: NULL
    ref: NULL
    rows: 1
    filtered: 100.00
    Extra: Using where; Using join buffer (hash join)

EXPLAIN ANALYZE also displays information about hash joins used.

The hash join is used for queries involving multiple joins as well, as long as at least one join condition for each pair of tables is an equi-join, like the query shown here:

```
SELECT * FROM t1
    
    JOIN t2 ON (t1.c1 = t2.c1 AND t1.c2 < t2.c2)
    
    JOIN t3 ON (t2.c1 = t3.c1);
```

In cases like the one just shown, which makes use of an inner join, any extra conditions which are not equi-joins are applied as filters after the join is executed. (For outer joins, such as left joins, semijoins, and antijoins, they are printed as part of the join.) This can be seen here in the output of EXPLAIN:

As also can be seen from the output just shown, multiple hash joins can be (and are) used for joins having multiple equi-join conditions.

A hash join is used even if any pair of joined tables does not have at least one equi-join condition, as shown here:
**Optimizing SELECT Statements**

```sql
mysql> EXPLAIN FORMAT=TREE
    -> SELECT * FROM t1
    -> JOIN t2 ON (t1.c1 = t2.c1)
    -> JOIN t3 ON (t2.c1 < t3.c1)
G
EXPLAIN: -> Filter: (t1.c1 < t3.c1)  (cost=1.05 rows=1)
    -> Inner hash join (no condition)  (cost=1.05 rows=1)
    -> Table scan on t3  (cost=0.35 rows=1)
    -> Hash
    -> Inner hash join (t2.c1 = t1.c1)  (cost=0.70 rows=1)
    -> Table scan on t2  (cost=0.35 rows=1)
    -> Hash
    -> Table scan on t1  (cost=0.35 rows=1)
```

(Additional examples are provided later in this section.)

A hash join is also applied for a Cartesian product—that is, when no join condition is specified, as shown here:

```sql
mysql> EXPLAIN FORMAT=TREE
    -> SELECT * FROM t1 JOIN t2 WHERE t1.c2 > 50
G
EXPLAIN: -> Inner hash join  (cost=0.70 rows=1)
    -> Table scan on t2  (cost=0.35 rows=1)
    -> Filter: (t1.c2 > 50)  (cost=0.35 rows=1)
    -> Table scan on t1  (cost=0.35 rows=1)
```

It is not necessary for the join to contain at least one equi-join condition in order for a hash join to be used. This means that the types of queries which can be optimized using hash joins include those in the following list (with examples):

- **Inner non-equi-join**:

```sql
mysql> EXPLAIN FORMAT=TREE SELECT * FROM t1 JOIN t2 ON t1.c1 < t2.c1
G
EXPLAIN: -> Filter: (t1.c1 < t2.c1)  (cost=4.70 rows=12)
    -> Inner hash join (no condition)  (cost=4.70 rows=12)
    -> Table scan on t2  (cost=0.08 rows=6)
    -> Hash
    -> Filter: (t1.c2 > 50)  (cost=0.35 rows=1)
    -> Table scan on t1  (cost=0.35 rows=1)
```

- **Semijoin**:

```sql
mysql> EXPLAIN FORMAT=TREE SELECT * FROM t1 WHERE t1.c1 IN (SELECT t2.c2 FROM t2)
G
EXPLAIN: -> Hash semijoin (t2.c2 = t1.c1)  (cost=0.70 rows=1)
    -> Table scan on t1  (cost=0.35 rows=1)
    -> Hash
    -> Table scan on t2  (cost=0.35 rows=1)
```

- **Antijoin**:

```sql
mysql> EXPLAIN FORMAT=TREE SELECT * FROM t2 WHERE NOT EXISTS (SELECT * FROM t1 WHERE t1.c1 = t2.c1)
G
EXPLAIN: -> Hash antijoin (t1.c1 = t2.c1)  (cost=0.70 rows=1)
    -> Table scan on t2  (cost=0.35 rows=1)
    -> Hash
    -> Table scan on t1  (cost=0.35 rows=1)
```
Optimizing SELECT Statements

1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Note
Code: 1276
Message: Field or reference 't3.t2.c1' of SELECT #2 was resolved in SELECT #1

• Left outer join:

mysql> EXPLAIN FORMAT=TREE SELECT * FROM t1 LEFT JOIN t2 ON t1.c1 = t2.c1\G
*************************** 1. row ***************************
EXPLAIN: -> Left hash join (t2.c1 = t1.c1)  (cost=0.70 rows=1)
  -> Table scan on t1  (cost=0.35 rows=1)
  -> Hash
  -> Table scan on t2  (cost=0.35 rows=1)

• Right outer join (observe that MySQL rewrites all right outer joins as left outer joins):

mysql> EXPLAIN FORMAT=TREE SELECT * FROM t1 RIGHT JOIN t2 ON t1.c1 = t2.c1\G
*************************** 1. row ***************************
EXPLAIN: -> Left hash join (t1.c1 = t2.c1)  (cost=0.70 rows=1)
  -> Table scan on t2  (cost=0.35 rows=1)
  -> Hash
  -> Table scan on t1  (cost=0.35 rows=1)

By default, MySQL employs hash joins whenever possible. It is possible to control whether hash joins are employed using one of the BNL and NO_BNL optimizer hints.

Memory usage by hash joins can be controlled using the join_buffer_size system variable; a hash join cannot use more memory than this amount. When the memory required for a hash join exceeds the amount available, MySQL handles this by using files on disk. If this happens, you should be aware that the join may not succeed if a hash join cannot fit into memory and it creates more files than set for open_files_limit. To avoid such problems, make either of the following changes:

• Increase join_buffer_size so that the hash join does not spill over to disk.

• Increase open_files_limit.

Join buffers for hash joins are allocated incrementally; thus, you can set join_buffer_size higher without small queries allocating very large amounts of RAM, but outer joins allocate the entire buffer. Hash joins are used for outer joins (including antijoins and semijoins) as well, so this is no longer an issue.

8.2.1.5 Engine Condition Pushdown Optimization

This optimization improves the efficiency of direct comparisons between a nonindexed column and a constant. In such cases, the condition is “pushed down” to the storage engine for evaluation. This optimization can be used only by the NDB storage engine.

For NDB Cluster, this optimization can eliminate the need to send nonmatching rows over the network between the cluster's data nodes and the MySQL server that issued the query, and can speed up queries where it is used by a factor of 5 to 10 times over cases where condition pushdown could be but is not used.

Suppose that an NDB Cluster table is defined as follows:

```sql
CREATE TABLE t1 (  
a INT,  
b INT,  
KEY(a)  
) ENGINE=NDB;
```
Engine condition pushdown can be used with queries such as the one shown here, which includes a comparison between a nonindexed column and a constant:

```sql
SELECT a, b FROM t1 WHERE b = 10;
```

The use of engine condition pushdown can be seen in the output of `EXPLAIN`:

```
mysql> EXPLAIN SELECT a, b FROM t1 WHERE b = 10\G
*************************** 1. row ***************************
  id: 1
 select_type: SIMPLE
  table: t1
   type: ALL
possible_keys: NULL
   key: NULL
key_len: NULL
 ref: NULL
 rows: 10
Extra: Using where with pushed condition
```

However, engine condition pushdown cannot be used with the following query:

```sql
SELECT a,b FROM t1 WHERE a = 10;
```

Engine condition pushdown is not applicable here because an index exists on column `a`. (An index access method would be more efficient and so would be chosen in preference to condition pushdown.)

Engine condition pushdown may also be employed when an indexed column is compared with a constant using a `>` or `<` operator:

```
mysql> EXPLAIN SELECT a, b FROM t1 WHERE a < 2\G
*************************** 1. row ***************************
  id: 1
 select_type: SIMPLE
  table: t1
   type: range
possible_keys: a
   key: a
key_len: 5
 ref: NULL
 rows: 2
Extra: Using where with pushed condition
```

Other supported comparisons for engine condition pushdown include the following:

- `column [NOT] LIKE pattern`
  - `pattern` must be a string literal containing the pattern to be matched; for syntax, see Section 12.8.1, “String Comparison Functions and Operators”.

- `column IS [NOT] NULL`

- `column IN (value_list)`
  - Each item in the `value_list` must be a constant, literal value.

- `column BETWEEN constant1 AND constant2`
  - `constant1` and `constant2` must each be a constant, literal value.

In all of the cases in the preceding list, it is possible for the condition to be converted into the form of one or more direct comparisons between a column and a constant.
Optimizing SELECT Statements

Engine condition pushdown is enabled by default. To disable it at server startup, set the `optimizer_switch` system variable's `engine_condition_pushdown` flag to `off`. For example, in a `my.cnf` file, use these lines:

```
[mysqld]
optimizer_switch=engine_condition_pushdown=off
```

At runtime, disable condition pushdown like this:

```
SET optimizer_switch='engine_condition_pushdown=off';
```

**Limitations.** Engine condition pushdown is subject to the following limitations:

- Engine condition pushdown is supported only by the **NDB** storage engine.
- In NDB 8.2, columns can be compared with one another as long as they are of exactly the same type, including the same signedness, length, character set, precision, and scale, where these are applicable.
- Columns used in comparisons cannot be of any of the **BLOB** or **TEXT** types. This exclusion extends to **JSON**, **BIT**, and **ENUM** columns as well.
- A string value to be compared with a column must use the same collation as the column.
- Joins are not directly supported; conditions involving multiple tables are pushed separately where possible. Use extended `EXPLAIN` output to determine which conditions are actually pushed down. See Section 8.8.3, “Extended EXPLAIN Output Format”.

Previously, engine condition pushdown was limited to terms referring to column values from the same table to which the condition was being pushed. In NDB 8.2, column values from tables earlier in the query plan can also be referred to from pushed conditions. This reduces the number of rows which must be handled by the SQL node during join processing. Filtering can be also performed in parallel in the LDM threads, rather than in a single `mysqld` process. This has the potential to improve performance of queries by a significant margin.

**NDB** can push an outer join using a scan if there are no unpushable conditions on any table used in the same join nest, or on any table in join nests above it on which it depends. This is also true for a semijoin, provided the optimization strategy employed is **firstMatch** (see Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations).

Join algorithms cannot be combined with referring columns from previous tables in the following two situations:

1. When any of the referred previous tables are in a join buffer. In this case, each row retrieved from the scan-filtered table is matched against every row in the buffer. This means that there is no single specific row from which column values can be fetched from when generating the scan filter.
2. When the column originates from a child operation in a pushed join. This is because rows referenced from ancestor operations in the join have not yet been retrieved when the scan filter is generated.

Columns from ancestor tables in a join can be pushed down, provided that they meet the requirements listed previously. An example of such a query, using the table `t1` created previously, is shown here:

```
mysql> EXPLAIN
    -> SELECT * FROM t1 AS x
    -> LEFT JOIN t1 AS y
    -> ON x.a=0 AND y.b>=3\G
```

```
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: x
```
8.2.1.6 Index Condition Pushdown Optimization

Index Condition Pushdown (ICP) is an optimization for the case where MySQL retrieves rows from a table using an index. Without ICP, the storage engine traverses the index to locate rows in the base table and returns them to the MySQL server which evaluates the \texttt{WHERE} condition for the rows. With ICP enabled, and if parts of the \texttt{WHERE} condition can be evaluated by using only columns from the index, the MySQL server pushes this part of the \texttt{WHERE} condition down to the storage engine. The storage engine then evaluates the pushed index condition by using the index entry and only if this is satisfied is the row read from the table. ICP can reduce the number of times the storage engine must access the base table and the number of times the MySQL server must access the storage engine.

Applicability of the Index Condition Pushdown optimization is subject to these conditions:

- ICP is used for the \texttt{range}, \texttt{ref}, \texttt{eq_ref}, and \texttt{ref_or_null} access methods when there is a need to access full table rows.
- ICP can be used for InnoDB and MyISAM tables, including partitioned InnoDB and MyISAM tables.
- For InnoDB tables, ICP is used only for secondary indexes. The goal of ICP is to reduce the number of full-row reads and thereby reduce I/O operations. For InnoDB clustered indexes, the complete record is already read into the InnoDB buffer. Using ICP in this case does not reduce I/O.
- ICP is not supported with secondary indexes created on virtual generated columns. InnoDB supports secondary indexes on virtual generated columns.
- Conditions that refer to subqueries cannot be pushed down.
- Conditions that refer to stored functions cannot be pushed down. Storage engines cannot invoke stored functions.
- Triggered conditions cannot be pushed down. (For information about triggered conditions, see Section 8.2.2.3, “Optimizing Subqueries with the EXISTS Strategy”.)
- Conditions cannot be pushed down to derived tables containing references to system variables.

To understand how this optimization works, first consider how an index scan proceeds when Index Condition Pushdown is not used:
1. Get the next row, first by reading the index tuple, and then by using the index tuple to locate and read the full table row.

2. Test the part of the **WHERE** condition that applies to this table. Accept or reject the row based on the test result.

Using Index Condition Pushdown, the scan proceeds like this instead:

1. Get the next row’s index tuple (but not the full table row).

2. Test the part of the **WHERE** condition that applies to this table and can be checked using only index columns. If the condition is not satisfied, proceed to the index tuple for the next row.

3. If the condition is satisfied, use the index tuple to locate and read the full table row.

4. Test the remaining part of the **WHERE** condition that applies to this table. Accept or reject the row based on the test result.

**EXPLAIN** output shows **Using index condition** in the **Extra** column when Index Condition Pushdown is used. It does not show **Using index** because that does not apply when full table rows must be read.

Suppose that a table contains information about people and their addresses and that the table has an index defined as **INDEX (zipcode, lastname, firstname)**. If we know a person’s **zipcode** value but are not sure about the last name, we can search like this:

```sql
SELECT * FROM people
WHERE zipcode='95054'
AND lastname LIKE '%etrunia%'
AND address LIKE '%Main Street%';
```

MySQL can use the index to scan through people with **zipcode='95054'**. The second part (**lastname LIKE '%etrunia%'**) cannot be used to limit the number of rows that must be scanned, so without Index Condition Pushdown, this query must retrieve full table rows for all people who have **zipcode='95054'**.

With Index Condition Pushdown, MySQL checks the **lastname LIKE '%etrunia%'** part before reading the full table row. This avoids reading full rows corresponding to index tuples that match the **zipcode** condition but not the **lastname** condition.

Index Condition Pushdown is enabled by default. It can be controlled with the **optimizer_switch** system variable by setting the **index_condition_pushdown** flag:

```sql
SET optimizer_switch = 'index_condition_pushdown-off';
SET optimizer_switch = 'index_condition_pushdown-on';
```

See Section 8.9.2, “Switchable Optimizations”.

### 8.2.1.7 Nested-Loop Join Algorithms

MySQL executes joins between tables using a nested-loop algorithm or variations on it.

- **Nested-Loop Join Algorithm**
- **Block Nested-Loop Join Algorithm**

**Nested-Loop Join Algorithm**

A simple nested-loop join (NLJ) algorithm reads rows from the first table in a loop one at a time, passing each row to a nested loop that processes the next table in the join. This process is repeated as many times as there remain tables to be joined.
Assume that a join between three tables \( t_1, t_2, \) and \( t_3 \) is to be executed using the following join types:

<table>
<thead>
<tr>
<th>Table</th>
<th>Join Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>( t_1 )</td>
<td>range</td>
</tr>
<tr>
<td>( t_2 )</td>
<td>ref</td>
</tr>
<tr>
<td>( t_3 )</td>
<td>ALL</td>
</tr>
</tbody>
</table>

If a simple NLJ algorithm is used, the join is processed like this:

```sql
for each row in \( t_1 \) matching range {
    for each row in \( t_2 \) matching reference key {
        for each row in \( t_3 \) {
            if row satisfies join conditions, send to client
        }
    }
}
```

Because the NLJ algorithm passes rows one at a time from outer loops to inner loops, it typically reads tables processed in the inner loops many times.

**Block Nested-Loop Join Algorithm**

A Block Nested-Loop (BNL) join algorithm uses buffering of rows read in outer loops to reduce the number of times that tables in inner loops must be read. For example, if 10 rows are read into a buffer and the buffer is passed to the next inner loop, each row read in the inner loop can be compared against all 10 rows in the buffer. This reduces by an order of magnitude the number of times the inner table must be read.

MySQL employs the hash join optimization for equi-joins when no indexes can be used.

MySQL join buffering has these characteristics:

- Join buffering can be used when the join is of type `ALL` or `index` (in other words, when no possible keys can be used, and a full scan is done, of either the data or index rows, respectively), or `range`. Use of buffering is also applicable to outer joins, as described in Section 8.2.1.12, "Block Nested-Loop and Batched Key Access Joins".

- A join buffer is never allocated for the first nonconstant table, even if it would be of type `ALL` or `index`.

- Only columns of interest to a join are stored in its join buffer, not whole rows.

- The `join_buffer_size` system variable determines the size of each join buffer used to process a query.

- One buffer is allocated for each join that can be buffered, so a given query might be processed using multiple join buffers.

- A join buffer is allocated prior to executing the join and freed after the query is done.

For the example join described previously for the NLJ algorithm (without buffering), the join is done as follows using join buffering:

```sql
for each row in \( t_1 \) matching range {
    for each row in \( t_2 \) matching reference key {
        store used columns from \( t_1, t_2 \) in join buffer
        if buffer is full {
            for each row in \( t_3 \) {
                for each \( t_1, t_2 \) combination in join buffer {
                    if row satisfies join conditions, send to client
                }
            }
        }
        empty join buffer
    }
}
```
If \( S \) is the size of each stored \( t_1, t_2 \) combination in the join buffer and \( C \) is the number of combinations in the buffer, the number of times table \( t_3 \) is scanned is:

\[
\frac{(S \cdot C)}{\text{join_buffer_size}} + 1
\]

The number of \( t_3 \) scans decreases as the value of \( \text{join_buffer_size} \) increases, up to the point when \( \text{join_buffer_size} \) is large enough to hold all previous row combinations. At that point, no speed is gained by making it larger.

### 8.2.1.8 Nested Join Optimization

The syntax for expressing joins permits nested joins. The following discussion refers to the join syntax described in Section 13.2.13.2, “JOIN Clause”.

The syntax of table factor is extended in comparison with the SQL Standard. The latter accepts only table reference, not a list of them inside a pair of parentheses. This is a conservative extension if we consider each comma in a list of table reference items as equivalent to an inner join. For example:

```sql
SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
    ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

Is equivalent to:

```sql
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
    ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

In MySQL, CROSS JOIN is syntactically equivalent to INNER JOIN; they can replace each other. In standard SQL, they are not equivalent. INNER JOIN is used with an ON clause; CROSS JOIN is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. Consider this join expression:

```sql
t1 LEFT JOIN (t2 LEFT JOIN t3 ON t2.b=t3.b OR t2.b IS NULL)
    ON t1.a=t2.a
```

After removing parentheses and grouping operations to the left, that join expression transforms into this expression:

```sql
(t1 LEFT JOIN t2 ON t1.a=t2.a) LEFT JOIN t3
    ON t2.b=t3.b OR t2.b IS NULL
```

Yet, the two expressions are not equivalent. To see this, suppose that the tables \( t_1, t_2, \) and \( t_3 \) have the following state:

- Table \( t_1 \) contains rows \((1), (2)\)
- Table \( t_2 \) contains row \((1,101)\)
- Table \( t_3 \) contains row \((101)\)
In this case, the first expression returns a result set including the rows (1,1,101,101), (2,NULL,NULL,NULL), whereas the second expression returns the rows (1,1,101,101), (2,NULL,NULL,101):

```sql
mysql> SELECT *
FROM t1
LEFT JOIN
  (t2 LEFT JOIN t3 ON t2.b=t3.b OR t2.b IS NULL)
  ON t1.a=t2.a;
```

```
<table>
<thead>
<tr>
<th>a</th>
<th>a</th>
<th>b</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>101</td>
<td>101</td>
</tr>
<tr>
<td>2</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
</tr>
</tbody>
</table>
```

```sql
mysql> SELECT *
FROM (t1 LEFT JOIN t2 ON t1.a=t2.a)
LEFT JOIN t3
ON t2.b=t3.b OR t2.b IS NULL;
```

```
<table>
<thead>
<tr>
<th>a</th>
<th>a</th>
<th>b</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>101</td>
<td>101</td>
</tr>
<tr>
<td>2</td>
<td>NULL</td>
<td>NULL</td>
<td>101</td>
</tr>
</tbody>
</table>
```

In the following example, an outer join operation is used together with an inner join operation:

```sql
t1 LEFT JOIN (t2, t3) ON t1.a=t2.a
```

That expression cannot be transformed into the following expression:

```sql
t1 LEFT JOIN t2 ON t1.a=t2.a, t3
```

For the given table states, the two expressions return different sets of rows:

```sql
mysql> SELECT *
FROM t1 LEFT JOIN (t2, t3) ON t1.a=t2.a;
```

```
<table>
<thead>
<tr>
<th>a</th>
<th>a</th>
<th>b</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>101</td>
<td>101</td>
</tr>
<tr>
<td>2</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
</tr>
</tbody>
</table>
```

```sql
mysql> SELECT *
FROM t1 LEFT JOIN t2 ON t1.a=t2.a, t3;
```

```
<table>
<thead>
<tr>
<th>a</th>
<th>a</th>
<th>b</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>101</td>
<td>101</td>
</tr>
<tr>
<td>2</td>
<td>NULL</td>
<td>NULL</td>
<td>101</td>
</tr>
</tbody>
</table>
```

Therefore, if we omit parentheses in a join expression with outer join operators, we might change the result set for the original expression.

More exactly, we cannot ignore parentheses in the right operand of the left outer join operation and in the left operand of a right join operation. In other words, we cannot ignore parentheses for the inner table expressions of outer join operations. Parentheses for the other operand (operand for the outer table) can be ignored.

The following expression:
Optimizing SELECT Statements

(t1,t2) LEFT JOIN t3 ON P(t2.b,t3.b)

Is equivalent to this expression for any tables t1,t2,t3 and any condition P over attributes t2.b and t3.b:

t1, t2 LEFT JOIN t3 ON P(t2.b,t3.b)

Whenever the order of execution of join operations in a join expression (joined_table) is not from left to right, we talk about nested joins. Consider the following queries:

SELECT * FROM t1 LEFT JOIN (t2 LEFT JOIN t3 ON t2.b=t3.b) ON t1.a=t2.a
WHERE t1.a > 1

SELECT * FROM t1 LEFT JOIN (t2, t3) ON t1.a=t2.a
WHERE (t2.b=t3.b OR t2.b IS NULL) AND t1.a > 1

Those queries are considered to contain these nested joins:

t2 LEFT JOIN t3 ON t2.b=t3.b
t2, t3

In the first query, the nested join is formed with a left join operation. In the second query, it is formed with an inner join operation.

In the first query, the parentheses can be omitted: The grammatical structure of the join expression dictates the same order of execution for join operations. For the second query, the parentheses cannot be omitted, although the join expression here can be interpreted unambiguously without them. In our extended syntax, the parentheses in (t2, t3) of the second query are required, although theoretically the query could be parsed without them: We still would have unambiguous syntactical structure for the query because LEFT JOIN and ON play the role of the left and right delimiters for the expression (t2,t3).

The preceding examples demonstrate these points:

• For join expressions involving only inner joins (and not outer joins), parentheses can be removed and joins evaluated left to right. In fact, tables can be evaluated in any order.

• The same is not true, in general, for outer joins or for outer joins mixed with inner joins. Removal of parentheses may change the result.

Queries with nested outer joins are executed in the same pipeline manner as queries with inner joins. More exactly, a variation of the nested-loop join algorithm is exploited. Recall the algorithm by which the nested-loop join executes a query (see Section 8.2.1.7, “Nested-Loop Join Algorithms”). Suppose that a join query over 3 tables T1,T2,T3 has this form:

SELECT * FROM T1 INNER JOIN T2 ON P1(T1,T2)
INNER JOIN T3 ON P2(T2,T3)
WHERE P(T1,T2,T3)

Here, P1(T1,T2) and P2(T3,T3) are some join conditions (on expressions), whereas P(T1,T2,T3) is a condition over columns of tables T1,T2,T3.

The nested-loop join algorithm would execute this query in the following manner:

FOR each row t1 in T1 {
  FOR each row t2 in T2 such that P1(t1,t2) {
    FOR each row t3 in T3 such that P2(t2,t3) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
    }
  }
}
The notation \( t_1 \| t_2 \| t_3 \) indicates a row constructed by concatenating the columns of rows \( t_1, t_2, \) and \( t_3 \). In some of the following examples, \textbf{NULL} where a table name appears means a row in which \textbf{NULL} is used for each column of that table. For example, \( t_1 \| t_2 \| \text{NULL} \) indicates a row constructed by concatenating the columns of rows \( t_1 \) and \( t_2 \), and \textbf{NULL} for each column of \( t_3 \). Such a row is said to be \textbf{NULL}-complemented.

Now consider a query with nested outer joins:

```sql
SELECT * FROM T1 LEFT JOIN
  (T2 LEFT JOIN T3 ON P2(T2,T3))
ON P1(T1,T2)
WHERE P(T1,T2,T3)
```

For this query, modify the nested-loop pattern to obtain:

```sql
FOR each row \( t_1 \) in T1 {
  BOOL \( f_1 := \text{FALSE} \);
  FOR each row \( t_2 \) in T2 such that \( \text{P1}(t_1,t_2) \) {
    BOOL \( f_2 := \text{FALSE} \);
    FOR each row \( t_3 \) in T3 such that \( \text{P2}(t_2,t_3) \) {
      IF \( \text{P}(t_1,t_2,t_3) \) {
        \( t := t_1 \| t_2 \| t_3; \) OUTPUT \( t \);
        \( f_2 := \text{TRUE}; \)
        \( f_1 := \text{TRUE}; \)
      }
      IF \( \neg f_2 \) {
        IF \( \text{P}(t_1,t_2,\text{NULL}) \) {
          \( t := t_1 \| t_2 \| \text{NULL}; \) OUTPUT \( t \);
        }
        \( f_1 := \text{TRUE}; \)
      }
    }
    IF \( \neg f_1 \) {
      IF \( \text{P}(t_1,\text{NULL},\text{NULL}) \) {
        \( t := t_1 \| \text{NULL} \| \text{NULL}; \) OUTPUT \( t \);
      }
    }
  }
}
```

In general, for any nested loop for the first inner table in an outer join operation, a flag is introduced that is turned off before the loop and is checked after the loop. The flag is turned on when for the current row from the outer table a match from the table representing the inner operand is found. If at the end of the loop cycle the flag is still off, no match has been found for the current row of the outer table. In this case, the row is complemented by \textbf{NULL} values for the columns of the inner tables. The result row is passed to the final check for the output or into the next nested loop, but only if the row satisfies the join condition of all embedded outer joins.

In the example, the outer join table expressed by the following expression is embedded:

```
(T2 LEFT JOIN T3 ON P2(T2,T3))
```

For the query with inner joins, the optimizer could choose a different order of nested loops, such as this one:

```sql
FOR each row \( t_3 \) in T3 {
  FOR each row \( t_2 \) in T2 such that \( \text{P2}(t_2,t_3) \) {
    FOR each row \( t_1 \) in T1 such that \( \text{P1}(t_1,t_2) \) {
      IF \( \text{P}(t_1,t_2,t_3) \) {
        \( t := t_1 \| t_2 \| t_3; \) OUTPUT \( t \);
      }
    }
  }
}
```
For queries with outer joins, the optimizer can choose only such an order where loops for outer tables precede loops for inner tables. Thus, for our query with outer joins, only one nesting order is possible. For the following query, the optimizer evaluates two different nestings. In both nestings, \( T_1 \) must be processed in the outer loop because it is used in an outer join. \( T_2 \) and \( T_3 \) are used in an inner join, so that join must be processed in the inner loop. However, because the join is an inner join, \( T_2 \) and \( T_3 \) can be processed in either order.

```
SELECT * T1 LEFT JOIN (T2,T3) ON P1(T1,T2) AND P2(T1,T3)
WHERE P(T1,T2,T3)
```

One nesting evaluates \( T_2 \), then \( T_3 \):

```sql
FOR each row t1 in T1 {
    BOOL f1:=FALSE;
    FOR each row t2 in T2 such that P1(t1,t2) {
        FOR each row t3 in T3 such that P2(t1,t3) {
            IF P(t1,t2,t3) {
                t:=t1||t2||t3; OUTPUT t;
            }
        }
    }
    IF (!f1) {
        IF P(t1,NULL,NULL) {
            t:=t1||NULL||NULL; OUTPUT t;
        }
    }
}
```

The other nesting evaluates \( T_3 \), then \( T_2 \):

```sql
FOR each row t1 in T1 {
    BOOL f1:=FALSE;
    FOR each row t3 in T3 such that P2(t1,t3) {
        FOR each row t2 in T2 such that P1(t1,t2) {
            IF P(t1,t2,t3) {
                t:=t1||t2||t3; OUTPUT t;
            }
        }
    }
    IF (!f1) {
        IF P(t1,NULL,NULL) {
            t:=t1||NULL||NULL; OUTPUT t;
        }
    }
}
```

When discussing the nested-loop algorithm for inner joins, we omitted some details whose impact on the performance of query execution may be huge. We did not mention so-called “pushed-down” conditions. Suppose that our \textit{WHERE} condition \( P(T_1,T_2,T_3) \) can be represented by a conjunctive formula:

\[
P(T_1,T_2,T_2) = C_1(T_1) \land C_2(T_2) \land C_3(T_3).
\]

In this case, MySQL actually uses the following nested-loop algorithm for the execution of the query with inner joins:

```sql
FOR each row t1 in T1 such that C1(t1) {
    FOR each row t2 in T2 such that P1(t1,t2) AND C2(t2) {
        FOR each row t3 in T3 such that P2(t2,t3) AND C3(t3) {
            IF P(t1,t2,t3) {
                t:=t1||t2||t3; OUTPUT t;
            }
        }
    }
}
```
Optimizing SELECT Statements

You see that each of the conjuncts \( C_1(T_1) \), \( C_2(T_2) \), \( C_3(T_3) \) are pushed out of the most inner loop to the most outer loop where it can be evaluated. If \( C_1(T_1) \) is a very restrictive condition, this condition pushdown may greatly reduce the number of rows from table \( T_1 \) passed to the inner loops. As a result, the execution time for the query may improve immensely.

For a query with outer joins, the \texttt{WHERE} condition is to be checked only after it has been found that the current row from the outer table has a match in the inner tables. Thus, the optimization of pushing conditions out of the inner nested loops cannot be applied directly to queries with outer joins. Here we must introduce conditional pushed-down predicates guarded by the flags that are turned on when a match has been encountered.

Recall this example with outer joins:

\[
P(T_1,T_2,T_3) = C_1(T_1) \text{ AND } C(T_2) \text{ AND } C_3(T_3)
\]

For that example, the nested-loop algorithm using guarded pushed-down conditions looks like this:

```
FOR each row \( t_1 \) in \( T_1 \) such that \( C_1(t_1) \) { 
    BOOL \( f_1 := \text{FALSE} \); 
    FOR each row \( t_2 \) in \( T_2 \)
        such that \( P_1(t_1,t_2) \) AND (\( f_1 \Rightarrow C_2(t_2) \)?\( \text{TRUE} \)) { 
            BOOL \( f_2 := \text{FALSE} \); 
            FOR each row \( t_3 \) in \( T_3 \)
                such that \( P_2(t_2,t_3) \) AND (\( f_1 \&\& f_2 \Rightarrow C_3(t_3) \)?\( \text{TRUE} \)) { 
                    \( t := t_1 \| t_2 \| t_3 \); 
                    OUTPUT \( t \); 
                    \( f_3 := \text{TRUE} \); 
                    \( f_1 := \text{TRUE} \); 
                } 
            \( f_2 := \text{TRUE} \); 
            \( f_1 := \text{TRUE} \); 
        } 
    \( f_1 := \text{TRUE} \); 
    \( f_2 := \text{NULL} \); 
    \( f_1 := \text{TRUE} \); 
} 
```

In general, pushed-down predicates can be extracted from join conditions such as \( P_1(T_1,T_2) \) and \( P(T_2,T_3) \). In this case, a pushed-down predicate is guarded also by a flag that prevents checking the predicate for the \texttt{NULL}-complemented row generated by the corresponding outer join operation.

Access by key from one inner table to another in the same nested join is prohibited if it is induced by a predicate from the \texttt{WHERE} condition.

**8.2.1.9 Outer Join Optimization**

Outer joins include \texttt{LEFT JOIN} and \texttt{RIGHT JOIN}.

MySQL implements an \texttt{A LEFT JOIN B join_specification} as follows:

- Table \( B \) is set to depend on table \( A \) and all tables on which \( A \) depends.
- Table \( A \) is set to depend on all tables (except \( B \)) that are used in the \texttt{LEFT JOIN} condition.
• The **LEFT JOIN** condition is used to decide how to retrieve rows from table **B**. (In other words, any condition in the **WHERE** clause is not used.)

• All standard join optimizations are performed, with the exception that a table is always read after all tables on which it depends. If there is a circular dependency, an error occurs.

• All standard **WHERE** optimizations are performed.

• If there is a row in **A** that matches the **WHERE** clause, but there is no row in **B** that matches the **ON** condition, an extra **B** row is generated with all columns set to **NULL**.

• If you use **LEFT JOIN** to find rows that do not exist in some table and you have the following test:  
  
  ```sql
  col_name IS NULL
  ```
  
  in the **WHERE** part, where **col_name** is a column that is declared as **NOT NULL**, MySQL stops searching for more rows (for a particular key combination) after it has found one row that matches the **LEFT JOIN** condition.

The **RIGHT JOIN** implementation is analogous to that of **LEFT JOIN** with the table roles reversed. Right joins are converted to equivalent left joins, as described in Section 8.2.1.10, “Outer Join Simplification”.

For a **LEFT JOIN**, if the **WHERE** condition is always false for the generated **NULL** row, the **LEFT JOIN** is changed to an inner join. For example, the **WHERE** clause would be false in the following query if **t2.column1** were **NULL**:

```sql
SELECT * FROM t1 LEFT JOIN t2 ON (column1) WHERE t2.column2=5;
```

Therefore, it is safe to convert the query to an inner join:

```sql
SELECT * FROM t1, t2 WHERE t2.column2=5 AND t1.column1=t2.column1;
```

Trivial **WHERE** conditions arising from constant literal expressions are removed during preparation, rather than at a later stage in optimization, by which time joins have already been simplified. Earlier removal of trivial conditions allows the optimizer to convert outer joins to inner joins; this can result in improved plans for queries with outer joins containing trivial conditions in the **WHERE** clause, such as this one:

```sql
SELECT * FROM t1 LEFT JOIN t2 ON condition_1 WHERE condition_2 OR 0 = 1
```

The optimizer now sees during preparation that **0 = 1** is always false, making **OR 0 = 1** redundant, and removes it, leaving this:

```sql
SELECT * FROM t1 LEFT JOIN t2 ON condition_1 WHERE condition_2
```

Now the optimizer can rewrite the query as an inner join, like this:

```sql
SELECT * FROM t1 JOIN t2 WHERE condition_1 AND condition_2
```

Now the optimizer can use table **t2** before table **t1** if doing so would result in a better query plan. To provide a hint about the table join order, use optimizer hints; see Section 8.9.3, “Optimizer Hints”. Alternatively, use **STRAIGHT_JOIN**; see Section 13.2.13, “SELECT Statement”. However, **STRAIGHT_JOIN** may prevent indexes from being used because it disables semijoin transformations; see Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations.

### 8.2.1.10 Outer Join Simplification

Table expressions in the **FROM** clause of a query are simplified in many cases.

At the parser stage, queries with right outer join operations are converted to equivalent queries containing only left join operations. In the general case, the conversion is performed such that this right join:

```
(T1, ...) RIGHT JOIN (T2, ...) ON P(T1, ..., T2, ...)
```
Optimizing SELECT Statements

Becomes this equivalent left join:

\[(T2, \ldots) \text{ LEFT JOIN } (T1, \ldots) \text{ ON } P(T1, \ldots, T2, \ldots)\]

All inner join expressions of the form \(T1 \text{ INNER JOIN } T2 \text{ ON } P(T1, T2)\) are replaced by the list \(T1, T2, P(T1, T2)\) being joined as a conjunct to the \textbf{WHERE} condition (or to the join condition of the embedding join, if there is any).

When the optimizer evaluates plans for outer join operations, it takes into consideration only plans where, for each such operation, the outer tables are accessed before the inner tables. The optimizer choices are limited because only such plans enable outer joins to be executed using the nested-loop algorithm.

Consider a query of this form, where \(R(T2)\) greatly narrows the number of matching rows from table \(T2\):

\[
\text{SELECT * FROM } T1 \text{ LEFT JOIN } T2 \text{ ON } P1(T1, T2) \text{ WHERE } P(T1, T2) \text{ AND } R(T2)
\]

If the query is executed as written, the optimizer has no choice but to access the less-restricted table \(T1\) before the more-restricted table \(T2\), which may produce a very inefficient execution plan.

Instead, MySQL converts the query to a query with no outer join operation if the \textbf{WHERE} condition is null-rejected. (That is, it converts the outer join to an inner join.) A condition is said to be null-rejected for an outer join operation if it evaluates to \texttt{FALSE} or \texttt{UNKNOWN} for any \texttt{NULL}-complemented row generated for the operation.

Thus, for this outer join:

\[
T1 \text{ LEFT JOIN } T2 \text{ ON } T1.A=T2.A
\]

Conditions such as these are null-rejected because they cannot be true for any \texttt{NULL}-complemented row (with \(T2\) columns set to \texttt{NULL}):

\[
\begin{align*}
T2.B \text{ IS NOT NULL} \\
T2.B & > 3 \\
T2.C & <= T1.C \\
T2.B & < 2 \text{ OR } T2.C > 1
\end{align*}
\]

Conditions such as these are not null-rejected because they might be true for a \texttt{NULL}-complemented row:

\[
\begin{align*}
T2.B & \text{ IS NULL} \\
T1.B & < 3 \text{ OR } T2.B \text{ IS NOT NULL} \\
T1.B & < 3 \text{ OR } T2.B > 3
\end{align*}
\]

The general rules for checking whether a condition is null-rejected for an outer join operation are simple:

- It is of the form \(A \text{ IS NOT NULL}\), where \(A\) is an attribute of any of the inner tables
- It is a predicate containing a reference to an inner table that evaluates to \texttt{UNKNOWN} when one of its arguments is \texttt{NULL}
- It is a conjunction containing a null-rejected condition as a conjunct
- It is a disjunction of null-rejected conditions

A condition can be null-rejected for one outer join operation in a query and not null-rejected for another. In this query, the \textbf{WHERE} condition is null-rejected for the second outer join operation but is not null-rejected for the first one:

\[
\text{SELECT * FROM } T1 \text{ LEFT JOIN } T2 \text{ ON } T2.A=T1.A \text{ LEFT JOIN } T3 \text{ ON } T3.B=T1.B \text{ WHERE } T3.C > 0
\]
Optimizing SELECT Statements

If the `WHERE` condition is null-rejected for an outer join operation in a query, the outer join operation is replaced by an inner join operation.

For example, in the preceding query, the second outer join is null-rejected and can be replaced by an inner join:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
    INNER JOIN T3 ON T3.B=T1.B
WHERE T3.C > 0
```

For the original query, the optimizer evaluates only plans compatible with the single table-access order `T1,T2,T3`. For the rewritten query, it additionally considers the access order `T3,T1,T2`.

A conversion of one outer join operation may trigger a conversion of another. Thus, the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
    LEFT JOIN T3 ON T3.B=T2.B
WHERE T3.C > 0
```

Is first converted to the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
    INNER JOIN T3 ON T3.B=T2.B
WHERE T3.C > 0
```

Which is equivalent to the query:

```
SELECT * FROM (T1 LEFT JOIN T2 ON T2.A=T1.A), T3
WHERE T3.C > 0 AND T3.B=T2.B
```

The remaining outer join operation can also be replaced by an inner join because the condition `T3.B=T2.B` is null-rejected. This results in a query with no outer joins at all:

```
SELECT * FROM (T1 INNER JOIN T2 ON T2.A=T1.A), T3
WHERE T3.C > 0 AND T3.B=T2.B
```

Sometimes the optimizer succeeds in replacing an embedded outer join operation, but cannot convert the embedding outer join. The following query:

```
SELECT * FROM T1 LEFT JOIN
    (T2 LEFT JOIN T3 ON T3.B=T2.B)
ON T2.A=T1.A
WHERE T3.C > 0
```

Is converted to:

```
SELECT * FROM T1 LEFT JOIN
    (T2 INNER JOIN T3 ON T3.B=T2.B)
ON T2.A=T1.A
WHERE T3.C > 0
```

That can be rewritten only to the form still containing the embedding outer join operation:

```
SELECT * FROM T1 LEFT JOIN
    (T2,T3)
WHERE T3.C > 0
```

Any attempt to convert an embedded outer join operation in a query must take into account the join condition for the embedding outer join together with the `WHERE` condition. In this query, the `WHERE` condition is not null-rejected for the embedded outer join, but the join condition of the embedding outer join `T2.A=T1.A AND T3.C=T1.C` is null-rejected:

```
SELECT * FROM T1 LEFT JOIN
```
Optimizing SELECT Statements

Consequently, the query can be converted to:

```
SELECT * FROM T1 LEFT JOIN
    (T2, T3)
WHERE T3.D > 0 OR T1.D > 0
```

### 8.2.1.11 Multi-Range Read Optimization

Reading rows using a range scan on a secondary index can result in many random disk accesses to the base table when the table is large and not stored in the storage engine’s cache. With the Disk-Sweep Multi-Range Read (MRR) optimization, MySQL tries to reduce the number of random disk access for range scans by first scanning the index only and collecting the keys for the relevant rows. Then the keys are sorted and finally the rows are retrieved from the base table using the order of the primary key. The motivation for Disk-sweep MRR is to reduce the number of random disk accesses and instead achieve a more sequential scan of the base table data.

The Multi-Range Read optimization provides these benefits:

- MRR enables data rows to be accessed sequentially rather than in random order, based on index tuples. The server obtains a set of index tuples that satisfy the query conditions, sorts them according to data row ID order, and uses the sorted tuples to retrieve data rows in order. This makes data access more efficient and less expensive.

- MRR enables batch processing of requests for key access for operations that require access to data rows through index tuples, such as range index scans and equi-joins that use an index for the join attribute. MRR iterates over a sequence of index ranges to obtain qualifying index tuples. As these results accumulate, they are used to access the corresponding data rows. It is not necessary to acquire all index tuples before starting to read data rows.

The MRR optimization is not supported with secondary indexes created on virtual generated columns. **InnoDB** supports secondary indexes on virtual generated columns.

The following scenarios illustrate when MRR optimization can be advantageous:

**Scenario A:** MRR can be used for **InnoDB** and **MyISAM** tables for index range scans and equi-join operations.

1. A portion of the index tuples are accumulated in a buffer.
2. The tuples in the buffer are sorted by their data row ID.
3. Data rows are accessed according to the sorted index tuple sequence.

**Scenario B:** MRR can be used for **NDB** tables for multiple-range index scans or when performing an equi-join by an attribute.

1. A portion of ranges, possibly single-key ranges, is accumulated in a buffer on the central node where the query is submitted.
2. The ranges are sent to the execution nodes that access data rows.
3. The accessed rows are packed into packages and sent back to the central node.
4. The received packages with data rows are placed in a buffer.
5. Data rows are read from the buffer. When MRR is used, the `Extra` column in `EXPLAIN` output shows `Using MRR`.

*InnoDB* and *MyISAM* do not use MRR if full table rows need not be accessed to produce the query result. This is the case if results can be produced entirely on the basis on information in the index tuples (through a covering index); MRR provides no benefit.

Two `optimizer_switch` system variable flags provide an interface to the use of MRR optimization. The `mrr` flag controls whether MRR is enabled. If `mrr` is enabled *(on)*, the `mrr_cost_based` flag controls whether the optimizer attempts to make a cost-based choice between using and not using MRR *(on)* or uses MRR whenever possible *(off)*. By default, `mrr` is *on* and `mrr_cost_based` is *on*. See Section 8.9.2, "Switchable Optimizations".

For MRR, a storage engine uses the value of the `read_rnd_buffer_size` system variable as a guideline for how much memory it can allocate for its buffer. The engine uses up to `read_rnd_buffer_size` bytes and determines the number of ranges to process in a single pass.

### 8.2.1.12 Block Nested-Loop and Batched Key Access Joins

In MySQL, a Batched Key Access (BKA) Join algorithm is available that uses both index access to the joined table and a join buffer. The BKA algorithm supports inner join, outer join, and semijoin operations, including nested outer joins. Benefits of BKA include improved join performance due to more efficient table scanning. Also, the Block Nested-Loop (BNL) Join algorithm previously used only for inner joins is extended and can be employed for outer join and semijoin operations, including nested outer joins.

The following sections discuss the join buffer management that underlies the extension of the original BNL algorithm, the extended BNL algorithm, and the BKA algorithm. For information about semijoin strategies, see Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations

- Join Buffer Management for Block Nested-Loop and Batched Key Access Algorithms
- Block Nested-Loop Algorithm for Outer Joins and Semijoins
- Batched Key Access Joins
- Optimizer Hints for Block Nested-Loop and Batched Key Access Algorithms

#### Join Buffer Management for Block Nested-Loop and Batched Key Access Algorithms

MySQL can employ join buffers to execute not only inner joins without index access to the inner table, but also outer joins and semijoins that appear after subquery flattening. Moreover, a join buffer can be effectively used when there is an index access to the inner table.

The join buffer management code slightly more efficiently utilizes join buffer space when storing the values of the interesting row columns: No additional bytes are allocated in buffers for a row column if its value is `NULL`, and the minimum number of bytes is allocated for any value of the *VARCHAR* type.

The code supports two types of buffers, regular and incremental. Suppose that join buffer B1 is employed to join tables `t1` and `t2` and the result of this operation is joined with table `t3` using join buffer B2:

- A regular join buffer contains columns from each join operand. If B2 is a regular join buffer, each row `r` put into B2 is composed of the columns of a row `r1` from B1 and the interesting columns of a matching row `r2` from table `t3`.
- An incremental join buffer contains only columns from rows of the table produced by the second join operand. That is, it is incremental to a row from the first operand buffer. If B2 is an incremental join buffer, it contains the interesting columns of the row `r2` together with a link to the row `r1` from B1.
Optimizing SELECT Statements

Incremental join buffers are always incremental relative to a join buffer from an earlier join operation, so the buffer from the first join operation is always a regular buffer. In the example just given, the buffer $B_1$ used to join tables $t_1$ and $t_2$ must be a regular buffer.

Each row of the incremental buffer used for a join operation contains only the interesting columns of a row from the table to be joined. These columns are augmented with a reference to the interesting columns of the matched row from the table produced by the first join operand. Several rows in the incremental buffer can refer to the same row $r$ whose columns are stored in the previous join buffers insofar as all these rows match row $r$.

Incremental buffers enable less frequent copying of columns from buffers used for previous join operations. This provides a savings in buffer space because in the general case a row produced by the first join operand can be matched by several rows produced by the second join operand. It is unnecessary to make several copies of a row from the first operand. Incremental buffers also provide a savings in processing time due to the reduction in copying time.

The `block_nested_loop` flag of the `optimizer_switch` system variable controls hash joins.

The `batched_key_access` flag controls how the optimizer uses the Batched Key Access join algorithms.

By default, `block_nested_loop` is on and `batched_key_access` is off. See Section 8.9.2, “Switchable Optimizations”. Optimizer hints may also be applied; see Optimizer Hints for Block Nested-Loop and Batched Key Access Algorithms.

For information about semijoin strategies, see Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations.

**Block Nested-Loop Algorithm for Outer Joins and Semijoins**

The original implementation of the MySQL BNL algorithm was extended to support outer join and semijoin operations (and was later superseded by the hash join algorithm; see Section 8.2.1.4, “Hash Join Optimization”).

When these operations are executed with a join buffer, each row put into the buffer is supplied with a match flag.

If an outer join operation is executed using a join buffer, each row of the table produced by the second operand is checked for a match against each row in the join buffer. When a match is found, a new extended row is formed (the original row plus columns from the second operand) and sent for further extensions by the remaining join operations. In addition, the match flag of the matched row in the buffer is enabled. After all rows of the table to be joined have been examined, the join buffer is scanned. Each row from the buffer that does not have its match flag enabled is extended by NULL complements (NULL values for each column in the second operand) and sent for further extensions by the remaining join operations.

The `block_nested_loop` flag of the `optimizer_switch` system variable controls hash joins.

See Section 8.9.2, “Switchable Optimizations”, for more information. Optimizer hints may also be applied; see Optimizer Hints for Block Nested-Loop and Batched Key Access Algorithms.

In `EXPLAIN` output, use of BNL for a table is signified when the `Extra` value contains Using join buffer (Block Nested Loop) and the `type` value is ALL, index, or range.

For information about semijoin strategies, see Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations.

**Batched Key Access Joins**
MySQL implements a method of joining tables called the Batched Key Access (BKA) join algorithm. BKA can be applied when there is an index access to the table produced by the second join operand. Like the BNL join algorithm, the BKA join algorithm employs a join buffer to accumulate the interesting columns of the rows produced by the first operand of the join operation. Then the BKA algorithm builds keys to access the table to be joined for all rows in the buffer and submits these keys in a batch to the database engine for index lookups. The keys are submitted to the engine through the Multi-Range Read (MRR) interface (see Section 8.2.1.11, “Multi-Range Read Optimization”). After submission of the keys, the MRR engine performs lookups in the index in an optimal way, fetching the rows of the joined table found by these keys, and starts feeding the BKA join algorithm with matching rows. Each matching row is coupled with a reference to a row in the join buffer.

When BKA is used, the value of \texttt{join_buffer_size} defines how large the batch of keys is in each request to the storage engine. The larger the buffer, the more sequential access is made to the right hand table of a join operation, which can significantly improve performance.

For BKA to be used, the \texttt{batched_key_access} flag of the \texttt{optimizer_switch} system variable must be set to \texttt{on}. BKA uses MRR, so the \texttt{mrr} flag must also be \texttt{on}. Currently, the cost estimation for MRR is too pessimistic. Hence, it is also necessary for \texttt{mrr_cost_based} to be \texttt{off} for BKA to be used. The following setting enables BKA:

```
mysql> SET optimizer_switch='mrr=on,mrr_cost_based=off,batched_key_access=on';
```

There are two scenarios by which MRR functions execute:

- The first scenario is used for conventional disk-based storage engines such as InnoDB and MyISAM. For these engines, usually the keys for all rows from the join buffer are submitted to the MRR interface at once. Engine-specific MRR functions perform index lookups for the submitted keys, get row IDs (or primary keys) from them, and then fetch rows for all these selected row IDs one by one by request from BKA algorithm. Every row is returned with an association reference that enables access to the matched row in the join buffer. The rows are fetched by the MRR functions in an optimal way: They are fetched in the row ID (primary key) order. This improves performance because reads are in disk order rather than random order.

- The second scenario is used for remote storage engines such as NDB. A package of keys for a portion of rows from the join buffer, together with their associations, is sent by a MySQL Server (SQL node) to MySQL Cluster data nodes. In return, the SQL node receives a package (or several packages) of matching rows coupled with corresponding associations. The BKA join algorithm takes these rows and builds new joined rows. Then a new set of keys is sent to the data nodes and the rows from the returned packages are used to build new joined rows. The process continues until the last keys from the join buffer are sent to the data nodes, and the SQL node has received and joined all rows matching these keys. This improves performance because fewer key-bearing packages sent by the SQL node to the data nodes means fewer round trips between it and the data nodes to perform the join operation.

With the first scenario, a portion of the join buffer is reserved to store row IDs (primary keys) selected by index lookups and passed as a parameter to the MRR functions.

There is no special buffer to store keys built for rows from the join buffer. Instead, a function that builds the key for the next row in the buffer is passed as a parameter to the MRR functions.

In EXPLAIN output, use of BKA for a table is signified when the \texttt{Extra} value contains \texttt{Using join buffer (Batched Key Access)} and the \texttt{type} value is \texttt{ref} or \texttt{eq_ref}.

### Optimizer Hints for Block Nested-Loop and Batched Key Access Algorithms

In addition to using the \texttt{optimizer_switch} system variable to control optimizer use of the BNL and BKA algorithms session-wide, MySQL supports optimizer hints to influence the optimizer on a per-statement basis. See Section 8.9.3, “Optimizer Hints”.

1802
To use a BNL or BKA hint to enable join buffering for any inner table of an outer join, join buffering must be enabled for all inner tables of the outer join.

### 8.2.1.13 Condition Filtering

In join processing, prefix rows are those rows passed from one table in a join to the next. In general, the optimizer attempts to put tables with low prefix counts early in the join order to keep the number of row combinations from increasing rapidly. To the extent that the optimizer can use information about conditions on rows selected from one table and passed to the next, the more accurately it can compute row estimates and choose the best execution plan.

Without condition filtering, the prefix row count for a table is based on the estimated number of rows selected by the `WHERE` clause according to whichever access method the optimizer chooses. Condition filtering enables the optimizer to use other relevant conditions in the `WHERE` clause not taken into account by the access method, and thus improve its prefix row count estimates. For example, even though there might be an index-based access method that can be used to select rows from the current table in a join, there might also be additional conditions for the table in the `WHERE` clause that can filter (further restrict) the estimate for qualifying rows passed to the next table.

A condition contributes to the filtering estimate only if:

- It refers to the current table.
- It depends on a constant value or values from earlier tables in the join sequence.
- It was not already taken into account by the access method.

In `EXPLAIN` output, the `rows` column indicates the row estimate for the chosen access method, and the `filtered` column reflects the effect of condition filtering. `filtered` values are expressed as percentages. The maximum value is 100, which means no filtering of rows occurred. Values decreasing from 100 indicate increasing amounts of filtering.

The prefix row count (the number of rows estimated to be passed from the current table in a join to the next) is the product of the `rows` and `filtered` values. That is, the prefix row count is the estimated row count, reduced by the estimated filtering effect. For example, if `rows` is 1000 and `filtered` is 20%, condition filtering reduces the estimated row count of 1000 to a prefix row count of 1000 × 20% = 1000 × .2 = 200.

Consider the following query:

```sql
SELECT *
FROM employee JOIN department ON employee.dept_no = department.dept_no
WHERE employee.first_name = 'John'
AND employee.hire_date BETWEEN '2018-01-01' AND '2018-06-01';
```

Suppose that the data set has these characteristics:

- The `employee` table has 1024 rows.
- The `department` table has 12 rows.
- Both tables have an index on `dept_no`.
- The `employee` table has an index on `first_name`.
- 8 rows satisfy this condition on `employee.first_name`:
  
  ```sql
  employee.first_name = 'John'
  ```
Optimizing SELECT Statements

- 150 rows satisfy this condition on employee.hire_date:
  
  ```sql
  employee.hire_date BETWEEN '2018-01-01' AND '2018-06-01'
  ```

- 1 row satisfies both conditions:
  
  ```sql
  employee.first_name = 'John'
  AND employee.hire_date BETWEEN '2018-01-01' AND '2018-06-01'
  ```

Without condition filtering, `EXPLAIN` produces output like this:

```sql
+----+------------+--------+------------------+---------+---------+------+----------+
| id | table      | type   | possible_keys    | key     | ref     | rows | filtered |
|----|------------|--------|------------------+---------+---------+------+----------+
| 1  | employee   | ref    | name,h_date,dept | name    | const   | 8    | 100.00   |
| 1  | department | eq_ref | PRIMARY          | PRIMARY | dept_no | 1    | 100.00   |
+----+------------+--------+------------------+---------+---------+------+----------+
```

For `employee`, the access method on the `name` index picks up the 8 rows that match a name of 'John'. No filtering is done (`filtered` is 100%), so all rows are prefix rows for the next table: The prefix row count is `rows × filtered = 8 × 100% = 8`.

With condition filtering, the optimizer additionally takes into account conditions from the `WHERE` clause not taken into account by the access method. In this case, the optimizer uses heuristics to estimate a filtering effect of 16.31% for the `BETWEEN` condition on `employee.hire_date`. As a result, `EXPLAIN` produces output like this:

```sql
+----+------------+--------+------------------+---------+---------+------+----------+
| id | table      | type   | possible_keys    | key     | ref     | rows | filtered |
|----|------------|--------|------------------+---------+---------+------+----------+
| 1  | employee   | ref    | name,h_date,dept | name    | const   | 8    | 16.31    |
| 1  | department | eq_ref | PRIMARY          | PRIMARY | dept_no | 1    | 100.00   |
+----+------------+--------+------------------+---------+---------+------+----------+
```

Now the prefix row count is `rows × filtered = 8 × 16.31% = 1.3`, which more closely reflects actual data set.

Normally, the optimizer does not calculate the condition filtering effect (prefix row count reduction) for the last joined table because there is no next table to pass rows to. An exception occurs for `EXPLAIN`: To provide more information, the filtering effect is calculated for all joined tables, including the last one.

To control whether the optimizer considers additional filtering conditions, use the `condition_fanout_filter` flag of the `optimizer_switch` system variable (see Section 8.9.2, "Switchable Optimizations"). This flag is enabled by default but can be disabled to suppress condition filtering (for example, if a particular query is found to yield better performance without it).

If the optimizer overestimates the effect of condition filtering, performance may be worse than if condition filtering is not used. In such cases, these techniques may help:

- If a column is not indexed, index it so that the optimizer has some information about the distribution of column values and can improve its row estimates.

- Similarly, if no column histogram information is available, generate a histogram (see Section 8.9.6, "Optimizer Statistics").

- Change the join order. Ways to accomplish this include join-order optimizer hints (see Section 8.9.3, "Optimizer Hints"), `STRAIGHT_JOIN` immediately following the `SELECT`, and the `STRAIGHT_JOIN` join operator.

- Disable condition filtering for the session:
Optimizing SELECT Statements

Set optimizer_switch = 'condition_fanout_filter=off';

Or, for a given query, using an optimizer hint:

SELECT /*+ SET_VAR(optimizer_switch = 'condition_fanout_filter=off') */ ...

8.2.1.14 Constant-Folding Optimization

Comparisons between constants and column values in which the constant value is out of range or of the wrong type with respect to the column type are now handled once during query optimization rather row-by-row than during execution. The comparisons that can be treated in this manner are >, >=, <, <=, <>, /=, =, and <=>.

Consider the table created by the following statement:

CREATE TABLE t (c TINYINT UNSIGNED NOT NULL);

The WHERE condition in the query SELECT * FROM t WHERE c < 256 contains the integral constant 256 which is out of range for a TINYINT UNSIGNED column. Previously, this was handled by treating both operands as the larger type, but now, since any allowed value for c is less than the constant, the WHERE expression can instead be folded as WHERE 1, so that the query is rewritten as SELECT * FROM t WHERE 1.

This makes it possible for the optimizer to remove the WHERE expression altogether. If the column c were nullable (that is, defined only as TINYINT UNSIGNED) the query would be rewritten like this:

SELECT * FROM t WHERE ti IS NOT NULL

Folding is performed for constants compared to supported MySQL column types as follows:

- **Integer column type.** Integer types are compared with constants of the following types as described here:
  - **Integer value.** If the constant is out of range for the column type, the comparison is folded to 1 or IS NOT NULL, as already shown.

  If the constant is a range boundary, the comparison is folded to =. For example (using the same table as already defined):

```sql
mysql> EXPLAIN SELECT * FROM t WHERE c >= 255;
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: t
partitions: NULL
type: ALL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: 5
filtered: 20.00
Extra: Using where
1 row in set, 1 warning (0.00 sec)
```

```sql
mysql> SHOW WARNINGS;
*************************** 1. row ***************************
Level: Note
Code: 1003
Message: /* select#1 */ select `test`.`t`.`ti` AS `ti` from `test`.`t` where (`test`.`t`.`ti` = 255)
```
• **Floating- or fixed-point value.** If the constant is one of the decimal types (such as DECIMAL, REAL, DOUBLE, or FLOAT) and has a nonzero decimal portion, it cannot be equal; fold accordingly. For other comparisons, round up or down to an integer value according to the sign, then perform a range check and handle as already described for integer-integer comparisons.

A REAL value that is too small to be represented as DECIMAL is rounded to .01 or -.01 depending on the sign, then handled as a DECIMAL.

• **String types.** Try to interpret the string value as an integer type, then handle the comparison as between integer values. If this fails, attempt to handle the value as a REAL.

• **DECIMAL or REAL column.** Decimal types are compared with constants of the following types as described here:

  • **Integer value.** Perform a range check against the column value's integer part. If no folding results, convert the constant to DECIMAL with the same number of decimal places as the column value, then check it as a DECIMAL (see next).

  • **DECIMAL or REAL value.** Check for overflow (that is, whether the constant has more digits in its integer part than allowed for the column's decimal type). If so, fold.

    If the constant has more significant fractional digits than column's type, truncate the constant. If the comparison operator is = or <>, fold. If the operator is >= or <=, adjust the operator due to truncation. For example, if column's type is DECIMAL(3,1), SELECT * FROM t WHERE f >= 10.13 becomes SELECT * FROM t WHERE f > 10.1. If the constant has fewer decimal digits than the column's type, convert it to a constant with same number of digits. For underflow of a REAL value (that is, too few fractional digits to represent it), convert the constant to decimal 0.

• **String value.** If the value can be interpreted as an integer type, handle it as such. Otherwise, try to handle it as REAL.

• **FLOAT or DOUBLE column.** FLOAT(\(m, n\)) or DOUBLE(\(m, n\)) values compared with constants are handled as follows:

  If the value overflows the range of the column, fold.

  If the value has more than \(n\) decimals, truncate, compensating during folding. For = and < comparisons, fold to TRUE, FALSE, or IS [NOT] NULL as described previously; for other operators, adjust the operator.

  If the value has more than \(m\) integer digits, fold.

**Limitations.** This optimization cannot be used in the following cases:

1. With comparisons using BETWEEN or IN.

2. With BIT columns or columns using date or time types.

3. During the preparation phase for a prepared statement, although it can be applied during the optimization phase when the prepared statement is actually executed. This due to the fact that, during statement preparation, the value of the constant is not yet known.

**8.2.1.15 IS NULL Optimization**
MySQL can perform the same optimization on `col_name IS NULL` that it can use for `col_name = constant_value`. For example, MySQL can use indexes and ranges to search for `NULL` with `IS NULL`.

Examples:

```sql
SELECT * FROM tbl_name WHERE key_col IS NULL;
SELECT * FROM tbl_name WHERE key_col <=> NULL;
SELECT * FROM tbl_name
    WHERE key_col=const1 OR key_col=const2 OR key_col IS NULL;
```

If a `WHERE` clause includes a `col_name IS NULL` condition for a column that is declared as `NOT NULL`, that expression is optimized away. This optimization does not occur in cases when the column might produce `NULL` anyway (for example, if it comes from a table on the right side of a `LEFT JOIN`).

MySQL can also optimize the combination `col_name = expr OR col_name IS NULL`, a form that is common in resolved subqueries. `EXPLAIN` shows `ref_or_null` when this optimization is used.

This optimization can handle one `IS NULL` for any key part.

Some examples of queries that are optimized, assuming that there is an index on columns `a` and `b` of table `t2`:

```sql
SELECT * FROM t1 WHERE t1.a=expr OR t1.a IS NULL;
SELECT * FROM t1, t2 WHERE t1.a=t2.a OR t2.a IS NULL;
SELECT * FROM t1, t2
    WHERE (t1.a=t2.a OR t2.a IS NULL) AND t2.b=t1.b;
SELECT * FROM t1, t2
    WHERE t1.a=t2.a AND (t2.b=t1.b OR t2.b IS NULL);
SELECT * FROM t1, t2
    WHERE (t1.a=t2.a AND t2.a IS NULL AND ...)
    OR (t1.a=t2.a AND t2.a IS NULL AND ...);
```

`ref_or_null` works by first doing a read on the reference key, and then a separate search for rows with a `NULL` key value.

The optimization can handle only one `IS NULL` level. In the following query, MySQL uses key lookups only on the expression `(t1.a=t2.a AND t2.a IS NULL)` and is not able to use the key part on `b`:

```sql
SELECT * FROM t1, t2
    WHERE (t1.a=t2.a AND t2.a IS NULL)
    OR (t1.b=t2.b AND t2.b IS NULL);
```

### 8.2.16 ORDER BY Optimization

This section describes when MySQL can use an index to satisfy an `ORDER BY` clause, the `filesort` operation used when an index cannot be used, and execution plan information available from the optimizer about `ORDER BY`.

An `ORDER BY` with and without `LIMIT` may return rows in different orders, as discussed in Section 8.2.19, “LIMIT Query Optimization”.

- Use of Indexes to Satisfy ORDER BY
- Use of `filesort` to Satisfy ORDER BY
Use of Indexes to Satisfy ORDER BY

In some cases, MySQL may use an index to satisfy an ORDER BY clause and avoid the extra sorting involved in performing a filesort operation.

The index may also be used even if the ORDER BY does not match the index exactly, as long as all unused portions of the index and all extra ORDER BY columns are constants in the WHERE clause. If the index does not contain all columns accessed by the query, the index is used only if index access is cheaper than other access methods.

Assuming that there is an index on (key_part1, key_part2), the following queries may use the index to resolve the ORDER BY part. Whether the optimizer actually does so depends on whether reading the index is more efficient than a table scan if columns not in the index must also be read.

- In this query, the index on (key_part1, key_part2) enables the optimizer to avoid sorting:

```sql
SELECT * FROM t1
ORDER BY key_part1, key_part2;
```

However, the query uses SELECT *, which may select more columns than key_part1 and key_part2. In that case, scanning an entire index and looking up table rows to find columns not in the index may be more expensive than scanning the table and sorting the results. If so, the optimizer probably does not use the index. If SELECT * selects only the index columns, the index is used and sorting avoided.

If t1 is an InnoDB table, the table primary key is implicitly part of the index, and the index can be used to resolve the ORDER BY for this query:

```sql
SELECT pk, key_part1, key_part2 FROM t1
ORDER BY key_part1, key_part2;
```

- In this query, key_part1 is constant, so all rows accessed through the index are in key_part2 order, and an index on (key_part1, key_part2) avoids sorting if the WHERE clause is selective enough to make an index range scan cheaper than a table scan:

```sql
SELECT * FROM t1
WHERE key_part1 = constant
ORDER BY key_part2;
```

- In the next two queries, whether the index is used is similar to the same queries without DESC shown previously:

```sql
SELECT * FROM t1
ORDER BY key_part1 DESC, key_part2 DESC;
```

```sql
SELECT * FROM t1
WHERE key_part1 = constant
ORDER BY key_part2 DESC;
```

- Two columns in an ORDER BY can sort in the same direction (both ASC, or both DESC) or in opposite directions (one ASC, one DESC). A condition for index use is that the index must have the same homogeneity, but need not have the same actual direction.

If a query mixes ASC and DESC, the optimizer can use an index on the columns if the index also uses corresponding mixed ascending and descending columns:
SELECT * FROM t1
ORDER BY key_part1 DESC, key_part2 ASC;

The optimizer can use an index on \((\text{key_part1}, \text{key_part2})\) if \text{key_part1} is descending and \text{key_part2} is ascending. It can also use an index on those columns (with a backward scan) if \text{key_part1} is ascending and \text{key_part2} is descending. See Section 8.3.13, “Descending Indexes”.

• In the next two queries, \text{key_part1} is compared to a constant. The index is used if the \text{WHERE} clause is selective enough to make an index range scan cheaper than a table scan:

SELECT * FROM t1
WHERE key_part1 > constant
ORDER BY key_part1 ASC;

SELECT * FROM t1
WHERE key_part1 < constant
ORDER BY key_part1 DESC;

• In the next query, the \text{ORDER BY} does not name \text{key_part1}, but all rows selected have a constant \text{key_part1} value, so the index can still be used:

SELECT * FROM t1
WHERE key_part1 = constant1 AND key_part2 > constant2
ORDER BY key_part2;

In some cases, MySQL \texttt{cannot} use indexes to resolve the \text{ORDER BY}, although it may still use indexes to find the rows that match the \text{WHERE} clause. Examples:

• The query uses \text{ORDER BY} on different indexes:

SELECT * FROM t1 ORDER BY key1, key2;

• The query uses \text{ORDER BY} on nonconsecutive parts of an index:

SELECT * FROM t1 WHERE key2 = constant ORDER BY key1_part1, key1_part3;

• The index used to fetch the rows differs from the one used in the \text{ORDER BY}:

SELECT * FROM t1 WHERE key2 = constant ORDER BY key1;

• The query uses \text{ORDER BY} with an expression that includes terms other than the index column name:

SELECT * FROM t1 ORDER BY ABS(key);
SELECT * FROM t1 ORDER BY -key;

• The query joins many tables, and the columns in the \text{ORDER BY} are not all from the first nonconstant table that is used to retrieve rows. (This is the first table in the \texttt{EXPLAIN} output that does not have a \texttt{const} join type.)

• There is an index on only a prefix of a column named in the \text{ORDER BY} clause. In this case, the index cannot be used to fully resolve the sort order. For example, if only the first 10 bytes of a \texttt{CHAR(20)} column are indexed, the index cannot distinguish values past the 10th byte and a \texttt{filesort} is needed.

• The index does not store rows in order. For example, this is true for a \texttt{HASH} index in a \texttt{MEMORY} table.

Availability of an index for sorting may be affected by the use of column aliases. Suppose that the column \texttt{t1.a} is indexed. In this statement, the name of the column in the select list is \texttt{a}. It refers to \texttt{t1.a}, as does the reference to \texttt{a} in the \text{ORDER BY}, so the index on \texttt{t1.a} can be used:
Optimizing SELECT Statements

SELECT a FROM t1 ORDER BY a;

In this statement, the name of the column in the select list is also a, but it is the alias name. It refers to ABS(a), as does the reference to a in the ORDER BY, so the index on t1.a cannot be used:

SELECT ABS(a) AS a FROM t1 ORDER BY a;

In the following statement, the ORDER BY refers to a name that is not the name of a column in the select list. But there is a column in t1 named a, so the ORDER BY refers to t1.a and the index on t1.a can be used. (The resulting sort order may be completely different from the order for ABS(a), of course.)

SELECT ABS(a) AS b FROM t1 ORDER BY a;

Previously (MySQL 8.1 and lower), GROUP BY sorted implicitly under certain conditions. In MySQL 8.2, that no longer occurs, so specifying ORDER BY NULL at the end to suppress implicit sorting (as was done previously) is no longer necessary. However, query results may differ from previous MySQL versions. To produce a given sort order, provide an ORDER BY clause.

Use of filesort to Satisfy ORDER BY

If an index cannot be used to satisfy an ORDER BY clause, MySQL performs a filesort operation that reads table rows and sorts them. A filesort constitutes an extra sorting phase in query execution.

To obtain memory for filesort operations, the optimizer allocates memory buffers incrementally as needed, up to the size indicated by the sort_buffer_size system variable. This enables users to set sort_buffer_size to larger values to speed up larger sorts, without concern for excessive memory use for small sorts. (This benefit may not occur for multiple concurrent sorts on Windows, which has a weak multithreaded malloc.)

A filesort operation uses temporary disk files as necessary if the result set is too large to fit in memory. Some types of queries are particularly suited to completely in-memory filesort operations. For example, the optimizer can use filesort to efficiently handle in memory, without temporary files, the ORDER BY operation for queries (and subqueries) of the following form:

SELECT ... FROM single_table ... ORDER BY non_index_column [DESC] LIMIT [M,N];

Such queries are common in web applications that display only a few rows from a larger result set. Examples:

SELECT col1, ... FROM t1 ... ORDER BY name LIMIT 10;
SELECT col1, ... FROM t1 ... ORDER BY RAND() LIMIT 15;

Influencing ORDER BY Optimization

To increase ORDER BY speed, check whether you can get MySQL to use indexes rather than an extra sorting phase. If this is not possible, try the following strategies:

- Increase the sort_buffer_size variable value. Ideally, the value should be large enough for the entire result set to fit in the sort buffer (to avoid writes to disk and merge passes).

  Take into account that the size of column values stored in the sort buffer is affected by the max_sort_length system variable value. For example, if tuples store values of long string columns and you increase the value of max_sort_length, the size of sort buffer tuples increases as well and may require you to increase sort_buffer_size.

  To monitor the number of merge passes (to merge temporary files), check the Sort_merge_passes status variable.
• Increase the `read_rnd_buffer_size` variable value so that more rows are read at a time.

• Change the `tmpdir` system variable to point to a dedicated file system with large amounts of free space. The variable value can list several paths that are used in round-robin fashion; you can use this feature to spread the load across several directories. Separate the paths by colon characters (`:`) on Unix and semicolon characters (`;`) on Windows. The paths should name directories in file systems located on different physical disks, not different partitions on the same disk.

ORDER BY Execution Plan Information Available

With `EXPLAIN` (see Section 8.8.1, “Optimizing Queries with EXPLAIN”), you can check whether MySQL can use indexes to resolve an `ORDER BY` clause:

• If the `Extra` column of `EXPLAIN` output does not contain `Using filesort`, the index is used and a `filesort` is not performed.

• If the `Extra` column of `EXPLAIN` output contains `Using filesort`, the index is not used and a `filesort` is performed.

In addition, if a `filesort` is performed, optimizer trace output includes a `filesort_summary` block. For example:

```json
"filesort_summary": {
  "rows": 100,
  "examined_rows": 100,
  "number_of_tmp_files": 0,
  "peak_memory_used": 25192,
  "sort_mode": "<sort_key, packed_additional_fields>"
}
```

`peak_memory_used` indicates the maximum memory used at any one time during the sort. This is a value up to but not necessarily as large as the value of the `sort_buffer_size` system variable. The optimizer allocates sort-buffer memory incrementally, beginning with a small amount and adding more as necessary, up to `sort_buffer_size` bytes.)

The `sort_mode` value provides information about the contents of tuples in the sort buffer:

• `<sort_key, rowid>`: This indicates that sort buffer tuples are pairs that contain the sort key value and row ID of the original table row. Tuples are sorted by sort key value and the row ID is used to read the row from the table.

• `<sort_key, additional_fields>`: This indicates that sort buffer tuples contain the sort key value and columns referenced by the query. Tuples are sorted by sort key value and column values are read directly from the tuple.

• `<sort_key, packed_additional_fields>`: Like the previous variant, but the additional columns are packed tightly together instead of using a fixed-length encoding.

`EXPLAIN` does not distinguish whether the optimizer does or does not perform a `filesort` in memory. Use of an in-memory `filesort` can be seen in optimizer trace output. Look for `filesort_priority_queue_optimization`. For information about the optimizer trace, see MySQL Internals: Tracing the Optimizer.

8.2.1.17 GROUP BY Optimization

The most general way to satisfy a `GROUP BY` clause is to scan the whole table and create a new temporary table where all rows from each group are consecutive, and then use this temporary table to discover groups and apply aggregate functions (if any). In some cases, MySQL is able to do much better than that and avoid creation of temporary tables by using index access.
The most important preconditions for using indexes for GROUP BY are that all GROUP BY columns reference attributes from the same index, and that the index stores its keys in order (as is true, for example, for a BTREE index, but not for a HASH index). Whether use of temporary tables can be replaced by index access also depends on which parts of an index are used in a query, the conditions specified for these parts, and the selected aggregate functions.

There are two ways to execute a GROUP BY query through index access, as detailed in the following sections. The first method applies the grouping operation together with all range predicates (if any). The second method first performs a range scan, and then groups the resulting tuples.

- **Loose Index Scan**
- **Tight Index Scan**

Loose Index Scan can also be used in the absence of GROUP BY under some conditions. See Skip Scan Range Access Method.

**Loose Index Scan**

The most efficient way to process GROUP BY is when an index is used to directly retrieve the grouping columns. With this access method, MySQL uses the property of some index types that the keys are ordered (for example, BTREE). This property enables use of lookup groups in an index without having to consider all keys in the index that satisfy all WHERE conditions. This access method considers only a fraction of the keys in an index, so it is called a Loose Index Scan. When there is no WHERE clause, a Loose Index Scan reads as many keys as the number of groups, which may be a much smaller number than that of all keys. If the WHERE clause contains range predicates (see the discussion of the range join type in Section 8.8.1, “Optimizing Queries with EXPLAIN”), a Loose Index Scan looks up the first key of each group that satisfies the range conditions, and again reads the smallest possible number of keys. This is possible under the following conditions:

- The query is over a single table.
- The GROUP BY names only columns that form a leftmost prefix of the index and no other columns. (If, instead of GROUP BY, the query has a DISTINCT clause, all distinct attributes refer to columns that form a leftmost prefix of the index.) For example, if a table t1 has an index on (c1,c2,c3), Loose Index Scan is applicable if the query has GROUP BY c1, c2. It is not applicable if the query has GROUP BY c2, c3 (the columns are not a leftmost prefix) or GROUP BY c1, c2, c4 (c4 is not in the index).
- The only aggregate functions used in the select list (if any) are MIN() and MAX(), and all of them refer to the same column. The column must be in the index and must immediately follow the columns in the GROUP BY.
- Any other parts of the index than those from the GROUP BY referenced in the query must be constants (that is, they must be referenced in equalities with constants), except for the argument of MIN() or MAX() functions.
- For columns in the index, full column values must be indexed, not just a prefix. For example, with c1 VARCHAR(20), INDEX (c1(10)), the index uses only a prefix of c1 values and cannot be used for Loose Index Scan.

If Loose Index Scan is applicable to a query, the EXPLAIN output shows Using index for group-by in the Extra column.

Assume that there is an index idx(c1,c2,c3) on table t1(c1,c2,c3,c4). The Loose Index Scan access method can be used for the following queries:

```sql
SELECT c1, c2 FROM t1 GROUP BY c1, c2;
```
SELECT DISTINCT c1, c2 FROM t1;
SELECT c1, MIN(c2) FROM t1 GROUP BY c1, c2;
SELECT MAX(c3), MIN(c3), c1, c2 FROM t1 WHERE c2 > const GROUP BY c1, c2;
SELECT c2 FROM t1 WHERE c1 < const GROUP BY c1, c2;
SELECT c1, c2 FROM t1 WHERE c3 = const GROUP BY c1, c2;

The following queries cannot be executed with this quick select method, for the reasons given:

- There are aggregate functions other than \( \text{MIN()} \) or \( \text{MAX()} \):

  ```sql
  SELECT c1, SUM(c2) FROM t1 GROUP BY c1;
  ```

- The columns in the `GROUP BY` clause do not form a leftmost prefix of the index:

  ```sql
  SELECT c1, c2 FROM t1 GROUP BY c2, c3;
  ```

- The query refers to a part of a key that comes after the `GROUP BY` part, and for which there is no equality with a constant:

  ```sql
  SELECT c1, c3 FROM t1 GROUP BY c1, c2;
  ```

  Were the query to include `WHERE c3 = const`, Loose Index Scan could be used.

The Loose Index Scan access method can be applied to other forms of aggregate function references in the select list, in addition to the `MIN()` and `MAX()` references already supported:

- \( \text{AVG(DISTINCT)} \), \( \text{SUM(DISTINCT)} \), and \( \text{COUNT(DISTINCT)} \) are supported. \( \text{AVG(DISTINCT)} \) and \( \text{SUM(DISTINCT)} \) take a single argument. \( \text{COUNT(DISTINCT)} \) can have more than one column argument.

- There must be no `GROUP BY` or `DISTINCT` clause in the query.

- The Loose Index Scan limitations described previously still apply.

Assume that there is an index `idx(c1,c2,c3)` on table `t1(c1,c2,c3,c4)`. The Loose Index Scan access method can be used for the following queries:

- `SELECT COUNT(DISTINCT c1), SUM(DISTINCT c1) FROM t1;`
- `SELECT COUNT(DISTINCT c1, c2), COUNT(DISTINCT c2, c1) FROM t1;`

**Tight Index Scan**

A Tight Index Scan may be either a full index scan or a range index scan, depending on the query conditions.

When the conditions for a Loose Index Scan are not met, it still may be possible to avoid creation of temporary tables for `GROUP BY` queries. If there are range conditions in the `WHERE` clause, this method reads only the keys that satisfy these conditions. Otherwise, it performs an index scan. Because this method reads all keys in each range defined by the `WHERE` clause, or scans the whole index if there are no range conditions, it is called a **Tight Index Scan**. With a Tight Index Scan, the grouping operation is performed only after all keys that satisfy the range conditions have been found.

For this method to work, it is sufficient that there be a constant equality condition for all columns in a query referring to parts of the key coming before or in between parts of the `GROUP BY` key. The constants from the equality conditions fill in any “gaps” in the search keys so that it is possible to form complete prefixes of the index. These index prefixes then can be used for index lookups. If the `GROUP BY` result requires sorting, and it is possible to form search keys that are prefixes of the index, MySQL also avoids extra
Optimizing SELECT Statements

sorting operations because searching with prefixes in an ordered index already retrieves all the keys in order.

Assume that there is an index \textit{idx(c1,c2,c3)} on table \textit{t1(c1,c2,c3,c4)}. The following queries do not work with the Loose Index Scan access method described previously, but still work with the Tight Index Scan access method.

- There is a gap in the \texttt{GROUP BY}, but it is covered by the condition \texttt{c2 = 'a'}:

  ```sql
  SELECT c1, c2, c3 FROM t1 WHERE c2 = 'a' GROUP BY c1, c3;
  ```

- The \texttt{GROUP BY} does not begin with the first part of the key, but there is a condition that provides a constant for that part:

  ```sql
  SELECT c1, c2, c3 FROM t1 WHERE c1 = 'a' GROUP BY c2, c3;
  ```

8.2.1.18 DISTINCT Optimization

\texttt{DISTINCT} combined with \texttt{ORDER BY} needs a temporary table in many cases.

Because \texttt{DISTINCT} may use \texttt{GROUP BY}, learn how MySQL works with columns in \texttt{ORDER BY} or \texttt{HAVING} clauses that are not part of the selected columns. See Section 12.19.3, “MySQL Handling of GROUP BY”.

In most cases, a \texttt{DISTINCT} clause can be considered as a special case of \texttt{GROUP BY}. For example, the following two queries are equivalent:

```sql
SELECT DISTINCT c1, c2, c3 FROM t1 WHERE c1 > const;
SELECT c1, c2, c3 FROM t1 WHERE c1 > const GROUP BY c1, c2, c3;
```

Due to this equivalence, the optimizations applicable to \texttt{GROUP BY} queries can be also applied to queries with a \texttt{DISTINCT} clause. Thus, for more details on the optimization possibilities for \texttt{DISTINCT} queries, see Section 8.2.1.17, “GROUP BY Optimization”.

When combining \texttt{LIMIT row_count} with \texttt{DISTINCT}, MySQL stops as soon as it finds \texttt{row_count} unique rows.

If you do not use columns from all tables named in a query, MySQL stops scanning any unused tables as soon as it finds the first match. In the following case, assuming that \textit{t1} is used before \textit{t2} (which you can check with \texttt{EXPLAIN}), MySQL stops reading from \textit{t2} (for any particular row in \textit{t1}) when it finds the first row in \textit{t2}:

```sql
SELECT DISTINCT t1.a FROM t1, t2 where t1.a=t2.a;
```

8.2.1.19 LIMIT Query Optimization

If you need only a specified number of rows from a result set, use a \texttt{LIMIT} clause in the query, rather than fetching the whole result set and throwing away the extra data.

MySQL sometimes optimizes a query that has a \texttt{LIMIT row_count} clause and no \texttt{HAVING} clause:

- If you select only a few rows with \texttt{LIMIT}, MySQL uses indexes in some cases when normally it would prefer to do a full table scan.

- If you combine \texttt{LIMIT row_count} with \texttt{ORDER BY}, MySQL stops sorting as soon as it has found the first \texttt{row_count} rows of the sorted result, rather than sorting the entire result. If ordering is done by using an index, this is very fast. If a filesort must be done, all rows that match the query without the
**LIMIT** clause are selected, and most or all of them are sorted, before the first **row_count** are found. After the initial rows have been found, MySQL does not sort any remainder of the result set.

One manifestation of this behavior is that an **ORDER BY** query with and without **LIMIT** may return rows in different order, as described later in this section.

- **If you combine** **LIMIT row_count** with **DISTINCT**, MySQL stops as soon as it finds **row_count** unique rows.

- In some cases, a **GROUP BY** can be resolved by reading the index in order (or doing a sort on the index), then calculating summaries until the index value changes. In this case, **LIMIT row_count** does not calculate any unnecessary **GROUP BY** values.

- **As soon as MySQL has sent the required number of rows to the client,** it aborts the query unless you are using **SQL_CALC_FOUND_ROWS**. In that case, the number of rows can be retrieved with **SELECT FOUND_ROWS()**. See Section 12.15, “Information Functions”.

- **LIMIT 0** quickly returns an empty set. This can be useful for checking the validity of a query. It can also be employed to obtain the types of the result columns within applications that use a MySQL API that makes result set metadata available. With the mysql client program, you can use the **--column-type-info** option to display result column types.

- If the server uses temporary tables to resolve a query, it uses the **LIMIT row_count** clause to calculate how much space is required.

- **If an index is not used for** **ORDER BY** but a **LIMIT** clause is also present, the optimizer may be able to avoid using a merge file and sort the rows in memory using an in-memory **filesort** operation.

If multiple rows have identical values in the **ORDER BY** columns, the server is free to return those rows in any order, and may do so differently depending on the overall execution plan. In other words, the sort order of those rows is nondeterministic with respect to the nonordered columns.

One factor that affects the execution plan is **LIMIT**, so an **ORDER BY** query with and without **LIMIT** may return rows in different orders. Consider this query, which is sorted by the **category** column but nondeterministic with respect to the **id** and **rating** columns:

```
mysql> SELECT * FROM ratings ORDER BY category;
```

```
+----+----------+--------+
<table>
<thead>
<tr>
<th>id</th>
<th>category</th>
<th>rating</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>4.5</td>
</tr>
<tr>
<td>5</td>
<td>1</td>
<td>3.2</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>3.7</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
<td>3.5</td>
</tr>
<tr>
<td>6</td>
<td>2</td>
<td>3.5</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>5.0</td>
</tr>
<tr>
<td>7</td>
<td>3</td>
<td>2.7</td>
</tr>
</tbody>
</table>
```

Including **LIMIT** may affect order of rows within each **category** value. For example, this is a valid query result:

```
mysql> SELECT * FROM ratings ORDER BY category LIMIT 5;
```

```
+----+----------+--------+
<table>
<thead>
<tr>
<th>id</th>
<th>category</th>
<th>rating</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>4.5</td>
</tr>
<tr>
<td>5</td>
<td>1</td>
<td>3.2</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
<td>3.5</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>3.7</td>
</tr>
<tr>
<td>6</td>
<td>2</td>
<td>3.5</td>
</tr>
</tbody>
</table>
```

---

1815
In each case, the rows are sorted by the ORDER BY column, which is all that is required by the SQL standard.

If it is important to ensure the same row order with and without LIMIT, include additional columns in the ORDER BY clause to make the order deterministic. For example, if id values are unique, you can make rows for a given category value appear in id order by sorting like this:

```sql
mysql> SELECT * FROM ratings ORDER BY category, id;
+----+----------+--------+
| id | category | rating |
+----+----------+--------+
|  1 |        1 |    4.5 |
|  5 |        1 |    3.2 |
|  3 |        2 |    3.7 |
|  4 |        2 |    3.5 |
|  6 |        2 |    3.5 |
|  2 |        3 |    5.0 |
|  7 |        3 |    2.7 |
+----+----------+--------+
mysql> SELECT * FROM ratings ORDER BY category, id LIMIT 5;
+----+----------+--------+
| id | category | rating |
+----+----------+--------+
|  1 |        1 |    4.5 |
|  5 |        1 |    3.2 |
|  3 |        2 |    3.7 |
|  4 |        2 |    3.5 |
|  6 |        2 |    3.5 |
+----+----------+--------+
```

For a query with an ORDER BY or GROUP BY and a LIMIT clause, the optimizer tries to choose an ordered index by default when it appears doing so would speed up query execution. In cases where using some other optimization might be faster, it is possible to turn off this optimization by setting the optimizer_switch system variable's prefer_ordering_index flag to off.

**Example**: First we create and populate a table t as shown here:

```sql
# Create and populate a table t:
mysql> CREATE TABLE t (id1 BIGINT NOT NULL, id2 BIGINT NOT NULL, c1 VARCHAR(50) NOT NULL, c2 VARCHAR(50) NOT NULL, PRIMARY KEY (id1), INDEX i (id2, c1));
# [Insert some rows into table t - not shown]
```

Verify that the prefer_ordering_index flag is enabled:

```sql
mysql> SELECT @@optimizer_switch LIKE '%prefer_ordering_index=on%';
+------------------------------------------------------+
| @@optimizer_switch LIKE '%prefer_ordering_index=on%' |
+------------------------------------------------------+
|                                                    1 |
+------------------------------------------------------+
```

Since the following query has a LIMIT clause, we expect it to use an ordered index, if possible. In this case, as we can see from the EXPLAIN output, it uses the table's primary key.
### Optimizing SELECT Statements

```sql
mysql> EXPLAIN SELECT c2 FROM t
    -> WHERE id2 > 3
    -> ORDER BY id1 ASC LIMIT 2
G
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: t
partitions: NULL
type: index
possible_keys: i
    key: PRIMARY
    key_len: 8
    ref: NULL
    rows: 2
    filtered: 70.00
    Extra: Using where
```

Now we disable the `prefer_ordering_index` flag, and re-run the same query; this time it uses the index `i` (which includes the `id2` column used in the `WHERE` clause), and a filesort:

```sql
mysql> SET optimizer_switch = "prefer_ordering_index=off";

mysql> EXPLAIN SELECT c2 FROM t
    -> WHERE id2 > 3
    -> ORDER BY id1 ASC LIMIT 2
G
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: t
partitions: NULL
type: range
possible_keys: i
    key: i
    key_len: 8
    ref: NULL
    rows: 14
    filtered: 100.00
    Extra: Using index condition; Using filesort
```

See also [Section 8.9.2, “Switchable Optimizations”](#).

### 8.2.1.20 Function Call Optimization

MySQL functions are tagged internally as deterministic or nondeterministic. A function is nondeterministic if, given fixed values for its arguments, it can return different results for different invocations. Examples of nondeterministic functions: `RAND()`, `UUID()`.

If a function is tagged nondeterministic, a reference to it in a `WHERE` clause is evaluated for every row (when selecting from one table) or combination of rows (when selecting from a multiple-table join).

MySQL also determines when to evaluate functions based on types of arguments, whether the arguments are table columns or constant values. A deterministic function that takes a table column as argument must be evaluated whenever that column changes value.

Nondeterministic functions may affect query performance. For example, some optimizations may not be available, or more locking might be required. The following discussion uses `RAND()` but applies to other nondeterministic functions as well.

Suppose that a table `t` has this definition:

```sql
CREATE TABLE t (id INT NOT NULL PRIMARY KEY, col_a VARCHAR(100));
```

Consider these two queries:
Both queries appear to use a primary key lookup because of the equality comparison against the primary key, but that is true only for the first of them:

- The first query always produces a maximum of one row because `POW()` with constant arguments is a constant value and is used for index lookup.

- The second query contains an expression that uses the nondeterministic function `RAND()`, which is not constant in the query but in fact has a new value for every row of the table `t`. Consequently, the query reads every row of the table, evaluates the predicate for each row, and outputs all rows for which the primary key matches the random value. This might be zero, one, or multiple rows, depending on the `id` column values and the values in the `RAND()` sequence.

The effects of nondeterminism are not limited to `SELECT` statements. This `UPDATE` statement uses a nondeterministic function to select rows to be modified:

```sql
UPDATE t SET col_a = some_expr WHERE id = FLOOR(1 + RAND() * 49);
```

Presumably the intent is to update at most a single row for which the primary key matches the expression. However, it might update zero, one, or multiple rows, depending on the `id` column values and the values in the `RAND()` sequence.

The behavior just described has implications for performance and replication:

- Because a nondeterministic function does not produce a constant value, the optimizer cannot use strategies that might otherwise be applicable, such as index lookups. The result may be a table scan.

- `InnoDB` might escalate to a range-key lock rather than taking a single row lock for one matching row.

- Updates that do not execute deterministically are unsafe for replication.

The difficulties stem from the fact that the `RAND()` function is evaluated once for every row of the table. To avoid multiple function evaluations, use one of these techniques:

- Move the expression containing the nondeterministic function to a separate statement, saving the value in a variable. In the original statement, replace the expression with a reference to the variable, which the optimizer can treat as a constant value:
  ```sql
  SET @keyval = FLOOR(1 + RAND() * 49);
  UPDATE t SET col_a = some_expr WHERE id = @keyval;
  ```

- Assign the random value to a variable in a derived table. This technique causes the variable to be assigned a value, once, prior to its use in the comparison in the `WHERE` clause:
  ```sql
  UPDATE /*+ NO_MERGE(dt) */ t, (SELECT FLOOR(1 + RAND() * 49) AS r) AS dt
  SET col_a = some_expr WHERE id = dt.r;
  ```

As mentioned previously, a nondeterministic expression in the `WHERE` clause might prevent optimizations and result in a table scan. However, it may be possible to partially optimize the `WHERE` clause if other expressions are deterministic. For example:

```sql
SELECT * FROM t WHERE partial_key=5 AND some_column=RAND();
```

If the optimizer can use `partial_key` to reduce the set of rows selected, `RAND()` is executed fewer times, which diminishes the effect of nondeterminism on optimization.

### 8.2.1.21 Window Function Optimization
Optimizing SELECT Statements

Window functions affect the strategies the optimizer considers:

- Derived table merging for a subquery is disabled if the subquery has window functions. The subquery is always materialized.

- Semijoins are not applicable to window function optimization because semijoins apply to subqueries in WHERE and JOIN ... ON, which cannot contain window functions.

- The optimizer processes multiple windows that have the same ordering requirements in sequence, so sorting can be skipped for windows following the first one.

- The optimizer makes no attempt to merge windows that could be evaluated in a single step (for example, when multiple OVER clauses contain identical window definitions). The workaround is to define the window in a WINDOW clause and refer to the window name in the OVER clauses.

An aggregate function not used as a window function is aggregated in the outermost possible query. For example, in this query, MySQL sees that \texttt{COUNT(t1.b)} is something that cannot exist in the outer query because of its placement in the WHERE clause:

\begin{verbatim}
SELECT * FROM t1 WHERE t1.a = (SELECT COUNT(t1.b) FROM t2);
\end{verbatim}

Consequently, MySQL aggregates inside the subquery, treating \texttt{t1.b} as a constant and returning the count of rows of \texttt{t2}.

Replacing \texttt{WHERE} with \texttt{HAVING} results in an error:

\begin{verbatim}
mysql> SELECT * FROM t1 HAVING t1.a = (SELECT COUNT(t1.b) FROM t2);
ERROR 1140 (42000): In aggregated query without GROUP BY, expression #1 of SELECT list contains nonaggregated column 'test.t1.a'; this is incompatible with sql_mode=only_full_group_by
\end{verbatim}

The error occurs because \texttt{COUNT(t1.b)} can exist in the HAVING, and so makes the outer query aggregated.

Window functions (including aggregate functions used as window functions) do not have the preceding complexity. They always aggregate in the subquery where they are written, never in the outer query.

Window function evaluation may be affected by the value of the \texttt{windowing_use_high_precision} system variable, which determines whether to compute window operations without loss of precision. By default, \texttt{windowing_use_high_precision} is enabled.

For some moving frame aggregates, the inverse aggregate function can be applied to remove values from the aggregate. This can improve performance but possibly with a loss of precision. For example, adding a very small floating-point value to a very large value causes the very small value to be “hidden” by the large value. When inverting the large value later, the effect of the small value is lost.

Loss of precision due to inverse aggregation is a factor only for operations on floating-point (approximate-value) data types. For other types, inverse aggregation is safe; this includes \texttt{DECIMAL}, which permits a fractional part but is an exact-value type.

For faster execution, MySQL always uses inverse aggregation when it is safe:

- For floating-point values, inverse aggregation is not always safe and might result in loss of precision. The default is to avoid inverse aggregation, which is slower but preserves precision. If it is permissible to sacrifice safety for speed, \texttt{windowing_use_high_precision} can be disabled to permit inverse aggregation.

- For nonfloating-point data types, inverse aggregation is always safe and is used regardless of the \texttt{windowing_use_high_precision} value.
• windowing_use_high_precision has no effect on MIN() and MAX(), which do not use inverse
aggregation in any case.

For evaluation of the variance functions STDDEV_POP(), STDDEV_SAMP(), VAR_POP(), VAR_SAMP(),
and their synonyms, evaluation can occur in optimized mode or default mode. Optimized mode may
produce slightly different results in the last significant digits. If such differences are permissible,
windowing_use_high_precision can be disabled to permit optimized mode.

For EXPLAIN, windowing execution plan information is too extensive to display in traditional output format.
To see windowing information, use EXPLAIN FORMAT=JSON and look for the windowing element.

8.2.1.22 Row Constructor Expression Optimization

Row constructors permit simultaneous comparisons of multiple values. For example, these two statements
are semantically equivalent:

```sql
SELECT * FROM t1 WHERE (column1,column2) = (1,1);
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;
```

In addition, the optimizer handles both expressions the same way.

The optimizer is less likely to use available indexes if the row constructor columns do not cover the prefix
of an index. Consider the following table, which has a primary key on (c1, c2, c3):

```sql
CREATE TABLE t1 {
  c1 INT, c2 INT, c3 INT, c4 CHAR(100),
  PRIMARY KEY(c1,c2,c3)
};
```

In this query, the WHERE clause uses all columns in the index. However, the row constructor itself does not
cover an index prefix, with the result that the optimizer uses only c1 (key_len=4, the size of c1):

```sql
mysql> EXPLAIN SELECT * FROM t1
      WHERE c1=1 AND (c2,c3) > (1,1)\G
```

```plaintext
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: t1
partitions: NULL
type: ref
possible_keys: PRIMARY
key: PRIMARY
key_len: 4
ref: const
rows: 3
filtered: 100.00
Extra: Using where
```

In such cases, rewriting the row constructor expression using an equivalent nonconstructor expression
may result in more complete index use. For the given query, the row constructor and equivalent
nonconstructor expressions are:

```sql
(c2,c3) > (1,1)
c2 > 1 OR ((c2 = 1) AND (c3 > 1))
```

Rewriting the query to use the nonconstructor expression results in the optimizer using all three columns in
the index (key_len=12):

```sql
mysql> EXPLAIN SELECT * FROM t1
      WHERE c1 = 1 AND (c2 > 1 OR ((c2 = 1) AND (c3 > 1)))\G
```

```plaintext
*************************** 1. row ***************************
id: 1
```
Thus, for better results, avoid mixing row constructors with **AND** or **OR** expressions. Use one or the other.

Under certain conditions, the optimizer can apply the range access method to **IN()** expressions that have row constructor arguments. See Range Optimization of Row Constructor Expressions.

### 8.2.1.23 Avoiding Full Table Scans

The output from **EXPLAIN** shows **ALL** in the **type** column when MySQL uses a full table scan to resolve a query. This usually happens under the following conditions:

- The table is so small that it is faster to perform a table scan than to bother with a key lookup. This is common for tables with fewer than 10 rows and a short row length.

- There are no usable restrictions in the **ON** or **WHERE** clause for indexed columns.

- You are comparing indexed columns with constant values and MySQL has calculated (based on the index tree) that the constants cover too large a part of the table and that a table scan would be faster. See Section 8.2.1.1, “WHERE Clause Optimization”.

- You are using a key with low cardinality (many rows match the key value) through another column. In this case, MySQL assumes that by using the key probably requires many key lookups and that a table scan would be faster.

For small tables, a table scan often is appropriate and the performance impact is negligible. For large tables, try the following techniques to avoid having the optimizer incorrectly choose a table scan:

- Use **ANALYZE TABLE tbl_name** to update the key distributions for the scanned table. See Section 13.7.3.1, “ANALYZE TABLE Statement”.

- Use **FORCE INDEX** for the scanned table to tell MySQL that table scans are very expensive compared to using the given index:

  ```sql
  SELECT * FROM t1, t2 FORCE INDEX (index_for_column)
  WHERE t1.col_name=t2.col_name;
  ```

  See Section 8.9.4, “Index Hints”.

- Start **mysqld** with the **--max-seeks-for-key=1000** option or use **SET max_seeks_for_key=1000** to tell the optimizer to assume that no key scan causes more than 1,000 key seeks. See Section 5.1.8, “Server System Variables”.

### 8.2.2 Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions

The MySQL query optimizer has different strategies available to evaluate subqueries:

- For a subquery used with an **IN**, **= ANY**, or **EXISTS** predicate, the optimizer has these choices:
Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions

- Semijoin
- Materialization
- \textit{EXISTS} strategy

- For a subquery used with a \texttt{NOT IN}, \texttt{<> ALL} or \texttt{NOT EXISTS} predicate, the optimizer has these choices:
  - Materialization
  - \textit{EXISTS} strategy

For a derived table, the optimizer has these choices (which also apply to view references and common table expressions):

- Merge the derived table into the outer query block
- Materialize the derived table to an internal temporary table

The following discussion provides more information about the preceding optimization strategies.

\textbf{Note}
A limitation on \texttt{UPDATE} and \texttt{DELETE} statements that use a subquery to modify a single table is that the optimizer does not use semijoin or materialization subquery optimizations. As a workaround, try rewriting them as multiple-table \texttt{UPDATE} and \texttt{DELETE} statements that use a join rather than a subquery.

\textbf{8.2.2.1 Optimizing IN and EXISTS Subquery Predicates with Semijoin and Antijoin Transformations}

A semijoin is a preparation-time transformation that enables multiple execution strategies such as table pullout, duplicate weedout, first match, loose scan, and materialization. The optimizer uses semijoin strategies to improve subquery execution, as described in this section.

For an inner join between two tables, the join returns a row from one table as many times as there are matches in the other table. But for some questions, the only information that matters is whether there is a match, not the number of matches. Suppose that there are tables named \texttt{class} and \texttt{roster} that list classes in a course curriculum and class rosters (students enrolled in each class), respectively. To list the classes that actually have students enrolled, you could use this join:

\begin{verbatim}
SELECT class.class_num, class.class_name
FROM class
INNER JOIN roster
WHERE class.class_num = roster.class_num;
\end{verbatim}

However, the result lists each class once for each enrolled student. For the question being asked, this is unnecessary duplication of information.

Assuming that \texttt{class_num} is a primary key in the \texttt{class} table, duplicate suppression is possible by using \texttt{SELECT DISTINCT}, but it is inefficient to generate all matching rows first only to eliminate duplicates later.

The same duplicate-free result can be obtained by using a subquery:

\begin{verbatim}
SELECT class_num, class_name
FROM class
WHERE class_num IN
\end{verbatim}
(SELECT class_num FROM roster);

Here, the optimizer can recognize that the IN clause requires the subquery to return only one instance of each class number from the roster table. In this case, the query can use a semijoin; that is, an operation that returns only one instance of each row in class that is matched by rows in roster.

The following statement, which contains an EXISTS subquery predicate, is equivalent to the previous statement containing an IN subquery predicate:

```
SELECT class_num, class_name
FROM class
WHERE EXISTS
    (SELECT * FROM roster WHERE class.class_num = roster.class_num);
```

Any statement with an EXISTS subquery predicate is subject to the same semijoin transforms as a statement with an equivalent IN subquery predicate.

The following subqueries are transformed into antijoins:

- NOT IN (SELECT ... FROM ...)
- NOT EXISTS (SELECT ... FROM ...).
- IN (SELECT ... FROM ...) IS NOT TRUE
- EXISTS (SELECT ... FROM ...) IS NOT TRUE.
- IN (SELECT ... FROM ...) IS FALSE
- EXISTS (SELECT ... FROM ...) IS FALSE.

In short, any negation of a subquery of the form IN (SELECT ... FROM ...) or EXISTS (SELECT ... FROM ...) is transformed into an antijoin.

An antijoin is an operation that returns only rows for which there is no match. Consider the query shown here:

```
SELECT class_num, class_name
FROM class
WHERE class_num NOT IN
    (SELECT class_num FROM roster);
```

This query is rewritten internally as the antijoin SELECT class_num, class_name FROM class ANTIJOIN roster ON class_num, which returns one instance of each row in class that is not matched by any rows in roster. This means that, for each row in class, as soon as a match is found in roster, the row in class can be discarded.

Antijoin transformations cannot in most cases be applied if the expressions being compared are nullable. An exception to this rule is that (... NOT IN (SELECT ...)) IS NOT FALSE and its equivalent (... IN (SELECT ...)) IS NOT TRUE can be transformed into antijoins.

Outer join and inner join syntax is permitted in the outer query specification, and table references may be base tables, derived tables, view references, or common table expressions.

In MySQL, a subquery must satisfy these criteria to be handled as a semijoin (or an antijoin, if NOT modifies the subquery):

- It must be part of an IN, = ANY, or EXISTS predicate that appears at the top level of the WHERE or ON clause, possibly as a term in an AND expression. For example:

```
SELECT ...
FROM ot1, ...
WHERE (oe1, ...) IN
(SELECT ie1, ... FROM it1, ... WHERE ...);

Here, ot_i and it_i represent tables in the outer and inner parts of the query, and oe_i and ie_i represent expressions that refer to columns in the outer and inner tables.

The subquery can also be the argument to an expression modified by NOT, IS [NOT] TRUE, or IS [NOT] FALSE.

- It must be a single SELECT without UNION constructs.
- It must not contain a HAVING clause.
- It must not contain any aggregate functions (whether it is explicitly or implicitly grouped).
- It must not have a LIMIT clause.
- The statement must not use the STRAIGHT_JOIN join type in the outer query.
- The STRAIGHT_JOIN modifier must not be present.
- The number of outer and inner tables together must be less than the maximum number of tables permitted in a join.
- The subquery may be correlated or uncorrelated. Decorrelation looks at trivially correlated predicates in the WHERE clause of a subquery used as the argument to EXISTS, and makes it possible to optimize it as if it was used within IN (SELECT b FROM ...). The term trivially correlated means that the predicate is an equality predicate, that it is the sole predicate in the WHERE clause (or is combined with AND), and that one operand is from a table referenced in the subquery and the other operand is from the outer query block.
- The DISTINCT keyword is permitted but ignored. Semijoin strategies automatically handle duplicate removal.
- A GROUP BY clause is permitted but ignored, unless the subquery also contains one or more aggregate functions.
- An ORDER BY clause is permitted but ignored, since ordering is irrelevant to the evaluation of semijoin strategies.

If a subquery meets the preceding criteria, MySQL converts it to a semijoin (or to an antijoin if applicable) and makes a cost-based choice from these strategies:

- Convert the subquery to a join, or use table pullout and run the query as an inner join between subquery tables and outer tables. Table pullout pulls a table out from the subquery to the outer query.
- Duplicate Weedout: Run the semijoin as if it was a join and remove duplicate records using a temporary table.
- FirstMatch: When scanning the inner tables for row combinations and there are multiple instances of a given value group, choose one rather than returning them all. This "shortcuts" scanning and eliminates production of unnecessary rows.
- LooseScan: Scan a subquery table using an index that enables a single value to be chosen from each subquery's value group.
- Materialize the subquery into an indexed temporary table that is used to perform a join, where the index is used to remove duplicates. The index might also be used later for lookups when joining the temporary
table with the outer tables; if not, the table is scanned. For more information about materialization, see Section 8.2.2.2, “Optimizing Subqueries with Materialization”.

Each of these strategies can be enabled or disabled using the following \texttt{optimizer\_switch} system variable flags:

- The \texttt{semijoin} flag controls whether semijoins and antijoins are used.
  
  - If \texttt{semijoin} is enabled, the \texttt{firstmatch}, \texttt{loosescan}, \texttt{duplicateweedout}, and \texttt{materialization} flags enable finer control over the permitted semijoin strategies.
  
  - If the \texttt{duplicateweedout} semijoin strategy is disabled, it is not used unless all other applicable strategies are also disabled.
  
  - If \texttt{duplicateweedout} is disabled, on occasion the optimizer may generate a query plan that is far from optimal. This occurs due to heuristic pruning during greedy search, which can be avoided by setting \texttt{optimizer\_prune\_level}=0.

These flags are enabled by default. See Section 8.9.2, “Switchable Optimizations”.

The optimizer minimizes differences in handling of views and derived tables. This affects queries that use the \texttt{STRAIGHT\_JOIN} modifier and a view with an \texttt{IN} subquery that can be converted to a semijoin. The following query illustrates this because the change in processing causes a change in transformation, and thus a different execution strategy:

```sql
CREATE VIEW v AS
  SELECT *
  FROM t1
  WHERE a IN (SELECT b
               FROM t2);

SELECT STRAIGHT_JOIN *
  FROM t3 JOIN v ON t3.x = v.a;
```

The optimizer first looks at the view and converts the \texttt{IN} subquery to a semijoin, then checks whether it is possible to merge the view into the outer query. Because the \texttt{STRAIGHT\_JOIN} modifier in the outer query prevents semijoin, the optimizer refuses the merge, causing derived table evaluation using a materialized table.

\texttt{EXPLAIN} output indicates the use of semijoin strategies as follows:

- For extended \texttt{EXPLAIN} output, the text displayed by a following \texttt{SHOW WARNINGS} shows the rewritten query, which displays the semijoin structure. (See Section 8.8.3, “Extended EXPLAIN Output Format”.) From this you can get an idea about which tables were pulled out of the semijoin. If a subquery was converted to a semijoin, you should see that the subquery predicate is gone and its tables and \texttt{WHERE} clause were merged into the outer query join list and \texttt{WHERE} clause.

- Temporary table use for Duplicate Weedout is indicated by \texttt{Start temporary} and \texttt{End temporary} in the \texttt{Extra} column. Tables that were not pulled out and are in the range of \texttt{EXPLAIN} output rows covered by \texttt{Start temporary} and \texttt{End temporary} have their \texttt{rowid} in the temporary table.

- \texttt{FirstMatch(tbl\_name)} in the \texttt{Extra} column indicates join shortccuting.

- \texttt{LooseScan(m..n)} in the \texttt{Extra} column indicates use of the LooseScan strategy. \texttt{m} and \texttt{n} are key part numbers.

- Temporary table use for materialization is indicated by rows with a \texttt{select\_type} value of \texttt{MATERIALIZED} and rows with a \texttt{table} value of \texttt{<subqueryN>}.
A semijoin transformation can also be applied to a single-table UPDATE or DELETE statement that uses a [NOT] IN or [NOT] EXISTS subquery predicate, provided that the statement does not use ORDER BY or LIMIT, and that semijoin transformations are allowed by an optimizer hint or by the optimizer_switch setting.

### 8.2.2.2 Optimizing Subqueries with Materialization

The optimizer uses materialization to enable more efficient subquery processing. Materialization speeds up query execution by generating a subquery result as a temporary table, normally in memory. The first time MySQL needs the subquery result, it materializes that result into a temporary table. Any subsequent time the result is needed, MySQL refers again to the temporary table. The optimizer may index the table with a hash index to make lookups fast and inexpensive. The index contains unique values to eliminate duplicates and make the table smaller.

Subquery materialization uses an in-memory temporary table when possible, falling back to on-disk storage if the table becomes too large. See Section 8.4.4, “Internal Temporary Table Use in MySQL”.

If materialization is not used, the optimizer sometimes rewrites a noncorrelated subquery as a correlated subquery. For example, the following IN subquery is noncorrelated (where_condition involves only columns from t2 and not t1):

```sql
SELECT * FROM t1
WHERE t1.a IN (SELECT t2.b FROM t2 WHERE where_condition);
```

The optimizer might rewrite this as an EXISTS correlated subquery:

```sql
SELECT * FROM t1
WHERE EXISTS (SELECT t2.b FROM t2 WHERE where_condition AND t1.a=t2.b);
```

Subquery materialization using a temporary table avoids such rewrites and makes it possible to execute the subquery only once rather than once per row of the outer query.

For subquery materialization to be used in MySQL, the optimizer_switch system variable materialization flag must be enabled. (See Section 8.9.2, “Switchable Optimizations”.) With the materialization flag enabled, materialization applies to subquery predicates that appear anywhere (in the select list, WHERE, ON, GROUP BY, HAVING, or ORDER BY), for predicates that fall into any of these use cases:

- The predicate has this form, when no outer expression oe_i or inner expression ie_i is nullable. N is 1 or larger.

  ```sql
  (oe_1, oe_2, ..., oe_N) [NOT] IN (SELECT ie_1, ie_2, ..., ie_N ...)
  ```

- The predicate has this form, when there is a single outer expression oe and inner expression ie. The expressions can be nullable.

  ```sql
  oe [NOT] IN (SELECT ie ...)
  ```

- The predicate is IN or NOT IN and a result of UNKNOWN (NULL) has the same meaning as a result of FALSE.

The following examples illustrate how the requirement for equivalence of UNKNOWN and FALSE predicate evaluation affects whether subquery materialization can be used. Assume that where_condition involves columns only from t2 and not t1 so that the subquery is noncorrelated.

This query is subject to materialization:

```sql
SELECT * FROM t1
```
WHERE t1.a IN (SELECT t2.b FROM t2 WHERE where_condition);

Here, it does not matter whether the \texttt{IN} predicate returns \texttt{UNKNOWN} or \texttt{FALSE}. Either way, the row from \texttt{t1} is not included in the query result.

An example where subquery materialization is not used is the following query, where \texttt{t2.b} is a nullable column:

\begin{verbatim}
SELECT * FROM t1
WHERE (t1.a,t1.b) NOT IN (SELECT t2.a,t2.b FROM t2
WHERE where_condition);
\end{verbatim}

The following restrictions apply to the use of subquery materialization:

- The types of the inner and outer expressions must match. For example, the optimizer might be able to use materialization if both expressions are integer or both are decimal, but cannot if one expression is integer and the other is decimal.

- The inner expression cannot be a \texttt{BLOB}.

Use of \texttt{EXPLAIN} with a query provides some indication of whether the optimizer uses subquery materialization:

- Compared to query execution that does not use materialization, \texttt{select_type} may change from \texttt{DEPENDENT SUBQUERY} to \texttt{SUBQUERY}. This indicates that, for a subquery that would be executed once per outer row, materialization enables the subquery to be executed just once.

- For extended \texttt{EXPLAIN} output, the text displayed by a following \texttt{SHOW WARNINGS} includes \texttt{materialize} and \texttt{materialized-subquery}.

MySQL can also apply subquery materialization to a single-table \texttt{UPDATE} or \texttt{DELETE} statement that uses a \texttt{[NOT] IN} or \texttt{[NOT] EXISTS} subquery predicate, provided that the statement does not use \texttt{ORDER BY} or \texttt{LIMIT}, and that subquery materialization is allowed by an optimizer hint or by the \texttt{optimizer_switch} setting.

### 8.2.2.3 Optimizing Subqueries with the EXISTS Strategy

Certain optimizations are applicable to comparisons that use the \texttt{IN} (or \texttt{=ANY}) operator to test subquery results. This section discusses these optimizations, particularly with regard to the challenges that \texttt{NULL} values present. The last part of the discussion suggests how you can help the optimizer.

Consider the following subquery comparison:

\begin{verbatim}
outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
\end{verbatim}

MySQL evaluates queries “from outside to inside.” That is, it first obtains the value of the outer expression \texttt{outer_expr}, and then runs the subquery and captures the rows that it produces.

A very useful optimization is to “inform” the subquery that the only rows of interest are those where the inner expression \texttt{inner_expr} is equal to \texttt{outer_expr}. This is done by pushing down an appropriate equality into the subquery’s \texttt{WHERE} clause to make it more restrictive. The converted comparison looks like this:

\begin{verbatim}
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND outer_expr=inner_expr)
\end{verbatim}

After the conversion, MySQL can use the pushed-down equality to limit the number of rows it must examine to evaluate the subquery.
Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions

More generally, a comparison of \( N \) values to a subquery that returns \( N \)-value rows is subject to the same conversion. If \( oe_i \) and \( ie_i \) represent corresponding outer and inner expression values, this subquery comparison:

\[
(oe_1, \ldots, oe_N) \text{ IN } (SELECT ie_1, \ldots, ie_N \text{ FROM } \ldots \text{ WHERE subquery_where})
\]

Becomes:

\[
\text{EXISTS (SELECT 1 FROM } \ldots \text{ WHERE subquery_where AND oe_1 = ie_1 AND } \ldots \text{ AND oe_N = ie_N)}
\]

For simplicity, the following discussion assumes a single pair of outer and inner expression values.

The “pushdown” strategy just described works if either of these conditions is true:

- \( outer_expr \) and \( inner_expr \) cannot be NULL.

- You need not distinguish NULL from FALSE subquery results. If the subquery is a part of an OR or AND expression in the WHERE clause, MySQL assumes that you do not care. Another instance where the optimizer notices that NULL and FALSE subquery results need not be distinguished is this construct:

\[ \ldots \text{ WHERE } outer_expr \text{ IN (subquery)} \]

In this case, the WHERE clause rejects the row whether IN (subquery) returns NULL or FALSE.

Suppose that \( outer_expr \) is known to be a non-NULL value but the subquery does not produce a row such that \( outer_expr = inner_expr \). Then \( outer_expr \text{ IN (SELECT } \ldots \text{)} \) evaluates as follows:

- NULL, if the SELECT produces any row where \( inner_expr \) is NULL

- FALSE, if the SELECT produces only non-NULL values or produces nothing

In this situation, the approach of looking for rows with \( outer_expr = inner_expr \) is no longer valid. It is necessary to look for such rows, but if none are found, also look for rows where \( inner_expr \) is NULL. Roughly speaking, the subquery can be converted to something like this:

\[
\text{EXISTS (SELECT 1 FROM } \ldots \text{ WHERE subquery_where AND (outer_expr=inner_expr OR inner_expr IS NULL))}
\]

The need to evaluate the extra IS NULL condition is why MySQL has the ref_or_null access method:

```
mysql> EXPLAIN
  \+-----------------------------+ 1. row +-----------------------------+
  | id: 1| select_type: PRIMARY| table: t1 |
  +-----------------------------+ 2. row +-----------------------------+
  | id: 2| select_type: DEPENDENT SUBQUERY| table: t2 |
  +-----------------------------+ 3. row +-----------------------------+
  | id: 3| select_type: DEPENDENT SUBQUERY| table: t3 |
  +-----------------------------+
```
The `unique_subquery` and `index_subquery` subquery-specific access methods also have “or NULL” variants.

The additional `OR ... IS NULL` condition makes query execution slightly more complicated (and some optimizations within the subquery become inapplicable), but generally this is tolerable.

The situation is much worse when `outer_expr` can be `NULL`. According to the SQL interpretation of `NULL` as “unknown value,” `NULL IN (SELECT inner_expr ...)` should evaluate to:

- **NULL**, if the `SELECT` produces any rows
- **FALSE**, if the `SELECT` produces no rows

For proper evaluation, it is necessary to be able to check whether the `SELECT` has produced any rows at all, so `outer_expr = inner_expr` cannot be pushed down into the subquery. This is a problem because many real world subqueries become very slow unless the equality can be pushed down.

Essentially, there must be different ways to execute the subquery depending on the value of `outer_expr`.

The optimizer chooses SQL compliance over speed, so it accounts for the possibility that `outer_expr` might be `NULL`:

- **If `outer_expr` is NULL**, to evaluate the following expression, it is necessary to execute the `SELECT` to determine whether it produces any rows:

  ```sql
  NULL IN (SELECT inner_expr FROM ... WHERE subquery_where)
  ```

  It is necessary to execute the original `SELECT` here, without any pushed-down equalities of the kind mentioned previously.

- **On the other hand**, when `outer_expr` is not `NULL`, it is absolutely essential that this comparison:

  ```sql
  outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
  ```

  Be converted to this expression that uses a pushed-down condition:

  ```sql
  EXISTS (SELECT 1 FROM ... WHERE subquery_where AND trigcond(outer_expr = inner_expr))
  ```

  Without this conversion, subqueries are slow.

To solve the dilemma of whether or not to push down conditions into the subquery, the conditions are wrapped within “trigger” functions. Thus, an expression of the following form:

```sql
outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

Is converted into:

```sql
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND trigcond(outer_expr = inner_expr))
```

More generally, if the subquery comparison is based on several pairs of outer and inner expressions, the conversion takes this comparison:

```sql
(o_1, ..., o_N) IN (SELECT i_1, ..., i_N FROM ... WHERE subquery_where)
```

And converts it to this expression:
Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions

```sql
EXISTS (SELECT 1 FROM ... WHERE subquery_where
    AND trigcond(oe_i=ie_i)
    AND ...
    AND trigcond(oe_N=ie_N)
)}
```

Each `trigcond(X)` is a special function that evaluates to the following values:

- `X` when the “linked” outer expression `oe_i` is not NULL
- `TRUE` when the “linked” outer expression `oe_i` is NULL

**Note**

Trigger functions are not triggers of the kind that you create with `CREATE TRIGGER`.

Equalities that are wrapped within `trigcond()` functions are not first class predicates for the query optimizer. Most optimizations cannot deal with predicates that may be turned on and off at query execution time, so they assume any `trigcond(X)` to be an unknown function and ignore it. Triggered equalities can be used by those optimizations:

- **Reference optimizations**: `trigcond(X=Y [OR Y IS NULL])` can be used to construct `ref`, `eq_ref`, or `ref_or_null` table accesses.
- **Index lookup-based subquery execution engines**: `trigcond(X=Y)` can be used to construct `unique_subquery` or `index_subquery` accesses.
- **Table-condition generator**: If the subquery is a join of several tables, the triggered condition is checked as soon as possible.

When the optimizer uses a triggered condition to create some kind of index lookup-based access (as for the first two items of the preceding list), it must have a fallback strategy for the case when the condition is turned off. This fallback strategy is always the same: Do a full table scan. In `EXPLAIN` output, the fallback shows up as **Full scan on NULL key** in the `Extra` column:

```
mysql> EXPLAIN SELECT t1.col1, t1.col1 IN (SELECT t2.key1 FROM t2 WHERE t2.col2=t1.col2) FROM t1\G
```

```
*************************** 1. row ***************************
id: 1
select_type: PRIMARY
table: t1
...
*************************** 2. row ***************************
id: 2
select_type: DEPENDENT SUBQUERY
table: t2
type: index_subquery
possible_keys: key1
key: key1
key_len: 5
ref: func
rows: 2
Extra: Using where; Full scan on NULL key
```

If you run `EXPLAIN` followed by `SHOW WARNINGS`, you can see the triggered condition:

```
*************************** 1. row ***************************
Level: Note
Code: 1003
Message: select `test`.`t1`.`col1` AS `col1`,
```

1830
The use of triggered conditions has some performance implications. A `NULL IN (SELECT ...)` expression now may cause a full table scan (which is slow) when it previously did not. This is the price paid for correct results (the goal of the trigger-condition strategy is to improve compliance, not speed).

For multiple-table subqueries, execution of `NULL IN (SELECT ...)` is particularly slow because the join optimizer does not optimize for the case where the outer expression is `NULL`. It assumes that subquery evaluations with `NULL` on the left side are very rare, even if there are statistics that indicate otherwise. On the other hand, if the outer expression might be `NULL` but never actually is, there is no performance penalty.

To help the query optimizer better execute your queries, use these suggestions:

- Declare a column as `NOT NULL` if it really is. This also helps other aspects of the optimizer by simplifying condition testing for the column.
- If you need not distinguish a `NULL` from `FALSE` subquery result, you can easily avoid the slow execution path. Replace a comparison that looks like this:
  
  ```sql
  outer_expr [NOT] IN (SELECT inner_expr FROM ...)
  ```

  with this expression:

  ```sql
  (outer_expr IS NOT NULL) AND (outer_expr [NOT] IN (SELECT inner_expr FROM ...))
  ```

  Then `NULL IN (SELECT ...)` is never evaluated because MySQL stops evaluating `AND` parts as soon as the expression result is clear.

  Another possible rewrite:

  ```sql
  [NOT] EXISTS (SELECT inner_expr FROM ...
  WHERE inner_expr=outer_expr)
  ```

  The `subquery_materialization_cost_based` flag of the `optimizer_switch` system variable enables control over the choice between subquery materialization and `IN-to-EXISTS` subquery transformation. See Section 8.9.2, “Switchable Optimizations”.

### 8.2.2.4 Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization

The optimizer can handle derived table references using two strategies (which also apply to view references and common table expressions):

- Merge the derived table into the outer query block
- Materialize the derived table to an internal temporary table

**Example 1:**

```sql
SELECT * FROM (SELECT * FROM t1) AS derived_t1;
```

With merging of the derived table `derived_t1`, that query is executed similar to:
Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions

Example 2:

```sql
SELECT * FROM t1;
```

```sql
SELECT *
FROM t1 JOIN (SELECT t2.f1 FROM t2) AS derived_t2 ON t1.f2=derived_t2.f1
WHERE t1.f1 > 0;
```

With merging of the derived table `derived_t2`, that query is executed similar to:

```sql
SELECT t1.*, t2.f1
FROM t1 JOIN t2 ON t1.f2=t2.f1
WHERE t1.f1 > 0;
```

With materialization, `derived_t1` and `derived_t2` are each treated as a separate table within their respective queries.

The optimizer handles derived tables, view references, and common table expressions the same way: It avoids unnecessary materialization whenever possible, which enables pushing down conditions from the outer query to derived tables and produces more efficient execution plans. (For an example, see Section 8.2.2.2, “Optimizing Subqueries with Materialization”.)

If merging would result in an outer query block that references more than 61 base tables, the optimizer chooses materialization instead.

The optimizer propagates an `ORDER BY` clause in a derived table or view reference to the outer query block if these conditions are all true:

- The outer query is not grouped or aggregated.
- The outer query does not specify `DISTINCT`, `HAVING`, or `ORDER BY`.
- The outer query has this derived table or view reference as the only source in the `FROM` clause.

Otherwise, the optimizer ignores the `ORDER BY` clause.

The following means are available to influence whether the optimizer attempts to merge derived tables, view references, and common table expressions into the outer query block:

- The `MERGE` and `NO_MERGE` optimizer hints can be used. They apply assuming that no other rule prevents merging. See Section 8.9.3, “Optimizer Hints”.

- Similarly, you can use the `derived_merge` flag of the `optimizer_switch` system variable. See Section 8.9.2, “Switchable Optimizations”. By default, the flag is enabled to permit merging. Disabling the flag prevents merging and avoids `ER_UPDATE_TABLE_USED` errors.

The `derived_merge` flag also applies to views that contain no `ALGORITHM` clause. Thus, if an `ER_UPDATE_TABLE_USED` error occurs for a view reference that uses an expression equivalent to the subquery, adding `ALGORITHM=TEMPTABLE` to the view definition prevents merging and takes precedence over the `derived_merge` value.

- It is possible to disable merging by using in the subquery any constructs that prevent merging, although these are not as explicit in their effect on materialization. Constructs that prevent merging are the same for derived tables, common table expressions, and view references:
  - Aggregate functions or window functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)
  - `DISTINCT`
Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions

- `GROUP BY`
- `HAVING`
- `LIMIT`
- `UNION` or `UNION ALL`

- Subqueries in the select list
- Assignments to user variables
- References only to literal values (in this case, there is no underlying table)

If the optimizer chooses the materialization strategy rather than merging for a derived table, it handles the query as follows:

- The optimizer postpones derived table materialization until its contents are needed during query execution. This improves performance because delaying materialization may result in not having to do it at all. Consider a query that joins the result of a derived table to another table: If the optimizer processes that other table first and finds that it returns no rows, the join need not be carried out further and the optimizer can completely skip materializing the derived table.

- During query execution, the optimizer may add an index to a derived table to speed up row retrieval from it.

Consider the following `EXPLAIN` statement, for a `SELECT` query that contains a derived table:

```
EXPLAIN SELECT * FROM (SELECT * FROM t1) AS derived_t1;
```

The optimizer avoids materializing the derived table by delaying it until the result is needed during `SELECT` execution. In this case, the query is not executed (because it occurs in an `EXPLAIN` statement), so the result is never needed.

Even for queries that are executed, delay of derived table materialization may enable the optimizer to avoid materialization entirely. When this happens, query execution is quicker by the time needed to perform materialization. Consider the following query, which joins the result of a derived table to another table:

```
SELECT *
FROM t1 JOIN (SELECT t2.f1 FROM t2) AS derived_t2
ON t1.f2=derived_t2.f1
WHERE t1.f1 > 0;
```

If the optimization processes `t1` first and the `WHERE` clause produces an empty result, the join must necessarily be empty and the derived table need not be materialized.

For cases when a derived table requires materialization, the optimizer may add an index to the materialized table to speed up access to it. If such an index enables `ref` access to the table, it can greatly reduce amount of data read during query execution. Consider the following query:

```
SELECT *
FROM t1 JOIN (SELECT DISTINCT f1 FROM t2) AS derived_t2
ON t1.f1=derived_t2.f1;
```

The optimizer constructs an index over column `f1` from `derived_t2` if doing so would enable use of `ref` access for the lowest cost execution plan. After adding the index, the optimizer can treat the materialized derived table the same as a regular table with an index, and it benefits similarly from the generated index. The overhead of index creation is negligible compared to the cost of query execution without the index. If
ref access would result in higher cost than some other access method, the optimizer creates no index and loses nothing.

For optimizer trace output, a merged derived table or view reference is not shown as a node. Only its underlying tables appear in the top query's plan.

What is true for materialization of derived tables is also true for common table expressions (CTEs). In addition, the following considerations pertain specifically to CTEs.

If a CTE is materialized by a query, it is materialized once for the query, even if the query references it several times.

A recursive CTE is always materialized.

If a CTE is materialized, the optimizer automatically adds relevant indexes if it estimates that indexing can speed up access by the top-level statement to the CTE. This is similar to automatic indexing of derived tables, except that if the CTE is referenced multiple times, the optimizer may create multiple indexes, to speed up access by each reference in the most appropriate way.

The MERGE and NO_MERGE optimizer hints can be applied to CTEs. Each CTE reference in the top-level statement can have its own hint, permitting CTE references to be selectively merged or materialized. The following statement uses hints to indicate that cte1 should be merged and cte2 should be materialized:

```sql
WITH
c1 AS (SELECT a, b FROM table1),
c2 AS (SELECT c, d FROM table2)
SELECT /*+ MERGE(cte1) NO_MERGE(cte2) */ cte1.b, cte2.d
FROM cte1 JOIN cte2
WHERE cte1.a = cte2.c;
```

The ALGORITHM clause for CREATE VIEW does not affect materialization for any WITH clause preceding the SELECT statement in the view definition. Consider this statement:

```sql
CREATE ALGORITHM={TEMPTABLE|MERGE} VIEW v1 AS WITH ...
```

The ALGORITHM value affects materialization only of the SELECT, not the WITH clause.

As mentioned previously, a CTE, if materialized, is materialized once, even if referenced multiple times. To indicate one-time materialization, optimizer trace output contains an occurrence of creating_tmp_table plus one or more occurrences of reusing_tmp_table.

CTEs are similar to derived tables, for which the materialized_from_subquery node follows the reference. This is true for a CTE that is referenced multiple times, so there is no duplication of materialized_from_subquery nodes (which would give the impression that the subquery is executed multiple times, and produce unnecessarily verbose output). Only one reference to the CTE has a complete materialized_from_subquery node with the description of its subquery plan. Other references have a reduced materialized_from_subquery node. The same idea applies to EXPLAIN output in TRADITIONAL format: Subqueries for other references are not shown.

### 8.2.2.5 Derived Condition Pushdown Optimization

MySQL supports derived condition pushdown for eligible subqueries. For a query such as SELECT * FROM (SELECT i, j FROM t1) AS dt WHERE i > constant, it is possible in many cases to push the outer WHERE condition down to the derived table, in this case resulting in SELECT * FROM (SELECT i, j FROM t1 WHERE i > constant) AS dt. When a derived table cannot be merged into the outer query (for example, if the derived table uses aggregation), pushing the outer WHERE condition down to the derived table should decrease the number of rows that need to be processed and thus speed up execution of the query.
Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions

Outer \textit{WHERE} conditions can be pushed down to derived materialized tables under the following circumstances:

- When the derived table uses no aggregate or window functions, the outer \textit{WHERE} condition can be pushed down to it directly. This includes \textit{WHERE} conditions having multiple predicates joined with \texttt{AND}, \texttt{OR}, or both.

  For example, the query \texttt{SELECT * FROM (SELECT f1, f2 FROM t1) AS dt WHERE f1 < 3 AND f2 > 11} is rewritten as \texttt{SELECT f1, f2 FROM (SELECT f1, f2 FROM t1 WHERE f1 < 3 AND f2 > 11) AS dt}.

- When the derived table has a \texttt{GROUP BY} and uses no window functions, an outer \textit{WHERE} condition referencing one or more columns which are not part of the \texttt{GROUP BY} can be pushed down to the derived table as a \texttt{HAVING} condition.

  For example, \texttt{SELECT * FROM (SELECT i, j, \texttt{SUM(k) AS sum} FROM t1 GROUP BY i, j) AS dt WHERE \texttt{sum} > 100} is rewritten following derived condition pushdown as \texttt{SELECT * FROM (SELECT i, j, \texttt{SUM(k) AS sum} FROM t1 GROUP BY i, j \texttt{HAVING sum} > 100) AS dt}.

- When the derived table uses a \texttt{GROUP BY} and the columns in the outer \textit{WHERE} condition are \texttt{GROUP BY} columns, the \textit{WHERE} conditions referencing those columns can be pushed down directly to the derived table.

  For example, the query \texttt{SELECT * FROM (SELECT i,j, \texttt{SUM(k) AS sum} FROM t1 GROUP BY i,j) AS dt WHERE i > 10} is rewritten as \texttt{SELECT * FROM (SELECT i,j, \texttt{SUM(k) AS sum FROM t1 WHERE i > 10 GROUP BY i,j}) AS dt}.

In the event that the outer \textit{WHERE} condition has predicates referencing columns which are part of the \texttt{GROUP BY} as well as predicates referencing columns which are not, predicates of the former sort are pushed down as \textit{WHERE} conditions, while those of the latter type are pushed down as \texttt{HAVING} conditions. For example, in the query \texttt{SELECT * FROM (SELECT i, j, \texttt{SUM(k) AS sum FROM t1 GROUP BY i,j}) AS dt WHERE i > 10 AND \texttt{sum} > 100}, the predicate \texttt{i > 10} in the outer \textit{WHERE} clause references a \texttt{GROUP BY} column, whereas the predicate \texttt{sum > 100} does not reference any \texttt{GROUP BY} column. Thus the derived table pushdown optimization causes the query to be rewritten in a manner similar to what is shown here:

```sql
SELECT * FROM {
  SELECT i, j, \texttt{SUM(k) AS sum} FROM t1
  WHERE i > 10
  GROUP BY i, j
  HAVING sum > 100
} AS dt;
```

To enable derived condition pushdown, the \texttt{optimizer_switch} system variable's \texttt{derived_condition_pushdown} flag (added in this release) must be set to \texttt{on}, which is the default setting. If this optimization is disabled by \texttt{optimizer_switch}, you can enable it for a specific query using the \texttt{DERIVED_CONDITION_PUSHDOWN} optimizer hint. To disable the optimization for a given query, use the \texttt{NO_DERIVED_CONDITION_PUSHDOWN} optimizer hint.

The following restrictions and limitations apply to the derived table condition pushdown optimization:

- The derived table condition pushdown optimization can be employed with \texttt{UNION} queries, with the following exceptions:
  - Condition pushdown cannot be used with a \texttt{UNION} query if any materialized derived table that is part of the \texttt{UNION} is a recursive common table expression (see \texttt{Recursive Common Table Expressions}).
  - Conditions containing nondeterministic expressions cannot be pushed down to a derived table.
• The derived table cannot use a **LIMIT** clause.

• Conditions containing subqueries cannot be pushed down.

• The optimization cannot be used if the derived table is an inner table of an outer join.

• If a materialized derived table is a common table expression, conditions are not pushed down to it if it is referenced multiple times.

• Conditions using parameters can be pushed down if the condition is of the form `derived_column > ?`. If a derived column in an outer **WHERE** condition is an expression having a `?` in the underlying derived table, this condition cannot be pushed down.

• For a query in which the condition is on the tables of a view created using **ALGORITHM=TEMPTABLE** instead of on the view itself, the multiple equality is not recognized at resolution, and thus the condition cannot be not pushed down. This because, when optimizing a query, condition pushdown takes place during resolution phase while multiple equality propagation occurs during optimization.

  This is not an issue in such cases for a view using **ALGORITHM=MERGE**, where the equality can be propagated and the condition pushed down.

• A condition cannot be pushed down if the derived table’s **SELECT** list contain any assignments to user variables.

### 8.2.3 Optimizing INFORMATION_SCHEMA Queries

Applications that monitor databases may make frequent use of INFORMATION_SCHEMA tables. To write queries for these tables most efficiently, use the following general guidelines:

• Try to query only INFORMATION_SCHEMA tables that are views on data dictionary tables.

• Try to query only for static metadata. Selecting columns or using retrieval conditions for dynamic metadata along with static metadata adds overhead to process the dynamic metadata.

**Note**

Comparison behavior for database and table names in INFORMATION_SCHEMA queries might differ from what you expect. For details, see Section 10.8.7, “Using Collation in INFORMATION_SCHEMA Searches”.

These INFORMATION_SCHEMA tables are implemented as views on data dictionary tables, so queries on them retrieve information from the data dictionary:

```sql
CHARACTER_SETS
CHECK_CONSTRAINTS
COLLATIONS
COLLATION_CHARACTER_SET_APPLICABILITY
COLUMNS
EVENTS
FILES
INNODB_COLUMNS
INNODB_DATAFILES
INNODB_FIELDS
INNODB_FOREIGN
INNODB_FOREIGN_COLS
INNODB_INDEXES
INNODB_TABLES
INNODB_TABLESPACES
INNODB_TABLESPACES_BRIEF
INNODB_TABLESTATS
```
Some types of values, even for a non-view INFORMATION_SCHEMA table, are retrieved by lookups from the data dictionary. This includes values such as database and table names, table types, and storage engines.

Some INFORMATION_SCHEMA tables contain columns that provide table statistics:

<table>
<thead>
<tr>
<th>STATISTICS.CARDINALITY</th>
<th>TABLES.AUTO_INCREMENT</th>
<th>TABLES.AVG_ROW_LENGTH</th>
<th>TABLES.CHECKSUM</th>
<th>TABLES.CREATE_TIME</th>
<th>TABLES.DATA_FREE</th>
<th>TABLES.DATA_LENGTH</th>
<th>TABLES.INDEX_LENGTH</th>
<th>TABLES.MAX_DATA_LENGTH</th>
<th>TABLES.TABLE_ROWS</th>
<th>TABLES.UPDATE_TIME</th>
</tr>
</thead>
</table>

Those columns represent dynamic table metadata; that is, information that changes as table contents change.

By default, MySQL retrieves cached values for those columns from the mysql.index_stats and mysql.innodb_table_stats dictionary tables when the columns are queried, which is more efficient than retrieving statistics directly from the storage engine. If cached statistics are not available or have expired, MySQL retrieves the latest statistics from the storage engine and caches them in the mysql.index_stats and mysql.innodb_table_stats dictionary tables. Subsequent queries retrieve the cached statistics until the cached statistics expire. A server restart or the first opening of the mysql.index_stats and mysql.innodb_table_stats tables do not update cached statistics automatically.

The information_schema.stats_expiry session variable defines the period of time before cached statistics expire. The default is 86400 seconds (24 hours), but the time period can be extended to as much as one year.

To update cached values at any time for a given table, use ANALYZE TABLE.

Querying statistics columns does not store or update statistics in the mysql.index_stats and mysql.innodb_table_stats dictionary tables under these circumstances:

- When cached statistics have not expired.
- When information_schema.stats_expiry is set to 0.
- When the server is in read_only, super_read_only, transaction_read_only, or innodb_read_only mode.
Optimizing INFORMATION_SCHEMA Queries

- When the query also fetches Performance Schema data.

`information_schema_stats_expiry` is a session variable, and each client session can define its own expiration value. Statistics that are retrieved from the storage engine and cached by one session are available to other sessions.

**Note**

If the `innodb_read_only` system variable is enabled, `ANALYZE TABLE` may fail because it cannot update statistics tables in the data dictionary, which use InnoDB. For `ANALYZE TABLE` operations that update the key distribution, failure may occur even if the operation updates the table itself (for example, if it is a MyISAM table). To obtain the updated distribution statistics, set `information_schema_stats_expiry=0`.

For `INFORMATION_SCHEMA` tables implemented as views on data dictionary tables, indexes on the underlying data dictionary tables permit the optimizer to construct efficient query execution plans. To see the choices made by the optimizer, use `EXPLAIN`. To also see the query used by the server to execute an `INFORMATION_SCHEMA` query, use `SHOW WARNINGS` immediately following `EXPLAIN`.

Consider this statement, which identifies collations for the `utf8mb4` character set:

```
mysql> SELECT COLLATION_NAME
    FROM INFORMATION_SCHEMA.COLLATION_CHARACTER_SET_APPLICABILITY
    WHERE CHARACTER_SET_NAME = 'utf8mb4';
```

<table>
<thead>
<tr>
<th>COLLATION_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>utf8mb4_general_ci</td>
</tr>
<tr>
<td>utf8mb4_bin</td>
</tr>
<tr>
<td>utf8mb4_unicode_ci</td>
</tr>
<tr>
<td>utf8mb4_icelandic_ci</td>
</tr>
<tr>
<td>utf8mb4_latvian_ci</td>
</tr>
<tr>
<td>utf8mb4_romanian_ci</td>
</tr>
<tr>
<td>utf8mb4_slovenian_ci</td>
</tr>
<tr>
<td>...</td>
</tr>
</tbody>
</table>

How does the server process that statement? To find out, use `EXPLAIN`:

```
mysql> EXPLAIN SELECT COLLATION_NAME
    FROM INFORMATION_SCHEMA.COLLATION_CHARACTER_SET_APPLICABILITY
    WHERE CHARACTER_SET_NAME = 'utf8mb4';
```

```
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: cs
partitions: NULL
type: const
possible_keys: PRIMARY,name
key: name
key_len: 194
ref: const
rows: 1
filtered: 100.00
Extra: Using index
*************************** 2. row ***************************
id: 1
select_type: SIMPLE
table: col
partitions: NULL
type: ref
possible_keys: character_set_id
key: character_set_id
```
To see the query used to satisfy that statement, use `SHOW WARNINGS`:

```
mysql> SHOW WARNINGS
*************************** 1. row ***************************
Level: Note
Code: 1003
Message: /* select#1 */ select `mysql`\`\`col`\`\`.name` AS `COLLATION_NAME` from `mysql`\`\`character_sets` `cs` join `mysql`\`\`collations` `col` where ((`mysql`\`\`col`\`\`.character_set_id` = '45') and ('utf8mb4' = 'utf8mb4'))
```

As indicated by `SHOW WARNINGS`, the server handles the query on `COLLATION_CHARACTER_SET_APPLICABILITY` as a query on the `character_sets` and `collations` data dictionary tables in the `mysql` system database.

### 8.2.4 Optimizing Performance Schema Queries

Applications that monitor databases may make frequent use of Performance Schema tables. To write queries for these tables most efficiently, take advantage of their indexes. For example, include a `WHERE` clause that restricts retrieved rows based on comparison to specific values in an indexed column.

Most Performance Schema tables have indexes. Tables that do not are those that normally contain few rows or are unlikely to be queried frequently. Performance Schema indexes give the optimizer access to execution plans other than full table scans. These indexes also improve performance for related objects, such as `sys` schema views that use those tables.

To see whether a given Performance Schema table has indexes and what they are, use `SHOW INDEX` or `SHOW CREATE TABLE`:

```
mysql> SHOW INDEX FROM performance_schema.accounts
*************************** 1. row ***************************
Table: accounts
Non_unique: 0
Key_name: ACCOUNT
Seq_in_index: 1
Column_name: USER
Collation: NULL
Cardinality: NULL
Sub_part: NULL
Packed: NULL
Null: YES
Index_type: HASH
Comment:
Index_comment:
Visible: YES
```

```
*************************** 2. row ***************************
Table: accounts
Non_unique: 0
Key_name: ACCOUNT
Seq_in_index: 2
Column_name: HOST
Collation: NULL
Cardinality: NULL
Sub_part: NULL
Packed: NULL
```
Null: YES
Index_type: HASH
Comment:
Index_comment:
Visible: YES

mysql> SHOW CREATE TABLE performance_schema.rwlock_instances\G
*************************** 1. row ***************************
Table: rwlock_instances
Create Table: CREATE TABLE `rwlock_instances` (  
  `NAME` varchar(128) NOT NULL,
  `OBJECT_INSTANCE_BEGIN` bigint(20) unsigned NOT NULL,
  `WRITE_LOCKED_BY_THREAD_ID` bigint(20) unsigned DEFAULT NULL,
  `READ_LOCKED_BY_COUNT` int(10) unsigned NOT NULL,
  PRIMARY KEY (`OBJECT_INSTANCE_BEGIN`),
  KEY `NAME` (`NAME`),
  KEY `WRITE_LOCKED_BY_THREAD_ID` (`WRITE_LOCKED_BY_THREAD_ID`) ) ENGINE=PERFORMANCE_SCHEMA DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci

To see the execution plan for a Performance Schema query and whether it uses any indexes, use EXPLAIN:

mysql> EXPLAIN SELECT * FROM performance_schema.accounts
    WHERE (USER,HOST) = ('root','localhost')\G
*************************** 1. row ***************************
  id: 1
  select_type: SIMPLE
  table: accounts
  partitions: NULL
  type: const
  possible_keys: ACCOUNT
  key: ACCOUNT
  key_len: 278
  ref: const,const
  rows: 1
  filtered: 100.00
  Extra: NULL

The EXPLAIN output indicates that the optimizer uses the accounts table ACCOUNT index that comprises the USER and HOST columns.

Performance Schema indexes are virtual: They are a construct of the Performance Schema storage engine and use no memory or disk storage. The Performance Schema reports index information to the optimizer so that it can construct efficient execution plans. The Performance Schema in turn uses optimizer information about what to look for (for example, a particular key value), so that it can perform efficient lookups without building actual index structures. This implementation provides two important benefits:

- It entirely avoids the maintenance cost normally incurred for tables that undergo frequent updates.
- It reduces at an early stage of query execution the amount of data retrieved. For conditions on the indexed columns, the Performance Schema efficiently returns only table rows that satisfy the query conditions. Without an index, the Performance Schema would return all rows in the table, requiring that the optimizer later evaluate the conditions against each row to produce the final result.

Performance Schema indexes are predefined and cannot be dropped, added, or altered.

Performance Schema indexes are similar to hash indexes. For example:

- They are used only for equality comparisons that use the = or <=> operators.
- They are unordered. If a query result must have specific row ordering characteristics, include an ORDER BY clause.
Optimizing Data Change Statements

For additional information about hash indexes, see Section 8.3.9, “Comparison of B-Tree and Hash
Indexes”.

8.2.5 Optimizing Data Change Statements

This section explains how to speed up data change statements: INSERT, UPDATE, and DELETE.
Traditional OLTP applications and modern web applications typically do many small data change
operations, where concurrency is vital. Data analysis and reporting applications typically run data change
operations that affect many rows at once, where the main considerations is the I/O to write large amounts
of data and keep indexes up-to-date. For inserting and updating large volumes of data (known in the
industry as ETL, for “extract-transform-load”), sometimes you use other SQL statements or external
commands, that mimic the effects of INSERT, UPDATE, and DELETE statements.

8.2.5.1 Optimizing INSERT Statements

To optimize insert speed, combine many small operations into a single large operation. Ideally, you make a
single connection, send the data for many new rows at once, and delay all index updates and consistency
checking until the very end.

The time required for inserting a row is determined by the following factors, where the numbers indicate
approximate proportions:

- Connecting: (3)
- Sending query to server: (2)
- Parsing query: (2)
- Inserting row: (1 × size of row)
- Inserting indexes: (1 × number of indexes)
- Closing: (1)

This does not take into consideration the initial overhead to open tables, which is done once for each
concurrently running query.

The size of the table slows down the insertion of indexes by log \( N \), assuming B-tree indexes.

You can use the following methods to speed up inserts:

- If you are inserting many rows from the same client at the same time, use INSERT statements with
  multiple VALUES lists to insert several rows at a time. This is considerably faster (many times faster in
  some cases) than using separate single-row INSERT statements. If you are adding data to a nonempty
  table, you can tune the bulk_insert_buffer_size variable to make data insertion even faster. See
  Section 5.1.8, “Server System Variables”.

- When loading a table from a text file, use LOAD DATA. This is usually 20 times faster than using INSERT
  statements. See Section 13.2.9, “LOAD DATA Statement”.

- Take advantage of the fact that columns have default values. Insert values explicitly only when the value
to be inserted differs from the default. This reduces the parsing that MySQL must do and improves the
insert speed.

- See Section 8.5.5, “Bulk Data Loading for InnoDB Tables” for tips specific to InnoDB tables.

- See Section 8.6.2, “Bulk Data Loading for MyISAM Tables” for tips specific to MyISAM tables.
8.2.5.2 Optimizing UPDATE Statements

An update statement is optimized like a `SELECT` query with the additional overhead of a write. The speed of the write depends on the amount of data being updated and the number of indexes that are updated. Indexes that are not changed do not get updated.

Another way to get fast updates is to delay updates and then do many updates in a row later. Performing multiple updates together is much quicker than doing one at a time if you lock the table.

For a `MyISAM` table that uses dynamic row format, updating a row to a longer total length may split the row. If you do this often, it is very important to use `OPTIMIZE TABLE` occasionally. See Section 13.7.3.4, “OPTIMIZE TABLE Statement”.

8.2.5.3 Optimizing DELETE Statements

The time required to delete individual rows in a `MyISAM` table is exactly proportional to the number of indexes. To delete rows more quickly, you can increase the size of the key cache by increasing the `key_buffer_size` system variable. See Section 5.1.1, “Configuring the Server”.

To delete all rows from a `MyISAM` table, `TRUNCATE TABLE tbl_name` is faster than `DELETE FROM tbl_name`. Truncate operations are not transaction-safe; an error occurs when attempting one in the course of an active transaction or active table lock. See Section 13.1.37, “TRUNCATE TABLE Statement”.

8.2.6 Optimizing Database Privileges

The more complex your privilege setup, the more overhead applies to all SQL statements. Simplifying the privileges established by `GRANT` statements enables MySQL to reduce permission-checking overhead when clients execute statements. For example, if you do not grant any table-level or column-level privileges, the server need not ever check the contents of the `tables_priv` and `columns_priv` tables. Similarly, if you place no resource limits on any accounts, the server does not have to perform resource counting. If you have a very high statement-processing load, consider using a simplified grant structure to reduce permission-checking overhead.

8.2.7 Other Optimization Tips

This section lists a number of miscellaneous tips for improving query processing speed:

- If your application makes several database requests to perform related updates, combining the statements into a stored routine can help performance. Similarly, if your application computes a single result based on several column values or large volumes of data, combining the computation into a loadable function can help performance. The resulting fast database operations are then available to be reused by other queries, applications, and even code written in different programming languages. See Section 25.2, “Using Stored Routines” and Adding Functions to MySQL for more information.

- To fix any compression issues that occur with `ARCHIVE` tables, use `OPTIMIZE TABLE`. See Section 16.5, “The ARCHIVE Storage Engine”.

- If possible, classify reports as “live” or as “statistical”, where data needed for statistical reports is created only from summary tables that are generated periodically from the live data.

- If you have data that does not conform well to a rows-and-columns table structure, you can pack and store data into a `BLOB` column. In this case, you must provide code in your application to pack and unpack information, but this might save I/O operations to read and write the sets of related values.

- With Web servers, store images and other binary assets as files, with the path name stored in the database rather than the file itself. Most Web servers are better at caching files than database contents,
so using files is generally faster. (Although you must handle backups and storage issues yourself in this case.)

• If you need really high speed, look at the low-level MySQL interfaces. For example, by accessing the MySQL InnoDB or MyISAM storage engine directly, you could get a substantial speed increase compared to using the SQL interface.

Similarly, for databases using the NDBCLUSTER storage engine, you may wish to investigate possible use of the NDB API (see MySQL NDB Cluster API Developer Guide).

• Replication can provide a performance benefit for some operations. You can distribute client retrievals among replicas to split up the load. To avoid slowing down the source while making backups, you can make backups using a replica. See Chapter 17, Replication.

8.3 Optimization and Indexes

The best way to improve the performance of SELECT operations is to create indexes on one or more of the columns that are tested in the query. The index entries act like pointers to the table rows, allowing the query to quickly determine which rows match a condition in the WHERE clause, and retrieve the other column values for those rows. All MySQL data types can be indexed.

Although it can be tempting to create an indexes for every possible column used in a query, unnecessary indexes waste space and waste time for MySQL to determine which indexes to use. Indexes also add to the cost of inserts, updates, and deletes because each index must be updated. You must find the right balance to achieve fast queries using the optimal set of indexes.

8.3.1 How MySQL Uses Indexes

Indexes are used to find rows with specific column values quickly. Without an index, MySQL must begin with the first row and then read through the entire table to find the relevant rows. The larger the table, the more this costs. If the table has an index for the columns in question, MySQL can quickly determine the position to seek to in the middle of the data file without having to look at all the data. This is much faster than reading every row sequentially.

Most MySQL indexes (PRIMARY KEY, UNIQUE, INDEX, and FULLTEXT) are stored in B-trees. Exceptions: Indexes on spatial data types use R-trees; MEMORY tables also support hash indexes; InnoDB uses inverted lists for FULLTEXT indexes.

In general, indexes are used as described in the following discussion. Characteristics specific to hash indexes (as used in MEMORY tables) are described in Section 8.3.9, “Comparison of B-Tree and Hash Indexes”.

MySQL uses indexes for these operations:

• To find the rows matching a WHERE clause quickly.

• To eliminate rows from consideration. If there is a choice between multiple indexes, MySQL normally uses the index that finds the smallest number of rows (the most selective index).

• If the table has a multiple-column index, any leftmost prefix of the index can be used by the optimizer to look up rows. For example, if you have a three-column index on (col1, col2, col3), you have indexed search capabilities on (col1), (col1, col2), and (col1, col2, col3). For more information, see Section 8.3.6, “Multiple-Column Indexes”.

• To retrieve rows from other tables when performing joins. MySQL can use indexes on columns more efficiently if they are declared as the same type and size. In this context, VARCHAR and CHAR are
Primary Key Optimization

considered the same if they are declared as the same size. For example, `VARCHAR(10)` and `CHAR(10)` are the same size, but `VARCHAR(10)` and `CHAR(15)` are not.

For comparisons between nonbinary string columns, both columns should use the same character set. For example, comparing a `utf8mb4` column with a `latin1` column precludes use of an index.

Comparison of dissimilar columns (comparing a string column to a temporal or numeric column, for example) may prevent use of indexes if values cannot be compared directly without conversion. For a given value such as 1 in the numeric column, it might compare equal to any number of values in the string column such as ’1’, ’1’, ’00001’, or ’01.e1’. This rules out use of any indexes for the string column.

- To find the `MIN()` or `MAX()` value for a specific indexed column `key_col`. This is optimized by a preprocessor that checks whether you are using `WHERE key_part_N = constant` on all key parts that occur before `key_col` in the index. In this case, MySQL does a single key lookup for each `MIN()` or `MAX()` expression and replaces it with a constant. If all expressions are replaced with constants, the query returns at once. For example:

```sql
SELECT MIN(key_part2), MAX(key_part2)
FROM tbl_name WHERE key_part1=10;
```

- To sort or group a table if the sorting or grouping is done on a leftmost prefix of a usable index (for example, `ORDER BY key_part1, key_part2`). If all key parts are followed by `DESC`, the key is read in reverse order. (Or, if the index is a descending index, the key is read in forward order.) See Section 8.2.1.16, "ORDER BY Optimization", Section 8.2.1.17, "GROUP BY Optimization", and Section 8.3.13, "Descending Indexes".

- In some cases, a query can be optimized to retrieve values without consulting the data rows. (An index that provides all the necessary results for a query is called a covering index.) If a query uses from a table only columns that are included in some index, the selected values can be retrieved from the index tree for greater speed:

```sql
SELECT key_part3 FROM tbl_name
WHERE key_part1=1
```

Indexes are less important for queries on small tables, or big tables where report queries process most or all of the rows. When a query needs to access most of the rows, reading sequentially is faster than working through an index. Sequential reads minimize disk seeks, even if not all the rows are needed for the query. See Section 8.2.1.23, "Avoiding Full Table Scans" for details.

8.3.2 Primary Key Optimization

The primary key for a table represents the column or set of columns that you use in your most vital queries. It has an associated index, for fast query performance. Query performance benefits from the NOT NULL optimization, because it cannot include any NULL values. With the InnoDB storage engine, the table data is physically organized to do ultra-fast lookups and sorts based on the primary key column or columns.

If your table is big and important, but does not have an obvious column or set of columns to use as a primary key, you might create a separate column with auto-increment values to use as the primary key. These unique IDs can serve as pointers to corresponding rows in other tables when you join tables using foreign keys.

8.3.3 SPATIAL Index Optimization

MySQL permits creation of SPATIAL indexes on NOT NULL geometry-valued columns (see Section 11.4.10, "Creating Spatial Indexes"). The optimizer checks the SRID attribute for indexed columns
to determine which spatial reference system (SRS) to use for comparisons, and uses calculations appropriate to the SRS. (Prior to MySQL 8.2, the optimizer performs comparisons of \textit{SPATIAL} index values using Cartesian calculations; the results of such operations are undefined if the column contains values with non-Cartesian SRIDs.)

For comparisons to work properly, each column in a \textit{SPATIAL} index must be SRID-restricted. That is, the column definition must include an explicit \textit{SRID} attribute, and all column values must have the same SRID.

The optimizer considers \textit{SPATIAL} indexes only for SRID-restricted columns:

- Indexes on columns restricted to a Cartesian SRID enable Cartesian bounding box computations.
- Indexes on columns restricted to a geographic SRID enable geographic bounding box computations.

The optimizer ignores \textit{SPATIAL} indexes on columns that have no \textit{SRID} attribute (and thus are not SRID-restricted). MySQL still maintains such indexes, as follows:

- They are updated for table modifications (\texttt{INSERT}, \texttt{UPDATE}, \texttt{DELETE}, and so forth). Updates occur as though the index was Cartesian, even though the column might contain a mix of Cartesian and geographical values.

- They exist only for backward compatibility (for example, the ability to perform a dump in MySQL 8.0 and restore in MySQL 8.1). Because \textit{SPATIAL} indexes on columns that are not SRID-restricted are of no use to the optimizer, each such column should be modified:
  
  - Verify that all values within the column have the same SRID. To determine the SRIDs contained in a geometry column \texttt{col\_name}, use the following query:

  ```sql
  SELECT DISTINCT ST_SRID(col\_name) FROM tbl\_name;
  ```

  If the query returns more than one row, the column contains a mix of SRIDs. In that case, modify its contents so all values have the same SRID.

  - Redefine the column to have an explicit \textit{SRID} attribute.

  - Recreate the \textit{SPATIAL} index.

### 8.3.4 Foreign Key Optimization

If a table has many columns, and you query many different combinations of columns, it might be efficient to split the less-frequently used data into separate tables with a few columns each, and relate them back to the main table by duplicating the numeric ID column from the main table. That way, each small table can have a primary key for fast lookups of its data, and you can query just the set of columns that you need using a join operation. Depending on how the data is distributed, the queries might perform less I/O and take up less cache memory because the relevant columns are packed together on disk. (To maximize performance, queries try to read as few data blocks as possible from disk; tables with only a few columns can fit more rows in each data block.)

### 8.3.5 Column Indexes

The most common type of index involves a single column, storing copies of the values from that column in a data structure, allowing fast lookups for the rows with the corresponding column values. The B-tree data structure lets the index quickly find a specific value, a set of values, or a range of values, corresponding to operators such as \texttt{=}, \texttt{>}, \texttt{<}, \texttt{BETWEEN}, \texttt{IN}, and so on, in a \texttt{WHERE} clause.

The maximum number of indexes per table and the maximum index length is defined per storage engine. See Chapter 15, \textit{The InnoDB Storage Engine}, and Chapter 16, \textit{Alternative Storage Engines}. All storage
Column Indexes

engines support at least 16 indexes per table and a total index length of at least 256 bytes. Most storage engines have higher limits.

For additional information about column indexes, see Section 13.1.15, “CREATE INDEX Statement”.

• Index Prefixes
• FULLTEXT Indexes
• Spatial Indexes
• Indexes in the MEMORY Storage Engine

Index Prefixes

With \texttt{col\_name(N)} syntax in an index specification for a string column, you can create an index that uses only the first \(N\) characters of the column. Indexing only a prefix of column values in this way can make the index file much smaller. When you index a BLOB or TEXT column, you \textit{must} specify a prefix length for the index. For example:

\begin{verbatim}
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));  
\end{verbatim}

Prefixes can be up to 767 bytes long for InnoDB tables that use the REDUNDANT or COMPACT row format. The prefix length limit is 3072 bytes for InnoDB tables that use the DYNAMIC or COMPRESSED row format. For MyISAM tables, the prefix length limit is 1000 bytes.

\begin{itemize}
  \item \textbf{Note}
  \begin{quote}
    Prefix limits are measured in bytes, whereas the prefix length in CREATE TABLE, ALTER TABLE, and CREATE INDEX statements is interpreted as number of characters for nonbinary string types (CHAR, VARCHAR, TEXT) and number of bytes for binary string types (BINARY, VARBINARY, BLOB). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.
  \end{quote}
\end{itemize}

If a search term exceeds the index prefix length, the index is used to exclude non-matching rows, and the remaining rows are examined for possible matches.

For additional information about index prefixes, see Section 13.1.15, “CREATE INDEX Statement”.

FULLTEXT Indexes

FULLTEXT indexes are used for full-text searches. Only the InnoDB and MyISAM storage engines support FULLTEXT indexes and only for CHAR, VARCHAR, and TEXT columns. Indexing always takes place over the entire column and column prefix indexing is not supported. For details, see Section 12.9, “Full-Text Search Functions”.

Optimizations are applied to certain kinds of FULLTEXT queries against single InnoDB tables. Queries with these characteristics are particularly efficient:

• FULLTEXT queries that only return the document ID, or the document ID and the search rank.
• FULLTEXT queries that sort the matching rows in descending order of score and apply a LIMIT clause to take the top N matching rows. For this optimization to apply, there must be no WHERE clauses and only a single ORDER BY clause in descending order.
• FULLTEXT queries that retrieve only the COUNT(*) value of rows matching a search term, with no additional WHERE clauses. Code the WHERE clause as WHERE MATCH(text) AGAINST ('other_text'), without any > 0 comparison operator.
Multiple-Column Indexes

For queries that contain full-text expressions, MySQL evaluates those expressions during the optimization phase of query execution. The optimizer does not just look at full-text expressions and make estimates, it actually evaluates them in the process of developing an execution plan.

An implication of this behavior is that `EXPLAIN` for full-text queries is typically slower than for non-full-text queries for which no expression evaluation occurs during the optimization phase.

`EXPLAIN` for full-text queries may show `Select tables optimized away` in the `Extra` column due to matching occurring during optimization; in this case, no table access need occur during later execution.

Spatial Indexes

You can create indexes on spatial data types. `MyISAM` and `InnoDB` support R-tree indexes on spatial types. Other storage engines use B-trees for indexing spatial types (except for `ARCHIVE`, which does not support spatial type indexing).

Indexes in the MEMORY Storage Engine

The `MEMORY` storage engine uses `HASH` indexes by default, but also supports `BTREE` indexes.

8.3.6 Multiple-Column Indexes

MySQL can create composite indexes (that is, indexes on multiple columns). An index may consist of up to 16 columns. For certain data types, you can index a prefix of the column (see Section 8.3.5, "Column Indexes").

MySQL can use multiple-column indexes for queries that test all the columns in the index, or queries that test just the first column, the first two columns, the first three columns, and so on. If you specify the columns in the right order in the index definition, a single composite index can speed up several kinds of queries on the same table.

A multiple-column index can be considered a sorted array, the rows of which contain values that are created by concatenating the values of the indexed columns.

Note

As an alternative to a composite index, you can introduce a column that is “hashed” based on information from other columns. If this column is short, reasonably unique, and indexed, it might be faster than a “wide” index on many columns. In MySQL, it is very easy to use this extra column:

```sql
SELECT * FROM tbl_name
WHERE hash_col=MD5(CONCAT(val1, val2))
AND col1=val1 AND col2=val2;
```

Suppose that a table has the following specification:

```sql
CREATE TABLE test (
    id INT NOT NULL,
    last_name CHAR(30) NOT NULL,
    first_name CHAR(30) NOT NULL,
    PRIMARY KEY (id),
    INDEX name (last_name, first_name)
);
```

The `name` index is an index over the `last_name` and `first_name` columns. The index can be used for lookups in queries that specify values in a known range for combinations of `last_name` and `first_name` values. It can also be used for queries that specify just a `last_name` value because that column is a
Verifying Index Usage

leftmost prefix of the index (as described later in this section). Therefore, the *name* index is used for lookups in the following queries:

```sql
SELECT * FROM test WHERE last_name='Jones';
SELECT * FROM test
  WHERE last_name='Jones' AND first_name='John';
SELECT * FROM test
  WHERE last_name='Jones'
  AND (first_name='John' OR first_name='Jon');
SELECT * FROM test
  WHERE last_name='Jones'
  AND first_name >='M' AND first_name < 'N';
```

However, the *name* index is not used for lookups in the following queries:

```sql
SELECT * FROM test WHERE first_name='John';
SELECT * FROM test
  WHERE last_name='Jones' OR first_name='John';
```

Suppose that you issue the following `SELECT` statement:

```sql
SELECT * FROM tbl_name
  WHERE col1=val1 AND col2=val2;
```

If a multiple-column index exists on `col1` and `col2`, the appropriate rows can be fetched directly. If separate single-column indexes exist on `col1` and `col2`, the optimizer attempts to use the Index Merge optimization (see Section 8.2.1.3, “Index Merge Optimization”), or attempts to find the most restrictive index by deciding which index excludes more rows and using that index to fetch the rows.

If the table has a multiple-column index, any leftmost prefix of the index can be used by the optimizer to look up rows. For example, if you have a three-column index on `(col1, col2, col3)`, you have indexed search capabilities on `(col1)`, `(col1, col2)`, and `(col1, col2, col3)`. MySQL cannot use the index to perform lookups if the columns do not form a leftmost prefix of the index. Suppose that you have the `SELECT` statements shown here:

```sql
SELECT * FROM tbl_name WHERE col1=val1;
SELECT * FROM tbl_name WHERE col1=val1 AND col2=val2;
SELECT * FROM tbl_name WHERE col2=val2;
SELECT * FROM tbl_name WHERE col2=val2 AND col3=val3;
```

If an index exists on `(col1, col2, col3)`, only the first two queries use the index. The third and fourth queries do involve indexed columns, but do not use an index to perform lookups because `(col2)` and `(col2, col3)` are not leftmost prefixes of `(col1, col2, col3)).

### 8.3.7 Verifying Index Usage

Always check whether all your queries really use the indexes that you have created in the tables. Use the `EXPLAIN` statement, as described in Section 8.8.1, “Optimizing Queries with EXPLAIN”.

### 8.3.8 InnoDB and MyISAM Index Statistics Collection

Storage engines collect statistics about tables for use by the optimizer. Table statistics are based on value groups, where a value group is a set of rows with the same key prefix value. For optimizer purposes, an important statistic is the average value group size.

MySQL uses the average value group size in the following ways:
InnoDB and MyISAM Index Statistics Collection

- To estimate how many rows must be read for each ref access
- To estimate how many rows a partial join produces, that is, the number of rows produced by an operation of the form

\[
(...) \text{JOIN } tbl\_name \text{ ON } tbl\_name\_key = expr
\]

As the average value group size for an index increases, the index is less useful for those two purposes because the average number of rows per lookup increases. For the index to be good for optimization purposes, it is best that each index value target a small number of rows in the table. When a given index value yields a large number of rows, the index is less useful and MySQL is less likely to use it.

The average value group size is related to table cardinality, which is the number of value groups. The `SHOW INDEX` statement displays a cardinality value based on \(N/S\), where \(N\) is the number of rows in the table and \(S\) is the average value group size. That ratio yields an approximate number of value groups in the table.

For a join based on the \(<=>\) comparison operator, NULL is not treated differently from any other value: \(NULL \leftrightarrow NULL\), just as \(N \leftrightarrow N\) for any other \(N\).

However, for a join based on the \(=\) operator, NULL is different from non-NULL values: \(expr1 = expr2\) is not true when \(expr1\) or \(expr2\) (or both) are NULL. This affects ref accesses for comparisons of the form \(tbl\_name\_key = expr\): MySQL does not access the table if the current value of \(expr\) is NULL, because the comparison cannot be true.

For \(=\) comparisons, it does not matter how many NULL values are in the table. For optimization purposes, the relevant value is the average size of the non-NULL value groups. However, MySQL does not currently enable that average size to be collected or used.

For InnoDB and MyISAM tables, you have some control over collection of table statistics by means of the `innodb_stats_method` and `myisam_stats_method` system variables, respectively. These variables have three possible values, which differ as follows:

- When the variable is set to `nulls_equal`, all NULL values are treated as identical (that is, they all form a single value group).
  
  If the NULL value group size is much higher than the average non-NULL value group size, this method skews the average value group size upward. This makes index appear to the optimizer to be less useful than it really is for joins that look for non-NULL values. Consequently, the `nulls_equal` method may cause the optimizer not to use the index for ref accesses when it should.

- When the variable is set to `nulls_unequal`, NULL values are not considered the same. Instead, each NULL value forms a separate value group of size 1.
  
  If you have many NULL values, this method skews the average value group size downward. If the average non-NULL value group size is large, counting NULL values each as a group of size 1 causes the optimizer to overestimate the value of the index for joins that look for non-NULL values. Consequently, the `nulls_unequal` method may cause the optimizer to use this index for ref lookups when other methods may be better.

- When the variable is set to `nulls_ignored`, NULL values are ignored.
  
  If you tend to use many joins that use \(<=>\) rather than \(=\), NULL values are not special in comparisons and one NULL is equal to another. In this case, `nulls_equal` is the appropriate statistics method.

The `innodb_stats_method` system variable has a global value; the `myisam_stats_method` system variable has both global and session values. Setting the global value affects statistics collection for tables from the corresponding storage engine. Setting the session value affects statistics collection only for the
current client connection. This means that you can force a table’s statistics to be regenerated with a given method without affecting other clients by setting the session value of `myisam_stats_method`.

To regenerate MyISAM table statistics, you can use any of the following methods:

- Execute `myisamchk --stats_method=method_name --analyze`
- Change the table to cause its statistics to go out of date (for example, insert a row and then delete it), and then set `myisam_stats_method` and issue an `ANALYZE TABLE` statement

Some caveats regarding the use of `innodb_stats_method` and `myisam_stats_method`:

- You can force table statistics to be collected explicitly, as just described. However, MySQL may also collect statistics automatically. For example, if during the course of executing statements for a table, some of those statements modify the table, MySQL may collect statistics. (This may occur for bulk inserts or deletes, or some `ALTER TABLE` statements, for example.) If this happens, the statistics are collected using whatever value `innodb_stats_method` or `myisam_stats_method` has at the time. Thus, if you collect statistics using one method, but the system variable is set to the other method when a table’s statistics are collected automatically later, the other method is used.
- There is no way to tell which method was used to generate statistics for a given table.
- These variables apply only to InnoDB and MyISAM tables. Other storage engines have only one method for collecting table statistics. Usually it is closer to the `nulls_equal` method.

### 8.3.9 Comparison of B-Tree and Hash Indexes

Understanding the B-tree and hash data structures can help predict how different queries perform on different storage engines that use these data structures in their indexes, particularly for the MEMORY storage engine that lets you choose B-tree or hash indexes.

- **B-Tree Index Characteristics**
- **Hash Index Characteristics**

#### B-Tree Index Characteristics

A B-tree index can be used for column comparisons in expressions that use the `=`, `>`, `>=`, `<`, `<=`, or `BETWEEN` operators. The index also can be used for LIKE comparisons if the argument to LIKE is a constant string that does not start with a wildcard character. For example, the following `SELECT` statements use indexes:

```sql
SELECT * FROM tbl_name WHERE key_col LIKE 'Patrick%';
SELECT * FROM tbl_name WHERE key_col LIKE 'Pat%_ck%';
```

In the first statement, only rows with 'Patrick' <= `key_col` < 'Patrickl' are considered. In the second statement, only rows with 'Pat' <= `key_col` < 'Pau' are considered.

The following `SELECT` statements do not use indexes:

```sql
SELECT * FROM tbl_name WHERE key_col LIKE '%Patrick%';
SELECT * FROM tbl_name WHERE key_col LIKE other_col;
```

In the first statement, the LIKE value begins with a wildcard character. In the second statement, the LIKE value is not a constant.

If you use `... LIKE '%string%'` and `string` is longer than three characters, MySQL uses the Turbo Boyer-Moore algorithm to initialize the pattern for the string and then uses this pattern to perform the search more quickly.
Use of Index Extensions

A search using \texttt{col\_name IS NULL} employs indexes if \texttt{col\_name} is indexed.

Any index that does not span all AND levels in the WHERE clause is not used to optimize the query. In other words, to be able to use an index, a prefix of the index must be used in every AND group.

The following WHERE clauses use indexes:

\begin{verbatim}
... WHERE index\_part1=1 AND index\_part2=2 AND other\_column=3
  /* index = 1 OR index = 2 */
... WHERE index=1 OR A=10 AND index=2
  /* optimized like "index\_part1='hello'" */
... WHERE index\_part1='hello' AND index\_part3=5
  /* Can use index on index1 but not on index2 or index3 */
... WHERE index1=1 AND index2=2 OR index1=3 AND index3=3;
\end{verbatim}

These WHERE clauses do not use indexes:

\begin{verbatim}
/* index\_part1 is not used */
... WHERE index\_part2=1 AND index\_part3=2
  /* Index is not used in both parts of the WHERE clause */
... WHERE index=1 OR A=10
  /* No index spans all rows */
... WHERE index\_part1=1 OR index\_part2=10
\end{verbatim}

Sometimes MySQL does not use an index, even if one is available. One circumstance under which this occurs is when the optimizer estimates that using the index would require MySQL to access a very large percentage of the rows in the table. (In this case, a table scan is likely to be much faster because it requires fewer seeks.) However, if such a query uses \texttt{LIMIT} to retrieve only some of the rows, MySQL uses an index anyway, because it can much more quickly find the few rows to return in the result.

Hash Index Characteristics

Hash indexes have somewhat different characteristics from those just discussed:

- They are used only for equality comparisons that use the = or \texttt{<>} operators (but are very fast). They are not used for comparison operators such as < that find a range of values. Systems that rely on this type of single-value lookup are known as “key-value stores”; to use MySQL for such applications, use hash indexes wherever possible.

- The optimizer cannot use a hash index to speed up ORDER BY operations. (This type of index cannot be used to search for the next entry in order.)

- MySQL cannot determine approximately how many rows there are between two values (this is used by the range optimizer to decide which index to use). This may affect some queries if you change a MyISAM or InnoDB table to a hash-indexed MEMORY table.

- Only whole keys can be used to search for a row. (With a B-tree index, any leftmost prefix of the key can be used to find rows.)

8.3.10 Use of Index Extensions

InnoDB automatically extends each secondary index by appending the primary key columns to it. Consider this table definition:

\begin{verbatim}
CREATE TABLE t1 (  
  i1 INT NOT NULL DEFAULT 0,
\end{verbatim}
This table defines the primary key on columns \((i_1, i_2)\). It also defines a secondary index \(k_d\) on column \(d\), but internally InnoDB extends this index and treats it as columns \((d, i_1, i_2)\).

The optimizer takes into account the primary key columns of the extended secondary index when determining how and whether to use that index. This can result in more efficient query execution plans and better performance.

The optimizer can use extended secondary indexes for \texttt{ref}, \texttt{range}, and \texttt{index_merge} index access, for Loose Index Scan access, for join and sorting optimization, and for \texttt{MIN()}\texttt{/MAX()} optimization.

The following example shows how execution plans are affected by whether the optimizer uses extended secondary indexes. Suppose that \texttt{t1} is populated with these rows:

```sql
INSERT INTO t1 VALUES
(1, 1, '1998-01-01'), (1, 2, '1999-01-01'),
(1, 3, '2000-01-01'), (1, 4, '2001-01-01'),
(1, 5, '2002-01-01'), (2, 1, '1998-01-01'),
(2, 2, '1999-01-01'), (2, 3, '2000-01-01'),
(2, 4, '2001-01-01'), (2, 5, '2002-01-01'),
(3, 1, '1998-01-01'), (3, 2, '1999-01-01'),
(3, 3, '2000-01-01'), (3, 4, '2001-01-01'),
(3, 5, '2002-01-01'), (4, 1, '1998-01-01'),
(4, 2, '1999-01-01'), (4, 3, '2000-01-01'),
(4, 4, '2001-01-01'), (4, 5, '2002-01-01'),
(5, 1, '1998-01-01'), (5, 2, '1999-01-01'),
(5, 3, '2000-01-01'), (5, 4, '2001-01-01'),
(5, 5, '2002-01-01');
```

Now consider this query:

```sql
EXPLAIN SELECT COUNT(*) FROM t1 WHERE i1 = 3 AND d = '2000-01-01'
```

The execution plan depends on whether the extended index is used.

When the optimizer does not consider index extensions, it treats the index \(k_d\) as only \((d)\). \texttt{EXPLAIN} for the query produces this result:

```sql
mysql> EXPLAIN SELECT COUNT(*) FROM t1 WHERE i1 = 3 AND d = '2000-01-01'\G
*************************** 1. row ***************************
    id: 1
  select_type: SIMPLE
     table: t1
       type: ref
possible_keys: PRIMARY,k_d
      key: k_d
   key_len: 4
     ref: const
    rows: 5
 Extra: Using where; Using index
```

When the optimizer takes index extensions into account, it treats \(k_d\) as \((d, i_1, i_2)\). In this case, it can use the leftmost index prefix \((d, i_1)\) to produce a better execution plan:

```sql
mysql> EXPLAIN SELECT COUNT(*) FROM t1 WHERE i1 = 3 AND d = '2000-01-01'\G
*************************** 1. row ***************************
    id: 1
  select_type: SIMPLE
     table: t1
```
Use of Index Extensions

In both cases, `key` indicates that the optimizer uses secondary index `k_d` but the EXPLAIN output shows these improvements from using the extended index:

- `key_len` goes from 4 bytes to 8 bytes, indicating that key lookups use columns `d` and `i1`, not just `d`.
- The `ref` value changes from `const` to `const,const` because the key lookup uses two key parts, not one.
- The `rows` count decreases from 5 to 1, indicating that InnoDB should need to examine fewer rows to produce the result.
- The `Extra` value changes from `Using where; Using index` to `Using index`. This means that rows can be read using only the index, without consulting columns in the data row.

Differences in optimizer behavior for use of extended indexes can also be seen with `SHOW STATUS`:

```sql
FLUSH TABLE t1;
FLUSH STATUS;
SELECT COUNT(*) FROM t1 WHERE i1 = 3 AND d = '2000-01-01';
SHOW STATUS LIKE 'handler_read%'
```

The preceding statements include `FLUSH TABLES` and `FLUSH STATUS` to flush the table cache and clear the status counters.

Without index extensions, `SHOW STATUS` produces this result:

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Handler_read_first</td>
<td>0</td>
</tr>
<tr>
<td>Handler_read_key</td>
<td>1</td>
</tr>
<tr>
<td>Handler_read_last</td>
<td>0</td>
</tr>
<tr>
<td>Handler_read_next</td>
<td>5</td>
</tr>
<tr>
<td>Handler_read_prev</td>
<td>0</td>
</tr>
<tr>
<td>Handler_read_rnd</td>
<td>0</td>
</tr>
<tr>
<td>Handler_read_rnd_next</td>
<td>0</td>
</tr>
</tbody>
</table>

With index extensions, `SHOW STATUS` produces this result. The `Handler_read_next` value decreases from 5 to 1, indicating more efficient use of the index:

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Handler_read_first</td>
<td>0</td>
</tr>
<tr>
<td>Handler_read_key</td>
<td>1</td>
</tr>
<tr>
<td>Handler_read_last</td>
<td>0</td>
</tr>
<tr>
<td>Handler_read_next</td>
<td>1</td>
</tr>
<tr>
<td>Handler_read_prev</td>
<td>0</td>
</tr>
<tr>
<td>Handler_read_rnd</td>
<td>0</td>
</tr>
<tr>
<td>Handler_read_rnd_next</td>
<td>0</td>
</tr>
</tbody>
</table>

The `use_index_extensions` flag of the `optimizer_switch` system variable permits control over whether the optimizer takes the primary key columns into account when determining how to use an
Optimizer Use of Generated Column Indexes

InnoDB table’s secondary indexes. By default, use_index_extensions is enabled. To check whether disabling use of index extensions can improve performance, use this statement:

```sql
SET optimizer_switch = 'use_index_extensions=off';
```

Use of index extensions by the optimizer is subject to the usual limits on the number of key parts in an index (16) and the maximum key length (3072 bytes).

### 8.3.11 Optimizer Use of Generated Column Indexes

MySQL supports indexes on generated columns. For example:

```sql
CREATE TABLE t1 (f1 INT, gc INT AS (f1 + 1) STORED, INDEX (gc));
```

The generated column, `gc`, is defined as the expression `f1 + 1`. The column is also indexed and the optimizer can take that index into account during execution plan construction. In the following query, the `WHERE` clause refers to `gc` and the optimizer considers whether the index on that column yields a more efficient plan:

```sql
SELECT * FROM t1 WHERE gc > 9;
```

The optimizer can use indexes on generated columns to generate execution plans, even in the absence of direct references in queries to those columns by name. This occurs if the `WHERE`, `ORDER BY`, or `GROUP BY` clause refers to an expression that matches the definition of some indexed generated column. The following query does not refer directly to `gc` but does use an expression that matches the definition of `gc`:

```sql
SELECT * FROM t1 WHERE f1 + 1 > 9;
```

The optimizer recognizes that the expression `f1 + 1` matches the definition of `gc` and that `gc` is indexed, so it considers that index during execution plan construction. You can see this using `EXPLAIN`:

```sql
mysql> EXPLAIN SELECT * FROM t1 WHERE f1 + 1 > 9
+----+
| id |
+----+
|  1 |
| type: range |
| possible_keys: gc |
| key: gc |
| key_len: 5 |
| rows: 1 |
| filtered: 100.00 |
| Extra: Using index condition |
```

In effect, the optimizer has replaced the expression `f1 + 1` with the name of the generated column that matches the expression. That is also apparent in the rewritten query available in the extended `EXPLAIN` information displayed by `SHOW WARNINGS`:

```sql
mysql> SHOW WARNINGS
+----+
| Level |
+----+
| Note |
| Code |
| Message |
| Column types |
```

The following restrictions and conditions apply to the optimizer’s use of generated column indexes:

- For a query expression to match a generated column definition, the expression must be identical and it must have the same result type. For example, if the generated column expression is `f1 + 1`, the...
optimizer does not recognize a match if the query uses $1 + f1$, or if $f1 + 1$ (an integer expression) is compared with a string.

- The optimization applies to these operators: $=, <, <=, >, >=, BETWEEN, and IN()$. For operators other than BETWEEN and IN(), either operand can be replaced by a matching generated column. For BETWEEN and IN(), only the first argument can be replaced by a matching generated column, and the other arguments must have the same result type. BETWEEN and IN() are not yet supported for comparisons involving JSON values.

- The generated column must be defined as an expression that contains at least a function call or one of the operators mentioned in the preceding item. The expression cannot consist of a simple reference to another column. For example, $gc$ INT AS (f1) STORED consists only of a column reference, so indexes on $gc$ are not considered.

- For comparisons of strings to indexed generated columns that compute a value from a JSON function that returns a quoted string, JSON_UNQUOTE() is needed in the column definition to remove the extra quotes from the function value. (For direct comparison of a string to the function result, the JSON comparator handles quote removal, but this does not occur for index lookups.) For example, instead of writing a column definition like this:

  
  ```
  doc_name TEXT AS (JSON_EXTRACT(jdoc, '$.name')) STORED
  ```

  Write it like this:

  ```
  doc_name TEXT AS (JSON_UNQUOTE(JSON_EXTRACT(jdoc, '$.name'))) STORED
  ```

  With the latter definition, the optimizer can detect a match for both of these comparisons:

  ```
  ... WHERE JSON_EXTRACT(jdoc, '$.name') = 'some_string' ...
  ... WHERE JSON_UNQUOTE(JSON_EXTRACT(jdoc, '$.name')) = 'some_string' ...
  ```

  Without JSON_UNQUOTE() in the column definition, the optimizer detects a match only for the first of those comparisons.

- If the optimizer picks the wrong index, an index hint can be used to disable it and force the optimizer to make a different choice.

### 8.3.12 Invisible Indexes

MySQL supports invisible indexes; that is, indexes that are not used by the optimizer. The feature applies to indexes other than primary keys (either explicit or implicit).

Indexes are visible by default. To control visibility explicitly for a new index, use a VISIBLE or INVISIBLE keyword as part of the index definition for CREATE TABLE, CREATE INDEX, or ALTER TABLE:

```sql
CREATE TABLE t1 (  
  i INT,  
  j INT,  
  k INT,  
  INDEX i_idx (i) INVISIBLE  
) ENGINE = InnoDB;
CREATE INDEX j_idx ON t1 (j) INVISIBLE;
ALTER TABLE t1 ADD INDEX k_idx (k) INVISIBLE;
```

To alter the visibility of an existing index, use a VISIBLE or INVISIBLE keyword with the ALTER TABLE ... ALTER INDEX operation:

```sql
ALTER TABLE t1 ALTER INDEX i_idx INVISIBLE;
ALTER TABLE t1 ALTER INDEX i_idx VISIBLE;
```
Invisible Indexes

Information about whether an index is visible or invisible is available from the Information Schema STATISTICS table or SHOW INDEX output. For example:

```
mysql> SELECT INDEX_NAME, IS_VISIBLE
    -> FROM INFORMATION_SCHEMA.STATISTICS
    -> WHERE TABLE_SCHEMA = 'db1' AND TABLE_NAME = 't1';
```

+------------+------------+
<table>
<thead>
<tr>
<th>INDEX_NAME</th>
<th>IS_VISIBLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>i_idx</td>
<td>YES</td>
</tr>
<tr>
<td>j_idx</td>
<td>NO</td>
</tr>
<tr>
<td>k_idx</td>
<td>NO</td>
</tr>
</tbody>
</table>
+------------+------------+

Invisible indexes make it possible to test the effect of removing an index on query performance, without making a destructive change that must be undone should the index turn out to be required. Dropping and re-adding an index can be expensive for a large table, whereas making it invisible and visible are fast, in-place operations.

If an index made invisible actually is needed or used by the optimizer, there are several ways to notice the effect of its absence on queries for the table:

- Errors occur for queries that include index hints that refer to the invisible index.
- Performance Schema data shows an increase in workload for affected queries.
- Queries have different EXPLAIN execution plans.
- Queries appear in the slow query log that did not appear there previously.

The use_invisible_indexes flag of the optimizer_switch system variable controls whether the optimizer uses invisible indexes for query execution plan construction. If the flag is off (the default), the optimizer ignores invisible indexes (the same behavior as prior to the introduction of this flag). If the flag is on, invisible indexes remain invisible but the optimizer takes them into account for execution plan construction.

Using the SET_VAR optimizer hint to update the value of optimizer_switch temporarily, you can enable invisible indexes for the duration of a single query only, like this:

```
mysql> EXPLAIN SELECT /*+ SET_VAR(optimizer_switch = 'use_invisible_indexes=on') */
    > i, j FROM t1 WHERE j >= 50\G
```

```
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: t1
partitions: NULL
type: range
possible_keys: j_idx
key: j_idx
key_len: 5
ref: NULL
rows: 2
filtered: 100.00
Extra: Using index condition
```

```
mysql> EXPLAIN SELECT i, j FROM t1 WHERE j >= 50\G
```

```
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: t1
partitions: NULL
type: ALL
```
### Index visibility does not affect index maintenance.

For example, an index continues to be updated per changes to table rows, and a unique index prevents insertion of duplicates into a column, regardless of whether the index is visible or invisible.

A table with no explicit primary key may still have an effective implicit primary key if it has any `UNIQUE` indexes on `NOT NULL` columns. In this case, the first such index places the same constraint on table rows as an explicit primary key and that index cannot be made invisible. Consider the following table definition:

```sql
CREATE TABLE t2 (
  i INT NOT NULL,
  j INT NOT NULL,
  UNIQUE j_idx (j)
) ENGINE = InnoDB;
```

The definition includes no explicit primary key, but the index on `NOT NULL` column `j` places the same constraint on rows as a primary key and cannot be made invisible:

```
mysql> ALTER TABLE t2 ALTER INDEX j_idx INVISIBLE;
ERROR 3522 (HY000): A primary key index cannot be invisible.
```

Now suppose that an explicit primary key is added to the table:

```
ALTER TABLE t2 ADD PRIMARY KEY (i);
```

The explicit primary key cannot be made invisible. In addition, the unique index on `j` no longer acts as an implicit primary key and as a result can be made invisible:

```
mysql> ALTER TABLE t2 ALTER INDEX j_idx INVISIBLE;
Query OK, 0 rows affected (0.03 sec)
```

### 8.3.13 Descending Indexes

MySQL supports descending indexes: `DESC` in an index definition is no longer ignored but causes storage of key values in descending order. Previously, indexes could be scanned in reverse order but at a performance penalty. A descending index can be scanned in forward order, which is more efficient. Descending indexes also make it possible for the optimizer to use multiple-column indexes when the most efficient scan order mixes ascending order for some columns and descending order for others.

Consider the following table definition, which contains two columns and four two-column index definitions for the various combinations of ascending and descending indexes on the columns:

```sql
CREATE TABLE t (
  c1 INT, c2 INT,
  INDEX idx1 (c1 ASC, c2 ASC),
  INDEX idx2 (c1 ASC, c2 DESC),
  INDEX idx3 (c1 DESC, c2 ASC),
  INDEX idx4 (c1 DESC, c2 DESC)
);
```

The table definition results in four distinct indexes. The optimizer can perform a forward index scan for each of the `ORDER BY` clauses and need not use a `filesort` operation:

```
ORDER BY c1 ASC, c2 ASC -- optimizer can use idx1
ORDER BY c1 DESC, c2 DESC -- optimizer can use idx4
```
Descending Indexes

ORDER BY c1 ASC, c2 DESC -- optimizer can use idx2
ORDER BY c1 DESC, c2 ASC -- optimizer can use idx3

Use of descending indexes is subject to these conditions:

- Descending indexes are supported only for the InnoDB storage engine, with these limitations:
  - Change buffering is not supported for a secondary index if the index contains a descending index key column or if the primary key includes a descending index column.
  - The InnoDB SQL parser does not use descending indexes. For InnoDB full-text search, this means that the index required on the FTS_DOC_ID column of the indexed table cannot be defined as a descending index. For more information, see Section 15.6.2.4, “InnoDB Full-Text Indexes”.
- Descending indexes are supported for all data types for which ascending indexes are available.
- Descending indexes are supported for ordinary (nongenerated) and generated columns (both VIRTUAL and STORED).
- DISTINCT can use any index containing matching columns, including descending key parts.
- Indexes that have descending key parts are not used for MIN() / MAX() optimization of queries that invoke aggregate functions but do not have a GROUP BY clause.
- Descending indexes are supported for BTREE but not HASH indexes. Descending indexes are not supported for FULLTEXT or SPATIAL indexes.

Explicitly specified ASC and DESC designators for HASH, FULLTEXT, and SPATIAL indexes results in an error.

You can see in the Extra column of the output of EXPLAIN that the optimizer is able to use a descending index, as shown here:

```sql
mysql> CREATE TABLE t1 (
    -> a INT,
    -> b INT,
    -> INDEX a_desc_b_asc (a DESC, b ASC)
    -> );

mysql> EXPLAIN SELECT * FROM t1 ORDER BY a ASC\G
```

```
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: t1
partitions: NULL
type: index
possible_keys: NULL
    key: a_desc_b_asc
key_len: 10
ref: NULL
rows: 1
filtered: 100.00
Extra: Backward index scan; Using index
```

In EXPLAIN FORMAT=TREE output, use of a descending index is indicated by the addition of (reverse) following the name of the index, like this:

```sql
mysql> EXPLAIN FORMAT=TREE SELECT * FROM t1 ORDER BY a ASC\G
```

```
EXPLAIN: --> Index scan on t1 using a_desc_b_asc (reverse) (cost=0.35 rows=1)
```

See also EXPLAIN Extra Information.
Indexed Lookups from TIMESTAMP Columns

8.3.14 Indexed Lookups from TIMESTAMP Columns

Temporal values are stored in TIMESTAMP columns as UTC values, and values inserted into and retrieved from TIMESTAMP columns are converted between the session time zone and UTC. (This is the same type of conversion performed by the CONVERT_TZ() function. If the session time zone is UTC, there is effectively no time zone conversion.)

Due to conventions for local time zone changes such as Daylight Saving Time (DST), conversions between UTC and non-UTC time zones are not one-to-one in both directions. UTC values that are distinct may not be distinct in another time zone. The following example shows distinct UTC values that become identical in a non-UTC time zone:

```sql
mysql> CREATE TABLE tstable (ts TIMESTAMP);
mysql> SET time_zone = 'UTC'; -- insert UTC values
mysql> INSERT INTO tstable VALUES ('2018-10-28 00:30:00'),
                                      ('2018-10-28 01:30:00');
mysql> SELECT ts FROM tstable;
+---------------------+
<table>
<thead>
<tr>
<th>ts</th>
</tr>
</thead>
<tbody>
<tr>
<td>2018-10-28 00:30:00</td>
</tr>
<tr>
<td>2018-10-28 01:30:00</td>
</tr>
</tbody>
</table>
+---------------------+
mysql> SET time_zone = 'MET'; -- retrieve non-UTC values
mysql> SELECT ts FROM tstable;
+---------------------+
<table>
<thead>
<tr>
<th>ts</th>
</tr>
</thead>
<tbody>
<tr>
<td>2018-10-28 02:30:00</td>
</tr>
<tr>
<td>2018-10-28 02:30:00</td>
</tr>
</tbody>
</table>
+---------------------+
```

Note

To use named time zones such as 'MET' or 'Europe/Amsterdam', the time zone tables must be properly set up. For instructions, see Section 5.1.15, “MySQL Server Time Zone Support”.

You can see that the two distinct UTC values are the same when converted to the 'MET' time zone. This phenomenon can lead to different results for a given TIMESTAMP column query, depending on whether the optimizer uses an index to execute the query.

Suppose that a query selects values from the table shown earlier using a WHERE clause to search the ts column for a single specific value such as a user-provided timestamp literal:

```sql
SELECT ts FROM tstable
WHERE ts = 'literal';
```

Suppose further that the query executes under these conditions:

- The session time zone is not UTC and has a DST shift. For example:
  ```sql
  SET time_zone = 'MET';
  ```

- Unique UTC values stored in the TIMESTAMP column are not unique in the session time zone due to DST shifts. (The example shown earlier illustrates how this can occur.)

- The query specifies a search value that is within the hour of entry into DST in the session time zone.

Under those conditions, the comparison in the WHERE clause occurs in different ways for nonindexed and indexed lookups and leads to different results:
Indexed Lookups from TIMESTAMP Columns

- If there is no index or the optimizer cannot use it, comparisons occur in the session time zone. The optimizer performs a table scan in which it retrieves each ts column value, converts it from UTC to the session time zone, and compares it to the search value (also interpreted in the session time zone):

```
mysql> SELECT ts FROM tstable
    > WHERE ts = '2018-10-28 02:30:00';
+---------------------+
| ts                  |
+---------------------+
| 2018-10-28 02:30:00 |
| 2018-10-28 02:30:00 |
+---------------------+
```

Because the stored ts values are converted to the session time zone, it is possible for the query to return two timestamp values that are distinct as UTC values but equal in the session time zone: One value that occurs before the DST shift when clocks are changed, and one value that was occurs after the DST shift.

- If there is a usable index, comparisons occur in UTC. The optimizer performs an index scan, first converting the search value from the session time zone to UTC, then comparing the result to the UTC index entries:

```
mysql> ALTER TABLE tstable ADD INDEX (ts);
mysql> SELECT ts FROM tstable
    > WHERE ts = '2018-10-28 02:30:00';
+---------------------+
| ts                  |
+---------------------+
| 2018-10-28 02:30:00 |
+---------------------+
```

In this case, the (converted) search value is matched only to index entries, and because the index entries for the distinct stored UTC values are also distinct, the search value can match only one of them.

Due to different optimizer operation for nonindexed and indexed lookups, the query produces different results in each case. The result from the nonindexed lookup returns all values that match in the session time zone. The indexed lookup cannot do so:

- It is performed within the storage engine, which knows only about UTC values.
- For the two distinct session time zone values that map to the same UTC value, the indexed lookup matches only the corresponding UTC index entry and returns only a single row.

In the preceding discussion, the data set stored in tstable happens to consist of distinct UTC values. In such cases, all index-using queries of the form shown match at most one index entry.

If the index is not UNIQUE, it is possible for the table (and the index) to store multiple instances of a given UTC value. For example, the ts column might contain multiple instances of the UTC value '2018-10-28 00:30:00'. In this case, the index-using query would return each of them (converted to the MET value '2018-10-28 02:30:00' in the result set). It remains true that index-using queries match the converted search value to a single value in the UTC index entries, rather than matching multiple UTC values that convert to the search value in the session time zone.

If it is important to return all ts values that match in the session time zone, the workaround is to suppress use of the index with an IGNORE INDEX hint:

```
mysql> SELECT ts FROM tstable
    > IGNORE INDEX (ts)
    > WHERE ts = '2018-10-28 02:30:00';
+---------------------+
| ts                  |
+---------------------+
```

1860
8.4 Optimizing Database Structure

In your role as a database designer, look for the most efficient way to organize your schemas, tables, and columns. As when tuning application code, you minimize I/O, keep related items together, and plan ahead so that performance stays high as the data volume increases. Starting with an efficient database design makes it easier for team members to write high-performing application code, and makes the database likely to endure as applications evolve and are rewritten.

8.4.1 Optimizing Data Size

Design your tables to minimize their space on the disk. This can result in huge improvements by reducing the amount of data written to and read from disk. Smaller tables normally require less main memory while their contents are being actively processed during query execution. Any space reduction for table data also results in smaller indexes that can be processed faster.

MySQL supports many different storage engines (table types) and row formats. For each table, you can decide which storage and indexing method to use. Choosing the proper table format for your application can give you a big performance gain. See Chapter 15, The InnoDB Storage Engine, and Chapter 16, Alternative Storage Engines.

You can get better performance for a table and minimize storage space by using the techniques listed here:

- **Table Columns**
- **Row Format**
- **Indexes**
- **Joins**
- **Normalization**

**Table Columns**

- Use the most efficient (smallest) data types possible. MySQL has many specialized types that save disk space and memory. For example, use the smaller integer types if possible to get smaller tables. **MEDIUMINT** is often a better choice than **INT** because a **MEDIUMINT** column uses 25% less space.

- Declare columns to be **NOT NULL** if possible. It makes SQL operations faster, by enabling better use of indexes and eliminating overhead for testing whether each value is **NULL**. You also save some storage space, one bit per column. If you really need **NULL** values in your tables, use them. Just avoid the default setting that allows **NULL** values in every column.

**Row Format**

- **InnoDB** tables are created using the **DYNAMIC** row format by default. To use a row format other than **DYNAMIC**, configure **innodb_default_row_format**, or specify the **ROW_FORMAT** option explicitly in a **CREATE TABLE** or **ALTER TABLE** statement.
The compact family of row formats, which includes COMPACT, DYNAMIC, and COMPRESSED, decreases row storage space at the cost of increasing CPU use for some operations. If your workload is a typical one that is limited by cache hit rates and disk speed it is likely to be faster. If it is a rare case that is limited by CPU speed, it might be slower.

The compact family of row formats also optimizes CHAR column storage when using a variable-length character set such as utf8mb3 or utf8mb4. With ROW_FORMAT=REDUNDANT, CHAR(N) occupies \( N \times \) the maximum byte length of the character set. Many languages can be written primarily using single-byte utf8mb3 or utf8mb4 characters, so a fixed storage length often wastes space. With the compact family of rows formats, InnoDB allocates a variable amount of storage in the range of \( N \) to \( N \times \) the maximum byte length of the character set for these columns by stripping trailing spaces. The minimum storage length is \( N \) bytes to facilitate in-place updates in typical cases. For more information, see Section 15.10, “InnoDB Row Formats”.

• To minimize space even further by storing table data in compressed form, specify ROW_FORMAT=COMPRESSED when creating InnoDB tables, or run the myisampack command on an existing MyISAM table. (InnoDB compressed tables are readable and writable, while MyISAM compressed tables are read-only.)

• For MyISAM tables, if you do not have any variable-length columns (VARCHAR, TEXT, or BLOB columns), a fixed-size row format is used. This is faster but may waste some space. See Section 16.2.3, “MyISAM Table Storage Formats”. You can hint that you want to have fixed length rows even if you have VARCHAR columns with the CREATE TABLE option ROW_FORMAT=FIXED.

Indexes

• The primary index of a table should be as short as possible. This makes identification of each row easy and efficient. For InnoDB tables, the primary key columns are duplicated in each secondary index entry, so a short primary key saves considerable space if you have many secondary indexes.

• Create only the indexes that you need to improve query performance. Indexes are good for retrieval, but slow down insert and update operations. If you access a table mostly by searching on a combination of columns, create a single composite index on them rather than a separate index for each column. The first part of the index should be the column most used. If you always use many columns when selecting from the table, the first column in the index should be the one with the most duplicates, to obtain better compression of the index.

• If it is very likely that a long string column has a unique prefix on the first number of characters, it is better to index only this prefix, using MySQL’s support for creating an index on the leftmost part of the column (see Section 13.1.15, “CREATE INDEX Statement”). Shorter indexes are faster, not only because they require less disk space, but because they also give you more hits in the index cache, and thus fewer disk seeks. See Section 5.1.1, “Configuring the Server”.

Joins

• In some circumstances, it can be beneficial to split into two a table that is scanned very often. This is especially true if it is a dynamic-format table and it is possible to use a smaller static format table that can be used to find the relevant rows when scanning the table.

• Declare columns with identical information in different tables with identical data types, to speed up joins based on the corresponding columns.

• Keep column names simple, so that you can use the same name across different tables and simplify join queries. For example, in a table named customer, use a column name of name instead of customer_name. To make your names portable to other SQL servers, consider keeping them shorter than 18 characters.
Normalizing

- Normally, try to keep all data nonredundant (observing what is referred to in database theory as third normal form). Instead of repeating lengthy values such as names and addresses, assign them unique IDs, repeat these IDs as needed across multiple smaller tables, and join the tables in queries by referencing the IDs in the join clause.

- If speed is more important than disk space and the maintenance costs of keeping multiple copies of data, for example in a business intelligence scenario where you analyze all the data from large tables, you can relax the normalization rules, duplicating information or creating summary tables to gain more speed.

8.4.2 Optimizing MySQL Data Types

8.4.2.1 Optimizing for Numeric Data

- For unique IDs or other values that can be represented as either strings or numbers, prefer numeric columns to string columns. Since large numeric values can be stored in fewer bytes than the corresponding strings, it is faster and takes less memory to transfer and compare them.

- If you are using numeric data, it is faster in many cases to access information from a database (using a live connection) than to access a text file. Information in the database is likely to be stored in a more compact format than in the text file, so accessing it involves fewer disk accesses. You also save code in your application because you can avoid parsing the text file to find line and column boundaries.

8.4.2.2 Optimizing for Character and String Types

For character and string columns, follow these guidelines:

- Use binary collation order for fast comparison and sort operations, when you do not need language-specific collation features. You can use the `BINARY` operator to use binary collation within a particular query.

- When comparing values from different columns, declare those columns with the same character set and collation wherever possible, to avoid string conversions while running the query.

- For column values less than 8KB in size, use binary `VARCHAR` instead of `BLOB`. The `GROUP BY` and `ORDER BY` clauses can generate temporary tables, and these temporary tables can use the `MEMORY` storage engine if the original table does not contain any `BLOB` columns.

- If a table contains string columns such as name and address, but many queries do not retrieve those columns, consider splitting the string columns into a separate table and using join queries with a foreign key when necessary. When MySQL retrieves any value from a row, it reads a data block containing all the columns of that row (and possibly other adjacent rows). Keeping each row small, with only the most frequently used columns, allows more rows to fit in each data block. Such compact tables reduce disk I/O and memory usage for common queries.

- When you use a randomly generated value as a primary key in an `InnoDB` table, prefix it with an ascending value such as the current date and time if possible. When consecutive primary values are physically stored near each other, `InnoDB` can insert and retrieve them faster.

- See Section 8.4.2.1, “Optimizing for Numeric Data” for reasons why a numeric column is usually preferable to an equivalent string column.

8.4.2.3 Optimizing for BLOB Types
Optimizing for Many Tables

- When storing a large blob containing textual data, consider compressing it first. Do not use this technique when the entire table is compressed by InnoDB or MyISAM.

- For a table with several columns, to reduce memory requirements for queries that do not use the BLOB column, consider splitting the BLOB column into a separate table and referencing it with a join query when needed.

- Since the performance requirements to retrieve and display a BLOB value might be very different from other data types, you could put the BLOB-specific table on a different storage device or even a separate database instance. For example, to retrieve a BLOB might require a large sequential disk read that is better suited to a traditional hard drive than to an SSD device.

- See Section 8.4.2.2, “Optimizing for Character and String Types” for reasons why a binary VARCHAR column is sometimes preferable to an equivalent BLOB column.

- Rather than testing for equality against a very long text string, you can store a hash of the column value in a separate column, index that column, and test the hashed value in queries. (Use the MD5() or CRC32() function to produce the hash value.) Since hash functions can produce duplicate results for different inputs, you still include a clause AND blob_column = long_string_value in the query to guard against false matches; the performance benefit comes from the smaller, easily scanned index for the hashed values.

8.4.3 Optimizing for Many Tables

Some techniques for keeping individual queries fast involve splitting data across many tables. When the number of tables runs into the thousands or even millions, the overhead of dealing with all these tables becomes a new performance consideration.

8.4.3.1 How MySQL Opens and Closes Tables

When you execute a mysqladmin status command, you should see something like this:

Uptime: 426 Running threads: 1 Questions: 11082
Reloads: 1 Open tables: 12

The Open tables value of 12 can be somewhat puzzling if you have fewer than 12 tables.

MySQL is multithreaded, so there may be many clients issuing queries for a given table simultaneously. To minimize the problem with multiple client sessions having different states on the same table, the table is opened independently by each concurrent session. This uses additional memory but normally increases performance. With MyISAM tables, one extra file descriptor is required for the data file for each client that has the table open. (By contrast, the index file descriptor is shared between all sessions.)

The table_open_cache and max_connections system variables affect the maximum number of files the server keeps open. If you increase one or both of these values, you may run up against a limit imposed by your operating system on the per-process number of open file descriptors. Many operating systems permit you to increase the open-files limit, although the method varies widely from system to system.

Consult your operating system documentation to determine whether it is possible to increase the limit and how to do so.

table_open_cache is related to max_connections. For example, for 200 concurrent running connections, specify a table cache size of at least 200 * N, where N is the maximum number of tables per join in any of the queries which you execute. You must also reserve some extra file descriptors for temporary tables and files.

Make sure that your operating system can handle the number of open file descriptors implied by the table_open_cache setting. If table_open_cache is set too high, MySQL may run out of file descriptors and exhibit symptoms such as refusing connections or failing to perform queries.
Also take into account that the MyISAM storage engine needs two file descriptors for each unique open table. To increase the number of file descriptors available to MySQL, set the `open_files_limit` system variable. See Section B.3.2.16, “File Not Found and Similar Errors”.

The cache of open tables is kept at a level of `table_open_cache` entries. The server autosizes the cache size at startup. To set the size explicitly, set the `table_open_cache` system variable at startup. MySQL may temporarily open more tables than this to execute queries, as described later in this section.

MySQL closes an unused table and removes it from the table cache under the following circumstances:

- When the cache is full and a thread tries to open a table that is not in the cache.
- When the cache contains more than `table_open_cache` entries and a table in the cache is no longer being used by any threads.
- When a table-flushing operation occurs. This happens when someone issues a `FLUSH TABLES` statement or executes a `mysqladmin flush-tables` or `mysqladmin refresh` command.

When the table cache fills up, the server uses the following procedure to locate a cache entry to use:

- Tables not currently in use are released, beginning with the table least recently used.
- If a new table must be opened, but the cache is full and no tables can be released, the cache is temporarily extended as necessary. When the cache is in a temporarily extended state and a table goes from a used to unused state, the table is closed and released from the cache.

A MyISAM table is opened for each concurrent access. This means the table needs to be opened twice if two threads access the same table or if a thread accesses the table twice in the same query (for example, by joining the table to itself). Each concurrent open requires an entry in the table cache. The first open of any MyISAM table takes two file descriptors: one for the data file and one for the index file. Each additional use of the table takes only one file descriptor for the data file. The index file descriptor is shared among all threads.

If you are opening a table with the `HANDLER tbl_name OPEN` statement, a dedicated table object is allocated for the thread. This table object is not shared by other threads and is not closed until the thread calls `HANDLER tbl_name CLOSE` or the thread terminates. When this happens, the table is put back in the table cache (if the cache is not full). See Section 13.2.5, “HANDLER Statement”.

To determine whether your table cache is too small, check the `Opened_tables` status variable, which indicates the number of table-opening operations since the server started:

```sql
mysql> SHOW GLOBAL STATUS LIKE 'Opened_tables';
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| Opened_tables | 2741  |
+---------------+-------+
```

If the value is very large or increases rapidly, even when you have not issued many `FLUSH TABLES` statements, increase the `table_open_cache` value at server startup.

### 8.4.3.2 Disadvantages of Creating Many Tables in the Same Database

If you have many MyISAM tables in the same database directory, open, close, and create operations are slow. If you execute `SELECT` statements on many different tables, there is a little overhead when the table cache is full, because for every table that has to be opened, another must be closed. You can reduce this overhead by increasing the number of entries permitted in the table cache.

### 8.4.4 Internal Temporary Table Use in MySQL
In some cases, the server creates internal temporary tables while processing statements. Users have no direct control over when this occurs.

The server creates temporary tables under conditions such as these:

- Evaluation of **UNION** statements, with some exceptions described later.
- Evaluation of some views, such those that use the **TEMPTABLE** algorithm, **UNION**, or aggregation.
- Evaluation of derived tables (see Section 13.2.15.8, “Derived Tables”).
- Evaluation of common table expressions (see Section 13.2.20, “WITH (Common Table Expressions)”).
- Tables created for subquery or semijoin materialization (see Section 8.2.2, “Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions”).
- Evaluation of statements that contain an **ORDER BY** clause and a different **GROUP BY** clause, or for which the **ORDER BY** or **GROUP BY** contains columns from tables other than the first table in the join queue.
- Evaluation of **DISTINCT** combined with **ORDER BY** may require a temporary table.
- For queries that use the **SQL_SMALL_RESULT** modifier, MySQL uses an in-memory temporary table, unless the query also contains elements (described later) that require on-disk storage.
- To evaluate **INSERT ... SELECT** statements that select from and insert into the same table, MySQL creates an internal temporary table to hold the rows from the **SELECT**, then inserts those rows into the target table. See Section 13.2.7.1, “INSERT ... SELECT Statement”.
- Evaluation of multiple-table **UPDATE** statements.
- Evaluation of **GROUP_CONCAT()** or **COUNT(DISTINCT)** expressions.
- Evaluation of window functions (see Section 12.20, “Window Functions”) uses temporary tables as necessary.

To determine whether a statement requires a temporary table, use **EXPLAIN** and check the **Extra** column to see whether it says **Using temporary** (see Section 8.8.1, “Optimizing Queries with EXPLAIN”). **EXPLAIN** does not necessarily say **Using temporary** for derived or materialized temporary tables. For statements that use window functions, **EXPLAIN** with **FORMAT=JSON** always provides information about the windowing steps. If the windowing functions use temporary tables, it is indicated for each step.

Some query conditions prevent the use of an in-memory temporary table, in which case the server uses an on-disk table instead:

- Presence of a **BLOB** or **TEXT** column in the table. The **TempTable** storage engine, which is the default storage engine for in-memory internal temporary tables in MySQL 8.2, supports binary large object types. See Internal Temporary Table Storage Engine.
- Presence of any string column with a maximum length larger than 512 (bytes for binary strings, characters for nonbinary strings) in the **SELECT** list, if **UNION** or **UNION ALL** is used.
- The **SHOW COLUMNS** and **DESCRIBE** statements use **BLOB** as the type for some columns, thus the temporary table used for the results is an on-disk table.

The server does not use a temporary table for **UNION** statements that meet certain qualifications. Instead, it retains from temporary table creation only the data structures necessary to perform result column typecasting. The table is not fully instantiated and no rows are written to or read from it; rows are sent directly to the client. The result is reduced memory and disk requirements, and smaller delay before
the first row is sent to the client because the server need not wait until the last query block is executed. `EXPLAIN` and optimizer trace output reflects this execution strategy: The `UNION RESULT` query block is not present because that block corresponds to the part that reads from the temporary table.

These conditions qualify a `UNION` for evaluation without a temporary table:

- The union is `UNION ALL`, not `UNION` or `UNION DISTINCT`.
- There is no global `ORDER BY` clause.
- The union is not the top-level query block of an `{INSERT | REPLACE} ... SELECT ...` statement.

### Internal Temporary Table Storage Engine

An internal temporary table can be held in memory and processed by the `TempTable` or `MEMORY` storage engine, or stored on disk by the `InnoDB` storage engine.

#### Storage Engine for In-Memory Internal Temporary Tables

The `internal_tmp_mem_storage_engine` variable defines the storage engine used for in-memory internal temporary tables. Permitted values are `TempTable` (the default) and `MEMORY`.

**Note**

Configuring a session setting for `internal_tmp_mem_storage_engine` requires the `SESSION_VARIABLES_ADMIN` or `SYSTEM_VARIABLES_ADMIN` privilege.

The `TempTable` storage engine provides efficient storage for `VARCHAR` and `VARBINARY` columns, and other binary large object types.

The following variables control `TempTable` storage engine limits and behavior:

- `tmp_table_size`: Defines the maximum size of any individual in-memory internal temporary table created by the `TempTable` storage engine. When the `tmp_table_size` limit is reached, MySQL automatically converts the in-memory internal temporary table to an `InnoDB` on-disk internal temporary table. The default `tmp_table_size` setting is 16777216 bytes (16 MiB).

  The `tmp_table_size` limit is intended to prevent individual queries from consuming an inordinate amount of global `TempTable` resources, which can affect the performance of concurrent queries that require `TempTable` resources. Global `TempTable` resources are controlled by the `temptable_max_ram` and `temptable_max_mmap` settings.

  If the `tmp_table_size` limit is less than the `temptable_max_ram` limit, it is not possible for an in-memory temporary table to contain more data than permitted by the `tmp_table_size` limit. If the `tmp_table_size` limit is greater than the sum of the `temptable_max_ram` and `temptable_max_mmap` limits, it is not possible for an in-memory temporary table to contain more than the sum of the `temptable_max_ram` and `temptable_max_mmap` limits.

- `temptable_max_ram`: Defines the maximum amount of RAM that can be used by the `TempTable` storage engine before it starts allocating space from memory-mapped files or before MySQL starts using `InnoDB` on-disk internal temporary tables, depending on your configuration. The default `temptable_max_ram` setting is 1073741824 bytes (1GiB).

  **Note**

  The `temptable_max_ram` setting does not account for the thread-local memory block allocated to each thread that uses the `TempTable` storage engine. The
size of the thread-local memory block depends on the size of the thread’s first memory allocation request. If the request is less than 1MB, which it is in most cases, the thread-local memory block size is 1MB. If the request is greater than 1MB, the thread-local memory block is approximately the same size as the initial memory request. The thread-local memory block is held in thread-local storage until thread exit.

- **temptable_use_mmap**: Controls whether the TempTable storage engine allocates space from memory-mapped files or MySQL uses InnoDB on-disk internal temporary tables when the temptable_max_ram limit is exceeded. The default setting is temptable_use_mmap=ON.

  **Note**
  
  The temptable_use_mmap variable is deprecated; expect support for it to be removed in a future version of MySQL. Setting temptable_max_mmap=0 is equivalent to setting temptable_use_mmap=OFF.

- **temptable_max_mmap**: Sets the maximum amount of memory the TempTable storage engine is permitted to allocate from memory-mapped files before MySQL starts using InnoDB on-disk internal temporary tables. The default setting is 1073741824 bytes (1GiB). The limit is intended to address the risk of memory mapped files using too much space in the temporary directory (tmpdir). temptable_max_mmap = 0 disables allocation from memory-mapped files, effectively disabling their use, regardless of the temptable_use_mmap setting.

Use of memory-mapped files by the TempTable storage engine is governed by these rules:

- Temporary files are created in the directory defined by the tmpdir variable.

- Temporary files are deleted immediately after they are created and opened, and therefore do not remain visible in the tmpdir directory. The space occupied by temporary files is held by the operating system while temporary files are open. The space is reclaimed when temporary files are closed by the TempTable storage engine, or when the mysql process is shut down.

- Data is never moved between RAM and temporary files, within RAM, or between temporary files.

- New data is stored in RAM if space becomes available within the limit defined by temptable_max_ram. Otherwise, new data is stored in temporary files.

- If space becomes available in RAM after some of the data for a table is written to temporary files, it is possible for the remaining table data to be stored in RAM.

When using the MEMORY storage engine for in-memory temporary tables (internal_tmp_mem_storage_engine=MEMORY), MySQL automatically converts an in-memory temporary table to an on-disk table if it becomes too large. The maximum size of an in-memory temporary table is defined by the tmp_table_size or max_heap_table_size value, whichever is smaller. This differs from MEMORY tables explicitly created with CREATE TABLE. For such tables, only the max_heap_table_size variable determines how large a table can grow, and there is no conversion to on-disk format.

**Storage Engine for On-Disk Internal Temporary Tables**

MySQL 8.2 uses only the InnoDB storage engine for on-disk internal temporary tables. (The MYISAM storage engine is no longer supported for this purpose.)

InnoDB on-disk internal temporary tables are created in session temporary tablespaces that reside in the data directory by default. For more information, see Section 15.6.3.5, “Temporary Tablespaces”. 

1868
Limits on Number of Databases and Tables

Internal Temporary Table Storage Format

When in-memory internal temporary tables are managed by the **TempTable** storage engine, rows that include **VARCHAR** columns, **VARBINARY** columns, and other binary large object type columns are represented in memory by an array of cells, with each cell containing a **NULL** flag, the data length, and a data pointer. Column values are placed in consecutive order after the array, in a single region of memory, without padding. Each cell in the array uses 16 bytes of storage. The same storage format applies when the **TempTable** storage engine allocates space from memory-mapped files.

When in-memory internal temporary tables are managed by the **MEMORY** storage engine, fixed-length row format is used. **VARCHAR** and **VARBINARY** column values are padded to the maximum column length, in effect storing them as **CHAR** and **BINARY** columns.

Internal temporary tables on disk are always managed by **InnoDB**.

When using the **MEMORY** storage engine, statements can initially create an in-memory internal temporary table and then convert it to an on-disk table if the table becomes too large. In such cases, better performance might be achieved by skipping the conversion and creating the internal temporary table on disk to begin with. The **big_tables** variable can be used to force disk storage of internal temporary tables.

Monitoring Internal Temporary Table Creation

When an internal temporary table is created in memory or on disk, the server increments the **Created_tmp_tables** value. When an internal temporary table is created on disk, the server increments the **Created_tmp_disk_tables** value. If too many internal temporary tables are created on disk, consider adjusting the engine-specific limits described in Internal Temporary Table Storage Engine.

---

**Note**

Due to a known limitation, **Created_tmp_disk_tables** does not count on-disk temporary tables created in memory-mapped files. By default, the TempTable storage engine overflow mechanism creates internal temporary tables in memory-mapped files. See Internal Temporary Table Storage Engine.

The **memory/temptable/physical_ram** and **memory/temptable/physical_disk** Performance Schema instruments can be used to monitor TempTable space allocation from memory and disk. **memory/temptable/physical_ram** reports the amount of allocated RAM. **memory/temptable/physical_disk** reports the amount of space allocated from disk when memory-mapped files are used as the TempTable overflow mechanism. If the **physical_disk** instrument reports a value other than 0 and memory-mapped files are used as the TempTable overflow mechanism, a TempTable memory limit was reached at some point. Data can be queried in Performance Schema memory summary tables such as **memory_summary_global_by_event_name**. See Section 27.12.20.10, “Memory Summary Tables”.

8.4.5 Limits on Number of Databases and Tables

MySQL has no limit on the number of databases. The underlying file system may have a limit on the number of directories.

MySQL has no limit on the number of tables. The underlying file system may have a limit on the number of files that represent tables. Individual storage engines may impose engine-specific constraints. **InnoDB** permits up to 4 billion tables.

8.4.6 Limits on Table Size
The effective maximum table size for MySQL databases is usually determined by operating system constraints on file sizes, not by MySQL internal limits. For up-to-date information on operating system file size limits, refer to the documentation specific to your operating system.

Windows users, please note that FAT and VFAT (FAT32) are not considered suitable for production use with MySQL. Use NTFS instead.

If you encounter a full-table error, there are several reasons why it might have occurred:

- The disk might be full.
- You are using InnoDB tables and have run out of room in an InnoDB tablesapce file. The maximum tablespace size is also the maximum size for a table. For tablespace size limits, see Section 15.22, “InnoDB Limits”.

Generally, partitioning of tables into multiple tablesapce files is recommended for tables larger than 1TB in size.

- You have hit an operating system file size limit. For example, you are using MyISAM tables on an operating system that supports files only up to 2GB in size and you have hit this limit for the data file or index file.

- You are using a MyISAM table and the space required for the table exceeds what is permitted by the internal pointer size. MyISAM permits data and index files to grow up to 256TB by default, but this limit can be changed up to the maximum permissible size of 65,536TB (256^7 – 1 bytes).

If you need a MyISAM table that is larger than the default limit and your operating system supports large files, the CREATE TABLE statement supports AVG_ROW_LENGTH and MAX_ROWS options. See Section 13.1.20, “CREATE TABLE Statement”. The server uses these options to determine how large a table to permit.

If the pointer size is too small for an existing table, you can change the options with ALTER TABLE to increase a table’s maximum permissible size. See Section 13.1.9, “ALTER TABLE Statement”.

```
ALTER TABLE tbl_name MAX_ROWS=1000000000 AVG_ROW_LENGTH=nnn;
```

You have to specify AVG_ROW_LENGTH only for tables with BLOB or TEXT columns; in this case, MySQL cannot optimize the space required based only on the number of rows.

To change the default size limit for MyISAM tables, set the myisam_data_pointer_size, which sets the number of bytes used for internal row pointers. The value is used to set the pointer size for new tables if you do not specify the MAX_ROWS option. The value of myisam_data_pointer_size can be from 2 to 7. For example, for tables that use the dynamic storage format, a value of 4 permits tables up to 4GB; a value of 6 permits tables up to 256TB. Tables that use the fixed storage format have a larger maximum data length. For storage format characteristics, see Section 16.2.3, “MyISAM Table Storage Formats”.

You can check the maximum data and index sizes by using this statement:

```
SHOW TABLE STATUS FROM db_name LIKE ‘tbl_name’;
```

You also can use myisamchk -dv /path/to/table-index-file. See Section 13.7.7, “SHOW Statements”, or Section 4.6.4, “myisamchk — MyISAM Table-Maintenance Utility”.

Other ways to work around file-size limits for MyISAM tables are as follows:

- If your large table is read only, you can use myisampack to compress it. myisampack usually compresses a table by at least 50%, so you can have, in effect, much bigger tables. myisampack
also can merge multiple tables into a single table. See Section 4.6.6, “mysampack — Generate Compressed, Read-Only MyISAM Tables”.

• MySQL includes a **MERGE** library that enables you to handle a collection of **MyISAM** tables that have identical structure as a single **MERGE** table. See Section 16.7, “The MERGE Storage Engine”.

• You are using the **MEMORY** (**HEAP**) storage engine; in this case you need to increase the value of the **max_heap_table_size** system variable. See Section 5.1.8, “Server System Variables”.

### 8.4.7 Limits on Table Column Count and Row Size

This section describes limits on the number of columns in tables and the size of individual rows.

**• Column Count Limits**

**• Row Size Limits**

**Column Count Limits**

MySQL has a hard limit of 4096 columns per table, but the effective maximum may be less for a given table. The exact column limit depends on several factors:

• The maximum row size for a table constrains the number (and possibly size) of columns because the total length of all columns cannot exceed this size. See Row Size Limits.

• The storage requirements of individual columns constrain the number of columns that fit within a given maximum row size. Storage requirements for some data types depend on factors such as storage engine, storage format, and character set. See Section 11.7, “Data Type Storage Requirements”.

• Storage engines may impose additional restrictions that limit table column count. For example, **InnoDB** has a limit of 1017 columns per table. See Section 15.22, “InnoDB Limits”. For information about other storage engines, see Chapter 16, Alternative Storage Engines.

• Functional key parts (see Section 13.1.15, “CREATE INDEX Statement”) are implemented as hidden virtual generated stored columns, so each functional key part in a table index counts against the table total column limit.

**Row Size Limits**

The maximum row size for a given table is determined by several factors:

• The internal representation of a MySQL table has a maximum row size limit of 65,535 bytes, even if the storage engine is capable of supporting larger rows. **BLOB** and **TEXT** columns only contribute 9 to 12 bytes toward the row size limit because their contents are stored separately from the rest of the row.

• The maximum row size for an **InnoDB** table, which applies to data stored locally within a database page, is slightly less than half a page for 4KB, 8KB, 16KB, and 32KB **innodb_page_size** settings. For example, the maximum row size is slightly less than 8KB for the default 16KB **InnoDB** page size. For 64KB pages, the maximum row size is slightly less than 16KB. See Section 15.22, “InnoDB Limits”.

If a row containing variable-length columns exceeds the **InnoDB** maximum row size, **InnoDB** selects variable-length columns for external off-page storage until the row fits within the **InnoDB** row size limit. The amount of data stored locally for variable-length columns that are stored off-page differs by row format. For more information, see Section 15.10, “InnoDB Row Formats”.

• Different storage formats use different amounts of page header and trailer data, which affects the amount of storage available for rows.

• For information about **InnoDB** row formats, see Section 15.10, “InnoDB Row Formats”.

---

1871
Limits on Table Column Count and Row Size

- For information about MyISAM storage formats, see Section 16.2.3, “MyISAM Table Storage Formats”.

Row Size Limit Examples

- The MySQL maximum row size limit of 65,535 bytes is demonstrated in the following InnoDB and MyISAM examples. The limit is enforced regardless of storage engine, even though the storage engine may be capable of supporting larger rows.

  ```
  mysql> CREATE TABLE t (a VARCHAR(10000), b VARCHAR(10000),
  \n  c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
  f VARCHAR(10000), g VARCHAR(6000)) ENGINE=InnoDB CHARACTER SET latin1;
  ERROR 1118 (42000): Row size too large. The maximum row size for the used
  table type, not counting BLOBs, is 65535. This includes storage overhead,
  check the manual. You have to change some columns to TEXT or BLOBs.
  ```

  ```
  mysql> CREATE TABLE t (a VARCHAR(10000), b VARCHAR(10000),
  \n  c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
  f VARCHAR(10000), g VARCHAR(6000)) ENGINE=MyISAM CHARACTER SET latin1;
  ERROR 1118 (42000): Row size too large. The maximum row size for the used
  table type, not counting BLOBs, is 65535. This includes storage overhead,
  check the manual. You have to change some columns to TEXT or BLOBs.
  ```

  In the following MyISAM example, changing a column to TEXT avoids the 65,535-byte row size limit and permits the operation to succeed because BLOB and TEXT columns only contribute 9 to 12 bytes toward the row size.

  ```
  mysql> CREATE TABLE t (a VARCHAR(10000), b VARCHAR(10000),
  \n  c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
  f VARCHAR(10000), g TEXT(6000)) ENGINE=MyISAM CHARACTER SET latin1;
  Query OK, 0 rows affected (0.02 sec)
  ```

  The operation succeeds for an InnoDB table because changing a column to TEXT avoids the MySQL 65,535-byte row size limit, and InnoDB off-page storage of variable-length columns avoids the InnoDB row size limit.

  ```
  mysql> CREATE TABLE t (a VARCHAR(10000), b VARCHAR(10000),
  \n  c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
  f VARCHAR(10000), g TEXT(6000)) ENGINE=InnoDB CHARACTER SET latin1;
  Query OK, 0 rows affected (0.02 sec)
  ```

- Storage for variable-length columns includes length bytes, which are counted toward the row size. For example, a `VARCHAR(255)` CHARACTER SET `utf8mb3` column takes two bytes to store the length of the value, so each value can take up to 767 bytes.

  The statement to create table `t1` succeeds because the columns require 32,765 + 2 bytes and 32,766 + 2 bytes, which falls within the maximum row size of 65,535 bytes:

  ```
  mysql> CREATE TABLE t1
  \n  (c1 VARCHAR(32765) NOT NULL, c2 VARCHAR(32766) NOT NULL)
  ENGINE = InnoDB CHARACTER SET latin1;
  Query OK, 0 rows affected (0.02 sec)
  ```

  The statement to create table `t2` fails because, although the column length is within the maximum length of 65,535 bytes, two additional bytes are required to record the length, which causes the row size to exceed 65,535 bytes:

  ```
  mysql> CREATE TABLE t2
  (c1 VARCHAR(65535) NOT NULL)
  ENGINE = InnoDB CHARACTER SET latin1;
  ERROR 1118 (42000): Row size too large. The maximum row size for the used
  table type, not counting BLOBs, is 65535. This includes storage overhead,
  ```
check the manual. You have to change some columns to TEXT or BLOBS

Reducing the column length to 65,533 or less permits the statement to succeed.

```sql
mysql> CREATE TABLE t2
    -> (c1 VARCHAR(65533) NOT NULL)
    -> ENGINE = InnoDB CHARACTER SET latin1;
Query OK, 0 rows affected (0.01 sec)
```

- For **MyISAM** tables, NULL columns require additional space in the row to record whether their values are NULL. Each NULL column takes one bit extra, rounded up to the nearest byte.

The statement to create table `t3` fails because **MyISAM** requires space for NULL columns in addition to the space required for variable-length column length bytes, causing the row size to exceed 65,535 bytes:

```sql
mysql> CREATE TABLE t3
    -> (c1 VARCHAR(32765) NULL, c2 VARCHAR(32766) NULL)
    -> ENGINE = MyISAM CHARACTER SET latin1;
ERROR 1118 (42000): Row size too large. The maximum row size for the used table type, not counting BLOBs, is 65535. This includes storage overhead, check the manual. You have to change some columns to TEXT or BLOBs
```

For information about **InnoDB** NULL column storage, see Section 15.10, “InnoDB Row Formats”.

- **InnoDB** restricts row size (for data stored locally within the database page) to slightly less than half a database page for 4KB, 8KB, 16KB, and 32KB `innodb_page_size` settings, and to slightly less than 16KB for 64KB pages.

The statement to create table `t4` fails because the defined columns exceed the row size limit for a 16KB **InnoDB** page.

```sql
mysql> CREATE TABLE t4
    -> (c1 CHAR(255), c2 CHAR(255), c3 CHAR(255),
    ->     c4 CHAR(255), c5 CHAR(255), c6 CHAR(255),
    ->     c7 CHAR(255), c8 CHAR(255), c9 CHAR(255),
    ->     c10 CHAR(255), c11 CHAR(255), c12 CHAR(255),
    ->     c13 CHAR(255), c14 CHAR(255), c15 CHAR(255),
    ->     c16 CHAR(255), c17 CHAR(255), c18 CHAR(255),
    ->     c19 CHAR(255), c20 CHAR(255), c21 CHAR(255),
    ->     c22 CHAR(255), c23 CHAR(255), c24 CHAR(255),
    ->     c25 CHAR(255), c26 CHAR(255), c27 CHAR(255),
    ->     c28 CHAR(255), c29 CHAR(255), c30 CHAR(255),
    ->     c31 CHAR(255), c32 CHAR(255), c33 CHAR(255))
    -> ENGINE=InnoDB ROW_FORMAT=DYNAMIC DEFAULT CHARSET latin1;
ERROR 1118 (42000): Row size too large (> 8126). Changing some columns to TEXT or BLOB may help.
```

### 8.5 Optimizing for InnoDB Tables

**InnoDB** is the storage engine that MySQL customers typically use in production databases where reliability and concurrency are important. **InnoDB** is the default storage engine in MySQL. This section explains how to optimize database operations for **InnoDB** tables.

#### 8.5.1 Optimizing Storage Layout for InnoDB Tables

- Once your data reaches a stable size, or a growing table has increased by tens or some hundreds of megabytes, consider using the `OPTIMIZE TABLE` statement to reorganize the table and compact any wasted space. The reorganized tables require less disk I/O to perform full table scans. This is a straightforward technique that can improve performance when other techniques such as improving index usage or tuning application code are not practical.
To optimize InnoDB transaction processing, find the ideal balance between the performance overhead of transactional features and the workload of your server. For example, an application might encounter performance issues if it commits thousands of times per second, and different performance issues if it commits only every 2-3 hours.

- The default MySQL setting `AUTOCOMMIT=1` can impose performance limitations on a busy database server. Where practical, wrap several related data change operations into a single transaction, by issuing `SET AUTOCOMMIT=0` or a `START TRANSACTION` statement, followed by a `COMMIT` statement after making all the changes.

  InnoDB must flush the log to disk at each transaction commit if that transaction made modifications to the database. When each change is followed by a commit (as with the default autocommit setting), the I/O throughput of the storage device puts a cap on the number of potential operations per second.

- Alternatively, for transactions that consist only of a single `SELECT` statement, turning on `AUTOCOMMIT` helps InnoDB to recognize read-only transactions and optimize them. See Section 8.5.3, “Optimizing InnoDB Read-Only Transactions” for requirements.

- Avoid performing rollbacks after inserting, updating, or deleting huge numbers of rows. If a big transaction is slowing down server performance, rolling it back can make the problem worse, potentially taking several times as long to perform as the original data change operations. Killing the database process does not help, because the rollback starts again on server startup.

To minimize the chance of this issue occurring:

- Increase the size of the buffer pool so that all the data change changes can be cached rather than immediately written to disk.
• Set `innodb_change_buffering=all` so that update and delete operations are buffered in addition to inserts.

• Consider issuing `COMMIT` statements periodically during the big data change operation, possibly breaking a single delete or update into multiple statements that operate on smaller numbers of rows.

To get rid of a runaway rollback once it occurs, increase the buffer pool so that the rollback becomes CPU-bound and runs fast, or kill the server and restart with `innodb_force_recovery=3`, as explained in Section 15.18.2, “InnoDB Recovery”.

This issue is expected to be infrequent with the default setting `innodb_change_buffering=all`, which allows update and delete operations to be cached in memory, making them faster to perform in the first place, and also faster to roll back if needed. Make sure to use this parameter setting on servers that process long-running transactions with many inserts, updates, or deletes.

• If you can afford the loss of some of the latest committed transactions if an unexpected exit occurs, you can set the `innodb_flush_log_at_trx_commit` parameter to 0. InnoDB tries to flush the log once per second anyway, although the flush is not guaranteed.

• When rows are modified or deleted, the rows and associated undo logs are not physically removed immediately, or even immediately after the transaction commits. The old data is preserved until transactions that started earlier or concurrently are finished, so that those transactions can access the previous state of modified or deleted rows. Thus, a long-running transaction can prevent InnoDB from purging data that was changed by a different transaction.

• When rows are modified or deleted within a long-running transaction, other transactions using the `READ COMMITTED` and `REPEATABLE READ` isolation levels have to do more work to reconstruct the older data if they read those same rows.

• When a long-running transaction modifies a table, queries against that table from other transactions do not make use of the covering index technique. Queries that normally could retrieve all the result columns from a secondary index, instead look up the appropriate values from the table data.

If secondary index pages are found to have a `PAGE_MAX_TRX_ID` that is too new, or if records in the secondary index are delete-marked, InnoDB may need to look up records using a clustered index.

### 8.5.3 Optimizing InnoDB Read-Only Transactions

**InnoDB** can avoid the overhead associated with setting up the transaction ID (TRX_ID field) for transactions that are known to be read-only. A transaction ID is only needed for a transaction that might perform write operations or locking reads such as `SELECT ... FOR UPDATE`. Eliminating unnecessary transaction IDs reduces the size of internal data structures that are consulted each time a query or data change statement constructs a read view.

**InnoDB** detects read-only transactions when:

• The transaction is started with the `START TRANSACTION READ ONLY` statement. In this case, attempting to make changes to the database (for InnoDB, MyISAM, or other types of tables) causes an error, and the transaction continues in read-only state:

  ```
  ERROR 1792 (25006): Cannot execute statement in a READ ONLY transaction.
  ```

You can still make changes to session-specific temporary tables in a read-only transaction, or issue locking queries for them, because those changes and locks are not visible to any other transaction.
Optimizing InnoDB Redo Logging

- The `autocommit` setting is turned on, so that the transaction is guaranteed to be a single statement, and the single statement making up the transaction is a “non-locking” `SELECT` statement. That is, a `SELECT` that does not use a `FOR UPDATE` or `LOCK IN SHARED MODE` clause.

- The transaction is started without the `READ ONLY` option, but no updates or statements that explicitly lock rows have been executed yet. Until updates or explicit locks are required, a transaction stays in read-only mode.

Thus, for a read-intensive application such as a report generator, you can tune a sequence of InnoDB queries by grouping them inside `START TRANSACTION READ ONLY` and `COMMIT`, or by turning on the `autocommit` setting before running the `SELECT` statements, or simply by avoiding any data change statements interspersed with the queries.

For information about `START TRANSACTION` and `autocommit`, see Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Statements”.

**Note**
Transactions that qualify as auto-commit, non-locking, and read-only (AC-NL-RO) are kept out of certain internal InnoDB data structures and are therefore not listed in `SHOW ENGINE INNODB STATUS` output.

### 8.5.4 Optimizing InnoDB Redo Logging

Consider the following guidelines for optimizing redo logging:

- Increase the size of your redo log files. When InnoDB has written redo log files full, it must write the modified contents of the buffer pool to disk in a **checkpoint**. Small redo log files cause many unnecessary disk writes.

  The redo log file size is determined by `innodb_redo_log_capacity`. InnoDB tries to maintain 32 redo log files of the same size, with each file equal to `1/32 * innodb_redo_log_capacity`. Therefore, changing the `innodb_redo_log_capacity` setting changes the size of the redo log files.

  For information about modifying your redo log file configuration, see Section 15.6.5, “Redo Log”.

- Consider increasing the size of the **log buffer**. A large log buffer enables large transactions to run without a need to write the log to disk before the transactions **commit**. Thus, if you have transactions that update, insert, or delete many rows, making the log buffer larger saves disk I/O. Log buffer size is configured using the `innodb_log_buffer_size` configuration option, which can be configured dynamically in MySQL 8.2.

- Configure the `innodb_log_write_ahead_size` configuration option to avoid “read-on-write”. This option defines the write-ahead block size for the redo log. Set `innodb_log_write_ahead_size` to match the operating system or file system cache block size. Read-on-write occurs when redo log blocks are not entirely cached to the operating system or file system due to a mismatch between write-ahead block size for the redo log and operating system or file system cache block size.

  Valid values for `innodb_log_write_ahead_size` are multiples of the InnoDB log file block size ($2^n$). The minimum value is the InnoDB log file block size (512). Write-ahead does not occur when the minimum value is specified. The maximum value is equal to the `innodb_page_size` value. If you specify a value for `innodb_log_write_ahead_size` that is larger than the `innodb_page_size` value, the `innodb_log_write_ahead_size` setting is truncated to the `innodb_page_size` value.

  Setting the `innodb_log_write_ahead_size` value too low in relation to the operating system or file system cache block size results in read-on-write. Setting the value too high may have a slight impact on `fsync` performance for log file writes due to several blocks being written at once.
MySQL provides dedicated log writer threads for writing redo log records from the log buffer to the system buffers and flushing the system buffers to the redo log files. You can enable or disable log writer threads using the `innodb_log_writer_threads` variable. Dedicated log writer threads can improve performance on high-concurrency systems, but for low-concurrency systems, disabling dedicated log writer threads provides better performance.

Optimize the use of spin delay by user threads waiting for flushed redo. Spin delay helps reduce latency. During periods of low concurrency, reducing latency may be less of a priority, and avoiding the use of spin delay during these periods may reduce energy consumption. During periods of high concurrency, you may want to avoid expending processing power on spin delay so that it can be used for other work. The following system variables permit setting high and low watermark values that define boundaries for the use of spin delay.

- `innodb_log_wait_for_flush_spin_hwm`: Defines the maximum average log flush time beyond which user threads no longer spin while waiting for flushed redo. The default value is 400 microseconds.
- `innodb_log_spin_cpu_abs_lwm`: Defines the minimum amount of CPU usage below which user threads no longer spin while waiting for flushed redo. The value is expressed as a sum of CPU core usage. For example, The default value of 80 is 80% of a single CPU core. On a system with a multi-core processor, a value of 150 represents 100% usage of one CPU core plus 50% usage of a second CPU core.
- `innodb_log_spin_cpu_pct_hwm`: Defines the maximum amount of CPU usage above which user threads no longer spin while waiting for flushed redo. The value is expressed as a percentage of the combined total processing power of all CPU cores. The default value is 50%. For example, 100% usage of two CPU cores is 50% of the combined CPU processing power on a server with four CPU cores.

The `innodb_log_spin_cpu_pct_hwm` configuration option respects processor affinity. For example, if a server has 48 cores but the `mysqld` process is pinned to only four CPU cores, the other 44 CPU cores are ignored.

### 8.5.5 Bulk Data Loading for InnoDB Tables

These performance tips supplement the general guidelines for fast inserts in Section 8.2.5.1, “Optimizing INSERT Statements”.

- When importing data into InnoDB, turn off autocommit mode, because it performs a log flush to disk for every insert. To disable autocommit during your import operation, surround it with `SET autocommit` and `COMMIT` statements:

```sql
SET autocommit=0;
... SQL import statements ...
COMMIT;
```

The `mysqldump` option `--opt` creates dump files that are fast to import into an InnoDB table, even without wrapping them with the `SET autocommit` and `COMMIT` statements.

- If you have `UNIQUE` constraints on secondary keys, you can speed up table imports by temporarily turning off the uniqueness checks during the import session:

```sql
SET unique_checks=0;
... SQL import statements ...
SET unique_checks=1;
```
For big tables, this saves a lot of disk I/O because InnoDB can use its change buffer to write secondary index records in a batch. Be certain that the data contains no duplicate keys.

- If you have FOREIGN KEY constraints in your tables, you can speed up table imports by turning off the foreign key checks for the duration of the import session:

```sql
SET foreign_key_checks=0;
... SQL import statements ...
SET foreign_key_checks=1;
```

For big tables, this can save a lot of disk I/O.

- Use the multiple-row INSERT syntax to reduce communication overhead between the client and the server if you need to insert many rows:

```sql
INSERT INTO yourtable VALUES (1,2), (5,5), ...;
```

This tip is valid for inserts into any table, not just InnoDB tables.

- When doing bulk inserts into tables with auto-increment columns, set `innodb_autoinc_lock_mode` to 2 (interleaved) instead of 1 (consecutive). See Section 15.6.1.6, “AUTO_INCREMENT Handling in InnoDB” for details.

- When performing bulk inserts, it is faster to insert rows in PRIMARY KEY order. InnoDB tables use a clustered index, which makes it relatively fast to use data in the order of the PRIMARY KEY. Performing bulk inserts in PRIMARY KEY order is particularly important for tables that do not fit entirely within the buffer pool.

- For optimal performance when loading data into an InnoDB FULLTEXT index, follow this set of steps:

  1. Define a column `FTS_DOC_ID` at table creation time, of type BIGINT UNSIGNED NOT NULL, with a unique index named `FTS_DOC_ID_INDEX`. For example:

```sql
CREATE TABLE t1 (  
  FTS_DOC_ID BIGINT unsigned NOT NULL AUTO_INCREMENT,  
  title varchar(255) NOT NULL DEFAULT '',  
  text mediumtext NOT NULL,  
  PRIMARY KEY (`FTS_DOC_ID`)  
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4;  
CREATE UNIQUE INDEX FTS_DOC_ID_INDEX on t1(FTS_DOC_ID);
```

  2. Load the data into the table.

  3. Create the FULLTEXT index after the data is loaded.

- **Note**

  When adding `FTS_DOC_ID` column at table creation time, ensure that the `FTS_DOC_ID` column is updated when the FULLTEXT indexed column is updated, as the `FTS_DOC_ID` must increase monotonically with each INSERT or UPDATE. If you choose not to add the `FTS_DOC_ID` at table creation time and have InnoDB manage DOC IDs for you, InnoDB adds the `FTS_DOC_ID` as a hidden column with the next CREATE FULLTEXT INDEX call. This approach, however, requires a table rebuild which can impact performance.
• If loading data into a new MySQL instance, consider disabling redo logging using ALTER INSTANCE (ENABLE|DISABLE) INNODB REDO_LOG syntax. Disabling redo logging helps speed up data loading by avoiding redo log writes. For more information, see Disabling Redo Logging.

Warning

This feature is intended only for loading data into a new MySQL instance. Do not disable redo logging on a production system. It is permitted to shutdown and restart the server while redo logging is disabled, but an unexpected server stoppage while redo logging is disabled can cause data loss and instance corruption.

• Use MySQL Shell to import data. MySQL Shell's parallel table import utility `util.importTable()` provides rapid data import to a MySQL relational table for large data files. MySQL Shell's dump loading utility `util.loadDump()` also offers parallel load capabilities. See MySQL Shell Utilities.

8.5.6 Optimizing InnoDB Queries

To tune queries for InnoDB tables, create an appropriate set of indexes on each table. See Section 8.3.1, “How MySQL Uses Indexes” for details. Follow these guidelines for InnoDB indexes:

• Because each InnoDB table has a primary key (whether you request one or not), specify a set of primary key columns for each table, columns that are used in the most important and time-critical queries.

• Do not specify too many or too long columns in the primary key, because these column values are duplicated in each secondary index. When an index contains unnecessary data, the I/O to read this data and memory to cache it reduce the performance and scalability of the server.

• Do not create a separate secondary index for each column, because each query can only make use of one index. Indexes on rarely tested columns or columns with only a few different values might not be helpful for any queries. If you have many queries for the same table, testing different combinations of columns, try to create a small number of concatenated indexes rather than a large number of single-column indexes. If an index contains all the columns needed for the result set (known as a covering index), the query might be able to avoid reading the table data at all.

• If an indexed column cannot contain any NULL values, declare it as NOT NULL when you create the table. The optimizer can better determine which index is most effective to use for a query, when it knows whether each column contains NULL values.

• You can optimize single-query transactions for InnoDB tables, using the technique in Section 8.5.3, “Optimizing InnoDB Read-Only Transactions”.

8.5.7 Optimizing InnoDB DDL Operations

• Many DDL operations on tables and indexes (CREATE, ALTER, and DROP statements) can be performed online. See Section 15.12, “InnoDB and Online DDL” for details.

• Online DDL support for adding secondary indexes means that you can generally speed up the process of creating and loading a table and associated indexes by creating the table without secondary indexes, then adding secondary indexes after the data is loaded.

• Use TRUNCATE TABLE to empty a table, not DELETE FROM tbl_name. Foreign key constraints can make a TRUNCATE statement work like a regular DELETE statement, in which case a sequence of commands like DROP TABLE and CREATE TABLE might be fastest.
• Because the primary key is integral to the storage layout of each InnoDB table, and changing the definition of the primary key involves reorganizing the whole table, always set up the primary key as part of the CREATE TABLE statement, and plan ahead so that you do not need to ALTER or DROP the primary key afterward.

8.5.8 Optimizing InnoDB Disk I/O

If you follow best practices for database design and tuning techniques for SQL operations, but your database is still slow due to heavy disk I/O activity, consider these disk I/O optimizations. If the Unix top tool or the Windows Task Manager shows that the CPU usage percentage with your workload is less than 70%, your workload is probably disk-bound.

• Increase buffer pool size

When table data is cached in the InnoDB buffer pool, it can be accessed repeatedly by queries without requiring any disk I/O. Specify the size of the buffer pool with the innodb_buffer_pool_size option. This memory area is important enough that it is typically recommended that innodb_buffer_pool_size is configured to 50 to 75 percent of system memory. For more information see, Section 8.12.3.1, "How MySQL Uses Memory".

• Adjust the flush method

In some versions of GNU/Linux and Unix, flushing files to disk with the Unix fsync() call (which InnoDB uses by default) and similar methods is surprisingly slow. If database write performance is an issue, conduct benchmarks with the innodb_flush_method parameter set to O_DSYNC.

• Configure a threshold for operating system flushes

By default, when InnoDB creates a new data file, such as a new log file or tablespace file, the file is fully written to the operating system cache before it is flushed to disk, which can cause a large amount of disk write activity to occur at once. To force smaller, periodic flushes of data from the operating system cache, you can use the innodb_fsync_threshold variable to define a threshold value, in bytes. When the byte threshold is reached, the contents of the operating system cache are flushed to disk. The default value of 0 forces the default behavior, which is to flush data to disk only after a file is fully written to the cache.

Specifying a threshold to force smaller, periodic flushes may be beneficial in cases where multiple MySQL instances use the same storage devices. For example, creating a new MySQL instance and its associated data files could cause large surges of disk write activity, impeding the performance of other MySQL instances that use the same storage devices. Configuring a threshold helps avoid such surges in write activity.

• Use fdatasync() instead of fsync()

On platforms that support fdatasync() system calls, the innodb_use_fdatasync variable permits using fdatasync() instead of fsync() for operating system flushes. An fdatasync() system call does not flush changes to file metadata unless required for subsequent data retrieval, providing a potential performance benefit.

A subset of innodb_flush_method settings such as fsync, O_DSYNC, and O_DIRECT use fsync() system calls. The innodb_use_fdatasync variable is applicable when using those settings.

• Use a noop or deadline I/O scheduler with native AIO on Linux

InnoDB uses the asynchronous I/O subsystem (native AIO) on Linux to perform read-ahead and write requests for data file pages. This behavior is controlled by the innodb_use_native_aio configuration option.
Optimizing InnoDB Disk I/O

option, which is enabled by default. With native AIO, the type of I/O scheduler has greater influence on I/O performance. Generally, noop and deadline I/O schedulers are recommended. Conduct benchmarks to determine which I/O scheduler provides the best results for your workload and environment. For more information, see Section 15.8.6, “Using Asynchronous I/O on Linux”.

• Use direct I/O on Solaris 10 for x86_64 architecture

When using the InnoDB storage engine on Solaris 10 for x86_64 architecture (AMD Opteron), use direct I/O for InnoDB-related files to avoid degradation of InnoDB performance. To use direct I/O for an entire UFS file system used for storing InnoDB-related files, mount it with the forcedirectio option; see mount_ufs(1M). (The default on Solaris 10/x86_64 is not to use this option.) To apply direct I/O only to InnoDB file operations rather than the whole file system, set innodb_flush_method = O_DIRECT. With this setting, InnoDB calls directio() instead of fcntl() for I/O to data files (not for I/O to log files).

• Use raw storage for data and log files with Solaris 2.6 or later

When using the InnoDB storage engine with a large innodb_buffer_pool_size value on any release of Solaris 2.6 and up and any platform (sparc/x86/x64/amd64), conduct benchmarks with InnoDB data files and log files on raw devices or on a separate direct I/O UFS file system, using the forcedirectio mount option as described previously. (It is necessary to use the mount option rather than setting innodb_flush_method if you want direct I/O for the log files.) Users of the Veritas file system VxFS should use the convosync=direct mount option.

Do not place other MySQL data files, such as those for MyISAM tables, on a direct I/O file system. Executables or libraries must not be placed on a direct I/O file system.

• Use additional storage devices

Additional storage devices could be used to set up a RAID configuration. For related information, see Section 8.12.1, “Optimizing Disk I/O”.

Alternatively, InnoDB tablespace data files and log files can be placed on different physical disks. For more information, refer to the following sections:

• Section 15.8.1, “InnoDB Startup Configuration”
• Section 15.6.1.2, “Creating Tables Externally”
• Creating a General Tablespace
• Section 15.6.1.4, “Moving or Copying InnoDB Tables”

• Consider non-rotational storage

Non-rotational storage generally provides better performance for random I/O operations; and rotational storage for sequential I/O operations. When distributing data and log files across rotational and non-rotational storage devices, consider the type of I/O operations that are predominantly performed on each file.

Random I/O-oriented files typically include file-per-table and general tablespace data files, undo tablespace files, and temporary tablespace files. Sequential I/O-oriented files include InnoDB system tablespace files, doublewrite files, and log files such as binary log files and redo log files.

Review settings for the following configuration options when using non-rotational storage:

• innodb_checksum_algorithm
The **crc32** option uses a faster checksum algorithm and is recommended for fast storage systems.

- **innodb_flush_neighbors**
  
  Optimizes I/O for rotational storage devices. Disable it for non-rotational storage or a mix of rotational and non-rotational storage. It is disabled by default.

- **innodb_idle_flush_pct**
  
  Permits placing a limit on page flushing during idle periods, which can help extend the life of non-rotational storage devices.

- **innodb_io_capacity**
  
  The default setting of 200 is generally sufficient for a lower-end non-rotational storage device. For higher-end, bus-attached devices, consider a higher setting such as 1000.

- **innodb_io_capacity_max**
  
  The default value of 2000 is intended for workloads that use non-rotational storage. For a high-end, bus-attached non-rotational storage device, consider a higher setting such as 2500.

- **innodb_log_compressed_pages**
  
  If redo logs are on non-rotational storage, consider disabling this option to reduce logging. See Disable logging of compressed pages.

- **innodb_log_file_size** (deprecated)
  
  If redo logs are on non-rotational storage, configure this option to maximize caching and write combining.

- **innodb_redo_log_capacity**
  
  If redo logs are on non-rotational storage, configure this option to maximize caching and write combining.

- **innodb_page_size**
  
  Consider using a page size that matches the internal sector size of the disk. Early-generation SSD devices often have a 4KB sector size. Some newer devices have a 16KB sector size. The default InnoDB page size is 16KB. Keeping the page size close to the storage device block size minimizes the amount of unchanged data that is rewritten to disk.

- **binlog_row_image**
  
  If binary logs are on non-rotational storage and all tables have primary keys, consider setting this option to *minimal* to reduce logging.

Ensure that TRIM support is enabled for your operating system. It is typically enabled by default.

- Increase I/O capacity to avoid backlogs
  
  If throughput drops periodically because of InnoDB checkpoint operations, consider increasing the value of the **innodb_io_capacity** configuration option. Higher values cause more frequent flushing, avoiding the backlog of work that can cause dips in throughput.
• Lower I/O capacity if flushing does not fall behind

If the system is not falling behind with InnoDB flushing operations, consider lowering the value of the `innodb_io_capacity` configuration option. Typically, you keep this option value as low as practical, but not so low that it causes periodic drops in throughput as mentioned in the preceding bullet. In a typical scenario where you could lower the option value, you might see a combination like this in the output from `SHOW ENGINE INNODB STATUS`:

• History list length low, below a few thousand.
• Insert buffer merges close to rows inserted.
• Modified pages in buffer pool consistently well below `innodb_max_dirty_pages_pct` of the buffer pool. (Measure at a time when the server is not doing bulk inserts; it is normal during bulk inserts for the modified pages percentage to rise significantly.)

• Log sequence number — Last checkpoint is at less than 7/8 or ideally less than 6/8 of the total size of the InnoDB log files.

• Store system tablespace files on Fusion-io devices

You can take advantage of a doublewrite buffer-related I/O optimization by storing the files that contain the doublewrite storage area on Fusion-io devices that support atomic writes. (The doublewrite buffer storage area resides in doublewrite files. See Section 15.6.4, “Doublewrite Buffer.”) When doublewrite storage area files are placed on Fusion-io devices that support atomic writes, the doublewrite buffer is automatically disabled and Fusion-io atomic writes are used for all data files. This feature is only supported on Fusion-io hardware and is only enabled for Fusion-io NVMFS on Linux. To take full advantage of this feature, an `innodb_flush_method` setting of `O_DIRECT` is recommended.

Note

Because the doublewrite buffer setting is global, the doublewrite buffer is also disabled for data files that do not reside on Fusion-io hardware.

• Disable logging of compressed pages

When using the InnoDB table compression feature, images of re-compressed pages are written to the redo log when changes are made to compressed data. This behavior is controlled by `innodb_log_compressed_pages`, which is enabled by default to prevent corruption that can occur if a different version of the zlib compression algorithm is used during recovery. If you are certain that the zlib version is not subject to change, disable `innodb_log_compressed_pages` to reduce redo log generation for workloads that modify compressed data.

8.5.9 Optimizing InnoDB Configuration Variables

Different settings work best for servers with light, predictable loads, versus servers that are running near full capacity all the time, or that experience spikes of high activity.

Because the InnoDB storage engine performs many of its optimizations automatically, many performance-tuning tasks involve monitoring to ensure that the database is performing well, and changing configuration options when performance drops. See Section 15.16, “InnoDB Integration with MySQL Performance Schema” for information about detailed InnoDB performance monitoring.

The main configuration steps you can perform include:
• Controlling the types of data change operations for which InnoDB buffers the changed data, to avoid frequent small disk writes. See Configuring Change Buffering. Because the default is to buffer all types of data change operations, only change this setting if you need to reduce the amount of buffering.

• Turning the adaptive hash indexing feature on and off using the innodb_adaptive_hash_index option. See Section 15.5.3, “Adaptive Hash Index” for more information. You might change this setting during periods of unusual activity, then restore it to its original setting.

• Setting a limit on the number of concurrent threads that InnoDB processes, if context switching is a bottleneck. See Section 15.8.4, “Configuring Thread Concurrency for InnoDB”.

• Controlling the amount of prefetching that InnoDB does with its read-ahead operations. When the system has unused I/O capacity, more read-ahead can improve the performance of queries. Too much read-ahead can cause periodic drops in performance on a heavily loaded system. See Section 15.8.3.4, “Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)”.

• Increasing the number of background threads for read or write operations, if you have a high-end I/O subsystem that is not fully utilized by the default values. See Section 15.8.5, “Configuring the Number of Background InnoDB I/O Threads”.

• Controlling how much I/O InnoDB performs in the background. See Section 15.8.7, “Configuring InnoDB I/O Capacity”. You might scale back this setting if you observe periodic drops in performance.

• Controlling the algorithm that determines when InnoDB performs certain types of background writes. See Section 15.8.3.5, “Configuring Buffer Pool Flushing”. The algorithm works for some types of workloads but not others, so you might disable this feature if you observe periodic drops in performance.

• Taking advantage of multicore processors and their cache memory configuration, to minimize delays in context switching. See Section 15.8.8, “Configuring Spin Lock Polling”.

• Preventing one-time operations such as table scans from interfering with the frequently accessed data stored in the InnoDB buffer cache. See Section 15.8.3.3, “Making the Buffer Pool Scan Resistant”.

• Adjusting log files to a size that makes sense for reliability and crash recovery. InnoDB log files have often been kept small to avoid long startup times after a crash. Optimizations introduced in MySQL 5.5 speed up certain steps of the crash recovery process. In particular, scanning the redo log and applying the redo log are faster due to improved algorithms for memory management. If you have kept your log files artificially small to avoid long startup times, you can now consider increasing log file size to reduce the I/O that occurs due recycling of redo log records.

• Configuring the size and number of instances for the InnoDB buffer pool, especially important for systems with multi-gigabyte buffer pools. See Section 15.8.3.2, “Configuring Multiple Buffer Pool Instances”.

• Increasing the maximum number of concurrent transactions, which dramatically improves scalability for the busiest databases. See Section 15.6.6, “Undo Logs”.

• Moving purge operations (a type of garbage collection) into a background thread. See Section 15.8.9, “Purge Configuration”. To effectively measure the results of this setting, tune the other I/O-related and thread-related configuration settings first.

• Reducing the amount of switching that InnoDB does between concurrent threads, so that SQL operations on a busy server do not queue up and form a “traffic jam”. Set a value for the innodb_thread_concurrency option, up to approximately 32 for a high-powered modern system. Increase the value for the innodb_concurrency_tickets option, typically to 5000 or so. This combination of options sets a cap on the number of threads that InnoDB processes at any one time, and allows each thread to do substantial work before being swapped out, so that the number of waiting threads stays low and operations can complete without excessive context switching.
8.5.10 Optimizing InnoDB for Systems with Many Tables

- If you have configured non-persistent optimizer statistics (a non-default configuration), InnoDB computes index cardinality values for a table the first time that table is accessed after startup, instead of storing such values in the table. This step can take significant time on systems that partition the data into many tables. Since this overhead only applies to the initial table open operation, to “warm up” a table for later use, access it immediately after startup by issuing a statement such as `SELECT 1 FROM tbl_name LIMIT 1`.

Optimizer statistics are persisted to disk by default, enabled by the `innodb_stats_persistent` configuration option. For information about persistent optimizer statistics, see Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”.

8.6 Optimizing for MyISAM Tables

The MyISAM storage engine performs best with read-mostly data or with low-concurrency operations, because table locks limit the ability to perform simultaneous updates. In MySQL, InnoDB is the default storage engine rather than MyISAM.

8.6.1 Optimizing MyISAM Queries

Some general tips for speeding up queries on MyISAM tables:

- To help MySQL better optimize queries, use `ANALYZE TABLE` or run `myisamchk --analyze` on a table after it has been loaded with data. This updates a value for each index part that indicates the average number of rows that have the same value. (For unique indexes, this is always 1.) MySQL uses this to decide which index to choose when you join two tables based on a nonconstant expression. You can check the result from the table analysis by using `SHOW INDEX FROM tbl_name` and examining the `Cardinality` value. `myisamchk --description --verbose` shows index distribution information.

- To sort an index and data according to an index, use `myisamchk --sort-index --sort-records=1` (assuming that you want to sort on index 1). This is a good way to make queries faster if you have a unique index from which you want to read all rows in order according to the index. The first time you sort a large table this way, it may take a long time.

- Try to avoid complex `SELECT` queries on MyISAM tables that are updated frequently, to avoid problems with table locking that occur due to contention between readers and writers.

- MyISAM supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can `INSERT` new rows into it at the same time that other threads are reading from the table. If it is important to be able to do this, consider using the table in ways that avoid deleting rows. Another possibility is to run `OPTIMIZE TABLE` to defragment the table after you have deleted a lot of rows from it. This behavior is altered by setting the `concurrent_insert` variable. You can force new rows to be appended (and therefore permit concurrent inserts), even in tables that have deleted rows. See Section 8.11.3, “Concurrent Inserts”.

- For MyISAM tables that change frequently, try to avoid all variable-length columns (VARCHAR, BLOB, and TEXT). The table uses dynamic row format if it includes even a single variable-length column. See Chapter 16, Alternative Storage Engines.

- It is normally not useful to split a table into different tables just because the rows become large. In accessing a row, the biggest performance hit is the disk seek needed to find the first byte of the row. After finding the data, most modern disks can read the entire row fast enough for most applications. The only cases where splitting up a table makes an appreciable difference is if it is a MyISAM table using dynamic row format that you can change to a fixed row size, or if you very often need to scan the table but do not need most of the columns. See Chapter 16, Alternative Storage Engines.
Bulk Data Loading for MyISAM Tables

- Use `ALTER TABLE ... ORDER BY expr1, expr2, ...` if you usually retrieve rows in `expr1, expr2, ...` order. By using this option after extensive changes to the table, you may be able to get higher performance.

- If you often need to calculate results such as counts based on information from a lot of rows, it may be preferable to introduce a new table and update the counter in real time. An update of the following form is very fast:

```
UPDATE tbl_name SET count_col=count_col+1 WHERE key_col=constant;
```

This is very important when you use MySQL storage engines such as MyISAM that has only table-level locking (multiple readers with single writers). This also gives better performance with most database systems, because the row locking manager in this case has less to do.

- Use `OPTIMIZE TABLE` periodically to avoid fragmentation with dynamic-format MyISAM tables. See Section 16.2.3, “MyISAM Table Storage Formats”.

- Declaring a MyISAM table with the `DELAY_KEY_WRITE=1` table option makes index updates faster because they are not flushed to disk until the table is closed. The downside is that if something kills the server while such a table is open, you must ensure that the table is okay by running the server with the `mysqld_safe` as a means to recover. (However, even in this case, you should not lose anything by using `DELAY_KEY_WRITE`, because the key information can always be generated from the data rows.)

- Strings are automatically prefix- and end-space compressed in MyISAM indexes. See Section 13.1.15, “CREATE INDEX Statement”.

- You can increase performance by caching queries or answers in your application and then executing many inserts or updates together. Locking the table during this operation ensures that the index cache is only flushed once after all updates.

### 8.6.2 Bulk Data Loading for MyISAM Tables

These performance tips supplement the general guidelines for fast inserts in Section 8.2.5.1, “Optimizing INSERT Statements”.

- For a MyISAM table, you can use concurrent inserts to add rows at the same time that `SELECT` statements are running, if there are no deleted rows in middle of the data file. See Section 8.11.3, “Concurrent Inserts”.

- With some extra work, it is possible to make `LOAD DATA` run even faster for a MyISAM table when the table has many indexes. Use the following procedure:

  1. Execute a `FLUSH TABLES` statement or a `mysqladmin flush-tables` command.

  2. Use `mysqld --keys-used=0 -r` to remove all use of indexes for the table.

  3. Insert data into the table with `LOAD DATA`. This does not update any indexes and therefore is very fast.

  4. If you intend only to read from the table in the future, use `mysampack` to compress it. See Section 16.2.3.3, “Compressed Table Characteristics”.

  5. Re-create the indexes with `mysqld --keys-used=0 -r` to maintain the index tree in memory before writing it to disk, which is much faster than updating the index during `LOAD DATA` because it avoids lots of disk seeks. The resulting index tree is also perfectly balanced.
6. Execute a `FLUSH TABLES` statement or a `mysqladmin flush-tables` command.

`LOAD DATA` performs the preceding optimization automatically if the `MyISAM` table into which you insert data is empty. The main difference between automatic optimization and using the procedure explicitly is that you can let `myisamchk` allocate much more temporary memory for the index creation than you might want the server to allocate for index re-creation when it executes the `LOAD DATA` statement.

You can also disable or enable the nonunique indexes for a `MyISAM` table by using the following statements rather than `myisamchk`. If you use these statements, you can skip the `FLUSH TABLES` operations:

```sql
ALTER TABLE tbl_name DISABLE KEYS;
ALTER TABLE tbl_name ENABLE KEYS;
```

- To speed up `INSERT` operations that are performed with multiple statements for nontransactional tables, lock your tables:

```sql
LOCK TABLES a WRITE;
INSERT INTO a VALUES (1,23),(2,34),(4,33);
INSERT INTO a VALUES (8,26),(6,29);
...
UNLOCK TABLES;
```

This benefits performance because the index buffer is flushed to disk only once, after all `INSERT` statements have completed. Normally, there would be as many index buffer flushes as there are `INSERT` statements. Explicit locking statements are not needed if you can insert all rows with a single `INSERT`.

Locking also lowers the total time for multiple-connection tests, although the maximum wait time for individual connections might go up because they wait for locks. Suppose that five clients attempt to perform inserts simultaneously as follows:

- Connection 1 does 1000 inserts
- Connections 2, 3, and 4 do 1 insert
- Connection 5 does 1000 inserts

If you do not use locking, connections 2, 3, and 4 finish before 1 and 5. If you use locking, connections 2, 3, and 4 probably do not finish before 1 or 5, but the total time should be about 40% faster.

`INSERT`, `UPDATE`, and `DELETE` operations are very fast in MySQL, but you can obtain better overall performance by adding locks around everything that does more than about five successive inserts or updates. If you do very many successive inserts, you could do a `LOCK TABLES` followed by an `UNLOCK TABLES` once in a while (each 1,000 rows or so) to permit other threads to access table. This would still result in a nice performance gain.

`INSERT` is still much slower for loading data than `LOAD DATA`, even when using the strategies just outlined.

- To increase performance for `MyISAM` tables, for both `LOAD DATA` and `INSERT`, enlarge the key cache by increasing the `key_buffer_size` system variable. See Section 5.1.1, “Configuring the Server”.

### 8.6.3 Optimizing REPAIR TABLE Statements

`REPAIR TABLE` for `MyISAM` tables is similar to using `myisamchk` for repair operations, and some of the same performance optimizations apply:
Optimizing REPAIR TABLE Statements

- *myisamchk* has variables that control memory allocation. You may be able to improve performance by setting these variables, as described in Section 4.6.4.6, “myisamchk Memory Usage”.

- For REPAIR TABLE, the same principle applies, but because the repair is done by the server, you set server system variables instead of *myisamchk* variables. Also, in addition to setting memory-allocation variables, increasing the *myisam_max_sort_file_size* system variable increases the likelihood that the repair uses the faster file sort method and avoids the slower repair by key cache method. Set the variable to the maximum file size for your system, after checking to be sure that there is enough free space to hold a copy of the table files. The free space must be available in the file system containing the original table files.

Suppose that a *myisamchk* table-repair operation is done using the following options to set its memory-allocation variables:

```
--key_buffer_size=128M --myisam_sort_buffer_size=256M
--read_buffer_size=64M --write_buffer_size=64M
```

Some of those *myisamchk* variables correspond to server system variables:

<table>
<thead>
<tr>
<th><em>myisamchk</em> Variable</th>
<th>System Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>key_buffer_size</td>
<td>key_buffer_size</td>
</tr>
<tr>
<td>myisam_sort_buffer_size</td>
<td>myisam_sort_buffer_size</td>
</tr>
<tr>
<td>read_buffer_size</td>
<td>read_buffer_size</td>
</tr>
<tr>
<td>write_buffer_size</td>
<td>none</td>
</tr>
</tbody>
</table>

Each of the server system variables can be set at runtime, and some of them (*myisam_sort_buffer_size, read_buffer_size*) have a session value in addition to a global value. Setting a session value limits the effect of the change to your current session and does not affect other users. Changing a global-only variable (*key_buffer_size, myisam_max_sort_file_size*) affects other users as well. For *key_buffer_size*, you must take into account that the buffer is shared with those users. For example, if you set the *myisamchk* *key_buffer_size* variable to 128MB, you could set the corresponding *key_buffer_size* system variable larger than that (if it is not already set larger), to permit key buffer use by activity in other sessions. However, changing the global key buffer size invalidates the buffer, causing increased disk I/O and slowdown for other sessions. An alternative that avoids this problem is to use a separate key cache, assign to it the indexes from the table to be repaired, and deallocate it when the repair is complete. See Section 8.10.2.2, “Multiple Key Caches”.

Based on the preceding remarks, a REPAIR TABLE operation can be done as follows to use settings similar to the *myisamchk* command. Here a separate 128MB key buffer is allocated and the file system is assumed to permit a file size of at least 100GB.

```
SET SESSION myisam_sort_buffer_size = 256*1024*1024;
SET SESSION read_buffer_size = 64*1024*1024;
SET GLOBAL myisam_max_sort_file_size = 100*1024*1024*1024;
SET GLOBAL repair_cache.key_buffer_size = 128*1024*1024;
CACHE INDEX tbl_name IN repair_cache;
LOAD INDEX INTO CACHE tbl_name;
REPAIR TABLE tbl_name;
SET GLOBAL repair_cache.key_buffer_size = 0;
```

If you intend to change a global variable but want to do so only for the duration of a REPAIR TABLE operation to minimally affect other users, save its value in a user variable and restore it afterward. For example:

```
SET @old_myisam_sort_buffer_size = @@GLOBAL.myisam_max_sort_file_size;
SET GLOBAL myisam_max_sort_file_size = 100*1024*1024*1024;
```
REPAIR TABLE tbl_name;
SET GLOBAL myisam_max_sort_file_size = @old_myisam_max_sort_file_size;

The system variables that affect REPAIR TABLE can be set globally at server startup if you want the values to be in effect by default. For example, add these lines to the server my.cnf file:

```
[mysqld]
myisam_sort_buffer_size=256M
key_buffer_size=1G
myisam_max_sort_file_size=100G
```

These settings do not include read_buffer_size. Setting read_buffer_size globally to a large value does so for all sessions and can cause performance to suffer due to excessive memory allocation for a server with many simultaneous sessions.

### 8.7 Optimizing for MEMORY Tables

Consider using MEMORY tables for noncritical data that is accessed often, and is read-only or rarely updated. Benchmark your application against equivalent InnoDB or MyISAM tables under a realistic workload, to confirm that any additional performance is worth the risk of losing data, or the overhead of copying data from a disk-based table at application start.

For best performance with MEMORY tables, examine the kinds of queries against each table, and specify the type to use for each associated index, either a B-tree index or a hash index. On the CREATE INDEX statement, use the clause USING BTREE or USING HASH. B-tree indexes are fast for queries that do greater-than or less-than comparisons through operators such as > or BETWEEN. Hash indexes are only fast for queries that look up single values through the = operator, or a restricted set of values through the IN operator. For why USING BTREE is often a better choice than the default USING HASH, see Section 8.2.1.23, “Avoiding Full Table Scans”. For implementation details of the different types of MEMORY indexes, see Section 8.3.9, “Comparison of B-Tree and Hash Indexes”.

### 8.8 Understanding the Query Execution Plan

Depending on the details of your tables, columns, indexes, and the conditions in your WHERE clause, the MySQL optimizer considers many techniques to efficiently perform the lookups involved in an SQL query. A query on a huge table can be performed without reading all the rows; a join involving several tables can be performed without comparing every combination of rows. The set of operations that the optimizer chooses to perform is called the “query execution plan”, also known as the EXPLAIN plan. Your goals are to recognize the aspects of the EXPLAIN plan that indicate a query is optimized well, and to learn the SQL syntax and indexing techniques to improve the plan if you see some inefficient operations.

#### 8.8.1 Optimizing Queries with EXPLAIN

The EXPLAIN statement provides information about how MySQL executes statements:

- **EXPLAIN** works with SELECT, DELETE, INSERT, REPLACE, and UPDATE statements.

- When **EXPLAIN** is used with an explainable statement, MySQL displays information from the optimizer about the statement execution plan. That is, MySQL explains how it would process the statement, including information about how tables are joined and in which order. For information about using **EXPLAIN** to obtain execution plan information, see Section 8.8.2, “EXPLAIN Output Format”.

  - When **EXPLAIN** is used with FOR CONNECTION connection_id rather than an explainable statement, it displays the execution plan for the statement executing in the named connection. See Section 8.8.4, “Obtaining Execution Plan Information for a Named Connection”.
EXPLAIN Output Format

- For `SELECT` statements, `EXPLAIN` produces additional execution plan information that can be displayed using `SHOW WARNINGS`. See Section 8.8.3, “Extended EXPLAIN Output Format”.
- `EXPLAIN` is useful for examining queries involving partitioned tables. See Section 24.3.5, “Obtaining Information About Partitions”.
- The `FORMAT` option can be used to select the output format. `TRADITIONAL` presents the output in tabular format. This is the default if no `FORMAT` option is present. `JSON` format displays the information in JSON format.

With the help of `EXPLAIN`, you can see where you should add indexes to tables so that the statement executes faster by using indexes to find rows. You can also use `EXPLAIN` to check whether the optimizer joins the tables in an optimal order. To give a hint to the optimizer to use a join order corresponding to the order in which the tables are named in a `SELECT` statement, begin the statement with `SELECT STRAIGHT_JOIN` rather than just `SELECT`. (See Section 13.2.13, “SELECT Statement”.) However, `STRAIGHT_JOIN` may prevent indexes from being used because it disables semijoin transformations. See Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations.

The optimizer trace may sometimes provide information complementary to that of `EXPLAIN`. However, the optimizer trace format and content are subject to change between versions. For details, see MySQL Internals: Tracing the Optimizer.

If you have a problem with indexes not being used when you believe that they should be, run `ANALYZE TABLE` to update table statistics, such as cardinality of keys, that can affect the choices the optimizer makes. See Section 13.7.3.1, “ANALYZE TABLE Statement”.

Note
`EXPLAIN` can also be used to obtain information about the columns in a table. `EXPLAIN tbl_name` is synonymous with `DESCRIBE tbl_name` and `SHOW COLUMNS FROM tbl_name`. For more information, see Section 13.8.1, “DESCRIBE Statement”, and Section 13.7.7.6, “SHOW COLUMNS Statement”.

8.8.2 EXPLAIN Output Format

The `EXPLAIN` statement provides information about how MySQL executes statements. `EXPLAIN` works with `SELECT`, `DELETE`, `INSERT`, `REPLACE`, and `UPDATE` statements.

`EXPLAIN` returns a row of information for each table used in the `SELECT` statement. It lists the tables in the output in the order that MySQL would read them while processing the statement. This means that MySQL reads a row from the first table, then finds a matching row in the second table, and then in the third table, and so on. When all tables are processed, MySQL outputs the selected columns and backtracks through the table list until a table is found for which there are more matching rows. The next row is read from this table and the process continues with the next table.

Note
MySQL Workbench has a Visual Explain capability that provides a visual representation of `EXPLAIN` output. See Tutorial: Using Explain to Improve Query Performance.

- `EXPLAIN` Join Types
- `EXPLAIN` Extra Information
- `EXPLAIN` Output Interpretation
EXPLAIN Output Format

EXPLAIN Output Columns

This section describes the output columns produced by EXPLAIN. Later sections provide additional information about the type and Extra columns.

Each output row from EXPLAIN provides information about one table. Each row contains the values summarized in Table 8.1, “EXPLAIN Output Columns”, and described in more detail following the table. Column names are shown in the table’s first column; the second column provides the equivalent property name shown in the output when FORMAT=JSON is used.

Table 8.1 EXPLAIN Output Columns

<table>
<thead>
<tr>
<th>Column</th>
<th>JSON Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>select_id</td>
<td>The SELECT identifier</td>
</tr>
<tr>
<td>select_type</td>
<td>None</td>
<td>The SELECT type</td>
</tr>
<tr>
<td>table</td>
<td>table_name</td>
<td>The table for the output row</td>
</tr>
<tr>
<td>partitions</td>
<td>partitions</td>
<td>The matching partitions</td>
</tr>
<tr>
<td>type</td>
<td>access_type</td>
<td>The join type</td>
</tr>
<tr>
<td>possible_keys</td>
<td>possible_keys</td>
<td>The possible indexes to choose</td>
</tr>
<tr>
<td>key</td>
<td>key</td>
<td>The index actually chosen</td>
</tr>
<tr>
<td>key_len</td>
<td>key_length</td>
<td>The length of the chosen key</td>
</tr>
<tr>
<td>ref</td>
<td>ref</td>
<td>The columns compared to the index</td>
</tr>
<tr>
<td>rows</td>
<td>rows</td>
<td>Estimate of rows to be examined</td>
</tr>
<tr>
<td>filtered</td>
<td>filtered</td>
<td>Percentage of rows filtered by table condition</td>
</tr>
<tr>
<td>Extra</td>
<td>None</td>
<td>Additional information</td>
</tr>
</tbody>
</table>

Note

JSON properties which are NULL are not displayed in JSON-formatted EXPLAIN output.

- **id (JSON name: select_id)**

  The SELECT identifier. This is the sequential number of the SELECT within the query. The value can be NULL if the row refers to the union result of other rows. In this case, the table column shows a value like <unionM, N> to indicate that the row refers to the union of the rows with id values of M and N.

- **select_type (JSON name: none)**

  The type of SELECT, which can be any of those shown in the following table. A JSON-formatted EXPLAIN exposes the SELECT type as a property of a query_block, unless it is SIMPLE or PRIMARY. The JSON names (where applicable) are also shown in the table.

<table>
<thead>
<tr>
<th>select_type Value</th>
<th>JSON Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIMPLE</td>
<td>None</td>
<td>Simple SELECT (not using UNION or subqueries)</td>
</tr>
<tr>
<td>PRIMARY</td>
<td>None</td>
<td>Outermost SELECT</td>
</tr>
<tr>
<td>UNION</td>
<td>None</td>
<td>Second or later SELECT statement in a UNION</td>
</tr>
</tbody>
</table>
### EXPLAIN Output Format

<table>
<thead>
<tr>
<th>select_type Value</th>
<th>JSON Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEPENDENT UNION</td>
<td>dependent (true)</td>
<td>Second or later SELECT statement in a UNION, dependent on outer query</td>
</tr>
<tr>
<td>UNION RESULT</td>
<td>union_result</td>
<td>Result of a UNION.</td>
</tr>
<tr>
<td>SUBQUERY</td>
<td>None</td>
<td>First SELECT in subquery</td>
</tr>
<tr>
<td>DEPENDENT SUBQUERY</td>
<td>dependent (true)</td>
<td>First SELECT in subquery, dependent on outer query</td>
</tr>
<tr>
<td>DERIVED</td>
<td>None</td>
<td>Derived table</td>
</tr>
<tr>
<td>DEPENDENT DERIVED</td>
<td>dependent (true)</td>
<td>Derived table dependent on another table</td>
</tr>
<tr>
<td>MATERIALIZED</td>
<td>materialized_from_subquery</td>
<td>Materialized subquery</td>
</tr>
<tr>
<td>UNCACHEABLE SUBQUERY</td>
<td>cacheable (false)</td>
<td>A subquery for which the result cannot be cached and must be re-evaluated for each row of the outer query</td>
</tr>
<tr>
<td>UNCACHEABLE UNION</td>
<td>cacheable (false)</td>
<td>The second or later select in a UNION that belongs to an uncacheable subquery (see UNCACHEABLE SUBQUERY)</td>
</tr>
</tbody>
</table>

**DEPENDENT** typically signifies the use of a correlated subquery. See Section 13.2.15.7, “Correlated Subqueries”.

**DEPENDENT SUBQUERY** evaluation differs from UNCACHEABLE SUBQUERY evaluation. For DEPENDENT SUBQUERY, the subquery is re-evaluated only once for each set of different values of the variables from its outer context. For UNCACHEABLE SUBQUERY, the subquery is re-evaluated for each row of the outer context.

When you specify `FORMAT=JSON` with EXPLAIN, the output has no single property directly equivalent to `select_type`; the `query_block` property corresponds to a given SELECT. Properties equivalent to most of the SELECT subquery types just shown are available (an example being `materialized_from_subquery` for MATERIALIZED), and are displayed when appropriate. There are no JSON equivalents for SIMPLE or PRIMARY.

The `select_type` value for non-SELECT statements displays the statement type for affected tables. For example, `select_type` is DELETE for DELETE statements.

- **table** (JSON name: `table_name`)

The name of the table to which the row of output refers. This can also be one of the following values:

- `<unionM, N>`: The row refers to the union of the rows with id values of M and N.
- `<derivedN>`: The row refers to the derived table result for the row with an id value of N. A derived table may result, for example, from a subquery in the FROM clause.
- `<subqueryN>`: The row refers to the result of a materialized subquery for the row with an id value of N. See Section 8.2.2.2, “Optimizing Subqueries with Materialization”.
EXPLAIN Output Format

• **partitions** (JSON name: `partitions`)

  The partitions from which records would be matched by the query. The value is **NULL** for nonpartitioned tables. See Section 24.3.5, “Obtaining Information About Partitions”.

• **type** (JSON name: `access_type`)

  The join type. For descriptions of the different types, see EXPLAIN Join Types.

• **possible_keys** (JSON name: `possible_keys`)

  The `possible_keys` column indicates the indexes from which MySQL can choose to find the rows in this table. Note that this column is totally independent of the order of the tables as displayed in the output from EXPLAIN. That means that some of the keys in `possible_keys` might not be usable in practice with the generated table order.

  If this column is **NULL** (or undefined in JSON-formatted output), there are no relevant indexes. In this case, you may be able to improve the performance of your query by examining the **WHERE** clause to check whether it refers to some column or columns that would be suitable for indexing. If so, create an appropriate index and check the query with EXPLAIN again. See Section 13.1.9, “ALTER TABLE Statement”.

  To see what indexes a table has, use `SHOW INDEX FROM tbl_name`.

• **key** (JSON name: `key`)

  The `key` column indicates the key (index) that MySQL actually decided to use. If MySQL decides to use one of the `possible_keys` indexes to look up rows, that index is listed as the key value.

  It is possible that `key` may name an index that is not present in the `possible_keys` value. This can happen if none of the `possible_keys` indexes are suitable for looking up rows, but all the columns selected by the query are columns of some other index. That is, the named index covers the selected columns, so although it is not used to determine which rows to retrieve, an index scan is more efficient than a data row scan.

  For InnoDB, a secondary index might cover the selected columns even if the query also selects the primary key because InnoDB stores the primary key value with each secondary index. If `key` is **NULL**, MySQL found no index to use for executing the query more efficiently.

  To force MySQL to use or ignore an index listed in the `possible_keys` column, use `FORCE INDEX`, `USE INDEX`, or `IGNORE INDEX` in your query. See Section 8.9.4, “Index Hints”.

  For MyISAM tables, running `ANALYZE TABLE` helps the optimizer choose better indexes. For MyISAM tables, `myisamchk --analyze` does the same. See Section 13.7.3.1, “ANALYZE TABLE Statement”, and Section 7.6, “MyISAM Table Maintenance and Crash Recovery”.

• **key_len** (JSON name: `key_length`)

  The `key_len` column indicates the length of the key that MySQL decided to use. The value of `key_len` enables you to determine how many parts of a multiple-part key MySQL actually uses. If the `key` column says **NULL**, the `key_len` column also says **NULL**.

  Due to the key storage format, the key length is one greater for a column that can be **NULL** than for a **NOT NULL** column.
EXPLAIN Output Format

- **ref (JSON name: ref)**

  The *ref* column shows which columns or constants are compared to the index named in the *key* column to select rows from the table.

  If the value is *func*, the value used is the result of some function. To see which function, use *SHOW WARNINGS* following *EXPLAIN* to see the extended *EXPLAIN* output. The function might actually be an operator such as an arithmetic operator.

- **rows (JSON name: rows)**

  The *rows* column indicates the number of rows MySQL believes it must examine to execute the query.

  For InnoDB tables, this number is an estimate, and may not always be exact.

- **filtered (JSON name: filtered)**

  The *filtered* column indicates an estimated percentage of table rows that are filtered by the table condition. The maximum value is 100, which means no filtering of rows occurred. Values decreasing from 100 indicate increasing amounts of filtering. *rows* shows the estimated number of rows examined and *rows × filtered* shows the number of rows that are joined with the following table. For example, if *rows* is 1000 and *filtered* is 50.00 (50%), the number of rows to be joined with the following table is 1000 × 50% = 500.

- **Extra (JSON name: none)**

  This column contains additional information about how MySQL resolves the query. For descriptions of the different values, see *EXPLAIN Extra Information*.

  There is no single JSON property corresponding to the *Extra* column; however, values that can occur in this column are exposed as JSON properties, or as the text of the *message* property.

**EXPLAIN Join Types**

The *type* column of *EXPLAIN* output describes how tables are joined. In JSON-formatted output, these are found as values of the *access_type* property. The following list describes the join types, ordered from the best type to the worst:

- **system**

  The table has only one row (= system table). This is a special case of the *const* join type.

- **const**

  The table has at most one matching row, which is read at the start of the query. Because there is only one row, values from the column in this row can be regarded as constants by the rest of the optimizer. *const* tables are very fast because they are read only once.

  *const* is used when you compare all parts of a PRIMARY KEY or UNIQUE index to constant values. In the following queries, *tbl_name* can be used as a *const* table:

  ```sql
  SELECT * FROM tbl_name WHERE primary_key=1;
  SELECT * FROM tbl_name WHERE primary_key_part1=1 AND primary_key_part2=2;
  ```

- **eq_ref**
One row is read from this table for each combination of rows from the previous tables. Other than the `system` and `const` types, this is the best possible join type. It is used when all parts of an index are used by the join and the index is a `PRIMARY KEY` or `UNIQUE NOT NULL` index.

`eq_ref` can be used for indexed columns that are compared using the `=` operator. The comparison value can be a constant or an expression that uses columns from tables that are read before this table. In the following examples, MySQL can use an `eq_ref` join to process `ref_table`:

```sql
SELECT * FROM ref_table, other_table
WHERE ref_table.key_column = other_table.column;
SELECT * FROM ref_table, other_table
WHERE ref_table.key_column_part1 = other_table.column
AND ref_table.key_column_part2 = 1;
```

- `ref`

All rows with matching index values are read from this table for each combination of rows from the previous tables. `ref` is used if the join uses only a leftmost prefix of the key or if the key is not a `PRIMARY KEY` or `UNIQUE` index (in other words, if the join cannot select a single row based on the key value). If the key that is used matches only a few rows, this is a good join type.

`ref` can be used for indexed columns that are compared using the `=` or `<>` operator. In the following examples, MySQL can use a `ref` join to process `ref_table`:

```sql
SELECT * FROM ref_table WHERE key_column = expr;
SELECT * FROM ref_table, other_table
WHERE ref_table.key_column = other_table.column;
SELECT * FROM ref_table, other_table
WHERE ref_table.key_column_part1 = other_table.column
AND ref_table.key_column_part2 = 1;
```

- `fulltext`

The join is performed using a `FULLTEXT` index.

- `ref_or_null`

This join type is like `ref`, but with the addition that MySQL does an extra search for rows that contain `NULL` values. This join type optimization is used most often in resolving subqueries. In the following examples, MySQL can use a `ref_or_null` join to process `ref_table`:

```sql
SELECT * FROM ref_table WHERE key_column = expr OR key_column IS NULL;
```

See Section 8.2.1.15, “IS NULL Optimization”.

- `index_merge`

This join type indicates that the Index Merge optimization is used. In this case, the `key` column in the output row contains a list of indexes used, and `key_len` contains a list of the longest key parts for the indexes used. For more information, see Section 8.2.1.3, “Index Merge Optimization”.

- `unique_subquery`

This type replaces `eq_ref` for some `IN` subqueries of the following form:

```sql
value IN (SELECT primary_key FROM single_table WHERE some_expr)
```
**unique_subquery** is just an index lookup function that replaces the subquery completely for better efficiency.

- **index_subquery**

  This join type is similar to **unique_subquery**. It replaces **IN** subqueries, but it works for nonunique indexes in subqueries of the following form:

  ```sql
  value IN (SELECT key_column FROM single_table WHERE some_expr)
  ```

- **range**

  Only rows that are in a given range are retrieved, using an index to select the rows. The **key** column in the output row indicates which index is used. The **key_len** contains the longest key part that was used. The **ref** column is **NULL** for this type.

  **range** can be used when a key column is compared to a constant using any of the **=, <>, >, >=, <, <=, IS NULL, <=>, BETWEEN, LIKE, or IN()** operators:

  ```sql
  SELECT * FROM tbl_name WHERE key_column = 10;
  
  SELECT * FROM tbl_name WHERE key_column BETWEEN 10 and 20;
  
  SELECT * FROM tbl_name WHERE key_column IN (10,20,30);
  
  SELECT * FROM tbl_name WHERE key_part1 = 10 AND key_part2 IN (10,20,30);
  ```

- **index**

  The **index** join type is the same as **ALL**, except that the index tree is scanned. This occurs two ways:

  - If the index is a covering index for the queries and can be used to satisfy all data required from the table, only the index tree is scanned. In this case, the **Extra** column says **Using index**. An index-only scan usually is faster than **ALL** because the size of the index usually is smaller than the table data.

  - A full table scan is performed using reads from the index to look up data rows in index order. **Uses index** does not appear in the **Extra** column.

  MySQL can use this join type when the query uses only columns that are part of a single index.

- **ALL**

  A full table scan is done for each combination of rows from the previous tables. This is normally not good if the table is the first table not marked **const**, and usually very bad in all other cases. Normally, you can avoid **ALL** by adding indexes that enable row retrieval from the table based on constant values or column values from earlier tables.

**EXPLAIN Extra Information**

The **Extra** column of **EXPLAIN** output contains additional information about how MySQL resolves the query. The following list explains the values that can appear in this column. Each item also indicates for JSON-formatted output which property displays the **Extra** value. For some of these, there is a specific property. The others display as the text of the **message** property.
If you want to make your queries as fast as possible, look out for Extra column values of Using filesort and Using temporary, or, in JSON-formatted EXPLAIN output, for using_filesort and using_temporary_table properties equal to true.

- **Backward index scan (JSON: backward_index_scan)**

  The optimizer is able to use a descending index on an InnoDB table. Shown together with Using index. For more information, see Section 8.3.13, “Descending Indexes”.

- **Child of 'table' pushed join@1 (JSON: message text)**

  This table is referenced as the child of table in a join that can be pushed down to the NDB kernel. Applies only in NDB Cluster, when pushed-down joins are enabled. See the description of the ndb_join_pushdown server system variable for more information and examples.

- **const row not found (JSON property: const_row_not_found)**

  For a query such as SELECT ... FROM tbl_name, the table was empty.

- **Deleting all rows (JSON property: message)**

  For DELETE, some storage engines (such as MyISAM) support a handler method that removes all table rows in a simple and fast way. This Extra value is displayed if the engine uses this optimization.

- **Distinct (JSON property: distinct)**

  MySQL is looking for distinct values, so it stops searching for more rows for the current row combination after it has found the first matching row.

- **FirstMatch(tbl_name) (JSON property: first_match)**

  The semijoin FirstMatch join shortcutting strategy is used for tbl_name.

- **Full scan on NULL key (JSON property: message)**

  This occurs for subquery optimization as a fallback strategy when the optimizer cannot use an index-lookup access method.

- **Impossible HAVING (JSON property: message)**

  The HAVING clause is always false and cannot select any rows.

- **Impossible WHERE (JSON property: message)**

  The WHERE clause is always false and cannot select any rows.

- **Impossible WHERE noticed after reading const tables (JSON property: message)**

  MySQL has read all const (and system) tables and notice that the WHERE clause is always false.

- **LooseScan(m..n) (JSON property: message)**

  The semijoin LooseScan strategy is used. m and n are key part numbers.

- **No matching min/max row (JSON property: message)**

  No row satisfies the condition for a query such as SELECT MIN(...) FROM ... WHERE condition.

- **no matching row in const table (JSON property: message)**
For a query with a join, there was an empty table or a table with no rows satisfying a unique index condition.

- **No matching rows after partition pruning** (JSON property: `message`)

  For `DELETE` or `UPDATE`, the optimizer found nothing to delete or update after partition pruning. It is similar in meaning to **Impossible WHERE** for `SELECT` statements.

- **No tables used** (JSON property: `message`)

  The query has no `FROM` clause, or has a `FROM DUAL` clause.

  For `INSERT` or `REPLACE` statements, `EXPLAIN` displays this value when there is no `SELECT` part. For example, it appears for `EXPLAIN INSERT INTO t VALUES(10)` because that is equivalent to `EXPLAIN INSERT INTO t SELECT 10 FROM DUAL`.

- **Not exists** (JSON property: `message`)

  MySQL was able to do a **LEFT JOIN** optimization on the query and does not examine more rows in this table for the previous row combination after it finds one row that matches the **LEFT JOIN** criteria. Here is an example of the type of query that can be optimized this way:

  ```sql
  SELECT * FROM t1 LEFT JOIN t2 ON t1.id=t2.id
  WHERE t2.id IS NULL;
  ```

  Assume that `t2.id` is defined as **NOT NULL**. In this case, MySQL scans `t1` and looks up the rows in `t2` using the values of `t1.id`. If MySQL finds a matching row in `t2`, it knows that `t2.id` can never be **NULL**, and does not scan through the rest of the rows in `t2` that have the same `id` value. In other words, for each row in `t1`, MySQL needs to do only a single lookup in `t2`, regardless of how many rows actually match in `t2`.

  This can also indicate that a **WHERE** condition of the form **NOT IN (subquery)** or **NOT EXISTS (subquery)** has been transformed internally into an antijoin. This removes the subquery and brings its tables into the plan for the topmost query, providing improved cost planning. By merging semijoins and antijoins, the optimizer can reorder tables in the execution plan more freely, in some cases resulting in a faster plan.

  You can see when an antijoin transformation is performed for a given query by checking the **Message** column from `SHOW WARNINGS` following execution of `EXPLAIN`, or in the output of `EXPLAIN FORMAT=TREE`.

  **Note**

  An antijoin is the complement of a semijoin `table_a JOIN table_b ON condition`. The antijoin returns all rows from `table_b` which matches `condition`.

- **Plan isn't ready yet** (JSON property: `none`)

  This value occurs with `EXPLAIN FOR CONNECTION` when the optimizer has not finished creating the execution plan for the statement executing in the named connection. If execution plan output comprises multiple lines, any or all of them could have this **Extra** value, depending on the progress of the optimizer in determining the full execution plan.
EXPLAIN Output Format

• **Range checked for each record (index map: N) (JSON property: message)**

MySQL found no good index to use, but found that some of indexes might be used after column values from preceding tables are known. For each row combination in the preceding tables, MySQL checks whether it is possible to use a range or index_merge access method to retrieve rows. This is not very fast, but is faster than performing a join with no index at all. The applicability criteria are as described in Section 8.2.1.2, “Range Optimization”, and Section 8.2.1.3, “Index Merge Optimization”, with the exception that all column values for the preceding table are known and considered to be constants.

Indexes are numbered beginning with 1, in the same order as shown by `SHOW INDEX` for the table. The index map value `N` is a bitmask value that indicates which indexes are candidates. For example, a value of `0x19` (binary 11001) means that indexes 1, 4, and 5 are considered.

• **Recursive (JSON property: recursive)**

This indicates that the row applies to the recursive SELECT part of a recursive common table expression. See Section 13.2.20, “WITH (Common Table Expressions)”.

• **Rematerialize (JSON property: rematerialize)**

Rematerialize `(X,...)` is displayed in the EXPLAIN row for table `T`, where `X` is any lateral derived table whose rematerialization is triggered when a new row of `T` is read. For example:

```sql
SELECT ...
FROM t,
     LATERAL (derived table that refers to t) AS dt ...
```

The content of the derived table is rematerialized to bring it up to date each time a new row of `t` is processed by the top query.

• **Scanned N databases (JSON property: message)**

This indicates how many directory scans the server performs when processing a query for INFORMATION_SCHEMA tables, as described in Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”. The value of `N` can be 0, 1, or all.

• **Select tables optimized away (JSON property: message)**

The optimizer determined 1) that at most one row should be returned, and 2) that to produce this row, a deterministic set of rows must be read. When the rows to be read can be read during the optimization phase (for example, by reading index rows), there is no need to read any tables during query execution.

The first condition is fulfilled when the query is implicitly grouped (contains an aggregate function but no GROUP BY clause). The second condition is fulfilled when one row lookup is performed per index used. The number of indexes read determines the number of rows to read.

Consider the following implicitly grouped query:

```sql
SELECT MIN(c1), MIN(c2) FROM t1;
```

Suppose that `MIN(c1)` can be retrieved by reading one index row and `MIN(c2)` can be retrieved by reading one row from a different index. That is, for each column `c1` and `c2`, there exists an index where
the column is the first column of the index. In this case, one row is returned, produced by reading two
deterministic rows.

This Extra value does not occur if the rows to read are not deterministic. Consider this query:

```
SELECT MIN(c2) FROM t1 WHERE c1 <= 10;
```

Suppose that \((c1, c2)\) is a covering index. Using this index, all rows with \(c1 \leq 10\) must be scanned
to find the minimum \(c2\) value. By contrast, consider this query:

```
SELECT MIN(c2) FROM t1 WHERE c1 = 10;
```

In this case, the first index row with \(c1 = 10\) contains the minimum \(c2\) value. Only one row must be
read to produce the returned row.

For storage engines that maintain an exact row count per table (such as MyISAM, but not InnoDB), this
Extra value can occur for COUNT(*) queries for which the WHERE clause is missing or always true
and there is no GROUP BY clause. (This is an instance of an implicitly grouped query where the storage
engine influences whether a deterministic number of rows can be read.)

- **Skip_open_table**, **Open_frm_only**, **Open_full_table** (JSON property: message)

These values indicate file-opening optimizations that apply to queries for INFORMATION_SCHEMA tables.

- **Skip_open_table**: Table files do not need to be opened. The information is already available from
  the data dictionary.

- **Open_frm_only**: Only the data dictionary need be read for table information.

- **Open_full_table**: Unoptimized information lookup. Table information must be read from the data
dictionary and by reading table files.

- **Start temporary, End temporary** (JSON property: message)

This indicates temporary table use for the semijoin Duplicate Weedout strategy.

- **unique row not found** (JSON property: message)

For a query such as `SELECT ... FROM tbl_name`, no rows satisfy the condition for a UNIQUE index
or PRIMARY KEY on the table.

- **Using filesort** (JSON property: using_filesort)

MySQL must do an extra pass to find out how to retrieve the rows in sorted order. The sort is done by
going through all rows according to the join type and storing the sort key and pointer to the row for all
rows that match the WHERE clause. The keys then are sorted and the rows are retrieved in sorted order.
See Section 8.2.1.16, “ORDER BY Optimization”.

1900
EXPLAIN Output Format

- **Using index (JSON property: using_index)**

  The column information is retrieved from the table using only information in the index tree without having to do an additional seek to read the actual row. This strategy can be used when the query uses only columns that are part of a single index.

  For InnoDB tables that have a user-defined clustered index, that index can be used even when Using index is absent from the Extra column. This is the case if type is index and key is PRIMARY.

  Information about any covering indexes used is shown for EXPLAIN FORMAT=TRADITIONAL and EXPLAIN FORMAT=JSON. It is also shown for EXPLAIN FORMAT=TREE.

- **Using index condition (JSON property: using_index_condition)**

  Tables are read by accessing index tuples and testing them first to determine whether to read full table rows. In this way, index information is used to defer (“push down”) reading full table rows unless it is necessary. See Section 8.2.1.6, “Index Condition Pushdown Optimization”.

- **Using index for group-by (JSON property: using_index_for_group_by)**

  Similar to the Using index table access method, Using index for group-by indicates that MySQL found an index that can be used to retrieve all columns of a GROUP BY or DISTINCT query without any extra disk access to the actual table. Additionally, the index is used in the most efficient way so that for each group, only a few index entries are read. For details, see Section 8.2.1.17, “GROUP BY Optimization”.

- **Using index for skip scan (JSON property: using_index_for_skip_scan)**

  Indicates that the Skip Scan access method is used. See Skip Scan Range Access Method.

- **Using join buffer (Block Nested Loop), Using join buffer (Batched Key Access), Using join buffer (hash join) (JSON property: using_join_buffer)**

  Tables from earlier joins are read in portions into the join buffer, and then their rows are used from the buffer to perform the join with the current table. (Block Nested Loop) indicates use of the Block Nested-Loop algorithm, (Batched Key Access) indicates use of the Batched Key Access algorithm, and (hash join) indicates use of a hash join. That is, the keys from the table on the preceding line of the EXPLAIN output are buffered, and the matching rows are fetched in batches from the table represented by the line in which Using join buffer appears.

  In JSON-formatted output, the value of using_join_buffer is always one of Block Nested Loop, Batched Key Access, or hash join.

  For more information about hash joins, see Section 8.2.1.4, “Hash Join Optimization”, and Block Nested-Loop Join Algorithm.

  See Batched Key Access Joins, for information about the Batched Key Access algorithm.

- **Using MRR (JSON property: message)**

  Tables are read using the Multi-Range Read optimization strategy. See Section 8.2.1.11, “Multi-Range Read Optimization”.

- **Using sort_union(...), Using union(...), Using intersect(...) (JSON property: message)**

  These indicate the particular algorithm showing how index scans are merged for the index_merge join type. See Section 8.2.1.3, “Index Merge Optimization”.
EXPLAIN Output Format

- **Using temporary (JSON property: using_temporary_table)**
  
  To resolve the query, MySQL needs to create a temporary table to hold the result. This typically happens if the query contains GROUP BY and ORDER BY clauses that list columns differently.

- **Using where (JSON property: attached_condition)**
  
  A WHERE clause is used to restrict which rows to match against the next table or send to the client. Unless you specifically intend to fetch or examine all rows from the table, you may have something wrong in your query if the Extra value is not Using where and the table join type is ALL or index.

  Using where has no direct counterpart in JSON-formatted output; the attached_condition property contains any WHERE condition used.

- **Using where with pushed condition (JSON property: message)**
  
  This item applies to NDB tables only. It means that NDB Cluster is using the Condition Pushdown optimization to improve the efficiency of a direct comparison between a nonindexed column and a constant. In such cases, the condition is “pushed down” to the cluster's data nodes and is evaluated on all data nodes simultaneously. This eliminates the need to send nonmatching rows over the network, and can speed up such queries by a factor of 5 to 10 times over cases where Condition Pushdown could be but is not used. For more information, see Section 8.2.1.5, “Engine Condition Pushdown Optimization”.

- **Zero limit (JSON property: message)**
  
  The query had a LIMIT 0 clause and cannot select any rows.

EXPLAIN Output Interpretation

You can get a good indication of how good a join is by taking the product of the values in the rows column of the EXPLAIN output. This should tell you roughly how many rows MySQL must examine to execute the query. If you restrict queries with the max_join_size system variable, this row product also is used to determine which multiple-table SELECT statements to execute and which to abort. See Section 5.1.1, “Configuring the Server”.

The following example shows how a multiple-table join can be optimized progressively based on the information provided by EXPLAIN.

Suppose that you have the SELECT statement shown here and that you plan to examine it using EXPLAIN:

```sql
EXPLAIN SELECT tt.TicketNumber, tt.TimeIn,
    tt.ProjectReference, tt.EstimatedShipDate,
    tt.ActualShipDate, tt.ClientID,
    tt.ServiceCodes, tt.RepetitiveID,
    tt.CurrentProcess, tt.CurrentDPPerson,
    tt.RecordVolume, tt.DPPrinted, et.COUNTRY,
    et_1.COUNTRY, do.CUSTNAME
FROM tt, et, et AS et_1, do
WHERE tt.SubmitTime IS NULL
    AND tt.ActualPC = et.EMPLOYID
    AND tt.AssignedPC = et_1.EMPLOYID
    AND tt.ClientID = do.CUSTNMBR;
```

For this example, make the following assumptions:

- The columns being compared have been declared as follows.

<table>
<thead>
<tr>
<th>Table</th>
<th>Column</th>
<th>Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>tt</td>
<td>ActualPC</td>
<td>CHAR(10)</td>
</tr>
</tbody>
</table>
The tables have the following indexes.

<table>
<thead>
<tr>
<th>Table</th>
<th>Index</th>
</tr>
</thead>
<tbody>
<tr>
<td>tt</td>
<td>ActualPC</td>
</tr>
<tr>
<td>tt</td>
<td>AssignedPC</td>
</tr>
<tr>
<td>tt</td>
<td>ClientID</td>
</tr>
<tr>
<td>et</td>
<td>EMPLOYID (primary key)</td>
</tr>
<tr>
<td>do</td>
<td>CUSTNMBR (primary key)</td>
</tr>
</tbody>
</table>

The `tt.ActualPC` values are not evenly distributed.

Initially, before any optimizations have been performed, the `EXPLAIN` statement produces the following information:

<table>
<thead>
<tr>
<th>table type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>
<th>rows</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>et</td>
<td>PRIMARY</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>74</td>
<td></td>
</tr>
<tr>
<td>do</td>
<td>PRIMARY</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>2135</td>
<td></td>
</tr>
<tr>
<td>et_1</td>
<td>PRIMARY</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>74</td>
<td></td>
</tr>
<tr>
<td>tt</td>
<td>PRIMARY</td>
<td>PRIMARY</td>
<td>PRIMARY</td>
<td>tt.ActualPC</td>
<td>3872</td>
<td>Using where</td>
</tr>
</tbody>
</table>

Because `type` is `ALL` for each table, this output indicates that MySQL is generating a Cartesian product of all the tables; that is, every combination of rows. This takes quite a long time, because the product of the number of rows in each table must be examined. For the case at hand, this product is $74 \times 2135 \times 74 \times 3872 = 45,268,558,720$ rows. If the tables were bigger, you can only imagine how long it would take.

One problem here is that MySQL can use indexes on columns more efficiently if they are declared as the same type and size. In this context, `VARCHAR` and `CHAR` are considered the same if they are declared as the same size. `tt.ActualPC` is declared as `CHAR(10)` and `et.EMPLOYID` is `CHAR(15)`, so there is a length mismatch.

To fix this disparity between column lengths, use `ALTER TABLE` to lengthen `ActualPC` from 10 characters to 15 characters:

```
mysql> ALTER TABLE tt MODIFY ActualPC VARCHAR(15);
```

Now `tt.ActualPC` and `et.EMPLOYID` are both `VARCHAR(15)`. Executing the `EXPLAIN` statement again produces this result:

<table>
<thead>
<tr>
<th>table type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>
<th>rows</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>tt</td>
<td>PRIMARY</td>
<td>PRIMARY</td>
<td>PRIMARY</td>
<td>tt.ActualPC</td>
<td>3872</td>
<td>Using where</td>
</tr>
<tr>
<td>do</td>
<td>PRIMARY</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>2135</td>
<td></td>
</tr>
<tr>
<td>et_1</td>
<td>PRIMARY</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>74</td>
<td></td>
</tr>
<tr>
<td>et</td>
<td>eq_ref</td>
<td>PRIMARY</td>
<td>15</td>
<td>tt.ActualPC</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>
This is not perfect, but is much better: The product of the `rows` values is less by a factor of 74. This version executes in a couple of seconds.

A second alteration can be made to eliminate the column length mismatches for the `tt.AssignedPC = et_1.EMPLOYID` and `tt.ClientID = do.CUSTNMBR` comparisons:

```
mysql> ALTER TABLE tt
    > MODIFY AssignedPC VARCHAR(15),
    > MODIFY ClientID VARCHAR(15);
```

After that modification, `EXPLAIN` produces the output shown here:

<table>
<thead>
<tr>
<th>table type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>
<th>rows</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>et</td>
<td>ALL</td>
<td>PRIMARY</td>
<td>NULL</td>
<td>NULL</td>
<td>74</td>
<td></td>
</tr>
<tr>
<td>tt</td>
<td>ref</td>
<td>AssignedPC, ClientID, ActualPC</td>
<td>15</td>
<td>et.EMPLOYID</td>
<td>52</td>
<td>Using where</td>
</tr>
<tr>
<td>et_1</td>
<td>eq_ref PRIMARY</td>
<td>PRIMARY</td>
<td>15</td>
<td>tt.AssignedPC</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>do</td>
<td>eq_ref PRIMARY</td>
<td>PRIMARY</td>
<td>15</td>
<td>tt.ClientID</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

At this point, the query is optimized almost as well as possible. The remaining problem is that, by default, MySQL assumes that values in the `tt.ActualPC` column are evenly distributed, and that is not the case for the `tt` table. Fortunately, it is easy to tell MySQL to analyze the key distribution:

```
mysql> ANALYZE TABLE tt;
```

With the additional index information, the join is perfect and `EXPLAIN` produces this result:

<table>
<thead>
<tr>
<th>table type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>
<th>rows</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>tt</td>
<td>ALL</td>
<td>AssignedPC, ClientID, ActualPC</td>
<td>NULL</td>
<td>NULL</td>
<td>3872</td>
<td>Using where</td>
</tr>
<tr>
<td>et</td>
<td>eq_ref PRIMARY</td>
<td>PRIMARY</td>
<td>15</td>
<td>tt.ActualPC</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>et_1</td>
<td>eq_ref PRIMARY</td>
<td>PRIMARY</td>
<td>15</td>
<td>tt.AssignedPC</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>do</td>
<td>eq_ref PRIMARY</td>
<td>PRIMARY</td>
<td>15</td>
<td>tt.ClientID</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

The `rows` column in the output from `EXPLAIN` is an educated guess from the MySQL join optimizer. Check whether the numbers are even close to the truth by comparing the `rows` product with the actual number of rows that the query returns. If the numbers are quite different, you might get better performance by using `STRAIGHT_JOIN` in your `SELECT` statement and trying to list the tables in a different order in the `FROM` clause. (However, `STRAIGHT_JOIN` may prevent indexes from being used because it disables semijoin transformations. See Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations.)

It is possible in some cases to execute statements that modify data when `EXPLAIN SELECT` is used with a subquery; for more information, see Section 13.2.15.8, “Derived Tables”.

### 8.8.3 Extended EXPLAIN Output Format

The `EXPLAIN` statement produces extra (“extended”) information that is not part of `EXPLAIN` output but can be viewed by issuing a `SHOW WARNINGS` statement following `EXPLAIN`. Extended information is available for `SELECT`, `DELETE`, `INSERT`, `REPLACE`, and `UPDATE` statements.

The `Message` value in `SHOW WARNINGS` output displays how the optimizer qualifies table and column names in the `SELECT` statement, what the `SELECT` looks like after the application of rewriting and optimization rules, and possibly other notes about the optimization process.

The extended information displayable with a `SHOW WARNINGS` statement following `EXPLAIN` is produced only for `SELECT` statements. `SHOW WARNINGS` displays an empty result for other explainable statements (`DELETE`, `INSERT`, `REPLACE`, and `UPDATE`).

Here is an example of extended `EXPLAIN` output:
mysql> EXPLAIN
SELECT t1.a, t1.a IN (SELECT t2.a FROM t2) FROM t1\G
*************************** 1. row ***************************
  id: 1
  select_type: PRIMARY
  table: t1
  type: index
  possible_keys: NULL
  key: PRIMARY
  key_len: 4
  ref: NULL
  rows: 4
  filtered: 100.00
  Extra: Using index
*************************** 2. row ***************************
  id: 2
  select_type: SUBQUERY
  table: t2
  type: index
  possible_keys: a
  key: a
  key_len: 5
  ref: NULL
  rows: 3
  filtered: 100.00
  Extra: Using index
2 rows in set, 1 warning (0.00 sec)
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
  Level: Note
  Code: 1003
  Message: /* select#1 */ select `test`.`t1`.`a` AS `a`,
  <in_optimizer>(`test`.`t1`.`a`,`test`.`t1`.`a` in
  ( <materialize> /* select#2 */ select `test`.`t2`.`a`
  from `test`.`t2` where 1 having 1 ),
  <primary_index_lookup>(`test`.`t1`.`a` in
  <temporary table> on <auto_key>
  where ((`test`.`t1`.`a` = `materialized-subquery`.`a`))) AS `t1.a
1 row in set (0.00 sec)

Because the statement displayed by SHOW WARNINGS may contain special markers to provide information about query rewriting or optimizer actions, the statement is not necessarily valid SQL and is not intended to be executed. The output may also include rows with Message values that provide additional non-SQL explanatory notes about actions taken by the optimizer.

The following list describes special markers that can appear in the extended output displayed by SHOW WARNINGS:

- `<auto_key>`
  An automatically generated key for a temporary table.

- `<cache>(expr)`
  The expression (such as a scalar subquery) is executed once and the resulting value is saved in memory for later use. For results consisting of multiple values, a temporary table may be created and <temporary table> is shown instead.

- `<exists>(query fragment)`
  The subquery predicate is converted to an EXISTS predicate and the subquery is transformed so that it can be used together with the EXISTS predicate.
8.8.4 Obtaining Execution Plan Information for a Named Connection

To obtain the execution plan for an explainable statement executing in a named connection, use this statement:

```
EXPLAIN [options] FOR CONNECTION connection_id;
```

`EXPLAIN FOR CONNECTION` returns the `EXPLAIN` information that is currently being used to execute a query in a given connection. Because of changes to data (and supporting statistics) it may produce a
different result from running \texttt{EXPLAIN} on the equivalent query text. This difference in behavior can be useful in diagnosing more transient performance problems. For example, if you are running a statement in one session that is taking a long time to complete, using \texttt{EXPLAIN FOR CONNECTION} in another session may yield useful information about the cause of the delay.

\texttt{connection_id} is the connection identifier, as obtained from the \texttt{INFORMATION_SCHEMA.PROCESSLIST} table or the \texttt{SHOW PROCESSLIST} statement. If you have the \texttt{PROCESS} privilege, you can specify the identifier for any connection. Otherwise, you can specify the identifier only for your own connections. In all cases, you must have sufficient privileges to explain the query on the specified connection.

If the named connection is not executing a statement, the result is empty. Otherwise, \texttt{EXPLAIN FOR CONNECTION} applies only if the statement being executed in the named connection is explainable. This includes \texttt{SELECT}, \texttt{DELETE}, \texttt{INSERT}, \texttt{REPLACE}, and \texttt{UPDATE}. (However, \texttt{EXPLAIN FOR CONNECTION} does not work for prepared statements, even prepared statements of those types.)

If the named connection is executing an explainable statement, the output is what you would obtain by using \texttt{EXPLAIN} on the statement itself.

If the named connection is executing a statement that is not explainable, an error occurs. For example, you cannot name the connection identifier for your current session because \texttt{EXPLAIN} is not explainable:

```
mysql> SELECT CONNECTION_ID();
+------------------+
| CONNECTION_ID()  |
+------------------+
| 373              |
+------------------+
1 row in set (0.00 sec)

mysql> EXPLAIN FOR CONNECTION 373;
ERROR 1889 (HY000): EXPLAIN FOR CONNECTION command is supported only for SELECT/UPDATE/INSERT/DELETE/REPLACE
```

The \texttt{Com_explain_other} status variable indicates the number of \texttt{EXPLAIN FOR CONNECTION} statements executed.

### 8.8.5 Estimating Query Performance

In most cases, you can estimate query performance by counting disk seeks. For small tables, you can usually find a row in one disk seek (because the index is probably cached). For bigger tables, you can estimate that, using B-tree indexes, you need this many seeks to find a row:

\[
\text{number of seeks} = \frac{\log(row\_count)}{\log(index\_block\_length / 3 * 2 / (index\_length + data\_pointer\_length))} + 1.
\]

In MySQL, an index block is usually 1,024 bytes and the data pointer is usually four bytes. For a 500,000-row table with a key value length of three bytes (the size of \texttt{MEDIUMINT}), the formula indicates

\[
\text{number of seeks} = \frac{\log(500,000)}{\log(1024/3*2/(3+4))} + 1 = 4
\]

This index would require storage of about 500,000 * 7 * 3/2 = 5.2MB (assuming a typical index buffer fill ratio of 2/3), so you probably have much of the index in memory and so need only one or two calls to read data to find the row.

For writes, however, you need four seek requests to find where to place a new index value and normally two seeks to update the index and write the row.

The preceding discussion does not mean that your application performance slowly degenerates by \(\log N\). As long as everything is cached by the OS or the MySQL server, things become only marginally slower as the table gets bigger. After the data gets too big to be cached, things start to go much slower until your applications are bound only by disk seeks (which increase by \(\log N\)). To avoid this, increase the key cache...
size as the data grows. For MyISAM tables, the key cache size is controlled by the `key_buffer_size`

system variable. See Section 5.1.1, "Configuring the Server".

## 8.9 Controlling the Query Optimizer

MySQL provides optimizer control through system variables that affect how query plans are evaluated,
switchable optimizations, optimizer and index hints, and the optimizer cost model.

The server maintains histogram statistics about column values in the `column_statistics` data
dictionary table (see Section 8.9.6, "Optimizer Statistics"). Like other data dictionary tables, this
table is not directly accessible by users. Instead, you can obtain histogram information by querying
`INFORMATION_SCHEMA.COLUMN_STATISTICS`, which is implemented as a view on the data dictionary
table. You can also perform histogram management using the `ANALYZE TABLE` statement.

### 8.9.1 Controlling Query Plan Evaluation

The task of the query optimizer is to find an optimal plan for executing an SQL query. Because the
difference in performance between “good” and “bad” plans can be orders of magnitude (that is, seconds
versus hours or even days), most query optimizers, including that of MySQL, perform a more or less
exhaustive search for an optimal plan among all possible query evaluation plans. For join queries, the
number of possible plans investigated by the MySQL optimizer grows exponentially with the number of
tables referenced in a query. For small numbers of tables (typically less than 7 to 10) this is not a problem.
However, when larger queries are submitted, the time spent in query optimization may easily become the
major bottleneck in the server's performance.

A more flexible method for query optimization enables the user to control how exhaustive the optimizer
is in its search for an optimal query evaluation plan. The general idea is that the fewer plans that are
investigated by the optimizer, the less time it spends in compiling a query. On the other hand, because the
optimizer skips some plans, it may miss finding an optimal plan.

The behavior of the optimizer with respect to the number of plans it evaluates can be controlled using two
system variables:

- The `optimizer_prune_level` variable tells the optimizer to skip certain plans based on estimates of
  the number of rows accessed for each table. Our experience shows that this kind of “educated guess”
rarely misses optimal plans, and may dramatically reduce query compilation times. That is why this
option is on (`optimizer_prune_level=1`) by default. However, if you believe that the optimizer
missed a better query plan, this option can be switched off (`optimizer_prune_level=0`) with the risk
that query compilation may take much longer. Note that, even with the use of this heuristic, the optimizer
still explores a roughly exponential number of plans.

- The `optimizer_search_depth` variable tells how far into the “future” of each incomplete plan
  the optimizer should look to evaluate whether it should be expanded further. Smaller values of
  `optimizer_search_depth` may result in orders of magnitude smaller query compilation times. For
  example, queries with 12, 13, or more tables may easily require hours and even days to compile if
  `optimizer_search_depth` is close to the number of tables in the query. At the same time, if compiled
  with `optimizer_search_depth` equal to 3 or 4, the optimizer may compile in less than a minute for
  the same query. If you are unsure of what a reasonable value is for `optimizer_search_depth`, this
  variable can be set to 0 to tell the optimizer to determine the value automatically.

### 8.9.2 Switchable Optimizations

The `optimizer_switch` system variable enables control over optimizer behavior. Its value is a set of
flags, each of which has a value of `on` or `off` to indicate whether the corresponding optimizer behavior
is enabled or disabled. This variable has global and session values and can be changed at runtime. The
global default can be set at server startup.
To see the current set of optimizer flags, select the variable value:

```sql
mysql> SELECT @@optimizer_switch
+-----------------------------------------------------------------------+
| @@optimizer_switch: index_merge=on,index_merge_union=on,               |
| index_merge_sort_union=on,index_merge_intersection=on,                |
| engine_condition_pushdown=on,index_condition_pushdown=on,            |
| mrr=on,mrr_cost_based=on,block_nested_loop=on,                       |
| batched_key_access=off,materialization=on,semijoin=on,               |
| loosescan=on,firstmatch=on,duplicateweedout=on,                      |
| subquery_materialization_cost_based=on,                              |
| use_index_extensions=on,condition_fanout_filter=on,                  |
| derived_merge=on,use_invisible_indexes=off,skip_scan=on,             |
| hash_join=on,subquery_to_derived=off,                                |
| prefer_ordering_index=on,hypergraph_optimizer=off,                   |
| derived_condition_pushdown=on,hash_set_operations=on                 |
+-----------------------------------------------------------------------+
1 row in set (0.00 sec)
```

To change the value of `optimizer_switch`, assign a value consisting of a comma-separated list of one or more commands:

```sql
SET [GLOBAL|SESSION] optimizer_switch='command[,command]...';
```

Each `command` value should have one of the forms shown in the following table.

<table>
<thead>
<tr>
<th>Command Syntax</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>default</code></td>
<td>Reset every optimization to its default value</td>
</tr>
<tr>
<td><code>opt_name=default</code></td>
<td>Set the named optimization to its default value</td>
</tr>
<tr>
<td><code>opt_name=off</code></td>
<td>Disable the named optimization</td>
</tr>
<tr>
<td><code>opt_name=on</code></td>
<td>Enable the named optimization</td>
</tr>
</tbody>
</table>

The order of the commands in the value does not matter, although the `default` command is executed first if present. Setting an `opt_name` flag to `default` sets it to whichever of `on` or `off` is its default value.Specifying any given `opt_name` more than once in the value is not permitted and causes an error. Any errors in the value cause the assignment to fail with an error, leaving the value of `optimizer_switch` unchanged.

The following list describes the permissible `opt_name` flag names, grouped by optimization strategy:

- **Batched Key Access Flags**
  - `batched_key_access` (default `off`)
    
    Controls use of BKA join algorithm.

    For `batched_key_access` to have any effect when set to `on`, the `mrr` flag must also be `on`. Currently, the cost estimation for MRR is too pessimistic. Hence, it is also necessary for `mrr_cost_based` to be `off` for BKA to be used.

    For more information, see Section 8.2.1.12, “Block Nested-Loop and Batched Key Access Joins”.

- **Block Nested-Loop Flags**
  - `block_nested_loop` (default `on`)
    
    Controls use of hash joins, as do the `BNL` and `NO_BNL` optimizer hints.

    For more information, see Section 8.2.1.12, “Block Nested-Loop and Batched Key Access Joins”.
Switchable Optimizations

- **Condition Filtering Flags**
  - `condition_fanout_filter` *(default on)*
    Controls use of condition filtering.
    For more information, see Section 8.2.1.13, “Condition Filtering”.

- **Derived Condition Pushdown Flags**
  - `derived_condition_pushdown` *(default on)*
    Controls derived condition pushdown.
    For more information, see Section 8.2.2.5, “Derived Condition Pushdown Optimization”.

- **Derived Table Merging Flags**
  - `derived_merge` *(default on)*
    Controls merging of derived tables and views into outer query block.
    The `derived_merge` flag controls whether the optimizer attempts to merge derived tables, view references, and common table expressions into the outer query block, assuming that no other rule prevents merging; for example, an `ALGORITHM` directive for a view takes precedence over the `derived_merge` setting. By default, the flag is `on` to enable merging.
    For more information, see Section 8.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”.

- **Engine Condition Pushdown Flags**
  - `engine_condition_pushdown` *(default on)*
    Controls engine condition pushdown.
    For more information, see Section 8.2.1.5, “Engine Condition Pushdown Optimization”.

- **Hash Join Flags**
  - `hash_join` *(default on)*
    Has no effect in MySQL 8.2. Use the `block_nested_loop` flag, instead.
    For more information, see Section 8.2.1.4, “Hash Join Optimization”.

- **Index Condition Pushdown Flags**
  - `index_condition_pushdown` *(default on)*
    Controls index condition pushdown.
    For more information, see Section 8.2.1.6, “Index Condition Pushdown Optimization”.

- **Index Extensions Flags**
  - `use_index_extensions` *(default on)*
    Controls use of index extensions.
Switchable Optimizations

For more information, see Section 8.3.10, “Use of Index Extensions”.

• Index Merge Flags
  • `index_merge` (default `on`)
    Controls all Index Merge optimizations.
  • `index_merge_intersection` (default `on`)
    Controls the Index Merge Intersection Access optimization.
  • `index_merge_sort_union` (default `on`)
    Controls the Index Merge Sort-Union Access optimization.
  • `index_merge_union` (default `on`)
    Controls the Index Merge Union Access optimization.

For more information, see Section 8.2.1.3, “Index Merge Optimization”.

• Index Visibility Flags
  • `use_invisible_indexes` (default `off`)
    Controls use of invisible indexes.

For more information, see Section 8.3.12, “Invisible Indexes”.

• Limit Optimization Flags
  • `prefer_ordering_index` (default `on`)
    Controls whether, in the case of a query having an `ORDER BY` or `GROUP BY` with a `LIMIT` clause, the optimizer tries to use an ordered index instead of an unordered index, a filesort, or some other optimization. This optimization is performed by default whenever the optimizer determines that using it would allow for faster execution of the query.

    Because the algorithm that makes this determination cannot handle every conceivable case (due in part to the assumption that the distribution of data is always more or less uniform), there are cases in which this optimization may not be desirable. This optimization can be disabled by setting the `prefer_ordering_index` flag to `off`.

    For more information and examples, see Section 8.2.1.19, “LIMIT Query Optimization”.

• Multi-Range Read Flags
  • `mrr` (default `on`)
    Controls the Multi-Range Read strategy.
  • `mrr_cost_based` (default `on`)
    Controls use of cost-based MRR if `mrr=on`.

For more information, see Section 8.2.1.11, “Multi-Range Read Optimization”.
Switchable Optimizations

- **Semijoin Flags**
  
  - `duplicateweedout` *(default on)*
    
    Controls the semijoin Duplicate Weedout strategy.
  
  - `firstmatch` *(default on)*
    
    Controls the semijoin FirstMatch strategy.
  
  - `loosescan` *(default on)*
    
    Controls the semijoin LooseScan strategy (not to be confused with Loose Index Scan for `GROUP BY`).
  
  - `semijoin` *(default on)*
    
    Controls all semijoin strategies.

    This also applies to the antijoin optimization.

    The `semijoin, firstmatch, loosescan,` and `duplicateweedout` flags enable control over semijoin strategies. The `semijoin` flag controls whether semijoins are used. If it is set to `on`, the `firstmatch` and `loosescan` flags enable finer control over the permitted semijoin strategies.

    If the `duplicateweedout` semijoin strategy is disabled, it is not used unless all other applicable strategies are also disabled.

    If `semijoin` and `materialization` are both `on`, semijoins also use materialization where applicable. These flags are `on` by default.

    For more information, see [Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations](#).

- **Set Operations Flags**

  - `hash_set_operations` *(default on)*

    Enables the hash table optimization for set operations involving `EXCEPT` and `INTERSECT`; enabled by default. Otherwise, temporary table based de-duplication is used, as in previous versions of MySQL.

    The amount of memory used for hashing by this optimization can be controlled using the `set_operations_buffer_size` system variable; increasing this generally results in faster execution times for statements using these operations.

    Added in MySQL 8.2.0.

- **Skip Scan Flags**

  - `skip_scan` *(default on)*

    Controls use of Skip Scan access method.

    For more information, see [Skip Scan Range Access Method](#).
Switchable Optimizations

• Subquery Materialization Flags
  • materialization (default on)
    Controls materialization (including semijoin materialization).
  • subquery_materialization_cost_based (default on)
    Use cost-based materialization choice.

The materialization flag controls whether subquery materialization is used. If semijoin and materialization are both on, semijoins also use materialization where applicable. These flags are on by default.

The subquery_materialization_cost_based flag enables control over the choice between subquery materialization and IN-to-EXISTS subquery transformation. If the flag is on (the default), the optimizer performs a cost-based choice between subquery materialization and IN-to-EXISTS subquery transformation if either method could be used. If the flag is off, the optimizer chooses subquery materialization over IN-to-EXISTS subquery transformation.

For more information, see Section 8.2.2, “Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions”.

• Subquery Transformation Flags
  • subquery_to_derived (default off)

The optimizer is able in many cases to transform a scalar subquery in a SELECT, WHERE, JOIN, or HAVING clause into a left outer joins on a derived table. (Depending on the nullability of the derived table, this can sometimes be simplified further to an inner join.) This can be done for a subquery which meets the following conditions:

• The subquery does not make use of any nondeterministic functions, such as RAND().
• The subquery is not an ANY or ALL subquery which can be rewritten to use MIN() or MAX().
• The parent query does not set a user variable, since rewriting it may affect the order of execution, which could lead to unexpected results if the variable is accessed more than once in the same query.
• The subquery should not be correlated, that is, it should not reference a column from a table in the outer query, or contain an aggregate that is evaluated in the outer query.

This optimization can also be applied to a table subquery which is the argument to IN, NOT IN, EXISTS, or NOT EXISTS, that does not contain a GROUP BY.

The default value for this flag is off, since, in most cases, enabling this optimization does not produce any noticeable improvement in performance (and in many cases can even make queries run more slowly), but you can enable the optimization by setting the subquery_to_derived flag to on. It is primarily intended for use in testing.

Example, using a scalar subquery:

d
mysql> CREATE TABLE t1(a INT);
mysql> CREATE TABLE t2(a INT);
Switchable Optimizations

mysql> INSERT INTO t1 VALUES ROW(1), ROW(2), ROW(3), ROW(4);

mysql> INSERT INTO t2 VALUES ROW(1), ROW(2);

mysql> SELECT * FROM t1
    -> WHERE t1.a > (SELECT COUNT(a) FROM t2);
+-----+
<table>
<thead>
<tr>
<th>a</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
</tr>
<tr>
<td>4</td>
</tr>
</tbody>
</table>
+-----+

mysql> SELECT @@optimizer_switch LIKE '%subquery_to_derived=off%';
+-----------------------------------------------------+
| @@optimizer_switch LIKE '%subquery_to_derived=off%' |
| 1                                                   |
+-----------------------------------------------------+

mysql> SELECT @@optimizer_switch LIKE '%subquery_to_derived=on%';
+----------------------------------------------------+
| @@optimizer_switch LIKE '%subquery_to_derived=on%' |

+----------------------------------------------------+

mysql> EXPLAIN SELECT * FROM t1 WHERE t1.a > (SELECT COUNT(a) FROM t2)
G
*************************** 1. row ***************************

*************************** 2. row ***************************
| id: 2 | select_type: SUBQUERY | table: t2 | partitions: NULL | type: ALL | possible_keys: NULL | key: NULL | key_len: NULL | ref: NULL | rows: 2 | filtered: 100.00 | Extra: NULL |

mysql> SET @@optimizer_switch='subquery_to_derived=on';

mysql> SELECT @@optimizer_switch LIKE '%subquery_to_derived=off%';
+-----------------------------------------------------+
| @@optimizer_switch LIKE '%subquery_to_derived=off%' |
| 0                                                   |
+-----------------------------------------------------+

mysql> SELECT @@optimizer_switch LIKE '%subquery_to_derived=on%';
+----------------------------------------------------+
| @@optimizer_switch LIKE '%subquery_to_derived=on%' |
| 1                                                  |
+----------------------------------------------------+

mysql> EXPLAIN SELECT * FROM t1 WHERE t1.a > (SELECT COUNT(a) FROM t2)
G
*************************** 1. row ***************************

1914
As can be seen from executing `SHOW WARNINGS` immediately following the second `EXPLAIN` statement, with the optimization enabled, the query `SELECT * FROM t1 WHERE t1.a > (SELECT COUNT(a) FROM t2)` is rewritten in a form similar to what is shown here:

```
SELECT t1.a FROM t1
JOIN ( SELECT COUNT(t2.a) AS c FROM t2 ) AS d
WHERE t1.a > d.c;
```

Example, using a query with `IN (subquery)`:

```
mysql> DROP TABLE IF EXISTS t1, t2;

mysql> CREATE TABLE t1 (a INT, b INT);
mysql> CREATE TABLE t2 (a INT, b INT);

mysql> INSERT INTO t1 VALUES ROW(1,10), ROW(2,20), ROW(3,30);
mysql> INSERT INTO t2 VALUES ROW(1,110), ROW(2,120), ROW(3,130);

mysql> SELECT * FROM t1
JOIN ( SELECT COUNT(t2.a) AS c FROM t2 ) AS d
WHERE t1.a > d.c;
```

```
+------+------+
| a    | b    |
+------+------+
|    2 |   20 |
```
Switchable Optimizations

| 3 | 30 |

Switchable Optimizations

Checking and simplifying the result of `SHOW WARNINGS` after executing `EXPLAIN` on this query shows that, when the `subquery_to_derived` flag enabled, `SELECT * FROM t1 WHERE t1.b < 0 OR t1.a IN (SELECT t2.a + 1 FROM t2)` is rewritten in a form similar to what is shown here:

```
SELECT a, b FROM t1
LEFT JOIN (SELECT DISTINCT a + 1 AS e FROM t2) d
ON t1.a = d.e
WHERE   t1.b < 0
OR       d.e IS NOT NULL;
```

Example, using a query with `EXISTS (subquery)` and the same tables and data as in the previous example:

```
mysql> SELECT * FROM t1
    -> WHERE   t1.b < 0
    -> OR
    -> EXISTS(SELECT * FROM t2 WHERE t2.a = t1.a + 1);  
+-----+-----+
| a   | b   |
+-----+-----+
| 1   | 10  |
| 2   | 20  |
```

```
Switchable Optimizations

```sql
SHOW WARNINGS after running EXPLAIN on the query
SELECT * FROM t1
WHERE t1.b < 0 OR EXISTS(SELECT * FROM t2 WHERE t2.a = t1.a + 1)
when subquery_to_derived has been enabled, and simplify the second row of the result, we see that it
has been rewritten in a form which resembles this:

SELECT a, b FROM t1
LEFT JOIN (SELECT DISTINCT 1 AS e1, t2.a AS e2 FROM t2) d
ON t1.a + 1 = d.e2
WHERE t1.b < 0
OR
```
Optimizer Hints

For more information, see Section 8.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”, as well as Section 8.2.1.19, “LIMIT Query Optimization”, and Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations.

When you assign a value to optimizer_switch, flags that are not mentioned keep their current values. This makes it possible to enable or disable specific optimizer behaviors in a single statement without affecting other behaviors. The statement does not depend on what other optimizer flags exist and what their values are. Suppose that all Index Merge optimizations are enabled:

```
mysql> SELECT @@optimizer_switch\G
*************************** 1. row ***************************
@@optimizer_switch: index_merge=on,index_merge_union=on,
index_merge_sort_union=on,index_merge_intersection=on,
engine_condition_pushdown=on,index_condition_pushdown=on,
mrr=on,mrr_cost_based=on,block_nested_loop=on,
batched_key_access=off,materialization=on,semijoin=on,
loosescan=on,firstmatch=on,
subquery_materialization_cost_based=on,
use_index_extensions=on,condition_fanout_filter=on,
derived_merge=on,use_invisible_indexes=off,skip_scan=on,
hash_join=on,subquery_to_derived=off,
prefer_ordering_index=on
```

If the server is using the Index Merge Union or Index Merge Sort-Union access methods for certain queries and you want to check whether the optimizer can perform better without them, set the variable value like this:

```
mysql> SET optimizer_switch='index_merge_union=off,index_merge_sort_union=off';
```

```
mysql> SELECT @@optimizer_switch\G
*************************** 1. row ***************************
@@optimizer_switch: index_merge=on,index_merge_union=off,
index_merge_sort_union=off,index_merge_intersection=on,
engine_condition_pushdown=on,index_condition_pushdown=on,
mrr=on,mrr_cost_based=on,block_nested_loop=on,
batched_key_access=off,materialization=on,semijoin=on,
loosescan=on,firstmatch=on,
subquery_materialization_cost_based=on,
use_index_extensions=on,condition_fanout_filter=on,
derived_merge=on,use_invisible_indexes=off,skip_scan=on,
hash_join=on,subquery_to_derived=off,
prefer_ordering_index=on
```

8.9.3 Optimizer Hints

One means of control over optimizer strategies is to set the optimizer_switch system variable (see Section 8.9.2, “Switchable Optimizations”). Changes to this variable affect execution of all subsequent queries; to affect one query differently from another, it is necessary to change optimizer_switch before each one.

Another way to control the optimizer is by using optimizer hints, which can be specified within individual statements. Because optimizer hints apply on a per-statement basis, they provide finer control over statement execution plans than can be achieved using optimizer_switch. For example, you can enable an optimization for one table in a statement and disable the optimization for a different table. Hints within a statement take precedence over optimizer_switch flags.

Examples:

```
SELECT /*+ NO_RANGE_OPTIMIZATION(t3 PRIMARY, f2_idx) */ f1
```
Optimizer hints, described here, differ from index hints, described in Section 8.9.4, “Index Hints”. Optimizer and index hints may be used separately or together.

- Optimizer Hint Overview
- Optimizer Hint Syntax
- Join-Order Optimizer Hints

- Variable-Setting Hint Syntax
- Resource Group Hint Syntax
- Optimizer Hints for Naming Query Blocks

**Optimizer Hint Overview**

Optimizer hints apply at different scope levels:

- Global: The hint affects the entire statement
- Query block: The hint affects a particular query block within a statement
- Table-level: The hint affects a particular table within a query block
- Index-level: The hint affects a particular index within a table

The following table summarizes the available optimizer hints, the optimizer strategies they affect, and the scope or scopes at which they apply. More details are given later.

**Table 8.2 Optimizer Hints Available**

<table>
<thead>
<tr>
<th>Hint Name</th>
<th>Description</th>
<th>Applicable Scopes</th>
</tr>
</thead>
<tbody>
<tr>
<td>BKA, NO_BKA</td>
<td>Affects Batched Key Access join processing</td>
<td>Query block, table</td>

<tr>
<td>BNL, NO_BNL</td>
<td>Affects hash join optimization</td>
<td>Query block, table</td>
</tr>
<tr>
<td>DERIVED_CONDITION_PUSHDOWN</td>
<td>Use or ignore the derived condition pushdown optimization</td>
<td>Query block, table</td>
</tr>
<tr>
<td>NO_DERIVED_CONDITION_PUSHDOWN</td>
<td>Use or ignore the specified index or indexes for index scans in GROUP BY operations</td>
<td>Index</td>
</tr>
<tr>
<td>GROUP_INDEX, NO_GROUP_INDEX</td>
<td>Use or ignore the specified index or indexes for index scans in GROUP BY operations</td>
<td>Index</td>
</tr>
</tbody>
</table>

```
FROM t3 WHERE f1 > 30 AND f1 < 33;
SELECT /*+ BKA(t1) NO_BKA(t2) */ * FROM t1 INNER JOIN t2 WHERE ...;
SELECT /*+ NO_ICP(t1, t2) */ * FROM t1 INNER JOIN t2 WHERE ...;
SELECT /*+ SEMIJOIN(FIRSTMATCH, LOOSECAN) */ * FROM t1 ...;
EXPLAIN SELECT /*+ NO_ICP(t1) */ * FROM t1 WHERE ...;
SELECT /*+ MERGE(dt) */ * FROM (SELECT * FROM t1) AS dt;
INSERT /*+ SET_VAR(foreign_key_checks=OFF) */ INTO t2 VALUES(2);
```
<table>
<thead>
<tr>
<th>Hint Name</th>
<th>Description</th>
<th>Applicable Scopes</th>
</tr>
</thead>
<tbody>
<tr>
<td>HASH_JOIN, NO_HASH_JOIN</td>
<td>Affects Hash Join optimization (No effect in MySQL 8.2)</td>
<td>Query block, table</td>
</tr>
<tr>
<td>INDEX, NO_INDEX</td>
<td>Acts as the combination of JOIN_INDEX, GROUP_INDEX, and ORDER_INDEX, or as the combination of NO_JOIN_INDEX, NO_GROUP_INDEX, and NO_ORDER_INDEX</td>
<td>Index</td>
</tr>
<tr>
<td>INDEX_MERGE, NO_INDEX_MERGE</td>
<td>Affects Index Merge optimization</td>
<td>Table, index</td>
</tr>
<tr>
<td>JOIN_FIXED_ORDER</td>
<td>Use table order specified in FROM clause for join order</td>
<td>Query block</td>
</tr>
<tr>
<td>JOIN_INDEX, NO_JOIN_INDEX</td>
<td>Use or ignore the specified index or indexes for any access method</td>
<td>Index</td>
</tr>
<tr>
<td>JOIN_ORDER</td>
<td>Use table order specified in hint for join order</td>
<td>Query block</td>
</tr>
<tr>
<td>JOIN_PREFIX</td>
<td>Use table order specified in hint for first tables of join order</td>
<td>Query block</td>
</tr>
<tr>
<td>JOIN_SUFFIX</td>
<td>Use table order specified in hint for last tables of join order</td>
<td>Query block</td>
</tr>
<tr>
<td>MAX_EXECUTION_TIME</td>
<td>Limits statement execution time</td>
<td>Global</td>
</tr>
<tr>
<td>MERGE, NO_MERGE</td>
<td>Affects derived table/view merging into outer query block</td>
<td>Table</td>
</tr>
<tr>
<td>MRR, NO_MRR</td>
<td>Affects Multi-Range Read optimization</td>
<td>Table, index</td>
</tr>
<tr>
<td>NO_ICP</td>
<td>Affects Index Condition Pushdown optimization</td>
<td>Table, index</td>
</tr>
<tr>
<td>NO_RANGE_OPTIMIZATION</td>
<td>Affects range optimization</td>
<td>Table, index</td>
</tr>
<tr>
<td>ORDER_INDEX, NO_ORDER_INDEX</td>
<td>Use or ignore the specified index or indexes for sorting rows</td>
<td>Index</td>
</tr>
<tr>
<td>QB_NAME</td>
<td>Assigns name to query block</td>
<td>Query block</td>
</tr>
<tr>
<td>RESOURCE_GROUP</td>
<td>Set resource group during statement execution</td>
<td>Global</td>
</tr>
<tr>
<td>SEMIJOIN, NO_SEMIJOIN</td>
<td>Affects semijoin and antijoin strategies</td>
<td>Query block</td>
</tr>
<tr>
<td>SKIP_SCAN, NO_SKIP_SCAN</td>
<td>Affects Skip Scan optimization</td>
<td>Table, index</td>
</tr>
<tr>
<td>SET_VAR</td>
<td>Set variable during statement execution</td>
<td>Global</td>
</tr>
<tr>
<td>SUBQUERY</td>
<td>Affects materialization, IN-to-EXISTS subquery strategies</td>
<td>Query block</td>
</tr>
</tbody>
</table>

Disabling an optimization prevents the optimizer from using it. Enabling an optimization means the optimizer is free to use the strategy if it applies to statement execution, not that the optimizer necessarily uses it.
Optimizer Hints

Optimizer Hint Syntax

MySQL supports comments in SQL statements as described in Section 9.7, “Comments”. Optimizer hints must be specified within /*+ ... */ comments. That is, optimizer hints use a variant of /* ... */ C-style comment syntax, with a + character following the /* comment opening sequence. Examples:

```sql
/*+ BKA(t1) */
/*+ BNL(t1, t2) */
/*+ NO_RANGE_OPTIMIZATION(t4 PRIMARY) */
/*+ QB_NAME(qb2) */
```

Whitespace is permitted after the + character.

The parser recognizes optimizer hint comments after the initial keyword of SELECT, UPDATE, INSERT, REPLACE, and DELETE statements. Hints are permitted in these contexts:

- At the beginning of query and data change statements:

  ```sql
  SELECT /*+ ... */ ...
  INSERT /*+ ... */ ...
  REPLACE /*+ ... */ ...
  UPDATE /*+ ... */ ...
  DELETE /*+ ... */ ...
  ```

- At the beginning of query blocks:

  ```sql
  (SELECT /*+ ... */ ...)
  (SELECT ... ) UNION (SELECT /*+ ... */ ...)
  (SELECT /*+ ... */ ... ) UNION (SELECT /*+ ... */ ...)
  UPDATE ... WHERE x IN (SELECT /*+ ... */ ...)
  INSERT ... SELECT /*+ ... */ ...
  ```

- In hintable statements prefaced by EXPLAIN. For example:

  ```sql
  EXPLAIN SELECT /*+ ... */ ...
  EXPLAIN UPDATE ... WHERE x IN (SELECT /*+ ... */ ...)
  ```

The implication is that you can use EXPLAIN to see how optimizer hints affect execution plans. Use SHOW WARNINGS immediately after EXPLAIN to see how hints are used. The extended EXPLAIN output displayed by a following SHOW WARNINGS indicates which hints were used. Ignored hints are not displayed.

A hint comment may contain multiple hints, but a query block cannot contain multiple hint comments. This is valid:

```sql
SELECT /*+ BNL(t1) BKA(t2) */ ...
```

But this is invalid:

```sql
SELECT /*+ BNL(t1) */ /* BKA(t2) */ ...
```

When a hint comment contains multiple hints, the possibility of duplicates and conflicts exists. The following general guidelines apply. For specific hint types, additional rules may apply, as indicated in the hint descriptions.

- Duplicate hints: For a hint such as /*+ MRR(idx1) MRR(idx1) *//, MySQL uses the first hint and issues a warning about the duplicate hint.

- Conflicting hints: For a hint such as /*+ MRR(idx1) NO_MRR(idx1) *//, MySQL uses the first hint and issues a warning about the second conflicting hint.
Optimizer Hints

Query block names are identifiers and follow the usual rules about what names are valid and how to quote them (see Section 9.2, “Schema Object Names”).

Hint names, query block names, and strategy names are not case-sensitive. References to table and index names follow the usual identifier case-sensitivity rules (see Section 9.2.3, “Identifier Case Sensitivity”).

## Join-Order Optimizer Hints

Join-order hints affect the order in which the optimizer joins tables.

### Syntax of the JOIN_FIXED_ORDER hint:

```
hint_name[@query_block_name]
```

### Syntax of other join-order hints:

```
hint_name[@query_block_name] tbl_name [, tbl_name] ...
```

```
hint_name(tbl_name[@query_block_name] [, tbl_name[@query_block_name]] ...) ...
```

The syntax refers to these terms:

- **hint_name**: These hint names are permitted:

  - **JOIN_FIXED_ORDER**: Force the optimizer to join tables using the order in which they appear in the FROM clause. This is the same as specifying SELECT STRAIGHT_JOIN.

  - **JOIN_ORDER**: Instruct the optimizer to join tables using the specified table order. The hint applies to the named tables. The optimizer may place tables that are not named anywhere in the join order, including between specified tables.

  - **JOIN_PREFIX**: Instruct the optimizer to join tables using the specified table order for the first tables of the join execution plan. The hint applies to the named tables. The optimizer places all other tables after the named tables.

  - **JOIN_SUFFIX**: Instruct the optimizer to join tables using the specified table order for the last tables of the join execution plan. The hint applies to the named tables. The optimizer places all other tables before the named tables.

  - **tbl_name**: The name of a table used in the statement. A hint that names tables applies to all tables that it names. The JOIN_FIXED_ORDER hint names no tables and applies to all tables in the FROM clause of the query block in which it occurs.

  If a table has an alias, hints must refer to the alias, not the table name.

  Table names in hints cannot be qualified with schema names.

  - **query_block_name**: The query block to which the hint applies. If the hint includes no leading @query_block_name, the hint applies to the query block in which it occurs. For `tbl_name@query_block_name` syntax, the hint applies to the named table in the named query block. To assign a name to a query block, see Optimizer Hints for Naming Query Blocks.

### Example:

```
SELECT /*+ JOIN_PREFIX(t2, t5@subq2, t4@subq1)
    JOIN_ORDER(t4@subq1, t3)
    JOIN_SUFFIX(t1) */
COUNT(*) FROM t1 JOIN t2 JOIN t3
```
Hints control the behavior of semijoin tables that are merged to the outer query block. If subqueries subq1 and subq2 are converted to semijoins, tables t4@subq1 and t5@subq2 are merged to the outer query block. In this case, the hint specified in the outer query block controls the behavior of t4@subq1, t5@subq2 tables.

The optimizer resolves join-order hints according to these principles:

- **Multiple hint instances**
  
  Only one JOIN_PREFIX and JOIN_SUFFIX hint of each type are applied. Any later hints of the same type are ignored with a warning. JOIN_ORDER can be specified several times.

  **Examples:**

  ```
  /*+ JOIN_PREFIX(t1) JOIN_PREFIX(t2) */
  ```

  The second JOIN_PREFIX hint is ignored with a warning.

  ```
  /*+ JOIN_PREFIX(t1) JOIN_SUFFIX(t2) */
  ```

  Both hints are applicable. No warning occurs.

  ```
  /*+ JOIN_ORDER(t1, t2) JOIN_ORDER(t2, t3) */
  ```

  Both hints are applicable. No warning occurs.

- **Conflicting hints**

  In some cases hints can conflict, such as when JOIN_ORDER and JOIN_PREFIX have table orders that are impossible to apply at the same time:

  ```
  SELECT /*+ JOIN_ORDER(t1, t2) JOIN_PREFIX(t2, t1) */ ... FROM t1, t2;
  ```

  In this case, the first specified hint is applied and subsequent conflicting hints are ignored with no warning. A valid hint that is impossible to apply is silently ignored with no warning.

- **Ignored hints**

  A hint is ignored if a table specified in the hint has a circular dependency.

  **Example:**

  ```
  /*+ JOIN_ORDER(t1, t2) JOIN_PREFIX(t2, t1) */
  ```

  The JOIN_ORDER hint sets table t2 dependent on t1. The JOIN_PREFIX hint is ignored because table t1 cannot be dependent on t2. Ignored hints are not displayed in extended EXPLAIN output.

- **Interaction with const tables**

  The MySQL optimizer places const tables first in the join order, and the position of a const table cannot be affected by hints. References to const tables in join-order hints are ignored, although the hint is still applicable. For example, these are equivalent:

  ```
  JOIN_ORDER(t1, const_tbl, t2)
  JOIN_ORDER(t1, t2)
  ```

  Accepted hints shown in extended EXPLAIN output include const tables as they were specified.
Optimizer Hints

- Interaction with types of join operations

MySQL supports several types of joins: `LEFT, RIGHT, INNER, CROSS, STRAIGHT_JOIN`. A hint that conflicts with the specified type of join is ignored with no warning.

Example:

```sql
SELECT /*+ JOIN_PREFIX(t1, t2) */ FROM t2 LEFT JOIN t1;
```

Here a conflict occurs between the requested join order in the hint and the order required by the `LEFT JOIN`. The hint is ignored with no warning.

**Table-Level Optimizer Hints**

Table-level hints affect:

- Use of the Block Nested-Loop (BNL) and Batched Key Access (BKA) join-processing algorithms (see Section 8.2.1.12, “Block Nested-Loop and Batched Key Access Joins”).

- Whether derived tables, view references, or common table expressions should be merged into the outer query block, or materialized using an internal temporary table.

- Use of the derived table condition pushdown optimization. See Section 8.2.2.5, “Derived Condition Pushdown Optimization”.

These hint types apply to specific tables, or all tables in a query block.

Syntax of table-level hints:

```sql
hint_name([@query_block_name] [tbl_name [, tbl_name] ...])

hint_name([tbl_name@query_block_name [, tbl_name@query_block_name] ...])
```

The syntax refers to these terms:

- `hint_name`: These hint names are permitted:
  - `BKA, NO_BKA`: Enable or disable batched key access for the specified tables.
  - `BNL, NO_BNL`: Enable and disable the hash join optimization.
  - `DERIVED_CONDITION_PUSHDOWN, NO_DERIVED_CONDITION_PUSHDOWN`: Enable or disable use of derived table condition pushdown for the specified tables. For more information, see Section 8.2.2.5, “Derived Condition Pushdown Optimization”.
  - `HASH_JOIN, NO_HASH_JOIN`: These hints have no effect in MySQL 8.2; use `BNL` or `NO_BNL` instead.
  - `MERGE, NO_MERGE`: Enable merging for the specified tables, view references or common table expressions; or disable merging and use materialization instead.

**Note**

To use a block nested loop or batched key access hint to enable join buffering for any inner table of an outer join, join buffering must be enabled for all inner tables of the outer join.

- `tbl_name`: The name of a table used in the statement. The hint applies to all tables that it names. If the hint names no tables, it applies to all tables of the query block in which it occurs.

If a table has an alias, hints must refer to the alias, not the table name.
Table names in hints cannot be qualified with schema names.

- **query_block_name**: The query block to which the hint applies. If the hint includes no leading @query_block_name, the hint applies to the query block in which it occurs. For tbl_name@query_block_name syntax, the hint applies to the named table in the named query block. To assign a name to a query block, see Optimizer Hints for Naming Query Blocks.

Examples:

```
SELECT /*+ NO_BKA(t1, t2) */ t1.* FROM t1 INNER JOIN t2 INNER JOIN t3;
SELECT /*+ NO_BNL() BKA(t1) */ t1.* FROM t1 INNER JOIN t2 INNER JOIN t3;
SELECT /*+ NO_MERGE(dt) */ * FROM (SELECT * FROM t1) AS dt;
```

A table-level hint applies to tables that receive records from previous tables, not sender tables. Consider this statement:

```
SELECT /*+ BNL(t2) */ FROM t1, t2;
```

If the optimizer chooses to process t1 first, it applies a Block Nested-Loop join to t2 by buffering the rows from t1 before starting to read from t2. If the optimizer instead chooses to process t2 first, the hint has no effect because t2 is a sender table.

For the **MERGE** and **NO_MERGE** hints, these precedence rules apply:

- A hint takes precedence over any optimizer heuristic that is not a technical constraint. (If providing a hint as a suggestion has no effect, the optimizer has a reason for ignoring it.)
- A hint takes precedence over the derived_merge flag of the optimizer_switch system variable.
- For view references, an ALGORITHM=(MERGE|TEMPTABLE) clause in the view definition takes precedence over a hint specified in the query referencing the view.

### Index-Level Optimizer Hints

Index-level hints affect which index-processing strategies the optimizer uses for particular tables or indexes. These hint types affect use of Index Condition Pushdown (ICP), Multi-Range Read (MRR), Index Merge, and range optimizations (see Section 8.2.1, “Optimizing SELECT Statements”).

Syntax of index-level hints:

```
hint_name([@query_block_name] tbl_name [index_name [, index_name] ...])
hint_name(tbl_name@query_block_name [index_name [, index_name] ...])
```

The syntax refers to these terms:

- **hint_name**: These hint names are permitted:
  - **GROUP_INDEX, NO_GROUP_INDEX**: Enable or disable the specified index or indexes for index scans for **GROUP BY** operations. Equivalent to the index hints FORCE INDEX FOR GROUP BY, IGNORE INDEX FOR GROUP BY.
  - **INDEX, NO_INDEX**: Acts as the combination of JOIN_INDEX, GROUP_INDEX, and ORDER_INDEX, forcing the server to use the specified index or indexes for any and all scopes, or as the combination of NO_JOIN_INDEX, NO_GROUP_INDEX, and NO_ORDER_INDEX, which causes the server to ignore the specified index or indexes for any and all scopes. Equivalent to FORCE INDEX, IGNORE INDEX.
  - **INDEX_MERGE, NO_INDEX_MERGE**: Enable or disable the Index Merge access method for the specified table or indexes. For information about this access method, see Section 8.2.1.3, “Index Merge Optimization”. These hints apply to all three Index Merge algorithms.
Optimizer Hints

The `INDEX_MERGE` hint forces the optimizer to use Index Merge for the specified table using the specified set of indexes. If no index is specified, the optimizer considers all possible index combinations and selects the least expensive one. The hint may be ignored if the index combination is inapplicable to the given statement.

The `NO_INDEX_MERGE` hint disables Index Merge combinations that involve any of the specified indexes. If the hint specifies no indexes, Index Merge is not permitted for the table.

- `JOIN_INDEX, NO_JOIN_INDEX`: Forces MySQL to use or ignore the specified index or indexes for any access method, such as `ref`, `range`, `index_merge`, and so on. Equivalent to `FORCE INDEX FOR JOIN, IGNORE INDEX FOR JOIN`.

- `MRR, NO_MRR`: Enable or disable MRR for the specified table or indexes. MRR hints apply only to InnoDB and MyISAM tables. For information about this access method, see Section 8.2.1.11, “Multi-Range Read Optimization”.

- `NO_ICP`: Disable ICP for the specified table or indexes. By default, ICP is a candidate optimization strategy, so there is no hint for enabling it. For information about this access method, see Section 8.2.1.6, “Index Condition Pushdown Optimization”.

- `NO_RANGE_OPTIMIZATION`: Disable index range access for the specified table or indexes. This hint also disables Index Merge and Loose Index Scan for the table or indexes. By default, range access is a candidate optimization strategy, so there is no hint for enabling it.

This hint may be useful when the number of ranges may be high and range optimization would require many resources.

- `ORDER_INDEX, NO_ORDER_INDEX`: Cause MySQL to use or to ignore the specified index or indexes for sorting rows. Equivalent to `FORCE INDEX FOR ORDER BY, IGNORE INDEX FOR ORDER BY`.

- `SKIP_SCAN, NO_SKIP_SCAN`: Enable or disable the Skip Scan access method for the specified table or indexes. For information about this access method, see Skip Scan Range Access Method.

The `SKIP_SCAN` hint forces the optimizer to use Skip Scan for the specified table using the specified set of indexes. If no index is specified, the optimizer considers all possible indexes and selects the least expensive one. The hint may be ignored if the index is inapplicable to the given statement.

The `NO_SKIP_SCAN` hint disables Skip Scan for the specified indexes. If the hint specifies no indexes, Skip Scan is not permitted for the table.

- `tbl_name`: The table to which the hint applies.

- `index_name`: The name of an index in the named table. The hint applies to all indexes that it names. If the hint names no indexes, it applies to all indexes in the table.

  To refer to a primary key, use the name `PRIMARY`. To see the index names for a table, use `SHOW INDEX`.

- `query_block_name`: The query block to which the hint applies. If the hint includes no leading `@query_block_name`, the hint applies to the query block in which it occurs. For `tbl_name@query_block_name` syntax, the hint applies to the named table in the named query block.

  To assign a name to a query block, see Optimizer Hints for Naming Query Blocks.

Examples:

```sql
SELECT /*+ INDEX_MERGE(t1 f3, PRIMARY) */ f2 FROM t1
WHERE f1 = 'o' AND f2 = f3 AND f3 <= 4;
```
The following examples use the Index Merge hints, but other index-level hints follow the same principles regarding hint ignoring and precedence of optimizer hints in relation to the optimizer_switch system variable or index hints.

Assume that table `t1` has columns `a`, `b`, `c`, and `d`; and that indexes named `i_a`, `i_b`, and `i_c` exist on `a`, `b`, and `c`, respectively:

```sql
SELECT /*+ INDEX_MERGE(t1 i_a, i_b, i_c)*/ * FROM t1
WHERE a = 1 AND b = 2 AND c = 3 AND d = 4;
```

Index Merge is used for `(i_a, i_b, i_c)` in this case.

```sql
SELECT /*+ INDEX_MERGE(t1 i_a, i_b, i_c)*/ * FROM t1
WHERE b = 1 AND c = 2 AND d = 3;
```

Index Merge is used for `(i_b, i_c)` in this case.

```sql
/*+ INDEX_MERGE(t1 i_a, i_b) NO_INDEX_MERGE(t1 i_b) */
```

`NO_INDEX_MERGE` is ignored because there is a preceding hint for the same table.

```sql
/*+ NO_INDEX_MERGE(t1 i_a, i_b) INDEX_MERGE(t1 i_b) */
```

`INDEX_MERGE` is ignored because there is a preceding hint for the same table.

For the `INDEX_MERGE` and `NO_INDEX_MERGE` optimizer hints, these precedence rules apply:

- If an optimizer hint is specified and is applicable, it takes precedence over the Index Merge-related flags of the optimizer_switch system variable.

```sql
SET optimizer_switch='index_merge_intersection=off';
SELECT /*+ INDEX_MERGE(t1 i_b, i_c) */ * FROM t1
WHERE b = 1 AND c = 2 AND d = 3;
```

The hint takes precedence over optimizer_switch. Index Merge is used for `(i_b, i_c)` in this case.

```sql
SET optimizer_switch='index_merge_intersection=on';
SELECT /*+ INDEX_MERGE(t1 i_b) */ * FROM t1
WHERE b = 1 AND c = 2 AND d = 3;
```

The hint specifies only one index, so it is inapplicable, and the optimizer_switch flag (on) applies. Index Merge is used if the optimizer assesses it to be cost efficient.

```sql
SET optimizer_switch='index_merge_intersection=off';
SELECT /*+ INDEX_MERGE(t1 i_b) */ * FROM t1
WHERE b = 1 AND c = 2 AND d = 3;
```

The hint specifies only one index, so it is inapplicable, and the optimizer_switch flag (off) applies. Index Merge is not used.

- The index-level optimizer hints `GROUP_INDEX`, `INDEX`, `JOIN_INDEX`, and `ORDER_INDEX` all take precedence over the equivalent `FORCE_INDEX` hints; that is, they cause the `FORCE_INDEX` hints to be
Optimizer Hints

ignored. Likewise, the NO_GROUP_INDEX, NO_INDEX, NO_JOIN_INDEX, and NO_ORDER_INDEX hints all take precedence over any IGNORE_INDEX equivalents, also causing them to be ignored.

The index-level optimizer hints GROUP_INDEX, NO_GROUP_INDEX, INDEX, NO_INDEX, JOIN_INDEX, NO_JOIN_INDEX, ORDER_INDEX, and NO_ORDER_INDEX hints all take precedence over all other optimizer hints, including other index-level optimizer hints. Any other optimizer hints are applied only to the indexes permitted by these.

The GROUP_INDEX, INDEX, JOIN_INDEX, and ORDER_INDEX hints are all equivalent to FORCE_INDEX and not to USE_INDEX. This is because using one or more of these hints means that a table scan is used only if there is no way to use one of the named indexes to find rows in the table. To cause MySQL to use the same index or set of indexes as with a given instance of USE_INDEX, you can use NO_INDEX, NO_JOIN_INDEX, NO_GROUP_INDEX, NO_ORDER_INDEX, or some combination of these.

To replicate the effect that USE_INDEX has in the query SELECT a,c FROM t1 USE INDEX FOR ORDER BY (i_a) ORDER BY a, you can use the NO_ORDER_INDEX optimizer hint to cover all indexes on the table except the one that is desired like this:

```
SELECT /**+ NO_ORDER_INDEX(t1 i_b,i_c) */ a,c
  FROM t1
  ORDER BY a;
```

Attempting to combine NO_ORDER_INDEX for the table as a whole with USE_INDEX FOR ORDER BY does not work to do this, because NO_ORDER_BY causes USE_INDEX to be ignored, as shown here:

```
mysql> EXPLAIN SELECT /*+ NO_ORDER_INDEX(t1) */ a,c FROM t1
          -> USE_INDEX FOR ORDER BY (i_a) ORDER BY a\G
*************************** 1. row ***************************
 id: 1
 select_type: SIMPLE
 table: t1
 partitions: NULL
 type: ALL
 possible_keys: NULL
 key: NULL
 key_len: NULL
 ref: NULL
 rows: 256
 filtered: 100.00
 Extra: Using filesort
```

- The USE_INDEX, FORCE_INDEX, and IGNORE_INDEX index hints have higher priority than the INDEX_MERGE and NO_INDEX_MERGE optimizer hints.

```
/**+ INDEX_MERGE(t1 i_a, i_b, i_c) */ ... IGNORE_INDEX i_a
```

IGNORE_INDEX takes precedence over INDEX_MERGE, so index i_a is excluded from the possible ranges for Index Merge.

```
/**+ NO_INDEX_MERGE(t1 i_a, i_b) */ ... FORCE_INDEX i_a, i_b
```

Index Merge is disallowed for i_a, i_b because of FORCE_INDEX, but the optimizer is forced to use either i_a or i_b for range or ref access. There are no conflicts; both hints are applicable.

- If an IGNORE_INDEX hint names multiple indexes, those indexes are unavailable for Index Merge.

- The FORCE_INDEX and USE_INDEX hints make only the named indexes to be available for Index Merge.

```
SELECT /*+ INDEX_MERGE(t1 i_a, i_b, i_c) */ a FROM t1
FORCE_INDEX (i_a, i_b) WHERE c = 'h' AND a = 2 AND b = 'b';
```
The Index Merge intersection access algorithm is used for \((i_a, i_b)\). The same is true if \texttt{FORCE INDEX} is changed to \texttt{USE INDEX}.

### Subquery Optimizer Hints

Subquery hints affect whether to use semijoin transformations and which semijoin strategies to permit, and, when semijoins are not used, whether to use subquery materialization or IN-to-EXISTS transformations. For more information about these optimizations, see Section 8.2.2, “Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions”.

Syntax of hints that affect semijoin strategies:

```
hint_name[@query_block_name] [strategy [, strategy] ...]
```

The syntax refers to these terms:

- **hint_name**: These hint names are permitted:
  - \texttt{SEMIJOIN}, \texttt{NO_SEMIJOIN}: Enable or disable the named semijoin strategies.
  - \texttt{strategy}: A semijoin strategy to be enabled or disabled. These strategy names are permitted: \texttt{DUPSWEEDOUT}, \texttt{FIRSTMATCH}, \texttt{LOosescan}, \texttt{MATERIALIZATION}.

For \texttt{SEMIJOIN} hints, if no strategies are named, semijoin is used if possible based on the strategies enabled according to the \texttt{optimizer_switch} system variable. If strategies are named but inapplicable for the statement, \texttt{DUPSWEEDOUT} is used.

For \texttt{NO_SEMIJOIN} hints, if no strategies are named, semijoin is not used. If strategies are named that rule out all applicable strategies for the statement, \texttt{DUPSWEEDOUT} is used.

If one subquery is nested within another and both are merged into a semijoin of an outer query, any specification of semijoin strategies for the innermost query are ignored. \texttt{SEMIJOIN} and \texttt{NO_SEMIJOIN} hints can still be used to enable or disable semijoin transformations for such nested subqueries.

If \texttt{DUPSWEEDOUT} is disabled, on occasion the optimizer may generate a query plan that is far from optimal. This occurs due to heuristic pruning during greedy search, which can be avoided by setting \texttt{optimizer_prune_level=0}.

Examples:

```
SELECT /*+ NO_SEMIJOIN(@subq1 FIRSTMATCH, LOosescan) */ * FROM t2
  WHERE t2.a IN (SELECT /*+ QB_NAME(subq1) */ a FROM t3);
SELECT /*+ SEMIJOIN(@subq1 MATERIALIZATION, DUPSWEEDOUT) */ * FROM t2
  WHERE t2.a IN (SELECT /*+ QB_NAME(subq1) */ a FROM t3);
```

Syntax of hints that affect whether to use subquery materialization or IN-to-EXISTS transformations:

```
SUBQUERY([@query_block_name] strategy)
```

The hint name is always \texttt{SUBQUERY}.

For \texttt{SUBQUERY} hints, these \texttt{strategy} values are permitted: \texttt{INTOEXISTS}, \texttt{MATERIALIZATION}.

Examples:

```
SELECT id, a IN (SELECT /*+ SUBQUERY(MATERIALIZATION) */ a FROM t1) FROM t2;
SELECT * FROM t2 WHERE t2.a IN (SELECT /*+ SUBQUERY(INTOEXISTS) */ a FROM t1);
```
Optimizer Hints

For semijoin and SUBQUERY hints, a leading `@query_block_name` specifies the query block to which the hint applies. If the hint includes no leading `@query_block_name`, the hint applies to the query block in which it occurs. To assign a name to a query block, see Optimizer Hints for Naming Query Blocks.

If a hint comment contains multiple subquery hints, the first is used. If there are other following hints of that type, they produce a warning. Following hints of other types are silently ignored.

**Statement Execution Time Optimizer Hints**

The `MAX_EXECUTION_TIME` hint is permitted only for SELECT statements. It places a limit `N` (a timeout value in milliseconds) on how long a statement is permitted to execute before the server terminates it:

```
MAX_EXECUTION_TIME(N)
```

Example with a timeout of 1 second (1000 milliseconds):

```
SELECT /*+ MAX_EXECUTION_TIME(1000) */ * FROM t1 INNER JOIN t2 WHERE ...
```

The `MAX_EXECUTION_TIME(N)` hint sets a statement execution timeout of `N` milliseconds. If this option is absent or `N` is 0, the statement timeout established by the `max_execution_time` system variable applies.

The `MAX_EXECUTION_TIME` hint is applicable as follows:

- For statements with multiple SELECT keywords, such as unions or statements with subqueries, `MAX_EXECUTION_TIME` applies to the entire statement and must appear after the first SELECT.
- It applies to read-only SELECT statements. Statements that are not read only are those that invoke a stored function that modifies data as a side effect.
- It does not apply to SELECT statements in stored programs and is ignored.

**Variable-Setting Hint Syntax**

The `SET_VAR` hint sets the session value of a system variable temporarily (for the duration of a single statement). Examples:

```
SELECT /*+ SET_VAR(sort_buffer_size = 16M) */ name FROM people ORDER BY name;
INSERT /*+ SET_VAR(foreign_key_checks=OFF) */ INTO t2 VALUES(2);
SELECT /*+ SET_VAR(optimizer_switch = 'mrr_cost_based=off') */ 1;
```

Syntax of the `SET_VAR` hint:

```
SET_VAR(var_name=value)
```

`var_name` names a system variable that has a session value (although not all such variables can be named, as explained later). `value` is the value to assign to the variable; the value must be a scalar.

`SET_VAR` makes a temporary variable change, as demonstrated by these statements:

```
mysql> SELECT @@unique_checks;
+-----------------+
| @@unique_checks |
+-----------------+
| 1               |
+-----------------+
mysql> SELECT /*+ SET_VAR(unique_checks=OFF) */ @@unique_checks;
+-----------------+
| @@unique_checks |
+-----------------+
```

1931
Optimizer Hints

With `SET_VAR`, there is no need to save and restore the variable value. This enables you to replace multiple statements by a single statement. Consider this sequence of statements:

```
SET @saved_val = @@SESSION.var_name;
SET @@SESSION.var_name = value;
SELECT ...
SET @@SESSION.var_name = @saved_val;
```

The sequence can be replaced by this single statement:

```
SELECT /*+ SET_VAR(var_name = value) ...*/
```

Standalone `SET` statements permit any of these syntaxes for naming session variables:

```
SET SESSION var_name = value;
SET @@SESSION.var_name = value;
SET @.var_name = value;
```

Because the `SET_VAR` hint applies only to session variables, session scope is implicit, and `SESSION`, `@@SESSION`, and `@` are neither needed nor permitted. Including explicit session-indicator syntax results in the `SET_VAR` hint being ignored with a warning.

Not all session variables are permitted for use with `SET_VAR`. Individual system variable descriptions indicate whether each variable is hintable; see Section 5.1.8, “Server System Variables”. You can also check a system variable at runtime by attempting to use it with `SET_VAR`. If the variable is not hintable, a warning occurs:

```
mysql> SELECT /*+ SET_VAR(collation_server = 'utf8mb4') */ 1;
+---+
| 1 |
+---+
1 row in set, 1 warning (0.00 sec)
```

```
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Warning
Code: 4537
Message: Variable 'collation_server' cannot be set using SET_VAR hint.
```

`SET_VAR` syntax permits setting only a single variable, but multiple hints can be given to set multiple variables:

```
SELECT /*+ SET_VAR(optimizer_switch = 'mrr_cost_based=off')
SET_VAR(max_heap_table_size = 1G) */ 1;
```

If several hints with the same variable name appear in the same statement, the first one is applied and the others are ignored with a warning:

```
SELECT /*+ SET_VAR(max_heap_table_size = 1G)
SET_VAR(max_heap_table_size = 3G) */ 1;
```

In this case, the second hint is ignored with a warning that it is conflicting.
A **SET_VAR** hint is ignored with a warning if no system variable has the specified name or the variable value is incorrect:

```sql
SELECT /*+ SET_VAR(max_size = 1G) */ 1;
SELECT /*+ SET_VAR(optimizer_switch = 'mrr_cost_based=yes') */ 1;
```

For the first statement, there is no `max_size` variable. For the second statement, `mrr_cost_based` takes values of `on` or `off`, so attempting to set it to `yes` is incorrect. In each case, the hint is ignored with a warning.

The **SET_VAR** hint is permitted only at the statement level. If used in a subquery, the hint is ignored with a warning.

Replicas ignore **SET_VAR** hints in replicated statements to avoid the potential for security issues.

### Resource Group Hint Syntax

The **RESOURCE_GROUP** optimizer hint is used for resource group management (see Section 5.1.16, “Resource Groups”). This hint assigns the thread that executes a statement to the named resource group temporarily (for the duration of the statement). It requires the **RESOURCE_GROUP_ADMIN** or **RESOURCE_GROUP_USER** privilege.

Examples:

```sql
SELECT /*+ RESOURCE_GROUP(USR_default) */ name FROM people ORDER BY name;
INSERT /*+ RESOURCE_GROUP(Batch) */ INTO t2 VALUES(2);
```

Syntax of the **RESOURCE_GROUP** hint:

```
RESOURCE_GROUP(group_name)
```

`group_name` indicates the resource group to which the thread should be assigned for the duration of statement execution. If the group is nonexistent, a warning occurs and the hint is ignored.

The **RESOURCE_GROUP** hint must appear after the initial statement keyword (**SELECT**, **INSERT**, **REPLACE**, **UPDATE**, or **DELETE**).

An alternative to **RESOURCE_GROUP** is the **SET RESOURCE GROUP** statement, which nontemporarily assigns threads to a resource group. See Section 13.7.2.4, “SET RESOURCE GROUP Statement”.

### Optimizer Hints for Naming Query Blocks

Table-level, index-level, and subquery optimizer hints permit specific query blocks to be named as part of their argument syntax. To create these names, use the **QB_NAME** hint, which assigns a name to the query block in which it occurs:

```
QB_NAME(name)
```

**QB_NAME** hints can be used to make explicit in a clear way which query blocks other hints apply to. They also permit all non-query block name hints to be specified within a single hint comment for easier understanding of complex statements. Consider the following statement:

```sql
SELECT ... 
FROM (SELECT ... 
      FROM (SELECT ... FROM ...)) ...
```

**QB_NAME** hints assign names to query blocks in the statement:

```sql
SELECT /*+ QB_NAME(qb1) */ ...
```
Index Hints

Then other hints can use those names to refer to the appropriate query blocks:

```
SELECT /*+ QB_NAME(qb1) MRR(@qb1 t1) BKA(@qb2) NO_MRR(@qb3 t1 idx1, id2) */ ...
FROM (SELECT /*+ QB_NAME(qb2) */ ...
FROM (SELECT /*+ QB_NAME(qb3) */ ... FROM ...)) ...
```

The resulting effect is as follows:

- **MRR(@qb1 t1)** applies to table **t1** in query block **qb1**.
- **BKA(@qb2)** applies to query block **qb2**.
- **NO_MRR(@qb3 t1 idx1, id2)** applies to indexes **idx1** and **idx2** in table **t1** in query block **qb3**.

Query block names are identifiers and follow the usual rules about what names are valid and how to quote them (see [Section 9.2, “Schema Object Names”](#)). For example, a query block name that contains spaces must be quoted, which can be done using backticks:

```
SELECT /*+ BKA('my hint name') */ ...
FROM (SELECT /*+ QB_NAME('my hint name') */ ...) ...
```

If the **ANSI_QUOTES** SQL mode is enabled, it is also possible to quote query block names within double quotation marks:

```
SELECT /*+ BKA(@"my hint name") */ ...
FROM (SELECT /*+ QB_NAME("my hint name") */ ...) ...
```

### 8.9.4 Index Hints

Index hints give the optimizer information about how to choose indexes during query processing. Index hints, described here, differ from optimizer hints, described in [Section 8.9.3, “Optimizer Hints”](#). Index and optimizer hints may be used separately or together.

Index hints apply to **SELECT** and **UPDATE** statements. They also work with multi-table **DELETE** statements, but not with single-table **DELETE**, as shown later in this section.

Index hints are specified following a table name. (For the general syntax for specifying tables in a **SELECT** statement, see [Section 13.2.13.2, “JOIN Clause”](#).) The syntax for referring to an individual table, including index hints, looks like this:

```
tbl_name [[AS] alias] [index_hint_list]

indexHint_list:
  index_hint [index_hint] ...

index_hint:
  USE {INDEX|KEY} [FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
  | {IGNORE|FORCE} {INDEX|KEY} [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)

index_list:
  index_name [, index_name] ...
```

The **USE INDEX (index_list)** hint tells MySQL to use only one of the named indexes to find rows in the table. The alternative syntax **IGNORE INDEX (index_list)** tells MySQL to not use some particular index or indexes. These hints are useful if **EXPLAIN** shows that MySQL is using the wrong index from the list of possible indexes.
The **FORCE INDEX** hint acts like **USE INDEX (index_list)**, with the addition that a table scan is assumed to be *very* expensive. In other words, a table scan is used only if there is no way to use one of the named indexes to find rows in the table.

### Note

MySQL 8.2 supports the index-level optimizer hints **JOIN_INDEX**, **GROUP_INDEX**, **ORDER_INDEX**, and **INDEX**, which are equivalent to and intended to supersede **FORCE INDEX** index hints, as well as the **NO_JOIN_INDEX**, **NO_GROUP_INDEX**, **NO_ORDER_INDEX**, and **NO_INDEX** optimizer hints, which are equivalent to and intended to supersede **IGNORE_INDEX** index hints. Thus, you should expect **USE INDEX**, **FORCE INDEX**, and **IGNORE_INDEX** to be deprecated in a future release of MySQL, and at some time thereafter to be removed altogether.

These index-level optimizer hints are supported with both single-table and multi-table **DELETE** statements.

For more information, see [Index-Level Optimizer Hints](#).

Each hint requires index names, not column names. To refer to a primary key, use the name **PRIMARY**. To see the index names for a table, use the **SHOW INDEX** statement or the Information Schema **STATISTICS** table.

An **index_name** value need not be a full index name. It can be an unambiguous prefix of an index name. If a prefix is ambiguous, an error occurs.

**Examples:**

```sql
SELECT * FROM table1 USE INDEX (col1_index,col2_index) WHERE col1=1 AND col2=2 AND col3=3;
SELECT * FROM table1 IGNORE INDEX (col3_index) WHERE col1=1 AND col2=2 AND col3=3;
```

The syntax for index hints has the following characteristics:

- It is syntactically valid to omit **index_list** for **USE INDEX**, which means “use no indexes.” Omitting **index_list** for **FORCE INDEX** or **IGNORE INDEX** is a syntax error.

- You can specify the scope of an index hint by adding a **FOR** clause to the hint. This provides more fine-grained control over optimizer selection of an execution plan for various phases of query processing. To affect only the indexes used when MySQL decides how to find rows in the table and how to process joins, use **FOR JOIN**. To influence index usage for sorting or grouping rows, use **FOR ORDER BY** or **FOR GROUP BY**.

- You can specify multiple index hints:

```sql
SELECT * FROM t1 USE INDEX (i1) IGNORE INDEX FOR ORDER BY (i2) ORDER BY a;
```

It is not an error to name the same index in several hints (even within the same hint):

```sql
SELECT * FROM t1 USE INDEX (i1) USE INDEX (i1,i1);
```

However, it is an error to mix **USE INDEX** and **FORCE INDEX** for the same table:

```sql
SELECT * FROM t1 USE INDEX FOR JOIN (i1) FORCE INDEX FOR JOIN (i2);
```

If an index hint includes no **FOR** clause, the scope of the hint is to apply to all parts of the statement. For example, this hint:
Index Hints

is equivalent to this combination of hints:

<table>
<thead>
<tr>
<th>INDEX HINTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>IGNORE INDEX FOR JOIN (i1)</td>
</tr>
<tr>
<td>IGNORE INDEX FOR ORDER BY (i1)</td>
</tr>
<tr>
<td>IGNORE INDEX FOR GROUP BY (i1)</td>
</tr>
</tbody>
</table>

In MySQL 5.0, hint scope with no FOR clause was to apply only to row retrieval. To cause the server to use this older behavior when no FOR clause is present, enable the old system variable at server startup. Take care about enabling this variable in a replication setup. With statement-based binary logging, having different modes for the source and replicas might lead to replication errors.

When index hints are processed, they are collected in a single list by type (USE, FORCE, IGNORE) and by scope (FOR JOIN, FOR ORDER BY, FOR GROUP BY). For example:

```
SELECT * FROM t1
USE INDEX () IGNORE INDEX (i2) USE INDEX (i1) USE INDEX (i2);
```

is equivalent to:

```
SELECT * FROM t1
USE INDEX (i1,i2) IGNORE INDEX (i2);
```

The index hints then are applied for each scope in the following order:

1. **{USE|FORCE} INDEX** is applied if present. (If not, the optimizer-determined set of indexes is used.)

2. **IGNORE INDEX** is applied over the result of the previous step. For example, the following two queries are equivalent:

   ```
   SELECT * FROM t1 USE INDEX (i1) IGNORE INDEX (i2) USE INDEX (i2);
   SELECT * FROM t1 USE INDEX (i1);
   ```

For FULLTEXT searches, index hints work as follows:

- For natural language mode searches, index hints are silently ignored. For example, **IGNORE INDEX(i1)** is ignored with no warning and the index is still used.

- For boolean mode searches, index hints with **FOR ORDER BY** or **FOR GROUP BY** are silently ignored. Index hints with **FOR JOIN** or no **FOR** modifier are honored. In contrast to how hints apply for non-FULLTEXT searches, the hint is used for all phases of query execution (finding rows and retrieval, grouping, and ordering). This is true even if the hint is given for a non-FULLTEXT index.

For example, the following two queries are equivalent:

```
SELECT * FROM t
USE INDEX (index1)
IGNORE INDEX FOR ORDER BY (index1)
IGNORE INDEX FOR GROUP BY (index1)
WHERE ... IN BOOLEAN MODE ... ;
```

```
SELECT * FROM t
USE INDEX (index1)
WHERE ... IN BOOLEAN MODE ... ;
```

Index hints work with DELETE statements, but only if you use multi-table DELETE syntax, as shown here:

```
mysql> EXPLAIN DELETE FROM t1 USE INDEX(col2) -> WHERE col1 BETWEEN 1 AND 100 AND COL2 BETWEEN 1 AND 100\G
```
8.9.5 The Optimizer Cost Model

To generate execution plans, the optimizer uses a cost model that is based on estimates of the cost of various operations that occur during query execution. The optimizer has a set of compiled-in default “cost constants” available to it to make decisions regarding execution plans.

The optimizer also has a database of cost estimates to use during execution plan construction. These estimates are stored in the `server_cost` and `engine_cost` tables in the `mysql` system database and are configurable at any time. The intent of these tables is to make it possible to easily adjust the cost estimates that the optimizer uses when it attempts to arrive at query execution plans.

- Cost Model General Operation
- The Cost Model Database
- Making Changes to the Cost Model Database

Cost Model General Operation

The configurable optimizer cost model works like this:

- The server reads the cost model tables into memory at startup and uses the in-memory values at runtime. Any non-NULL cost estimate specified in the tables takes precedence over the corresponding compiled-in default cost constant. Any NULL estimate indicates to the optimizer to use the compiled-in default.

- At runtime, the server may re-read the cost tables. This occurs when a storage engine is dynamically loaded or when a `FLUSH OPTIMIZER_COSTS` statement is executed.

- Cost tables enable server administrators to easily adjust cost estimates by changing entries in the tables. It is also easy to revert to a default by setting an entry’s cost to NULL. The optimizer uses the in-memory cost values, so changes to the tables should be followed by `FLUSH OPTIMIZER_COSTS` to take effect.

- The in-memory cost estimates that are current when a client session begins apply throughout that session until it ends. In particular, if the server re-reads the cost tables, any changed estimates apply only to subsequently started sessions. Existing sessions are unaffected.

- Cost tables are specific to a given server instance. The server does not replicate cost table changes to replicas.
The Optimizer Cost Model

The Cost Model Database

The optimizer cost model database consists of two tables in the `mysql` system database that contain cost estimate information for operations that occur during query execution:

- `server_cost`: Optimizer cost estimates for general server operations
- `engine_cost`: Optimizer cost estimates for operations specific to particular storage engines

The `server_cost` table contains these columns:

- `cost_name`
  The name of a cost estimate used in the cost model. The name is not case-sensitive. If the server does not recognize the cost name when it reads this table, it writes a warning to the error log.

- `cost_value`
  The cost estimate value. If the value is non-`NULL`, the server uses it as the cost. Otherwise, it uses the default estimate (the compiled-in value). DBAs can change a cost estimate by updating this column. If the server finds that the cost value is invalid (nonpositive) when it reads this table, it writes a warning to the error log.

  To override a default cost estimate (for an entry that specifies `NULL`), set the cost to a non-`NULL` value. To revert to the default, set the value to `NULL`. Then execute `FLUSH OPTIMIZER_COSTS` to tell the server to re-read the cost tables.

- `last_update`
  The time of the last row update.

- `comment`
  A descriptive comment associated with the cost estimate. DBAs can use this column to provide information about why a cost estimate row stores a particular value.

- `default_value`
  The default (compiled-in) value for the cost estimate. This column is a read-only generated column that retains its value even if the associated cost estimate is changed. For rows added to the table at runtime, the value of this column is `NULL`.

The primary key for the `server_cost` table is the `cost_name` column, so it is not possible to create multiple entries for any cost estimate.

The server recognizes these `cost_name` values for the `server_cost` table:

- `disk_temptable_create_cost`, `disk_temptable_row_cost`
  The cost estimates for internally created temporary tables stored in a disk-based storage engine (either `InnoDB` or `MyISAM`). Increasing these values increases the cost estimate of using internal temporary tables and makes the optimizer prefer query plans with less use of them. For information about such tables, see Section 8.4.4, “Internal Temporary Table Use in MySQL”.

  The larger default values for these disk parameters compared to the default values for the corresponding memory parameters (`memory_temptable_create_cost`, `memory_temptable_row_cost`) reflects the greater cost of processing disk-based tables.

- `key_compare_cost`
The Optimizer Cost Model

The cost of comparing record keys. Increasing this value causes a query plan that compares many keys to become more expensive. For example, a query plan that performs a `filesort` becomes relatively more expensive compared to a query plan that avoids sorting by using an index.

- **memory_temptable_create_cost, memory_temptable_row_cost**

  The cost estimates for internally created temporary tables stored in the `MEMORY` storage engine. Increasing these values increases the cost estimate of using internal temporary tables and makes the optimizer prefer query plans with less use of them. For information about such tables, see Section 8.4.4, “Internal Temporary Table Use in MySQL”.

  The smaller default values for these memory parameters compared to the default values for the corresponding disk parameters (`disk_temptable_create_cost, disk_temptable_row_cost`) reflects the lesser cost of processing memory-based tables.

- **row_evaluate_cost**

  The cost of evaluating record conditions. Increasing this value causes a query plan that examines many rows to become more expensive compared to a query plan that examines fewer rows. For example, a table scan becomes relatively more expensive compared to a range scan that reads fewer rows.

The **engine_cost** table contains these columns:

- **engine_name**

  The name of the storage engine to which this cost estimate applies. The name is not case-sensitive. If the value is `default`, it applies to all storage engines that have no named entry of their own. If the server does not recognize the engine name when it reads this table, it writes a warning to the error log.

- **device_type**

  The device type to which this cost estimate applies. The column is intended for specifying different cost estimates for different storage device types, such as hard disk drives versus solid state drives. Currently, this information is not used and 0 is the only permitted value.

- **cost_name**

  Same as in the **server_cost** table.

- **cost_value**

  Same as in the **server_cost** table.

- **last_update**

  Same as in the **server_cost** table.

- **comment**

  Same as in the **server_cost** table.

- **default_value**

  The default (compiled-in) value for the cost estimate. This column is a read-only generated column that retains its value even if the associated cost estimate is changed. For rows added to the table at runtime, the value of this column is **NULL**, with the exception that if the row has the same **cost_name** value as one of the original rows, the **default_value** column has the same value as that row.
The primary key for the `engine_cost` table is a tuple comprising the `(cost_name, engine_name, device_type)` columns, so it is not possible to create multiple entries for any combination of values in those columns.

The server recognizes these `cost_name` values for the `engine_cost` table:

- **io_block_read_cost**

  The cost of reading an index or data block from disk. Increasing this value causes a query plan that reads many disk blocks to become more expensive compared to a query plan that reads fewer disk blocks. For example, a table scan becomes relatively more expensive compared to a range scan that reads fewer blocks.

- **memory_block_read_cost**

  Similar to `io_block_read_cost`, but represents the cost of reading an index or data block from an in-memory database buffer.

If the `io_block_read_cost` and `memory_block_read_cost` values differ, the execution plan may change between two runs of the same query. Suppose that the cost for memory access is less than the cost for disk access. In that case, at server startup before data has been read into the buffer pool, you may get a different plan than after the query has been run because then the data is in memory.

### Making Changes to the Cost Model Database

For DBAs who wish to change the cost model parameters from their defaults, try doubling or halving the value and measuring the effect.

Changes to the `io_block_read_cost` and `memory_block_read_cost` parameters are most likely to yield worthwhile results. These parameter values enable cost models for data access methods to take into account the costs of reading information from different sources; that is, the cost of reading information from disk versus reading information already in a memory buffer. For example, all other things being equal, setting `io_block_read_cost` to a value larger than `memory_block_read_cost` causes the optimizer to prefer query plans that read information already held in memory to plans that must read from disk.

This example shows how to change the default value for `io_block_read_cost`:

```sql
UPDATE mysql.engine_cost
SET cost_value = 2.0
WHERE cost_name = 'io_block_read_cost';
FLUSH OPTIMIZER_COSTS;
```

This example shows how to change the value of `io_block_read_cost` only for the InnoDB storage engine:

```sql
INSERT INTO mysql.engine_cost
VALUES ('InnoDB', 0, 'io_block_read_cost', 3.0,
CURRENT_TIMESTAMP, 'Using a slower disk for InnoDB');
FLUSH OPTIMIZER_COSTS;
```

### 8.9.6 Optimizer Statistics

The `column_statistics` data dictionary table stores histogram statistics about column values, for use by the optimizer in constructing query execution plans. To perform histogram management, use the `ANALYZE TABLE` statement.

The `column_statistics` table has these characteristics:
• The table contains statistics for columns of all data types except geometry types (spatial data) and JSON.
• The table is persistent so that column statistics need not be created each time the server starts.
• The server performs updates to the table; users do not.

The `column_statistics` table is not directly accessible by users because it is part of the data dictionary. Histogram information is available using `INFORMATION_SCHEMA.COLUMN_STATISTICS`, which is implemented as a view on the data dictionary table. `COLUMN_STATISTICS` has these columns:

• `SCHEMA_NAME`, `TABLE_NAME`, `COLUMN_NAME`: The names of the schema, table, and column for which the statistics apply.
• `HISTOGRAM`: A JSON value describing the column statistics, stored as a histogram.

Column histograms contain buckets for parts of the range of values stored in the column. Histograms are JSON objects to permit flexibility in the representation of column statistics. Here is a sample histogram object:

```json
{
  "buckets": [
    [1, 0.3333333333333333],
    [2, 0.6666666666666666],
    [3, 1]
  ],
  "null-values": 0,
  "last-updated": "2017-03-24 13:32:40.000000",
  "sampling-rate": 1,
  "histogram-type": "singleton",
  "number-of-buckets-specified": 128,
  "data-type": "int",
  "collation-id": 8
}
```

Histogram objects have these keys:

• `buckets`: The histogram buckets. Bucket structure depends on the histogram type.

  For `singleton` histograms, buckets contain two values:
  • Value 1: The value for the bucket. The type depends on the column data type.
  • Value 2: A double representing the cumulative frequency for the value. For example, .25 and .75 indicate that 25% and 75% of the values in the column are less than or equal to the bucket value.

  For `equi-height` histograms, buckets contain four values:
  • Values 1, 2: The lower and upper inclusive values for the bucket. The type depends on the column data type.
  • Value 3: A double representing the cumulative frequency for the value. For example, .25 and .75 indicate that 25% and 75% of the values in the column are less than or equal to the bucket upper value.
Optimizer Statistics

- **Value 4**: The number of distinct values in the range from the bucket lower value to its upper value.

- **null-values**: A number between 0.0 and 1.0 indicating the fraction of column values that are SQL NULL values. If 0, the column contains no NULL values.

- **last-updated**: When the histogram was generated, as a UTC value in *YYYY-MM-DD hh:mm:ss.uuuuuu* format.

- **sampling-rate**: A number between 0.0 and 1.0 indicating the fraction of data that was sampled to create the histogram. A value of 1 means that all of the data was read (no sampling).

- **histogram-type**: The histogram type:
  - **singleton**: One bucket represents one single value in the column. This histogram type is created when the number of distinct values in the column is less than or equal to the number of buckets specified in the `ANALYZE TABLE` statement that generated the histogram.
  - **equi-height**: One bucket represents a range of values. This histogram type is created when the number of distinct values in the column is greater than the number of buckets specified in the `ANALYZE TABLE` statement that generated the histogram.

- **number-of-buckets-specified**: The number of buckets specified in the `ANALYZE TABLE` statement that generated the histogram.

- **data-type**: The type of data this histogram contains. This is needed when reading and parsing histograms from persistent storage into memory. The value is one of `int`, `uint` (unsigned integer), `double`, `decimal`, `datetime`, or `string` (includes character and binary strings).

- **collation-id**: The collation ID for the histogram data. It is mostly meaningful when the `data-type` value is `string`. Values correspond to ID column values in the Information Schema `COLLATIONS` table.

To extract particular values from the histogram objects, you can use JSON operations. For example:

```sql
mysql> SELECT
    TABLE_NAME, COLUMN_NAME,
    HISTOGRAM->>'$.data-type' AS 'data-type',
    JSON_LENGTH(HISTOGRAM->>'$.buckets') AS 'bucket-count'
FROM INFORMATION_SCHEMA.COLUMN_STATISTICS;
```

<table>
<thead>
<tr>
<th>TABLE_NAME</th>
<th>COLUMN_NAME</th>
<th>data-type</th>
<th>bucket-count</th>
</tr>
</thead>
<tbody>
<tr>
<td>country</td>
<td>Population</td>
<td>int</td>
<td>226</td>
</tr>
<tr>
<td>city</td>
<td>Population</td>
<td>int</td>
<td>1024</td>
</tr>
<tr>
<td>countrylanguage</td>
<td>Language</td>
<td>string</td>
<td>457</td>
</tr>
</tbody>
</table>

The optimizer uses histogram statistics, if applicable, for columns of any data type for which statistics are collected. The optimizer applies histogram statistics to determine row estimates based on the selectivity (filtering effect) of column value comparisons against constant values. Predicates of these forms qualify for histogram use:

- `col_name = constant`
- `col_name <> constant`
- `col_name ! = constant`
- `col_name > constant`
- `col_name < constant`
- `col_name >= constant`
- `col_name <= constant`
- `col_name IS NULL`
- `col_name IS NOT NULL`
Buffering and Caching

For example, these statements contain predicates that qualify for histogram use:

```sql
SELECT * FROM orders WHERE amount BETWEEN 100.0 AND 300.0;
SELECT * FROM tbl WHERE col1 = 15 AND col2 > 100;
```

The requirement for comparison against a constant value includes functions that are constant, such as `ABS()` and `FLOOR()`:

```sql
SELECT * FROM tbl WHERE col1 < ABS(-34);
```

Histogram statistics are useful primarily for nonindexed columns. Adding an index to a column for which histogram statistics are applicable might also help the optimizer make row estimates. The tradeoffs are:

- An index must be updated when table data is modified.
- A histogram is created or updated only on demand, so it adds no overhead when table data is modified. On the other hand, the statistics become progressively more out of date when table modifications occur, until the next time they are updated.

The optimizer prefers range optimizer row estimates to those obtained from histogram statistics. If the optimizer determines that the range optimizer applies, it does not use histogram statistics.

For columns that are indexed, row estimates can be obtained for equality comparisons using index dives (see Section 8.2.1.2, “Range Optimization”). In this case, histogram statistics are not necessarily useful because index dives can yield better estimates.

In some cases, use of histogram statistics may not improve query execution (for example, if the statistics are out of date). To check whether this is the case, use `ANALYZE TABLE` to regenerate the histogram statistics, then run the query again.

Alternatively, to disable histogram statistics, use `ANALYZE TABLE` to drop them. A different method of disabling histogram statistics is to turn off the `condition_fanout_filter` flag of the `optimizer_switch` system variable (although this may disable other optimizations as well):

```sql
SET optimizer_switch='condition_fanout_filter=off';
```

If histogram statistics are used, the resulting effect is visible using `EXPLAIN`. Consider the following query, where no index is available for column `col1`:

```sql
SELECT * FROM t1 WHERE col1 < 24;
```

If histogram statistics indicate that 57% of the rows in `t1` satisfy the `col1 < 24` predicate, filtering can occur even in the absence of an index, and `EXPLAIN` shows 57.00 in the `filtered` column.

8.10 Buffering and Caching

MySQL uses several strategies that cache information in memory buffers to increase performance.

8.10.1 InnoDB Buffer Pool Optimization

InnoDB maintains a storage area called the buffer pool for caching data and indexes in memory. Knowing how the InnoDB buffer pool works, and taking advantage of it to keep frequently accessed data in memory, is an important aspect of MySQL tuning.
The MyISAM Key Cache

For an explanation of the inner workings of the InnoDB buffer pool, an overview of its LRU replacement algorithm, and general configuration information, see Section 15.5.1, “Buffer Pool”.

For additional InnoDB buffer pool configuration and tuning information, see these sections:

• Section 15.8.3.4, “Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)"
• Section 15.8.3.5, “Configuring Buffer Pool Flushing”
• Section 15.8.3.3, “Making the Buffer Pool Scan Resistant”
• Section 15.8.3.2, “Configuring Multiple Buffer Pool Instances”
• Section 15.8.3.6, “Saving and Restoring the Buffer Pool State”
• Section 15.8.3.1, “Configuring InnoDB Buffer Pool Size”

8.10.2 The MyISAM Key Cache

To minimize disk I/O, the MyISAM storage engine exploits a strategy that is used by many database management systems. It employs a cache mechanism to keep the most frequently accessed table blocks in memory:

• For index blocks, a special structure called the key cache (or key buffer) is maintained. The structure contains a number of block buffers where the most-used index blocks are placed.

• For data blocks, MySQL uses no special cache. Instead it relies on the native operating system file system cache.

This section first describes the basic operation of the MyISAM key cache. Then it discusses features that improve key cache performance and that enable you to better control cache operation:

• Multiple sessions can access the cache concurrently.

• You can set up multiple key caches and assign table indexes to specific caches.

To control the size of the key cache, use the key_buffer_size system variable. If this variable is set equal to zero, no key cache is used. The key cache also is not used if the key_buffer_size value is too small to allocate the minimal number of block buffers (8).

When the key cache is not operational, index files are accessed using only the native file system buffering provided by the operating system. (In other words, table index blocks are accessed using the same strategy as that employed for table data blocks.)

An index block is a contiguous unit of access to the MyISAM index files. Usually the size of an index block is equal to the size of nodes of the index B-tree. (Indexes are represented on disk using a B-tree data structure. Nodes at the bottom of the tree are leaf nodes. Nodes above the leaf nodes are nonleaf nodes.)

All block buffers in a key cache structure are the same size. This size can be equal to, greater than, or less than the size of a table index block. Usually one these two values is a multiple of the other.

When data from any table index block must be accessed, the server first checks whether it is available in some block buffer of the key cache. If it is, the server accesses data in the key cache rather than on disk. That is, it reads from the cache or writes into it rather than reading from or writing to disk. Otherwise, the server chooses a cache block buffer containing a different table index block (or blocks) and replaces the data there by a copy of required table index block. As soon as the new index block is in the cache, the index data can be accessed.
The MyISAM Key Cache

If it happens that a block selected for replacement has been modified, the block is considered “dirty.” In this case, prior to being replaced, its contents are flushed to the table index from which it came.

Usually the server follows an LRU (Least Recently Used) strategy: When choosing a block for replacement, it selects the least recently used index block. To make this choice easier, the key cache module maintains all used blocks in a special list (LRU chain) ordered by time of use. When a block is accessed, it is the most recently used and is placed at the end of the list. When blocks need to be replaced, blocks at the beginning of the list are the least recently used and become the first candidates for eviction.

The InnoDB storage engine also uses an LRU algorithm, to manage its buffer pool. See Section 15.5.1, “Buffer Pool”.

8.10.2.1 Shared Key Cache Access

Threads can access key cache buffers simultaneously, subject to the following conditions:

• A buffer that is not being updated can be accessed by multiple sessions.

• A buffer that is being updated causes sessions that need to use it to wait until the update is complete.

• Multiple sessions can initiate requests that result in cache block replacements, as long as they do not interfere with each other (that is, as long as they need different index blocks, and thus cause different cache blocks to be replaced).

Shared access to the key cache enables the server to improve throughput significantly.

8.10.2.2 Multiple Key Caches

Note

As of MySQL 8.2, the compound-part structured-variable syntax discussed here for referring to multiple MyISAM key caches is deprecated.

Shared access to the key cache improves performance but does not eliminate contention among sessions entirely. They still compete for control structures that manage access to the key cache buffers. To reduce key cache access contention further, MySQL also provides multiple key caches. This feature enables you to assign different table indexes to different key caches.

Where there are multiple key caches, the server must know which cache to use when processing queries for a given MyISAM table. By default, all MyISAM table indexes are cached in the default key cache. To assign table indexes to a specific key cache, use the CACHE INDEX statement (see Section 13.7.8.2, “CACHE INDEX Statement”). For example, the following statement assigns indexes from the tables t1, t2, and t3 to the key cache named hot_cache:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
```

```
+---------+--------------------+----------+----------+
<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_type</th>
<th>Msg_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.t1</td>
<td>assign_to_keycache</td>
<td>status</td>
<td>OK</td>
</tr>
<tr>
<td>test.t2</td>
<td>assign_to_keycache</td>
<td>status</td>
<td>OK</td>
</tr>
<tr>
<td>test.t3</td>
<td>assign_to_keycache</td>
<td>status</td>
<td>OK</td>
</tr>
</tbody>
</table>
+---------+--------------------+----------+----------+
```

The key cache referred to in a CACHE INDEX statement can be created by setting its size with a SET GLOBAL parameter setting statement or by using server startup options. For example:

```
mysql> SET GLOBAL keycache1.key_buffer_size=128*1024;
```
To destroy a key cache, set its size to zero:

```sql
mysql> SET GLOBAL keycache1.key_buffer_size=0;
```

You cannot destroy the default key cache. Any attempt to do this is ignored:

```sql
mysql> SET GLOBAL key_buffer_size = 0;

mysql> SHOW VARIABLES LIKE 'key_buffer_size';
+-----------------+---------+
| Variable_name   | Value   |
+-----------------+---------+
| key_buffer_size | 8384512 |
+-----------------+---------+
```

Key cache variables are structured system variables that have a name and components. For `keycache1.key_buffer_size`, `keycache1` is the cache variable name and `key_buffer_size` is the cache component. See Section 5.1.9.5, “Structured System Variables”, for a description of the syntax used for referring to structured key cache system variables.

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it are reassigned to the default key cache.

For a busy server, you can use a strategy that involves three key caches:

- A “hot” key cache that takes up 20% of the space allocated for all key caches. Use this for tables that are heavily used for searches but that are not updated.

- A “cold” key cache that takes up 20% of the space allocated for all key caches. Use this cache for medium-sized, intensively modified tables, such as temporary tables.

- A “warm” key cache that takes up 60% of the key cache space. Employ this as the default key cache, to be used by default for all other tables.

One reason the use of three key caches is beneficial is that access to one key cache structure does not block access to the others. Statements that access tables assigned to one cache do not compete with statements that access tables assigned to another cache. Performance gains occur for other reasons as well:

- The hot cache is used only for retrieval queries, so its contents are never modified. Consequently, whenever an index block needs to be pulled in from disk, the contents of the cache block chosen for replacement need not be flushed first.

- For an index assigned to the hot cache, if there are no queries requiring an index scan, there is a high probability that the index blocks corresponding to nonleaf nodes of the index B-tree remain in the cache.

- An update operation most frequently executed for temporary tables is performed much faster when the updated node is in the cache and need not be read from disk first. If the size of the indexes of the temporary tables are comparable with the size of cold key cache, the probability is very high that the updated node is in the cache.

The `CACHE INDEX` statement sets up an association between a table and a key cache, but the association is lost each time the server restarts. If you want the association to take effect each time the server starts, one way to accomplish this is to use an option file: Include variable settings that configure your key caches, and an `init_file` system variable that names a file containing `CACHE INDEX` statements to be executed. For example:

```sql
key_buffer_size = 4G
hot_cache.key_buffer_size = 2G
```

```sql```
The MyISAM Key Cache

cold_cache.key_buffer_size = 2G
init_file=/path/to/data-directory/mysqld_init.sql

The statements in `mysqld_init.sql` are executed each time the server starts. The file should contain one SQL statement per line. The following example assigns several tables each to `hot_cache` and `cold_cache`:

```
CACHE INDEX db1.t1, db1.t2, db2.t3 IN hot_cache
CACHE INDEX db1.t4, db2.t5, db2.t6 IN cold_cache
```

### 8.10.2.3 Midpoint Insertion Strategy

By default, the key cache management system uses a simple LRU strategy for choosing key cache blocks to be evicted, but it also supports a more sophisticated method called the **midpoint insertion strategy**.

When using the midpoint insertion strategy, the LRU chain is divided into two parts: a hot sublist and a warm sublist. The division point between two parts is not fixed, but the key cache management system takes care that the warm part is not “too short,” always containing at least `key_cache_division_limit` percent of the key cache blocks. `key_cache_division_limit` is a component of structured key cache variables, so its value is a parameter that can be set per cache.

When an index block is read from a table into the key cache, it is placed at the end of the warm sublist. After a certain number of hits (accesses of the block), it is promoted to the hot sublist. At present, the number of hits required to promote a block (3) is the same for all index blocks.

A block promoted into the hot sublist is placed at the end of the list. The block then circulates within this sublist. If the block stays at the beginning of the sublist for a long enough time, it is demoted to the warm sublist. This time is determined by the value of the `key_cache_age_threshold` component of the key cache.

The threshold value prescribes that, for a key cache containing \( N \) blocks, the block at the beginning of the hot sublist not accessed within the last \( N \times \text{key_cache_age_threshold} / 100 \) hits is to be moved to the beginning of the warm sublist. It then becomes the first candidate for eviction, because blocks for replacement always are taken from the beginning of the warm sublist.

The midpoint insertion strategy enables you to keep more-valued blocks always in the cache. If you prefer to use the plain LRU strategy, leave the `key_cache_division_limit` value set to its default of 100.

The midpoint insertion strategy helps to improve performance when execution of a query that requires an index scan effectively pushes out of the cache all the index blocks corresponding to valuable high-level B-tree nodes. To avoid this, you must use a midpoint insertion strategy with the `key_cache_division_limit` set to much less than 100. Then valuable frequently hit nodes are preserved in the hot sublist during an index scan operation as well.

### 8.10.2.4 Index Preloading

If there are enough blocks in a key cache to hold blocks of an entire index, or at least the blocks corresponding to its nonleaf nodes, it makes sense to preload the key cache with index blocks before starting to use it. Preloading enables you to put the table index blocks into a key cache buffer in the most efficient way: by reading the index blocks from disk sequentially.

Without preloading, the blocks are still placed into the key cache as needed by queries. Although the blocks stay in the cache, because there are enough buffers for all of them, they are fetched from disk in random order, and not sequentially.

To preload an index into a cache, use the `LOAD INDEX INTO CACHE` statement. For example, the following statement preloads nodes (index blocks) of indexes of the tables `t1` and `t2`:
Caching of Prepared Statements and Stored Programs

mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;

+---------+--------------+----------+----------+
| Table   | Op           | Msg_type | Msg_text |
+---------+--------------+----------+----------+
| test.t1 | preload_keys | status   | OK       |
| test.t2 | preload_keys | status   | OK       |
+---------+--------------+----------+----------+

The IGNORE LEAVES modifier causes only blocks for the nonleaf nodes of the index to be preloaded. Thus, the statement shown preloads all index blocks from t1, but only blocks for the nonleaf nodes from t2.

If an index has been assigned to a key cache using a CACHE INDEX statement, preloading places index blocks into that cache. Otherwise, the index is loaded into the default key cache.

8.10.2.5 Key Cache Block Size

It is possible to specify the size of the block buffers for an individual key cache using the key_cache_block_size variable. This permits tuning of the performance of I/O operations for index files.

The best performance for I/O operations is achieved when the size of read buffers is equal to the size of the native operating system I/O buffers. But setting the size of key nodes equal to the size of the I/O buffer does not always ensure the best overall performance. When reading the big leaf nodes, the server pulls in a lot of unnecessary data, effectively preventing reading other leaf nodes.

To control the size of blocks in the .MYI index file of MyISAM tables, use the --myisam-block-size option at server startup.

8.10.2.6 Restructuring a Key Cache

A key cache can be restructured at any time by updating its parameter values. For example:

```sql
mysql> SET GLOBAL cold_cache.key_buffer_size=4*1024*1024;
```

If you assign to either the key_buffer_size or key_cache_block_size key cache component a value that differs from the component's current value, the server destroys the cache's old structure and creates a new one based on the new values. If the cache contains any dirty blocks, the server saves them to disk before destroying and re-creating the cache. Restructuring does not occur if you change other key cache parameters.

When restructuring a key cache, the server first flushes the contents of any dirty buffers to disk. After that, the cache contents become unavailable. However, restructuring does not block queries that need to use indexes assigned to the cache. Instead, the server directly accesses the table indexes using native file system caching. File system caching is not as efficient as using a key cache, so although queries execute, a slowdown can be anticipated. After the cache has been restructured, it becomes available again for caching indexes assigned to it, and the use of file system caching for the indexes ceases.

8.10.3 Caching of Prepared Statements and Stored Programs

For certain statements that a client might execute multiple times during a session, the server converts the statement to an internal structure and caches that structure to be used during execution. Caching enables the server to perform more efficiently because it avoids the overhead of reconverting the statement should it be needed again during the session. Conversion and caching occurs for these statements:

• Prepared statements, both those processed at the SQL level (using the PREPARE statement) and those processed using the binary client/server protocol (using the mysql_stmt_prepare() C API function).
Caching of Prepared Statements and Stored Programs

The `max_prepared_stmt_count` system variable controls the total number of statements the server caches. (The sum of the number of prepared statements across all sessions.)

- Stored programs (stored procedures and functions, triggers, and events). In this case, the server converts and caches the entire program body. The `stored_program_cache` system variable indicates the approximate number of stored programs the server caches per session.

The server maintains caches for prepared statements and stored programs on a per-session basis. Statements cached for one session are not accessible to other sessions. When a session ends, the server discards any statements cached for it.

When the server uses a cached internal statement structure, it must take care that the structure does not go out of date. Metadata changes can occur for an object used by the statement, causing a mismatch between the current object definition and the definition as represented in the internal statement structure. Metadata changes occur for DDL statements such as those that create, drop, alter, rename, or truncate tables, or that analyze, optimize, or repair tables. Table content changes (for example, with `INSERT` or `UPDATE`) do not change metadata, nor do `SELECT` statements.

Here is an illustration of the problem. Suppose that a client prepares this statement:

```
PREPARE s1 FROM 'SELECT * FROM t1';
```

The `SELECT *` expands in the internal structure to the list of columns in the table. If the set of columns in the table is modified with `ALTER TABLE`, the prepared statement goes out of date. If the server does not detect this change the next time the client executes `s1`, the prepared statement returns incorrect results.

To avoid problems caused by metadata changes to tables or views referred to by the prepared statement, the server detects these changes and automatically reprepares the statement when it is next executed. That is, the server reparses the statement and rebuilds the internal structure. Reparsing also occurs after referenced tables or views are flushed from the table definition cache, either implicitly to make room for new entries in the cache, or explicitly due to `FLUSH TABLES`.

Similarly, if changes occur to objects used by a stored program, the server reparses affected statements within the program.

The server also detects metadata changes for objects in expressions. These might be used in statements specific to stored programs, such as `DECLARE CURSOR` or flow-control statements such as `IF`, `CASE`, and `RETURN`.

To avoid reparsing entire stored programs, the server reparses affected statements or expressions within a program only as needed. Examples:

- Suppose that metadata for a table or view is changed. Reparsing occurs for a `SELECT *` within the program that accesses the table or view, but not for a `SELECT *` that does not access the table or view.

- When a statement is affected, the server reparses it only partially if possible. Consider this `CASE` statement:

  ```
  CASE case_expr
    WHEN when_expr1 ... 
    WHEN when_expr2 ... 
    WHEN when_expr3 ... 
    ... 
  END CASE
  ```

  If a metadata change affects only `WHEN when_expr3`, that expression is reparsed. `case_expr` and the other `WHEN` expressions are not reparsed.
8.11 Optimizing Locking Operations

MySQL manages contention for table contents using locking:

- Internal locking is performed within the MySQL server itself to manage contention for table contents by multiple threads. This type of locking is internal because it is performed entirely by the server and involves no other programs. See Section 8.11.1, “Internal Locking Methods”.

- External locking occurs when the server and other programs lock MyISAM table files to coordinate among themselves which program can access the tables at which time. See Section 8.11.5, “External Locking”.

8.11.1 Internal Locking Methods

This section discusses internal locking; that is, locking performed within the MySQL server itself to manage contention for table contents by multiple sessions. This type of locking is internal because it is performed entirely by the server and involves no other programs. For locking performed on MySQL files by other programs, see Section 8.11.5, “External Locking”.

- Row-Level Locking
- Table-Level Locking
- Choosing the Type of Locking

Row-Level Locking

MySQL uses row-level locking for InnoDB tables to support simultaneous write access by multiple sessions, making them suitable for multi-user, highly concurrent, and OLTP applications.

To avoid deadlocks when performing multiple concurrent write operations on a single InnoDB table, acquire necessary locks at the start of the transaction by issuing a `SELECT ... FOR UPDATE` statement for each group of rows expected to be modified, even if the data change statements come later in the transaction. If transactions modify or lock more than one table, issue the applicable statements in the same order within each transaction. Deadlocks affect performance rather than representing a serious error, because InnoDB automatically detects deadlock conditions by default and rolls back one of the affected transactions.

On high concurrency systems, deadlock detection can cause a slowdown when numerous threads wait for the same lock. At times, it may be more efficient to disable deadlock detection and rely on the `innodb_lock_wait_timeout` setting for transaction rollback when a deadlock occurs. Deadlock detection can be disabled using the `innodb_deadlock_detect` configuration option.

Advantages of row-level locking:

- Fewer lock conflicts when different sessions access different rows.
Internal Locking Methods

- Fewer changes for rollbacks.
- Possible to lock a single row for a long time.

Table-Level Locking

MySQL uses **table-level locking** for **MyISAM**, **MEMORY**, and **MERGE** tables, permitting only one session to update those tables at a time. This locking level makes these storage engines more suitable for read-only, read-mostly, or single-user applications.

These storage engines avoid **deadlocks** by always requesting all needed locks at once at the beginning of a query and always locking the tables in the same order. The tradeoff is that this strategy reduces concurrency; other sessions that want to modify the table must wait until the current data change statement finishes.

Advantages of table-level locking:

- Relatively little memory required (row locking requires memory per row or group of rows locked)
- Fast when used on a large part of the table because only a single lock is involved.
- Fast if you often do **GROUP BY** operations on a large part of the data or must scan the entire table frequently.

MySQL grants table write locks as follows:

1. If there are no locks on the table, put a write lock on it.
2. Otherwise, put the lock request in the write lock queue.

MySQL grants table read locks as follows:

1. If there are no write locks on the table, put a read lock on it.
2. Otherwise, put the lock request in the read lock queue.

Table updates are given higher priority than table retrievals. Therefore, when a lock is released, the lock is made available to the requests in the write lock queue and then to the requests in the read lock queue. This ensures that updates to a table are not “starved” even when there is heavy **SELECT** activity for the table. However, if there are many updates for a table, **SELECT** statements wait until there are no more updates.

For information on altering the priority of reads and writes, see Section 8.11.2, “Table Locking Issues”.

You can analyze the table lock contention on your system by checking the **Table_locks_immediate** and **Table_locks_waited** status variables, which indicate the number of times that requests for table locks could be granted immediately and the number that had to wait, respectively:

```
mysql> SHOW STATUS LIKE 'Table%';
+-----------------------+---------+
| Variable_name         | Value   |
+-----------------------+---------+
| Table_locks_immediate | 1151552 |
| Table_locks_waited    | 15324   |
+-----------------------+---------+
```

The Performance Schema lock tables also provide locking information. See Section 27.12.13, “Performance Schema Lock Tables”. 
Table Locking Issues

The **MyISAM** storage engine supports concurrent inserts to reduce contention between readers and writers for a given table: If a **MyISAM** table has no free blocks in the middle of the data file, rows are always inserted at the end of the data file. In this case, you can freely mix concurrent **INSERT** and **SELECT** statements for a **MyISAM** table without locks. That is, you can insert rows into a **MyISAM** table at the same time other clients are reading from it. Holes can result from rows having been deleted from or updated in the middle of the table. If there are holes, concurrent inserts are disabled but are enabled again automatically when all holes have been filled with new data. To control this behavior, use the **concurrent_insert** system variable. See Section 8.11.3, “Concurrent Inserts”.

If you acquire a table lock explicitly with **LOCK TABLES**, you can request a **READ LOCAL** lock rather than a **READ** lock to enable other sessions to perform concurrent inserts while you have the table locked.

To perform many **INSERT** and **SELECT** operations on a table **t1** when concurrent inserts are not possible, you can insert rows into a temporary table **temp_t1** and update the real table with the rows from the temporary table:

```
mysql> LOCK TABLES t1 WRITE, temp_t1 WRITE;
mysql> INSERT INTO t1 SELECT * FROM temp_t1;
mysql> DELETE FROM temp_t1;
mysql> UNLOCK TABLES;
```

Choosing the Type of Locking

Generally, table locks are superior to row-level locks in the following cases:

- Most statements for the table are reads.
- Statements for the table are a mix of reads and writes, where writes are updates or deletes for a single row that can be fetched with one key read:
  ```
  UPDATE tbl_name SET column=value WHERE unique_key_col=key_value;
  DELETE FROM tbl_name WHERE unique_key_col=key_value;
  ```
- **SELECT** combined with concurrent **INSERT** statements, and very few **UPDATE** or **DELETE** statements.
- Many scans or **GROUP BY** operations on the entire table without any writers.

With higher-level locks, you can more easily tune applications by supporting locks of different types, because the lock overhead is less than for row-level locks.

Options other than row-level locking:

- Versioning (such as that used in MySQL for concurrent inserts) where it is possible to have one writer at the same time as many readers. This means that the database or table supports different views for the data depending on when access begins. Other common terms for this are “time travel,” “copy on write,” or “copy on demand.”
- Copy on demand is in many cases superior to row-level locking. However, in the worst case, it can use much more memory than using normal locks.
- Instead of using row-level locks, you can employ application-level locks, such as those provided by **GET_LOCK()** and **RELEASE_LOCK()** in MySQL. These are advisory locks, so they work only with applications that cooperate with each other. See Section 12.14, “Locking Functions”.

8.11.2 Table Locking Issues

**InnoDB** tables use row-level locking so that multiple sessions and applications can read from and write to the same table simultaneously, without making each other wait or producing inconsistent results. For this
Table Locking Issues

storage engine, avoid using the `LOCK TABLES` statement, because it does not offer any extra protection, but instead reduces concurrency. The automatic row-level locking makes these tables suitable for your busiest databases with your most important data, while also simplifying application logic since you do not need to lock and unlock tables. Consequently, the InnoDB storage engine is the default in MySQL.

MySQL uses table locking (instead of page, row, or column locking) for all storage engines except InnoDB. The locking operations themselves do not have much overhead. But because only one session can write to a table at any one time, for best performance with these other storage engines, use them primarily for tables that are queried often and rarely inserted into or updated.

- Performance Considerations Favoring InnoDB
- Workarounds for Locking Performance Issues

Performance Considerations Favoring InnoDB

When choosing whether to create a table using InnoDB or a different storage engine, keep in mind the following disadvantages of table locking:

- Table locking enables many sessions to read from a table at the same time, but if a session wants to write to a table, it must first get exclusive access, meaning it might have to wait for other sessions to finish with the table first. During the update, all other sessions that want to access this particular table must wait until the update is done.

- Table locking causes problems when a session is waiting because the disk is full and free space needs to become available before the session can proceed. In this case, all sessions that want to access the problem table are also put in a waiting state until more disk space is made available.

- A `SELECT` statement that takes a long time to run prevents other sessions from updating the table in the meantime, making the other sessions appear slow or unresponsive. While a session is waiting to get exclusive access to the table for updates, other sessions that issue `SELECT` statements queue up behind it, reducing concurrency even for read-only sessions.

Workarounds for Locking Performance Issues

The following items describe some ways to avoid or reduce contention caused by table locking:

- Consider switching the table to the InnoDB storage engine, either using `CREATE TABLE ... ENGINE=INNODB` during setup, or using `ALTER TABLE ... ENGINE=INNODB` for an existing table. See Chapter 15, The InnoDB Storage Engine for more details about this storage engine.

- Optimize `SELECT` statements to run faster so that they lock tables for a shorter time. You might have to create some summary tables to do this.

- Start `mysql` with `--low-priority-updates`. For storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE), this gives all statements that update (modify) a table lower priority than `SELECT` statements. In this case, the second `SELECT` statement in the preceding scenario would execute before the `UPDATE` statement, and would not wait for the first `SELECT` to finish.

- To specify that all updates issued in a specific connection should be done with low priority, set the `low_priority_updates` server system variable equal to 1.

- To give a specific `INSERT`, `UPDATE`, or `DELETE` statement lower priority, use the `LOW_PRIORITY` attribute.

- To give a specific `SELECT` statement higher priority, use the `HIGH_PRIORITY` attribute. See Section 13.2.13, “SELECT Statement”. 
Concurrent Inserts

- Start mysqld with a low value for the `max_write_lock_count` system variable to force MySQL to temporarily elevate the priority of all `SELECT` statements that are waiting for a table after a specific number of write locks to the table occur (for example, for insert operations). This permits read locks after a certain number of write locks.

- If you have problems with mixed `SELECT` and `DELETE` statements, the `LIMIT` option to `DELETE` may help. See Section 13.2.2, “DELETE Statement”.

- Using `SQL_BUFFER_RESULT` with `SELECT` statements can help to make the duration of table locks shorter. See Section 13.2.13, “SELECT Statement”.

- Splitting table contents into separate tables may help, by allowing queries to run against columns in one table, while updates are confined to columns in a different table.

- You could change the locking code in `mysys/thr_lock.c` to use a single queue. In this case, write locks and read locks would have the same priority, which might help some applications.

8.11.3 Concurrent Inserts

The MyISAM storage engine supports concurrent inserts to reduce contention between readers and writers for a given table: If a MyISAM table has no holes in the data file (deleted rows in the middle), an `INSERT` statement can be executed to add rows to the end of the table at the same time that `SELECT` statements are reading rows from the table. If there are multiple `INSERT` statements, they are queued and performed in sequence, concurrently with the `SELECT` statements. The results of a concurrent `INSERT` may not be visible immediately.

The `concurrent_insert` system variable can be set to modify the concurrent-insert processing. By default, the variable is set to `AUTO` (or 1) and concurrent inserts are handled as just described. If `concurrent_insert` is set to `NEVER` (or 0), concurrent inserts are disabled. If the variable is set to `ALWAYS` (or 2), concurrent inserts at the end of the table are permitted even for tables that have deleted rows. See also the description of the `concurrent_insert` system variable.

If you are using the binary log, concurrent inserts are converted to normal inserts for `CREATE ... SELECT` or `INSERT ... SELECT` statements. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation. See Section 5.4.4, “The Binary Log”. In addition, for those statements a read lock is placed on the selected-from table such that inserts into that table are blocked. The effect is that concurrent inserts for that table must wait as well.

With `LOAD DATA`, if you specify `CONCURRENT` with a MyISAM table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other sessions can retrieve data from the table while `LOAD DATA` is executing. Use of the `CONCURRENT` option affects the performance of `LOAD DATA` a bit, even if no other session is using the table at the same time.

If you specify `HIGH_PRIORITY`, it overrides the effect of the `--low-priority-updates` option if the server was started with that option. It also causes concurrent inserts not to be used.

For `LOCK TABLE`, the difference between `READ LOCAL` and `READ` is that `READ LOCAL` permits nonconflicting `INSERT` statements (concurrent inserts) to execute while the lock is held. However, this cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock.

8.11.4 Metadata Locking

MySQL uses metadata locking to manage concurrent access to database objects and to ensure data consistency. Metadata locking applies not just to tables, but also to schemas, stored programs (procedures, functions, triggers, scheduled events), tablespaces, user locks acquired with the
GET_LOCK() function (see Section 12.14, “Locking Functions”), and locks acquired with the locking service described in Section 5.6.9.1, “The Locking Service”.

The Performance Schema metadata_locks table exposes metadata lock information, which can be useful for seeing which sessions hold locks, are blocked waiting for locks, and so forth. For details, see Section 27.12.13.3, “The metadata_locks Table”.

Metadata locking does involve some overhead, which increases as query volume increases. Metadata contention increases the more that multiple queries attempt to access the same objects.

Metadata locking is not a replacement for the table definition cache, and its mutexes and locks differ from the LOCK_open mutex. The following discussion provides some information about how metadata locking works.

- **Metadata Lock Acquisition**
- **Metadata Lock Release**

**Metadata Lock Acquisition**

If there are multiple waiters for a given lock, the highest-priority lock request is satisfied first, with an exception related to the max_write_lock_count system variable. Write lock requests have higher priority than read lock requests. However, if max_write_lock_count is set to some low value (say, 10), read lock requests may be preferred over pending write lock requests if the read lock requests have already been passed over in favor of 10 write lock requests. Normally this behavior does not occur because max_write_lock_count by default has a very large value.

Statements acquire metadata locks one by one, not simultaneously, and perform deadlock detection in the process.

DML statements normally acquire locks in the order in which tables are mentioned in the statement.

DDL statements, LOCK TABLES, and other similar statements try to reduce the number of possible deadlocks between concurrent DDL statements by acquiring locks on explicitly named tables in name order. Locks might be acquired in a different order for implicitly used tables (such as tables in foreign key relationships that also must be locked).

For example, RENAME TABLE is a DDL statement that acquires locks in name order:

- This RENAME TABLE statement renames tbla to something else, and renames tblc to tbla:

  ```
  RENAME TABLE tbla TO tblb, tblc TO tbla;
  ```

  The statement acquires metadata locks, in order, on tbla, tblc, and tbld (because tbld follows tblc in name order):

- This slightly different statement also renames tbla to something else, and renames tblc to tbla:

  ```
  RENAME TABLE tbla TO tblb, tblc TO tbla;
  ```

  In this case, the statement acquires metadata locks, in order, on tbla, tblb, and tblc (because tblb precedes tblc in name order):

Both statements acquire locks on tbla and tblc, in that order, but differ in whether the lock on the remaining table name is acquired before or after tblc.

Metadata lock acquisition order can make a difference in operation outcome when multiple transactions execute concurrently, as the following example illustrates.
Begin with two tables $x$ and $x_{\text{new}}$ that have identical structure. Three clients issue statements that involve these tables:

Client 1:

LOCK TABLE $x$ WRITE, $x_{\text{new}}$ WRITE;

The statement requests and acquires write locks in name order on $x$ and $x_{\text{new}}$.

Client 2:

INSERT INTO $x$ VALUES(1);

The statement requests and blocks waiting for a write lock on $x$.

Client 3:

RENAME TABLE $x$ TO $x_{\text{old}}$, $x_{\text{new}}$ TO $x$;

The statement requests exclusive locks in name order on $x$, $x_{\text{new}}$, and $x_{\text{old}}$, but blocks waiting for the lock on $x$.

Client 1:

UNLOCK TABLES;

The statement releases the write locks on $x$ and $x_{\text{new}}$. The exclusive lock request for $x$ by Client 3 has higher priority than the write lock request by Client 2, so Client 3 acquires its lock on $x$, then also on $x_{\text{new}}$ and $x_{\text{old}}$, performs the renaming, and releases its locks. Client 2 then acquires its lock on $x$, performs the insert, and releases its lock.

Lock acquisition order results in the RENAME TABLE executing before the INSERT. The $x$ into which the insert occurs is the table that was named $x_{\text{new}}$ when Client 2 issued the insert and was renamed to $x$ by Client 3:

```
mysql> SELECT * FROM x;
+------+
<table>
<thead>
<tr>
<th>i</th>
</tr>
</thead>
</table>
mysql> SELECT * FROM x_{old};
Empty set (0.01 sec)
```

Now begin instead with tables named $x$ and $new_x$ that have identical structure. Again, three clients issue statements that involve these tables:

Client 1:

LOCK TABLE $x$ WRITE, $new_x$ WRITE;

The statement requests and acquires write locks in name order on $new_x$ and $x$.

Client 2:

INSERT INTO $x$ VALUES(1);

The statement requests and blocks waiting for a write lock on $x$. 

1956
Client 3:

```
RENAME TABLE x TO old_x, new_x TO x;
```

The statement requests exclusive locks in name order on `new_x`, `old_x`, and `x`, but blocks waiting for the lock on `new_x`.

Client 1:

```
UNLOCK TABLES;
```

The statement releases the write locks on `x` and `new_x`. For `x`, the only pending request is by Client 2, so Client 2 acquires its lock, performs the insert, and releases the lock. For `new_x`, the only pending request is by Client 3, which is permitted to acquire that lock (and also the lock on `old_x`). The rename operation still blocks for the lock on `x` until the Client 2 insert finishes and releases its lock. Then Client 3 acquires the lock on `x`, performs the rename, and releases its lock.

In this case, lock acquisition order results in the `INSERT` executing before the `RENAME TABLE`. The `x` into which the insert occurs is the original `x`, now renamed to `old_x` by the rename operation:

```
mysql> SELECT * FROM x;
Empty set (0.01 sec)
mysql> SELECT * FROM old_x;
+-----+
<table>
<thead>
<tr>
<th>i</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
+-----+
```

If order of lock acquisition in concurrent statements makes a difference to an application in operation outcome, as in the preceding example, you may be able to adjust the table names to affect the order of lock acquisition.

Metadata locks are extended, as necessary, to tables related by a foreign key constraint to prevent conflicting DML and DDL operations from executing concurrently on the related tables. When updating a parent table, a metadata lock is taken on the child table while updating foreign key metadata. Foreign key metadata is owned by the child table.

### Metadata Lock Release

To ensure transaction serializability, the server must not permit one session to perform a data definition language (DDL) statement on a table that is used in an uncompleted explicitly or implicitly started transaction in another session. The server achieves this by acquiring metadata locks on tables used within a transaction and deferring release of those locks until the transaction ends. A metadata lock on a table prevents changes to the table's structure. This locking approach has the implication that a table that is being used by a transaction within one session cannot be used in DDL statements by other sessions until the transaction ends.

This principle applies not only to transactional tables, but also to nontransactional tables. Suppose that a session begins a transaction that uses transactional table `t` and nontransactional table `nt` as follows:

```
START TRANSACTION;
SELECT * FROM t;
SELECT * FROM nt;
```

The server holds metadata locks on both `t` and `nt` until the transaction ends. If another session attempts a DDL or write lock operation on either table, it blocks until metadata lock release at transaction end. For example, a second session blocks if it attempts any of these operations:
External Locking

DROP TABLE t;
ALTER TABLE t ...;
DROP TABLE nt;
ALTER TABLE nt ...;
LOCK TABLE t ... WRITE;

The same behavior applies for the LOCK TABLES ... READ. That is, explicitly or implicitly started transactions that update any table (transactional or nontransactional) block and are blocked by LOCK TABLES ... READ for that table.

If the server acquires metadata locks for a statement that is syntactically valid but fails during execution, it does not release the locks early. Lock release is still deferred to the end of the transaction because the failed statement is written to the binary log and the locks protect log consistency.

In autocommit mode, each statement is in effect a complete transaction, so metadata locks acquired for the statement are held only to the end of the statement.

Metadata locks acquired during a PREPARE statement are released once the statement has been prepared, even if preparation occurs within a multiple-statement transaction.

For XA transactions in PREPARED state, metadata locks are maintained across client disconnects and server restarts, until an XA COMMIT or XA ROLLBACK is executed.

8.11.5 External Locking

External locking is the use of file system locking to manage contention for MyISAM database tables by multiple processes. External locking is used in situations where a single process such as the MySQL server cannot be assumed to be the only process that requires access to tables. Here are some examples:

- If you run multiple servers that use the same database directory (not recommended), each server must have external locking enabled.

- If you use myisamchk to perform table maintenance operations on MyISAM tables, you must either ensure that the server is not running, or that the server has external locking enabled so that it locks table files as necessary to coordinate with myisamchk for access to the tables. The same is true for use of myisampack to pack MyISAM tables.

If the server is run with external locking enabled, you can use myisamchk at any time for read operations such as a checking tables. In this case, if the server tries to update a table that myisamchk is using, the server waits for myisamchk to finish before it continues.

If you use myisamchk for write operations such as repairing or optimizing tables, or if you use myisampack to pack tables, you must always ensure that the mysqld server is not using the table. If you do not stop mysqld, at least do a mysqladmin flush-tables before you run myisamchk. Your tables may become corrupted if the server and myisamchk access the tables simultaneously.

With external locking in effect, each process that requires access to a table acquires a file system lock for the table files before proceeding to access the table. If all necessary locks cannot be acquired, the process is blocked from accessing the table until the locks can be obtained (after the process that currently holds the locks releases them).

External locking affects server performance because the server must sometimes wait for other processes before it can access tables.

External locking is unnecessary if you run a single server to access a given data directory (which is the usual case) and if no other programs such as myisamchk need to modify tables while the server is
running. If you only read tables with other programs, external locking is not required, although myisamchk might report warnings if the server changes tables while myisamchk is reading them.

With external locking disabled, to use myisamchk, you must either stop the server while myisamchk executes or else lock and flush the tables before running myisamchk. To avoid this requirement, use the CHECK TABLE and REPAIR TABLE statements to check and repair MyISAM tables.

For mysqld, external locking is controlled by the value of the skip_external_locking system variable. When this variable is enabled, external locking is disabled, and vice versa. External locking is disabled by default.

Use of external locking can be controlled at server startup by using the --external-locking or --skip-external-locking option.

If you do use external locking option to enable updates to MyISAM tables from many MySQL processes, do not start the server with the delay_key_write system variable set to ALL or use the DELAY_KEY_WRITE=1 table option for any shared tables. Otherwise, index corruption can occur.

The easiest way to satisfy this condition is to always use --external-locking together with --delay-key-write=OFF. (This is not done by default because in many setups it is useful to have a mixture of the preceding options.)

8.12 Optimizing the MySQL Server

This section discusses optimization techniques for the database server, primarily dealing with system configuration rather than tuning SQL statements. The information in this section is appropriate for DBAs who want to ensure performance and scalability across the servers they manage; for developers constructing installation scripts that include setting up the database; and people running MySQL themselves for development, testing, and so on who want to maximize their own productivity.

8.12.1 Optimizing Disk I/O

This section describes ways to configure storage devices when you can devote more and faster storage hardware to the database server. For information about optimizing an InnoDB configuration to improve I/O performance, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

- Disk seeks are a huge performance bottleneck. This problem becomes more apparent when the amount of data starts to grow so large that effective caching becomes impossible. For large databases where you access data more or less randomly, you can be sure that you need at least one disk seek to read and a couple of disk seeks to write things. To minimize this problem, use disks with low seek times.

- Increase the number of available disk spindles (and thereby reduce the seek overhead) by either symlinking files to different disks or striping the disks:
  - Using symbolic links
    
    This means that, for MyISAM tables, you symlink the index file and data files from their usual location in the data directory to another disk (that may also be striped). This makes both the seek and read times better, assuming that the disk is not used for other purposes as well. See Section 8.12.2, “Using Symbolic Links”.

    Symbolic links are not supported for use with InnoDB tables. However, it is possible to place InnoDB data and log files on different physical disks. For more information, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.
  - Striping
Using Symbolic Links

Striping means that you have many disks and put the first block on the first disk, the second block on the second disk, and the \( n \)-th block on the \((n \mod \text{number of disks})\) disk, and so on. This means if your normal data size is less than the stripe size (or perfectly aligned), you get much better performance. Striping is very dependent on the operating system and the stripe size, so benchmark your application with different stripe sizes. See Section 8.13.2, “Using Your Own Benchmarks”.

The speed difference for striping is very dependent on the parameters. Depending on how you set the striping parameters and number of disks, you may get differences measured in orders of magnitude. You have to choose to optimize for random or sequential access.

- For reliability, you may want to use RAID 0+1 (striping plus mirroring), but in this case, you need \(2 \times n\) drives to hold \(n\) drives of data. This is probably the best option if you have the money for it. However, you may also have to invest in some volume-management software to handle it efficiently.

- A good option is to vary the RAID level according to how critical a type of data is. For example, store semi-important data that can be regenerated on a RAID 0 disk, but store really important data such as host information and logs on a RAID 0+1 or RAID \(N\) disk. RAID \(N\) can be a problem if you have many writes, due to the time required to update the parity bits.

- You can also set the parameters for the file system that the database uses:

If you do not need to know when files were last accessed (which is not really useful on a database server), you can mount your file systems with the \(-o noatime\) option. That skips updates to the last access time in inodes on the file system, which avoids some disk seeks.

On many operating systems, you can set a file system to be updated asynchronously by mounting it with the \(-o async\) option. If your computer is reasonably stable, this should give you better performance without sacrificing too much reliability. (This flag is on by default on Linux.)

### Using NFS with MySQL

You should be cautious when considering whether to use NFS with MySQL. Potential issues, which vary by operating system and NFS version, include the following:

- MySQL data and log files placed on NFS volumes becoming locked and unavailable for use. Locking issues may occur in cases where multiple instances of MySQL access the same data directory or where MySQL is shut down improperly, due to a power outage, for example. NFS version 4 addresses underlying locking issues with the introduction of advisory and lease-based locking. However, sharing a data directory among MySQL instances is not recommended.

- Data inconsistencies introduced due to messages received out of order or lost network traffic. To avoid this issue, use TCP with \(\text{hard}\) and \(\text{intr}\) mount options.

- Maximum file size limitations. NFS Version 2 clients can only access the lowest 2GB of a file (signed 32 bit offset). NFS Version 3 clients support larger files (up to 64 bit offsets). The maximum supported file size also depends on the local file system of the NFS server.

Using NFS within a professional SAN environment or other storage system tends to offer greater reliability than using NFS outside of such an environment. However, NFS within a SAN environment may be slower than directly attached or bus-attached non-rotational storage.

If you choose to use NFS, NFS Version 4 or later is recommended, as is testing your NFS setup thoroughly before deploying into a production environment.

### 8.12.2 Using Symbolic Links
You can move databases or tables from the database directory to other locations and replace them with symbolic links to the new locations. You might want to do this, for example, to move a database to a file system with more free space or increase the speed of your system by spreading your tables to different disks.

For InnoDB tables, use the DATA DIRECTORY clause of the CREATE TABLE statement instead of symbolic links, as explained in Section 15.6.1.2, “Creating TablesExternally”. This new feature is a supported, cross-platform technique.

The recommended way to do this is to symlink entire database directories to a different disk. Symlink MyISAM tables only as a last resort.

To determine the location of your data directory, use this statement:

```sql
SHOW VARIABLES LIKE 'datadir';
```

### 8.12.2.1 Using Symbolic Links for Databases on Unix

On Unix, symlink a database using this procedure:

1. Create the database using CREATE DATABASE:

   ```sql
   mysql> CREATE DATABASE mydb1;
   ```

   Using CREATE DATABASE creates the database in the MySQL data directory and permits the server to update the data dictionary with information about the database directory.

2. Stop the server to ensure that no activity occurs in the new database while it is being moved.

3. Move the database directory to some disk where you have free space. For example, use `tar` or `mv`. If you use a method that copies rather than moves the database directory, remove the original database directory after copying it.

4. Create a soft link in the data directory to the moved database directory:

   ```bash
   $> ln -s /path/to/mydb1 /path/to/datadir
   ```

   The command creates a symlink named `mydb1` in the data directory.

5. Restart the server.

### 8.12.2.2 Using Symbolic Links for MyISAM Tables on Unix

Note

Symbolic link support as described here, along with the `--symbolic-links` option that controls it, and is deprecated; expect these to be removed in a future version of MySQL. In addition, the option is disabled by default.

Symlinks are fully supported only for MyISAM tables. For files used by tables for other storage engines, you may get strange problems if you try to use symbolic links. For InnoDB tables, use the alternative technique explained in Section 15.6.1.2, “Creating TablesExternally” instead.

Do not symlink tables on systems that do not have a fully operational `realpath()` call. (Linux and Solaris support `realpath()`). To determine whether your system supports symbolic links, check the value of the `have_symlink` system variable using this statement:

```sql
SHOW VARIABLES LIKE 'have_symlink';
```
Using Symbolic Links

The handling of symbolic links for MyISAM tables works as follows:

- In the data directory, you always have the data (.MYD) file and the index (.MYI) file. The data file and index file can be moved elsewhere and replaced in the data directory by symlinks.

- You can symlink the data file and the index file independently to different directories.

- To instruct a running MySQL server to perform the symlinking, use the DATA DIRECTORY and INDEX DIRECTORY options to CREATE TABLE. See Section 13.1.20, "CREATE TABLE Statement". Alternatively, if mysqld is not running, symlinking can be accomplished manually using ln -s from the command line.

  **Note**
  
  The path used with either or both of the DATA DIRECTORY and INDEX DIRECTORY options may not include the MySQL data directory. (Bug #32167)

- myisamchk does not replace a symlink with the data file or index file. It works directly on the file to which the symlink points. Any temporary files are created in the directory where the data file or index file is located. The same is true for the ALTER TABLE, OPTIMIZE TABLE, and REPAIR TABLE statements.

  **Note**
  
  When you drop a table that is using symlinks, both the symlink and the file to which the symlink points are dropped. This is an extremely good reason not to run mysqld as the root operating system user or permit operating system users to have write access to MySQL database directories.

- If you rename a table with ALTER TABLE ... RENAME or RENAME TABLE and you do not move the table to another database, the symlinks in the database directory are renamed to the new names and the data file and index file are renamed accordingly.

- If you use ALTER TABLE ... RENAME or RENAME TABLE to move a table to another database, the table is moved to the other database directory. If the table name changed, the symlinks in the new database directory are renamed to the new names and the data file and index file are renamed accordingly.

- If you are not using symlinks, start mysqld with the --skip-symbolic-links option to ensure that no one can use mysqld to drop or rename a file outside of the data directory.

These table symlink operations are not supported:

- ALTER TABLE ignores the DATA DIRECTORY and INDEX DIRECTORY table options.

### 8.12.2.3 Using Symbolic Links for Databases on Windows

On Windows, symbolic links can be used for database directories. This enables you to put a database directory at a different location (for example, on a different disk) by setting up a symbolic link to it. Use of database symlinks on Windows is similar to their use on Unix, although the procedure for setting up the link differs.

Suppose that you want to place the database directory for a database named mydb at D:\data\mydb. To do this, create a symbolic link in the MySQL data directory that points to D:\data\mydb. However, before creating the symbolic link, make sure that the D:\data\mydb directory exists by creating it if necessary. If you already have a database directory named mydb in the data directory, move it to D:\data. Otherwise, the symbolic link has no effect. To avoid problems, make sure that the server is not running when you move the database directory.
On Windows, you can create a symlink using the `mklink` command. This command requires administrative privileges.

1. Make sure that the desired path to the database exists. For this example, we use `D:\data\mydb`, and a database named `mydb`.

2. If the database does not already exist, issue `CREATE DATABASE mydb` in the `mysql` client to create it.

3. Stop the MySQL service.

4. Using Windows Explorer or the command line, move the directory `mydb` from the data directory to `D: \data`, replacing the directory of the same name.

5. If you are not already using the command prompt, open it, and change location to the data directory, like this:

   ```
   C:\> cd \path\to\datadir
   ```

   If your MySQL installation is in the default location, you can use this:

   ```
   C:\> cd C:\ProgramData\MySQL\MySQL Server 8.2\Data
   ```

6. In the data directory, create a symlink named `mydb` that points to the location of the database directory:

   ```
   C:\> mklink /d mydb D:\data\mydb
   ```

7. Start the MySQL service.

   After this, all tables created in the database `mydb` are created in `D:\data\mydb`.

Alternatively, on any version of Windows supported by MySQL, you can create a symbolic link to a MySQL database by creating a `.sym` file in the data directory that contains the path to the destination directory. The file should be named `db_name.sym`, where `db_name` is the database name.

Support for database symbolic links on Windows using `.sym` files is enabled by default. If you do not need `.sym` file symbolic links, you can disable support for them by starting `mysqld` with the `--skip-symbolic-links` option. To determine whether your system supports `.sym` file symbolic links, check the value of the `have_symlink` system variable using this statement:

```
SHOW VARIABLES LIKE 'have_symlink';
```

To create a `.sym` file symlink, use this procedure:

1. Change location into the data directory:

   ```
   C:\> cd \path\to\datadir
   ```

2. In the data directory, create a text file named `mydb.sym` that contains this path name: `D:\data\mydb`.

   ```
   Note
   The path name to the new database and tables should be absolute. If you specify a relative path, the location is relative to the `mydb.sym` file.
   ```

   After this, all tables created in the database `mydb` are created in `D:\data\mydb`.

8.12.3 Optimizing Memory Use

1963
8.12.3.1 How MySQL Uses Memory

MySQL allocates buffers and caches to improve performance of database operations. The default configuration is designed to permit a MySQL server to start on a virtual machine that has approximately 512MB of RAM. You can improve MySQL performance by increasing the values of certain cache and buffer-related system variables. You can also modify the default configuration to run MySQL on systems with limited memory.

The following list describes some of the ways that MySQL uses memory. Where applicable, relevant system variables are referenced. Some items are storage engine or feature specific.

• The InnoDB buffer pool is a memory area that holds cached InnoDB data for tables, indexes, and other auxiliary buffers. For efficiency of high-volume read operations, the buffer pool is divided into pages that can potentially hold multiple rows. For efficiency of cache management, the buffer pool is implemented as a linked list of pages; data that is rarely used is aged out of the cache, using a variation of the LRU algorithm. For more information, see Section 15.5.1, “Buffer Pool”.

The size of the buffer pool is important for system performance:

• InnoDB allocates memory for the entire buffer pool at server startup, using malloc() operations. The innodb_buffer_pool_size system variable defines the buffer pool size. Typically, a recommended innodb_buffer_pool_size value is 50 to 75 percent of system memory. innodb_buffer_pool_size can be configured dynamically, while the server is running. For more information, see Section 15.8.3.1, “Configuring InnoDB Buffer Pool Size”.

• On systems with a large amount of memory, you can improve concurrency by dividing the buffer pool into multiple buffer pool instances. The innodb_buffer_pool_instances system variable defines the number of buffer pool instances.

• A buffer pool that is too small may cause excessive churning as pages are flushed from the buffer pool only to be required again a short time later.

• A buffer pool that is too large may cause swapping due to competition for memory.

• The storage engine interface enables the optimizer to provide information about the size of the record buffer to be used for scans that the optimizer estimates are likely to read multiple rows. The buffer size can vary based on the size of the estimate. InnoDB uses this variable-size buffering capability to take advantage of row prefetching, and to reduce the overhead of latching and B-tree navigation.

• All threads share the MyISAM key buffer. The key_buffer_size system variable determines its size.

For each MyISAM table the server opens, the index file is opened once; the data file is opened once for each concurrently running thread that accesses the table. For each concurrent thread, a table structure, column structures for each column, and a buffer of size $3 \times N$ are allocated (where $N$ is the maximum row length, not counting BLOB columns). A BLOB column requires five to eight bytes plus the length of the BLOB data. The MyISAM storage engine maintains one extra row buffer for internal use.

• The myisam_use_mmap system variable can be set to 1 to enable memory-mapping for all MyISAM tables.

• If an internal in-memory temporary table becomes too large (as determined using the tmp_table_size and max_heap_table_size system variables), MySQL automatically converts the table from in-memory to on-disk format, which uses the InnoDB storage engine. You can increase the permissible temporary table size as described in Section 8.4.4, “Internal Temporary Table Use in MySQL”.

For MEMORY tables explicitly created with CREATE TABLE, only the max_heap_table_size system variable determines how large a table can grow, and there is no conversion to on-disk format.
• The MySQL Performance Schema is a feature for monitoring MySQL server execution at a low level. The Performance Schema dynamically allocates memory incrementally, scaling its memory use to actual server load, instead of allocating required memory during server startup. Once memory is allocated, it is not freed until the server is restarted. For more information, see Section 27.17, “The Performance Schema Memory-Allocation Model”.

• Each thread that the server uses to manage client connections requires some thread-specific space. The following list indicates these and which system variables control their size:

  • A stack (\texttt{thread_stack})
  
  • A connection buffer (\texttt{net_buffer_length})
  
  • A result buffer (\texttt{net_buffer_length})

  The connection buffer and result buffer each begin with a size equal to \texttt{net_buffer_length} bytes, but are dynamically enlarged up to \texttt{max_allowed_packet} bytes as needed. The result buffer shrinks to \texttt{net_buffer_length} bytes after each SQL statement. While a statement is running, a copy of the current statement string is also allocated.

  Each connection thread uses memory for computing statement digests. The server allocates \texttt{max_digest_length} bytes per session. See Section 27.10, “Performance Schema Statement Digests and Sampling”.

• All threads share the same base memory.

• When a thread is no longer needed, the memory allocated to it is released and returned to the system unless the thread goes back into the thread cache. In that case, the memory remains allocated.

• Each request that performs a sequential scan of a table allocates a \textit{read buffer}. The \texttt{read_buffer_size} system variable determines the buffer size.

• When reading rows in an arbitrary sequence (for example, following a sort), a \textit{random-read buffer} may be allocated to avoid disk seeks. The \texttt{read_rnd_buffer_size} system variable determines the buffer size.

• All joins are executed in a single pass, and most joins can be done without even using a temporary table. Most temporary tables are memory-based hash tables. Temporary tables with a large row length (calculated as the sum of all column lengths) or that contain \texttt{BLOB} columns are stored on disk.

• Most requests that perform a sort allocate a sort buffer and zero to two temporary files depending on the result set size. See Section B.3.3.5, “Where MySQL Stores Temporary Files”.

• Almost all parsing and calculating is done in thread-local and reusable memory pools. No memory overhead is needed for small items, thus avoiding the normal slow memory allocation and freeing. Memory is allocated only for unexpectedly large strings.

• For each table having \texttt{BLOB} columns, a buffer is enlarged dynamically to read in larger \texttt{BLOB} values. If you scan a table, the buffer grows as large as the largest \texttt{BLOB} value.

• MySQL requires memory and descriptors for the table cache. Handler structures for all in-use tables are saved in the table cache and managed as “First In, First Out” (FIFO). The \texttt{table_open_cache} system variable defines the initial table cache size; see Section 8.4.3.1, “How MySQL Opens and Closes Tables”.

MySQL also requires memory for the table definition cache. The \texttt{table_definition_cache} system variable defines the number of table definitions that can be stored in the table definition cache. If you use
Optimizing Memory Use

A large number of tables, you can create a large table definition cache to speed up the opening of tables. The table definition cache takes less space and does not use file descriptors, unlike the table cache.

• A `FLUSH TABLES` statement or `mysqladmin flush-tables` command closes all tables that are not in use at once and marks all in-use tables to be closed when the currently executing thread finishes. This effectively frees most in-use memory. `FLUSH TABLES` does not return until all tables have been closed.

• The server caches information in memory as a result of `GRANT`, `CREATE USER`, `CREATE SERVER`, and `INSTALL PLUGIN` statements. This memory is not released by the corresponding `REVOKE`, `DROP USER`, `DROP SERVER`, and `UNINSTALL PLUGIN` statements, so for a server that executes many instances of the statements that cause caching, there is an increase in cached memory use unless it is freed with `FLUSH PRIVILEGES`.

• In a replication topology, the following settings affect memory usage, and can be adjusted as required:

  • The `max_allowed_packet` system variable on a replication source limits the maximum message size that the source sends to its replicas for processing. This setting defaults to 64M.

  • The system variable `replica_pending_jobs_size_max` on a multithreaded replica sets the maximum amount of memory that is made available for holding messages awaiting processing. This setting defaults to 128M. The memory is only allocated when needed, but it might be used if your replication topology handles large transactions sometimes. It is a soft limit, and larger transactions can be processed.

  • The `rpl_read_size` system variable on a replication source or replica controls the minimum amount of data in bytes that is read from the binary log files and relay log files. The default is 8192 bytes. A buffer the size of this value is allocated for each thread that reads from the binary log and relay log files, including dump threads on sources and coordinator threads on replicas.

  • The `binlog_transaction_dependency_history_size` system variable limits the number of row hashes held as an in-memory history.

  • The `max_binlog_cache_size` system variable specifies the upper limit of memory usage by an individual transaction.

  • The `max_binlog_stmt_cache_size` system variable specifies the upper limit of memory usage by the statement cache.

`ps` and other system status programs may report that `mysqld` uses a lot of memory. This may be caused by thread stacks on different memory addresses. For example, the Solaris version of `ps` counts the unused memory between stacks as used memory. To verify this, check available swap with `swap -s`. We test `mysqld` with several memory-leakage detectors (both commercial and Open Source), so there should be no memory leaks.

### 8.12.3.2 Monitoring MySQL Memory Usage

The following example demonstrates how to use `Performance Schema` and `sys schema` to monitor MySQL memory usage.

Most Performance Schema memory instrumentation is disabled by default. Instruments can be enabled by updating the `ENABLED` column of the Performance Schema `setup_instruments` table. Memory instruments have names in the form of `memory/code_area/instrument_name`, where `code_area` is a value such as `sql` or `innodb`, and `instrument_name` is the instrument detail.

1. To view available MySQL memory instruments, query the Performance Schema `setup_instruments` table. The following query returns hundreds of memory instruments for all code areas.
Optimizing Memory Use

You can narrow results by specifying a code area. For example, you can limit results to InnoDB memory instruments by specifying innodb as the code area.

Depending on your MySQL installation, code areas may include performance_schema, sql, client, innodb, myisam, csv, memory, blackhole, archive, partition, and others.

2. To enable memory instruments, add a performance-schema-instrument rule to your MySQL configuration file. For example, to enable all memory instruments, add this rule to your configuration file and restart the server:

   ```
   performance-schema-instrument='memory/%=COUNTED'
   ```

   Note
   Enabling memory instruments at startup ensures that memory allocations that occur at startup are counted.

   After restarting the server, the ENABLED column of the Performance Schema setup_instruments table should report YES for memory instruments that you enabled. The TIMED column in the setup_instruments table is ignored for memory instruments because memory operations are not timed.

3. Query memory instrument data. In this example, memory instrument data is queried in the Performance Schema memory_summary_global_by_event_name table, which summarizes data by EVENT_NAME. The EVENT_NAME is the name of the instrument.
The following query returns memory data for the InnoDB buffer pool. For column descriptions, see Section 27.12.20.10, “Memory Summary Tables”.

```
mysql> SELECT * FROM performance_schema.memory_summary_global_by_event_name
    -> WHERE EVENT_NAME LIKE 'memory/innodb/buf_buf_pool'
    ->
    -> EVENT_NAME: memory/innodb/buf_buf_pool
    -> COUNT_ALLOC: 1
    -> COUNT_FREE: 0
    -> SUM_NUMBER_OF_BYTES_ALLOC: 137428992
    -> SUM_NUMBER_OF_BYTES_FREE: 0
    -> LOW_COUNT_USED: 0
    -> CURRENT_COUNT_USED: 1
    -> HIGH_COUNT_USED: 1
    -> LOW_NUMBER_OF_BYTES_USED: 0
    -> CURRENT_NUMBER_OF_BYTES_USED: 137428992
    -> HIGH_NUMBER_OF_BYTES_USED: 137428992
```

The same underlying data can be queried using the sys schema memory_global_by_current_bytes table, which shows current memory usage within the server globally, broken down by allocation type.

```
mysql> SELECT * FROM sys.memory_global_by_current_bytes
    -> WHERE event_name LIKE 'memory/innodb/buf_buf_pool'
    ->
    -> *************************** 1. row ***************************
    -> event_name: memory/innodb/buf_buf_pool
    -> current_count: 1
    -> current_alloc: 131.06 MiB
    -> current_avg_alloc: 131.06 MiB
    -> high_count: 1
    -> high_alloc: 131.06 MiB
    -> high_avg_alloc: 131.06 MiB
```

This sys schema query aggregates currently allocated memory (current_alloc) by code area:

```
mysql> SELECT SUBSTRING_INDEX(event_name,'/',2) AS code_area,
    -> FORMAT_BYTES(SUM(current_alloc)) AS current_alloc
    -> FROM sys.x$memory_global_by_current_bytes
    -> GROUP BY SUBSTRING_INDEX(event_name,'/',2)
    -> ORDER BY SUM(current_alloc) DESC;
```

```
+---------------------------+---------------+
| code_area                 | current_alloc |
+---------------------------+---------------+
| memory/innodb             | 843.24 MiB    |
| memory/performance_schema | 81.29 MiB     |
| memory/mysys              | 8.20 MiB      |
| memory/sql                | 2.47 MiB      |
| memory/memory             | 174.01 KiB    |
| memory/myisam             | 46.53 KiB     |
| memory/blackhole          | 512 bytes     |
| memory/federated          | 512 bytes     |
| memory/csv                | 512 bytes     |
| memory/vio                | 496 bytes     |
```

For more information about sys schema, see Chapter 28, MySQL sys Schema.

### 8.12.3.3 Enabling Large Page Support

Some hardware and operating system architectures support memory pages greater than the default (usually 4KB). The actual implementation of this support depends on the underlying hardware and operating system. Applications that perform a lot of memory accesses may obtain performance improvements by using large pages due to reduced Translation Lookaside Buffer (TLB) misses.
In MySQL, large pages can be used by InnoDB, to allocate memory for its buffer pool and additional memory pool.

Standard use of large pages in MySQL attempts to use the largest size supported, up to 4MB. Under Solaris, a “super large pages” feature enables uses of pages up to 256MB. This feature is available for recent SPARC platforms. It can be enabled or disabled by using the `--super-large-pages` or `--skip-super-large-pages` option.

MySQL also supports the Linux implementation of large page support (which is called HugeTLB in Linux).

Before large pages can be used on Linux, the kernel must be enabled to support them and it is necessary to configure the HugeTLB memory pool. For reference, the HugeTBL API is documented in the `Documentation/vm/hugetlbpage.txt` file of your Linux sources.

The kernels for some recent systems such as Red Hat Enterprise Linux may have the large pages feature enabled by default. To check whether this is true for your kernel, use the following command and look for output lines containing “huge”:

```bash
grep -i huge /proc/meminfo
```

```
AnonHugePages: 2658304 kB
ShmemHugePages: 0 kB
HugePages_Total: 0
HugePages_Free: 0
HugePages_Rsvd: 0
HugePages_Surp: 0
Hugepagesize: 2048 kB
Hugetlb: 0 kB
```

The nonempty command output indicates that large page support is present, but the zero values indicate that no pages are configured for use.

If your kernel needs to be reconfigured to support large pages, consult the `hugetlbpage.txt` file for instructions.

Assuming that your Linux kernel has large page support enabled, configure it for use by MySQL using the following steps:

1. Determine the number of large pages needed. This is the size of the InnoDB buffer pool divided by the large page size, which we can calculate as `innodb_buffer_pool_size / Hugepagesize`. Assuming the default value for the buffer pool size and using the `Hugepagesize` value obtained from `/proc/meminfo`, this is 134217728 / 2048, or 65536 (64K). We call this value $P$.

2. As system root, open the file `/etc/sysctl.conf` in a text editor, and add the line shown here, where $P$ is the number of large pages obtained in the previous step:

   ```
   vm.nr_hugepages=$P
   ```

   Using the actual value obtained previously, the additional line should look like this:

   ```
   vm.nr_huge_pages=65536
   ```

   Save the updated file.

3. As system root, run the following command:

   ```
   $ sudo sysctl -p
   ```

   **Note**

   On some systems the large pages file may be named slightly differently; for example, some distributions call it `nr_hugepages`. In the event `sysctl` returns...
Measuring Performance (Benchmarking)

To verify the large page configuration, check /proc/meminfo again as described previously. Now you should see some additional nonzero values in the output, similar to this:

```
$> grep -i huge /proc/meminfo
AnonHugePages:   2686976 kB
ShmemHugePages:        0 kB
HugePages_Total:     233
HugePages_Free:      233
HugePages_Rsvd:        0
HugePages_Surp:        0
Hugepagesize:       2048 kB
Hugetlb:          477184 kB
```

4. Optionally, you may wish to compact the Linux VM. You can do this using a sequence of commands, possibly in a script file, similar to what is shown here:

```bash
sync
sync
sync
echo 3 > /proc/sys/vm/drop_caches
echo 1 > /proc/sys/vm/compact_memory
```

See your operating platform documentation for more information about how to do this.

5. Check any configuration files such as my.cnf used by the server, and make sure that innodb_buffer_pool_chunk_size is set larger than the huge page size. The default for this variable is 128M.

6. Large page support in the MySQL server is disabled by default. To enable it, start the server with --large-pages. You can also do so by adding the following line to the [mysqld] section of the server my.cnf file:

```ini
large-pages=ON
```

With this option enabled, InnoDB uses large pages automatically for its buffer pool and additional memory pool. If InnoDB cannot do this, it falls back to use of traditional memory and writes a warning to the error log: Warning: Using conventional memory pool.

You can verify that MySQL is now using large pages by checking /proc/meminfo again after restarting mysqld, like this:

```
$> grep -i huge /proc/meminfo
AnonHugePages:   2516992 kB
ShmemHugePages:        0 kB
HugePages_Total:     233
HugePages_Free:      222
HugePages_Rsvd:       55
HugePages_Surp:        0
Hugepagesize:       2048 kB
Hugetlb:          477184 kB
```

8.13 Measuring Performance (Benchmarking)

To measure performance, consider the following factors:

- Whether you are measuring the speed of a single operation on a quiet system, or how a set of operations (a “workload”) works over a period of time. With simple tests, you usually test how changing one aspect (a configuration setting, the set of indexes on a table, the SQL clauses in a query) affects
performance. Benchmarks are typically long-running and elaborate performance tests, where the results could dictate high-level choices such as hardware and storage configuration, or how soon to upgrade to a new MySQL version.

- For benchmarking, sometimes you must simulate a heavy database workload to get an accurate picture.
- Performance can vary depending on so many different factors that a difference of a few percentage points might not be a decisive victory. The results might shift the opposite way when you test in a different environment.
- Certain MySQL features help or do not help performance depending on the workload. For completeness, always test performance with those features turned on and turned off. The most important feature to try with each workload is the adaptive hash index for InnoDB tables.

This section progresses from simple and direct measurement techniques that a single developer can do, to more complicated ones that require additional expertise to perform and interpret the results.

8.13.1 Measuring the Speed of Expressions and Functions

To measure the speed of a specific MySQL expression or function, invoke the `BENCHMARK()` function using the `mysql` client program. Its syntax is `BENCHMARK(loop_count, expr)`. The return value is always zero, but `mysql` prints a line displaying approximately how long the statement took to execute. For example:

```
mysql> SELECT BENCHMARK(1000000,1+1);
+------------------------+
<table>
<thead>
<tr>
<th>BENCHMARK(1000000,1+1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
+------------------------+
1 row in set (0.32 sec)
```

This result was obtained on a Pentium II 400MHz system. It shows that MySQL can execute 1,000,000 simple addition expressions in 0.32 seconds on that system.

The built-in MySQL functions are typically highly optimized, but there may be some exceptions. `BENCHMARK()` is an excellent tool for finding out if some function is a problem for your queries.

8.13.2 Using Your Own Benchmarks

Benchmark your application and database to find out where the bottlenecks are. After fixing one bottleneck (or by replacing it with a “dummy” module), you can proceed to identify the next bottleneck. Even if the overall performance for your application currently is acceptable, you should at least make a plan for each bottleneck and decide how to solve it if someday you really need the extra performance.

It is very common for a problem to occur only when the system is very heavily loaded. We have had many customers who contact us when they have a (tested) system in production and have encountered load problems. In most cases, performance problems turn out to be due to issues of basic database design (for example, table scans are not good under high load) or problems with the operating system or libraries. Most of the time, these problems would be much easier to fix if the systems were not already in production.

To avoid problems like this, benchmark your whole application under the worst possible load:

- The `mysqlslap` program can be helpful for simulating a high load produced by multiple clients issuing queries simultaneously. See Section 4.5.8, “mysqlslap — A Load Emulation Client”.

1971
Measuring Performance with performance_schema

- You can also try benchmarking packages such as SysBench and DBT2, available at https://launchpad.net/sysbench, and http://osdlt2.sourceforge.net/#dbt2.

These programs or packages can bring a system to its knees, so be sure to use them only on your development systems.

8.13.3 Measuring Performance with performance_schema

You can query the tables in the `performance_schema` database to see real-time information about the performance characteristics of your server and the applications it is running. See Chapter 27, MySQL Performance Schema for details.

8.14 Examining Server Thread (Process) Information

To ascertain what your MySQL server is doing, it can be helpful to examine the process list, which indicates the operations currently being performed by the set of threads executing within the server. For example:

```
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
   Id: 5
User: event_scheduler
Host: localhost
   db: NULL
Command: Daemon
   Time: 2756681
   State: Waiting on empty queue
    Info: NULL
*************************** 2. row ***************************
   Id: 20
User: me
Host: localhost:52943
   db: test
Command: Query
   Time: 0
   State: starting
    Info: SHOW PROCESSLIST
```

Threads can be killed with the `KILL` statement. See Section 13.7.8.4, “KILL Statement”.

8.14.1 Accessing the Process List

The following discussion enumerates the sources of process information, the privileges required to see process information, and describes the content of process list entries.

- Sources of Process Information
- Privileges Required to Access the Process List
- Content of Process List Entries

Sources of Process Information

Process information is available from these sources:

- The `SHOW PROCESSLIST` statement: Section 13.7.7.31, “SHOW PROCESSLIST Statement”
- The `mysqladmin processlist` command: Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”
Accessing the Process List

- The `INFORMATION_SCHEMA PROCESSLIST` table: Section 26.3.23, “The INFORMATION_SCHEMA PROCESSLIST Table”

- The Performance Schema `processlist` table: Section 27.12.22.7, “The processlist Table”

- The Performance Schema `threads` table columns with names having a prefix of `PROCESSLIST_`: Section 27.12.22.8, “The threads Table”

- The `sys` schema `processlist` and `session` views: Section 28.4.3.22, “The processlist and x$processlist Views”, and Section 28.4.3.33, “The session and x$session Views”

The `threads` table compares to SHOW PROCESSLIST, INFORMATION_SCHEMA PROCESSLIST, and `mysqladmin processlist` as follows:

- Access to the `threads` table does not require a mutex and has minimal impact on server performance. The other sources have negative performance consequences because they require a mutex.

  **Note**

  An alternative implementation for SHOW PROCESSLIST is available based on the Performance Schema `processlist` table, which, like the `threads` table, does not require a mutex and has better performance characteristics. For details, see Section 27.12.22.7, “The processlist Table”.

- The `threads` table displays background threads, which the other sources do not. It also provides additional information for each thread that the other sources do not, such as whether the thread is a foreground or background thread, and the location within the server associated with the thread. This means that the `threads` table can be used to monitor thread activity the other sources cannot.

- You can enable or disable Performance Schema thread monitoring, as described in Section 27.12.22.8, “The threads Table”.

For these reasons, DBAs who perform server monitoring using one of the other thread information sources may wish to monitor using the `threads` table instead.

The `sys` schema `processlist` view presents information from the Performance Schema `threads` table in a more accessible format. The `sys` schema `session` view presents information about user sessions like the `sys` schema `processlist` view, but with background processes filtered out.

### Privileges Required to Access the Process List

For most sources of process information, if you have the `PROCESS` privilege, you can see all threads, even those belonging to other users. Otherwise (without the `PROCESS` privilege), nonanonymous users have access to information about their own threads but not threads for other users, and anonymous users have no access to thread information.

The Performance Schema `threads` table also provides thread information, but table access uses a different privilege model. See Section 27.12.22.8, “The threads Table”.

### Content of Process List Entries

Each process list entry contains several pieces of information. The following list describes them using the labels from SHOW PROCESSLIST output. Other process information sources use similar labels.

- **Id** is the connection identifier for the client associated with the thread.

- **User** and **Host** indicate the account associated with the thread.
Thread Command Values

- **db** is the default database for the thread, or **NULL** if none has been selected.

- **Command** and **State** indicate what the thread is doing.

  Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

  The following sections list the possible **Command** values, and **State** values grouped by category. The meaning for some of these values is self-evident. For others, additional description is provided.

  **Note**

  Applications that examine process list information should be aware that the commands and states are subject to change.

- **Time** indicates how long the thread has been in its current state. The thread's notion of the current time may be altered in some cases: The thread can change the time with `SET TIMESTAMP = value`. For a replica SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the replica host. See Section 17.2.3, “Replication Threads”.

- **Info** indicates the statement the thread is executing, or **NULL** if it is executing no statement. For `SHOW PROCESSLIST`, this value contains only the first 100 characters of the statement. To see complete statements, use `SHOW FULL PROCESSLIST` (or query a different process information source).

### 8.14.2 Thread Command Values

A thread can have any of the following **Command** values:

- **Binlog Dump**
  This is a thread on a replication source for sending binary log contents to a replica.

- **Change user**
  The thread is executing a change user operation.

- **Close stmt**
  The thread is closing a prepared statement.

- **Connect**
  Used by replication receiver threads connected to the source, and by replication worker threads.

- **Connect Out**
  A replica is connecting to its source.

- **Create DB**
  The thread is executing a create database operation.

- **Daemon**
  This thread is internal to the server, not a thread that services a client connection.

- **Debug**
  The thread is generating debugging information.
Thread Command Values

- **Delayed insert**
  The thread is a delayed insert handler.
- **Drop DB**
  The thread is executing a drop database operation.
- **Error**
- **Execute**
  The thread is executing a prepared statement.
- **Fetch**
  The thread is fetching the results from executing a prepared statement.
- **Field List**
  The thread is retrieving information for table columns.
- **Init DB**
  The thread is selecting a default database.
- **Kill**
  The thread is killing another thread.
- **Long Data**
  The thread is retrieving long data in the result of executing a prepared statement.
- **Ping**
  The thread is handling a server ping request.
- **Prepare**
  The thread is preparing a prepared statement.
- **Processlist**
  The thread is producing information about server threads.
- **Query**
  Employed for user clients while executing queries by single-threaded replication applier threads, as well as by the replication coordinator thread.
- **Quit**
  The thread is terminating.
- **Refresh**
  The thread is flushing table, logs, or caches, or resetting status variable or replication server information.
- **Register Slave**
General Thread States

The thread is registering a replica server.

- Reset stmt

The thread is resetting a prepared statement.

- Set option

The thread is setting or resetting a client statement execution option.

- Shutdown

The thread is shutting down the server.

- Sleep

The thread is waiting for the client to send a new statement to it.

- Statistics

The thread is producing server status information.

- Time

Unused.

8.14.3 General Thread States

The following list describes thread State values that are associated with general query processing and not more specialized activities such as replication. Many of these are useful only for finding bugs in the server.

- After create

  This occurs when the thread creates a table (including internal temporary tables), at the end of the function that creates the table. This state is used even if the table could not be created due to some error.

- altering table

  The server is in the process of executing an in-place ALTER TABLE.

- Analyzing

  The thread is calculating a MyISAM table key distributions (for example, for ANALYZE TABLE).

- checking permissions

  The thread is checking whether the server has the required privileges to execute the statement.

- Checking table

  The thread is performing a table check operation.

- cleaning up

  The thread has processed one command and is preparing to free memory and reset certain state variables.
General Thread States

- **closing tables**
  The thread is flushing the changed table data to disk and closing the used tables. This should be a fast operation. If not, verify that you do not have a full disk and that the disk is not in very heavy use.

- **committing alter table to storage engine**
  The server has finished an in-place `ALTER TABLE` and is committing the result.

- **converting HEAP to ondisk**
  The thread is converting an internal temporary table from a `MEMORY` table to an on-disk table.

- **copy to tmp table**
  The thread is processing an `ALTER TABLE` statement. This state occurs after the table with the new structure has been created but before rows are copied into it.

  For a thread in this state, the Performance Schema can be used to obtain about the progress of the copy operation. See Section 27.12.5, “Performance Schema Stage Event Tables”.

- **Copying to group table**
  If a statement has different `ORDER BY` and `GROUP BY` criteria, the rows are sorted by group and copied to a temporary table.

- **Copying to tmp table**
  The server is copying to a temporary table in memory.

- **Copying to tmp table on disk**
  The server is copying to a temporary table on disk. The temporary result set has become too large (see Section 8.4.4, “Internal Temporary Table Use in MySQL”). Consequently, the thread is changing the temporary table from in-memory to disk-based format to save memory.

- **Creating index**
  The thread is processing `ALTER TABLE ... ENABLE KEYS` for a `MyISAM` table.

- **Creating sort index**
  The thread is processing a `SELECT` that is resolved using an internal temporary table.

- **creating table**
  The thread is creating a table. This includes creation of temporary tables.

- **Creating tmp table**
  The thread is creating a temporary table in memory or on disk. If the table is created in memory but later is converted to an on-disk table, the state during that operation is **Copying to tmp table on disk**.

- **deleting from main table**
  The server is executing the first part of a multiple-table delete. It is deleting only from the first table, and saving columns and offsets to be used for deleting from the other (reference) tables.

- **deleting from reference tables**
General Thread States

The server is executing the second part of a multiple-table delete and deleting the matched rows from the other tables.

- **discard_or_import_tablespace**
  
The thread is processing an \texttt{ALTER \ TABLE ... DISCARD TABLESPACE} or \texttt{ALTER \ TABLE ... IMPORT TABLESPACE} statement.

- **end**
  
  This occurs at the end but before the cleanup of \texttt{ALTER \ TABLE, CREATE \ VIEW, DELETE, INSERT, SELECT, or UPDATE} statements.

  For the \texttt{end} state, the following operations could be happening:

  - Writing an event to the binary log
  - Freeing memory buffers, including for blobs

- **executing**
  
The thread has begun executing a statement.

- **Execution of \texttt{init\_command}**
  
The thread is executing statements in the value of the \texttt{init\_command} system variable.

- **freeing items**
  
The thread has executed a command. This state is usually followed by \texttt{cleaning up}.

- **FULLTEXT initialization**
  
The server is preparing to perform a natural-language full-text search.

- **init**
  
  This occurs before the initialization of \texttt{ALTER \ TABLE, DELETE, INSERT, SELECT, or UPDATE} statements. Actions taken by the server in this state include flushing the binary log and the \texttt{InnoDB} log.

- **Killed**
  
  Someone has sent a \texttt{KILL} statement to the thread and it should abort next time it checks the kill flag. The flag is checked in each major loop in MySQL, but in some cases it might still take a short time for the thread to die. If the thread is locked by some other thread, the kill takes effect as soon as the other thread releases its lock.

- **Locking system tables**
  
The thread is trying to lock a system table (for example, a time zone or log table).

- **logging slow query**
  
The thread is writing a statement to the slow-query log.

- **login**
  
The initial state for a connection thread until the client has been authenticated successfully.
• **manage keys**
  The server is enabling or disabling a table index.

• **Opening system tables**
  The thread is trying to open a system table (for example, a time zone or log table).

• **Opening tables**
  The thread is trying to open a table. This should be a very fast procedure, unless something prevents opening. For example, an `ALTER TABLE` or a `LOCK TABLE` statement can prevent opening a table until the statement is finished. It is also worth checking that your `table_open_cache` value is large enough.

For system tables, the **Opening system tables** state is used instead.

• **optimizing**
  The server is performing initial optimizations for a query.

• **preparing**
  This state occurs during query optimization.

• **preparing for alter table**
  The server is preparing to execute an in-place `ALTER TABLE`.

• **Purging old relay logs**
  The thread is removing unneeded relay log files.

• **query end**
  This state occurs after processing a query but before the **freeing items** state.

• **Receiving from client**
  The server is reading a packet from the client.

• **Removing duplicates**
  The query was using `SELECT DISTINCT` in such a way that MySQL could not optimize away the distinct operation at an early stage. Because of this, MySQL requires an extra stage to remove all duplicated rows before sending the result to the client.

• **removing tmp table**
  The thread is removing an internal temporary table after processing a `SELECT` statement. This state is not used if no temporary table was created.

• **rename**
  The thread is renaming a table.

• **rename result table**
  The thread is processing an `ALTER TABLE` statement, has created the new table, and is renaming it to replace the original table.
General Thread States

- **Reopen tables**
  The thread got a lock for the table, but noticed after getting the lock that the underlying table structure changed. It has freed the lock, closed the table, and is trying to reopen it.

- **Repair by sorting**
  The repair code is using a sort to create indexes.

- **Repair done**
  The thread has completed a multithreaded repair for a MyISAM table.

- **Repair with keycache**
  The repair code is using creating keys one by one through the key cache. This is much slower than Repair by sorting.

- **Rolling back**
  The thread is rolling back a transaction.

- **Saving state**
  For MyISAM table operations such as repair or analysis, the thread is saving the new table state to the .MYI file header. State includes information such as number of rows, the AUTO_INCREMENT counter, and key distributions.

- **Searching rows for update**
  The thread is doing a first phase to find all matching rows before updating them. This has to be done if the UPDATE is changing the index that is used to find the involved rows.

- **Sending data**
  This state is now included in the Executing state.

- **Sending to client**
  The server is writing a packet to the client.

- **setup**
  The thread is beginning an ALTER TABLE operation.

- **Sorting for group**
  The thread is doing a sort to satisfy a GROUP BY.

- **Sorting for order**
  The thread is doing a sort to satisfy an ORDER BY.

- **Sorting index**
  The thread is sorting index pages for more efficient access during a MyISAM table optimization operation.

- **Sorting result**
General Thread States

For a `SELECT` statement, this is similar to Creating sort index, but for nontemporary tables.

- **starting**
  The first stage at the beginning of statement execution.

- **statistics**
  The server is calculating statistics to develop a query execution plan. If a thread is in this state for a long time, the server is probably disk-bound performing other work.

- **System lock**
  The thread has called `mysql_lock_tables()` and the thread state has not been updated since. This is a very general state that can occur for many reasons.

  For example, the thread is going to request or is waiting for an internal or external system lock for the table. This can occur when InnoDB waits for a table-level lock during execution of `LOCK TABLES`. If this state is being caused by requests for external locks and you are not using multiple `mysqld` servers that are accessing the same MyISAM tables, you can disable external system locks with the `--skip-external-locking` option. However, external locking is disabled by default, so it is likely that this option has no effect. For `SHOW PROFILE`, this state means the thread is requesting the lock (not waiting for it).

  For system tables, the Locking system tables state is used instead.

- **update**
  The thread is getting ready to start updating the table.

- **Updating**
  The thread is searching for rows to update and is updating them.

- **updating main table**
  The server is executing the first part of a multiple-table update. It is updating only the first table, and saving columns and offsets to be used for updating the other (reference) tables.

- **updating reference tables**
  The server is executing the second part of a multiple-table update and updating the matched rows from the other tables.

- **User lock**
  The thread is going to request or is waiting for an advisory lock requested with a `GET_LOCK()` call. For `SHOW PROFILE`, this state means the thread is requesting the lock (not waiting for it).

- **User sleep**
  The thread has invoked a `SLEEP()` call.

- **Waiting for commit lock**
  `FLUSH TABLES WITH READ LOCK` is waiting for a commit lock.

- **waiting for handler commit**
The thread is waiting for a transaction to commit versus other parts of query processing.

- **Waiting for tables**

  The thread got a notification that the underlying structure for a table has changed and it needs to reopen the table to get the new structure. However, to reopen the table, it must wait until all other threads have closed the table in question.

  This notification takes place if another thread has used `FLUSH TABLES` or one of the following statements on the table in question: `FLUSH TABLES tbl_name`, `ALTER TABLE`, `RENAME TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, or `OPTIMIZE TABLE`.

- **Waiting for table flush**

  The thread is executing `FLUSH TABLES` and is waiting for all threads to close their tables, or the thread got a notification that the underlying structure for a table has changed and it needs to reopen the table to get the new structure. However, to reopen the table, it must wait until all other threads have closed the table in question.

  This notification takes place if another thread has used `FLUSH TABLES` or one of the following statements on the table in question: `FLUSH TABLES tbl_name`, `ALTER TABLE`, `RENAME TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, or `OPTIMIZE TABLE`.

- **Waiting for lock_type lock**

  The server is waiting to acquire a THR_LOCK lock or a lock from the metadata locking subsystem, where `lock_type` indicates the type of lock.

  This state indicates a wait for a THR_LOCK:

  - **Waiting for table level lock**

    These states indicate a wait for a metadata lock:

    - **Waiting for event metadata lock**
    - **Waiting for global read lock**
    - **Waiting for schema metadata lock**
    - **Waiting for stored function metadata lock**
    - **Waiting for stored procedure metadata lock**
    - **Waiting for table metadata lock**
    - **Waiting for trigger metadata lock**

    For information about table lock indicators, see Section 8.11.1, “Internal Locking Methods”. For information about metadata locking, see Section 8.11.4, “Metadata Locking”. To see which locks are blocking lock requests, use the Performance Schema lock tables described at Section 27.12.13, “Performance Schema Lock Tables”.

- **Waiting on cond**

  A generic state in which the thread is waiting for a condition to become true. No specific state information is available.
Replication Source Thread States

- **Writing to net**
  The server is writing a packet to the network.

### 8.14.4 Replication Source Thread States

The following list shows the most common states you may see in the `State` column for the `Binlog Dump` thread of the replication source. If you see no `Binlog Dump` threads on a source, this means that replication is not running; that is, that no replicas are currently connected.

In MySQL 8.0, incompatible changes were made to instrumentation names. Monitoring tools that work with these instrumentation names might be impacted. If the incompatible changes have an impact for you, set the `terminology_use_previous` system variable to `BEFORE_8_0_26` to make MySQL Server use the old versions of the names for the objects specified in the previous list. This enables monitoring tools that rely on the old names to continue working until they can be updated to use the new names.

Set the `terminology_use_previous` system variable with session scope to support individual functions, or global scope to be a default for all new sessions. When global scope is used, the slow query log contains the old versions of the names.

- **Finished reading one binlog; switching to next binlog**
  The thread has finished reading a binary log file and is opening the next one to send to the replica.

- **Master has sent all binlog to slave; waiting for more updates**
  Source has sent all binlog to replica; waiting for more updates
  The thread has read all remaining updates from the binary logs and sent them to the replica. The thread is now idle, waiting for new events to appear in the binary log resulting from new updates occurring on the source.

- **Sending binlog event to slave**
  Sending binlog event to replica
  Binary logs consist of events, where an event is usually an update plus some other information. The thread has read an event from the binary log and is now sending it to the replica.

- **Waiting to finalize termination**
  A very brief state that occurs as the thread is stopping.

### 8.14.5 Replication I/O (Receiver) Thread States

The following list shows the most common states you see in the `State` column for a replication I/O (receiver) thread on a replica server. This state also appears in the `Replica_IO_State` column displayed by `SHOW REPLICA STATUS`, so you can get a good view of what is happening by using that statement.

In MySQL 8.0, incompatible changes were made to instrumentation names. Monitoring tools that work with these instrumentation names might be impacted. If the incompatible changes have an impact for you, set the `terminology_use_previous` system variable to `BEFORE_8_0_26` to make MySQL Server use the old versions of the names for the objects specified in the previous list. This enables monitoring tools that rely on the old names to continue working until they can be updated to use the new names.

Set the `terminology_use_previous` system variable with session scope to support individual functions, or global scope to be a default for all new sessions. When global scope is used, the slow query log contains the old versions of the names.
Replication I/O (Receiver) Thread States

- **Checking master version**
  - Checking source version

  A state that occurs very briefly, after the connection to the source is established.

- **Connecting to master**
  - Connecting to source

  The thread is attempting to connect to the source.

- **Queueing master event to the relay log**
  - Queueing source event to the relay log

  The thread has read an event and is copying it to the relay log so that the SQL thread can process it.

- **Reconnecting after a failed binlog dump request**

  The thread is trying to reconnect to the source.

- **Reconnecting after a failed master event read**
  - Reconnecting after a failed source event read

  The thread is trying to reconnect to the source. When connection is established again, the state becomes **Waiting for master to send event**.

- **Registering slave on master**
  - Registering replica on source

  A state that occurs very briefly after the connection to the source is established.

- **Requesting binlog dump**

  A state that occurs very briefly, after the connection to the source is established. The thread sends to the source a request for the contents of its binary logs, starting from the requested binary log file name and position.

- **Waiting for its turn to commit**

  A state that occurs when the replica thread is waiting for older worker threads to commit if `replica_preserve_commit_order` is enabled.

- **Waiting for master to send event**
  - Waiting for source to send event

  The thread has connected to the source and is waiting for binary log events to arrive. This can last for a long time if the source is idle. If the wait lasts for `replica_net_timeout` seconds, a timeout occurs. At that point, the thread considers the connection to be broken and makes an attempt to reconnect.

- **Waiting for master update**
  - Waiting for source update

  The initial state before **Connecting to master** or **Connecting to source**.
Replication SQL Thread States

- Waiting for slave mutex on exit
  Waiting for replica mutex on exit
A state that occurs briefly as the thread is stopping.

- Waiting for the slave SQL thread to free enough relay log space
  Waiting for the replica SQL thread to free enough relay log space
You are using a nonzero relay_log_space_limit value, and the relay logs have grown large enough that their combined size exceeds this value. The I/O (receiver) thread is waiting until the SQL (applier) thread frees enough space by processing relay log contents so that it can delete some relay log files.

- Waiting to reconnect after a failed binlog dump request
  If the binary log dump request failed (due to disconnection), the thread goes into this state while it sleeps, then tries to reconnect periodically. The interval between retries can be specified using the CHANGE REPLICATION SOURCE TO.

- Waiting to reconnect after a failed master event read
  Waiting to reconnect after a failed source event read
An error occurred while reading (due to disconnection). The thread is sleeping for the number of seconds set by the CHANGE REPLICATION SOURCE TO statement before attempting to reconnect.

8.14.6 Replication SQL Thread States

The following list shows the most common states you may see in the State column for a replication SQL thread on a replica server.

In MySQL 8.0, incompatible changes were made to instrumentation names. Monitoring tools that work with these instrumentation names might be impacted. If the incompatible changes have an impact for you, set the terminology_use_previous system variable to BEFORE_8_0_26 to make MySQL Server use the old versions of the names for the objects specified in the previous list. This enables monitoring tools that rely on the old names to continue working until they can be updated to use the new names.

Set the terminology_use_previous system variable with session scope to support individual functions, or global scope to be a default for all new sessions. When global scope is used, the slow query log contains the old versions of the names.

- Making temporary file (append) before replaying LOAD DATA INFILE
  The thread is executing a LOAD DATA statement and is appending the data to a temporary file containing the data from which the replica reads rows.

- Making temporary file (create) before replaying LOAD DATA INFILE
  The thread is executing a LOAD DATA statement and is creating a temporary file containing the data from which the replica reads rows. This state can only be encountered if the original LOAD DATA statement was logged by a source running a version of MySQL lower than MySQL 5.0.3.

- Reading event from the relay log
  The thread has read an event from the relay log so that the event can be processed.
Replication Connection Thread States

- **Slave has read all relay log; waiting for more updates**
  Replica has read all relay log; waiting for more updates

  The thread has processed all events in the relay log files, and is now waiting for the I/O (receiver) thread to write new events to the relay log.

- **Waiting for an event from Coordinator**

  Using the multithreaded replica (replica_parallel_workers is greater than 1), one of the replica worker threads is waiting for an event from the coordinator thread.

- **Waiting for slave mutex on exit**
  Waiting for replica mutex on exit

  A very brief state that occurs as the thread is stopping.

- **Waiting for Slave Workers to free pending events**
  Waiting for Replica Workers to free pending events

  This waiting action occurs when the total size of events being processed by Workers exceeds the size of the replica_pending_jobs_size_max system variable. The Coordinator resumes scheduling when the size drops below this limit. This state occurs only when replica_parallel_workers is set greater than 0.

- **Waiting for the next event in relay log**

  The initial state before Reading event from the relay log.

- **Waiting until MASTER_DELAY seconds after master executed event**
  Waiting until SOURCE_DELAY seconds after master executed event

  The SQL thread has read an event but is waiting for the replica delay to lapse. This delay is set with the SOURCE_DELAY | MASTER_DELAY option of the CHANGE REPLICATION SOURCE TO.

  The Info column for the SQL thread may also show the text of a statement. This indicates that the thread has read an event from the relay log, extracted the statement from it, and may be executing it.

### 8.14.7 Replication Connection Thread States

These thread states occur on a replica server but are associated with connection threads, not with the I/O or SQL threads.

- **Changing master**
  Changing replication source

  The thread is processing a CHANGE REPLICATION SOURCE TO statement.

- **Killing slave**

  The thread is processing a STOP REPLICA statement.

- **Opening master dump table**

  This state occurs after Creating table from master dump.
NDB Cluster Thread States

- **Reading master dump table data**
  This state occurs after Opening master dump table.

- **Rebuilding the index on master dump table**
  This state occurs after Reading master dump table data.

### 8.14.8 NDB Cluster Thread States

- **Committing events to binlog**
- **Opening mysql.ndb_apply_status**
- **Processing events**
  The thread is processing events for binary logging.
- **Processing events from schema table**
  The thread is doing the work of schema replication.

- **Shutting down**

- **Syncing ndb table schema operation and binlog**
  This is used to have a correct binary log of schema operations for NDB.

- **Waiting for allowed to take ndbcluster global schema lock**
  The thread is waiting for permission to take a global schema lock.

- **Waiting for event from ndbcluster**
  The server is acting as an SQL node in an NDB Cluster, and is connected to a cluster management node.

- **Waiting for first event from ndbcluster**
- **Waiting for ndbcluster binlog update to reach current position**
- **Waiting for ndbcluster global schema lock**
  The thread is waiting for a global schema lock held by another thread to be released.

- **Waiting for ndbcluster to start**
- **Waiting for schema epoch**
  The thread is waiting for a schema epoch (that is, a global checkpoint).

### 8.14.9 Event Scheduler Thread States

These states occur for the Event Scheduler thread, threads that are created to execute scheduled events, or threads that terminate the scheduler.

- **Clearing**
  The scheduler thread or a thread that was executing an event is terminating and is about to end.
• **Initialized**
  The scheduler thread or a thread that executes an event has been initialized.

• **Waiting for next activation**
  The scheduler has a nonempty event queue but the next activation is in the future.

• **Waiting for scheduler to stop**
  The thread issued `SET GLOBAL event_scheduler=OFF` and is waiting for the scheduler to stop.

• **Waiting on empty queue**
  The scheduler's event queue is empty and it is sleeping.

This chapter discusses the rules for writing the following elements of SQL statements when using MySQL:

- Literal values such as strings and numbers
- Identifiers such as database, table, and column names
- Keywords and reserved words
- User-defined and system variables
- Expressions
- Query attributes
- Comments

9.1 Literal Values

This section describes how to write literal values in MySQL. These include strings, numbers, hexadecimal and bit values, boolean values, and NULL. The section also covers various nuances that you may encounter when dealing with these basic types in MySQL.

9.1.1 String Literals

A string is a sequence of bytes or characters, enclosed within either single quote (') or double quote ("") characters. Examples:

'a string'
Quoted strings placed next to each other are concatenated to a single string. The following lines are equivalent:

```sql
'a string'
'a' ' ' 'string'
```

If the `ANSI_QUOTES` SQL mode is enabled, string literals can be quoted only within single quotation marks because a string quoted within double quotation marks is interpreted as an identifier.

A **binary string** is a string of bytes. Every binary string has a character set and collation named `binary`. A **nonbinary string** is a string of characters. It has a character set other than `binary` and a collation that is compatible with the character set.

For both types of strings, comparisons are based on the numeric values of the string unit. For binary strings, the unit is the byte; comparisons use numeric byte values. For nonbinary strings, the unit is the character and some character sets support multibyte characters; comparisons use numeric character code values. Character code ordering is a function of the string collation. (For more information, see Section 10.8.5, “The binary Collation Compared to _bin Collations”.)

**Note**

Within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex` option. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

A character string literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name]'string' [COLLATE collation_name]
```

Examples:

```sql
SELECT _latin1'string';
SELECT _binary'string';
SELECT _utf8mb4'string' COLLATE utf8mb4_danish_ci;
```

You can use `N'literal'` (or `n'literal'`) to create a string in the national character set. These statements are equivalent:

```sql
SELECT N'some text';
SELECT n'some text';
SELECT _utf8'some text';
```

For information about these forms of string syntax, see Section 10.3.7, “The National Character Set”, and Section 10.3.8, “Character Set Introducers”.

Within a string, certain sequences have special meaning unless the `NO_BACKSLASH_ESCAPES` SQL mode is enabled. Each of these sequences begins with a backslash (`\`), known as the *escape character*. MySQL recognizes the escape sequences shown in Table 9.1, “Special Character Escape Sequences”. For all other escape sequences, backslash is ignored. That is, the escaped character is interpreted as if it was not escaped. For example, `\x` is just `x`. These sequences are case-sensitive. For example, `\b` is interpreted as a backspace, but `\B` is interpreted as `B`. Escape processing is done according to the character set indicated by the `character_set_connection` system variable. This is true even for strings that are preceded by an introducer that indicates a different character set, as discussed in Section 10.3.6, “Character String Literal Character Set and Collation”.

1990
Table 9.1 Special Character Escape Sequences

<table>
<thead>
<tr>
<th>Escape Sequence</th>
<th>Character Represented by Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>\0</td>
<td>An ASCII NUL (X'00') character</td>
</tr>
<tr>
<td>'</td>
<td>A single quote (') character</td>
</tr>
<tr>
<td>&quot;</td>
<td>A double quote (&quot;) character</td>
</tr>
<tr>
<td>\b</td>
<td>A backspace character</td>
</tr>
<tr>
<td>\n</td>
<td>A newline (linefeed) character</td>
</tr>
<tr>
<td>\r</td>
<td>A carriage return character</td>
</tr>
<tr>
<td>\t</td>
<td>A tab character</td>
</tr>
<tr>
<td>\Z</td>
<td>ASCII 26 (Control+Z); see note following the table</td>
</tr>
<tr>
<td>\</td>
<td>A backslash () character</td>
</tr>
<tr>
<td>%</td>
<td>A % character; see note following the table</td>
</tr>
<tr>
<td>_</td>
<td>A _ character; see note following the table</td>
</tr>
</tbody>
</table>

The ASCII 26 character can be encoded as \Z to enable you to work around the problem that ASCII 26 stands for END-OF-FILE on Windows. ASCII 26 within a file causes problems if you try to use mysql db_name < file_name.

The \% and \_ sequences are used to search for literal instances of % and _ in pattern-matching contexts where they would otherwise be interpreted as wildcard characters. See the description of the LIKE operator in Section 12.8.1, “String Comparison Functions and Operators”. If you use \% or \_ outside of pattern-matching contexts, they evaluate to the strings \% and \_, not to % and _.

There are several ways to include quote characters within a string:

- A ' inside a string quoted with ' may be written as ".
- A " inside a string quoted with " may be written as "".
- Precede the quote character by an escape character (\).
- A ' inside a string quoted with " needs no special treatment and need not be doubled or escaped. In the same way, " inside a string quoted with ' needs no special treatment.

The following SELECT statements demonstrate how quoting and escaping work:

```sql
mysql> SELECT 'hello', "hello", '"hello"', 'hel\'lo', '\\hello';
+-------+---------+-----------+--------+--------+
| hello | "hello" | "hello"   | hel\'lo| 'hello |
+-------+---------+-----------+--------+--------+
mysql> SELECT "hello", '\hello', '"hello"', "hel\"lo", \"hello";
+--------------------+--------+---------+---------+---------+
| hello              | 'hello'| "hello"| "hello" |
+--------------------+--------+---------+---------+---------+
mysql> SELECT 'This
Is
Four
Lines';
+-------------------+
| This              |
| Is                |
| Four              |
| Lines             |
+-------------------+
```

1991
To insert binary data into a string column (such as a BLOB column), you should represent certain characters by escape sequences. Backslash (\) and the quote character used to quote the string must be escaped. In certain client environments, it may also be necessary to escape NUL or Control+Z. The mysql client truncates quoted strings containing NUL characters if they are not escaped, and Control+Z may be taken for END-OF-FILE on Windows if not escaped. For the escape sequences that represent each of these characters, see Table 9.1, “Special Character Escape Sequences”.

When writing application programs, any string that might contain any of these special characters must be properly escaped before the string is used as a data value in an SQL statement that is sent to the MySQL server. You can do this in two ways:

- Process the string with a function that escapes the special characters. In a C program, you can use the mysql_real_escape_string_quote() C API function to escape characters. See mysql_real_escape_string_quote(). Within SQL statements that construct other SQL statements, you can use the QUOTE() function. The Perl DBI interface provides a quote method to convert special characters to the proper escape sequences. See Section 29.9, “MySQL Perl API”. Other language interfaces may provide a similar capability.

- As an alternative to explicitly escaping special characters, many MySQL APIs provide a placeholder capability that enables you to insert special markers into a statement string, and then bind data values to them when you issue the statement. In this case, the API takes care of escaping special characters in the values for you.

### 9.1.2 Numeric Literals

Number literals include exact-value (integer and DECIMAL) literals and approximate-value (floating-point) literals.

Integers are represented as a sequence of digits. Numbers may include . as a decimal separator. Numbers may be preceded by − or + to indicate a negative or positive value, respectively. Numbers represented in scientific notation with a mantissa and exponent are approximate-value numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: 1, .2, 3.4, −5, −6.78, +9.10.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: 1.2E3, 1.2E−3, −1.2E3, −1.2E−3.

Two numbers that look similar may be treated differently. For example, 2.34 is an exact-value (fixed-point) number, whereas 2.34E0 is an approximate-value (floating-point) number.

The DECIMAL data type is a fixed-point type and calculations are exact. In MySQL, the DECIMAL type has several synonyms: NUMERIC, DEC, FIXED. The integer types also are exact-value types. For more information about exact-value calculations, see Section 12.24, “Precision Math”.

The FLOAT and DOUBLE data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with FLOAT or DOUBLE are DOUBLE PRECISION and REAL.

An integer may be used in floating-point context; it is interpreted as the equivalent floating-point number.
9.1.3 Date and Time Literals

- Standard SQL and ODBC Date and Time Literals
- String and Numeric Literals in Date and Time Context

Date and time values can be represented in several formats, such as quoted strings or as numbers, depending on the exact type of the value and other factors. For example, in contexts where MySQL expects a date, it interprets any of '2015-07-21', '20150721', and 20150721 as a date.

This section describes the acceptable formats for date and time literals. For more information about the temporal data types, such as the range of permitted values, see Section 11.2, “Date and Time Data Types”.

Standard SQL and ODBC Date and Time Literals

Standard SQL requires temporal literals to be specified using a type keyword and a string. The space between the keyword and string is optional.

```
DATE 'str'
TIME 'str'
TIMESTAMP 'str'
```

MySQL recognizes but, unlike standard SQL, does not require the type keyword. Applications that are to be standard-compliant should include the type keyword for temporal literals.

MySQL also recognizes the ODBC syntax corresponding to the standard SQL syntax:

```
{ d 'str' }
{ t 'str' }
{ ts 'str' }
```

MySQL uses the type keywords and the ODBC constructions to produce DATE, TIME, and DATETIME values, respectively, including a trailing fractional seconds part if specified. The TIMESTAMP syntax produces a DATETIME value in MySQL because DATETIME has a range that more closely corresponds to the standard SQL TIMESTAMP type, which has a year range from 0001 to 9999. (The MySQL TIMESTAMP year range is 1970 to 2038.)

String and Numeric Literals in Date and Time Context

MySQL recognizes DATE values in these formats:

- As a string in either 'YYYY-MM-DD' or 'YY-MM-DD' format. A “relaxed” syntax is permitted, but is deprecated: Any punctuation character may be used as the delimiter between date parts. For example, '2012-12-31', '2012/12/31', '2012^12^31', and '2012@12@31' are equivalent. Using any character other than the dash (-) as the delimiter raises a warning, as shown here:

```
mysql> SELECT DATE'2012@12@31';
+------------------+
| DATE'2012@12@31' |
| 2012-12-31       |
+------------------+
1 row in set, 1 warning (0.00 sec)
```

```
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Warning
Code: 4095
Message: Delimiter '@' in position 4 in datetime value '2012@12@31' at row 1 is deprecated. Prefer the standard '-'.
```
- As a string with no delimiters in either 'YYYYMMDD' or 'YYMMDD' format, provided that the string makes sense as a date. For example, '20070523' and '070523' are interpreted as '2007-05-23', but '071332' is illegal (it has nonsensical month and day parts) and becomes '0000-00-00'.

- As a number in either YYYYMMDD or YYMMDD format, provided that the number makes sense as a date. For example, 19830905 and 830905 are interpreted as '1983-09-05'.

MySQL recognizes DATETIME and TIMESTAMP values in these formats:

- As a string in either 'YYYY-MM-DD hh:mm:ss' or 'YY-MM-DD hh:mm:ss' format. MySQL also permits a "relaxed" syntax here, although this is deprecated: Any punctuation character may be used as the delimiter between date parts or time parts. For example, '2012-12-31 11:30:45', '2012^12^31 11+30+45', '2012/12/31 11*30*45', and '2012@12@31 11^30^45' are equivalent. Use of any characters as delimiters in such values, other than the dash (−) for the date part and the colon (:) for the time part, raises a warning, as shown here:

  ```sql
  mysql> SELECT TIMESTAMP'2012^12^31 11*30*45';
  +----------------------------------+
  | TIMESTAMP'2012^12^31 11*30*45' |
  +----------------------------------+
  | 2012-12-31 11:30:45              |
  +----------------------------------+
  1 row in set, 1 warning (0.00 sec)
  mysql> SHOW WARNINGS\G
  *************************** 1. row ***************************
  Level: Warning
  Code: 4095
  Message: Delimiter '^' in position 4 in datetime value '2012^12^31 11*30*45' at row 1 is deprecated. Prefer the standard '-'.
  1 row in set (0.00 sec)
  ```

The only delimiter recognized between a date and time part and a fractional seconds part is the decimal point.

The date and time parts can be separated by T rather than a space. For example, '2012-12-31 11:30:45' '2012-12-31T11:30:45' are equivalent.

Previously, MySQL supported arbitrary numbers of leading and trailing whitespace characters in date and time values, as well as between the date and time parts of DATETIME and TIMESTAMP values. In MySQL 8.2, this behavior is deprecated, and the presence of excess whitespace characters triggers a warning, as shown here:

  ```sql
  mysql> SELECT TIMESTAMP'2012-12-31 11-30-45';
  +----------------------------------+
  | TIMESTAMP'2012-12-31 11-30-45' |
  +----------------------------------+
  | 2012-12-31 11:30:45              |
  +----------------------------------+
  1 row in set, 1 warning (0.00 sec)
  mysql> SHOW WARNINGS\G
  *************************** 1. row ***************************
  Level: Warning
  Code: 4096
  Message: Delimiter ' ' in position 11 in datetime value '2012-12-31 11-30-45' at row 1 is superfluous and is deprecated. Please remove.
  1 row in set (0.00 sec)
  ```

A warning is also raised when whitespace characters other than the space character is used, like this:
As a string with no delimiters in either 'YYYYMMDDhhmmss' or 'YYMMDDhhmmss' format, provided that the string makes sense as a date. For example, '20070523091528' and '070523091528' are interpreted as '2007-05-23 09:15:28', but '071122129015' is illegal (it has a nonsensical minute part) and becomes '0000-00-00 00:00:00'.
• As a number in either `YYYYMMDDhhmmss` or `YYMMDDhhmmss` format, provided that the number makes sense as a date. For example, `19830905132800` and `830905132800` are interpreted as '1983-09-05 13:28:00'.

A `DATETIME` or `TIMESTAMP` value can include a trailing fractional seconds part in up to microseconds (6 digits) precision. The fractional part should always be separated from the rest of the time by a decimal point; no other fractional seconds delimiter is recognized. For information about fractional seconds support in MySQL, see Section 11.2.6, "Fractional Seconds in Time Values".

Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using these rules:

• Year values in the range 70–99 become 1970–1999.
• Year values in the range 00–69 become 2000–2069.

See also Section 11.2.9, "2-Digit Years in Dates".

For values specified as strings that include date part delimiters, it is unnecessary to specify two digits for month or day values that are less than 10. '2015-6-9' is the same as '2015-06-09'. Similarly, for values specified as strings that include time part delimiters, it is unnecessary to specify two digits for hour, minute, or second values that are less than 10. '2015-10-30 1:2:3' is the same as '2015-10-30 01:02:03'.

Values specified as numbers should be 6, 8, 12, or 14 digits long. If a number is 8 or 14 digits long, it is assumed to be in `YYYYMMDD` or `YYYYMMDDhhmmss` format and that the year is given by the first 4 digits. If the number is 6 or 12 digits long, it is assumed to be in `YMMDD` or `YMMDDhhmmss` format and that the year is given by the first 2 digits. Numbers that are not one of these lengths are interpreted as though padded with leading zeros to the closest length.

Values specified as nondelimited strings are interpreted according their length. For a string 8 or 14 characters long, the year is assumed to be given by the first 2 characters. Otherwise, the year is assumed to be given by the first 2 characters. The string is interpreted from left to right to find year, month, day, hour, minute, and second values, for as many parts as are present in the string. This means you should not use strings that have fewer than 6 characters. For example, if you specify '9903', thinking that represents March, 1999, MySQL converts it to the "zero" date value. This occurs because the year and month values are 99 and 03, but the day part is completely missing. However, you can explicitly specify a value of zero to represent missing month or day parts. For example, to insert the value '1999-03-00', use '990300'.

MySQL recognizes `TIME` values in these formats:

• As a string in 'D hh:mm:ss' format. You can also use one of the following "relaxed" syntaxes: 'hh:mm:ss', 'hh:mm', 'D hh:mm', 'D hh', or 'ss'. Here D represents days and can have a value from 0 to 34.

• As a string with no delimiters in 'hhmmss' format, provided that it makes sense as a time. For example, '101112' is understood as '10:11:12', but '109712' is illegal (it has a nonsensical minute part) and becomes '00:00:00'.

• As a number in `hhmmss` format, provided that it makes sense as a time. For example, `101112` is understood as '10:11:12'. The following alternative formats are also understood: `ss, mmss, or hhmmss`.

A trailing fractional seconds part is recognized in the 'D hh:mm:ss.fraction', 'hh:mm:ss.fraction', 'hhmmss.fraction', and `hhmmss.fraction` time formats, where `fraction` is the fractional part in up to microseconds (6 digits) precision. The fractional part should
always be separated from the rest of the time by a decimal point; no other fractional seconds delimiter is recognized. For information about fractional seconds support in MySQL, see Section 11.2.6, “Fractional Seconds in Time Values”.

For TIME values specified as strings that include a time part delimiter, it is unnecessary to specify two digits for hours, minutes, or seconds values that are less than 10. '8:3:2' is the same as '08:03:02'.

You can specify a time zone offset when inserting TIMESTAMP and DATETIME values into a table. The offset is appended to the time part of a datetime literal, with no intravening spaces, and uses the same format used for setting the time_zone system variable, with the following exceptions:

- For hour values less than 10, a leading zero is required.
- The value '-00:00' is rejected.
- Time zone names such as 'EET' and 'Asia/Shanghai' cannot be used; 'SYSTEM' also cannot be used in this context.

The value inserted must not have a zero for the month part, the day part, or both parts. This is enforced regardless of the server SQL mode setting.

This example illustrates inserting datetime values with time zone offsets into TIMESTAMP and DATETIME columns using different time_zone settings, and then retrieving them:

```sql
mysql> CREATE TABLE ts (id INTEGER NOT NULL AUTO_INCREMENT PRIMARY KEY, col TIMESTAMP NOT NULL) AUTO_INCREMENT = 1;
mysql> CREATE TABLE dt (id INT NOT NULL AUTO_INCREMENT PRIMARY KEY, col DATETIME NOT NULL) AUTO_INCREMENT = 1;
mysql> SET @@time_zone = 'SYSTEM';
mysql> INSERT INTO ts (col) VALUES ('2020-01-01 10:10:10'), ('2020-01-01 10:10:10+05:30'), ('2020-01-01 10:10:10-08:00');
mysql> SET @@time_zone = '+00:00';
mysql> INSERT INTO ts (col) VALUES ('2020-01-01 10:10:10'), ('2020-01-01 10:10:10+05:30'), ('2020-01-01 10:10:10-08:00');
mysql> SET @@time_zone = 'SYSTEM';
mysql> INSERT INTO dt (col) VALUES ('2020-01-01 10:10:10'), ('2020-01-01 10:10:10+05:30'), ('2020-01-01 10:10:10-08:00');
mysql> SET @@time_zone = '+00:00';
mysql> INSERT INTO dt (col) VALUES ('2020-01-01 10:10:10'), ('2020-01-01 10:10:10+05:30'), ('2020-01-01 10:10:10-08:00');
mysql> SET @@time_zone = 'SYSTEM';
mysql> SELECT @@system_time_zone;
+--------------------+
| @@system_time_zone |
+--------------------+
| EST                |
```
The offset is not displayed when selecting a datetime value, even if one was used when inserting it.

The range of supported offset values is \(-13:59\) to \(+14:00\), inclusive.

Datetime literals that include time zone offsets are accepted as parameter values by prepared statements.

### 9.1.4 Hexadecimal Literals

Hexadecimal literal values are written using `X'val'` or `0xval` notation, where `val` contains hexadecimal digits (0..9, A..F). Lettercase of the digits and of any leading `X` does not matter. A leading `0x` is case-sensitive and cannot be written as `0X`.

**Legal hexadecimal literals:**

```
X'01AF'
X'01af'
x'01AF'
x'01af'
0x01AF
0x01af
```

**Illegal hexadecimal literals:**

```
X'0G'   (G is not a hexadecimal digit)
0X01AF  (0X must be written as 0x)
```

Values written using `X'val'` notation must contain an even number of digits or a syntax error occurs. To correct the problem, pad the value with a leading zero:

```
mysql> SET @s = X'FFF';
ERROR 1064 (42000): You have an error in your SQL syntax;
check the manual that corresponds to your MySQL server version for the right syntax to use near 'X'FFF''

mysql> SET @s = X'0FFF';
Query OK, 0 rows affected (0.00 sec)
```

Values written using `0xval` notation that contain an odd number of digits are treated as having an extra leading `0`. For example, `0xaaa` is interpreted as `0x0aaa`. 

---

**MySQL Query Example:**

```sql
mysql> SELECT col, UNIX_TIMESTAMP(col) FROM dt ORDER BY id;  
+---------------------+---------------------+  
<table>
<thead>
<tr>
<th>col</th>
<th>UNIX_TIMESTAMP(col)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-01-01 10:10:10</td>
<td>1577891410</td>
</tr>
<tr>
<td>2019-12-31 23:40:10</td>
<td>1577853610</td>
</tr>
<tr>
<td>2020-01-01 13:10:10</td>
<td>1577902210</td>
</tr>
<tr>
<td>2020-01-01 04:40:10</td>
<td>1577871610</td>
</tr>
<tr>
<td>2020-01-01 18:10:10</td>
<td>1577920210</td>
</tr>
</tbody>
</table>
+---------------------+---------------------+
```

```sql
mysql> SELECT col, UNIX_TIMESTAMP(col) FROM ts ORDER BY id;  
+---------------------+---------------------+  
<table>
<thead>
<tr>
<th>col</th>
<th>UNIX_TIMESTAMP(col)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-01-01 10:10:10</td>
<td>1577891410</td>
</tr>
<tr>
<td>2019-12-31 23:40:10</td>
<td>1577853610</td>
</tr>
<tr>
<td>2020-01-01 13:10:10</td>
<td>1577902210</td>
</tr>
<tr>
<td>2020-01-01 05:10:10</td>
<td>1577873410</td>
</tr>
<tr>
<td>2019-12-31 23:40:10</td>
<td>1577853610</td>
</tr>
<tr>
<td>2020-01-01 13:10:10</td>
<td>1577902210</td>
</tr>
</tbody>
</table>
+---------------------+---------------------+
```
Hexadecimal Literals

By default, a hexadecimal literal is a binary string, where each pair of hexadecimal digits represents a character:

```
mysql> SELECT X'4D7953514C', CHARSET(X'4D7953514C');
+---------------+------------------------+
| X'4D7953514C' | CHARSET(X'4D7953514C') |
| MySQL         | binary                 |
+---------------+------------------------+
mysql> SELECT 0x5461626c65, CHARSET(0x5461626c65);
+--------------+-----------------------+
| 0x5461626c65 | CHARSET(0x5461626c65) |
| Table        | binary                |
+--------------+-----------------------+
```

A hexadecimal literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[[_charset_name]] X'val' [COLLATE _collation_name]
```

Examples:

```
SELECT _latin1 X'4D7953514C';
SELECT _utf8mb4 0x4D7953514C COLLATE utf8mb4_danish_ci;
```

The examples use `X'val'` notation, but `0xval` notation permits introducers as well. For information about introducers, see Section 10.3.8, “Character Set Introducers”.

In numeric contexts, MySQL treats a hexadecimal literal like a `BIGINT UNSIGNED` (64-bit unsigned integer). To ensure numeric treatment of a hexadecimal literal, use it in numeric context. Ways to do this include adding 0 or using `CAST(... AS UNSIGNED)`. For example, a hexadecimal literal assigned to a user-defined variable is a binary string by default. To assign the value as a number, use it in numeric context:

```
mysql> SET @v1 = X'41';
mysql> SET @v2 = X'41'+0;
mysql> SET @v3 = CAST(X'41' AS UNSIGNED);
mysql> SELECT @v1, @v2, @v3;
+------+------+------+
| @v1  | @v2  | @v3  |
| A    |   65 |   65 |
+------+------+------+
```

An empty hexadecimal value (`X''`) evaluates to a zero-length binary string. Converted to a number, it produces 0:

```
mysql> SELECT CHARSET(X''), LENGTH(X'');
+---------------+-------------+
| CHARSET(X'')  | LENGTH(X'') |
| binary        | 0           |
+---------------+-------------+
mysql> SELECT X''+0;
+-------+
| X''+0  |
|       0|
+-------+
```

The `X'val'` notation is based on standard SQL. The `0x` notation is based on ODBC, for which hexadecimal strings are often used to supply values for BLOB columns.
To convert a string or a number to a string in hexadecimal format, use the `HEX()` function:

```sql
mysql> SELECT HEX('cat');
+------------+
| HEX('cat')  |
+------------+
| 636174     |
+------------+
mysql> SELECT X'636174';
+-----------+
| X'636174' |
+-----------+
| cat       |
+-----------+
```

For hexadecimal literals, bit operations are considered numeric context, but bit operations permit numeric or binary string arguments in MySQL 8.2 and higher. To explicitly specify binary string context for hexadecimal literals, use a `_binary` introducer for at least one of the arguments:

```sql
mysql> SET @v1 = X'000D' | X'0BC0';
mysql> SET @v2 = _binary X'000D' | X'0BC0';
mysql> SELECT HEX(@v1), HEX(@v2);
+----------+----------+
| HEX(@v1) | HEX(@v2) |
+----------+----------+
| BCD      | 0BCD     |
+----------+----------+
```

The displayed result appears similar for both bit operations, but the result without `_binary` is a `BIGINT` value, whereas the result with `_binary` is a binary string. Due to the difference in result types, the displayed values differ: High-order 0 digits are not displayed for the numeric result.

### 9.1.5 Bit-Value Literals

Bit-value literals are written using `b'val'` or `0bval` notation. `val` is a binary value written using zeros and ones. Lettercase of any leading `b` does not matter. A leading `0b` is case-sensitive and cannot be written as `0B`.

**Legal bit-value literals:**

- `b'01'`
- `B'01'`
- `0b01`

**Illegal bit-value literals:**

- `b'2'` (2 is not a binary digit)
- `0B01` (0B must be written as 0b)

By default, a bit-value literal is a binary string:

```sql
mysql> SELECT b'1000001', CHARSET(b'1000001');
+------------+---------------------+
| b'1000001' | CHARSET(b'1000001') |
+------------+---------------------+
| A          | binary              |
+------------+---------------------+
mysql> SELECT 0b1100001, CHARSET(0b1100001);
+-----------+--------------------+
| 0b1100001 | CHARSET(0b1100001) |
+-----------+--------------------+
| a         | binary             |
+-----------+--------------------+
```
A bit-value literal may have an optional character set introducer and COLLATE clause, to designate it as a string that uses a particular character set and collation:

\[ [\text{charset_name}] \ b'val' \ [\text{COLLATE collation_name}] \]

Examples:

```sql
SELECT _latin1 b'1000001';
SELECT _utf8mb4 0b1000001 COLLATE utf8mb4_danish_ci;
```

The examples use \( b'val' \) notation, but \( 0bval \) notation permits introducers as well. For information about introducers, see Section 10.3.8, “Character Set Introducers”.

In numeric contexts, MySQL treats a bit literal like an integer. To ensure numeric treatment of a bit literal, use it in numeric context. Ways to do this include adding 0 or using `CAST(... AS UNSIGNED)`. For example, a bit literal assigned to a user-defined variable is a binary string by default. To assign the value as a number, use it in numeric context:

```sql
mysql> SET @v1 = b'1100001';
mysql> SET @v2 = b'1100001'+0;
mysql> SET @v3 = CAST(b'1100001' AS UNSIGNED);
mysql> SELECT @v1, @v2, @v3;
```

```
+------+------+
| @v1  | @v2  | @v3  |
| a    | 97   | 97   |
+------+------+
```

An empty bit value (\( b'' \)) evaluates to a zero-length binary string. Converted to a number, it produces 0:

```sql
mysql> SELECT CHARSET(b''), LENGTH(b'');
```

```
+--------------+-------------+
| CHARSET(b'') | LENGTH(b'') |
| binary       |           0 |
+--------------+-------------+
```

Bit-value notation is convenient for specifying values to be assigned to \textit{BIT} columns:

```sql
mysql> CREATE TABLE t (b BIT(8));
mysql> INSERT INTO t SET b = b'11111111';
mysql> INSERT INTO t SET b = b'1010';
mysql> INSERT INTO t SET b = b'0101';
```

Bit values in result sets are returned as binary values, which may not display well. To convert a bit value to printable form, use it in numeric context or use a conversion function such as \textit{BIN()} or \textit{HEX()}. High-order 0 digits are not displayed in the converted value:

```sql
mysql> SELECT b+0, BIN(b), OCT(b), HEX(b) FROM t;`
### 9.1.6 Boolean Literals

The constants **TRUE** and **FALSE** evaluate to 1 and 0, respectively. The constant names can be written in any lettercase.

```sql
mysql> SELECT TRUE, true, FALSE, false;
-> 1, 1, 0, 0
```

### 9.1.7 NULL Values

The **NULL** value means “no data.” **NULL** can be written in any lettercase.

Be aware that the **NULL** value is different from values such as 0 for numeric types or the empty string for string types. For more information, see Section B.3.4.3, “Problems with NULL Values”.

For text file import or export operations performed with **LOAD DATA** or **SELECT ... INTO OUTFILE**, **NULL** is represented by the `\N` sequence. See Section 13.2.9, “LOAD DATA Statement”.

For sorting with **ORDER BY**, **NULL** values sort before other values for ascending sorts, after other values for descending sorts.

### 9.2 Schema Object Names

Certain objects within MySQL, including database, table, index, column, alias, view, stored procedure, partition, tablespace, resource group and other object names are known as identifiers. This section describes the permissible syntax for identifiers in MySQL. Section 9.2.1, “Identifier Length Limits”, indicates the maximum length of each type of identifier. Section 9.2.3, “Identifier Case Sensitivity”, describes which types of identifiers are case-sensitive and under what conditions.

An identifier may be quoted or unquoted. If an identifier contains special characters or is a reserved word, you **must** quote it whenever you refer to it. (Exception: A reserved word that follows a period in a qualified name must be an identifier, so it need not be quoted.) Reserved words are listed at Section 9.3, “Keywords and Reserved Words”.

Internally, identifiers are converted to and are stored as Unicode (UTF-8). The permissible Unicode characters in identifiers are those in the Basic Multilingual Plane (BMP). Supplementary characters are not permitted. Identifiers thus may contain these characters:
Schema Object Names

- Permitted characters in unquoted identifiers:
  - ASCII: [0-9,a-z,A-Z$_\_] (basic Latin letters, digits 0-9, dollar, underscore)
  - Extended: U+0080 .. U+FFFF

- Permitted characters in quoted identifiers include the full Unicode Basic Multilingual Plane (BMP), except U+0000:
  - ASCII: U+0001 .. U+007F
  - Extended: U+0080 .. U+FFFF

- ASCII NUL (U+0000) and supplementary characters (U+10000 and higher) are not permitted in quoted or unquoted identifiers.

- Identifiers may begin with a digit but unless quoted may not consist solely of digits.

- Database, table, and column names cannot end with space characters.

- Use of the dollar sign as the first character in the unquoted name of a database, table, view, column, stored program, or alias is deprecated, including such names used with qualifiers (see Section 9.2.2, “Identifier Qualifiers”). An unquoted identifier beginning with a dollar sign cannot contain any additional dollar sign characters. Otherwise, the leading dollar sign is permitted but triggers a deprecation warning.

The dollar sign can still be used as the leading character of such an identifier without producing the warning, when it is quoted according to the rules given later in this section.

The identifier quote character is the backtick (`):

```
mysql> SELECT * FROM `select` WHERE `select`.id > 100;
```

If the ANSI_QUOTES SQL mode is enabled, it is also permissible to quote identifiers within double quotation marks:

```
mysql> CREATE TABLE "test" (col INT);
ERROR 1064: You have an error in your SQL syntax...
mysql> SET sql_mode='ANSI_QUOTES';
mysql> CREATE TABLE "test" (col INT);  
Query OK, 0 rows affected (0.00 sec)
```

The ANSI_QUOTES mode causes the server to interpret double-quoted strings as identifiers. Consequently, when this mode is enabled, string literals must be enclosed within single quotation marks. They cannot be enclosed within double quotation marks. The server SQL mode is controlled as described in Section 5.1.11, “Server SQL Modes”.

Identifier quote characters can be included within an identifier if you quote the identifier. If the character to be included within the identifier is the same as that used to quote the identifier itself, then you need to double the character. The following statement creates a table named `a``b` that contains a column named `c"d`:

```
mysql> CREATE TABLE `a``b` (`c"d` INT);
```

In the select list of a query, a quoted column alias can be specified using identifier or string quoting characters:

```
mysql> SELECT 1 AS `one`, 2 AS 'two';
+-----+-----+
| one | two |
```

2003
Elsewhere in the statement, quoted references to the alias must use identifier quoting or the reference is treated as a string literal.

It is recommended that you do not use names that begin with \textit{Me} or \textit{MeN}, where \textit{M} and \textit{N} are integers. For example, avoid using \texttt{1e} as an identifier, because an expression such as \texttt{1e+3} is ambiguous. Depending on context, it might be interpreted as the expression \texttt{1e + 3} or as the number \texttt{1e+3}.

Be careful when using \texttt{MD5()} to produce table names because it can produce names in illegal or ambiguous formats such as those just described.

It is also recommended that you do not use column names that begin with \texttt{!hidden!} to ensure that new names do not collide with names used by existing hidden columns for functional indexes.

A user variable cannot be used directly in an SQL statement as an identifier or as part of an identifier. See \textsection{9.4, “User-Defined Variables”}, for more information and examples of workarounds.

Special characters in database and table names are encoded in the corresponding file system names as described in \textsection{9.2.4, “Mapping of Identifiers to File Names”}.

### 9.2.1 Identifier Length Limits

The following table describes the maximum length for each type of identifier.

<table>
<thead>
<tr>
<th>Identifier Type</th>
<th>Maximum Length (characters)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>64</td>
</tr>
<tr>
<td>Table</td>
<td>64</td>
</tr>
<tr>
<td>Column</td>
<td>64</td>
</tr>
<tr>
<td>Index</td>
<td>64</td>
</tr>
<tr>
<td>Constraint</td>
<td>64</td>
</tr>
<tr>
<td>Stored Program</td>
<td>64</td>
</tr>
<tr>
<td>View</td>
<td>64</td>
</tr>
<tr>
<td>Tablespace</td>
<td>64</td>
</tr>
<tr>
<td>Server</td>
<td>64</td>
</tr>
<tr>
<td>Log File Group</td>
<td>64</td>
</tr>
<tr>
<td>Alias</td>
<td>256 (see exception following table)</td>
</tr>
<tr>
<td>Compound Statement Label</td>
<td>16</td>
</tr>
<tr>
<td>User-Defined Variable</td>
<td>64</td>
</tr>
<tr>
<td>Resource Group</td>
<td>64</td>
</tr>
</tbody>
</table>

Aliases for column names in \texttt{CREATE VIEW} statements are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).

For constraint definitions that include no constraint name, the server internally generates a name derived from the associated table name. For example, internally generated foreign key and \texttt{CHECK} constraint names consist of the table name plus \_\texttt{ibfk}\_ or \_\texttt{chk}\_ and a number. If the table name is close to the length limit for constraint names, the additional characters required for the constraint name may cause that name to exceed the limit, resulting in an error.
Identifiers are stored using Unicode (UTF-8). This applies to identifiers in table definitions and to identifiers stored in the grant tables in the mysql database. The sizes of the identifier string columns in the grant tables are measured in characters. You can use multibyte characters without reducing the number of characters permitted for values stored in these columns.

Values such as user name and host names in MySQL account names are strings rather than identifiers. For information about the maximum length of such values as stored in grant tables, see Grant Table Scope Column Properties.

9.2.2 Identifier Qualifiers

Object names may be unqualified or qualified. An unqualified name is permitted in contexts where interpretation of the name is unambiguous. A qualified name includes at least one qualifier to clarify the interpretive context by overriding a default context or providing missing context.

For example, this statement creates a table using the unqualified name t1:

```sql
CREATE TABLE t1 (i INT);
```

Because t1 includes no qualifier to specify a database, the statement creates the table in the default database. If there is no default database, an error occurs.

This statement creates a table using the qualified name db1.t1:

```sql
CREATE TABLE db1.t1 (i INT);
```

Because db1.t1 includes a database qualifier db1, the statement creates t1 in the database named db1, regardless of the default database. The qualifier must be specified if there is no default database. The qualifier may be specified if there is a default database, to specify a database different from the default, or to make the database explicit if the default is the same as the one specified.

Qualifiers have these characteristics:

- An unqualified name consists of a single identifier. A qualified name consists of multiple identifiers.
- The components of a multiple-part name must be separated by period (.) characters. The initial parts of a multiple-part name act as qualifiers that affect the context within which to interpret the final identifier.
- The qualifier character is a separate token and need not be contiguous with the associated identifiers. For example, tbl_name.col_name and tbl_name . col_name are equivalent.
- If any components of a multiple-part name require quoting, quote them individually rather than quoting the name as a whole. For example, write `my-table`.`my-column`, not `my-table.my-column`.
- A reserved word that follows a period in a qualified name must be an identifier, so in that context it need not be quoted.

The permitted qualifiers for object names depend on the object type:

- A database name is fully qualified and takes no qualifier:

  ```sql
  CREATE DATABASE db1;
  ```

- A table, view, or stored program name may be given a database-name qualifier. Examples of unqualified and qualified names in CREATE statements:

  ```sql
  CREATE TABLE mytable ...;
  CREATE VIEW myview ...;
  CREATE PROCEDURE myproc ...;
  ```
CREATE FUNCTION myfunc ...
CREATE EVENT myevent ...
CREATE TABLE mydb.mytable ...
CREATE VIEW mydb.myview ...
CREATE PROCEDURE mydb.myproc ...
CREATE FUNCTION mydb.myfunc ...
CREATE EVENT mydb.myevent ...

• A trigger is associated with a table, so any qualifier applies to the table name:

CREATE TRIGGER mytrigger ... ON mytable ...
CREATE TRIGGER mytrigger ... ON mydb.mytable ...

• A column name may be given multiple qualifiers to indicate context in statements that reference it, as shown in the following table.

<table>
<thead>
<tr>
<th>Column Reference</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>col_name</td>
<td>Column col_name from whichever table used in the statement contains a column of that name</td>
</tr>
<tr>
<td>tbl_name.col_name</td>
<td>Column col_name from table tbl_name of the default database</td>
</tr>
<tr>
<td>db_name.tbl_name.col_name</td>
<td>Column col_name from table tbl_name of the database db_name</td>
</tr>
</tbody>
</table>

In other words, a column name may be given a table-name qualifier, which itself may be given a database-name qualifier. Examples of unqualified and qualified column references in SELECT statements:

```
SELECT c1 FROM mytable WHERE c2 > 100;
SELECT mytable.c1 FROM mytable WHERE mytable.c2 > 100;
SELECT mydb.mytable.c1 FROM mydb.mytable WHERE mydb.mytable.c2 > 100;
```

You need not specify a qualifier for an object reference in a statement unless the unqualified reference is ambiguous. Suppose that column c1 occurs only in table t1, c2 only in t2, and c in both t1 and t2. Any unqualified reference to c is ambiguous in a statement that refers to both tables and must be qualified as t1.c or t2.c to indicate which table you mean:

```
SELECT c1, c2, t1.c FROM t1 INNER JOIN t2 WHERE t2.c > 100;
```

Similarly, to retrieve from a table t in database db1 and from a table t in database db2 in the same statement, you must qualify the table references: For references to columns in those tables, qualifiers are required only for column names that appear in both tables. Suppose that column c1 occurs only in table db1.t, c2 only in db2.t, and c in both db1.t and db2.t. In this case, c is ambiguous and must be qualified but c1 and c2 need not be:

```
SELECT c1, c2, db1.t.c FROM db1.t INNER JOIN db2.t WHERE db2.t.c > 100;
```

Table aliases enable qualified column references to be written more simply:

```
SELECT c1, c2, t1.c FROM db1.t AS t1 INNER JOIN db2.t AS t2
```
WHERE t2.c > 100;

9.2.3 Identifier Case Sensitivity

In MySQL, databases correspond to directories within the data directory. Each table within a database corresponds to at least one file within the database directory (and possibly more, depending on the storage engine). Triggers also correspond to files. Consequently, the case sensitivity of the underlying operating system plays a part in the case sensitivity of database, table, and trigger names. This means such names are not case-sensitive in Windows, but are case-sensitive in most varieties of Unix. One notable exception is macOS, which is Unix-based but uses a default file system type (HFS+) that is not case-sensitive. However, macOS also supports UFS volumes, which are case-sensitive just as on any Unix. See Section 1.8.1, “MySQL Extensions to Standard SQL”. The lower_case_table_names system variable also affects how the server handles identifier case sensitivity, as described later in this section.

Note

Although database, table, and trigger names are not case-sensitive on some platforms, you should not refer to one of these using different cases within the same statement. The following statement would not work because it refers to a table both as my_table and as MY_TABLE:

```
mysql> SELECT * FROM my_table WHERE MY_TABLE.col=1;
```

Partition, subpartition, column, index, stored routine, event, and resource group names are not case-sensitive on any platform, nor are column aliases.

However, names of logfile groups are case-sensitive. This differs from standard SQL.

By default, table aliases are case-sensitive on Unix, but not so on Windows or macOS. The following statement would not work on Unix, because it refers to the alias both as a and as A:

```
mysql> SELECT col_name FROM tbl_name AS a
    
    WHERE a.col_name = 1 OR A.col_name = 2;
```

However, this same statement is permitted on Windows. To avoid problems caused by such differences, it is best to adopt a consistent convention, such as always creating and referring to databases and tables using lowercase names. This convention is recommended for maximum portability and ease of use.

How table and database names are stored on disk and used in MySQL is affected by the lower_case_table_names system variable. lower_case_table_names can take the values shown in the following table. This variable does not affect case sensitivity of trigger identifiers. On Unix, the default value of lower_case_table_names is 0. On Windows, the default value is 1. On macOS, the default value is 2.

```
<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Table and database names are stored on disk using the lowercase specified in the CREATE TABLE or CREATE DATABASE statement. Name comparisons are case-sensitive. You should not set this variable to 0 if you are running MySQL on a system that has case-insensitive file names (such as Windows or macOS). If you force this variable</td>
</tr>
</tbody>
</table>
```

lower_case_table_names can only be configured when initializing the server. Changing the lower_case_table_names setting after the server is initialized is prohibited.
If you are using MySQL on only one platform, you do not normally have to use a `lower_case_table_names` setting other than the default. However, you may encounter difficulties if you want to transfer tables between platforms that differ in file system case sensitivity. For example, on Unix, you can have two different tables named `my_table` and `MY_TABLE`, but on Windows these two names are considered identical. To avoid data transfer problems arising from lettercase of database or table names, you have two options:

- **Use `lower_case_table_names=1` on all systems.** The main disadvantage with this is that when you use `SHOW TABLES` or `SHOW DATABASES`, you do not see the names in their original lettercase.

- **Use `lower_case_table_names=0` on Unix and `lower_case_table_names=2` on Windows.** This preserves the lettercase of database and table names. The disadvantage of this is that you must ensure that your statements always refer to your database and table names with the correct lettercase on Windows. If you transfer your statements to Unix, where lettercase is significant, they do not work if the lettercase is incorrect. **Exception:** If you are using InnoDB tables and you are trying to avoid these data transfer problems, you should use `lower_case_table_names=1` on all platforms to force names to be converted to lowercase.

Object names may be considered duplicates if their uppercase forms are equal according to a binary collation. That is true for names of cursors, conditions, procedures, functions, savepoints, stored routine parameters, stored program local variables, and plugins. It is not true for names of columns, constraints, databases, partitions, statements prepared with `PREPARE`, tables, triggers, users, and user-defined variables.

File system case sensitivity can affect searches in string columns of `INFORMATION_SCHEMA` tables. For more information, see Section 10.8.7, “Using Collation in `INFORMATION_SCHEMA` Searches”.

### 9.2.4 Mapping of Identifiers to File Names

There is a correspondence between database and table identifiers and names in the file system. For the basic structure, MySQL represents each database as a directory in the data directory, and depending upon the storage engine, each table may be represented by one or more files in the appropriate database directory.
For the data and index files, the exact representation on disk is storage engine specific. These files may be stored in the database directory, or the information may be stored in a separate file. InnoDB data is stored in the InnoDB data files. If you are using tablespaces with InnoDB, then the specific tablespace files you create are used instead.

Any character is legal in database or table identifiers except ASCII NULL (X'00'). MySQL encodes any characters that are problematic in the corresponding file system objects when it creates database directories or table files:

- Basic Latin letters (a..zA..Z), digits (0..9) and underscore (_) are encoded as is. Consequently, their case sensitivity directly depends on file system features.

- All other national letters from alphabets that have uppercase/lowercase mapping are encoded as shown in the following table. Values in the Code Range column are UCS-2 values.

<table>
<thead>
<tr>
<th>Code Range</th>
<th>Pattern</th>
<th>Number</th>
<th>Used</th>
<th>Unused</th>
<th>Blocks</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>FF21..FF5A</td>
<td>[@][a..z][@]</td>
<td>26</td>
<td>26</td>
<td>0</td>
<td>Halfwidth and Fullwidth forms</td>
</tr>
</tbody>
</table>

One of the bytes in the sequence encodes lettercase. For example: LATIN CAPITAL LETTER A WITH GRAVE is encoded as @0G, whereas LATIN SMALL LETTER A WITH GRAVE is encoded as @0g. Here the third byte (G or g) indicates lettercase. (On a case-insensitive file system, both letters are treated as the same.)

For some blocks, such as Cyrillic, the second byte determines lettercase. For other blocks, such as Latin1 Supplement, the third byte determines lettercase. If two bytes in the sequence are letters (as in Greek Extended), the leftmost letter character stands for lettercase. All other letter bytes must be in lowercase.

- All nonletter characters except underscore (_), as well as letters from alphabets that do not have uppercase/lowercase mapping (such as Hebrew) are encoded using hexadecimal representation using lowercase letters for hexadecimal digits a..f:
Function Name Parsing and Resolution

<table>
<thead>
<tr>
<th>0x003F -&gt; @003F</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xFFFF -&gt; @ffff</td>
</tr>
</tbody>
</table>

The hexadecimal values correspond to character values in the ucs2 double-byte character set.

On Windows, some names such as nul, prn, and aux are encoded by appending @@ to the name when the server creates the corresponding file or directory. This occurs on all platforms for portability of the corresponding database object between platforms.

The following names are reserved and appended with @@ if used in schema or table names:

- CON
- PRN
- AUX
- NUL
- COM1 through COM9
- LPT1 through LPT9

CLOCK$ is also a member of this group of reserved names, but is not appended with @@, but @0024 instead. That is, if CLOCK$ is used as a schema or table name, it is written to the file system as CLOCK@0024. The same is true for any use of $ (dollar sign) in a schema or table name; it is replaced with @0024 on the filesystem.

Note

These names are also written to INNODB_TABLES in their appended forms, but are written to TABLES in their unappended form, as entered by the user.

9.2.5 Function Name Parsing and Resolution

MySQL supports built-in (native) functions, loadable functions, and stored functions. This section describes how the server recognizes whether the name of a built-in function is used as a function call or as an identifier, and how the server determines which function to use in cases when functions of different types exist with a given name.

- Built-In Function Name Parsing
- Function Name Resolution

Built-In Function Name Parsing

The parser uses default rules for parsing names of built-in functions. These rules can be changed by enabling the IGNORE_SPACE SQL mode.

When the parser encounters a word that is the name of a built-in function, it must determine whether the name signifies a function call or is instead a nonexpression reference to an identifier such as a table or column name. For example, in the following statements, the first reference to count is a function call, whereas the second reference is a table name:

```sql
SELECT COUNT(*) FROM mytable;
CREATE TABLE count (i INT);
```
The parser should recognize the name of a built-in function as indicating a function call only when parsing what is expected to be an expression. That is, in nonexpression context, function names are permitted as identifiers.

However, some built-in functions have special parsing or implementation considerations, so the parser uses the following rules by default to distinguish whether their names are being used as function calls or as identifiers in nonexpression context:

- To use the name as a function call in an expression, there must be no whitespace between the name and the following ( parenthesis character.
- Conversely, to use the function name as an identifier, it must not be followed immediately by a parenthesis.

The requirement that function calls be written with no whitespace between the name and the parenthesis applies only to the built-in functions that have special considerations. COUNT is one such name. The sql/lex.h source file lists the names of these special functions for which following whitespace determines their interpretation: names defined by the SYM_FN() macro in the symbols[] array.

The following list names the functions in MySQL 8.2 that are affected by the IGNORE_SPACE setting and listed as special in the sql/lex.h source file. You may find it easiest to treat the no-whitespace requirement as applying to all function calls.

- ADDDATE
- BIT_AND
- BIT_OR
- BIT_XOR
- CAST
- COUNT
- CURDATE
- CURTIME
- DATE_ADD
- DATE_SUB
- EXTRACT
- GROUP_CONCAT
- MAX
- MID
- MIN
- NOW
- POSITION
- SESSION_USER
- STD
Function Name Parsing and Resolution

- **STDDEV**
- **STDDEV_POP**
- **STDDEV_SAMP**
- **SUBDATE**
- **SUBSTR**
- **SUBSTRING**
- **SUM**
- **SYSDATE**
- **SYSTEM_USER**
- **TRIM**
- **VARIANCE**
- **VAR_POP**
- **VAR_SAMP**

For functions not listed as special in `sql/lex.h`, whitespace does not matter. They are interpreted as function calls only when used in expression context and may be used freely as identifiers otherwise. ASCII is one such name. However, for these nonaffected function names, interpretation may vary in expression context: `func_name()` is interpreted as a built-in function if there is one with the given name; if not, `func_name()` is interpreted as a loadable function or stored function if one exists with that name.

The **IGNORE_SPACE** SQL mode can be used to modify how the parser treats function names that are whitespace-sensitive:

- **With IGNORE_SPACE disabled**, the parser interprets the name as a function call when there is no whitespace between the name and the following parenthesis. This occurs even when the function name is used in nonexpression context:

```
mysql> CREATE TABLE count(i INT);
ERROR 1064 (42000): You have an error in your SQL syntax ...
```

To eliminate the error and cause the name to be treated as an identifier, either use whitespace following the name or write it as a quoted identifier (or both):

```
CREATE TABLE count {i INT};
CREATE TABLE `count`(i INT);
CREATE TABLE `count` {i INT};
```

- **With IGNORE_SPACE enabled**, the parser loosens the requirement that there be no whitespace between the function name and the following parenthesis. This provides more flexibility in writing function calls. For example, either of the following function calls are legal:

```
SELECT COUNT(*) FROM mytable;
SELECT COUNT(*) FROM mytable;
```

However, enabling **IGNORE_SPACE** also has the side effect that the parser treats the affected function names as reserved words (see Section 9.3, “Keywords and Reserved Words”). This means that a space following the name no longer signifies its use as an identifier. The name can be used in function calls.
Function Name Parsing and Resolution

with or without following whitespace, but causes a syntax error in nonexpression context unless it is quoted. For example, with `IGNORE_SPACE` enabled, both of the following statements fail with a syntax error because the parser interprets `count` as a reserved word:

```sql
CREATE TABLE count(i INT);
CREATE TABLE count (i INT);
```

To use the function name in nonexpression context, write it as a quoted identifier:

```sql
CREATE TABLE `count`(i INT);
CREATE TABLE `count` (i INT);
```

To enable the `IGNORE_SPACE` SQL mode, use this statement:

```sql
SET sql_mode = 'IGNORE_SPACE';
```

`IGNORE_SPACE` is also enabled by certain other composite modes such as `ANSI` that include it in their value:

```sql
SET sql_mode = 'ANSI';
```

Check Section 5.1.11, “Server SQL Modes”, to see which composite modes enable `IGNORE_SPACE`.

To minimize the dependency of SQL code on the `IGNORE_SPACE` setting, use these guidelines:

- Avoid creating loadable functions or stored functions that have the same name as a built-in function.

- Avoid using function names in nonexpression context. For example, these statements use `count` (one of the affected function names affected by `IGNORE_SPACE`), so they fail with or without whitespace following the name if `IGNORE_SPACE` is enabled:

```sql
CREATE TABLE count(i INT);
CREATE TABLE count (i INT);
```

If you must use a function name in nonexpression context, write it as a quoted identifier:

```sql
CREATE TABLE `count`(i INT);
CREATE TABLE `count` (i INT);
```

**Function Name Resolution**

The following rules describe how the server resolves references to function names for function creation and invocation:

- **Built-in functions and loadable functions**

  An error occurs if you try to create a loadable function with the same name as a built-in function.

  `IF NOT EXISTS` has no effect in such cases. See Section 13.7.4.1, “CREATE FUNCTION Statement for Loadable Functions”, for more information.

- **Built-in functions and stored functions**

  It is possible to create a stored function with the same name as a built-in function, but to invoke the stored function it is necessary to qualify it with a schema name. For example, if you create a stored function named `PI` in the `test` schema, invoke it as `test.PI()` because the server resolves `PI()` without a qualifier as a reference to the built-in function. The server generates a warning if the stored function name collides with a built-in function name. The warning can be displayed with `SHOW WARNINGS`.
Keywords and Reserved Words

- **IF NOT EXISTS** has no effect in such cases; see Section 13.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”.

- **Loadable functions and stored functions**

  It is possible to create a stored function with the same name as an existing loadable function, or the other way around. The server generates a warning if a proposed stored function name collides with an existing loadable function name, or if a proposed loadable function name would be the same as that of an existing stored function. In either case, once both functions exist, it is necessary thereafter to qualify the stored function with a schema name when invoking it; the server assumes in such cases that the unqualified name refers to the loadable function.

  MySQL 8.2 supports **IF NOT EXISTS** with **CREATE FUNCTION** statements, but it has no effect in such cases.

  The preceding function name resolution rules have implications for upgrading to versions of MySQL that implement new built-in functions:

  - If you have already created a loadable function with a given name and upgrade MySQL to a version that implements a new built-in function with the same name, the loadable function becomes inaccessible. To correct this, use **DROP FUNCTION** to drop the loadable function and **CREATE FUNCTION** to re-create the loadable function with a different nonconflicting name. Then modify any affected code to use the new name.

  - If a new version of MySQL implements a built-in function or loadable function with the same name as an existing stored function, you have two choices: Rename the stored function to use a nonconflicting name, or change any calls to the function that do not do so already to use a schema qualifier (**schema_name.func_name()** syntax). In either case, modify any affected code accordingly.

### 9.3 Keywords and Reserved Words

Keywords are words that have significance in SQL. Certain keywords, such as **SELECT**, **DELETE**, or **BIGINT**, are reserved and require special treatment for use as identifiers such as table and column names. This may also be true for the names of built-in functions.

Nonreserved keywords are permitted as identifiers without quoting. Reserved words are permitted as identifiers if you quote them as described in Section 9.2, “Schema Object Names”:

```
mysql> CREATE TABLE interval (begin INT, end INT);
ERROR 1064 (42000): You have an error in your SQL syntax ...
near 'interval (begin INT, end INT)'
```

**BEGIN** and **END** are keywords but not reserved, so their use as identifiers does not require quoting. **INTERVAL** is a reserved keyword and must be quoted to be used as an identifier:

```
mysql> CREATE TABLE `interval` (begin INT, end INT);
Query OK, 0 rows affected (0.01 sec)
```

Exception: A word that follows a period in a qualified name must be an identifier, so it need not be quoted even if it is reserved:

```
mysql> CREATE TABLE mydb.interval (begin INT, end INT);
Query OK, 0 rows affected (0.01 sec)
```

Names of built-in functions are permitted as identifiers but may require care to be used as such. For example, **COUNT** is acceptable as a column name. However, by default, no whitespace is permitted in
function invocations between the function name and the following \( ( \) character. This requirement enables the parser to distinguish whether the name is used in a function call or in nonfunction context. For further details on recognition of function names, see Section 9.2.5, “Function Name Parsing and Resolution”.

The INFORMATION_SCHEMA.KEYWORDS table lists the words considered keywords by MySQL and indicates whether they are reserved. See Section 26.3.17, “The INFORMATION_SCHEMA KEYWORDS Table”.

- MySQL 8.2 Keywords and Reserved Words
- MySQL 8.2 New Keywords and Reserved Words
- MySQL 8.2 Removed Keywords and Reserved Words

### MySQL 8.2 Keywords and Reserved Words

The following list shows the keywords and reserved words in MySQL 8.2, along with changes to individual words from version to version. Reserved keywords are marked with (R). In addition, \_FILENAME is reserved.

At some point, you might upgrade to a higher version, so it is a good idea to have a look at future reserved words, too. You can find these in the manuals that cover higher versions of MySQL. Most of the reserved words in the list are forbidden by standard SQL as column or table names (for example, \texttt{GROUP}). A few are reserved because MySQL needs them and uses a \texttt{yacc} parser.

MySQL 8.2 Removed Keywords and Reserved Words

The following list shows the keywords and reserved words that are removed in MySQL 8.2, compared to MySQL 8.1. Reserved keywords are marked with (R).

- ANALYSE
- DES_KEY_FILE
- MASTER_SERVER_ID
- PARSE_GCOL_EXPR
- REDOFILE
- SQL_CACHE

9.4 User-Defined Variables

You can store a value in a user-defined variable in one statement and refer to it later in another statement. This enables you to pass values from one statement to another.

User variables are written as `@var_name`, where the variable name `var_name` consists of alphanumerical characters, _, and $. A user variable name can contain other characters if you quote it as a string or identifier (for example, `@'my-var'`, `"my-var"`, or `@`my-var`).

User-defined variables are session specific. A user variable defined by one client cannot be seen or used by other clients. (Exception: A user with access to the Performance Schema `user_variables_by_thread` table can see all user variables for all sessions.) All variables for a given client session are automatically freed when that client exits.

User variable names are not case-sensitive. Names have a maximum length of 64 characters.

One way to set a user-defined variable is by issuing a `SET` statement:

```sql
SET @var_name = expr [, @var_name = expr] ...
```

For `SET`, either `=` or `:=` can be used as the assignment operator.

User variables can be assigned a value from a limited set of data types: integer, decimal, floating-point, binary or nonbinary string, or `NULL` value. Assignment of decimal and real values does not preserve the precision or scale of the value. A value of a type other than one of the permissible types is converted to a permissible type. For example, a value having a temporal or spatial data type is converted to a binary string. A value having the `JSON` data type is converted to a string with a character set of `utf8mb4` and a collation of `utf8mb4_bin`.

If a user variable is assigned a nonbinary (character) string value, it has the same character set and collation as the string. The coercibility of user variables is implicit. (This is the same coercibility as for table column values.)

Hexadecimal or bit values assigned to user variables are treated as binary strings. To assign a hexadecimal or bit value as a number to a user variable, use it in numeric context. For example, add 0 or use `CAST(... AS UNSIGNED)`:

```sql
mysql> SET @v1 = X'41';
mysql> SET @v2 = X'41'+0;
mysql> SET @v3 = CAST(X'41' AS UNSIGNED);
```
User-Defined Variables

If the value of a user variable is selected in a result set, it is returned to the client as a string.

If you refer to a variable that has not been initialized, it has a value of NULL and a type of string.

A reference to a user variable in a prepared statement has its type determined when the statement is first prepared, and retains this type each time the statement is executed thereafter. Similarly, the type of a user variable employed in a statement within a stored procedure is determined the first time the stored procedure is invoked, and retains this type with each subsequent invocation.

User variables may be used in most contexts where expressions are permitted. This does not currently include contexts that explicitly require a literal value, such as in the LIMIT clause of a SELECT statement, or the IGNORE N LINES clause of a LOAD DATA statement.

Previous releases of MySQL made it possible to assign a value to a user variable in statements other than SET. This functionality is supported in MySQL 8.2 for backward compatibility but is subject to removal in a future release of MySQL.

When making an assignment in this way, you must use := as the assignment operator; = is treated as the comparison operator in statements other than SET.

The order of evaluation for expressions involving user variables is undefined. For example, there is no guarantee that SELECT @a, @a:=@a+1 evaluates @a first and then performs the assignment.

In addition, the default result type of a variable is based on its type at the beginning of the statement. This may have unintended effects if a variable holds a value of one type at the beginning of a statement in which it is also assigned a new value of a different type.

To avoid problems with this behavior, either do not assign a value to and read the value of the same variable within a single statement, or else set the variable to 0, 0.0, or '' to define its type before you use it.

HAVING, GROUP BY, and ORDER BY, when referring to a variable that is assigned a value in the select expression list do not work as expected because the expression is evaluated on the client and thus can use stale column values from a previous row.

User variables are intended to provide data values. They cannot be used directly in an SQL statement as an identifier or as part of an identifier, such as in contexts where a table or database name is expected, or as a reserved word such as SELECT. This is true even if the variable is quoted, as shown in the following example:

mysql> SELECT c1 FROM t;
+---+
| c1 |
+---+
User-Defined Variables

```
+----+
| 0  |
+----+
| 1  |
+----+
2 rows in set (0.00 sec)

mysql> SET @col = "c1";
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @col FROM t;
+-------+
| @col   |
+-------+
| c1     |
+-------+
1 row in set (0.00 sec)

mysql> SELECT `@col` FROM t;
ERROR 1054 (42S22): Unknown column '@col' in 'field list'

mysql> SET @col = "'c1'";
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @col FROM t;
+-------+
| @col   |
+-------+
| 'c1'   |
+-------+
1 row in set (0.00 sec)

An exception to this principle that user variables cannot be used to provide identifiers, is when you are constructing a string for use as a prepared statement to execute later. In this case, user variables can be used to provide any part of the statement. The following example illustrates how this can be done:

mysql> SET @c = "c1";
Query OK, 0 rows affected (0.00 sec)

mysql> SET @s = CONCAT("SELECT ", @c, " FROM t");
Query OK, 0 rows affected (0.00 sec)

mysql> PREPARE stmt FROM @s;
Query OK, 0 rows affected (0.04 sec)
Statement prepared

mysql> EXECUTE stmt;
+----+
| c1  |
+----+
| 0   |
+----+
| 1   |
+----+
2 rows in set (0.00 sec)

mysql> DEALLOCATE PREPARE stmt;
Query OK, 0 rows affected (0.00 sec)

A similar technique can be used in application programs to construct SQL statements using program variables, as shown here using PHP 5:

```php
<?php
    $mysqli = new mysqli("localhost", "user", "pass", "test");
```
Assembling an SQL statement in this fashion is sometimes known as “Dynamic SQL”.

9.5 Expressions

This section lists the grammar rules that expressions must follow in MySQL and provides additional information about the types of terms that may appear in expressions.

- Expression Syntax
- Expression Term Notes
- Temporal Intervals

Expression Syntax

The following grammar rules define expression syntax in MySQL. The grammar shown here is based on that given in the sql/sql_yacc.yy file of MySQL source distributions. For additional information about some of the expression terms, see Expression Term Notes.

```
expr:    expr OR expr
    |   expr XOR expr
    |   expr AND expr
    |   expr && expr
    |   NOT expr
    |   boolean_primary IS [NOT] {TRUE | FALSE | UNKNOWN}
    |   boolean_primary

boolean_primary:  boolean_primary IS [NOT] NULL
                  |   boolean_primary <=> predicate
                  |   boolean_primary comparison_operator predicate
                  |   boolean_primary comparison_operator {ALL | ANY} {subquery}
                  |   predicate

comparison_operator:  = | <= | > | >= | < | < | <> | !=

predicate:  bit_expr [NOT] IN (subquery)
            | bit_expr [NOT] IN (expr [, expr] ...)
            | bit_expr [NOT] BETWEEN bit_expr AND predicate
```
Expression Term Notes

For operator precedence, see Section 12.4.1, “Operator Precedence”. The precedence and meaning of some operators depends on the SQL mode:

- By default, || is a logical OR operator. With PIPES_AS_CONCAT enabled, || is string concatenation, with a precedence between ^ and the unary operators.

- By default, ! has a higher precedence than NOT. With HIGH_NOT_PRECEDENCE enabled, ! and NOT have the same precedence.

See Section 5.1.11, “Server SQL Modes”.

Expression Term Notes

For literal value syntax, see Section 9.1, “Literal Values”.

For identifier syntax, see Section 9.2, “Schema Object Names”.

Variables can be user variables, system variables, or stored program local variables or parameters:

- User variables: Section 9.4, “User-Defined Variables”
Temporal Intervals

- System variables: Section 5.1.9, “Using System Variables”
- Stored program local variables: Section 13.6.4.1, “Local Variable DECLARE Statement”
- Stored program parameters: Section 13.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”

`param_marker` is `?` as used in prepared statements for placeholders. See Section 13.5.1, “PREPARE Statement”.

(subquery) indicates a subquery that returns a single value; that is, a scalar subquery. See Section 13.2.15.1, “The Subquery as Scalar Operand”.

{identifier expr} is ODBC escape syntax and is accepted for ODBC compatibility. The value is `expr`. The `{` and `}` curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

match_expr indicates a MATCH expression. See Section 12.9, “Full-Text Search Functions”.

case_expr indicates a CASE expression. See Section 12.5, “Flow Control Functions”.

interval_expr represents a temporal interval. See Temporal Intervals.

Temporal Intervals

`interval_expr` in expressions represents a temporal interval. Intervals have this syntax:

```
INTERVAL expr unit
```

`expr` represents a quantity. `unit` represents the unit for interpreting the quantity; it is a specifier such as HOUR, DAY, or WEEK. The `INTERVAL` keyword and the `unit` specifier are not case-sensitive.

The following table shows the expected form of the `expr` argument for each `unit` value.

<table>
<thead>
<tr>
<th>unit Value</th>
<th>Expected <code>expr</code> Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>MICROSECOND</td>
<td>MICROSECONDS</td>
</tr>
<tr>
<td>SECOND</td>
<td>SECONDS</td>
</tr>
<tr>
<td>MINUTE</td>
<td>MINUTES</td>
</tr>
<tr>
<td>HOUR</td>
<td>HOURS</td>
</tr>
<tr>
<td>DAY</td>
<td>DAYS</td>
</tr>
<tr>
<td>WEEK</td>
<td>WEEKS</td>
</tr>
<tr>
<td>MONTH</td>
<td>MONTHS</td>
</tr>
<tr>
<td>QUARTER</td>
<td>QUARTERS</td>
</tr>
<tr>
<td>YEAR</td>
<td>YEARS</td>
</tr>
<tr>
<td>SECOND_MICROSECOND</td>
<td>'SECONDS.MICROSECONDS'</td>
</tr>
<tr>
<td>MINUTE_MICROSECOND</td>
<td>'MINUTES:SECONDS.MICROSECONDS'</td>
</tr>
<tr>
<td>MINUTE_SECOND</td>
<td>'MINUTES:SECONDS'</td>
</tr>
<tr>
<td>HOUR_MICROSECOND</td>
<td>'HOURS:MINUTES:SECONDS.MICROSECONDS'</td>
</tr>
<tr>
<td>HOUR_SECOND</td>
<td>'HOURS:MINUTES:SECONDS'</td>
</tr>
</tbody>
</table>
Temporal Intervals

<table>
<thead>
<tr>
<th>unit Value</th>
<th>Expected expr Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>HOUR_MINUTE</td>
<td>'HOURS:MINUTES'</td>
</tr>
<tr>
<td>DAY_MICROSECOND</td>
<td>'DAYS HOURS:MINUTES:SECONDS.MICROSECONDS'</td>
</tr>
<tr>
<td>DAY_SECOND</td>
<td>'DAYS HOURS:MINUTES:SECONDS'</td>
</tr>
<tr>
<td>DAY_MINUTE</td>
<td>'DAYS HOURS:MINUTES'</td>
</tr>
<tr>
<td>DAY_HOUR</td>
<td>'DAYS HOURS'</td>
</tr>
<tr>
<td>YEAR_MONTH</td>
<td>'YEARS-MONTHS'</td>
</tr>
</tbody>
</table>

MySQL permits any punctuation delimiter in the \textit{expr} format. Those shown in the table are the suggested delimiters.

Temporal intervals are used for certain functions, such as \texttt{DATE_ADD()} and \texttt{DATE_SUB()}:

```sql
mysql> SELECT DATE_ADD('2018-05-01', INTERVAL 1 DAY);
-> '2018-05-02'
mysql> SELECT DATE_SUB('2018-05-01', INTERVAL 1 YEAR);
-> '2017-05-01'
```

Temporal arithmetic also can be performed in expressions using \texttt{INTERVAL} together with the + or - operator:

```sql
date + INTERVAL expr unit
```

\texttt{INTERVAL expr unit} is permitted on either side of the + operator if the expression on the other side is a date or datetime value. For the - operator, \texttt{INTERVAL expr unit} is permitted only on the right side, because it makes no sense to subtract a date or datetime value from an interval.

```sql
mysql> SELECT '2018-12-31 23:59:59' + INTERVAL 1 SECOND;
-> '2019-01-01 00:00:00'
mysql> SELECT INTERVAL 1 DAY + '2018-12-31';
-> '2019-01-01'
mysql> SELECT '2025-01-01' - INTERVAL 1 SECOND;
-> '2024-12-31 23:59:59'
```

The \texttt{EXTRACT()} function uses the same kinds of \textit{unit} specifiers as \texttt{DATE_ADD()} or \texttt{DATE_SUB()}, but extracts parts from the date rather than performing date arithmetic:

```sql
mysql> SELECT EXTRACT(YEAR FROM '2019-07-02');
-> 2019
```
Temporal Intervals

```sql
mysql> SELECT EXTRACT(YEAR_MONTH FROM '2019-07-02 01:02:03');
-> 201907
```

Temporal intervals can be used in `CREATE EVENT` statements:

```sql
CREATE EVENT myevent
ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
DO
  UPDATE myschema.mytable SET mycol = mycol + 1;
```

If you specify an interval value that is too short (does not include all the interval parts that would be expected from the `unit` keyword), MySQL assumes that you have left out the leftmost parts of the interval value. For example, if you specify a `unit` of `DAY_SECOND`, the value of `expr` is expected to have days, hours, minutes, and seconds parts. If you specify a value like `'1:10'`, MySQL assumes that the days and hours parts are missing and the value represents minutes and seconds. In other words, `'1:10'` `DAY_SECOND` is interpreted in such a way that it is equivalent to `'1:10'` `MINUTE_SECOND`. This is analogous to the way that MySQL interprets `TIME` values as representing elapsed time rather than as a time of day.

`expr` is treated as a string, so be careful if you specify a non-string value with `INTERVAL`. For example, with an interval specifier of `HOUR_MINUTE`, `'6/4'` is treated as 6 hours, four minutes, whereas `6/4` evaluates to `1.5000` and is treated as 1 hour, 5000 minutes:

```sql
mysql> SELECT '6/4', 6/4;
-> 1.5000
```

To ensure interpretation of the interval value as you expect, a `CAST()` operation may be used. To treat `6/4` as 1 hour, 5 minutes, cast it to a `DECIMAL` value with a single fractional digit:

```sql
mysql> SELECT CAST(6/4 AS DECIMAL(3,1));
-> 1.5
```

If you add to or subtract from a date value something that contains a time part, the result is automatically converted to a datetime value:

```sql
mysql> SELECT DATE_ADD('2023-01-01', INTERVAL 1 DAY);
-> '2023-01-02'
mysql> SELECT DATE_ADD('2023-01-01', INTERVAL 1 HOUR);
-> '2023-01-01 01:00:00'
```

If you add `MONTH`, `YEAR_MONTH`, or `YEAR` and the resulting date has a day that is larger than the maximum day for the new month, the day is adjusted to the maximum days in the new month:

```sql
mysql> SELECT DATE_ADD('2019-01-30', INTERVAL 1 MONTH);
-> '2019-02-28'
```

Date arithmetic operations require complete dates and do not work with incomplete dates such as `'2016-07-00'` or badly malformed dates:

```sql
mysql> SELECT DATE_ADD('2016-07-00', INTERVAL 1 DAY);
-> NULL
mysql> SELECT '2005-03-32' + INTERVAL 1 MONTH;
-> NULL
```
9.6 Query Attributes

The most visible part of an SQL statement is the text of the statement. Clients can also define query attributes that apply to the next statement sent to the server for execution:

- Attributes are defined prior to sending the statement.
- Attributes exist until statement execution ends, at which point the attribute set is cleared.
- While attributes exist, they can be accessed on the server side.

Examples of the ways query attributes may be used:

- A web application produces pages that generate database queries, and for each query must track the URL of the page that generated it.
- An application passes extra processing information with each query, for use by a plugin such as an audit plugin or query rewrite plugin.

MySQL supports these capabilities without the use of workarounds such as specially formatted comments included in query strings. The remainder of this section describes how to use query attribute support, including the prerequisites that must be satisfied.

- Defining and Accessing Query Attributes
- Prerequisites for Using Query Attributes
- Query Attribute Loadable Functions

Defining and Accessing Query Attributes

Applications that use the MySQL C API define query attributes by calling the `mysql_bind_param()` function. See `mysql_bind_param()`. Other MySQL connectors may also provide query-attribute support. See the documentation for individual connectors.

The `mysql` client has a `query_attributes` command that enables defining up to 32 pairs of attribute names and values. See Section 4.5.1.2, “mysql Client Commands”.

Query attribute names are transmitted using the character set indicated by the `character_set_client` system variable.

To access query attributes within SQL statements for which attributes have been defined, install the `query_attributes` component as described in Prerequisites for Using Query Attributes. The component implements a `mysql_query_attribute_string()` loadable function that takes an attribute name argument and returns the attribute value as a string, or `NULL` if the attribute does not exist. See Query Attribute Loadable Functions.

The following examples use the `mysql` client `query_attributes` command to define attribute name/value pairs, and the `mysql_query_attribute_string()` function to access attribute values by name.

This example defines two attributes named `n1` and `n2`. The first `SELECT` shows how to retrieve those attributes, and also demonstrates that retrieving a nonexistent attribute (`n3`) returns `NULL`. The second `SELECT` shows that attributes do not persist across statements.

```
mysql> query_attributes n1 v1 n2 v2;
mysql> SELECT
    mysql_query_attribute_string('n1') AS 'attr 1',
    mysql_query_attribute_string('n2') AS 'attr 2',
```
Defining and Accessing Query Attributes

```sql
mysql_query_attribute_string('n3') AS 'attr 3';
+--------+--------+--------+
| attr 1 | attr 2 | attr 3 |
| v1     | v2     | NULL   |
+--------+--------+--------+
```

As shown by the second `SELECT` statement, attributes defined prior to a given statement are available only to that statement and are cleared after the statement executes. To use an attribute value across multiple statements, assign it to a variable. The following example shows how to do this, and illustrates that attribute values are available in subsequent statements by means of the variables, but not by calling `mysql_query_attribute_string()`:

```sql
mysql> query_attributes n1 v1 n2 v2;
mysql> SET
   @attr1 = mysql_query_attribute_string('n1'),
   @attr2 = mysql_query_attribute_string('n2');
mysql> SELECT
   @attr1, mysql_query_attribute_string('n1') AS 'attr 1',
   @attr2, mysql_query_attribute_string('n2') AS 'attr 2';
```

Attributes can also be saved for later use by storing them in a table:

```sql
mysql> CREATE TABLE t1 (c1 CHAR(20), c2 CHAR(20));
mysql> query_attributes n1 v1 n2 v2;
mysql> INSERT INTO t1 (c1, c2) VALUES(
   mysql_query_attribute_string('n1'),
   mysql_query_attribute_string('n2'));
mysql> SELECT * FROM t1;
```

Query attributes are subject to these limitations and restrictions:

- If multiple attribute-definition operations occur prior to sending a statement to the server for execution, the most recent definition operation applies and replaces attributes defined in earlier operations.
- If multiple attributes are defined with the same name, attempts to retrieve the attribute value have an undefined result.
- An attribute defined with an empty name cannot be retrieved by name.
- Attributes are not available to statements prepared with `PREPARE`. 
Prerequisites for Using Query Attributes

- The **mysql_query_attribute_string()** function cannot be used in DDL statements.
- Attributes are not replicated. Statements that invoke the **mysql_query_attribute_string()** function will not get the same value on all servers.

**Prerequisites for Using Query Attributes**

To access query attributes within SQL statements for which attributes have been defined, the **query_attributes** component must be installed. Do so using this statement:

```
INSTALL COMPONENT "file://component_query_attributes";
```

Component installation is a one-time operation that need not be done per server startup. **INSTALL COMPONENT** loads the component, and also registers it in the **mysql.component** system table to cause it to be loaded during subsequent server startups.

The **query_attributes** component accesses query attributes to implement a **mysql_query_attribute_string()** function. See Section 5.5.4, “Query Attribute Components”.

To uninstall the **query_attributes** component, use this statement:

```
UNINSTALL COMPONENT "file://component_query_attributes";
```

**UNINSTALL COMPONENT** unloads the component, and unregisters it from the **mysql.component** system table to cause it not to be loaded during subsequent server startups.

Because installing and uninstalling the **query_attributes** component installs and uninstalls the **mysql_query_attribute_string()** function that the component implements, it is not necessary to use **CREATE FUNCTION** or **DROP FUNCTION** to do so.

**Query Attribute Loadable Functions**

- **mysql_query_attribute_string**(name)

  Applications can define attributes that apply to the next query sent to the server. The **mysql_query_attribute_string()** function returns an attribute value as a string, given the attribute name. This function enables a query to access and incorporate values of the attributes that apply to it.

  **mysql_query_attribute_string()** is installed by installing the **query_attributes** component. See Section 9.6, “Query Attributes”, which also discusses the purpose and use of query attributes.

  Arguments:
  - **name**: The attribute name.

  Return value:

  Returns the attribute value as a string for success, or **NULL** if the attribute does not exist.

  Example:

  The following example uses the **mysql client** **query_attributes** command to define query attributes that can be retrieved by **mysql_query_attribute_string()**. The **SELECT** shows that retrieving a nonexistent attribute (**n3**) returns **NULL**.

  ```
  mysql> query_attributes n1 v1 n2 v2;
  mysql> SELECT
  ```

  2057
9.7 Comments

MySQL Server supports three comment styles:

- From a `#` character to the end of the line.
- From a `--` sequence to the end of the line. In MySQL, the `--` (double-dash) comment style requires the second dash to be followed by at least one whitespace or control character (such as a space, tab, newline, and so on). This syntax differs slightly from standard SQL comment syntax, as discussed in Section 1.8.2.4, "`--` as the Start of a Comment".
- From a `/*` sequence to the following `*/` sequence, as in the C programming language. This syntax enables a comment to extend over multiple lines because the beginning and closing sequences need not be on the same line.

The following example demonstrates all three comment styles:

```sql
mysql> SELECT 1+1;  # This comment continues to the end of line
mysql> SELECT 1+1;  -- This comment continues to the end of line
mysql> SELECT 1 /* this is an in-line comment */ + 1;
mysql> SELECT 1 + /*
   * this is a
   * multiple-line comment
   */ + 1;
```

Nested comments are not supported, and are deprecated; expect them to be removed in a future MySQL release. (Under some conditions, nested comments might be permitted, but usually are not, and users should avoid them.)

MySQL Server supports certain variants of C-style comments. These enable you to write code that includes MySQL extensions, but is still portable, by using comments of the following form:

```sql
/*! MySQL-specific code */
```

In this case, MySQL Server parses and executes the code within the comment as it would any other SQL statement, but other SQL servers should ignore the extensions. For example, MySQL Server recognizes the `STRAIGHT_JOIN` keyword in the following statement, but other servers should not:

```sql
SELECT /*! STRAIGHT_JOIN */ col1 FROM table1,table2 WHERE ...
```

If you add a version number after the `!` character, the syntax within the comment is executed only if the MySQL version is greater than or equal to the specified version number. The `KEY_BLOCK_SIZE` keyword in the following comment is executed only by servers from MySQL 5.1.10 or higher:

```sql
CREATE TABLE t1(a INT, KEY (a)) /*!50110 KEY_BLOCK_SIZE=1024 */;
```

The version number uses the format `Mmmrr`, where `M` is a major version, `mm` is a two-digit minor version, and `rr` is a two-digit release number. For example: In a statement to be run only by a MySQL server version 8.2.0 or later, use `80200` in the comment.
In MySQL 8.2, the version number can also optionally be comprised of six digits in `MMmmrr` format, where `MM` is a two-digit major version, and `mm` and `rr` are the two-digit minor version and two-digit release numbers, respectively.

The version number should be followed by at least one whitespace character (or the end of the comment). If the comment begins with six digits followed by whitespace, this is interpreted as a six-digit version number. Otherwise, if it begins with at least five digits, these are interpreted as a five-digit version number (and any remaining characters ignored for this purpose); if it begins with fewer than five digits, the comment is handled as a normal MySQL comment.

The comment syntax just described applies to how the `mysqld` server parses SQL statements. The `mysql` client program also performs some parsing of statements before sending them to the server. (It does this to determine statement boundaries within a multiple-statement input line.) For information about differences between the server and `mysql` client parsers, see Section 4.5.1.6, “mysql Client Tips”.

Comments in `/*!12345 ... */` format are not stored on the server. If this format is used to comment stored programs, the comments are not retained in the program body.

Another variant of C-style comment syntax is used to specify optimizer hints. Hint comments include a `+` character following the `/*` comment opening sequence. Example:

```
SELECT /*+ BKA(t1) */ FROM ... ;
```

For more information, see Section 8.9.3, “Optimizer Hints”.

The use of short-form `mysql` commands such as `\C` within multiple-line `/* ... */` comments is not supported. Short-form commands do work within single-line `/*! ... */` version comments, as do `/ *+ ... */` optimizer-hint comments, which are stored in object definitions. If there is a concern that optimizer-hint comments may be stored in object definitions so that dump files when reloaded with `mysql` would result in execution of such commands, either invoke `mysql` with the `--binary-mode` option or use a reload client other than `mysql`.

MySQL includes character set support that enables you to store data using a variety of character sets and perform comparisons according to a variety of collations. The default MySQL server character set and collation are `utf8mb4` and `utf8mb4_0900_ai_ci`, but you can specify character sets at the server, database, table, column, and string literal levels.

This chapter discusses the following topics:

- What are character sets and collations?
- The multiple-level default system for character set assignment.
- Syntax for specifying character sets and collations.
- Affected functions and operations.
- Unicode support.
- The character sets and collations that are available, with notes.
- Selecting the language for error messages.
- Selecting the locale for day and month names.

Character set issues affect not only data storage, but also communication between client programs and the MySQL server. If you want the client program to communicate with the server using a character set different from the default, you'll need to indicate which one. For example, to use the `utf8mb4` Unicode character set, issue this statement after connecting to the server:

```
SET NAMES 'utf8mb4';
```

For more information about configuring character sets for application use and character set-related issues in client/server communication, see Section 10.5, “Configuring Application Character Set and Collation”, and Section 10.4, “Connection Character Sets and Collations”.

## 10.1 Character Sets and Collations in General

A **character set** is a set of symbols and encodings. A **collation** is a set of rules for comparing characters in a character set. Let's make the distinction clear with an example of an imaginary character set.

Suppose that we have an alphabet with four letters: A, B, a, b. We give each letter a number: A = 0, B = 1, a = 2, b = 3. The letter A is a symbol, the number 0 is the encoding for A, and the combination of all four letters and their encodings is a **character set**.

Suppose that we want to compare two string values, A and B. The simplest way to do this is to look at the encodings: 0 for A and 1 for B. Because 0 is less than 1, we say A is less than B. What we've just done is apply a collation to our character set. The collation is a set of rules (only one rule in this case): “compare the encodings.” We call this simplest of all possible collations a **binary collation**.
But what if we want to say that the lowercase and uppercase letters are equivalent? Then we would have at least two rules: (1) treat the lowercase letters $a$ and $b$ as equivalent to $A$ and $B$; (2) then compare the encodings. We call this a *case-insensitive* collation. It is a little more complex than a binary collation.

In real life, most character sets have many characters: not just $A$ and $B$ but whole alphabets, sometimes multiple alphabets or eastern writing systems with thousands of characters, along with many special symbols and punctuation marks. Also in real life, most collations have many rules, not just for whether to distinguish lettercase, but also for whether to distinguish accents (an “accent” is a mark attached to a character as in German $ö$), and for multiple-character mappings (such as the rule that $ö = òE$ in one of the two German collations).

MySQL can do these things for you:

- Store strings using a variety of character sets.
- Compare strings using a variety of collations.
- Mix strings with different character sets or collations in the same server, the same database, or even the same table.
- Enable specification of character set and collation at any level.

To use these features effectively, you must know what character sets and collations are available, how to change the defaults, and how they affect the behavior of string operators and functions.

## 10.2 Character Sets and Collations in MySQL

MySQL Server supports multiple character sets, including several Unicode character sets. To display the available character sets, use the `INFORMATION_SCHEMA CHARACTER_SETS` table or the `SHOW CHARACTER SET` statement. A partial listing follows. For more complete information, see Section 10.10, “Supported Character Sets and Collations”.

```
mysql> SHOW CHARACTER SET;
+----------+---------------------------------+---------------------+--------+
| Charset  | Description                     | Default collation   | Maxlen |
+----------+---------------------------------+---------------------+--------+
| big5     | Big5 Traditional Chinese        | big5_chinese_ci     | 2      |
| binary   | Binary pseudo charset           | binary              | 1      |
| latin1   | cp1252 West European            | latin1_swedish_ci   | 1      |
| ucs2     | UCS-2 Unicode                   | ucs2_general_ci     | 2      |
| utf8mb3  | UTF-8 Unicode                   | utf8mb3_general_ci  | 3      |
| utf8mb4  | UTF-8 Unicode                   | utf8mb4_0900_ai_ci  | 4      |
+----------+---------------------------------+---------------------+--------+
```

By default, the `SHOW CHARACTER SET` statement displays all available character sets. It takes an optional `LIKE` or `WHERE` clause that indicates which character set names to match. The following example shows some of the Unicode character sets (those based on Unicode Transformation Format):

```
mysql> SHOW CHARACTER SET LIKE 'utf%';
+----------+---------------------------------+---------------------+--------+
| Charset  | Description                     | Default collation   | Maxlen |
+----------+---------------------------------+---------------------+--------+
| utf16    | UTF-16 Unicode                   | utf16_general_ci    | 4      |
| utf16le  | UTF-16LE Unicode                 | utf16le_general_ci  | 4      |
| utf32    | UTF-32 Unicode                   | utf32_general_ci    | 4      |
| utf8mb3  | UTF-8 Unicode                    | utf8mb3_general_ci  | 3      |
| utf8mb4  | UTF-8 Unicode                    | utf8mb4_0900_ai_ci  | 4      |
+----------+---------------------------------+---------------------+--------+
```
A given character set always has at least one collation, and most character sets have several. To list the display collations for a character set, use the `INFORMATION_SCHEMA COLLATIONS` table or the `SHOW COLLATION` statement.

By default, the `SHOW COLLATION` statement displays all available collations. It takes an optional `LIKE` or `WHERE` clause that indicates which collation names to display. For example, to see the collations for the default character set, `utf8mb4`, use this statement:

```sql
mysql> SHOW COLLATION WHERE Charset = 'utf8mb4';
```

</table>

For more information about those collations, see Section 10.10.1, “Unicode Character Sets”.

Collations have these general characteristics:

- Two different character sets cannot have the same collation.
- Each character set has a default collation. For example, the default collations for utf8mb4 and latin1 are utf8mb4_0900_ai_ci and latin1_swedish_ci, respectively. The INFORMATION_SCHEMA CHARACTER_SETS table and the SHOW CHARACTER SET statement indicate the default collation for each character set. The INFORMATION_SCHEMA COLLATIONS table and the SHOW COLLATION statement have a column that indicates for each collation whether it is the default for its character set (Yes if so, empty if not).
- Collation names start with the name of the character set with which they are associated, generally followed by one or more suffixes indicating other collation characteristics. For additional information about naming conventions, see Section 10.3.1, “Collation Naming Naming Conventions”.

When a character set has multiple collations, it might not be clear which collation is most suitable for a given application. To avoid choosing an inappropriate collation, perform some comparisons with representative data values to make sure that a given collation sorts values the way you expect.

### 10.2.1 Character Set Repertoire

The **repertoire** of a character set is the collection of characters in the set.

String expressions have a repertoire attribute, which can have two values:

- **ASCII**: The expression can contain only ASCII characters; that is, characters in the Unicode range U+0000 to U+007F.
- **UNICODE**: The expression can contain characters in the Unicode range U+0000 to U+10FFFF. This includes characters in the Basic Multilingual Plane (BMP) range (U+0000 to U+FFFF) and supplementary characters outside the BMP range (U+10000 to U+10FFFF).

The ASCII range is a subset of UNICODE range, so a string with ASCII repertoire can be converted safely without loss of information to the character set of any string with UNICODE repertoire. It can also be converted safely to any character set that is a superset of the ascii character set. (All MySQL character...
sets are supersets of ascii with the exception of swe7, which reuses some punctuation characters for Swedish accented characters.)

The use of repertoire enables character set conversion in expressions for many cases where MySQL would otherwise return an “illegal mix of collations” error when the rules for collation coercibility are insufficient to resolve ambiguities. (For information about coercibility, see Section 10.8.4, “Collation Coercibility in Expressions”.)

The following discussion provides examples of expressions and their repertoires, and describes how the use of repertoire changes string expression evaluation:

- The repertoire for a string constant depends on string content and may differ from the repertoire of the string character set. Consider these statements:

  ```
  SET NAMES utf8mb4; SELECT 'abc';
  SELECT _utf8mb4'def';
  ```

  Although the character set is utf8mb4 in each of the preceding cases, the strings do not actually contain any characters outside the ASCII range, so their repertoire is ASCII rather than UNICODE.

- A column having the ascii character set has ASCII repertoire because of its character set. In the following table, c1 has ASCII repertoire:

  ```
  CREATE TABLE t1 (c1 CHAR(1) CHARACTER SET ascii);
  ```

  The following example illustrates how repertoire enables a result to be determined in a case where an error occurs without repertoire:

  ```
  CREATE TABLE t1 (c1 CHAR(1) CHARACTER SET latin1,
                  c2 CHAR(1) CHARACTER SET ascii);
  INSERT INTO t1 VALUES ('a','b');
  SELECT CONCAT(c1,c2) FROM t1;
  ```

  Without repertoire, this error occurs:

  ```
  ERROR 1267 (HY000): Illegal mix of collations (latin1_swedish_ci,IMPLICIT)
  and (ascii_general_ci,IMPLICIT) for operation 'concat'
  ```

  Using repertoire, subset to superset (ascii to latin1) conversion can occur and a result is returned:

  ```
  +---------------+
  | CONCAT(c1,c2) |
  +---------------+
  | ab            |
  +---------------+
  ```

- Functions with one string argument inherit the repertoire of their argument. The result of
  `UPPER(_utf8mb4'abc')` has ASCII repertoire because its argument has ASCII repertoire. (Despite the _utf8mb4 introducer, the string 'abc' contains no characters outside the ASCII range.)

- For functions that return a string but do not have string arguments and use `character_set_connection` as the result character set, the result repertoire is ASCII if `character_set_connection` is ascii, and UNICODE otherwise:

  ```
  FORMAT(numeric_column, 4);
  ```

  Use of repertoire changes how MySQL evaluates the following example:

  ```
  SET NAMES ascii;
  ```
CREATE TABLE t1 (a INT, b VARCHAR(10) CHARACTER SET latin1);
INSERT INTO t1 VALUES (1,'b');
SELECT CONCAT(FORMAT(a, 4), b) FROM t1;

Without repertoire, this error occurs:

ERROR 1267 (HY000): Illegal mix of collations (ascii_general_ci,COERCIBLE)
and (latin1_swedish_ci,IMPLICIT) for operation 'concat'

With repertoire, a result is returned:

```
+-------------------------+
<table>
<thead>
<tr>
<th>CONCAT(FORMAT(a, 4), b)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.0000b</td>
</tr>
</tbody>
</table>
+-------------------------+
```

• Functions with two or more string arguments use the “widest” argument repertoire for the result repertoire, where UNICODE is wider than ASCII. Consider the following CONCAT() calls:

CONCAT(_ucs2 X'0041', _ucs2 X'0042')
CONCAT(_ucs2 X'0041', _ucs2 X'00C2')

For the first call, the repertoire is ASCII because both arguments are within the ASCII range. For the second call, the repertoire is UNICODE because the second argument is outside the ASCII range.

• The repertoire for function return values is determined based on the repertoire of only those arguments that affect the result's character set and collation.

IF(column1 < column2, 'smaller', 'greater')

The result repertoire is ASCII because the two string arguments (the second argument and the third argument) both have ASCII repertoire. The first argument does not matter for the result repertoire, even if the expression uses string values.

10.2.2 UTF-8 for Metadata

Metadata is “the data about the data.” Anything that describes the database—as opposed to being the contents of the database—is metadata. Thus column names, database names, user names, version names, and most of the string results from SHOW are metadata. This is also true of the contents of tables in INFORMATION_SCHEMA because those tables by definition contain information about database objects.

Representation of metadata must satisfy these requirements:

• All metadata must be in the same character set. Otherwise, neither the SHOW statements nor SELECT statements for tables in INFORMATION_SCHEMA would work properly because different rows in the same column of the results of these operations would be in different character sets.

• Metadata must include all characters in all languages. Otherwise, users would not be able to name columns and tables using their own languages.

To satisfy both requirements, MySQL stores metadata in a Unicode character set, namely UTF-8. This does not cause any disruption if you never use accented or non-Latin characters. But if you do, you should be aware that metadata is in UTF-8.

The metadata requirements mean that the return values of the USER(), CURRENT_USER(), SESSION_USER(), SYSTEM_USER(), DATABASE(), and VERSION() functions have the UTF-8 character set by default.

The server sets the character_set_system system variable to the name of the metadata character set:
Storage of metadata using Unicode does not mean that the server returns headers of columns and the results of `DESCRIBE` functions in the `character_set_system` character set by default. When you use `SELECT column1 FROM t`, the name `column1` itself is returned from the server to the client in the character set determined by the value of the `character_set_results` system variable, which has a default value of `utf8mb4`. If you want the server to pass metadata results back in a different character set, use the `SET NAMES` statement to force the server to perform character set conversion. `SET NAMES` sets the `character_set_results` and other related system variables. (See Section 10.4, “Connection Character Sets and Collations”.) Alternatively, a client program can perform the conversion after receiving the result from the server. It is more efficient for the client to perform the conversion, but this option is not always available for all clients.

If `character_set_results` is set to `NULL`, no conversion is performed and the server returns metadata using its original character set (the set indicated by `character_set_system`).

Error messages returned from the server to the client are converted to the client character set automatically, as with metadata.

If you are using (for example) the `USER()` function for comparison or assignment within a single statement, don't worry. MySQL performs some automatic conversion for you.

```sql
SELECT * FROM t1 WHERE USER() = latin1_column;
```

This works because the contents of `latin1_column` are automatically converted to UTF-8 before the comparison.

```sql
INSERT INTO t1 (latin1_column) SELECT USER();
```

This works because the contents of `USER()` are automatically converted to `latin1` before the assignment.

Although automatic conversion is not in the SQL standard, the standard does say that every character set is (in terms of supported characters) a “subset” of Unicode. Because it is a well-known principle that “what applies to a superset can apply to a subset,” we believe that a collation for Unicode can apply for comparisons with non-Unicode strings. For more information about coercion of strings, see Section 10.8.4, “Collation Coercibility in Expressions”.

### 10.3 Specifying Character Sets and Collations

There are default settings for character sets and collations at four levels: server, database, table, and column. The description in the following sections may appear complex, but it has been found in practice that multiple-level defaulting leads to natural and obvious results.

`CHARACTER SET` is used in clauses that specify a character set. `CHARSET` can be used as a synonym for `CHARACTER SET`.

Character set issues affect not only data storage, but also communication between client programs and the MySQL server. If you want the client program to communicate with the server using a character set different from the default, you'll need to indicate which one. For example, to use the `utf8mb4` Unicode character set, issue this statement after connecting to the server:

```sql
SET NAMES 'utf8mb4';
```
For more information about character set-related issues in client/server communication, see Section 10.4, "Connection Character Sets and Collations".

10.3.1 Collation Naming Conventions

MySQL collation names follow these conventions:

- A collation name starts with the name of the character set with which it is associated, generally followed by one or more suffixes indicating other collation characteristics. For example, `utf8mb4_0900_ai_ci` and `latin1_swedish_ci` are collations for the `utf8mb4` and `latin1` character sets, respectively. The `binary` character set has a single collation, also named `binary`, with no suffixes.

- A language-specific collation includes a locale code or language name. For example, `utf8mb4_tr_0900_ai_ci` and `utf8mb4_hu_0900_ai_ci` sort characters for the `utf8mb4` character set using the rules of Turkish and Hungarian, respectively. `utf8mb4_turkish_ci` and `utf8mb4_hungarian_ci` are similar but based on a less recent version of the Unicode Collation Algorithm.

- Collation suffixes indicate whether a collation is case-sensitive, accent-sensitive, or kana-sensitive (or some combination thereof), or binary. The following table shows the suffixes used to indicate these characteristics.

<table>
<thead>
<tr>
<th>Suffix</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>_ai</td>
<td>Accent-insensitive</td>
</tr>
<tr>
<td>_as</td>
<td>Accent-sensitive</td>
</tr>
<tr>
<td>_ci</td>
<td>Case-insensitive</td>
</tr>
<tr>
<td>_cs</td>
<td>Case-sensitive</td>
</tr>
<tr>
<td>_ks</td>
<td>Kana-sensitive</td>
</tr>
<tr>
<td>_bin</td>
<td>Binary</td>
</tr>
</tbody>
</table>

For nonbinary collation names that do not specify accent sensitivity, it is determined by case sensitivity. If a collation name does not contain `_ai` or `_as`, `_ci` in the name implies `_ai` and `_cs` in the name implies `_as`. For example, `latin1_general_ci` is explicitly case-insensitive and implicitly accent-insensitive, `latin1_general_cs` is explicitly case-sensitive and implicitly accent-sensitive, and `utf8mb4_0900_ai_ci` is explicitly case-insensitive and accent-insensitive.

For Japanese collations, the `_ks` suffix indicates that a collation is kana-sensitive; that is, it distinguishes Katakana characters from Hiragana characters. Japanese collations without the `_ks` suffix are not kana-sensitive and treat Katakana and Hiragana characters equal for sorting.

For the `binary` collation of the `binary` character set, comparisons are based on numeric byte values. For the `_bin` collation of a nonbinary character set, comparisons are based on numeric character code values, which differ from byte values for multibyte characters. For information about the differences between the `binary` collation of the `binary` character set and the `_bin` collations of nonbinary character sets, see Section 10.8.5, “The binary Collation Compared to _bin Collations”.

- Collation names for Unicode character sets may include a version number to indicate the version of the Unicode Collation Algorithm (UCA) on which the collation is based. UCA-based collations without a version number in the name use the version-4.0.0 UCA weight keys. For example:
  - `utf8mb4_0900_ai_ci` is based on UCA 9.0.0 weight keys (http://www.unicode.org/Public/UCA/9.0.0/allkeys.txt).
10.3.2 Server Character Set and Collation

MySQL Server has a server character set and a server collation. By default, these are utf8mb4 and utf8mb4_0900_ai_ci, but they can be set explicitly at server startup on the command line or in an option file and changed at runtime.

Initially, the server character set and collation depend on the options that you use when you start mysqld. You can use --character-set-server for the character set. Along with it, you can add --collation-server for the collation. If you don't specify a character set, that is the same as saying --character-set-server=utf8mb4. If you specify only a character set (for example, utf8mb4) but not a collation, that is the same as saying --character-set-server=utf8mb4 --collation-server=utf8mb4_0900_ai_ci because utf8mb4_0900_ai_ci is the default collation for utf8mb4. Therefore, the following three commands all have the same effect:

```bash
mysqld
mysqld --character-set-server=utf8mb4
mysqld --character-set-server=utf8mb4 --collation-server=utf8mb4_0900_ai_ci
```

One way to change the settings is by recompiling. To change the default server character set and collation when building from sources, use the DEFAULT_CHARSET and DEFAULT_COLLATION options for CMake. For example:

```bash
cmake . -DDEFAULT_CHARSET=latin1
```

Or:

```bash
cmake . -DDEFAULT_CHARSET=latin1 -DDEFAULT_COLLATION=latin1_german1_ci
```

Both mysqld and CMake verify that the character set/collation combination is valid. If not, each program displays an error message and terminates.

The server character set and collation are used as default values if the database character set and collation are not specified in CREATE DATABASE statements. They have no other purpose.

The current server character set and collation can be determined from the values of the character_set_server and collation_server system variables. These variables can be changed at runtime.

10.3.3 Database Character Set and Collation

Every database has a database character set and a database collation. The CREATE DATABASE and ALTER DATABASE statements have optional clauses for specifying the database character set and collation:

```sql
CREATE DATABASE db_name
    [[DEFAULT] CHARACTER SET charset_name]
```
Database Character Set and Collation

ALTER DATABASE db_name
  [[DEFAULT] CHARACTER SET charset_name]
  [[DEFAULT] COLLATE collation_name]

The keyword ‌SCHEMA‌ can be used instead of ‌DATABASE‌.

The ‌CHARACTER SET‌ and ‌COLLATE‌ clauses make it possible to create databases with different character sets and collations on the same MySQL server.

Database options are stored in the data dictionary and can be examined by checking the Information Schema ‌SCHEMATA‌ table.

Example:

CREATE DATABASE db_name CHARACTER SET latin1 COLLATE latin1_swedish_ci;

MySQL chooses the database character set and database collation in the following manner:

- If both ‌CHARACTER SET‌ ‌charset_name‌ and ‌COLLATE‌ ‌collation_name‌ are specified, character set ‌charset_name‌ and collation ‌collation_name‌ are used.

- If ‌CHARACTER SET‌ ‌charset_name‌ is specified without ‌COLLATE‌, character set ‌charset_name‌ and its default collation are used. To see the default collation for each character set, use the ‌SHOW CHARACTER SET‌ statement or query the ‌INFORMATION_SCHEMA CHARACTER_SETS‌ table.

- If ‌COLLATE‌ ‌collation_name‌ is specified without ‌CHARACTER SET‌, the character set associated with ‌collation_name‌ and collation ‌collation_name‌ are used.

- Otherwise (neither ‌CHARACTER SET‌ nor ‌COLLATE‌ is specified), the server character set and server collation are used.

The character set and collation for the default database can be determined from the values of the ‌character_set_database‌ and ‌collation_database‌ system variables. The server sets these variables whenever the default database changes. If there is no default database, the variables have the same value as the corresponding server-level system variables, ‌character_set_server‌ and ‌collation_server‌.

To see the default character set and collation for a given database, use these statements:

```
USE db_name;
SELECT @@character_set_database, @@collation_database;
```

Alternatively, to display the values without changing the default database:

```
SELECT DEFAULT_CHARACTER_SET_NAME, DEFAULT_COLLATION_NAME
FROM INFORMATION_SCHEMA.SCHEMATA WHERE SCHEMA_NAME = 'db_name';
```

The database character set and collation affect these aspects of server operation:

- For ‌CREATE TABLE‌ statements, the database character set and collation are used as default values for table definitions if the table character set and collation are not specified. To override this, provide explicit ‌CHARACTER SET‌ and ‌COLLATE‌ table options.

- For ‌LOAD DATA‌ statements that include no ‌CHARACTER SET‌ clause, the server uses the character set indicated by the ‌character_set_database‌ system variable to interpret the information in the file. To override this, provide an explicit ‌CHARACTER SET‌ clause.

- For stored routines (procedures and functions), the database character set and collation in effect at routine creation time are used as the character set and collation of character data parameters for
Table Character Set and Collation

which the declaration includes no CHARACTER SET or a COLLATE attribute. To override this, provide CHARACTER SET and COLLATE explicitly.

10.3.4 Table Character Set and Collation

Every table has a table character set and a table collation. The CREATE TABLE and ALTER TABLE statements have optional clauses for specifying the table character set and collation:

```
CREATE TABLE  
  tbl_name (column_list)  
  [[DEFAULT] CHARACTER SET charset_name]  
  [COLLATE collation_name]]
ALTER TABLE  
  tbl_name  
  [[DEFAULT] CHARACTER SET charset_name]  
  [COLLATE collation_name]
```

Example:

```
CREATE TABLE t1 { ... }  
CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

MySQL chooses the table character set and collation in the following manner:

- If both CHARACTER SET charset_name and COLLATE collation_name are specified, character set charset_name and collation collation_name are used.
- If CHARACTER SET charset_name is specified without COLLATE, character set charset_name and its default collation are used. To see the default collation for each character set, use the SHOW CHARACTER SET statement or query the INFORMATION_SCHEMA CHARACTER_SETS table.
- If COLLATE collation_name is specified without CHARACTER SET, the character set associated with collation_name and collation collation_name are used.
- Otherwise (neither CHARACTER SET nor COLLATE is specified), the database character set and collation are used.

The table character set and collation are used as default values for column definitions if the column character set and collation are not specified in individual column definitions. The table character set and collation are MySQL extensions; there are no such things in standard SQL.

10.3.5 Column Character Set and Collation

Every “character” column (that is, a column of type CHAR, VARCHAR, a TEXT type, or any synonym) has a column character set and a column collation. Column definition syntax for CREATE TABLE and ALTER TABLE has optional clauses for specifying the column character set and collation:

```
col_name {CHAR | VARCHAR | TEXT} (col_length)  
  [CHARACTER SET charset_name]  
  [COLLATE collation_name]
```

These clauses can also be used for ENUM and SET columns:

```
col_name {ENUM | SET} (val_list)  
  [CHARACTER SET charset_name]  
  [COLLATE collation_name]
```

Examples:

```
CREATE TABLE t1  
  {  
    col1 VARCHAR(5)  
  }
```
Column Character Set and Collation

```sql
ALTER TABLE t1 MODIFY
    col1 VARCHAR(5)
    CHARACTER SET latin1
    COLLATE latin1_swedish_ci;
```

MySQL chooses the column character set and collation in the following manner:

- If both **CHARACTER SET** `charset_name` and **COLLATE** `collation_name` are specified, character set `charset_name` and collation `collation_name` are used.

```sql
CREATE TABLE t1
(
    col1 CHAR(10) CHARACTER SET utf8mb4 COLLATE utf8mb4_unicode_ci
) CHARACTER SET latin1 COLLATE latin1_bin;
```

The character set and collation are specified for the column, so they are used. The column has character set `utf8mb4` and collation `utf8mb4_unicode_ci`.

- If **CHARACTER SET** `charset_name` is specified without **COLLATE**, character set `charset_name` and its default collation are used.

```sql
CREATE TABLE t1
(
    col1 CHAR(10) CHARACTER SET utf8mb4
) CHARACTER SET latin1 COLLATE latin1_bin;
```

The character set is specified for the column, but the collation is not. The column has character set `utf8mb4` and the default collation for `utf8mb4`, which is `utf8mb4_0900_ai_ci`. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA CHARACTER_SETS` table.

- If **COLLATE** `collation_name` is specified without **CHARACTER SET**, the character set associated with `collation_name` and collation `collation_name` are used.

```sql
CREATE TABLE t1
(
    col1 CHAR(10) COLLATE utf8mb4_polish_ci
) CHARACTER SET latin1 COLLATE latin1_bin;
```

The collation is specified for the column, but the character set is not. The column has collation `utf8mb4_polish_ci` and the character set is the one associated with the collation, which is `utf8mb4`.

- Otherwise (neither **CHARACTER SET** nor **COLLATE** is specified), the table character set and collation are used.

```sql
CREATE TABLE t1
(
    col1 CHAR(10)
) CHARACTER SET latin1 COLLATE latin1_bin;
```

Neither the character set nor collation is specified for the column, so the table defaults are used. The column has character set `latin1` and collation `latin1_bin`.

The **CHARACTER SET** and **COLLATE** clauses are standard SQL.

If you use **ALTER TABLE** to convert a column from one character set to another, MySQL attempts to map the data values, but if the character sets are incompatible, there may be data loss.
10.3.6 Character String Literal Character Set and Collation

Every character string literal has a character set and a collation.

For the simple statement `SELECT 'string'`, the string has the connection default character set and collation defined by the `character_set_connection` and `collation_connection` system variables.

A character string literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[\_charset_name]'string' [COLLATE collation_name]
```

The `\_charset_name` expression is formally called an introducer. It tells the parser, “the string that follows uses character set \_charset_name.” An introducer does not change the string to the introducer character set like `CONVERT()` would do. It does not change the string value, although padding may occur. The introducer is just a signal. See Section 10.3.8, “Character Set Introducers”.

Examples:

```
SELECT 'abc';
SELECT _latin1'abc';
SELECT _binary'abc';
SELECT _utf8mb4'abc' COLLATE utf8mb4_danish_ci;
```

Character set introducers and the `COLLATE` clause are implemented according to standard SQL specifications.

MySQL determines the character set and collation of a character string literal in the following manner:

- If both `\_charset_name` and `COLLATE collation_name` are specified, character set \_charset_name and collation collation_name are used. collation_name must be a permitted collation for \_charset_name.

- If \_charset_name is specified but `COLLATE` is not specified, character set \_charset_name and its default collation are used. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA CHARACTER_SETS` table.

- If \_charset_name is not specified but `COLLATE` collation_name is specified, the connection default character set given by the `character_set_connection` system variable and collation collation_name are used. collation_name must be a permitted collation for the connection default character set.

- Otherwise (neither \_charset_name nor `COLLATE` collation_name is specified), the connection default character set and collation given by the `character_set_connection` and `collation_connection` system variables are used.

Examples:

- A nonbinary string with `latin1` character set and `latin1_german1_ci` collation:
  
  ```
  SELECT _latin1'Müller' COLLATE latin1_german1_ci;
  ```

- A nonbinary string with `utf8mb4` character set and its default collation (that is, `utf8mb4_0900_ai_ci`):
  
  ```
  SELECT _utf8mb4'Müller';
  ```

- A binary string with `binary` character set and its default collation (that is, `binary`):
  
  ```
  SELECT _binary'Müller';
  ```
The National Character Set

- A nonbinary string with the connection default character set and utf8mb4_0900_ai_ci collation (fails if the connection character set is not utf8mb4):

  ```sql
  SELECT 'Müller' COLLATE utf8mb4_0900_ai_ci;
  ```

- A string with the connection default character set and collation:

  ```sql
  SELECT 'Müller';
  ```

An introducer indicates the character set for the following string, but does not change how the parser performs escape processing within the string. Escapes are always interpreted by the parser according to the character set given by `character_set_connection`.

The following examples show that escape processing occurs using `character_set_connection` even in the presence of an introducer. The examples use `SET NAMES` (which changes `character_set_connection`, as discussed in Section 10.4, “Connection Character Sets and Collations”), and display the resulting strings using the `HEX()` function so that the exact string contents can be seen.

Example 1:

```sql
mysql> SET NAMES latin1;
mysql> SELECT HEX('à\n'), HEX(_sjis'à\n');
+------------+-----------------+
| HEX('à\n')  | HEX(_sjis'à\n')  |
| E00A       | E00A            |
+------------+-----------------+
```

Here, à (hexadecimal value E0) is followed by \n, the escape sequence for newline. The escape sequence is interpreted using the `character_set_connection` value of `latin1` to produce a literal newline (hexadecimal value 0A). This happens even for the second string. That is, the _sjis introducer does not affect the parser’s escape processing.

Example 2:

```sql
mysql> SET NAMES sjis;
mysql> SELECT HEX('à\n'), HEX(_latin1'à\n');
+------------+-------------------+
| HEX('à\n')  | HEX(_latin1'à\n')  |
| E05C6E     | E05C6E            |
+------------+-------------------+
```

Here, `character_set_connection` is sjis, a character set in which the sequence of à followed by \ (hexadecimal values 05 and 5C) is a valid multibyte character. Hence, the first two bytes of the string are interpreted as a single sjis character, and the \ is not interpreted as an escape character. The following n (hexadecimal value 6E) is not interpreted as part of an escape sequence. This is true even for the second string; the _latin1 introducer does not affect escape processing.

10.3.7 The National Character Set

Standard SQL defines NCHAR or NATIONAL CHAR as a way to indicate that a CHAR column should use some predefined character set. MySQL uses utf8 as this predefined character set. For example, these data type declarations are equivalent:

```sql
CHAR(10) CHARACTER SET utf8
NATIONAL CHARACTER(10)
NCHAR(10)
```

As are these:
Character Set Introducers

You can use `N'literal'` (or `n'literal'`) to create a string in the national character set. These statements are equivalent:

```sql
SELECT N'some text';
SELECT n'some text';
SELECT _utf8'some text';
```

MySQL 8.2 interprets the national character set as `utf8mb3`, which is now deprecated. Thus, using `NATIONAL CHARACTER` or one of its synonyms to define the character set for a database, table, or column raises a warning similar to this one:

```
NATIONAL/NCHAR/NVARCHAR implies the character set UTF8MB3, which will be replaced by UTF8MB4 in a future release. Please consider using CHAR(x) CHARACTER SET UTF8MB4 in order to be unambiguous.
```

10.3.8 Character Set Introducers

A character string literal, hexadecimal literal, or bit-value literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[_[charsetName]_] literal [COLLATE _collationName_]
```

The `_[charsetName]_` expression is formally called an *introducer*. It tells the parser, “the string that follows uses character set `charsetName`.” An introducer does not change the string to the introducer character set like `CONVERT()` would do. It does not change the string value, although padding may occur. The introducer is just a signal.

For character string literals, space between the introducer and the string is permitted but optional.

For character set literals, an introducer indicates the character set for the following string, but does not change how the parser performs escape processing within the string. Escapes are always interpreted by the parser according to the character set given by `character_set_connection`. For additional discussion and examples, see Section 10.3.6, “Character String Literal Character Set and Collation”.

Examples:

```sql
SELECT 'abc';
SELECT _latin1'abc';
SELECT _binary'abc';
SELECT _utf8mb4'abc' COLLATE utf8mb4_danish_ci;

SELECT _latin1 X'4D7953514C';
SELECT _utf8mb4 0x4D7953514C COLLATE utf8mb4_danish_ci;

SELECT _latin1 b'1000001';
SELECT _utf8mb4 0b1000001 COLLATE utf8mb4_danish_ci;
```

Character set introducers and the `COLLATE` clause are implemented according to standard SQL specifications.

Character string literals can be designated as binary strings by using the `_binary` introducer. Hexadecimal literals and bit-value literals are binary strings by default, so `_binary` is permitted, but normally unnecessary. `_binary` may be useful to preserve a hexadecimal or bit literal as a binary string in contexts for which the literal is otherwise treated as a number. For example, bit operations permit numeric
or binary string arguments in MySQL 8.2 and higher, but treat hexadecimal and bit literals as numbers by default. To explicitly specify binary string context for such literals, use a _binary introducer for at least one of the arguments:

```sql
mysql> SET @v1 = X'000D' | X'0BC0';
mysql> SET @v2 = _binary X'000D' | X'0BC0';
mysql> SELECT HEX(@v1), HEX(@v2);
+----------+----------+
| HEX(@v1) | HEX(@v2) |
+----------+----------+
| BCD      | 0BCD     |
+----------+----------+
```

The displayed result appears similar for both bit operations, but the result without _binary is a BIGINT value, whereas the result with _binary is a binary string. Due to the difference in result types, the displayed values differ: High-order 0 digits are not displayed for the numeric result.

MySQL determines the character set and collation of a character string literal, hexadecimal literal, or bit-value literal in the following manner:

- If both _charset_name and COLLATE collation_name are specified, character set _charset_name and collation collation_name are used. collation_name must be a permitted collation for _charset_name.
- If _charset_name is specified but COLLATE is not specified, character set _charset_name and its default collation are used. To see the default collation for each character set, use the SHOW CHARACTER SET statement or query the INFORMATION_SCHEMA CHARACTER_SETS table.
- If _charset_name is not specified but COLLATE collation_name is specified:
  - For a character string literal, the connection default character set given by the character_set_connection system variable and collation collation_name are used. collation_name must be a permitted collation for the connection default character set.
  - For a hexadecimal literal or bit-value literal, the only permitted collation is binary because these types of literals are binary strings by default.
- Otherwise (neither _charset_name nor COLLATE collation_name is specified):
  - For a character string literal, the connection default character set and collation given by the character_set_connection and collation_connection system variables are used.
  - For a hexadecimal literal or bit-value literal, the character set and collation are binary.

Examples:

- Nonbinary strings with latin1 character set and latin1_german1_ci collation:
  ```sql
  SELECT _latin1'Müller' COLLATE latin1_german1_ci;
  SELECT _latin1 X'0A0D' COLLATE latin1_german1_ci;
  SELECT _latin1 b'0110' COLLATE latin1_german1_ci;
  ```

- Nonbinary strings with utf8mb4 character set and its default collation (that is, utf8mb4_0900_ai_ci):
  ```sql
  SELECT _utf8mb4'Müller';
  SELECT _utf8mb4 X'0A0D';
  SELECT _utf8mb4 b'0110';
  ```

- Binary strings with binary character set and its default collation (that is, binary):
  ```sql
  SELECT _binary'Müller';
  ```
SELECT X'0A0D';
SELECT b'0110';

The hexadecimal literal and bit-value literal need no introducer because they are binary strings by default.

- A nonbinary string with the connection default character set and utf8mb4_0900_ai_ci collation (fails if the connection character set is not utf8mb4):

```
SELECT 'Müller' COLLATE utf8mb4_0900_ai_ci;
```

This construction (COLLATE only) does not work for hexadecimal literals or bit literals because their character set is binary no matter the connection character set, and binary is not compatible with the utf8mb4_0900_ai_ci collation. The only permitted COLLATE clause in the absence of an introducer is COLLATE binary.

- A string with the connection default character set and collation:

```
SELECT 'Müller';
```

### 10.3.9 Examples of Character Set and Collation Assignment

The following examples show how MySQL determines default character set and collation values.

**Example 1: Table and Column Definition**

```
CREATE TABLE t1
    (
        c1 CHAR(10) CHARACTER SET latin1 COLLATE latin1_german1_ci
    ) DEFAULT CHARACTER SET latin2 COLLATE latin2_bin;
```

Here we have a column with a latin1 character set and a latin1_german1_ci collation. The definition is explicit, so that is straightforward. Notice that there is no problem with storing a latin1 column in a latin2 table.

**Example 2: Table and Column Definition**

```
CREATE TABLE t1
    (
        c1 CHAR(10) CHARACTER SET latin1
    ) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

This time we have a column with a latin1 character set and a default collation. Although it might seem natural, the default collation is not taken from the table character set, and binary is not compatible with the utf8mb4_0900_ai_ci collation. The only permitted COLLATE clause in the absence of an introducer is COLLATE binary.

**Example 3: Table and Column Definition**

```
CREATE TABLE t1
    (
        c1 CHAR(10)
    ) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

We have a column with a default character set and a default collation. In this circumstance, MySQL checks the table level to determine the column character set and collation. Consequently, the character set for column c1 is latin1 and its collation is latin1_danish_ci.

**Example 4: Database, Table, and Column Definition**

```
CREATE DATABASE d1
```

2078
We create a column without specifying its character set and collation. We're also not specifying a character set and a collation at the table level. In this circumstance, MySQL checks the database level to determine the table settings, which thereafter become the column settings.) Consequently, the character set for column `c1` is `latin2` and its collation is `latin2_czech_cs`.

10.3.10 Compatibility with Other DBMSs

For MaxDB compatibility these two statements are the same:

```
CREATE TABLE t1 (f1 CHAR(10) UNICODE);
CREATE TABLE t1 (f1 CHAR(10) CHARACTER SET ucs2);
```

Both the `UNICODE` attribute and the `ucs2` character set are deprecated; you should expect them to be removed in a future version of MySQL.

10.4 Connection Character Sets and Collations

A “connection” is what a client program makes when it connects to the server, to begin a session within which it interacts with the server. The client sends SQL statements, such as queries, over the session connection. The server sends responses, such as result sets or error messages, over the connection back to the client.

- Connection Character Set and Collation System Variables
- Impermissible Client Character Sets
- Client Program Connection Character Set Configuration
- SQL Statements for Connection Character Set Configuration
- Connection Character Set Error Handling

Connection Character Set and Collation System Variables

Several character set and collation system variables relate to a client's interaction with the server. Some of these have been mentioned in earlier sections:

- The `character_set_server` and `collation_server` system variables indicate the server character set and collation. See Section 10.3.2, “Server Character Set and Collation”.

- The `character_set_database` and `collation_database` system variables indicate the character set and collation of the default database. See Section 10.3.3, “Database Character Set and Collation”.

Additional character set and collation system variables are involved in handling traffic for the connection between a client and the server. Every client has session-specific connection-related character set and collation system variables. These session system variable values are initialized at connect time, but can be changed within the session.

Several questions about character set and collation handling for client connections can be answered in terms of system variables:

- What character set are statements in when they leave the client?
The server takes the `character_set_client` system variable to be the character set in which statements are sent by the client.

**Note**
Some character sets cannot be used as the client character set. See [Impermissible Client Character Sets](#).

- What character set should the server translate statements to after receiving them?

  To determine this, the server uses the `character_set_connection` and `collation_connection` system variables:

  - The server converts statements sent by the client from `character_set_client` to `character_set_connection`. Exception: For string literals that have an introducer such as `_utf8mb4` or `_latin2`, the introducer determines the character set. See [Section 10.3.8, “Character Set Introducers”](#).

  - `collation_connection` is important for comparisons of literal strings. For comparisons of strings with column values, `collation_connection` does not matter because columns have their own collation, which has a higher collation precedence (see [Section 10.8.4, “Collation Coercibility in Expressions”](#)).

- What character set should the server translate query results to before shipping them back to the client?

  The `character_set_results` system variable indicates the character set in which the server returns query results to the client. This includes result data such as column values, result metadata such as column names, and error messages.

  To tell the server to perform no conversion of result sets or error messages, set `character_set_results` to `NULL` or `binary`:

  ```sql
  SET character_set_results = NULL;
  SET character_set_results = binary;
  ```

  For more information about character sets and error messages, see [Section 10.6, “Error Message Character Set”](#).

  To see the values of the character set and collation system variables that apply to the current session, use this statement:

  ```sql
  SELECT * FROM performance_schema.session_variables
  WHERE VARIABLE_NAME IN ('character_set_client', 'character_set_connection', 'character_set_results', 'collation_connection')
  ORDER BY VARIABLE_NAME;
  ```

  The following simpler statements also display the connection variables, but include other related variables as well. They can be useful to see all character set and collation system variables:

  ```sql
  SHOW SESSION VARIABLES LIKE 'character_set\_%';
  SHOW SESSION VARIABLES LIKE 'collation\_%';
  ```

  Clients can fine-tune the settings for these variables, or depend on the defaults (in which case, you can skip the rest of this section). If you do not use the defaults, you must change the character settings for each connection to the server.

---

**Impermissible Client Character Sets**
The `character_set_client` system variable cannot be set to certain character sets:

- ucs2
- utf16
- utf16le
- utf32

Attempting to use any of those character sets as the client character set produces an error:

```sql
mysql> SET character_set_client = 'ucs2';
ERROR 1231 (42000): Variable 'character_set_client' can't be set to the value of 'ucs2'
```

The same error occurs if any of those character sets are used in the following contexts, all of which result in an attempt to set `character_set_client` to the named character set:

- The `--default-character-set=charset_name` command option used by MySQL client programs such as `mysql` and `mysqladmin`.
- The `SET NAMES 'charset_name'` statement.
- The `SET CHARACTER SET 'charset_name'` statement.

### Client Program Connection Character Set Configuration

When a client connects to the server, it indicates which character set it wants to use for communication with the server. (Actually, the client indicates the default collation for that character set, from which the server can determine the character set.) The server uses this information to set the `character_set_client`, `character_set_results`, `character_set_connection` system variables to the character set, and `collation_connection` to the character set default collation. In effect, the server performs the equivalent of a `SET NAMES` operation.

If the server does not support the requested character set or collation, it falls back to using the server character set and collation to configure the connection. For additional detail about this fallback behavior, see Connection Character Set Error Handling.

The `mysql`, `mysqladmin`, `mysqlcheck`, `mysqlimport`, and `mysqlshow` client programs determine the default character set to use as follows:

- In the absence of other information, each client uses the compiled-in default character set, usually `utf8mb4`.
- Each client can autodetect which character set to use based on the operating system setting, such as the value of the `LANG` or `LC_ALL` locale environment variable on Unix systems or the code page setting on Windows systems. For systems on which the locale is available from the OS, the client uses it to set the default character set rather than using the compiled-in default. For example, setting `LANG` to `ru_RU.KOI8-R` causes the `koi8r` character set to be used. Thus, users can configure the locale in their environment for use by MySQL clients.

The OS character set is mapped to the closest MySQL character set if there is no exact match. If the client does not support the matching character set, it uses the compiled-in default. For example, `utf8` and `utf-8` map to `utf8mb4`, and `ucs2` is not supported as a connection character set, so it maps to the compiled-in default.

C applications can use character set autodetection based on the OS setting by invoking `mysql_options()` as follows before connecting to the server:

```c
mysql_options(mysql, MYSQL_SET_CHARSET_NAME,
```
SQL Statements for Connection Character Set Configuration

Each client supports a --default-character-set option, which enables users to specify the character set explicitly to override whatever default the client otherwise determines.

Note
Some character sets cannot be used as the client character set. Attempting to use them with --default-character-set produces an error. See Impermissible Client Character Sets.

With the mysql client, to use a character set different from the default, you could explicitly execute a SET NAMES statement every time you connect to the server (see Client Program Connection Character Set Configuration). To accomplish the same result more easily, specify the character set in your option file. For example, the following option file setting changes the three connection-related character set system variables set to koi8r each time you invoke mysql:

```
[mysql]
default-character-set=koi8r
```

If you are using the mysql client with auto-reconnect enabled (which is not recommended), it is preferable to use the charset command rather than SET NAMES. For example:

```
mysql> charset koi8r
Charset changed
```

The charset command issues a SET NAMES statement, and also changes the default character set that mysql uses when it reconnects after the connection has dropped.

When configuration client programs, you must also consider the environment within which they execute. See Section 10.5, “Configuring Application Character Set and Collation”.

SQL Statements for Connection Character Set Configuration

After a connection has been established, clients can change the character set and collation system variables for the current session. These variables can be changed individually using SET statements, but two more convenient statements affect the connection-related character set system variables as a group:

- **SET NAMES 'charset_name' [COLLATE 'collation_name']**

  SET NAMES indicates what character set the client uses to send SQL statements to the server. Thus, SET NAMES 'cp1251' tells the server, “future incoming messages from this client are in character set cp1251.” It also specifies the character set that the server should use for sending results back to the client. (For example, it indicates what character set to use for column values if you use a SELECT statement that produces a result set.)

  A SET NAMES 'charset_name' statement is equivalent to these three statements:

  ```
  SET character_set_client = charset_name;
  SET character_set_results = charset_name;
  SET character_set_connection = charset_name;
  ```

  Setting character_set_connection to charset_name also implicitly sets collation_connection to the default collation for charset_name. It is unnecessary to set that collation explicitly. To specify a particular collation to use for collation_connection, add a COLLATE clause:

  ```
  SET NAMES 'charset_name' COLLATE 'collation_name'
  ```
Connection Character Set Error Handling

- **SET CHARACTER SET 'charset_name'**

  `SET CHARACTER SET` is similar to `SET NAMES` but sets `character_set_connection` and `collation_connection` to `character_set_database` and `collation_database` (which, as mentioned previously, indicate the character set and collation of the default database).

  A `SET CHARACTER SET charset_name` statement is equivalent to these three statements:

  ```
  SET character_set_client = charset_name;
  SET character_set_results = charset_name;
  SET collation_connection = @@collation_database;
  ```

  Setting `collation_connection` also implicitly sets `character_set_connection` to the character set associated with the collation (equivalent to executing `SET character_set_connection = @@character_set_database`). It is unnecessary to set `character_set_connection` explicitly.

  **Note**
  Some character sets cannot be used as the client character set. Attempting to use them with `SET NAMES` or `SET CHARACTER SET` produces an error. See [Impermissible Client Character Sets](#).

  Example: Suppose that `column1` is defined as `CHAR(5) CHARACTER SET latin2`. If you do not say `SET NAMES` or `SET CHARACTER SET`, then for `SELECT column1 FROM t`, the server sends back all the values for `column1` using the character set that the client specified when it connected. On the other hand, if you say `SET NAMES 'latin1'` or `SET CHARACTER SET 'latin1'` before issuing the `SELECT` statement, the server converts the `latin2` values to `latin1` just before sending results back. Conversion may be lossy for characters that are not in both character sets.

### Connection Character Set Error Handling

Attempts to use an inappropriate connection character set or collation can produce an error, or cause the server to fall back to its default character set and collation for a given connection. This section describes problems that can occur when configuring the connection character set. These problems can occur when establishing a connection or when changing the character set within an established connection.

- **Connect-Time Error Handling**

- **Runtime Error Handling**

  **Connect-Time Error Handling**

  Some character sets cannot be used as the client character set; see [Impermissible Client Character Sets](#).

  If you specify a character set that is valid but not permitted as a client character set, the server returns an error:

  ```
  $> mysql --default-character-set=ucs2
  ERROR 1231 (42000): Variable 'character_set_client' can't be set to the value of 'ucs2'
  ```

  If you specify a character set that the client does not recognize, it produces an error:

  ```
  $> mysql --default-character-set=bogus
  mysql: Character set 'bogus' is not a compiled character set and is not specified in the '/usr/local/mysql/share/charsets/Index.xml' file
  ERROR 2019 (HY000): Can't initialize character set bogus
  ```

  If you specify a character set that the client recognizes but the server does not, the server falls back to its default character set and collation. Suppose that the server is configured to use `latin1` and...
Configuring Application Character Set and Collation

**latin1_swedish_ci** as its defaults, and that it does not recognize **gb18030** as a valid character set. A client that specifies **--default-character-set=gb18030** is able to connect to the server, but the resulting character set is not what the client wants:

```sql
SHOW SESSION VARIABLES LIKE 'character_set_%';
```

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>character_set_client</td>
<td>latin1</td>
</tr>
<tr>
<td>character_set_connection</td>
<td>latin1</td>
</tr>
</tbody>
</table>

You can see that the connection system variables have been set to reflect a character set and collation of **latin1** and **latin1_swedish_ci**. This occurs because the server cannot satisfy the client character set request and falls back to its defaults.

In this case, the client cannot use the character set that it wants because the server does not support it. The client must either be willing to use a different character set, or connect to a different server that supports the desired character set.

The same problem occurs when the client tells the server to use a character set that the server recognizes, but the default collation for that character set on the client side is not known on the server side.

### Runtime Error Handling

Within an established connection, the client can request a change of connection character set and collation with **SET NAMES** or **SET CHARACTER SET**.

Some character sets cannot be used as the client character set; see Impermissible Client Character Sets.

If you specify a character set that is valid but not permitted as a client character set, the server returns an error:

```sql
SET NAMES 'ucs2';
```

```
ERROR 1231 (42000): Variable 'character_set_client' can't be set to the value of 'ucs2'
```

If the server does not recognize the character set (or the collation), it produces an error:

```sql
SET NAMES 'bogus';
```

```
ERROR 1115 (42000): Unknown character set: 'bogus'
```

```sql
SET NAMES 'utf8mb4' COLLATE 'bogus';
```

```
ERROR 1273 (HY000): Unknown collation: 'bogus'
```

**Tip**

A client that wants to verify whether its requested character set was honored by the server can execute the following statement after connecting and checking that the result is the expected character set:

```sql
SELECT @@character_set_client;
```

### 10.5 Configuring Application Character Set and Collation
For applications that store data using the default MySQL character set and collation (utf8mb4, utf8mb4_0900_ai_ci), no special configuration should be needed. If applications require data storage using a different character set or collation, you can configure character set information several ways:

- Specify character settings per database. For example, applications that use one database might use the default of utf8mb4, whereas applications that use another database might use sjis.

- Specify character settings at server startup. This causes the server to use the given settings for all applications that do not make other arrangements.

- Specify character settings at configuration time, if you build MySQL from source. This causes the server to use the given settings as the defaults for all applications, without having to specify them at server startup.

When different applications require different character settings, the per-database technique provides a good deal of flexibility. If most or all applications use the same character set, specifying character settings at server startup or configuration time may be most convenient.

For the per-database or server-startup techniques, the settings control the character set for data storage. Applications must also tell the server which character set to use for client/server communications, as described in the following instructions.

The examples shown here assume use of the latin1 character set and latin1_swedish_ci collation in particular contexts as an alternative to the defaults of utf8mb4 and utf8mb4_0900_ai_ci.

- **Specify character settings per database.** To create a database such that its tables use a given default character set and collation for data storage, use a `CREATE DATABASE` statement like this:

```
CREATE DATABASE mydb
    CHARACTER SET latin1
    COLLATE latin1_swedish_ci;
```

Tables created in the database use latin1 and latin1_swedish_ci by default for any character columns.

Applications that use the database should also configure their connection to the server each time they connect. This can be done by executing a `SET NAMES 'latin1'` statement after connecting. The statement can be used regardless of connection method (the `mysql` client, PHP scripts, and so forth).

In some cases, it may be possible to configure the connection to use the desired character set some other way. For example, to connect using `mysql`, you can specify the `--default-character-set=latin1` command-line option to achieve the same effect as `SET NAMES 'latin1'.`

For more information about configuring client connections, see Section 10.4, “Connection Character Sets and Collations”.

**Note**

If you use `ALTER DATABASE` to change the database default character set or collation, existing stored routines in the database that use those defaults must be dropped and recreated so that they use the new defaults. (In a stored routine, variables with character data types use the database defaults if the character set or collation are not specified explicitly. See Section 13.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”.)

- **Specify character settings at server startup.** To select a character set and collation at server startup, use the `--character-set-server` and `--collation-server` options. For example, to specify the options in an option file, include these lines:
These settings apply server-wide and apply as the defaults for databases created by any application, and for tables created in those databases.

It is still necessary for applications to configure their connection using `SET NAMES` or equivalent after they connect, as described previously. You might be tempted to start the server with the `--init_connect="SET NAMES 'latin1'"` option to cause `SET NAMES` to be executed automatically for each client that connects. However, this may yield inconsistent results because the `init_connect` value is not executed for users who have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege).

Specify character settings at MySQL configuration time. To select a character set and collation if you configure and build MySQL from source, use the `DEFAULT_CHARSET` and `DEFAULT_COLLATION` CMake options:

```
cmake . -DDEFAULT_CHARSET=latin1 \
-DDEFAULT_COLLATION=latin1_swedish_ci
```

The resulting server uses `latin1` and `latin1_swedish_ci` as the default for databases and tables and for client connections. It is unnecessary to use `--character-set-server` and `--collation-server` to specify those defaults at server startup. It is also unnecessary for applications to configure their connection using `SET NAMES` or equivalent after they connect to the server.

Regardless of how you configure the MySQL character set for application use, you must also consider the environment within which those applications execute. For example, if you intend to send statements using UTF-8 text taken from a file that you create in an editor, you should edit the file with the locale of your environment set to UTF-8 so that the file encoding is correct and so that the operating system handles it correctly. If you use the `mysql` client from within a terminal window, the window must be configured to use UTF-8 or characters may not display properly. For a script that executes in a Web environment, the script must handle character encoding properly for its interaction with the MySQL server, and it must generate pages that correctly indicate the encoding so that browsers know how to display the content of the pages. For example, you can include this `<meta>` tag within your `<head>` element:

```
<meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
```

10.6 Error Message Character Set

This section describes how the MySQL server uses character sets for constructing error messages. For information about the language of error messages (rather than the character set), see Section 10.12, “Setting the Error Message Language”. For general information about configuring error logging, see Section 5.4.2, “The Error Log”.

Character Set for Error Message Construction

The server constructs error messages as follows:

- The message template uses UTF-8 (`utf8mb3`).
- Parameters in the message template are replaced with values that apply to a specific error occurrence:
Character Set for Error Message Disposition

An error message, once constructed, can be written by the server to the error log or sent to clients:

- If the server writes the error message to the error log, it writes it in UTF-8, as constructed, without conversion to another character set.

- If the server sends the error message to a client program, the server converts it from UTF-8 to the character set specified by the `character_set_results` system variable. If `character_set_results` has a value of `NULL` or `binary`, no conversion occurs. No conversion occurs if the variable value is `utf8mb3` or `utf8mb4`, either, because those character sets have a repertoire that includes all UTF-8 characters used in message construction.

If characters cannot be represented in `character_set_results`, some encoding may occur during the conversion. The encoding uses Unicode code point values:

- Characters in the Basic Multilingual Plane (BMP) range (0x0000 to 0xFFFF) are written using \nnnn notation.

- Characters outside the BMP range (0x10000 to 0x10FFFF) are written using \+nnnnnn notation.

Clients can set `character_set_results` to control the character set in which they receive error messages. The variable can be set directly, or indirectly by means such as `SET NAMES`. For more information about `character_set_results`, see Section 10.4, “Connection Character Sets and Collations”.

10.7 Column Character Set Conversion

To convert a binary or nonbinary string column to use a particular character set, use `ALTER TABLE`. For successful conversion to occur, one of the following conditions must apply:

- If the column has a binary data type (`BINARY`, `VARBINARY`, `BLOB`), all the values that it contains must be encoded using a single character set (the character set you're converting the column to). If you use a binary column to store information in multiple character sets, MySQL has no way to know which values use which character set and cannot convert the data properly.

- If the column has a nonbinary data type (`CHAR`, `VARCHAR`, `TEXT`), its contents should be encoded in the column character set, not some other character set. If the contents are encoded in a different character set, you can convert the column to use a binary data type first, and then to a nonbinary column with the desired character set.

Suppose that a table `t` has a binary column named `col1` defined as `VARBINARY(50)`. Assuming that the information in the column is encoded using a single character set, you can convert it to a nonbinary column that has that character set. For example, if `col1` contains binary data representing characters in the `greek` character set, you can convert it as follows:
ALTER TABLE t MODIFY col1 VARCHAR(50) CHARACTER SET greek;

If your original column has a type of BINARY(50), you could convert it to CHAR(50), but the resulting values are padded with 0x00 bytes at the end, which may be undesirable. To remove these bytes, use the TRIM() function:

UPDATE t SET col1 = TRIM(TRAILING 0x00 FROM col1);

Suppose that table t has a nonbinary column named col1 defined as CHAR(50) CHARACTER SET latin1 but you want to convert it to use utf8mb4 so that you can store values from many languages. The following statement accomplishes this:

ALTER TABLE t MODIFY col1 CHAR(50) CHARACTER SET utf8mb4;

Conversion may be lossy if the column contains characters that are not in both character sets.

A special case occurs if you have old tables from before MySQL 4.1 where a nonbinary column contains values that actually are encoded in a character set different from the server's default character set. For example, an application might have stored sjis values in a column, even though MySQL's default character set was different. It is possible to convert the column to use the proper character set but an additional step is required. Suppose that the server's default character set was latin1 and col1 is defined as CHAR(50) but its contents are sjis values. The first step is to convert the column to a binary data type, which removes the existing character set information without performing any character conversion:

ALTER TABLE t MODIFY col1 BLOB;

The next step is to convert the column to a nonbinary data type with the proper character set:

ALTER TABLE t MODIFY col1 CHAR(50) CHARACTER SET sjis;

This procedure requires that the table not have been modified already with statements such as INSERT or UPDATE after an upgrade to MySQL 4.1 or higher. In that case, MySQL would store new values in the column using latin1, and the column would contain a mix of sjis and latin1 values and cannot be converted properly.

If you specified attributes when creating a column initially, you should also specify them when altering the table with ALTER TABLE. For example, if you specified NOT NULL and an explicit DEFAULT value, you should also provide them in the ALTER TABLE statement. Otherwise, the resulting column definition does not include those attributes.

To convert all character columns in a table, the ALTER TABLE ... CONVERT TO CHARACTER SET charset statement may be useful. See Section 13.1.9, “ALTER TABLE Statement”.

10.8 Collation Issues

The following sections discuss various aspects of character set collations.

10.8.1 Using COLLATE in SQL Statements

With the COLLATE clause, you can override whatever the default collation is for a comparison. COLLATE may be used in various parts of SQL statements. Here are some examples:

- With ORDER BY:

  SELECT k
  FROM t1
  ORDER BY k COLLATE latin1_german2_ci;
COLLATE Clause Precedence

- With **AS**:

  ```sql
  SELECT k COLLATE latin1_german2_ci AS k1
  FROM t1
  ORDER BY k1;
  ```

- With **GROUP BY**:

  ```sql
  SELECT k
  FROM t1
  GROUP BY k COLLATE latin1_german2_ci;
  ```

- With aggregate functions:

  ```sql
  SELECT MAX(k COLLATE latin1_german2_ci)
  FROM t1;
  ```

- With **DISTINCT**:

  ```sql
  SELECT DISTINCT k COLLATE latin1_german2_ci
  FROM t1;
  ```

- With **WHERE**:

  ```sql
  SELECT *
  FROM t1
  WHERE _latin1 'Müller' COLLATE latin1_german2_ci = k;
  SELECT *
  FROM t1
  WHERE k LIKE _latin1 'Müller' COLLATE latin1_german2_ci;
  ```

- With **HAVING**:

  ```sql
  SELECT k
  FROM t1
  GROUP BY k
  HAVING k = _latin1 'Müller' COLLATE latin1_german2_ci;
  ```

10.8.2 COLLATE Clause Precedence

The **COLLATE** clause has high precedence (higher than | |), so the following two expressions are equivalent:

```
x  ||  y COLLATE z
x  ||  (y COLLATE z)
```

10.8.3 Character Set and Collation Compatibility

Each character set has one or more collations, but each collation is associated with one and only one character set. Therefore, the following statement causes an error message because the *latin2_bin* collation is not legal with the *latin1* character set:

```sql
mysql> SELECT _latin1 'x' COLLATE latin2_bin;
ERROR 1253 (42000): COLLATION 'latin2_bin' is not valid for CHARACTER SET 'latin1'
```

10.8.4 Collation Coercibility in Expressions

In the great majority of statements, it is obvious what collation MySQL uses to resolve a comparison operation. For example, in the following cases, it should be clear that the collation is the collation of column `x`:
However, with multiple operands, there can be ambiguity. For example, this statement performs a comparison between the column \texttt{x} and the string literal \texttt{'Y'}:

\begin{verbatim}
SELECT x FROM T WHERE x = 'Y';
\end{verbatim}

If \texttt{x} and \texttt{'Y'} have the same collation, there is no ambiguity about the collation to use for the comparison. But if they have different collations, should the comparison use the collation of \texttt{x}, or of \texttt{'Y'}? Both \texttt{x} and \texttt{'Y'} have collations, so which collation takes precedence?

A mix of collations may also occur in contexts other than comparison. For example, a multiple-argument concatenation operation such as \texttt{CONCAT(x, 'Y')} combines its arguments to produce a single string. What collation should the result have?

To resolve questions like these, MySQL checks whether the collation of one item can be coerced to the collation of the other. MySQL assigns coercibility values as follows:

- A mix of collations may also occur in contexts other than comparison. For example, a multiple-argument concatenation operation such as \texttt{CONCAT(x, 'Y')} combines its arguments to produce a single string. What collation should the result have?

MySQL uses coercibility values with the following rules to resolve ambiguities:

- Use the collation with the lowest coercibility value.
- If both sides have the same coercibility, then:
  - If both sides are Unicode, or both sides are not Unicode, it is an error.
  - If one of the sides has a Unicode character set, and another side has a non-Unicode character set, the side with Unicode character set wins, and automatic character set conversion is applied to the non-Unicode side. For example, the following statement does not return an error:

\begin{verbatim}
SELECT CONCAT(utf8mb4_column, latin1_column) FROM t1;
\end{verbatim}

It returns a result that has a character set of \texttt{utf8mb4} and the same collation as \texttt{utf8mb4_column}. Values of \texttt{latin1_column} are automatically converted to \texttt{utf8mb4} before concatenating.

- For an operation with operands from the same character set but that mix a \texttt{_bin} collation and a \texttt{_ci} or \texttt{_cs} collation, the \texttt{_bin} collation is used. This is similar to how operations that mix nonbinary and binary strings evaluate the operands as binary strings, applied to collations rather than data types.

Although automatic conversion is not in the SQL standard, the standard does say that every character set is (in terms of supported characters) a “subset” of Unicode. Because it is a well-known principle that “what applies to a superset can apply to a subset,” we believe that a collation for Unicode can apply for comparisons with non-Unicode strings. More generally, MySQL uses the concept of character set
The binary Collation Compared to _bin Collations

repertoire, which can sometimes be used to determine subset relationships among character sets and enable conversion of operands in operations that would otherwise produce an error. See Section 10.2.1, “Character Set Repertoire”.

The following table illustrates some applications of the preceding rules.

<table>
<thead>
<tr>
<th>Comparison</th>
<th>Collation Used</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>column1 = 'A'</code></td>
<td>Use collation of <code>column1</code></td>
</tr>
<tr>
<td><code>column1 = 'A' COLLATE x</code></td>
<td>Use collation of <code>A' COLLATE x</code></td>
</tr>
<tr>
<td><code>column1 COLLATE x = 'A' COLLATE y</code></td>
<td>Error</td>
</tr>
</tbody>
</table>

To determine the coercibility of a string expression, use the COERCIBILITY() function (see Section 12.15, “Information Functions”):

```sql
mysql> SELECT COERCIBILITY(_utf8mb4'A' COLLATE utf8mb4_bin);  
-> 0
mysql> SELECT COERCIBILITY(VERSION());  
-> 3
mysql> SELECT COERCIBILITY('A');  
-> 4
mysql> SELECT COERCIBILITY(1000);  
-> 5
mysql> SELECT COERCIBILITY(NULL);  
-> 6
```

For implicit conversion of a numeric or temporal value to a string, such as occurs for the argument 1 in the expression CONCAT(1, 'abc'), the result is a character (nonbinary) string that has a character set and collation determined by the character_set_connection and collation_connection system variables. See Section 12.3, “Type Conversion in Expression Evaluation”.

10.8.5 The binary Collation Compared to _bin Collations

This section describes how the binary collation for binary strings compares to _bin collations for nonbinary strings.

Binary strings (as stored using the BINARY, VARBINARY, and BLOB data types) have a character set and collation named binary. Binary strings are sequences of bytes and the numeric values of those bytes determine comparison and sort order. See Section 10.10.8, “The Binary Character Set”.

Nonbinary strings (as stored using the CHAR, VARCHAR, and TEXT data types) have a character set and collation other than binary. A given nonbinary character set can have several collations, each of which defines a particular comparison and sort order for the characters in the set. For most character sets, one of these is the binary collation, indicated by a _bin suffix in the collation name. For example, the binary collations for latin1 and big5 are named latin1_bin and big5_bin, respectively. utf8mb4 is an exception that has two binary collations, utf8mb4_bin and utf8mb4_0900_bin; see Section 10.10.1, “Unicode Character Sets”.

The binary collation differs from _bin collations in several respects, discussed in the following sections:

- The Unit for Comparison and Sorting
- Character Set Conversion
- Lettercase Conversion
- Trailing Space Handling in Comparisons
- Trailing Space Handling for Inserts and Retrievals
The Unit for Comparison and Sorting

Binary strings are sequences of bytes. For the binary collation, comparison and sorting are based on numeric byte values. Nonbinary strings are sequences of characters, which might be multibyte. Collations for nonbinary strings define an ordering of the character values for comparison and sorting. For _bin collations, this ordering is based on numeric character code values, which is similar to ordering for binary strings except that character code values might be multibyte.

Character Set Conversion

A nonbinary string has a character set and is automatically converted to another character set in many cases, even when the string has a _bin collation:

- When assigning column values to another column that has a different character set:

  ```
  UPDATE t1 SET utf8mb4_bin_column=latin1_column;
  INSERT INTO t1 (latin1_column) SELECT utf8mb4_bin_column FROM t2;
  ```

- When assigning column values for INSERT or UPDATE using a string literal:

  ```
  SET NAMES latin1;
  INSERT INTO t1 (utf8mb4_bin_column) VALUES ('string-in-latin1');
  ```

- When sending results from the server to a client:

  ```
  SET NAMES latin1;
  SELECT utf8mb4_bin_column FROM t2;
  ```

For binary string columns, no conversion occurs. For cases similar to those preceding, the string value is copied byte-wise.

Lettercase Conversion

Collations for nonbinary character sets provide information about lettercase of characters, so characters in a nonbinary string can be converted from one lettercase to another, even for _bin collations that ignore lettercase for ordering:

```
mysql> SET NAMES utf8mb4 COLLATE utf8mb4_bin;
mysql> SELECT LOWER('aA'), UPPER('zZ');
+-------------+-------------+
| LOWER('aA') | UPPER('zZ') |
| aa          | ZZ          |
+-------------+-------------+
```

The concept of lettercase does not apply to bytes in a binary string. To perform lettercase conversion, the string must first be converted to a nonbinary string using a character set appropriate for the data stored in the string:

```
mysql> SET NAMES binary;
mysql> SELECT LOWER('aA'), LOWER(CONVERT('aA' USING utf8mb4));
+-------------+-------------+
| LOWER('aA') | LOWER(CONVERT('aA' USING utf8mb4)) |
| aA          | aa          |
+-------------+-------------+
```

Trailing Space Handling in Comparisons

MySQL collations have a pad attribute, which has a value of PAD SPACE or NO PAD:

- Most MySQL collations have a pad attribute of PAD SPACE.
The binary Collation Compared to _bin Collations

- The Unicode collations based on UCA 9.0.0 and higher have a pad attribute of NO PAD; see Section 10.10.1, “Unicode Character Sets”.

For nonbinary strings (CHAR, VARCHAR, and TEXT values), the string collation pad attribute determines treatment in comparisons of trailing spaces at the end of strings:

- For PAD SPACE collations, trailing spaces are insignificant in comparisons; strings are compared without regard to trailing spaces.
- NO PAD collations treat trailing spaces as significant in comparisons, like any other character.

The differing behaviors can be demonstrated using the two utf8mb4 binary collations, one of which is PAD SPACE, the other of which is NO PAD. The example also shows how to use the INFORMATION_SCHEMA COLLATIONS table to determine the pad attribute for collations.

```
mysql> SELECT COLLATION_NAME, PAD_ATTRIBUTE
                  FROM INFORMATION_SCHEMA.COLLATIONS
                     WHERE COLLATION_NAME LIKE 'utf8mb4%bin';
+------------------+---------------+
| COLLATION_NAME   | PAD_ATTRIBUTE |
+------------------+---------------+
| utf8mb4_bin      | PAD SPACE     |
| utf8mb4_0900_bin | NO PAD        |
+------------------+---------------+

mysql> SET NAMES utf8mb4 COLLATE utf8mb4_bin;
mysql> SELECT 'a ' = 'a';
+------------+
| 'a ' = 'a' |
+------------+
|          1 |
+------------+

mysql> SET NAMES utf8mb4 COLLATE utf8mb4_0900_bin;
mysql> SELECT 'a ' = 'a';
+------------+
| 'a ' = 'a' |
+------------+
|          0 |
+------------+
```

Note

“Comparison” in this context does not include the LIKE pattern-matching operator, for which trailing spaces are significant, regardless of collation.

For binary strings (BINARY, VARBINARY, and BLOB values), all bytes are significant in comparisons, including trailing spaces:

```
mysql> SET NAMES binary;
mysql> SELECT 'a ' = 'a';
+------------+
| 'a ' = 'a' |
+------------+
|          0 |
+------------+
```

**Trailing Space Handling for Inserts and Retrievals**

- CHAR(N) columns store nonbinary strings N characters long. For inserts, values shorter than N characters are extended with spaces. For retrievals, trailing spaces are removed.
- BINARY(N) columns store binary strings N bytes long. For inserts, values shorter than N bytes are extended with 0x00 bytes. For retrievals, nothing is removed; a value of the declared length is always returned.
Examples of the Effect of Collation

10.8.6 Examples of the Effect of Collation

Example 1: Sorting German Umlauts

Suppose that column X in table T has these latin1 column values:

Muffler
Müller
MX Systems
MySQL

Suppose also that the column values are retrieved using the following statement:

SELECT X FROM T ORDER BY X COLLATE collation_name;

The following table shows the resulting order of the values if we use ORDER BY with different collations.

<table>
<thead>
<tr>
<th>latin1_swedish_ci</th>
<th>latin1_german1_ci</th>
<th>latin1_german2_ci</th>
</tr>
</thead>
<tbody>
<tr>
<td>Muffler</td>
<td>Muffler</td>
<td>Müller</td>
</tr>
<tr>
<td>MX Systems</td>
<td>Müller</td>
<td>Muffler</td>
</tr>
<tr>
<td>Müller</td>
<td>MX Systems</td>
<td>MX Systems</td>
</tr>
<tr>
<td>MySQL</td>
<td>MySQL</td>
<td>MySQL</td>
</tr>
</tbody>
</table>

The character that causes the different sort orders in this example is ü (German “U-umlaut”).

- The first column shows the result of the SELECT using the Swedish/Finnish collating rule, which says that U-umlaut sorts with Y.
- The second column shows the result of the SELECT using the German DIN-1 rule, which says that U-umlaut sorts with U.
- The third column shows the result of the SELECT using the German DIN-2 rule, which says that U-umlaut sorts with UE.

Example 2: Searching for German Umlauts

Suppose that you have three tables that differ only by the character set and collation used:

```sql
mysql> SET NAMES utf8mb4;
mysql> CREATE TABLE german1 (c CHAR(10) CHARACTER SET latin1 COLLATE latin1_german1_ci);
mysql> CREATE TABLE german2 (c CHAR(10) CHARACTER SET latin1 COLLATE latin1_german2_ci);
mysql> CREATE TABLE germanutf8 (c CHAR(10) CHARACTER SET utf8mb4 COLLATE utf8mb4_bin);
```
Using Collation in INFORMATION_SCHEMA Searches

Each table contains two records:

mysql> INSERT INTO german1 VALUES ('Bar'), ('Bär');
mysql> INSERT INTO german2 VALUES ('Bar'), ('Bär');
mysql> INSERT INTO germanutf8 VALUES ('Bar'), ('Bär');

Two of the above collations have an A = Ä equality, and one has no such equality (latin1_german2_ci). For that reason, comparisons yield the results shown here:

mysql> SELECT * FROM german1 WHERE c = 'Bär';
+------+
| c    |
+------+
| Bar  |
| Bär  |
+------+
mysql> SELECT * FROM german2 WHERE c = 'Bär';
+------+
| c    |
+------+
| Bär  |
+------+
mysql> SELECT * FROM germanutf8 WHERE c = 'Bär';
+------+
| c    |
+------+
| Bar  |
| Bär  |
+------+

This is not a bug but rather a consequence of the sorting properties of latin1_german1_ci and utf8mb4_unicode_ci (the sorting shown is done according to the German DIN 5007 standard).

10.8.7 Using Collation in INFORMATION_SCHEMA Searches

String columns in INFORMATION_SCHEMA tables have a collation of utf8mb3_general_ci, which is case-insensitive. However, for values that correspond to objects that are represented in the file system, such as databases and tables, searches in INFORMATION_SCHEMA string columns can be case-sensitive or case-insensitive, depending on the characteristics of the underlying file system and the lower_case_table_names system variable setting. For example, searches may be case-sensitive if the file system is case-sensitive. This section describes this behavior and how to modify it if necessary.

Suppose that a query searches the SCHEMATA.SCHEMA_NAME column for the test database. On Linux, file systems are case-sensitive, so comparisons of SCHEMATA.SCHEMA_NAME with 'test' match, but comparisons with 'TEST' do not:

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATAS
     WHERE SCHEMA_NAME = 'test';
+-------------+
| SCHEMA_NAME |
+-------------+
| test        |
+-------------+
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATAS
     WHERE SCHEMA_NAME = 'TEST';
Empty set (0.00 sec)

These results occur with the lower_case_table_names system variable set to 0. A lower_case_table_names setting of 1 or 2 causes the second query to return the same (nonempty) result as the first query.
Note

It is prohibited to start the server with a lower_case_table_names setting that is different from the setting used when the server was initialized.

On Windows or macOS, file systems are not case-sensitive, so comparisons match both 'test' and 'TEST':

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
    -> WHERE SCHEMA_NAME = 'test';
```

```
+-------------+
<table>
<thead>
<tr>
<th>SCHEMA_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>test</td>
</tr>
</tbody>
</table>
+-------------+
```

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
    -> WHERE SCHEMA_NAME = 'TEST';
```

```
+-------------+
<table>
<thead>
<tr>
<th>SCHEMA_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>TEST</td>
</tr>
</tbody>
</table>
+-------------+
```

The value of lower_case_table_names makes no difference in this context.

The preceding behavior occurs because the utf8mb3_general_ci collation is not used for INFORMATION_SCHEMA queries when searching for values that correspond to objects represented in the file system.

If the result of a string operation on an INFORMATION_SCHEMA column differs from expectations, a workaround is to use an explicit COLLATE clause to force a suitable collation (see Section 10.8.1, “Using COLLATE in SQL Statements”). For example, to perform a case-insensitive search, use COLLATE with the INFORMATION_SCHEMA column name:

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
    -> WHERE SCHEMA_NAME COLLATE utf8mb3_general_ci = 'test';
```

```
+-------------+
<table>
<thead>
<tr>
<th>SCHEMA_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>test</td>
</tr>
</tbody>
</table>
+-------------+
```

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
    -> WHERE SCHEMA_NAME COLLATE utf8mb3_general_ci = 'TEST';
```

```
+-------------+
<table>
<thead>
<tr>
<th>SCHEMA_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>test</td>
</tr>
</tbody>
</table>
+-------------+
```

You can also use the UPPER() or LOWER() function:

```
WHERE UPPER(SCHEMA_NAME) = 'TEST'
WHERE LOWER(SCHEMA_NAME) = 'test'
```

Although a case-insensitive comparison can be performed even on platforms with case-sensitive file systems, as just shown, it is not necessarily always the right thing to do. On such platforms, it is possible to have multiple objects with names that differ only in lettercase. For example, tables named city, CITY, and City can all exist simultaneously. Consider whether a search should match all such names or just one and write queries accordingly. The first of the following comparisons (with utf8mb3_bin) is case-sensitive; the others are not:
10.9 Unicode Support

The Unicode Standard includes characters from the Basic Multilingual Plane (BMP) and supplementary characters that lie outside the BMP. This section describes support for Unicode in MySQL. For information about the Unicode Standard itself, visit the Unicode Consortium website.

BMP characters have these characteristics:

• Their code point values are between 0 and 65535 (or \u0000 and \uFFFF).

• They can be encoded in a variable-length encoding using 8, 16, or 24 bits (1 to 3 bytes).

• They can be encoded in a fixed-length encoding using 16 bits (2 bytes).

• They are sufficient for almost all characters in major languages.

Supplementary characters lie outside the BMP:

• Their code point values are between \u10000 and \u10FFFF.

• Unicode support for supplementary characters requires character sets that have a range outside BMP characters and therefore take more space than BMP characters (up to 4 bytes per character).

The UTF-8 (Unicode Transformation Format with 8-bit units) method for encoding Unicode data is implemented according to RFC 3629, which describes encoding sequences that take from one to four bytes. The idea of UTF-8 is that various Unicode characters are encoded using byte sequences of different lengths:

• Basic Latin letters, digits, and punctuation signs use one byte.

• Most European and Middle East script letters fit into a 2-byte sequence: extended Latin letters (with tilde, macron, acute, grave and other accents), Cyrillic, Greek, Armenian, Hebrew, Arabic, Syriac, and others.

• Korean, Chinese, and Japanese ideographs use 3-byte or 4-byte sequences.

MySQL supports these Unicode character sets:
• **utf8mb4**: A UTF-8 encoding of the Unicode character set using one to four bytes per character.

• **utf8mb3**: A UTF-8 encoding of the Unicode character set using one to three bytes per character. This character set is deprecated and subject to removal in a future release; use utf8mb4 instead.

• **utf8**: A deprecated alias for utf8mb3; use utf8mb4 instead.

**Note**

utf8 is expected in a future version of MySQL to become an alias for utf8mb4.

• **ucs2**: The UCS-2 encoding of the Unicode character set using two bytes per character. Deprecated; expect support for this character set to be removed in a future release.

• **utf16**: The UTF-16 encoding for the Unicode character set using two or four bytes per character. Like ucs2 but with an extension for supplementary characters.

• **utf16le**: The UTF-16LE encoding for the Unicode character set. Like utf16 but little-endian rather than big-endian.

• **utf32**: The UTF-32 encoding for the Unicode character set using four bytes per character.

**Note**

The utf8mb3 character set is deprecated and you should expect it to be removed in a future MySQL release. Please use utf8mb4 instead. utf8 is currently an alias for utf8mb3, but it is now deprecated as such, and utf8 is expected subsequently to become a reference to utf8mb4. MySQL 8.2 also displays utf8mb3 in place of utf8 in the columns of Information Schema tables, and in the output of SQL `SHOW` statements.

In addition, you should be aware that collations using the utf8_prefix in older releases of MySQL have since been renamed using the prefix utf8mb3_, instead.

To avoid ambiguity about the meaning of utf8, consider specifying utf8mb4 explicitly for character set references.

Table 10.2, "Unicode Character Set General Characteristics", summarizes the general characteristics of Unicode character sets supported by MySQL.

**Table 10.2 Unicode Character Set General Characteristics**

<table>
<thead>
<tr>
<th>Character Set</th>
<th>Supported Characters</th>
<th>Required Storage Per Character</th>
</tr>
</thead>
<tbody>
<tr>
<td>utf8mb3, utf8 (deprecated)</td>
<td>BMP only</td>
<td>1, 2, or 3 bytes</td>
</tr>
<tr>
<td>ucs2</td>
<td>BMP only</td>
<td>2 bytes</td>
</tr>
<tr>
<td>utf8mb4</td>
<td>BMP and supplementary</td>
<td>1, 2, 3, or 4 bytes</td>
</tr>
<tr>
<td>utf16</td>
<td>BMP and supplementary</td>
<td>2 or 4 bytes</td>
</tr>
<tr>
<td>utf16le</td>
<td>BMP and supplementary</td>
<td>2 or 4 bytes</td>
</tr>
<tr>
<td>utf32</td>
<td>BMP and supplementary</td>
<td>4 bytes</td>
</tr>
</tbody>
</table>

Characters outside the BMP compare as `REPLACEMENT CHARACTER` and convert to `'? '` when converted to a Unicode character set that supports only BMP characters (utf8mb3 or ucs2).

If you use character sets that support supplementary characters and thus are “wider” than the BMP-only utf8mb3 and ucs2 character sets, there are potential incompatibility issues for your applications;
The utf8mb4 Character Set (4-Byte UTF-8 Unicode Encoding)

see Section 10.9.8, “Converting Between 3-Byte and 4-Byte Unicode Character Sets”. That section also
describes how to convert tables from the (3-byte) utf8mb3 to the (4-byte) utf8mb4, and what constraints
may apply in doing so.

A similar set of collations is available for most Unicode character sets. For example, each has a
Danish collation, the names of which are utf8mb4_danish_ci, utf8mb3_danish_ci (deprecated),
utf8_danish_ci (deprecated), ucs2_danish_ci, utf16_danish_ci, and utf32_danish_ci. The
exception is utf16le, which has only two collations. For information about Unicode collations and their
differentiating properties, including collation properties for supplementary characters, see Section 10.10.1,
“Unicode Character Sets”.

The MySQL implementation of UCS-2, UTF-16, and UTF-32 stores characters in big-endian byte order
and does not use a byte order mark (BOM) at the beginning of values. Other database systems might use little-
endian byte order or a BOM. In such cases, conversion of values needs to be performed when transferring
data between those systems and MySQL. The implementation of UTF-16LE is little-endian.

MySQL uses no BOM for UTF-8 values.

Client applications that communicate with the server using Unicode should set the client character set
accordingly (for example, by issuing a SET NAMES 'utf8mb4' statement). Some character sets cannot
be used as the client character set. Attempting to use them with SET NAMES or SET CHARACTER SET
produces an error. See Impermissible Client Character Sets.

The following sections provide additional detail on the Unicode character sets in MySQL.

10.9.1 The utf8mb4 Character Set (4-Byte UTF-8 Unicode Encoding)

The utf8mb4 character set has these characteristics:

• Supports BMP and supplementary characters.

• Requires a maximum of four bytes per multibyte character.

utf8mb4 contrasts with the utf8mb3 character set, which supports only BMP characters and uses a
maximum of three bytes per character:

• For a BMP character, utf8mb4 and utf8mb3 have identical storage characteristics: same code values,
same encoding, same length.

• For a supplementary character, utf8mb4 requires four bytes to store it, whereas utf8mb3 cannot
store the character at all. When converting utf8mb3 columns to utf8mb4, you need not worry about
converting supplementary characters because there are none.

utf8mb4 is a superset of utf8mb3, so for an operation such as the following concatenation, the result has
character set utf8mb4 and the collation of utf8mb4_col:

```sql
SELECT CONCAT(utf8mb3_col, utf8mb4_col);
```

Similarly, the following comparison in the WHERE clause works according to the collation of utf8mb4_col:

```sql
SELECT * FROM utf8mb3_tbl, utf8mb4_tbl
WHERE utf8mb3_tbl.utf8mb3_col = utf8mb4_tbl.utf8mb4_col;
```

For information about data type storage as it relates to multibyte character sets, see String Type Storage
Requirements.

10.9.2 The utf8mb3 Character Set (3-Byte UTF-8 Unicode Encoding)

The utf8mb3 character set has these characteristics:
• Supports BMP characters only (no support for supplementary characters)
• Requires a maximum of three bytes per multibyte character.

Applications that use UTF-8 data but require supplementary character support should use utf8mb4 rather than utf8mb3 (see Section 10.9.1, “The utf8mb4 Character Set (4-Byte UTF-8 Unicode Encoding”).

Exactly the same set of characters is available in utf8mb3 and ucs2. That is, they have the same repertoire.

Note

Historically, MySQL has used utf8 as an alias for utf8mb3; in MySQL 8.2, utf8mb3 is used exclusively in the output of SHOW statements and in Information Schema tables when this character set is meant.

At some point in the future utf8 is expected to become a reference to utf8mb4. To avoid ambiguity about the meaning of utf8, consider specifying utf8mb4 explicitly for character set references instead of utf8.

You should also be aware that the utf8mb3 character set is deprecated and you should expect it to be removed in a future MySQL release. Please use utf8mb4 instead.

utf8mb3 can be used in CHARACTER SET clauses, and utf8mb3_collation_substring in COLLATE clauses, where collation_substring is bin, czech_ci, danish_ci, esperanto_ci, estonian_ci, and so forth. For example:

```sql
CREATE TABLE t (s1 CHAR(1)) CHARACTER SET utf8mb3;
SELECT * FROM t WHERE s1 COLLATE utf8mb3_general_ci = 'x';
DECLARE x VARCHAR(5) CHARACTER SET utf8mb3 COLLATE utf8mb3_danish_ci;
SELECT CAST('a' AS CHAR CHARACTER SET utf8mb4) COLLATE utf8mb4_czech_ci;
```

In statements such as SHOW CREATE TABLE or SELECT CHARACTER_SET_NAME FROM INFORMATION_SCHEMA.COLUMNS or SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLUMNS, character sets or collation names prefixed with utf8 or utf8_ are displayed using utf8mb3 or utf8mb3_, respectively.

utf8mb3 is also valid (but deprecated) in contexts other than CHARACTER SET clauses. For example:

```sql
mysql --character-set-server=utf8mb3
SET NAMES 'utf8mb3'; /* and other SET statements that have similar effect */
SELECT _utf8mb3 'a';
```

For information about data type storage as it relates to multibyte character sets, see String Type Storage Requirements.

10.9.3 The utf8 Character Set (Alias for utf8mb3)

utf8 has been used by MySQL in the past as an alias for the utf8mb3 character set, but this usage is now deprecated; in MySQL 8.2, SHOW statements and columns of Information Schema tables display utf8mb3 instead. For more information, see Section 10.9.2, “The utf8mb3 Character Set (3-Byte UTF-8 Unicode Encoding”).

Note

The utf8mb3 character set is deprecated and you should expect it to be removed in a future MySQL release. Please use utf8mb4 instead. utf8 is currently an alias
The ucs2 Character Set (UCS-2 Unicode Encoding)

Note

The ucs2 character set is deprecated; expect it to be removed in a future MySQL release. You should use utf8mb4 instead.

In UCS-2, every character is represented by a 2-byte Unicode code with the most significant byte first. For example: LATIN CAPITAL LETTER A has the code 0x0041 and it is stored as a 2-byte sequence: 0x00 0x41. CYRILLIC SMALL LETTER YERU (Unicode 0x044B) is stored as a 2-byte sequence: 0x04 0x4B. For Unicode characters and their codes, please refer to the Unicode Consortium website.

The ucs2 character set has these characteristics:

- Supports BMP characters only (no support for supplementary characters)
- Uses a fixed-length 16-bit encoding and requires two bytes per character.

10.9.5 The utf16 Character Set (UTF-16 Unicode Encoding)

The utf16 character set is the ucs2 character set with an extension that enables encoding of supplementary characters:

- For a BMP character, utf16 and ucs2 have identical storage characteristics: same code values, same encoding, same length.

- For a supplementary character, utf16 has a special sequence for representing the character using 32 bits. This is called the “surrogate” mechanism: For a number greater than 0xffff, take 10 bits and add them to 0xd800 and put them in the first 16-bit word, take 10 more bits and add them to 0xdc00 and put them in the next 16-bit word. Consequently, all supplementary characters require 32 bits, where the first 16 bits are a number between 0xd800 and 0xdbff, and the last 16 bits are a number between 0xdc00 and 0xdfff. Examples are in Section 15.5 Surrogates Area of the Unicode 4.0 document.

Because utf16 supports surrogates and ucs2 does not, there is a validity check that applies only in utf16: You cannot insert a top surrogate without a bottom surrogate, or vice versa. For example:

```
INSERT INTO t (ucs2_column) VALUES (0xd800); /* legal */
INSERT INTO t (utf16_column) VALUES (0xd800); /* illegal */
```

There is no validity check for characters that are technically valid but are not true Unicode (that is, characters that Unicode considers to be “unassigned code points” or “private use” characters or even “illegals” like 0xffff). For example, since U+F8FF is the Apple Logo, this is legal:

```
INSERT INTO t (utf16_column) VALUES (0xf8ff); /* legal */
```

Such characters cannot be expected to mean the same thing to everyone.

Because MySQL must allow for the worst case (that one character requires four bytes) the maximum length of a utf16 column or index is only half of the maximum length for a ucs2 column or index. For example, the maximum length of a MEMORY table index key is 3072 bytes, so these statements create tables with the longest permitted indexes for ucs2 and utf16 columns:
10.9.6 The utf16le Character Set (UTF-16LE Unicode Encoding)

This is the same as utf16 but is little-endian rather than big-endian.

10.9.7 The utf32 Character Set (UTF-32 Unicode Encoding)

The utf32 character set is fixed length (like ucs2 and unlike utf16). utf32 uses 32 bits for every character, unlike ucs2 (which uses 16 bits for every character), and unlike utf16 (which uses 16 bits for some characters and 32 bits for others).

utf32 takes twice as much space as ucs2 and more space than utf16, but utf32 has the same advantage as ucs2 that it is predictable for storage: The required number of bytes for utf32 equals the number of characters times 4. Also, unlike utf16, there are no tricks for encoding in utf32, so the stored value equals the code value.

To demonstrate how the latter advantage is useful, here is an example that shows how to determine a utf8mb4 value given the utf32 code value:

```sql
/* Assume code value = 100cc LINEAR B WHEELED CHARIOT */
CREATE TABLE tmp (utf32_col CHAR(1) CHARACTER SET utf32, utf8mb4_col CHAR(1) CHARACTER SET utf8mb4);
INSERT INTO tmp VALUES (0x000100cc,NULL);
UPDATE tmp SET utf8mb4_col = utf32_col;
SELECT HEX(utf32_col),HEX(utf8mb4_col) FROM tmp;
```

MySQL is very forgiving about additions of unassigned Unicode characters or private-use-area characters. There is in fact only one validity check for utf32: No code value may be greater than 0x10ffff. For example, this is illegal:

```sql
INSERT INTO t (utf32_column) VALUES (0x110000); /* illegal */
```

10.9.8 Converting Between 3-Byte and 4-Byte Unicode Character Sets

This section describes issues that you may face when converting character data between the utf8mb3 and utf8mb4 character sets.

**Note**

This discussion focuses primarily on converting between utf8mb3 and utf8mb4, but similar principles apply to converting between the ucs2 character set and character sets such as utf16 or utf32.

The utf8mb3 and utf8mb4 character sets differ as follows:

- utf8mb3 supports only characters in the Basic Multilingual Plane (BMP). utf8mb4 additionally supports supplementary characters that lie outside the BMP.
- utf8mb3 uses a maximum of three bytes per character. utf8mb4 uses a maximum of four bytes per character.

**Note**

This discussion refers to the utf8mb3 and utf8mb4 character set names to be explicit about referring to 3-byte and 4-byte UTF-8 character set data.
One advantage of converting from utf8mb3 to utf8mb4 is that this enables applications to use supplementary characters. One tradeoff is that this may increase data storage space requirements.

In terms of table content, conversion from utf8mb3 to utf8mb4 presents no problems:

- For a BMP character, utf8mb4 and utf8mb3 have identical storage characteristics: same code values, same encoding, same length.
- For a supplementary character, utf8mb4 requires four bytes to store it, whereas utf8mb3 cannot store the character at all. When converting utf8mb3 columns to utf8mb4, you need not worry about converting supplementary characters because there are none.

In terms of table structure, these are the primary potential incompatibilities:

- For the variable-length character data types (VARCHAR and the TEXT types), the maximum permitted length in characters is less for utf8mb4 columns than for utf8mb3 columns.
- For all character data types (CHAR, VARCHAR, and the TEXT types), the maximum number of characters that can be indexed is less for utf8mb4 columns than for utf8mb3 columns.

Consequently, to convert tables from utf8mb3 to utf8mb4, it may be necessary to change some column or index definitions.

Tables can be converted from utf8mb3 to utf8mb4 by using ALTER TABLE. Suppose that a table has this definition:

```sql
CREATE TABLE t1 (  
  col1 CHAR(10) CHARACTER SET utf8mb3 COLLATE utf8mb3_unicode_ci NOT NULL,  
  col2 CHAR(10) CHARACTER SET utf8mb3 COLLATE utf8mb3_bin NOT NULL  
) CHARACTER SET utf8mb3;
```

The following statement converts `t1` to use utf8mb4:

```sql
ALTER TABLE t1  
  DEFAULT CHARACTER SET utf8mb4,  
  MODIFY col1 CHAR(10) CHARACTER SET utf8mb4 COLLATE utf8mb4_unicode_ci NOT NULL,  
  MODIFY col2 CHAR(10) CHARACTER SET utf8mb4 COLLATE utf8mb4_bin NOT NULL;
```

The catch when converting from utf8mb3 to utf8mb4 is that the maximum length of a column or index key is unchanged in terms of bytes. Therefore, it is smaller in terms of characters because the maximum length of a character is four bytes instead of three. For the CHAR, VARCHAR, and TEXT data types, watch for these issues when converting your MySQL tables:

- Check all definitions of utf8mb3 columns and make sure they do not exceed the maximum length for the storage engine.
- Check all indexes on utf8mb3 columns and make sure they do not exceed the maximum length for the storage engine. Sometimes the maximum can change due to storage engine enhancements.

If the preceding conditions apply, you must either reduce the defined length of columns or indexes, or continue to use utf8mb3 rather than utf8mb4.

Here are some examples where structural changes may be needed:

- A TINYTEXT column can hold up to 255 bytes, so it can hold up to 85 3-byte or 63 4-byte characters. Suppose that you have a TINYTEXT column that uses utf8mb3 but must be able to contain more than
63 characters. You cannot convert it to utf8mb4 unless you also change the data type to a longer type such as TEXT.

Similarly, a very long VARCHAR column may need to be changed to one of the longer TEXT types if you want to convert it from utf8mb3 to utf8mb4.

• InnoDB has a maximum index length of 767 bytes for tables that use COMPACT or REDUNDANT row format, so for utf8mb3 or utf8mb4 columns, you can index a maximum of 255 or 191 characters, respectively. If you currently have utf8mb3 columns with indexes longer than 191 characters, you must index a smaller number of characters.

In an InnoDB table that uses COMPACT or REDUNDANT row format, these column and index definitions are legal:

```
coll VARCHAR(500) CHARACTER SET utf8mb3, INDEX (coll(255))
```

To use utf8mb4 instead, the index must be smaller:

```
coll VARCHAR(500) CHARACTER SET utf8mb4, INDEX (coll(191))
```

**Note**

For InnoDB tables that use COMPRESSED or DYNAMIC row format, index key prefixes longer than 767 bytes (up to 3072 bytes) are permitted. Tables created with these row formats enable you to index a maximum of 1024 or 768 characters for utf8mb3 or utf8mb4 columns, respectively. For related information, see Section 15.22, “InnoDB Limits”, and DYNAMIC Row Format.

The preceding types of changes are most likely to be required only if you have very long columns or indexes. Otherwise, you should be able to convert your tables from utf8mb3 to utf8mb4 without problems, using ALTER TABLE as described previously.

The following items summarize other potential incompatibilities:

• SET NAMES 'utf8mb4' causes use of the 4-byte character set for connection character sets. As long as no 4-byte characters are sent from the server, there should be no problems. Otherwise, applications that expect to receive a maximum of three bytes per character may have problems. Conversely, applications that expect to send 4-byte characters must ensure that the server understands them.

• For replication, if character sets that support supplementary characters are to be used on the source, all replicas must understand them as well.

Also, keep in mind the general principle that if a table has different definitions on the source and replica, this can lead to unexpected results. For example, the differences in maximum index key length make it risky to use utf8mb3 on the source and utf8mb4 on the replica.

If you have converted to utf8mb4, utf8, utf16, utf16le, or utf32, and then decide to convert back to utf8mb3 or ucs2 (for example, to downgrade to an older version of MySQL), these considerations apply:

• utf8mb3 and ucs2 data should present no problems.

• The server must be recent enough to recognize definitions referring to the character set from which you are converting.

• For object definitions that refer to the utf8mb4 character set, you can dump them with mysqldump prior to downgrading, edit the dump file to change instances of utf8mb4 to utf8, and reload the file in the older server, as long as there are no 4-byte characters in the data. The older server sees utf8 in the dump file object definitions and create new objects that use the (3-byte) utf8 character set.
10.10 Supported Character Sets and Collations

This section indicates which character sets MySQL supports. There is one subsection for each group of related character sets. For each character set, the permissible collations are listed.

To list the available character sets and their default collations, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA CHARACTER_SETS` table. For example:

```
mysql> SHOW CHARACTER SET;
```

<table>

</tr>
</tbody>
</table>

In cases where a character set has multiple collations, it might not be clear which collation is most suitable for a given application. To avoid choosing the wrong collation, it can be helpful to perform some comparisons with representative data values to make sure that a given collation sorts values the way you expect.

10.10.1 Unicode Character Sets

This section describes the collations available for Unicode character sets and their differentiating properties. For general information about Unicode, see Section 10.9, “Unicode Support”. 

2105
MySQL supports multiple Unicode character sets:

- **utf8mb4**: A UTF-8 encoding of the Unicode character set using one to four bytes per character.

- **utf8mb3**: A UTF-8 encoding of the Unicode character set using one to three bytes per character. This character set is deprecated; please use utf8mb4 instead.

- **utf8**: A deprecated alias for utf8mb3. Use utf8mb4 instead.

**Note**

utf8 is expected in a future release to become an alias for utf8mb4.

- **ucs2**: The UCS-2 encoding of the Unicode character set using two bytes per character. Deprecated; expect support for this character set to be removed in a future version of MySQL.

- **utf16**: The UTF-16 encoding for the Unicode character set using two or four bytes per character. Like ucs2 but with an extension for supplementary characters.

- **utf16le**: The UTF-16LE encoding for the Unicode character set. Like utf16 but little-endian rather than big-endian.

- **utf32**: The UTF-32 encoding for the Unicode character set using four bytes per character.

**Note**

The utf8mb3 character set is deprecated and you should expect it to be removed in a future MySQL release. Please use utf8mb4 instead. utf8 is currently an alias for utf8mb4, but it is now deprecated as such, and utf8 is expected subsequently to become a reference to utf8mb4. utf8mb3 is also displayed in place of utf8 in columns of Information Schema tables, and in the output of SQL SHOW statements.

To avoid ambiguity about the meaning of utf8, consider specifying utf8mb4 explicitly for character set references.

utf8mb4, utf16, utf16le, and utf32 support Basic Multilingual Plane (BMP) characters and supplementary characters that lie outside the BMP. utf8mb3 and ucs2 support only BMP characters.

Most Unicode character sets have a general collation (indicated by _general in the name or by the absence of a language specifier), a binary collation (indicated by _bin in the name), and several language-specific collations (indicated by language specifiers). For example, for utf8mb4, utf8mb4_general_ci and utf8mb4_bin are its general and binary collations, and utf8mb4_danish_ci is one of its language-specific collations.

Most character sets have a single binary collation. utf8mb4 is an exception that has two: utf8mb4_bin and utf8mb4_0900_bin. These two binary collations have the same sort order but are distinguished by their pad attribute and collating weight characteristics. See Collation Pad Attributes, and Character Collating Weights.

Collation support for utf16le is limited. The only collations available are utf16le_general_ci and utf16le_bin. These are similar to utf16_general_ci and utf16_bin.

- **Unicode Collation Algorithm (UCA) Versions**
- **Collation Pad Attributes**
- **Language-Specific Collations**
- **_general_ci Versus _unicode_ci Collations**
Unicode Character Sets

- Character Collating Weights
- Miscellaneous Information

Unicode Collation Algorithm (UCA) Versions

MySQL implements the xxx_unicode_ci collations according to the Unicode Collation Algorithm (UCA) described at http://www.unicode.org/reports/tr10/. The collation uses the version-4.0.0 UCA weight keys: http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt. The xxx_unicode_ci collations have only partial support for the Unicode Collation Algorithm. Some characters are not supported, and combining marks are not fully supported. This affects languages such as Vietnamese, Yoruba, and Navajo. A combined character is considered different from the same character written with a single unicode character in string comparisons, and the two characters are considered to have a different length (for example, as returned by the CHAR_LENGTH() function or in result set metadata).

Unicode collations based on UCA versions higher than 4.0.0 include the version in the collation name. Examples:

- utf8mb4_unicode_520_ci is based on UCA 5.2.0 weight keys (http://www.unicode.org/Public/UCA/5.2.0/allkeys.txt),
- utf8mb4_0900_ai_ci is based on UCA 9.0.0 weight keys (http://www.unicode.org/Public/UCA/9.0.0/allkeys.txt).

The LOWER() and UPPER() functions perform case folding according to the collation of their argument. A character that has uppercase and lowercase versions only in a Unicode version higher than 4.0.0 is converted by these functions only if the argument collation uses a high enough UCA version.

Collation Pad Attributes

Collations based on UCA 9.0.0 and higher are faster than collations based on UCA versions prior to 9.0.0. They also have a pad attribute of NO PAD, in contrast to PAD SPACE as used in collations based on UCA versions prior to 9.0.0. For comparison of nonbinary strings, NO PAD collations treat spaces at the end of strings like any other character (see Trailing Space Handling in Comparisons).

To determine the pad attribute for a collation, use the INFORMATION_SCHEMA.COLLATIONS table, which has a PAD_ATTRIBUTE column. For example:

```
mysql> SELECT COLLATION_NAME, PAD_ATTRIBUTE
FROM INFORMATION_SCHEMA.COLLATIONS
WHERE CHARACTER_SET_NAME = 'utf8mb4';
```

<table>
<thead>
<tr>
<th>COLLATION_NAME</th>
<th>PAD_ATTRIBUTE</th>
</tr>
</thead>
<tbody>
<tr>
<td>utf8mb4_general_ci</td>
<td>PAD SPACE</td>
</tr>
<tr>
<td>utf8mb4_bin</td>
<td>PAD SPACE</td>
</tr>
<tr>
<td>utf8mb4_unicode_ci</td>
<td>PAD SPACE</td>
</tr>
<tr>
<td>utf8mb4_icelandic_ci</td>
<td>PAD SPACE</td>
</tr>
<tr>
<td>utf8mb4_0900_ai_ci</td>
<td>NO PAD</td>
</tr>
<tr>
<td>utf8mb4_de_pb_0900_ai_ci</td>
<td>NO PAD</td>
</tr>
<tr>
<td>utf8mb4_is_0900_ai_ci</td>
<td>NO PAD</td>
</tr>
<tr>
<td>utf8mb4_ja_0900_as_cs</td>
<td>NO PAD</td>
</tr>
<tr>
<td>utf8mb4_ja_0900_as_cs_ks</td>
<td>NO PAD</td>
</tr>
<tr>
<td>utf8mb4_0900_as_ci</td>
<td>NO PAD</td>
</tr>
<tr>
<td>utf8mb4_ru_0900_ai_ci</td>
<td>NO PAD</td>
</tr>
<tr>
<td>utf8mb4_ru_0900_as_cs</td>
<td>NO PAD</td>
</tr>
<tr>
<td>utf8mb4_zh_0900_as_cs</td>
<td>NO PAD</td>
</tr>
<tr>
<td>utf8mb4_0900_bin</td>
<td>NO PAD</td>
</tr>
</tbody>
</table>
```

2107
Comparison of nonbinary string values (CHAR, VARCHAR, and TEXT) that have a NO PAD collation differ from other collations with respect to trailing spaces. For example, 'a' and 'a ' compare as different strings. This can be seen using the binary collations for utf8mb4. The pad attribute for utf8mb4_bin is PAD SPACE, whereas for utf8mb4_0900_bin it is NO PAD. Consequently, operations involving utf8mb4_0900_bin do not add trailing spaces, and comparisons involving strings with trailing spaces may differ for the two collations:

```sql
mysql> CREATE TABLE t1 (c CHAR(10) COLLATE utf8mb4_bin);
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO t1 VALUES('a');
Query OK, 1 row affected (0.01 sec)

mysql> SELECT * FROM t1 WHERE c = 'a ';
+------+
| c    |
+------+
| a    |
+------+
1 row in set (0.00 sec)

mysql> ALTER TABLE t1 MODIFY c CHAR(10) COLLATE utf8mb4_0900_bin;
Query OK, 0 rows affected (0.02 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM t1 WHERE c = 'a ';
Empty set (0.00 sec)
```

Language-Specific Collations

MySQL implements language-specific Unicode collations if the ordering based only on the Unicode Collation Algorithm (UCA) does not work well for a language. Language-specific collations are UCA-based, with additional language tailoring rules. Examples of such rules appear later in this section. For questions about particular language orderings, http://unicode.org provides Common Locale Data Repository (CLDR) collation charts at http://www.unicode.org/cldr/charts/30/collation/index.html.

For example, the nonlanguage-specific utf8mb4_0900_ai_ci and language-specific utf8mb4_LOCALE_0900_ai_ci Unicode collations each have these characteristics:

- The collation is based on UCA 9.0.0 and CLDR v30, is accent-insensitive and case-insensitive. These characteristics are indicated by _0900, _ai, and _ci in the collation name. Exception: utf8mb4_la_0900_ai_ci is not based on CLDR because Classical Latin is not defined in CLDR.

- The collation works for all characters in the range [U+0, U+10FFFF].

- If the collation is not language specific, it sorts all characters, including supplementary characters, in default order (described following). If the collation is language specific, it sorts characters of the language correctly according to language-specific rules, and characters not in the language in default order.

- By default, the collation sorts characters having a code point listed in the DUCET table (Default Unicode Collation Element Table) according to the weight value assigned in the table. The collation sorts characters not having a code point listed in the DUCET table using their implicit weight value, which is constructed according to the UCA.

- For non-language-specific collations, characters in contraction sequences are treated as separate characters. For language-specific collations, contractions might change character sorting order.

A collation name that includes a locale code or language name shown in the following table is a language-specific collation. Unicode character sets may include collations for one or more of these languages.

</tbody>
</table>

MySQL provides the Bulgarian collations `utf8mb4_bg_0900_ai_ci` and `utf8mb4_bg_0900_as_cs`.

Croatian collations are tailored for these Croatian letters: Č, Ć, Đ, Đ, Lj, Nj, Š, Ž.

MySQL provides the `utf8mb4_sr_latn_0900_ai_ci` and `utf8mb4_sr_latn_0900_as_cs` collations for Serbian and the `utf8mb4_bs_0900_ai_ci` and `utf8mb4_bs_0900_as_cs` collations for Bosnian, when these languages are written with the Latin alphabet.
Unicode Character Sets

MySQL provides collations for both major varieties of Norwegian: for Bokmål, you can use `utf8mb4_nb_0900_ai_ci` and `utf8mb4_nb_0900_as_cs`; for Nynorsk, MySQL now provides `utf8mb4_nn_0900_ai_ci` and `utf8mb4_nn_0900_as_cs`.

For Japanese, the `utf8mb4` character set includes `utf8mb4_ja_0900_as_cs` and `utf8mb4_ja_0900_as_cs_ks` collations. Both collations are accent-sensitive and case-sensitive. `utf8mb4_ja_0900_as_cs_ks` is also kana-sensitive and distinguishes Katakana characters from Hiragana characters, whereas `utf8mb4_ja_0900_as_cs` treats Katakana and Hiragana characters as equal for sorting. Applications that require a Japanese collation but not kana sensitivity may use `utf8mb4_ja_0900_as_cs` for better sort performance. `utf8mb4_ja_0900_as_cs` uses three weight levels for sorting; `utf8mb4_ja_0900_as_cs_ks` uses four.

For Classical Latin collations that are accent-insensitive, I and J compare as equal, and U and V compare as equal. I and J, and U and V compare as equal on the base letter level. In other words, J is regarded as an accented I, and ü is regarded as an accented v.

MySQL provides collations for the Mongolian language when written with Cyrillic characters, `utf8mb4_mn_cyrl_0900_ai_ci` and `utf8mb4_mn_cyrl_0900_as_cs`.

Spanish collations are available for modern and traditional Spanish. For both, ñ (n-tilde) is a separate letter between n and o. In addition, for traditional Spanish, ch is a separate letter between c and d, and ll is a separate letter between l and m.

Traditional Spanish collations may also be used for Asturian and Galician. MySQL also provides `utf8mb4_gl_0900_ai_ci` and `utf8mb4_gl_0900_as_cs` collations for Galician. (These are the same collations as `utf8mb4_es_0900_ai_ci` and `utf8mb4_es_0900_as_cs`, respectively.)

Swedish collations include Swedish rules. For example, in Swedish, the following relationship holds, which is not something expected by a German or French speaker:

\[ Ù = Y < Ö \]

___general_ci Versus _unicode_ci Collations___

For any Unicode character set, operations performed using the xxx_general_ci collation are faster than those for the xxx_unicode_ci collation. For example, comparisons for the `utf8mb4_general_ci` collation are faster, but slightly less correct, than comparisons for `utf8mb4_unicode_ci`. The reason is that `utf8mb4_unicode_ci` supports mappings such as expansions; that is, when one character compares as equal to combinations of other characters. For example, ß is equal to ss in German and some other languages. `utf8mb4_unicode_ci` also supports contractions and ignorable characters. `utf8mb4_general_ci` is a legacy collation that does not support expansions, contractions, or ignorable characters. It can make only one-to-one comparisons between characters.

To further illustrate, the following equalities hold in both `utf8mb4_general_ci` and `utf8mb4_unicode_ci` (for the effect of this in comparisons or searches, see Section 10.8.6, “Examples of the Effect of Collation”):

\[ Ä = A \]
\[ Ö = O \]
\[ Ü = U \]

A difference between the collations is that this is true for `utf8mb4_general_ci`:

\[ Ä = s \]

Whereas this is true for `utf8mb4_unicode_ci`, which supports the German DIN-1 ordering (also known as dictionary order):
Unicode Character Sets

MySQL implements language-specific Unicode collations if the ordering with utf8mb4_unicode_ci does not work well for a language. For example, utf8mb4_unicode_ci works fine for German dictionary order and French, so there is no need to create special utf8mb4 collations.

utf8mb4_general_ci also is satisfactory for both German and French, except that ß is equal to s, and not to ss. If this is acceptable for your application, you should use utf8mb4_general_ci because it is faster. If this is not acceptable (for example, if you require German dictionary order), use utf8mb4_unicode_ci because it is more accurate.

If you require German DIN-2 (phone book) ordering, use the utf8mb4_german2_ci collation, which compares the following sets of characters equal:

| Æ = ÆE | Ò = ÓE | Ù = ÚE | ß = ss |

utf8mb4_german2_ci is similar to latin1_german2_ci, but the latter does not compare Æ equal to AE or ÓE equal to OE. There is no utf8mb4_german_ci corresponding to latin1_german_ci for German dictionary order because utf8mb4_general_ci suffices.

Character Collating Weights

A character's collating weight is determined as follows:

- For all Unicode collations except the _bin (binary) collations, MySQL performs a table lookup to find a character's collating weight.
- For _bin collations except utf8mb4_0900_bin, the weight is based on the code point, possibly with leading zero bytes added.
- For utf8mb4_0900_bin, the weight is the utf8mb4 encoding bytes. The sort order is the same as for utf8mb4_bin, but much faster.

Collating weights can be displayed using the WEIGHT_STRING() function. (See Section 12.8, "String Functions and Operators"). If a collation uses a weight lookup table, but a character is not in the table (for example, because it is a “new” character), collating weight determination becomes more complex:

- For BMP characters in general collations (xxx_general_ci), the weight is the code point.
- For BMP characters in UCA collations (for example, xxx_unicode_ci and language-specific collations), the following algorithm applies:

```sql
if (code >= 0x3400 && code <= 0x4DB5)  
  base= 0xFB80; /* CJK Ideograph Extension */ 
else if (code >= 0x4E00 && code <= 0x9FA5)  
  base= 0xFB40; /* CJK Ideograph */ 
else 
  base= 0xFBC0; /* All other characters */ 
```

The result is a sequence of two collating elements, aaaa followed by bbbb. For example:
Thus, U+04cf CYRILLIC SMALL LETTER PALOCHKA (ӏ) is, with all UCA 4.0.0 collations, greater than U+04c0 CYRILLIC LETTER PALOCHKA (Ӏ). With UCA 5.2.0 collations, all palochkas sort together.

- For supplementary characters in general collations, the weight is the weight for 0xfffd REPLACEMENT CHARACTER. For supplementary characters in UCA 4.0.0 collations, their collating weight is 0xfffd. That is, to MySQL, all supplementary characters are equal to each other, and greater than almost all BMP characters.

An example with Deseret characters and COUNT(DISTINCT):

```sql
CREATE TABLE t (s1 VARCHAR(5) CHARACTER SET utf32 COLLATE utf32_unicode_ci);
INSERT INTO t VALUES (0xfffd);   /* REPLACEMENT CHARACTER */
INSERT INTO t VALUES (0x010412); /* DESERET CAPITAL LETTER BEE */
INSERT INTO t VALUES (0x010413); /* DESERET CAPITAL LETTER TEE */
SELECT COUNT(DISTINCT s1) FROM t;
```

The result is 2 because in the MySQL xxx_unicode_ci collations, the replacement character has a weight of 0x0dc6, whereas Deseret Bee and Deseret Tee both have a weight of 0xfffd. (Were the utf32_general_ci collation used instead, the result is 1 because all three characters have a weight of 0xfffd in that collation.)

An example with cuneiform characters and WEIGHT_STRING():

```sql
CREATE TABLE t (s1 CHAR(4) CHARACTER SET utf32 COLLATE utf32_unicode_ci);
INSERT INTO t VALUES (0x000000410001218f000121a700000042);
SELECT HEX(WEIGHT_STRING(s1)) FROM t;
```

The result is:

0E33 FFFD FFFD 0E4A

0E33 and 0E4A are primary weights as in UCA 4.0.0. FFFD is the weight for KAB and also for KISH.

The rule that all supplementary characters are equal to each other is nonoptimal but is not expected to cause trouble. These characters are very rare, so it is very rare that a multi-character string consists entirely of supplementary characters. In Japan, since the supplementary characters are obscure Kanji ideographs, the typical user does not care what order they are in, anyway. If you really want rows sorted by the MySQL rule and secondarily by code point value, it is easy:

```
ORDER BY s1 COLLATE utf32_unicode_ci, s1 COLLATE utf32_bin
```

- For supplementary characters based on UCA versions higher than 4.0.0 (for example, xxx_unicode_520_ci), supplementary characters do not necessarily all have the same collating weight. Some have explicit weights from the UCA allkeys.txt file. Others have weights calculated from this algorithm:

```
aaaa= base + (code >> 15);
bbbb= (code & 0x7FFF) | 0x8000;
```

There is a difference between “ordering by the character’s code value” and “ordering by the character’s binary representation,” a difference that appears only with utf16_bin, because of surrogates.

2112
Suppose that `utf16_bin` (the binary collation for `utf16`) was a binary comparison “byte by byte” rather than “character by character.” If that were so, the order of characters in `utf16_bin` would differ from the order in `utf8mb4_bin`. For example, the following chart shows two rare characters. The first character is in the range `E000-FFFF`, so it is greater than a surrogate but less than a supplementary. The second character is a supplementary.

<table>
<thead>
<tr>
<th>Code point</th>
<th>Character</th>
<th>utf8mb4</th>
<th>utf16</th>
</tr>
</thead>
<tbody>
<tr>
<td>0FF9D</td>
<td>HALFWIDTH KATAKANA LETTER N</td>
<td>EF BE 9D</td>
<td>FF 9D</td>
</tr>
<tr>
<td>10384</td>
<td>UGARITIC LETTER DELTA</td>
<td>F0 90 8E 84</td>
<td>D8 00 DF 84</td>
</tr>
</tbody>
</table>

The two characters in the chart are in order by code point value because `0xFF9D < 0x10384`. And they are in order by `utf8mb4` value because `0xef < 0xf0`. But they are not in order by `utf16` value, if we use byte-by-byte comparison, because `0xff > 0xd8`.

So MySQL’s `utf16_bin` collation is not “byte by byte.” It is “by code point.” When MySQL sees a supplementary-character encoding in `utf16`, it converts to the character’s code-point value, and then compares. Therefore, `utf8mb4_bin` and `utf16_bin` are the same ordering. This is consistent with the SQL:2008 standard requirement for a UCS_BASIC collation: “UCS_BASIC is a collation in which the ordering is determined entirely by the Unicode scalar values of the characters in the strings being sorted. It is applicable to the UCS character repertoire. Since every character repertoire is a subset of the UCS repertoire, the UCS_BASIC collation is potentially applicable to every character set. NOTE 11: The Unicode scalar value of a character is its code point treated as an unsigned integer.”

If the character set is `ucs2`, comparison is byte-by-byte, but `ucs2` strings should not contain surrogates, anyway.

**Miscellaneous Information**

The `xxx_general_mysql500_ci` collations preserve the pre-5.1.24 ordering of the original `xxx_general_ci` collations and permit upgrades for tables created before MySQL 5.1.24 (Bug #27877).

**10.10.2 West European Character Sets**

Western European character sets cover most West European languages, such as French, Spanish, Catalan, Basque, Portuguese, Italian, Albanian, Dutch, German, Danish, Swedish, Norwegian, Finnish, Faroese, Icelandic, Irish, Scottish, and English.

- `ascii` (US ASCII) collations:
  - `ascii_bin`
  - `ascii_general_ci` (default)

- `cp850` (DOS West European) collations:
  - `cp850_bin`
  - `cp850_general_ci` (default)

- `dec8` (DEC Western European) collations:
  - `dec8_bin`
  - `dec8_swedish_ci` (default)

The `dec` character set is deprecated; expect support for it to be removed in a subsequent MySQL release.
West European Character Sets

- **hp8** (HP Western European) collations:
  - hp8_bin
  - hp8_english_ci (default)

  The **hp8** character set is deprecated; expect support for it to be removed in a subsequent MySQL release.

- **latin1** (cp1252 West European) collations:
  - latin1_bin
  - latin1_danish_ci
  - latin1_general_ci
  - latin1_general_cs
  - latin1_german1_ci
  - latin1_german2_ci
  - latin1_spanish_ci
  - latin1_swedish_ci (default)

MySQL's **latin1** is the same as the Windows **cp1252** character set. This means it is the same as the official ISO 8859-1 or IANA (Internet Assigned Numbers Authority) **latin1**, except that IANA **latin1** treats the code points between 0x80 and 0x9f as “undefined,” whereas cp1252, and therefore MySQL's **latin1**, assign characters for those positions. For example, 0x80 is the Euro sign. For the “undefined” entries in cp1252, MySQL translates 0x81 to Unicode 0x0081, 0x8d to 0x008d, 0x8f to 0x008f, 0x90 to 0x0090, and 0x9d to 0x009d.

The **latin1_swedish_ci** collation is the default that probably is used by the majority of MySQL customers. Although it is frequently said that it is based on the Swedish/Finnish collation rules, there are Swedes and Finns who disagree with this statement.

The **latin1_german1_ci** and **latin1_german2_ci** collations are based on the DIN-1 and DIN-2 standards, where DIN stands for **Deutsches Institut für Normung** (the German equivalent of ANSI). DIN-1 is called the “dictionary collation” and DIN-2 is called the “phone book collation.” For an example of the effect this has in comparisons or when doing searches, see Section 10.8.6, “Examples of the Effect of Collation”.

- **latin1_german1_ci** (dictionary) rules:

<table>
<thead>
<tr>
<th>Æ</th>
<th>A</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ö</td>
<td>O</td>
</tr>
<tr>
<td>Ū</td>
<td>U</td>
</tr>
<tr>
<td>ß</td>
<td>s</td>
</tr>
</tbody>
</table>

- **latin1_german2_ci** (phone-book) rules:

<table>
<thead>
<tr>
<th>Æ</th>
<th>AE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ö</td>
<td>OE</td>
</tr>
<tr>
<td>Ū</td>
<td>UE</td>
</tr>
<tr>
<td>ß</td>
<td>ss</td>
</tr>
</tbody>
</table>

In the **latin1_spanish_ci** collation, Ñ (n-tilde) is a separate letter between n and o.
Central European Character Sets

- **macroman** (Mac West European) collations:
  - macroman_bin
  - macroman_general_ci (default)

macroroman is deprecated; expect support for it to be removed in a subsequent MySQL release.

- **swe7** (7bit Swedish) collations:
  - swe7_bin
  - swe7_swedish_ci (default)

10.10.3 Central European Character Sets

MySQL provides some support for character sets used in the Czech Republic, Slovakia, Hungary, Romania, Slovenia, Croatia, Poland, and Serbia (Latin).

- **cp1250** (Windows Central European) collations:
  - cp1250_bin
  - cp1250_croatian_ci
  - cp1250_czech_cs
  - cp1250_general_ci (default)
  - cp1250_polish_ci

- **cp852** (DOS Central European) collations:
  - cp852_bin
  - cp852_general_ci (default)

- **keybcs2** (DOS Kamenicky Czech-Slovak) collations:
  - keybcs2_bin
  - keybcs2_general_ci (default)

- **latin2** (ISO 8859-2 Central European) collations:
  - latin2_bin
  - latin2_croatian_ci
  - latin2_czech_cs
  - latin2_general_ci (default)
  - latin2_hungarian_ci

- **macce** (Mac Central European) collations:
  - macce_bin
South European and Middle East Character Sets

- `macce_general_ci` (default)
  `macce` is deprecated; expect support for it to be removed in a subsequent MySQL release.

### 10.10.4 South European and Middle East Character Sets

South European and Middle Eastern character sets supported by MySQL include Armenian, Arabic, Georgian, Greek, Hebrew, and Turkish.

- `armscii8` (ARMSCL-8 Armenian) collations:
  - `armscii8`  
  - `armscii8_general_ci` (default)

- `cp1256` (Windows Arabic) collations:
  - `cp1256`  
  - `cp1256_general_ci` (default)

- `geostd8` (GEOSTD8 Georgian) collations:
  - `geostd8`  
  - `geostd8_general_ci` (default)

- `greek` (ISO 8859-7 Greek) collations:
  - `greek`  
  - `greek_general_ci` (default)

- `hebrew` (ISO 8859-8 Hebrew) collations:
  - `hebrew`  
  - `hebrew_general_ci` (default)

- `latin5` (ISO 8859-9 Turkish) collations:
  - `latin5`  
  - `latin5_turkish_ci` (default)

### 10.10.5 Baltic Character Sets

The Baltic character sets cover Estonian, Latvian, and Lithuanian languages.

- `cp1257` (Windows Baltic) collations:
  - `cp1257`  
  - `cp1257_general_ci` (default)

- `latin7` (ISO 8859-13 Baltic) collations:
Cyrillic Character Sets

• latin7_bin
• latin7_estonian_cs
• latin7_general_ci (default)
• latin7_general_cs

10.10.6 Cyrillic Character Sets

The Cyrillic character sets and collations are for use with Belarusian, Bulgarian, Russian, Ukrainian, and Serbian (Cyrillic) languages.

• cp1251 (Windows Cyrillic) collations:
  • cp1251_bin
  • cp1251_bulgarian_ci
  • cp1251_general_ci (default)
  • cp1251_general_cs
  • cp1251_ukrainian_ci

• cp866 (DOS Russian) collations:
  • cp866_bin
  • cp866_general_ci (default)

• koi8r (KOI8-R Relcom Russian) collations:
  • koi8r_bin
  • koi8r_general_ci (default)

• koi8u (KOI8-U Ukrainian) collations:
  • koi8u_bin
  • koi8u_general_ci (default)

10.10.7 Asian Character Sets

The Asian character sets that we support include Chinese, Japanese, Korean, and Thai. These can be complicated. For example, the Chinese sets must allow for thousands of different characters. See Section 10.10.7.1, “The cp932 Character Set”, for additional information about the cp932 and sjis character sets. See Section 10.10.7.2, “The gb18030 Character Set”, for additional information about character set support for the Chinese National Standard GB 18030.

For answers to some common questions and problems relating support for Asian character sets in MySQL, see Section A.11, “MySQL 8.2 FAQ: MySQL Chinese, Japanese, and Korean Character Sets”.

• big5 (Big5 Traditional Chinese) collations:
  • big5_bin
Asian Character Sets

- **big5_chinese_ci** (default)
- **cp932** (SJIS for Windows Japanese) collations:
  - cp932_bin
  - cp932_japanese_ci (default)
- **eucjpms** (UJIS for Windows Japanese) collations:
  - eucjpms_bin
  - eucjpms_japanese_ci (default)
- **euckr** (EUC-KR Korean) collations:
  - euckr_bin
  - euckr_korean_ci (default)
- **gb2312** (GB2312 Simplified Chinese) collations:
  - gb2312_bin
  - gb2312_chinese_ci (default)
- **gbk** (GBK Simplified Chinese) collations:
  - gbk_bin
  - gbk_chinese_ci (default)
- **gb18030** (China National Standard GB18030) collations:
  - gb18030_bin
  - gb18030_chinese_ci (default)
  - gb18030_unicode_520_ci
- **sjis** (Shift-JIS Japanese) collations:
  - sjis_bin
  - sjis_japanese_ci (default)
- **tis620** (TIS620 Thai) collations:
  - tis620_bin
  - tis620_thai_ci (default)
- **ujis** (EUC-JP Japanese) collations:
  - ujis_bin
  - ujis_japanese_ci (default)

The **big5_chinese_ci** collation sorts on number of strokes.
10.10.7.1 The cp932 Character Set

Why is cp932 needed?

In MySQL, the sjis character set corresponds to the Shift_JIS character set defined by IANA, which supports JIS X0201 and JIS X0208 characters. (See http://www.iana.org/assignments/character-sets.)

However, the meaning of “SHIFT JIS” as a descriptive term has become very vague and it often includes the extensions to Shift_JIS that are defined by various vendors.

For example, “SHIFT JIS” used in Japanese Windows environments is a Microsoft extension of Shift_JIS and its exact name is Microsoft Windows Codepage : 932 or cp932. In addition to the characters supported by Shift_JIS, cp932 supports extension characters such as NEC special characters, NEC selected—IBM extended characters, and IBM selected characters.

Many Japanese users have experienced problems using these extension characters. These problems stem from the following factors:

• MySQL automatically converts character sets.
• Character sets are converted using Unicode (ucs2).
• The sjis character set does not support the conversion of these extension characters.
• There are several conversion rules from so-called “SHIFT JIS” to Unicode, and some characters are converted to Unicode differently depending on the conversion rule. MySQL supports only one of these rules (described later).

The MySQL cp932 character set is designed to solve these problems.

Because MySQL supports character set conversion, it is important to separate IANA Shift_JIS and cp932 into two different character sets because they provide different conversion rules.

How does cp932 differ from sjis?

The cp932 character set differs from sjis in the following ways:

• cp932 supports NEC special characters, NEC selected—IBM extended characters, and IBM selected characters.
• Some cp932 characters have two different code points, both of which convert to the same Unicode code point. When converting from Unicode back to cp932, one of the code points must be selected. For this “round trip conversion,” the rule recommended by Microsoft is used. (See http://support.microsoft.com/kb/170559/EN-US/.)

The conversion rule works like this:

• If the character is in both JIS X 0208 and NEC special characters, use the code point of JIS X 0208.
• If the character is in both NEC special characters and IBM selected characters, use the code point of NEC special characters.
• If the character is in both IBM selected characters and NEC selected—IBM extended characters, use the code point of IBM extended characters.

The table shown at https://msdn.microsoft.com/en-us/goglobal/cc305152.aspx provides information about the Unicode values of cp932 characters. For cp932 table entries with characters under which a four-digit number appears, the number represents the corresponding Unicode (ucs2) encoding. For
Asian Character Sets

table entries with an underlined two-digit value appears, there is a range of \textit{cp932} character values that begin with those two digits. Clicking such a table entry takes you to a page that displays the Unicode value for each of the \textit{cp932} characters that begin with those digits.

The following links are of special interest. They correspond to the encodings for the following sets of characters:

- NEC special characters (lead byte \texttt{0x87}):
  
  \url{https://msdn.microsoft.com/en-us/goglobal/gg674964}

- NEC selected—IBM extended characters (lead byte \texttt{0xED} and \texttt{0xEE}):
  
  \url{https://msdn.microsoft.com/en-us/goglobal/gg671837}
  \url{https://msdn.microsoft.com/en-us/goglobal/gg671838}

- IBM selected characters (lead byte \texttt{0xFA}, \texttt{0xFB}, \texttt{0xFC}):
  
  \url{https://msdn.microsoft.com/en-us/goglobal/gg671839}
  \url{https://msdn.microsoft.com/en-us/goglobal/gg671840}
  \url{https://msdn.microsoft.com/en-us/goglobal/gg671841}

- \textit{cp932} supports conversion of user-defined characters in combination with \textit{eucjps}, and solves the problems with \textit{sjis/ujis} conversion. For details, please refer to \url{http://www.sljfaq.org/afaq/encodings.html}.

For some characters, conversion to and from \textit{ucs2} is different for \textit{sjis} and \textit{cp932}. The following tables illustrate these differences.

Conversion to \textit{ucs2}:

<table>
<thead>
<tr>
<th>\textit{sjis/cp932} Value</th>
<th>\textit{sjis} -&gt; \textit{ucs2} Conversion</th>
<th>\textit{cp932} -&gt; \textit{ucs2} Conversion</th>

Users of any Japanese character sets should be aware that using --character-set-client-handshake (or --skip-character-set-client-handshake) has an important effect. See Section 5.1.7, "Server Command Options".

10.10.7.2 The gb18030 Character Set

In MySQL, the \texttt{gb18030} character set corresponds to the “Chinese National Standard GB 18030-2005: Information technology—Chinese coded character set”, which is the official character set of the People’s Republic of China (PRC).

Characteristics of the MySQL gb18030 Character Set

- Supports all code points defined by the GB 18030-2005 standard. Unassigned code points in the ranges (GB+8431A439, GB+90308130) and (GB+E3329A36, GB+EF39EF39) are treated as '?' (0x3F). Conversion of unassigned code points return '?'.
- Supports UPPER and LOWER conversion for all GB18030 code points. Case folding defined by Unicode is also supported (based on \texttt{CaseFolding-6.3.0.txt}).
- Supports Conversion of data to and from other character sets.
- Supports SQL statements such as \texttt{SET NAMES}.
- Supports comparison between \texttt{gb18030} strings, and between \texttt{gb18030} strings and strings of other character sets. There is a conversion if strings have different character sets. Comparisons that include or ignore trailing spaces are also supported.
- The private use area (U+E000, U+F8FF) in Unicode is mapped to \texttt{gb18030}.
- There is no mapping between (U+D800, U+DFFF) and GB18030. Attempted conversion of code points in this range returns '?'.
- If an incoming sequence is illegal, an error or warning is returned. If an illegal sequence is used in \texttt{CONVERT()}, an error is returned. Otherwise, a warning is returned.
- For consistency with \texttt{utf8mb3} and \texttt{utf8mb4}, UPPER is not supported for ligatures.
- Searches for ligatures also match uppercase ligatures when using the \texttt{gb18030_unicode_520_ci} collation.
• If a character has more than one uppercase character, the chosen uppercase character is the one
  whose lowercase is the character itself.

• The minimum multibyte length is 1 and the maximum is 4. The character set determines the length of a
  sequence using the first 1 or 2 bytes.

**Supported Collations**

- `gb18030_bin`: A binary collation.

- `gb18030_chinese_ci`: The default collation, which supports Pinyin. Sorting of non-Chinese characters
  is based on the order of the original sort key. The original sort key is `GB(UPPER(ch))` if `UPPER(ch)`
  exists. Otherwise, the original sort key is `GB(ch)`. Chinese characters are sorted according to the Pinyin
  collation defined in the Unicode Common Locale Data Repository (CLDR 24). Non-Chinese characters
  are sorted before Chinese characters with the exception of `GB+FE39FE39`, which is the code point
  maximum.

- `gb18030_unicode_520_ci`: A Unicode collation. Use this collation if you need to ensure that ligatures
  are sorted correctly.

### 10.10.8 The Binary Character Set

The **binary** character set is the character set for binary strings, which are sequences of bytes. The
**binary** character set has one collation, also named **binary**. Comparison and sorting are based on
numeric byte values, rather than on numeric character code values (which for multibyte characters differ
from numeric byte values). For information about the differences between the **binary** collation of the
**binary** character set and the **_bin** collations of nonbinary character sets, see Section 10.8.5, “The binary
Collation Compared to **_bin Collations**”.

For the **binary** character set, the concepts of lettercase and accent equivalence do not apply:

- For single-byte characters stored as binary strings, character and byte boundaries are the same, so
  lettercase and accent differences are significant in comparisons. That is, the **binary** collation is case-
  sensitive and accent-sensitive.

```
mysql> SET NAMES 'binary';

mysql> SELECT CHARSET('abc'), COLLATION('abc');
+----------------+------------------+
| CHARSET('abc') | COLLATION('abc') |
+----------------+------------------+
| binary         | binary           |
+----------------+------------------+
mysql>
```

- For multibyte characters stored as binary strings, character and byte boundaries differ. Character
  boundaries are lost, so comparisons that depend on them are not meaningful.

To perform lettercase conversion of a binary string, first convert it to a nonbinary string using a character
set appropriate for the data stored in the string:

```
mysql> SET @str = BINARY 'New York';
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING utf8mb4));
+-------------+------------------------------------+
<table>
<thead>
<tr>
<th>LOWER(@str)</th>
<th>LOWER(CONVERT(@str USING utf8mb4))</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0</td>
</tr>
</tbody>
</table>
+-------------+------------------------------------+
```
### Restrictions on Character Sets

<table>
<thead>
<tr>
<th>New York</th>
<th>new york</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

To convert a string expression to a binary string, these constructs are equivalent:

- `BINARY expr`
- `CAST(expr AS BINARY)`
- `CONVERT(expr USING BINARY)`

If a value is a character string literal, the `_binary` introducer may be used to designate it as a binary string. For example:

```sql
_binary 'a'
```

The `_binary` introducer is permitted for hexadecimal literals and bit-value literals as well, but unnecessary; such literals are binary strings by default.

For more information about introducers, see Section 10.3.8, “Character Set Introducers”.

---

**Note**

Within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

## 10.11 Restrictions on Character Sets

- Identifiers are stored in `mysql` database tables (`user`, `db`, and so forth) using `utf8mb3`, but identifiers can contain only characters in the Basic Multilingual Plane (BMP). Supplementary characters are not permitted in identifiers.

- The `ucs2`, `utf16`, `utf16le`, and `utf32` character sets have the following restrictions:
  - None of them can be used as the client character set. See Impermissible Client Character Sets.
  - It is currently not possible to use `LOAD DATA` to load data files that use these character sets.
  - `FULLTEXT` indexes cannot be created on a column that uses any of these character sets. However, you can perform `IN BOOLEAN MODE` searches on the column without an index.
  - The `REGEXP` and `RLIKE` operators work in byte-wise fashion, so they are not multibyte safe and may produce unexpected results with multibyte character sets. In addition, these operators compare characters by their byte values and accented characters may not compare as equal even if a given collation treats them as equal.

## 10.12 Setting the Error Message Language

By default, `mysqld` produces error messages in English, but they can be displayed instead in any of several other languages: Czech, Danish, Dutch, Estonian, French, German, Greek, Hungarian, Italian, Japanese, Korean, Norwegian, Norwegian-ny, Polish, Portuguese, Romanian, Russian, Slovak, Spanish, or Swedish. This applies to messages the server writes to the error log and sends to clients.

To select the language in which the server writes error messages, follow the instructions in this section. For information about changing the character set for error messages (rather than the language), see Section 10.6, “Error Message Character Set”. For general information about configuring error logging, see Section 5.4.2, “The Error Log”.
Adding a Character Set

The server searches for the error message file using these rules:

- It looks for the file in a directory constructed from two system variable values, `lc_messages_dir` and `lc_messages`, with the latter converted to a language name. Suppose that you start the server using this command:

  ```
  mysqld --lc_messages_dir=/usr/share/mysql --lc_messages=fr_FR
  ```

  In this case, `mysqld` maps the locale `fr_FR` to the language `french` and looks for the error file in the `conf/directory`.

- By default, the language files are located in the `share/mysql/LANGUAGE` directory under the MySQL base directory.

- If the message file cannot be found in the directory constructed as just described, the server ignores the `lc_messages` value and uses only the `lc_messages_dir` value as the location in which to look.

- If the server cannot find the configured message file, it writes a message to the error log to indicate the problem and defaults to built-in English messages.

The `lc_messages_dir` system variable can be set only at server startup and has only a global read-only value at runtime. `lc_messages` can be set at server startup and has global and session values that can be modified at runtime. Thus, the error message language can be changed while the server is running, and each client can have its own error message language by setting its session `lc_messages` value to the desired locale name. For example, if the server is using the `fr_FR` locale for error messages, a client can execute this statement to receive error messages in English:

  ```
  SET lc_messages = 'en_US';
  ```

10.13 Adding a Character Set

This section discusses the procedure for adding a character set to MySQL. The proper procedure depends on whether the character set is simple or complex:

- If the character set does not need special string collating routines for sorting and does not need multibyte character support, it is simple.

- If the character set needs either of those features, it is complex.

For example, `greek` and `swe7` are simple character sets, whereas `big5` and `czech` are complex character sets.

To use the following instructions, you must have a MySQL source distribution. In the instructions, `MYSET` represents the name of the character set that you want to add.

1. Add a `<charset>` element for `MYSET` to the `sql/share/charsets/Index.xml` file. Use the existing contents in the file as a guide to adding new contents. A partial listing for the `latin1` `<charset>` element follows:

   ```
   <charset name="latin1">
   <family>Western</family>
   <description>cp1252 West European</description>
   ...
   <collation name="latin1_swedish_ci" id="8" order="Finnish, Swedish">
     <flag>primary</flag>
     <flag>compiled</flag>
   </collation>
   <collation name="latin1_danish_ci" id="15" order="Danish"/>
   ...
   ```
Adding a Character Set

The `<charset>` element must list all the collations for the character set. These must include at least a binary collation and a default (primary) collation. The default collation is often named using a suffix of `general_ci` (general, case-insensitive). It is possible for the binary collation to be the default collation, but usually they are different. The default collation should have a `primary` flag. The binary collation should have a `binary` flag.

You must assign a unique ID number to each collation. The range of IDs from 1024 to 2047 is reserved for user-defined collations. To find the maximum of the currently used collation IDs, use this query:

```
SELECT MAX(ID) FROM INFORMATION_SCHEMA.COLLATIONS;
```

2. This step depends on whether you are adding a simple or complex character set. A simple character set requires only a configuration file, whereas a complex character set requires C source file that defines collation functions, multibyte functions, or both.

For a simple character set, create a configuration file, `MYSET.xml`, that describes the character set properties. Create this file in the `sql/share/charsets` directory. You can use a copy of `latin1.xml` as the basis for this file. The syntax for the file is very simple:

- Comments are written as ordinary XML comments (`<!-- text -->`).
- Words within `<map>` array elements are separated by arbitrary amounts of whitespace.
- Each word within `<map>` array elements must be a number in hexadecimal format.
- The `<map>` array element for the `<ctype>` element has 257 words. The other `<map>` array elements after that have 256 words. See Section 10.13.1, “Character Definition Arrays”.
- For each collation listed in the `<charset>` element for the character set in `Index.xml`, `MYSET.xml` must contain a `<collation>` element that defines the character ordering.

For a complex character set, create a C source file that describes the character set properties and defines the support routines necessary to properly perform operations on the character set:

- Create the file `ctype-MYSET.c` in the `strings` directory. Look at one of the existing `ctype-*.c` files (such as `ctype-big5.c`) to see what needs to be defined. The arrays in your file must have names like `ctype_MYSET`, `to_lower_MYSET`, and so on. These correspond to the arrays for a simple character set. See Section 10.13.1, “Character Definition Arrays”.
- For each `<collation>` element listed in the `<charset>` element for the character set in `Index.xml`, the `ctype-MYSET.c` file must provide an implementation of the collation.
- If the character set requires string collating functions, see Section 10.13.2, “String Collating Support for Complex Character Sets”.
- If the character set requires multibyte character support, see Section 10.13.3, “Multi-Byte Character Support for Complex Character Sets”.

3. Modify the configuration information. Use the existing configuration information as a guide to adding information for `MYSYS`. The example here assumes that the character set has default and binary collations, but more lines are needed if `MYSET` has additional collations.
a. Edit `mysys/charset-def.c`, and “register” the collations for the new character set.

Add these lines to the “declaration” section:

```c
#ifdef HAVE_CHARSET_MYSET
extern CHARSET_INFO my_charset_MYSET_general_ci;
extern CHARSET_INFO my_charset_MYSET_bin;
#endif
```

Add these lines to the “registration” section:

```c
#ifdef HAVE_CHARSET_MYSET
    add_compiled_collation(&my_charset_MYSET_general_ci);
    add_compiled_collation(&my_charset_MYSET_bin);
#endif
```

b. If the character set uses `ctype-MYSET.c`, edit `strings/CMakeLists.txt` and add `ctype-MYSET.c` to the definition of the `STRINGS_SOURCES` variable.

c. Edit `cmake/character_sets.cmake`:

i. Add `MYSET` to the value of `with CHARSETS_AVAILABLE` in alphabetic order.

ii. Add `MYSET` to the value of `CHARSETS_COMPLEX` in alphabetic order. This is needed even for simple character sets, so that `CMake` can recognize `-DDEFAULT_CHARSET=MYSET`.

4. Reconfigure, recompile, and test.

### 10.13.1 Character Definition Arrays

Each simple character set has a configuration file located in the `sql/share/charsets` directory. For a character set named `MYSYS`, the file is named `MYSET.xml`. It uses `<map>` array elements to list character set properties. `<map>` elements appear within these elements:

- `<ctype>` defines attributes for each character.
- `<lower>` and `<upper>` list the lowercase and uppercase characters.
- `<unicode>` maps 8-bit character values to Unicode values.
- `<collation>` elements indicate character ordering for comparison and sorting, one element per collation. Binary collations need no `<map>` element because the character codes themselves provide the ordering.

For a complex character set as implemented in a `ctype-MYSET.c` file in the `strings` directory, there are corresponding arrays: `ctype_MYSET[]`, `to_lower_MYSET[]`, and so forth. Not every complex character set has all of the arrays. See also the existing `ctype-*` files for examples. See the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

Most of the arrays are indexed by character value and have 256 elements. The `<ctype>` array is indexed by character value + 1 and has 257 elements. This is a legacy convention for handling `EOF`.

`<ctype>` array elements are bit values. Each element describes the attributes of a single character in the character set. Each attribute is associated with a bitmask, as defined in `include/m_ctype.h`:

```c
#define _MY_U   01      /* Upper case */
#define _MY_L   02      /* Lower case */
#define _MY_NMR 04      /* Numeral (digit) */
```
String Collating Support for Complex Character Sets

```c
#define _MY_SPC 010 /* Spacing character */
#define _MY_PNT 020 /* Punctuation */
#define _MY_CTR 040 /* Control character */
#define _MY_B 0100 /* Blank */
#define _MY_X 0200 /* hexadecimal digit */
```

The `<ctype>` value for a given character should be the union of the applicable bitmask values that describe the character. For example, 'A' is an uppercase character (_MY_U) as well as a hexadecimal digit (_MY_X), so its `ctype` value should be defined like this:

```c
ctype['A'+1] = _MY_U | _MY_X = 01 | 0200 = 0201
```

The bitmask values in `m_ctype.h` are octal values, but the elements of the `<ctype>` array in `MYSET.xml` should be written as hexadecimal values.

The `<lower>` and `<upper>` arrays hold the lowercase and uppercase characters corresponding to each member of the character set. For example:

```c
lower['A'] should contain 'a'
upper['a'] should contain 'A'
```

Each `<collation>` array indicates how characters should be ordered for comparison and sorting purposes. MySQL sorts characters based on the values of this information. In some cases, this is the same as the `<upper>` array, which means that sorting is case-insensitive. For more complicated sorting rules (for complex character sets), see the discussion of string collating in Section 10.13.2, “String Collating Support for Complex Character Sets”.

### 10.13.2 String Collating Support for Complex Character Sets

For a simple character set named `MYSET`, sorting rules are specified in the `MYSET.xml` configuration file using `<map>` array elements within `<collation>` elements. If the sorting rules for your language are too complex to be handled with simple arrays, you must define string collating functions in the `ctype-MYSET.c` source file in the `strings` directory.

The existing character sets provide the best documentation and examples to show how these functions are implemented. Look at the `ctype-* .c` files in the `strings` directory, such as the files for the `big5`, `czech`, `gbk`, `sjis`, and `tis160` character sets. Take a look at the `MY_COLLATION_HANDLER` structures to see how they are used. See also the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

### 10.13.3 Multi-Byte Character Support for Complex Character Sets

If you want to add support for a new character set named `MYSET` that includes multibyte characters, you must use multibyte character functions in the `ctype-MYSET.c` source file in the `strings` directory.

The existing character sets provide the best documentation and examples to show how these functions are implemented. Look at the `ctype-* .c` files in the `strings` directory, such as the files for the `euc_kr`, `gb2312`, `gbk`, `sjis`, and `ujis` character sets. Take a look at the `MY_CHARSET_HANDLER` structures to see how they are used. See also the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

### 10.14 Adding a Collation to a Character Set

**Warning**

User-defined collations are deprecated; you should expect support for them to be removed in a future version of MySQL. The MySQL 8.2 server issues a warning for
Adding a Collation to a Character Set

A collation is a set of rules that defines how to compare and sort character strings. Each collation in MySQL belongs to a single character set. Every character set has at least one collation, and most have two or more collations.

A collation orders characters based on weights. Each character in a character set maps to a weight. Characters with equal weights compare as equal, and characters with unequal weights compare according to the relative magnitude of their weights.

The \texttt{WEIGHT\_STRING()} function can be used to see the weights for the characters in a string. The value that it returns to indicate weights is a binary string, so it is convenient to use \texttt{HEX(WEIGHT\_STRING(str))} to display the weights in printable form. The following example shows that weights do not differ for lettercase for the letters in \texttt{'AaBb'} if it is a nonbinary case-insensitive string, but do differ if it is a binary string:

\begin{verbatim}
mysql> SELECT HEX(WEIGHT\_STRING('AaBb' COLLATE latin1\_swedish\_ci));
+------------------------------------------------------+
| HEX(WEIGHT\_STRING('AaBb' COLLATE latin1\_swedish\_ci)) |
| 41414242                                              |
+------------------------------------------------------+
mysql> SELECT HEX(WEIGHT\_STRING(BINARY 'AaBb'));
+-----------------------------------+
| HEX(WEIGHT\_STRING(BINARY 'AaBb')) |
| 41614262                          |
+-----------------------------------+
\end{verbatim}

MySQL supports several collation implementations, as discussed in Section 10.14.1, “Collation Implementation Types”. Some of these can be added to MySQL without recompiling:

- Simple collations for 8-bit character sets.
- UCA-based collations for Unicode character sets.
- Binary \texttt{(xxx\_bin)} collations.

The following sections describe how to add user-defined collations of the first two types to existing character sets. All existing character sets already have a binary collation, so there is no need here to describe how to add one.

\textbf{Warning}
Redefining built-in collations is not supported and may result in unexpected server behavior.

Summary of the procedure for adding a new user-defined collation:

1. Choose a collation ID.
2. Add configuration information that names the collation and describes the character-ordering rules.
3. Restart the server.
4. Verify that the server recognizes the collation.
The instructions here cover only user-defined collations that can be added without recompiling MySQL. To add a collation that does require recompiling (as implemented by means of functions in a C source file), use the instructions in Section 10.13, “Adding a Character Set”. However, instead of adding all the information required for a complete character set, just modify the appropriate files for an existing character set. That is, based on what is already present for the character set’s current collations, add data structures, functions, and configuration information for the new collation.

**Note**

If you modify an existing user-defined collation, that may affect the ordering of rows for indexes on columns that use the collation. In this case, rebuild any such indexes to avoid problems such as incorrect query results. See Section 2.10.13, “Rebuilding or Repairing Tables or Indexes”.

### Additional Resources

- Example showing how to add a collation for full-text searches: Section 12.9.7, “Adding a User-Defined Collation for Full-Text Indexing”
- The Unicode Collation Algorithm (UCA) specification: [http://www.unicode.org/reports/tr10/](http://www.unicode.org/reports/tr10/)
- The Locale Data Markup Language (LDML) specification: [http://www.unicode.org/reports/tr35/](http://www.unicode.org/reports/tr35/)

#### 10.14.1 Collation Implementation Types

MySQL implements several types of collations:

**Simple collations for 8-bit character sets**

This kind of collation is implemented using an array of 256 weights that defines a one-to-one mapping from character codes to weights. `latin1_swedish_ci` is an example. It is a case-insensitive collation, so the uppercase and lowercase versions of a character have the same weights and they compare as equal.

```
mysql> SET NAMES 'latin1' COLLATE 'latin1_swedish_ci';
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT HEX(WEIGHT_STRING('a')), HEX(WEIGHT_STRING('A'));
+-------------------------+-------------------------+
| HEX(WEIGHT_STRING('a')) | HEX(WEIGHT_STRING('A')) |
+-------------------------+-------------------------+
| 41                      | 41                      |
+-------------------------+-------------------------+
1 row in set (0.01 sec)

mysql> SELECT 'a' = 'A';
+-----------+
| 'a' = 'A' |
+-----------+
|         1 |
+-----------+
1 row in set (0.12 sec)
```

For implementation instructions, see Section 10.14.3, “Adding a Simple Collation to an 8-Bit Character Set”.

**Complex collations for 8-bit character sets**

This kind of collation is implemented using functions in a C source file that define how to order characters, as described in Section 10.13, “Adding a Character Set”.
Collations for non-Unicode multibyte character sets

For this type of collation, 8-bit (single-byte) and multibyte characters are handled differently. For 8-bit characters, character codes map to weights in case-insensitive fashion. (For example, the single-byte characters 'a' and 'A' both have a weight of 0x41.) For multibyte characters, there are two types of relationship between character codes and weights:

- Weights equal character codes. *sjis_japanese_ci* is an example of this kind of collation. The multibyte character ‘ぢ’ has a character code of 0x82C0, and the weight is also 0x82C0.

  ```
  mysql> CREATE TABLE t1
            (c1 VARCHAR(2) CHARACTER SET sjis COLLATE sjis_japanese_ci);
  Query OK, 0 rows affected (0.01 sec)
  mysql> INSERT INTO t1 VALUES ('a'), ('A'), (0x82C0);
  Query OK, 3 rows affected (0.00 sec)
  Records: 3  Duplicates: 0  Warnings: 0
  mysql> SELECT c1, HEX(c1), HEX(WEIGHT_STRING(c1)) FROM t1;
  +------+---------+------------------------+
  | c1   | HEX(c1) | HEX(WEIGHT_STRING(c1)) |
  +------+---------+------------------------+
  | a    | 61      | 41                     |
  | A    | 41      | 41                     |
  | ぢ    | 82C0    | 82C0                   |
  +------+---------+------------------------+
  3 rows in set (0.00 sec)
  ```

- Character codes map one-to-one to weights, but a code is not necessarily equal to the weight. *gbk_chinese_ci* is an example of this kind of collation. The multibyte character ‘膰’ has a character code of 0x81B0 but a weight of 0xC286.

  ```
  mysql> CREATE TABLE t1
            (c1 VARCHAR(2) CHARACTER SET gbk COLLATE gbk_chinese_ci);
  Query OK, 0 rows affected (0.33 sec)
  mysql> INSERT INTO t1 VALUES ('a'), ('A'), (0x81B0);
  Query OK, 3 rows affected (0.00 sec)
  Records: 3  Duplicates: 0  Warnings: 0
  mysql> SELECT c1, HEX(c1), HEX(WEIGHT_STRING(c1)) FROM t1;
  +------+---------+------------------------+
  | c1   | HEX(c1) | HEX(WEIGHT_STRING(c1)) |
  +------+---------+------------------------+
  | a    | 61      | 41                     |
  | A    | 41      | 41                     |
  | 膰    | 81B0    | C286                   |
  +------+---------+------------------------+
  3 rows in set (0.00 sec)
  ```

For implementation instructions, see Section 10.13, “Adding a Character Set”.

Collations for Unicode multibyte character sets

Some of these collations are based on the Unicode Collation Algorithm (UCA), others are not.

Non-UCA collations have a one-to-one mapping from character code to weight. In MySQL, such collations are case-insensitive and accent-insensitive. *utf8mb4_general_ci* is an example: 'a', 'A', 'À', and 'á' each have different character codes but all have a weight of 0x0041 and compare as equal.
Collation Implementation Types

MySQL>
CREATE TABLE t1
(c1 CHAR(1) CHARACTER SET UTF8MB4 COLLATE utf8mb4_general_ci);
Query OK, 0 rows affected (0.01 sec)

mysql>
INSERT INTO t1 VALUES ('a'), ('A'), ('À'), ('á');
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql>
SELECT c1, HEX(c1), HEX(WEIGHT_STRING(c1)) FROM t1;
+------+---------+------------------------+
| c1   | HEX(c1) | HEX(WEIGHT_STRING(c1)) |
| a    | 61      | 0041                   |
| A    | 41      | 0041                   |
| À    | C380    | 0041                   |
| á    | C3A1    | 0041                   |
+------+---------+------------------------+
4 rows in set (0.00 sec)

UCA-based collations in MySQL have these properties:

- If a character has weights, each weight uses 2 bytes (16 bits).
- A character may have zero weights (or an empty weight). In this case, the character is ignorable. Example: "U+0000 NULL" does not have a weight and is ignorable.
- A character may have one weight. Example: 'a' has a weight of 0x0E33.

mysql>
SET NAMES 'utf8mb4' COLLATE 'utf8mb4_unicode_ci';
Query OK, 0 rows affected (0.05 sec)

mysql>
SELECT HEX('a'), HEX(WEIGHT_STRING('a'));
+----------+-------------------------+
| HEX('a') | HEX(WEIGHT_STRING('a')) |
| 61       | 0E33                    |
+----------+-------------------------+
1 row in set (0.02 sec)

- A character may have many weights. This is an expansion. Example: The German letter 'ß' (SZ ligature, or SHARP S) has a weight of 0x0FEA0FEA.

mysql>
SET NAMES 'utf8mb4' COLLATE 'utf8mb4_unicode_ci';
Query OK, 0 rows affected (0.11 sec)

mysql>
SELECT HEX('ß'), HEX(WEIGHT_STRING('ß'));
+-----------+--------------------------+
| HEX('ß')  | HEX(WEIGHT_STRING('ß'))  |
| C39F      | 0FEA0FEA                 |
+-----------+--------------------------+
1 row in set (0.00 sec)

- Many characters may have one weight. This is a contraction. Example: 'ch' is a single letter in Czech and has a weight of 0x0EE2.

mysql>
SET NAMES 'utf8mb4' COLLATE 'utf8mb4_czech_ci';
Query OK, 0 rows affected (0.09 sec)

mysql>
SELECT HEX('ch'), HEX(WEIGHT_STRING('ch'));
+-----------+--------------------------+
| HEX('ch') | HEX(WEIGHT_STRING('ch')) |
| 6368      | 0EE2                     |
+-----------+--------------------------+
Choosing a Collation ID

A many-characters-to-many-weights mapping is also possible (this is contraction with expansion), but is not supported by MySQL.

For implementation instructions, for a non-UCA collation, see Section 10.13, “Adding a Character Set”. For a UCA collation, see Section 10.14.4, “Adding a UCA Collation to a Unicode Character Set”.

Miscellaneous collations

There are also a few collations that do not fall into any of the previous categories.

10.14.2 Choosing a Collation ID

Each collation must have a unique ID. To add a collation, you must choose an ID value that is not currently used. MySQL supports two-byte collation IDs. The range of IDs from 1024 to 2047 is reserved for user-defined collations.

The collation ID that you choose appears in these contexts:

- The ID column of the Information Schema COLLATIONS table.
- The Id column of SHOW COLLATION output.
- The charsetnr member of the MYSQL_FIELD C API data structure.
- The number member of the MY_CHARSET_INFO data structure returned by the mysql_get_character_set_info() C API function.

To determine the largest currently used ID, issue the following statement:

```
mysql> SELECT MAX(ID) FROM INFORMATION_SCHEMA.COLLATIONS;
```

```
+---------+
| MAX(ID) |
+---------+
|     247 |
```

To display a list of all currently used IDs, issue this statement:

```
mysql> SELECT ID FROM INFORMATION_SCHEMA.COLLATIONS ORDER BY ID;
```

```
+-----+
| ID  |
+-----+
|   1 |
|   2 |
| ... |
|  52 |
|  53 |
|  57 |
|  58 |
| ... |
|  98 |
|  99 |
| 128 |
| 129 |
| ... |
| 247 |
```

2132
Adding a Simple Collation to an 8-Bit Character Set

### Warning
Before upgrading, you should save the configuration files that you change. If you upgrade in place, the process replaces the modified files.

### 10.14.3 Adding a Simple Collation to an 8-Bit Character Set

This section describes how to add a simple collation for an 8-bit character set by writing the `<collation>` elements associated with a `<charset>` character set description in the MySQL Index.xml file. The procedure described here does not require recompiling MySQL. The example adds a collation named `latin1_test_ci` to the `latin1` character set.

1. Choose a collation ID, as shown in Section 10.14.2, “Choosing a Collation ID”. The following steps use an ID of 1024.

2. Modify the `Index.xml` and `latin1.xml` configuration files. These files are located in the directory named by the `character_sets_dir` system variable. You can check the variable value as follows, although the path name might be different on your system:

   ```
   mysql> SHOW VARIABLES LIKE 'character_sets_dir';
   +--------------------+-----------------------------------------+
   | Variable_name      | Value                                   |
   +--------------------+-----------------------------------------+
   | character_sets_dir | /user/local/mysql/share/mysql/charsets/  |
   +--------------------+-----------------------------------------+
   ```

3. Choose a name for the collation and list it in the `Index.xml` file. Find the `<charset>` element for the character set to which the collation is being added, and add a `<collation>` element that indicates the collation name and ID, to associate the name with the ID. For example:

   ```
   <charset name="latin1">
     ...
     <collation name="latin1_test_ci" id="1024"/>
     ...
   </charset>
   ```

4. In the `latin1.xml` configuration file, add a `<collation>` element that names the collation and that contains a `<map>` element that defines a character code-to-weight mapping table for character codes 0 to 255. Each value within the `<map>` element must be a number in hexadecimal format.

   ```
   <collation name="latin1_test_ci">
     <map>
       00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F  
       10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F  
       20 21 22 23 24 25 26 27 28 29 2A 2B 2C 2D 2E 2F  
       30 31 32 33 34 35 36 37 38 39 3A 3B 3C 3D 3E 3F  
       40 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F  
       50 51 52 53 54 55 56 57 58 59 5A 5B 5C 5D 5E 5F  
       60 61 62 63 64 65 66 67 68 69 6A 6B 6C 6D 6E 6F  
       70 71 72 73 74 75 76 77 78 79 7A 7B 7C 7D 7E 7F  
       80 81 82 83 84 85 86 87 88 89 8A 8B 8C 8D 8E 8F  
       90 91 92 93 94 95 96 97 98 99 9A 9B 9C 9D 9E 9F  
       A0 A1 A2 A3 A4 A5 A6 A7 A8 A9 AA AB AC AD AE AF  
       B0 B1 B2 B3 B4 B5 B6 B7 B8 B9 BA BB BC BD BE BF  
       C0 C1 C2 C3 C4 C5 C6 C7 C8 C9 CA CB CC CD CE CF  
       D0 D1 D2 D3 D4 D5 D6 D7 D8 D9 DA DB DC DD DE DF  
       E0 E1 E2 E3 E4 E5 E6 E7 E8 E9 EA EB EC ED EE EF  
       F0 F1 F2 F3 F4 F5 F6 F7 F8 F9 FA FB FC FD FE FF  
     </map>
   </collation>
   ```

5. Restart the server and use this statement to verify that the collation is present:
10.14.4 Adding a UCA Collation to a Unicode Character Set

This section describes how to add a UCA collation for a Unicode character set by writing the `<collation>` element within a `<charset>` character set description in the MySQL Index.xml file. The procedure described here does not require recompiling MySQL. It uses a subset of the Locale Data Markup Language (LDML) specification, which is available at http://www.unicode.org/reports/tr35/. With this method, you need not define the entire collation. Instead, you begin with an existing “base” collation and describe the new collation in terms of how it differs from the base collation. The following table lists the base collations of the Unicode character sets for which UCA collations can be defined. It is not possible to create user-defined UCA collations for `utf16le`; there is no `utf16le_unicode_ci` collation that would serve as the basis for such collations.

### Table 10.4 MySQL Character Sets Available for User-Defined UCA Collations

<table>
<thead>
<tr>
<th>Character Set</th>
<th>Base Collation</th>
</tr>
</thead>
<tbody>
<tr>
<td>utf8mb4</td>
<td>utf8mb4_unicode_ci</td>
</tr>
<tr>
<td>ucs2</td>
<td>ucs2_unicode_ci</td>
</tr>
<tr>
<td>utf16</td>
<td>utf16_unicode_ci</td>
</tr>
<tr>
<td>utf32</td>
<td>utf32_unicode_ci</td>
</tr>
</tbody>
</table>

The following sections show how to add a collation that is defined using LDML syntax, and provide a summary of LDML rules supported in MySQL.

10.14.4.1 Defining a UCA Collation Using LDML Syntax

To add a UCA collation for a Unicode character set without recompiling MySQL, use the following procedure. If you are unfamiliar with the LDML rules used to describe the collation's sort characteristics, see Section 10.14.4.2, “LDML Syntax Supported in MySQL”.

The example adds a collation named `utf8mb4_phone_ci` to the `utf8mb4` character set. The collation is designed for a scenario involving a Web application for which users post their names and phone numbers. Phone numbers can be given in very different formats:

+7-1234567
+7 1234567
+7 (12) 345 67
+71234567

The problem raised by dealing with these kinds of values is that the varying permissible formats make searching for a specific phone number very difficult. The solution is to define a new collation that reorders punctuation characters, making them ignorable.

1. Choose a collation ID, as shown in Section 10.14.2, “Choosing a Collation ID”. The following steps use an ID of 1029.

2. To modify the Index.xml configuration file. This file is located in the directory named by the `character_sets_dir` system variable. You can check the variable value as follows, although the path name might be different on your system:
Adding a UCA Collation to a Unicode Character Set

mysql> SHOW VARIABLES LIKE 'character_sets_dir';
+--------------------+-----------------------------------------+
| Variable_name      | Value                                   |
+--------------------+-----------------------------------------+
| character_sets_dir | /user/local/mysql/share/mysql/charsets/ |
+--------------------+-----------------------------------------+

3. Choose a name for the collation and list it in the Index.xml file. In addition, you'll need to provide the collation ordering rules. Find the <charset> element for the character set to which the collation is being added, and add a <collation> element that indicates the collation name and ID, to associate the name with the ID. Within the <collation> element, provide a <rules> element containing the ordering rules:

```xml
<charset name="utf8mb4">
  ...
  <collation name="utf8mb4_phone_ci" id="1029">
    <rules>
      <reset>\u0000</reset>
      <i>\u0020</i> <!-- space -->
      <i>\u0028</i> <!-- left parenthesis -->
      <i>\u0029</i> <!-- right parenthesis -->
      <i>\u002b</i> <!-- plus -->
      <i>\u002d</i> <!-- hyphen -->
    </rules>
  </collation>
  ...
</charset>
```

4. If you want a similar collation for other Unicode character sets, add other <collation> elements. For example, to define ucs2_phone_ci, add a <collation> element to the <charset name="ucs2"> element. Remember that each collation must have its own unique ID.

5. Restart the server and use this statement to verify that the collation is present:

```
mysql> SHOW COLLATION WHERE Collation = 'utf8mb4_phone_ci';
+------------------+---------+------+---------+----------+---------+
| Collation        | Charset | Id   | Default | Compiled | Sortlen |
+------------------+---------+------+---------+----------+---------+
| utf8mb4_phone_ci | utf8mb4 | 1029 |         |          |       8 |
+------------------+---------+------+---------+----------+---------+
```

Now test the collation to make sure that it has the desired properties.

Create a table containing some sample phone numbers using the new collation:

```
mysql> CREATE TABLE phonebook (
    name VARCHAR(64),
    phone VARCHAR(64) CHARACTER SET utf8mb4 COLLATE utf8mb4_phone_ci
);
Query OK, 0 rows affected (0.09 sec)

mysql> INSERT INTO phonebook VALUES ('Svoj','+7 912 800 80 02');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Hf','+7 (912) 800 80 04');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Bar','+7-912-800-80-01');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Ramil','(7912) 800 80 03');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Sanja','+380 (912) 8008005');
```
Adding a UCA Collation to a Unicode Character Set

Run some queries to see whether the ignored punctuation characters are in fact ignored for comparison and sorting:

```sql
mysql> SELECT * FROM phonebook ORDER BY phone;
+-------+--------------------+
<table>
<thead>
<tr>
<th>name</th>
<th>phone</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sanja</td>
<td>+380 (912) 8008005</td>
</tr>
<tr>
<td>Bar</td>
<td>+7-912-800-80-01</td>
</tr>
<tr>
<td>Svoj</td>
<td>+7 912 800 80 02</td>
</tr>
<tr>
<td>Ramil</td>
<td>(7912) 800 80 03</td>
</tr>
<tr>
<td>Hf</td>
<td>+7 (912) 800 80 04</td>
</tr>
</tbody>
</table>
+-------+--------------------+
5 rows in set (0.00 sec)
```

```sql
mysql> SELECT * FROM phonebook WHERE phone='+7(912)800-80-01';
+------+------------------+
<table>
<thead>
<tr>
<th>name</th>
<th>phone</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bar</td>
<td>+7-912-800-80-01</td>
</tr>
</tbody>
</table>
+------+------------------+
1 row in set (0.00 sec)
```

```sql
mysql> SELECT * FROM phonebook WHERE phone='79128008001';
+------+------------------+
<table>
<thead>
<tr>
<th>name</th>
<th>phone</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bar</td>
<td>+7-912-800-80-01</td>
</tr>
</tbody>
</table>
+------+------------------+
1 row in set (0.00 sec)
```

```sql
mysql> SELECT * FROM phonebook WHERE phone='7 9 1 2 8 0 0 8 0 0 1';
+------+------------------+
<table>
<thead>
<tr>
<th>name</th>
<th>phone</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bar</td>
<td>+7-912-800-80-01</td>
</tr>
</tbody>
</table>
+------+------------------+
1 row in set (0.00 sec)
```

10.14.4.2 LDML Syntax Supported in MySQL

This section describes the LDML syntax that MySQL recognizes. This is a subset of the syntax described in the LDML specification available at http://www.unicode.org/reports/tr35/, which should be consulted for further information. MySQL recognizes a large enough subset of the syntax that, in many cases, it is possible to download a collation definition from the Unicode Common Locale Data Repository and paste the relevant part (that is, the part between the `<rules>` and `</rules>` tags) into the MySQL `Index.xml` file. The rules described here are all supported except that character sorting occurs only at the primary level. Rules that specify differences at secondary or higher sort levels are recognized (and thus can be included in collation definitions) but are treated as equality at the primary level.

The MySQL server generates diagnostics when it finds problems while parsing the `Index.xml` file. See Section 10.14.4.3, “Diagnostics During Index.xml Parsing”.

**Character Representation**

Characters named in LDML rules can be written literally or in `\nnnn` format, where `nnnn` is the hexadecimal Unicode code point value. For example, `A` and `á` can be written literally or as `\u0041` and `\u00E1`. Within hexadecimal values, the digits A through F are not case-sensitive; `\u00E1` and `\u00e1` are equivalent. For UCA 4.0.0 collations, hexadecimal notation can be used only for characters in the Basic Multilingual Plane, not for characters outside the BMP range of `0000` to `FFFF`. For UCA 5.2.0 collations, hexadecimal notation can be used for any character.
The *Index.xml* file itself should be written using UTF-8 encoding.

**Syntax Rules**

LDML has reset rules and shift rules to specify character ordering. Orderings are given as a set of rules that begin with a reset rule that establishes an anchor point, followed by shift rules that indicate how characters sort relative to the anchor point.

- A `<reset>` rule does not specify any ordering in and of itself. Instead, it “resets” the ordering for subsequent shift rules to cause them to be taken in relation to a given character. Either of the following rules resets subsequent shift rules to be taken in relation to the letter 'A':

  ```xml
  <reset>A</reset>
  <reset>\u0041</reset>
  ```

- The `<p>`, `<s>`, and `<t>` shift rules define primary, secondary, and tertiary differences of a character from another character:
  - Use primary differences to distinguish separate letters.
  - Use secondary differences to distinguish accent variations.
  - Use tertiary differences to distinguish lettercase variations.

  Either of these rules specifies a primary shift rule for the 'G' character:

  ```xml
  <p>G</p>
  <p>\u0047</p>
  ```

- The `<i>` shift rule indicates that one character sorts identically to another. The following rules cause 'b' to sort the same as 'a':

  ```xml
  <reset>a</reset>
  <i>b</i>
  ```

- Abbreviated shift syntax specifies multiple shift rules using a single pair of tags. The following table shows the correspondence between abbreviated syntax rules and the equivalent nonabbreviated rules.

  **Table 10.5 Abbreviated Shift Syntax**

<table>
<thead>
<tr>
<th>Abbreviated Syntax</th>
<th>Nonabbreviated Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;pc&gt;xyz&lt;/pc&gt;</code></td>
<td><code>&lt;p&gt;x&lt;/p&gt;&lt;p&gt;y&lt;/p&gt;&lt;p&gt;z&lt;/p&gt;</code></td>
</tr>
<tr>
<td><code>&lt;sc&gt;xyz&lt;/sc&gt;</code></td>
<td><code>&lt;s&gt;x&lt;/s&gt;&lt;s&gt;y&lt;/s&gt;&lt;s&gt;z&lt;/s&gt;</code></td>
</tr>
<tr>
<td><code>&lt;tc&gt;xyz&lt;/tc&gt;</code></td>
<td><code>&lt;t&gt;x&lt;/t&gt;&lt;t&gt;y&lt;/t&gt;&lt;t&gt;z&lt;/t&gt;</code></td>
</tr>
<tr>
<td><code>&lt;ic&gt;xyz&lt;/ic&gt;</code></td>
<td><code>&lt;i&gt;x&lt;/i&gt;&lt;i&gt;y&lt;/i&gt;&lt;i&gt;z&lt;/i&gt;</code></td>
</tr>
</tbody>
</table>

- An expansion is a reset rule that establishes an anchor point for a multiple-character sequence. MySQL supports expansions 2 to 6 characters long. The following rules put 'z' greater at the primary level than the sequence of three characters 'abc':

  ```xml
  <reset>abc</reset>
  <p>z</p>
  ```

- A contraction is a shift rule that sorts a multiple-character sequence. MySQL supports contractions 2 to 6 characters long. The following rules put the sequence of three characters 'xyz' greater at the primary level than 'a':

  ```xml
  <t>xyz</t>
  ```
• Long expansions and long contractions can be used together. These rules put the sequence of three characters 'xyz' greater at the primary level than the sequence of three characters 'abc':

```
<reset>abc</reset>
<p>xyz</p>
```

• Normal expansion syntax uses `<x>` plus `<extend>` elements to specify an expansion. The following rules put the character 'k' greater at the secondary level than the sequence 'ch'. That is, 'k' behaves as if it expands to a character after 'c' followed by 'h':

```
<reset>c</reset>
<x><s>k</s><extend>h</extend></x>
```

This syntax permits long sequences. These rules sort the sequence 'ccs' greater at the tertiary level than the sequence 'cscs':

```
<reset>cs</reset>
<x><t>ccs</t><extend>cs</extend></x>
```

The LDML specification describes normal expansion syntax as “tricky.” See that specification for details.

• Previous context syntax uses `<x>` plus `<context>` elements to specify that the context before a character affects how it sorts. The following rules put '- ' greater at the secondary level than 'a ', but only when '- ' occurs after 'b':

```
<reset>a</reset>
<x><context>b</context><s>-</s></x>
```

• Previous context syntax can include the `<extend>` element. These rules put 'def' greater at the primary level than 'aghi', but only when 'def' comes after 'abc':

```
<reset>a</reset>
<x><context>abc</context><p>def</p><extend>ghi</extend></x>
```

• Reset rules permit a `before` attribute. Normally, shift rules after a reset rule indicate characters that sort after the reset character. Shift rules after a reset rule that has the `before` attribute indicate characters that sort before the reset character. The following rules put the character 'b' immediately before 'a' at the primary level:

```
<reset before="primary">a</reset>
<p>b</p>
```

Permissible `before` attribute values specify the sort level by name or the equivalent numeric value:

```
<reset before="primary"/>
<reset before="1"/>
<reset before="secondary"/>
<reset before="2"/>
<reset before="tertiary"/>
<reset before="3"/>
```

• A reset rule can name a logical reset position rather than a literal character:

```
<first_tertiary_ignorable/>
<last_tertiary_ignorable/>
<first_secondary_ignorable/>
<last_secondary_ignorable/>
```
These rules put 'z' greater at the primary level than nonignorable characters that have a Default Unicode Collation Element Table (DUCET) entry and that are not CJK:

\[ \text{Logical positions have the code points shown in the following table.} \]

**Table 10.6 Logical Reset Position Code Points**

<table>

<tr>
<td>&lt;last_variable/&gt;</td>
<td>U+2183</td>
<td>U+1D371</td>
</tr>
</tbody>
</table>

- The `<collation>` element permits a `shift-after-method` attribute that affects character weight calculation for shift rules. The attribute has these permitted values:
  - **simple**: Calculate character weights as for reset rules that do not have a `before` attribute. This is the default if the attribute is not given.
  - **expand**: Use expansions for shifts after reset rules.

Suppose that '0' and '1' have weights of 0E29 and 0E2A and we want to put all basic Latin letters between '0' and '1':

\[ \text{Suppose that '0' and '1' have weights of 0E29 and 0E2A and we want to put all basic Latin letters between '0' and '1':} \]
Adding a UCA Collation to a Unicode Character Set

For simple shift mode, weights are calculated as follows:

- 'a' has weight \(0E29+1\)
- 'b' has weight \(0E29+2\)
- 'c' has weight \(0E29+3\)
...

However, there are not enough vacant positions to put 26 characters between '0' and '1'. The result is that digits and letters are intermixed.

To solve this, use `shift-after-method="expand"`. Then weights are calculated like this:

- 'a' has weight \([0E29][233D+1]\)
- 'b' has weight \([0E29][233D+2]\)
- 'c' has weight \([0E29][233D+3]\)
...

\(233D\) is the UCA 4.0.0 weight for character \(0xA48C\), which is the last nonignorable character (a sort of the greatest character in the collation, excluding CJK). UCA 5.2.0 is similar but uses \(3ACA\), for character \(0x1342E\).

MySQL-Specific LDML Extensions

An extension to LDML rules permits the `<collation>` element to include an optional `version` attribute in `<collation>` tags to indicate the UCA version on which the collation is based. If the `version` attribute is omitted, its default value is 4.0.0. For example, this specification indicates a collation that is based on UCA 5.2.0:

```xml
<collation id="nnn" name="utf8mb4_xxx_ci" version="5.2.0">
...
</collation>
```

10.14.4.3 Diagnostics During Index.xml Parsing

The MySQL server generates diagnostics when it finds problems while parsing the `Index.xml` file:

- Unknown tags are written to the error log. For example, the following message results if a collation definition contains a `<aaa>` tag:

```sql
[Warning] Buffered warning: Unknown LDML tag: 'charsets/charset/collation/rules/aaa'
```

- If collation initialization is not possible, the server reports an “Unknown collation” error, and also generates warnings explaining the problems, such as in the previous example. In other cases, when a collation description is generally correct but contains some unknown tags, the collation is initialized and is available for use. The unknown parts are ignored, but a warning is generated in the error log.

- Problems with collations generate warnings that clients can display with `SHOW WARNINGS`. Suppose that a reset rule contains an expansion longer than the maximum supported length of 6 characters:

```sql
<reset>abcdefghi</reset>
<i>x</i>
```

An attempt to use the collation produces warnings:

```sql
mysql> SELECT _utf8mb4'test' COLLATE utf8mb4_test_ci;
ERROR 1273 (HY000): Unknown collation: 'utf8mb4_test_ci'
mysql> SHOW WARNINGS;
```
10.15 Character Set Configuration

The MySQL server has a compiled-in default character set and collation. To change these defaults, use the `--character-set-server` and `--collation-server` options when you start the server. See Section 5.1.7, “Server Command Options”. The collation must be a legal collation for the default character set. To determine which collations are available for each character set, use the `SHOW COLLATION` statement or query the `INFORMATION_SCHEMA COLLATIONS` table.

If you try to use a character set that is not compiled into your binary, you might run into the following problems:

- If your program uses an incorrect path to determine where the character sets are stored (which is typically the `share/mysql/charsets` or `share/charsets` directory under the MySQL installation directory), this can be fixed by using the `--character-sets-dir` option when you run the program. For example, to specify a directory to be used by MySQL client programs, list it in the `[client]` group of your option file. The examples given here show what the setting might look like for Unix or Windows, respectively:

  ```
  [client]
  character-sets-dir=/usr/local/mysql/share/mysql/charsets
  [client]
  character-sets-dir="C:/Program Files/MySQL/MySQL Server 8.2/share/charsets"
  ```

- If the character set is a complex character set that cannot be loaded dynamically, you must recompile the program with support for the character set.

  For Unicode character sets, you can define collations without recompiling by using LDML notation. See Section 10.14.4, “Adding a UCA Collation to a Unicode Character Set”.

- If the character set is a dynamic character set, but you do not have a configuration file for it, you should install the configuration file for the character set from a new MySQL distribution.

- If your character set index file (`Index.xml`) does not contain the name for the character set, your program displays an error message:

  ```
  Character set 'charset_name' is not a compiled character set and is not specified in the '/usr/share/mysql/charsets/Index.xml' file
  ```

  To solve this problem, you should either get a new index file or manually add the name of any missing character sets to the current file.

You can force client programs to use specific character set as follows:

```
[client]
default-character-set=charset_name
```

This is normally unnecessary. However, when `character_set_system` differs from `character_set_server` or `character_set_client`, and you input characters manually (as database object identifiers, column values, or both), these may be displayed incorrectly in output from the client or the output itself may be formatted incorrectly. In such cases, starting the mysql client with `--default-character-set=system_character_set`—that is, setting the client character set to match the system character set—should fix the problem.
MySQL Server Locale Support

10.16 MySQL Server Locale Support

The locale indicated by the `lc_time_names` system variable controls the language used to display day and month names and abbreviations. This variable affects the output from the `DATE_FORMAT()`, `DAYNAME()`, and `MONTHNAME()` functions.

`lc_time_names` does not affect the `STR_TO_DATE()` or `GET_FORMAT()` function.

The `lc_time_names` value does not affect the result from `FORMAT()`, but this function takes an optional third parameter that enables a locale to be specified to be used for the result number's decimal point, thousands separator, and grouping between separators. Permissible locale values are the same as the legal values for the `lc_time_names` system variable.

Locale names have language and region subtags listed by IANA (http://www.iana.org/assignments/language-subtag-registry) such as 'ja_JP' or 'pt_BR'. The default value is 'en_US' regardless of your system's locale setting, but you can set the value at server startup, or set the GLOBAL value at runtime if you have privileges sufficient to set global system variables; see Section 5.1.9.1, “System Variable Privileges”. Any client can examine the value of `lc_time_names` or set its SESSION value to affect the locale for its own connection.

```sql
mysql> SET NAMES 'utf8mb4';
Query OK, 0 rows affected (0.09 sec)

mysql> SELECT @@lc_time_names;
+-----------------+
| @@lc_time_names |
| en_US           |
+-----------------+
1 row in set (0.00 sec)

mysql> SELECT DAYNAME('2020-01-01'), MONTHNAME('2020-01-01');
+-----------------------+-------------------------+
| DAYNAME('2020-01-01') | MONTHNAME('2020-01-01') |
| Wednesday             | January                 |
+-----------------------+-------------------------+
1 row in set (0.00 sec)

mysql> SELECT DATE_FORMAT('2020-01-01','%W %a %M %b');
+-----------------------------------------+
| DATE_FORMAT('2020-01-01','%W %a %M %b') |
| Wednesday Wed January Jan               |
+-----------------------------------------+
1 row in set (0.00 sec)

mysql> SET lc_time_names = 'es_MX';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@lc_time_names;
+-----------------+
| @@lc_time_names |
| es_MX           |
+-----------------+
1 row in set (0.00 sec)

mysql> SELECT DAYNAME('2020-01-01'), MONTHNAME('2020-01-01');
+-----------------------+-------------------------+
| DAYNAME('2020-01-01') | MONTHNAME('2020-01-01') |
| miércoles             | enero                  |
+-----------------------+-------------------------+
1 row in set (0.00 sec)
```
The day or month name for each of the affected functions is converted from `utf8mb4` to the character set indicated by the `character_set_connection` system variable.

`lc_time_names` may be set to any of the following locale values. The set of locales supported by MySQL may differ from those supported by your operating system.

11.7 Data Type Storage Requirements ......................................................................................... 2221  
11.8 Choosing the Right Type for a Column ................................................................................... 2226  
11.9 Using Data Types from Other Database Engines ................................................................. 2226

MySQL supports SQL data types in several categories: numeric types, date and time types, string (character and byte) types, spatial types, and the JSON data type. This chapter provides an overview and more detailed description of the properties of the types in each category, and a summary of the data type storage requirements. The initial overviews are intentionally brief. Consult the more detailed descriptions.
for additional information about particular data types, such as the permissible formats in which you can specify values.

Data type descriptions use these conventions:

- For integer types, $M$ indicates the maximum display width. For floating-point and fixed-point types, $M$ is the total number of digits that can be stored (the precision). For string types, $M$ is the maximum length. The maximum permissible value of $M$ depends on the data type.

- $D$ applies to floating-point and fixed-point types and indicates the number of digits following the decimal point (the scale). The maximum possible value is 30, but should be no greater than $M-2$.

- $fsp$ applies to the TIME, DATETIME, and TIMESTAMP types and represents fractional seconds precision; that is, the number of digits following the decimal point for fractional parts of seconds. The $fsp$ value, if given, must be in the range 0 to 6. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0. (This differs from the standard SQL default of 6, for compatibility with previous MySQL versions.)

- Square brackets ([ and ]) indicate optional parts of type definitions.

## 11.1 Numeric Data Types

MySQL supports all standard SQL numeric data types. These types include the exact numeric data types (INTEGER, SMALLINT, DECIMAL, and NUMERIC), as well as the approximate numeric data types (FLOAT, REAL, and DOUBLE PRECISION). The keyword INT is a synonym for INTEGER, and the keywords DEC and FIXED are synonyms for DECIMAL. MySQL treats DOUBLE as a synonym for DOUBLE PRECISION (a nonstandard extension). MySQL also treats REAL as a synonym for DOUBLE PRECISION (a nonstandard variation), unless the REAL_AS_FLOAT SQL mode is enabled.

The BIT data type stores bit values and is supported for MyISAM, MEMORY, InnoDB, and NDB tables.

For information about how MySQL handles assignment of out-of-range values to columns and overflow during expression evaluation, see Section 11.1.7, “Out-of-Range and Overflow Handling”.

For information about storage requirements of the numeric data types, see Section 11.7, “Data Type Storage Requirements”.

For descriptions of functions that operate on numeric values, see Section 12.6, “Numeric Functions and Operators”. The data type used for the result of a calculation on numeric operands depends on the types of the operands and the operations performed on them. For more information, see Section 12.6.1, “Arithmetic Operators”.

### 11.1.1 Numeric Data Type Syntax

For integer data types, $M$ indicates the minimum display width. The maximum display width is 255. Display width is unrelated to the range of values a type can store, as described in Section 11.1.6, “Numeric Type Attributes”.

For floating-point and fixed-point data types, $M$ is the total number of digits that can be stored.

The display width attribute is deprecated for integer data types; you should expect support for it to be removed in a future version of MySQL.

If you specify ZEROFILL for a numeric column, MySQL automatically adds the UNSIGNED attribute to the column.

The ZEROFILL attribute is deprecated for numeric data types; you should expect support for it to be removed in a future version of MySQL. Consider using an alternative means of producing the effect of this
attribute. For example, applications could use the `LPAD()` function to zero-pad numbers up to the desired width, or they could store the formatted numbers in `CHAR` columns.

Numeric data types that permit the `UNSIGNED` attribute also permit `SIGNED`. However, these data types are signed by default, so the `SIGNED` attribute has no effect.

The `UNSIGNED` attribute is deprecated for columns of type `FLOAT`, `DOUBLE`, and `DECIMAL` (and any synonyms); you should expect support for it to be removed in a future version of MySQL. Consider using a simple `CHECK` constraint instead for such columns.

`SERIAL` is an alias for `BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE`.

`SERIAL DEFAULT VALUE` in the definition of an integer column is an alias for `NOT NULL AUTO_INCREMENT UNIQUE`.

### Warning

When you use subtraction between integer values where one is of type `UNSIGNED`, the result is unsigned unless the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled. See Section 12.10, “Cast Functions and Operators”.

- **BIT[(<M>)]**
  A bit-value type. `<M>` indicates the number of bits per value, from 1 to 64. The default is 1 if `<M>` is omitted.

- **TINYINT[(<M>)] [UNSIGNED] [ZEROFILL]**
  A very small integer. The signed range is `-128` to `127`. The unsigned range is `0` to `255`.

- **BOOL, BOOLEAN**
  These types are synonyms for `TINYINT(1)`. A value of zero is considered false. Nonzero values are considered true:

```sql
mysql> SELECT IF(0, 'true', 'false');
+------------------------+
| IF(0, 'true', 'false') |
+------------------------+
| false                  |
+------------------------+

mysql> SELECT IF(1, 'true', 'false');
+------------------------+
| IF(1, 'true', 'false') |
+------------------------+
| true                   |
+------------------------+

mysql> SELECT IF(2, 'true', 'false');
+------------------------+
| IF(2, 'true', 'false') |
+------------------------+
| true                   |
+------------------------+
```

However, the values `TRUE` and `FALSE` are merely aliases for `1` and `0`, respectively, as shown here:

```sql
mysql> SELECT IF(0 = FALSE, 'true', 'false');
+------------------------+
| IF(0 = FALSE, 'true', 'false') |
+------------------------+
| true                    |
+------------------------+
```
The last two statements display the results shown because **2** is equal to neither **1** nor **0**.

- **SMALLINT[(M)] [UNSIGNED] [ZEROFILL]**

  A small integer. The signed range is **-32768** to **32767**. The unsigned range is **0** to **65535**.

- **MEDIUMINT[(M)] [UNSIGNED] [ZEROFILL]**

  A medium-sized integer. The signed range is **-8388608** to **8388607**. The unsigned range is **0** to **16777215**.

- **INT[(M)] [UNSIGNED] [ZEROFILL]**

  A normal-size integer. The signed range is **-2147483648** to **2147483647**. The unsigned range is **0** to **4294967295**.

- **INTEGER[(M)] [UNSIGNED] [ZEROFILL]**

  This type is a synonym for **INT**.

- **BIGINT[(M)] [UNSIGNED] [ZEROFILL]**

  A large integer. The signed range is **-9223372036854775808** to **9223372036854775807**. The unsigned range is **0** to **18446744073709551615**.

**SERIAL** is an alias for **BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE**.

Some things you should be aware of with respect to **BIGINT** columns:

- All arithmetic is done using signed **BIGINT** or **DOUBLE** values, so you should not use unsigned big integers larger than **9223372036854775807** (63 bits) except with bit functions! If you do that, some of the last digits in the result may be wrong because of rounding errors when converting a **BIGINT** value to a **DOUBLE**.

MySQL can handle **BIGINT** in the following cases:

- When using integers to store large unsigned values in a **BIGINT** column.
- In **MIN(col_name)** or **MAX(col_name)**, where **col_name** refers to a **BIGINT** column.
• When using operators (+, -, *, and so on) where both operands are integers.

• You can always store an exact integer value in a BIGINT column by storing it using a string. In this case, MySQL performs a string-to-number conversion that involves no intermediate double-precision representation.

• The -, +, and * operators use BIGINT arithmetic when both operands are integer values. This means that if you multiply two big integers (or results from functions that return integers), you may get unexpected results when the result is larger than 9223372036854775807.

• DECIMAL[(M,D)] [UNSIGNED] [ZEROFILL]
A packed “exact” fixed-point number. M is the total number of digits (the precision) and D is the number of digits after the decimal point (the scale). The decimal point and (for negative numbers) the – sign are not counted in M. If D is 0, values have no decimal point or fractional part. The maximum number of digits (M) for DECIMAL is 65. The maximum number of supported decimals (D) is 30. If D is omitted, the default is 0. If M is omitted, the default is 10. (There is also a limit on how long the text of DECIMAL literals can be; see Section 12.24.3, “Expression Handling”.)

UNSIGNED, if specified, disallows negative values. The UNSIGNED attribute is deprecated for columns of type DECIMAL (and any synonyms); you should expect support for it to be removed in a future version of MySQL. Consider using a simple CHECK constraint instead for such columns.

All basic calculations (+, -, *, /) with DECIMAL columns are done with a precision of 65 digits.

• DEC[(M,D)] [UNSIGNED] [ZEROFILL], NUMERIC[(M,D)] [UNSIGNED] [ZEROFILL], FIXED[(M,D)] [UNSIGNED] [ZEROFILL]
These types are synonyms for DECIMAL. The FIXED synonym is available for compatibility with other database systems.

• FLOAT[(M,D)] [UNSIGNED] [ZEROFILL]

A small (single-precision) floating-point number. Permissible values are –3.402823466E+38 to –1.175494351E–38, 0, and 1.175494351E–38 to 3.402823466E+38. These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

M is the total number of digits and D is the number of digits following the decimal point. If M and D are omitted, values are stored to the limits permitted by the hardware. A single-precision floating-point number is accurate to approximately 7 decimal places.

FLOAT(M,D) is a nonstandard MySQL extension. This syntax is deprecated, and you should expect support for it to be removed in a future version of MySQL.

UNSIGNED, if specified, disallows negative values. The UNSIGNED attribute is deprecated for columns of type FLOAT (and any synonyms) and you should expect support for it to be removed in a future version of MySQL. Consider using a simple CHECK constraint instead for such columns.

Using FLOAT might give you some unexpected problems because all calculations in MySQL are done with double precision. See Section B.3.4.7, “Solving Problems with No Matching Rows”.

• FLOAT(p) [UNSIGNED] [ZEROFILL]

A floating-point number. p represents the precision in bits, but MySQL uses this value only to determine whether to use FLOAT or DOUBLE for the resulting data type. If p is from 0 to 24, the data type becomes
FLOAT with no $M$ or $D$ values. If $p$ is from 25 to 53, the data type becomes DOUBLE with no $M$ or $D$ values. The range of the resulting column is the same as for the single-precision FLOAT or double-precision DOUBLE data types described earlier in this section.

UNSIGNED, if specified, disallows negative values. The UNSIGNED attribute is deprecated for columns of type FLOAT (and any synonyms) and you should expect support for it to be removed in a future version of MySQL. Consider using a simple CHECK constraint instead for such columns.

FLOAT($p$) syntax is provided for ODBC compatibility.

- DOUBLE [(M, D)] [UNSIGNED] [ZEROFILL]

A normal-size (double-precision) floating-point number. Permissible values are $-1.7976931348623157E+308$ to $-2.2250738585072014E-308$, 0, and $2.2250738585072014E-308$ to $1.7976931348623157E+308$. These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

$M$ is the total number of digits and $D$ is the number of digits following the decimal point. If $M$ and $D$ are omitted, values are stored to the limits permitted by the hardware. A double-precision floating-point number is accurate to approximately 15 decimal places.

DOUBLE (M, D) is a nonstandard MySQL extension; and is deprecated. You should expect support for this syntax to be removed in a future version of MySQL.

UNSIGNED, if specified, disallows negative values. The UNSIGNED attribute is deprecated for columns of type DOUBLE (and any synonyms) and you should expect support for it to be removed in a future version of MySQL. Consider using a simple CHECK constraint instead for such columns.

- DOUBLE PRECISION [(M, D)] [UNSIGNED] [ZEROFILL], REAL [(M, D)] [UNSIGNED] [ZEROFILL]

These types are synonyms for DOUBLE. Exception: If the REAL_AS_FLOAT SQL mode is enabled, REAL is a synonym for FLOAT rather than DOUBLE.

11.1.2 Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT

MySQL supports the SQL standard integer types INTEGER (or INT) and SMALLINT. As an extension to the standard, MySQL also supports the integer types TINYINT, MEDIUMINT, and BIGINT. The following table shows the required storage and range for each integer type.

Table 11.1 Required Storage and Range for Integer Types Supported by MySQL

<table>
<thead>
<tr>
<th>Type</th>
<th>Storage (Bytes)</th>
<th>Minimum Value Signed</th>
<th>Minimum Value Unsigned</th>
<th>Maximum Value Signed</th>
<th>Maximum Value Unsigned</th>
</tr>
</thead>
<tbody>
<tr>
<td>TINYINT</td>
<td>1</td>
<td>-128</td>
<td>0</td>
<td>127</td>
<td>255</td>
</tr>
<tr>
<td>SMALLINT</td>
<td>2</td>
<td>-32768</td>
<td>0</td>
<td>32767</td>
<td>65535</td>
</tr>
<tr>
<td>MEDIUMINT</td>
<td>3</td>

<td>BIGINT</td>
<td>8</td>
<td>$-2^{63}$</td>
<td>0</td>
<td>$2^{63} - 1$</td>
<td>$2^{64} - 1$</td>
</tr>
</tbody>
</table>
11.1.3 Fixed-Point Types (Exact Value) - DECIMAL, NUMERIC

The DECIMAL and NUMERIC types store exact numeric data values. These types are used when it is important to preserve exact precision, for example with monetary data. In MySQL, NUMERIC is implemented as DECIMAL, so the following remarks about DECIMAL apply equally to NUMERIC.

MySQL stores DECIMAL values in binary format. See Section 12.24, “Precision Math”.

In a DECIMAL column declaration, the precision and scale can be (and usually is) specified. For example:

```plaintext
salary DECIMAL(5,2)
```

In this example, 5 is the precision and 2 is the scale. The precision represents the number of significant digits that are stored for values, and the scale represents the number of digits that can be stored following the decimal point.

Standard SQL requires that DECIMAL(5,2) be able to store any value with five digits and two decimals, so values that can be stored in the salary column range from -999.99 to 999.99.

In standard SQL, the syntax DECIMAL(M) is equivalent to DECIMAL(M,0). Similarly, the syntax DECIMAL is equivalent to DECIMAL(M,0), where the implementation is permitted to decide the value of M. MySQL supports both of these variant forms of DECIMAL syntax. The default value of M is 10.

If the scale is 0, DECIMAL values contain no decimal point or fractional part.

The maximum number of digits for DECIMAL is 65, but the actual range for a given DECIMAL column can be constrained by the precision or scale for a given column. When such a column is assigned a value with more digits following the decimal point than are permitted by the specified scale, the value is converted to that scale. (The precise behavior is operating system-specific, but generally the effect is truncation to the permissible number of digits.)

11.1.4 Floating-Point Types (Approximate Value) - FLOAT, DOUBLE

The FLOAT and DOUBLE types represent approximate numeric data values. MySQL uses four bytes for single-precision values and eight bytes for double-precision values.

For FLOAT, the SQL standard permits an optional specification of the precision (but not the range of the exponent) in bits following the keyword FLOAT in parentheses, that is, FLOAT(p). MySQL also supports this optional precision specification, but the precision value in FLOAT(p) is used only to determine storage size. A precision from 0 to 23 results in a 4-byte single-precision FLOAT column. A precision from 24 to 53 results in an 8-byte double-precision DOUBLE column.

MySQL permits a nonstandard syntax: FLOAT(M, D) or REAL(M, D) or DOUBLE PRECISION(M, D). Here, (M, D) means that values can be stored with up to M digits in total, of which D digits may be after the decimal point. For example, a column defined as FLOAT(7,4) is displayed as -999.9999. MySQL performs rounding when storing values, so if you insert 999.00009 into a FLOAT(7,4) column, the approximate result is 999.0001.

FLOAT(M, D) and DOUBLE(M, D) are nonstandard MySQL extensions; and are deprecated. You should expect support for these variants to be removed in a future version of MySQL.

Because floating-point values are approximate and not stored as exact values, attempts to treat them as exact in comparisons may lead to problems. They are also subject to platform or implementation dependencies. For more information, see Section B.3.4.8, “Problems with Floating-Point Values”.
For maximum portability, code requiring storage of approximate numeric data values should use \texttt{FLOAT} or \texttt{DOUBLE PRECISION} with no specification of precision or number of digits.

### 11.1.5 Bit-Value Type - BIT

The \texttt{BIT} data type is used to store bit values. A type of \texttt{BIT\( (M) \)} enables storage of \( M \)-bit values. \( M \) can range from 1 to 64.

To specify bit values, \texttt{b'value'} notation can be used. \texttt{value} is a binary value written using zeros and ones. For example, \texttt{b'111'} and \texttt{b'10000000'} represent 7 and 128, respectively. See Section 9.1.5, “Bit-Value Literals”.

If you assign a value to a \texttt{BIT\( (M) \)} column that is less than \( M \) bits long, the value is padded on the left with zeros. For example, assigning a value of \texttt{b'101'} to a \texttt{BIT(6)} column is, in effect, the same as assigning \texttt{b'000101'}.

\textbf{NDB Cluster.} The maximum combined size of all \texttt{BIT} columns used in a given NDB table must not exceed 4096 bits.

### 11.1.6 Numeric Type Attributes

MySQL supports an extension for optionally specifying the display width of integer data types in parentheses following the base keyword for the type. For example, \texttt{INT(4)} specifies an \texttt{INT} with a display width of four digits. This optional display width may be used by applications to display integer values having a width less than the width specified for the column by left-padding them with spaces. (That is, this width is present in the metadata returned with result sets. Whether it is used is up to the application.)

The display width does \textit{not} constrain the range of values that can be stored in the column. Nor does it prevent values wider than the column display width from being displayed correctly. For example, a column specified as \texttt{SMALLINT(3)} has the usual \texttt{SMALLINT} range of \(-32768\) to \(32767\), and values outside the range permitted by three digits are displayed in full using more than three digits.

When used in conjunction with the optional (nonstandard) \texttt{ZEROFILL} attribute, the default padding of spaces is replaced with zeros. For example, for a column declared as \texttt{INT(4) ZEROFILL}, a value of \texttt{5} is retrieved as \texttt{0005}.

\begin{note}

The \texttt{ZEROFILL} attribute is ignored for columns involved in expressions or \texttt{UNION} queries.

If you store values larger than the display width in an integer column that has the \texttt{ZEROFILL} attribute, you may experience problems when MySQL generates temporary tables for some complicated joins. In these cases, MySQL assumes that the data values fit within the column display width.

The \texttt{ZEROFILL} attribute is deprecated for numeric data types, as is the display width attribute for integer data types. You should expect support for \texttt{ZEROFILL} and display widths for integer data types to be removed in a future version of MySQL. Consider using an alternative means of producing the effect of these attributes. For example, applications can use the \texttt{LPAD()} function to zero-pad numbers up to the desired width, or they can store the formatted numbers in \texttt{CHAR} columns.

All integer types can have an optional (nonstandard) \texttt{UNSIGNED} attribute. An unsigned type can be used to permit only nonnegative numbers in a column or when you need a larger upper numeric range for the
column. For example, if an INT column is UNSIGNED, the size of the column's range is the same but its endpoints shift up, from \(-2147483648\) and \(2147483647\) to \(0\) and \(4294967295\).

Floating-point and fixed-point types also can be UNSIGNED. As with integer types, this attribute prevents negative values from being stored in the column. Unlike the integer types, the upper range of column values remains the same. UNSIGNED is deprecated for columns of type FLOAT, DOUBLE, and DECIMAL (and any synonyms) and you should expect support for it to be removed in a future version of MySQL. Consider using a simple CHECK constraint instead for such columns.

If you specify ZEROFILL for a numeric column, MySQL automatically adds the UNSIGNED attribute.

Integer or floating-point data types can have the AUTO_INCREMENT attribute. When you insert a value of NULL into an indexed AUTO_INCREMENT column, the column is set to the next sequence value. Typically this is \(value+1\), where \(value\) is the largest value for the column currently in the table. (AUTO_INCREMENT sequences begin with 1.)

Storing 0 into an AUTO_INCREMENT column has the same effect as storing NULL, unless the NO_AUTO_VALUE_ON_ZERO SQL mode is enabled.

Inserting NULL to generate AUTO_INCREMENT values requires that the column be declared NOT NULL. If the column is declared NULL, inserting NULL stores a NULL. When you insert any other value into an AUTO_INCREMENT column, the column is set to that value and the sequence is reset so that the next automatically generated value follows sequentially from the inserted value.

Negative values for AUTO_INCREMENT columns are not supported.

CHECK constraints cannot refer to columns that have the AUTO_INCREMENT attribute, nor can the AUTO_INCREMENT attribute be added to existing columns that are used in CHECK constraints.

AUTO_INCREMENT is deprecated for FLOAT and DOUBLE columns; you should expect support for it to be removed in a future version of MySQL. Consider removing the AUTO_INCREMENT attribute from such columns to avoid potential compatibility issues, or convert them to an integer type.

### 11.1.7 Out-of-Range and Overflow Handling

When MySQL stores a value in a numeric column that is outside the permissible range of the column data type, the result depends on the SQL mode in effect at the time:

- If strict SQL mode is enabled, MySQL rejects the out-of-range value with an error, and the insert fails, in accordance with the SQL standard.

- If no restrictive modes are enabled, MySQL clips the value to the appropriate endpoint of the column data type range and stores the resulting value instead.

  When an out-of-range value is assigned to an integer column, MySQL stores the value representing the corresponding endpoint of the column data type range.

  When a floating-point or fixed-point column is assigned a value that exceeds the range implied by the specified (or default) precision and scale, MySQL stores the value representing the corresponding endpoint of that range.

Suppose that a table \(t1\) has this definition:

```sql
CREATE TABLE t1 (i1 TINYINT, i2 TINYINT UNSIGNED);
```

With strict SQL mode enabled, an out-of-range error occurs:
Out-of-Range and Overflow Handling

mysql> SET sql_mode = 'TRADITIONAL';
mysql> INSERT INTO t1 (i1, i2) VALUES(256, 256);
ERROR 1264 (22003): Out of range value for column 'i1' at row 1
mysql> SELECT * FROM t1;
Empty set (0.00 sec)

With strict SQL mode not enabled, clipping with warnings occurs:

mysql> SET sql_mode = '';
mysql> INSERT INTO t1 (i1, i2) VALUES(256, 256);
mysql> SHOW WARNINGS;
+---------+------+---------------------------------------------+
<table>
<thead>
<tr>
<th>Level</th>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Warning</td>
<td>1264</td>
<td>Out of range value for column 'i1' at row 1</td>
</tr>
<tr>
<td>Warning</td>
<td>1264</td>
<td>Out of range value for column 'i2' at row 1</td>
</tr>
</tbody>
</table>
+---------+------+---------------------------------------------+
mysql> SELECT * FROM t1;
+------+------+
| i1   | i2   |
| 127  | 255  |
+------+------+

When strict SQL mode is not enabled, column-assignment conversions that occur due to clipping are reported as warnings for ALTER TABLE, LOAD DATA, UPDATE, and multiple-row INSERT statements. In strict mode, these statements fail, and some or all the values are not inserted or changed, depending on whether the table is a transactional table and other factors. For details, see Section 5.1.11, “Server SQL Modes”.

Overflow during numeric expression evaluation results in an error. For example, the largest signed BIGINT value is 9223372036854775807, so the following expression produces an error:

mysql> SELECT 9223372036854775807 + 1;
ERROR 1690 (22003): BIGINT value is out of range in '(9223372036854775807 + 1)'

To enable the operation to succeed in this case, convert the value to unsigned:

mysql> SELECT CAST(9223372036854775807 AS UNSIGNED) + 1;
+-------------------------------+
| CAST(9223372036854775807 AS UNSIGNED) + 1 |
| 9223372036854775808             |
+-------------------------------+

Whether overflow occurs depends on the range of the operands, so another way to handle the preceding expression is to use exact-value arithmetic because DECIMAL values have a larger range than integers:

mysql> SELECT 9223372036854775807.0 + 1;
+---------------------------+
| 9223372036854775807.0 + 1  |
| 9223372036854775808.0       |
+---------------------------+

Subtraction between integer values, where one is of type UNSIGNED, produces an unsigned result by default. If the result would otherwise have been negative, an error results:

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT CAST(0 AS UNSIGNED) - 1;

2156
If the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the result is negative:

```sql
mysql> SET sql_mode = 'NO_UNSIGNED_SUBTRACTION';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-------------------------+
<table>
<thead>
<tr>
<th>CAST(0 AS UNSIGNED) - 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
</tr>
</tbody>
</table>
+-------------------------+
```

If the result of such an operation is used to update an `UNSIGNED` integer column, the result is clipped to the maximum value for the column type, or clipped to 0 if `NO_UNSIGNED_SUBTRACTION` is enabled. If strict SQL mode is enabled, an error occurs and the column remains unchanged.

### 11.2 Date and Time Data Types

The date and time data types for representing temporal values are `DATE`, `TIME`, `DATETIME`, `TIMESTAMP`, and `YEAR`. Each temporal type has a range of valid values, as well as a “zero” value that may be used when you specify an invalid value that MySQL cannot represent. The `TIMESTAMP` and `DATETIME` types have special automatic updating behavior, described in Section 11.2.5, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”.

For information about storage requirements of the temporal data types, see Section 11.7, “Data Type Storage Requirements”.

For descriptions of functions that operate on temporal values, see Section 12.7, “Date and Time Functions”.

Keep in mind these general considerations when working with date and time types:

- MySQL retrieves values for a given date or time type in a standard output format, but it attempts to interpret a variety of formats for input values that you supply (for example, when you specify a value to be assigned to or compared to a date or time type). For a description of the permitted formats for date and time types, see Section 9.1.3, “Date and Time Literals”. It is expected that you supply valid values. Unpredictable results may occur if you use values in other formats.

- Although MySQL tries to interpret values in several formats, date parts must always be given in year-month-day order (for example, ‘98-09-04’), rather than in the month-day-year or day-month-year orders commonly used elsewhere (for example, ‘09-04-98’, ‘04-09-98’). To convert strings in other orders to year-month-day order, the `STR_TO_DATE()` function may be useful.

- Dates containing 2-digit year values are ambiguous because the century is unknown. MySQL interprets 2-digit year values using these rules:
  - Year values in the range 00–69 become 2000–2069.

See also Section 11.2.9, “2-Digit Years in Dates”.

- Conversion of values from one temporal type to another occurs according to the rules in Section 11.2.8, “Conversion Between Date and Time Types”.

- MySQL automatically converts a date or time value to a number if the value is used in numeric context and vice versa.
• By default, when MySQL encounters a value for a date or time type that is out of range or otherwise invalid for the type, it converts the value to the “zero” value for that type. The exception is that out-of-range TIME values are clipped to the appropriate endpoint of the TIME range.

• By setting the SQL mode to the appropriate value, you can specify more exactly what kind of dates you want MySQL to support. (See Section 5.1.11, “Server SQL Modes”.) You can get MySQL to accept certain dates, such as '2009-11-31', by enabling the ALLOW_INVALID_DATES SQL mode. This is useful when you want to store a “possibly wrong” value which the user has specified (for example, in a web form) in the database for future processing. Under this mode, MySQL verifies only that the month is in the range from 1 to 12 and that the day is in the range from 1 to 31.

• MySQL permits you to store dates where the day or month and day are zero in a DATE or DATETIME column. This is useful for applications that need to store birthdates for which you may not know the exact date. In this case, you simply store the date as '2009-00-00' or '2009-01-00'. However, with dates such as these, you should not expect to get correct results for functions such as DATE_SUB() or DATE_ADD() that require complete dates. To disallow zero month or day parts in dates, enable the NO_ZERO_IN_DATE mode.

• MySQL permits you to store a “zero” value of '0000-00-00' as a “dummy date.” In some cases, this is more convenient than using NULL values, and uses less data and index space. To disallow '0000-00-00', enable the NO_ZERO_DATE mode.

• “Zero” date or time values used through Connector/ODBC are converted automatically to NULL because ODBC cannot handle such values.

The following table shows the format of the “zero” value for each type. The “zero” values are special, but you can store or refer to them explicitly using the values shown in the table. You can also do this using the values '0' or 0, which are easier to write. For temporal types that include a date part (DATE, DATETIME, and TIMESTAMP), use of these values may produce warning or errors. The precise behavior depends on which, if any, of the strict and NO_ZERO_DATE SQL modes are enabled; see Section 5.1.11, “Server SQL Modes”.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>“Zero” Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>'0000-00-00'</td>
</tr>
<tr>
<td>TIME</td>
<td>'00:00:00'</td>
</tr>
<tr>
<td>DATETIME</td>
<td>'0000-00-00 00:00:00'</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>'0000-00-00 00:00:00'</td>
</tr>
<tr>
<td>YEAR</td>
<td>0000</td>
</tr>
</tbody>
</table>

11.2.1 Date and Time Data Type Syntax

The date and time data types for representing temporal values are DATE, TIME, DATETIME, TIMESTAMP, and YEAR.

For the DATE and DATETIME range descriptions, “supported” means that although earlier values might work, there is no guarantee.

MySQL permits fractional seconds for TIME, DATETIME, and TIMESTAMP values, with up to microseconds (6 digits) precision. To define a column that includes a fractional seconds part, use the syntax type_name(fsp), where type_name is TIME, DATETIME, or TIMESTAMP, and fsp is the fractional seconds precision. For example:

```sql
CREATE TABLE t1 (t TIME(3), dt DATETIME(6), ts TIMESTAMP(0));
```
The `fsp` value, if given, must be in the range 0 to 6. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0. (This differs from the standard SQL default of 6, for compatibility with previous MySQL versions.)

Any `TIMESTAMP` or `DATETIME` column in a table can have automatic initialization and updating properties; see Section 11.2.5, “Automatic Initialization and Updating for `TIMESTAMP` and `DATETIME`”.

- **DATE**

  A date. The supported range is '1000-01-01' to '9999-12-31'. MySQL displays `DATE` values in 'YYYY-MM-DD' format, but permits assignment of values to `DATE` columns using either strings or numbers.

- **DATETIME ([fsp])**

  A date and time combination. The supported range is '1000-01-01 00:00:00.000000' to '9999-12-31 23:59:59.499999'. MySQL displays `DATETIME` values in 'YYYY-MM-DD hh:mm:ss [.fraction]' format, but permits assignment of values to `DATETIME` columns using either strings or numbers.

An optional `fsp` value in the range from 0 to 6 may be given to specify fractional seconds precision. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0.

Automatic initialization and updating to the current date and time for `DATETIME` columns can be specified using `DEFAULT` and `ON UPDATE` column definition clauses, as described in Section 11.2.5, “Automatic Initialization and Updating for `TIMESTAMP` and `DATETIME`”.

- **TIMESTAMP ([fsp])**

  A timestamp. The range is '1970-01-01 00:00:01.000000' UTC to '2038-01-19 03:14:07.499999' UTC. `TIMESTAMP` values are stored as the number of seconds since the epoch ('1970-01-01 00:00:00' UTC). A `TIMESTAMP` cannot represent the value '1970-01-01 00:00:00' because that is equivalent to 0 seconds from the epoch and the value 0 is reserved for representing '0000-00-00 00:00:00', the "zero" `TIMESTAMP` value.

An optional `fsp` value in the range from 0 to 6 may be given to specify fractional seconds precision. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0.

The way the server handles `TIMESTAMP` definitions depends on the value of the `explicit_defaults_for_timestamp` system variable (see Section 5.1.8, “Server System Variables”).

If `explicit_defaults_for_timestamp` is enabled, there is no automatic assignment of the `DEFAULT CURRENT_TIMESTAMP` or `ON UPDATE CURRENT_TIMESTAMP` attributes to any `TIMESTAMP` column. They must be included explicitly in the column definition. Also, any `TIMESTAMP` not explicitly declared as `NOT NULL` permits `NULL` values.

If `explicit_defaults_for_timestamp` is disabled, the server handles `TIMESTAMP` as follows:

Unless specified otherwise, the first `TIMESTAMP` column in a table is defined to be automatically set to the date and time of the most recent modification if not explicitly assigned a value. This makes `TIMESTAMP` useful for recording the timestamp of an `INSERT` or `UPDATE` operation. You can also set any `TIMESTAMP` column to the current date and time by assigning it a `NULL` value, unless it has been defined with the `NULL` attribute to permit `NULL` values.

Automatic initialization and updating to the current date and time can be specified using `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` column definition clauses. By default,
the first `TIMESTAMP` column has these properties, as previously noted. However, any `TIMESTAMP` column in a table can be defined to have these properties.

- `TIME[(fsp)]`

  A time. The range is '−838:59:59.000000' to '838:59:59.000000'. MySQL displays `TIME` values in 'hh:mm:ss[.fraction]' format, but permits assignment of values to `TIME` columns using either strings or numbers.

  An optional `fsp` value in the range from 0 to 6 may be given to specify fractional seconds precision. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0.

- `YEAR[(4)]`

  A year in 4-digit format. MySQL displays `YEAR` values in `YYYY` format, but permits assignment of values to `YEAR` columns using either strings or numbers. Values display as 1901 to 2155, or 0000.

  For additional information about `YEAR` display format and interpretation of input values, see Section 11.2.4, "The YEAR Type".

  **Note**

  The `YEAR(4)` data type with an explicit display width is deprecated; you should expect support for it to be removed in a future version of MySQL. Instead, use `YEAR` without a display width, which has the same meaning.

The `SUM()` and `AVG()` aggregate functions do not work with temporal values. (They convert the values to numbers, losing everything after the first nonnumeric character.) To work around this problem, convert to numeric units, perform the aggregate operation, and convert back to a temporal value. Examples:

```sql
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

### 11.2.2 The DATE, DATETIME, and TIMESTAMP Types

The `DATE`, `DATETIME`, and `TIMESTAMP` types are related. This section describes their characteristics, how they are similar, and how they differ. MySQL recognizes `DATE`, `DATETIME`, and `TIMESTAMP` values in several formats, described in Section 9.1.3, "Date and Time Literals". For the `DATE` and `DATETIME` range descriptions, "supported" means that although earlier values might work, there is no guarantee.

The `DATE` type is used for values with a date part but no time part. MySQL retrieves and displays `DATE` values in 'YYYY-MM-DD' format. The supported range is '1000-01-01' to '9999-12-31'.

The `DATETIME` type is used for values that contain both date and time parts. MySQL retrieves and displays `DATETIME` values in 'YYYY-MM-DD hh:mm:ss' format. The supported range is '1000-01-01 00:00:00' to '9999-12-31 23:59:59'.

The `TIMESTAMP` data type is used for values that contain both date and time parts. `TIMESTAMP` has a range of '1970-01-01 00:00:01' UTC to '2038-01-19 03:14:07' UTC.

A `DATETIME` or `TIMESTAMP` value can include a trailing fractional seconds part in up to microseconds (6 digits) precision. In particular, any fractional part in a value inserted into a `DATETIME` or `TIMESTAMP` column is stored rather than discarded. With the fractional part included, the format for these values is 'YYYY-MM-DD hh:mm:ss[.Fraction]', the range for `DATETIME` values is '1000-01-01 00:00:00.000000' to '9999-12-31 23:59:59.499999', and the range for `TIMESTAMP` values is '1970-01-01 00:00:01.000000' to '2038-01-19 03:14:07.499999'. The fractional part should always be separated from the rest of the time by a decimal point; no other fractional seconds delimiter is
recognized. For information about fractional seconds support in MySQL, see Section 11.2.6, “Fractional Seconds in Time Values”.

The **TIMESTAMP** and **DATETIME** data types offer automatic initialization and updating to the current date and time. For more information, see Section 11.2.5, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”.

MySQL converts **TIMESTAMP** values from the current time zone to UTC for storage, and back from UTC to the current time zone for retrieval. (This does not occur for other types such as **DATETIME**.) By default, the current time zone for each connection is the server’s time. The time zone can be set on a per-connection basis. As long as the time zone setting remains constant, you get back the same value you store. If you store a **TIMESTAMP** value, and then change the time zone and retrieve the value, the retrieved value is different from the value you stored. This occurs because the same time zone was not used for conversion in both directions. The current time zone is available as the value of the `time_zone` system variable. For more information, see Section 5.1.15, “MySQL Server Time Zone Support”.

You can specify a time zone offset when inserting a **TIMESTAMP** or **DATETIME** value into a table. See Section 9.1.3, “Date and Time Literals”, for more information and examples.

Invalid **DATE**, **DATETIME**, or **TIMESTAMP** values are converted to the “zero” value of the appropriate type (`'0000-00-00'` or `'0000-00-00 00:00:00'`), if the SQL mode permits this conversion. The precise behavior depends on which if any of strict SQL mode and the **NO_ZERO_DATE** SQL mode are enabled; see Section 5.1.11, “Server SQL Modes”.

You can convert **TIMESTAMP** values to UTC **DATETIME** values when retrieving them using `CAST()` with the **AT TIME ZONE** operator, as shown here:

```sql
mysql> SELECT col,  
        > CAST(col AT TIME ZONE INTERVAL '+00:00' AS DATETIME) AS ut  
        > FROM ts ORDER BY id;
```

<table>
<thead>
<tr>
<th>col</th>
<th>ut</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-01-01 10:10:10</td>
<td>2020-01-01 15:10:10</td>
</tr>
<tr>
<td>2019-12-31 23:40:10</td>
<td>2020-01-01 04:40:10</td>
</tr>
<tr>
<td>2020-01-01 13:10:10</td>
<td>2020-01-01 18:10:10</td>
</tr>
<tr>
<td>2020-01-01 10:10:10</td>
<td>2020-01-01 15:10:10</td>
</tr>
<tr>
<td>2020-01-01 04:40:10</td>
<td>2020-01-01 09:40:10</td>
</tr>
<tr>
<td>2020-01-01 18:10:10</td>
<td>2020-01-01 23:10:10</td>
</tr>
</tbody>
</table>

For complete information regarding syntax and additional examples, see the description of the `CAST()` function.

Be aware of certain properties of date value interpretation in MySQL:

- MySQL permits a “relaxed” format for values specified as strings, in which any punctuation character may be used as the delimiter between date parts or time parts. In some cases, this syntax can be deceiving. For example, a value such as `'10:11:12'` might look like a time value because of the `.`, but is interpreted as the year `'2010-11-12'` if used in date context. The value `'10:45:15'` is converted to `'0000-00-00'` because `'45'` is not a valid month.

  The only delimiter recognized between a date and time part and a fractional seconds part is the decimal point.

- The server requires that month and day values be valid, and not merely in the range 1 to 12 and 1 to 31, respectively. With strict mode disabled, invalid dates such as `'2004-04-31'` are converted to `'0000-00-00'` and a warning is generated. With strict mode enabled, invalid dates generate an error. To permit such dates, enable `ALLOW_INVALID_DATES`. See Section 5.1.11, “Server SQL Modes”, for more information.
The TIME Type

- MySQL does not accept `TIMESTAMP` values that include a zero in the day or month column or values that are not a valid date. The sole exception to this rule is the special “zero” value ‘0000-00-00 00:00:00’, if the SQL mode permits this value. The precise behavior depends on which if any of strict SQL mode and the `NO_ZERO_DATE` SQL mode are enabled; see Section 5.1.11, “Server SQL Modes”.

- Dates containing 2-digit year values are ambiguous because the century is unknown. MySQL interprets 2-digit year values using these rules:
  - Year values in the range 00–69 become 2000–2069.

See also Section 11.2.9, “2-Digit Years in Dates”.

11.2.3 The TIME Type

MySQL retrieves and displays `TIME` values in 'hh:mm:ss' format (or 'hhh:mm:ss' format for large hours values). `TIME` values may range from '-838:59:59' to '838:59:59'. The hours part may be so large because the `TIME` type can be used not only to represent a time of day (which must be less than 24 hours), but also elapsed time or a time interval between two events (which may be much greater than 24 hours, or even negative).

MySQL recognizes `TIME` values in several formats, some of which can include a trailing fractional seconds part in up to microseconds (6 digits) precision. See Section 9.1.3, “Date and Time Literals”. For information about fractional seconds support in MySQL, see Section 11.2.6, “Fractional Seconds in Time Values”. In particular, any fractional part in a value inserted into a `TIME` column is stored rather than discarded. With the fractional part included, the range for `TIME` values is '-838:59:59.000000' to '838:59:59.000000'.

Be careful about assigning abbreviated values to a `TIME` column. MySQL interprets abbreviated `TIME` values with colons as time of the day. That is, '11:12' means '11:12:00', not '00:11:12'. MySQL interprets abbreviated values without colons using the assumption that the two rightmost digits represent seconds (that is, as elapsed time rather than as time of day). For example, you might think of '1112' and 1112 as meaning '11:12:00' (12 minutes after 11 o’clock), but MySQL interprets them as '00:11:12' (11 minutes, 12 seconds). Similarly, '12' and 12 are interpreted as '00:00:12'.

The only delimiter recognized between a time part and a fractional seconds part is the decimal point.

By default, values that lie outside the `TIME` range but are otherwise valid are clipped to the closest endpoint of the range. For example, '-850:00:00' and '850:00:00' are converted to '-838:59:59' and '838:59:59'. Invalid `TIME` values are converted to '00:00:00'. Note that because '00:00:00' is itself a valid `TIME` value, there is no way to tell, from a value of '00:00:00' stored in a table, whether the original value was specified as '00:00:00' or whether it was invalid.

For more restrictive treatment of invalid `TIME` values, enable strict SQL mode to cause errors to occur. See Section 5.1.11, “Server SQL Modes”.

11.2.4 The YEAR Type

The `YEAR` type is a 1-byte type used to represent year values. It can be declared as `YEAR` with an implicit display width of 4 characters, or equivalently as `YEAR(4)` with an explicit display width.

Note

For the `YEAR(4)` data type using an explicit display width is deprecated and you should expect support for it to be removed in a future version of MySQL. Instead, use `YEAR` without a display width, which has the same meaning.
MySQL displays **YEAR** values in **YYYY** format, with a range of **1901** to **2155**, and **0000**.

**YEAR** accepts input values in a variety of formats:

- As 4-digit strings in the range ’**1901**’ to ’**2155**’.
- As 4-digit numbers in the range **1901** to **2155**.
- As 1- or 2-digit strings in the range ’**0**’ to ’**99**’. MySQL converts values in the ranges ’**0**’ to ’**69**’ and ’**70**’ to ’**99**’ to **YEAR** values in the ranges **2000** to **2069** and **1970** to **1999**.
- As 1- or 2-digit numbers in the range **0** to **99**. MySQL converts values in the ranges **1** to **69** and **70** to **99** to **YEAR** values in the ranges **2001** to **2069** and **1970** to **1999**.

The result of inserting a numeric **0** has a display value of **0000** and an internal value of **0000**. To insert zero and have it be interpreted as **2000**, specify it as a string ’**0**’ or ’**00**’.

- As the result of functions that return a value that is acceptable in **YEAR** context, such as **NOW()**.

If strict SQL mode is not enabled, MySQL converts invalid **YEAR** values to **0000**. In strict SQL mode, attempting to insert an invalid **YEAR** value produces an error.

See also Section 11.2.9, “2-Digit Years in Dates”.

### 11.2.5 Automatic Initialization and Updating for **TIMESTAMP** and **DATETIME**

**TIMESTAMP** and **DATETIME** columns can be automatically initialized and updated to the current date and time (that is, the current timestamp).

For any **TIMESTAMP** or **DATETIME** column in a table, you can assign the current timestamp as the default value, the auto-update value, or both:

- An auto-initialized column is set to the current timestamp for inserted rows that specify no value for the column.

- An auto-updated column is automatically updated to the current timestamp when the value of any other column in the row is changed from its current value. An auto-updated column remains unchanged if all other columns are set to their current values. To prevent an auto-updated column from updating when other columns change, explicitly set it to its current value. To update an auto-updated column even when other columns do not change, explicitly set it to the value it should have (for example, set it to **CURRENT_TIMESTAMP**).

In addition, if the **explicit_defaults_for_timestamp** system variable is disabled, you can initialize or update any **TIMESTAMP** (but not **DATETIME**) column to the current date and time by assigning it a **NULL** value, unless it has been defined with the **NULL** attribute to permit **NULL** values.

To specify automatic properties, use the **DEFAULT CURRENT_TIMESTAMP** and **ON UPDATE CURRENT_TIMESTAMP** clauses in column definitions. The order of the clauses does not matter. If both are present in a column definition, either can occur first. Any of the synonyms for **CURRENT_TIMESTAMP** have the same meaning as **CURRENT_TIMESTAMP**. These are **CURRENT_TIMESTAMP()**, **NOW()**, **LOCALTIME()**, **LOCALTIMESTAMP()**, and **LOCALTIMESTAMP()**.

Use of **DEFAULT CURRENT_TIMESTAMP** and **ON UPDATE CURRENT_TIMESTAMP** is specific to **TIMESTAMP** and **DATETIME**. The **DEFAULT** clause also can be used to specify a constant (nonautomatic) default value (for example, **DEFAULT 0** or **DEFAULT '2000-01-01 00:00:00'**).
Note

The following examples use DEFAULT 0, a default that can produce warnings or errors depending on whether strict SQL mode or the NO_ZERO_DATE SQL mode is enabled. Be aware that the TRADITIONAL SQL mode includes strict mode and NO_ZERO_DATE. See Section 5.1.11, “Server SQL Modes”.

**TIMESTAMP** or **DATETIME** column definitions can specify the current timestamp for both the default and auto-update values, for one but not the other, or for neither. Different columns can have different combinations of automatic properties. The following rules describe the possibilities:

- With both **DEFAULT CURRENT_TIMESTAMP** and **ON UPDATE CURRENT_TIMESTAMP**, the column has the current timestamp for its default value and is automatically updated to the current timestamp.

  ```sql
  CREATE TABLE t1 (
    ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    dt DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
  );
  ```

- With a **DEFAULT** clause but no **ON UPDATE CURRENT_TIMESTAMP** clause, the column has the given default value and is not automatically updated to the current timestamp.

  The default depends on whether the **DEFAULT** clause specifies **CURRENT_TIMESTAMP** or a constant value. With **CURRENT_TIMESTAMP**, the default is the current timestamp.

  ```sql
  CREATE TABLE t1 (
    ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP,
    dt DATETIME DEFAULT CURRENT_TIMESTAMP
  );
  ```

  With a constant, the default is the given value. In this case, the column has no automatic properties at all.

  ```sql
  CREATE TABLE t1 (
    ts TIMESTAMP DEFAULT 0,
    dt DATETIME DEFAULT 0
  );
  ```

- With an **ON UPDATE CURRENT_TIMESTAMP** clause and a constant **DEFAULT** clause, the column is automatically updated to the current timestamp and has the given constant default value.

  ```sql
  CREATE TABLE t1 (
    ts TIMESTAMP DEFAULT 0 ON UPDATE CURRENT_TIMESTAMP,
    dt DATETIME DEFAULT 0 ON UPDATE CURRENT_TIMESTAMP
  );
  ```

- With an **ON UPDATE CURRENT_TIMESTAMP** clause but no **DEFAULT** clause, the column is automatically updated to the current timestamp but does not have the current timestamp for its default value.

  The default in this case is type dependent. **TIMESTAMP** has a default of 0 unless defined with the **NULL** attribute, in which case the default is **NULL**.

  ```sql
  CREATE TABLE t1 (
    ts1 TIMESTAMP ON UPDATE CURRENT_TIMESTAMP, -- default 0
    ts2 TIMESTAMP NULL ON UPDATE CURRENT_TIMESTAMP -- default NULL
  );
  ```

**DATETIME** has a default of **NULL** unless defined with the **NOT NULL** attribute, in which case the default is 0.

```sql
CREATE TABLE t1 (
```
TIMESTAMP and DATETIME columns have no automatic properties unless they are specified explicitly, with this exception: If the explicit_defaults_for_timestamp system variable is disabled, the first TIMESTAMP column has both DEFAULT CURRENT_TIMESTAMP and ON UPDATE CURRENT_TIMESTAMP if neither is specified explicitly. To suppress automatic properties for the first TIMESTAMP column, use one of these strategies:

- Enable the explicit_defaults_for_timestamp system variable. In this case, the DEFAULT CURRENT_TIMESTAMP and ON UPDATE CURRENT_TIMESTAMP clauses that specify automatic initialization and updating are available, but are not assigned to any TIMESTAMP column unless explicitly included in the column definition.

- Alternatively, if explicit_defaults_for_timestamp is disabled, do either of the following:
  - Define the column with a DEFAULT clause that specifies a constant default value.
  - Specify the NULL attribute. This also causes the column to permit NULL values, which means that you cannot assign the current timestamp by setting the column to NULL. Assigning NULL sets the column to NULL, not the current timestamp. To assign the current timestamp, set the column to CURRENT_TIMESTAMP or a synonym such as NOW().

Consider these table definitions:

```sql
CREATE TABLE t1 (  
  ts1 TIMESTAMP DEFAULT 0,  
  ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP  
  ON UPDATE CURRENT_TIMESTAMP);  
CREATE TABLE t2 (  
  ts1 TIMESTAMP NULL,  
  ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP  
  ON UPDATE CURRENT_TIMESTAMP);  
CREATE TABLE t3 (  
  ts1 TIMESTAMP NULL DEFAULT 0,  
  ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP  
  ON UPDATE CURRENT_TIMESTAMP);  
```

The tables have these properties:

- In each table definition, the first TIMESTAMP column has no automatic initialization or updating.

- The tables differ in how the ts1 column handles NULL values. For t1, ts1 is NOT NULL and assigning it a value of NULL sets it to the current timestamp. For t2 and t3, ts1 permits NULL and assigning it a value of NULL sets it to NULL.

- t2 and t3 differ in the default value for ts1. For t2, ts1 is defined to permit NULL, so the default is also NULL in the absence of an explicit DEFAULT clause. For t3, ts1 permits NULL but has an explicit default of 0.

If a TIMESTAMP or DATETIME column definition includes an explicit fractional seconds precision value anywhere, the same value must be used throughout the column definition. This is permitted:

```sql
CREATE TABLE t1 (  
  ts TIMESTAMP(6) DEFAULT CURRENT_TIMESTAMP(6) ON UPDATE CURRENT_TIMESTAMP(6)  
);  
```

This is not permitted:

```sql
CREATE TABLE t1 (  
  ts TIMESTAMP(6) DEFAULT CURRENT_TIMESTAMP(6)  
);  
```
**Fractional Seconds in Time Values**

MySQL has fractional seconds support for `TIME`, `DATETIME`, and `TIMESTAMP` values, with up to microseconds (6 digits) precision:

- To define a column that includes a fractional seconds part, use the syntax `type_name(fsp)`, where `type_name` is `TIME`, `DATETIME`, or `TIMESTAMP`, and `fsp` is the fractional seconds precision. For example:

  ```sql
  CREATE TABLE t1 (ts TIMESTAMP NULL DEFAULT '0000-00-00 00:00:00');
  CREATE TABLE t2 (ts TIMESTAMP NULL DEFAULT NULL);
  
  INSERT INTO t2 VALUES (CURRENT_TIMESTAMP);
  INSERT INTO t1 VALUES (NOW());
  ```
CREATE TABLE t1 (t TIME(3), dt DATETIME(6));

The \textit{fsp} value, if given, must be in the range 0 to 6. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0. (This differs from the standard SQL default of 6, for compatibility with previous MySQL versions.)

- Inserting a \textit{TIME}, \textit{DATE}, or \textit{TIMESTAMP} value with a fractional seconds part into a column of the same type but having fewer fractional digits results in rounding. Consider a table created and populated as follows:

```sql
CREATE TABLE fractest( c1 TIME(2), c2 DATETIME(2), c3 TIMESTAMP(2) );
```

The temporal values are inserted into the table with rounding:

```
mysql> SELECT * FROM fractest;
+-----------+------------------------+------------------------+
| c1        | c2                     | c3                     |
+-----------+------------------------+------------------------+
| 17:51:04.78| 2018-09-08 17:51:04.78 | 2018-09-08 17:51:04.78 |
+-----------+------------------------+------------------------+
```

No warning or error is given when such rounding occurs. This behavior follows the SQL standard.

To insert the values with truncation instead, enable the \texttt{TIME_TRUNCATE_FRACTIONAL} SQL mode:

```sql
SET @@sql_mode = sys.list_add(@@sql_mode, 'TIME_TRUNCATE_FRACTIONAL');
```

With that SQL mode enabled, the temporal values are inserted with truncation:

```
mysql> SELECT * FROM fractest;
+-----------+------------------------+------------------------+
| c1        | c2                     | c3                     |
+-----------+------------------------+------------------------+
| 17:51:04.77| 2018-09-08 17:51:04.77 | 2018-09-08 17:51:04.77 |
+-----------+------------------------+------------------------+
```

- Functions that take temporal arguments accept values with fractional seconds. Return values from temporal functions include fractional seconds as appropriate. For example, \texttt{NOW()} with no argument returns the current date and time with no fractional part, but takes an optional argument from 0 to 6 to specify that the return value includes a fractional seconds part of that many digits.

- Syntax for temporal literals produces temporal values: \texttt{DATE 'str'}, \texttt{TIME 'str'}, and \texttt{TIMESTAMP 'str'}, and the ODBC-syntax equivalents. The resulting value includes a trailing fractional seconds part if specified. Previously, the temporal type keyword was ignored and these constructs produced the string value. See \texttt{Standard SQL and ODBC Date and Time Literals}

### 11.2.7 What Calendar Is Used By MySQL?

MySQL uses what is known as a \textit{proleptic Gregorian calendar}.

Every country that has switched from the Julian to the Gregorian calendar has had to discard at least ten days during the switch. To see how this works, consider the month of October 1582, when the first Julian-to-Gregorian switch occurred.
There are no dates between October 4 and October 15. This discontinuity is called the cutover. Any dates before the cutover are Julian, and any dates following the cutover are Gregorian. Dates during a cutover are nonexistent.

A calendar applied to dates when it was not actually in use is called proleptic. Thus, if we assume there was never a cutover and Gregorian rules always rule, we have a proleptic Gregorian calendar. This is what is used by MySQL, as is required by standard SQL. For this reason, dates prior to the cutover stored as MySQL DATE or DATETIME values must be adjusted to compensate for the difference. It is important to realize that the cutover did not occur at the same time in all countries, and that the later it happened, the more days were lost. For example, in Great Britain, it took place in 1752, when Wednesday September 2 was followed by Thursday September 14. Russia remained on the Julian calendar until 1918, losing 13 days in the process, and what is popularly referred to as its “October Revolution” occurred in November according to the Gregorian calendar.

### 11.2.8 Conversion Between Date and Time Types

To some extent, you can convert a value from one temporal type to another. However, there may be some alteration of the value or loss of information. In all cases, conversion between temporal types is subject to the range of valid values for the resulting type. For example, although DATE, DATETIME, and TIMESTAMP values all can be specified using the same set of formats, the types do not all have the same range of values. TIMESTAMP values cannot be earlier than 1970 UTC or later than '2038-01-19 03:14:07' UTC. This means that a date such as '1968-01-01', while valid as a DATE or DATETIME value, is not valid as a TIMESTAMP value and is converted to 0.

Conversion of DATE values:

- Conversion to a DATETIME or TIMESTAMP value adds a time part of '00:00:00' because the DATE value contains no time information.

- Conversion to a TIME value is not useful; the result is '00:00:00'.

Conversion of DATETIME and TIMESTAMP values:

- Conversion to a DATE value takes fractional seconds into account and rounds the time part. For example, '1999-12-31 23:59:59.499' becomes '1999-12-31', whereas '1999-12-31 23:59:59.500' becomes '2000-01-01'.

- Conversion to a TIME value discards the date part because the TIME type contains no date information.

For conversion of TIME values to other temporal types, the value of CURRENT_DATE() is used for the date part. The TIME is interpreted as elapsed time (not time of day) and added to the date. This means that the date part of the result differs from the current date if the time value is outside the range from '00:00:00' to '23:59:59'.

Suppose that the current date is '2012-01-01'. TIME values of '12:00:00', '24:00:00', and '-12:00:00', when converted to DATETIME or TIMESTAMP values, result in '2012-01-01 12:00:00', '2012-01-02 00:00:00', and '2011-12-31 12:00:00', respectively.

Conversion of TIME to DATE is similar but discards the time part from the result: '2012-01-01', '2012-01-02', and '2011-12-31', respectively.
Explicit conversion can be used to override implicit conversion. For example, in comparison of DATE and DATETIME values, the DATE value is coerced to the DATETIME type by adding a time part of '00:00:00'. To perform the comparison by ignoring the time part of the DATETIME value instead, use the CAST() function in the following way:

\[
\text{date}_\text{col} = \text{CAST(}\text{datetime}_\text{col} \text{AS DATE)}
\]

Conversion of TIME and DATETIME values to numeric form (for example, by adding +0) depends on whether the value contains a fractional seconds part. TIME(\text{N}) or DATETIME(\text{N}) is converted to integer when \text{N} is 0 (or omitted) and to a DECIMAL value with \text{N} decimal digits when \text{N} is greater than 0:

```
mysql> SELECT CURTIME(), CURTIME()+0, CURTIME(3)+0;
+-----------+-------------+--------------+
| CURTIME() | CURTIME()+0 | CURTIME(3)+0 |
| 09:28:00  | 92800       | 92800.887    |
+-----------+-------------+--------------+
mysql> SELECT NOW(), NOW()+0, NOW(3)+0;
+---------------------+----------------+--------------------+
| NOW()               | NOW()+0        | NOW(3)+0           |
| 2012-08-15 09:28:00 | 20120815092800 | 20120815092800.889 |
+---------------------+----------------+--------------------+
```

11.2.9 2-Digit Years in Dates

Date values with 2-digit years are ambiguous because the century is unknown. Such values must be interpreted into 4-digit form because MySQL stores years internally using 4 digits.

For DATETIME, DATE, and TIMESTAMP types, MySQL interprets dates specified with ambiguous year values using these rules:

- Year values in the range 00–69 become 2000–2069.

For YEAR, the rules are the same, with this exception: A numeric \text{00} inserted into YEAR results in 0000 rather than 2000. To specify zero for YEAR and have it be interpreted as 2000, specify it as a string '0' or '00'.

Remember that these rules are only heuristics that provide reasonable guesses as to what your data values mean. If the rules used by MySQL do not produce the values you require, you must provide unambiguous input containing 4-digit year values.

ORDER BY properly sorts YEAR values that have 2-digit years.

Some functions like MIN() and MAX() convert a YEAR to a number. This means that a value with a 2-digit year does not work properly with these functions. The fix in this case is to convert the YEAR to 4-digit year format.

11.3 String Data Types

The string data types are CHAR, VARCHAR, BINARY, VARBINARY, BLOB, TEXT, ENUM, and SET.

For information about storage requirements of the string data types, see Section 11.7, "Data Type Storage Requirements".

For descriptions of functions that operate on string values, see Section 12.8, "String Functions and Operators".
11.3.1 String Data Type Syntax

The string data types are **CHAR, VARCHAR, BINARY, VARBINARY, BLOB, TEXT, ENUM, and SET**.

In some cases, MySQL may change a string column to a type different from that given in a `CREATE TABLE` or `ALTER TABLE` statement. See Section 13.1.20.7, “Silent Column Specification Changes”.

For definitions of character string columns (**CHAR, VARCHAR, and the TEXT types**), MySQL interprets length specifications in character units. For definitions of binary string columns (**BINARY, VARBINARY, and the BLOB types**), MySQL interprets length specifications in byte units.

Column definitions for character string data types **CHAR, VARCHAR, the TEXT types, ENUM, SET, and any synonyms** can specify the column character set and collation:

- **CHARACTER SET** specifies the character set. If desired, a collation for the character set can be specified with the **COLLATE** attribute, along with any other attributes. For example:

```sql
CREATE TABLE t
{
    c1 VARCHAR(20) CHARACTER SET utf8mb4,
    c2 TEXT CHARACTER SET latin1 COLLATE latin1_general_cs
};
```

This table definition creates a column named **c1** that has a character set of **utf8mb4** with the default collation for that character set, and a column named **c2** that has a character set of **latin1** and a case-sensitive (**_cs**) collation.

The rules for assigning the character set and collation when either or both of **CHARACTER SET** and the **COLLATE** attribute are missing are described in Section 10.3.5, “Column Character Set and Collation”.

**CHARSET** is a synonym for **CHARACTER SET**.

- Specifying the **CHARACTER SET binary** attribute for a character string data type causes the column to be created as the corresponding binary string data type: **CHAR** becomes **BINARY**, **VARCHAR** becomes **VARBINARY**, and **TEXT** becomes **BLOB**. For the **ENUM** and **SET** data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

```sql
CREATE TABLE t
{
    c1 VARCHAR(10) CHARACTER SET binary,
    c2 TEXT CHARACTER SET binary,
    c3 ENUM('a','b','c') CHARACTER SET binary
};
```

The resulting table has this definition:

```sql
CREATE TABLE t
{
    c1 VARBINARY(10),
    c2 BLOB,
    c3 ENUM('a','b','c') CHARACTER SET binary
};
```

- The **BINARY** attribute is a nonstandard MySQL extension that is shorthand for specifying the binary (**_bin**) collation of the column character set (or of the table default character set if no column character set is specified). In this case, comparison and sorting are based on numeric character code values. Suppose that you specify a table using this definition:

```sql
CREATE TABLE t
{
```
The resulting table has this definition:

```
CREATE TABLE t (
  c1 VARCHAR(10) CHARACTER SET latin1 COLLATE latin1_bin,
  c2 TEXT CHARACTER SET utf8mb4 COLLATE utf8mb4_bin
) CHARACTER SET utf8mb4;
```

In MySQL 8.2, the `BINARY` attribute is deprecated and you should expect support for it to be removed in a future version of MySQL. Applications should be adjusted to use an explicit `_bin` collation instead.

The use of `BINARY` to specify a data type or character set remains unchanged.

- The `ASCII` attribute is shorthand for `CHARACTER SET latin1`. Supported in older MySQL releases, `ASCII` is deprecated; use `CHARACTER SET` instead.

- The `UNICODE` attribute is shorthand for `CHARACTER SET ucs2`. Supported in older MySQL releases, `UNICODE` is deprecated; use `CHARACTER SET` instead.

Character column comparison and sorting are based on the collation assigned to the column. For the `CHAR`, `VARCHAR`, `TEXT`, `ENUM`, and `SET` data types, you can declare a column with a binary (_bin) collation or the `BINARY` attribute to cause comparison and sorting to use the underlying character code values rather than a lexical ordering.

For additional information about use of character sets in MySQL, see Chapter 10, `Character Sets, Collations, Unicode`.

- `[NATIONAL] CHAR[(M)] [CHARACTER SET charset_name] [COLLATE collation_name]`  
  
  A fixed-length string that is always right-padded with spaces to the specified length when stored.  
  
  `M` represents the column length in characters. The range of `M` is 0 to 255. If `M` is omitted, the length is 1.

  **Note**  
  Trailing spaces are removed when `CHAR` values are retrieved unless the `PAD_CHAR_TO_FULL_LENGTH` SQL mode is enabled.

  `CHAR` is shorthand for `CHARACTER`. `NATIONAL CHAR` (or its equivalent short form, `NCHAR`) is the standard SQL way to define that a `CHAR` column should use some predefined character set. MySQL uses `utf8mb3` as this predefined character set. Section 10.3.7, “The National Character Set”.

The `CHAR BYTE` data type is an alias for the `BINARY` data type. This is a compatibility feature.

MySQL permits you to create a column of type `CHAR(0)`. This is useful primarily when you must be compliant with old applications that depend on the existence of a column but that do not actually use its value. `CHAR(0)` is also quite nice when you need a column that can take only two values: A column that is defined as `CHAR(0) NULL` occupies only one bit and can take only the values `NULL` and `' ' (the empty string).

- `[NATIONAL] VARCHAR(M) [CHARACTER SET charset_name] [COLLATE collation_name]`  
  
  A variable-length string.  
  
  `M` represents the maximum column length in characters. The range of `M` is 0 to 65,535. The effective maximum length of a `VARCHAR` is subject to the maximum row size (65,535 bytes,
which is shared among all columns) and the character set used. For example, \texttt{utf8mb3} characters can require up to three bytes per character, so a \texttt{VARCHAR} column that uses the \texttt{utf8mb3} character set can be declared to be a maximum of 21,844 characters. See Section 8.4.7, “Limits on Table Column Count and Row Size”.

MySQL stores \texttt{VARCHAR} values as a 1-byte or 2-byte length prefix plus data. The length prefix indicates the number of bytes in the value. A \texttt{VARCHAR} column uses one length byte if values require no more than 255 bytes, two length bytes if values may require more than 255 bytes.

\textbf{Note}

MySQL follows the standard SQL specification, and does not remove trailing spaces from \texttt{VARCHAR} values.

\texttt{VARCHAR} is shorthand for \texttt{CHARACTER VARYING}. \texttt{NATIONAL VARCHAR} is the standard SQL way to define that a \texttt{VARCHAR} column should use some predefined character set. MySQL uses \texttt{utf8mb3} as this predefined character set. Section 10.3.7, “The National Character Set”. \texttt{NVARCHAR} is shorthand for \texttt{NATIONAL VARCHAR}.

- \texttt{BINARY[ (M) ]}

  The \texttt{BINARY} type is similar to the \texttt{CHAR} type, but stores binary byte strings rather than nonbinary character strings. An optional length \texttt{M} represents the column length in bytes. If omitted, \texttt{M} defaults to 1.

- \texttt{VARBINARY( M )}

  The \texttt{VARBINARY} type is similar to the \texttt{VARCHAR} type, but stores binary byte strings rather than nonbinary character strings. \texttt{M} represents the maximum column length in bytes.

- \texttt{TINYBLOB}

  A \texttt{BLOB} column with a maximum length of 255 ($2^8 - 1$) bytes. Each \texttt{TINYBLOB} value is stored using a 1-byte length prefix that indicates the number of bytes in the value.

- \texttt{TINYTEXT [ CHARACTER SET charset_name ] [ COLLATE collation_name ]}

  A \texttt{TEXT} column with a maximum length of 255 ($2^8 - 1$) characters. The effective maximum length is less if the value contains multibyte characters. Each \texttt{TINYTEXT} value is stored using a 1-byte length prefix that indicates the number of bytes in the value.

- \texttt{BLOB[ (M) ]}

  A \texttt{BLOB} column with a maximum length of 65,535 ($2^{16} - 1$) bytes. Each \texttt{BLOB} value is stored using a 2-byte length prefix that indicates the number of bytes in the value.

  An optional length \texttt{M} can be given for this type. If this is done, MySQL creates the column as the smallest \texttt{BLOB} type large enough to hold values \texttt{M} bytes long.

- \texttt{TEXT[(M)] [ CHARACTER SET charset_name ] [ COLLATE collation_name ]}

  A \texttt{TEXT} column with a maximum length of 65,535 ($2^{16} - 1$) characters. The effective maximum length is less if the value contains multibyte characters. Each \texttt{TEXT} value is stored using a 2-byte length prefix that indicates the number of bytes in the value.

  An optional length \texttt{M} can be given for this type. If this is done, MySQL creates the column as the smallest \texttt{TEXT} type large enough to hold values \texttt{M} characters long.

- \texttt{MEDIUMBLOB}
A **BLOB** column with a maximum length of 16,777,215 \(2^{24} - 1\) bytes. Each **MEDIUMBLOB** value is stored using a 3-byte length prefix that indicates the number of bytes in the value.

- **MEDIUMTEXT** [CHARACTER SET `charset_name`][COLLATE `collation_name`]

A **TEXT** column with a maximum length of 16,777,215 \(2^{24} - 1\) characters. The effective maximum length is less if the value contains multibyte characters. Each **MEDIUMTEXT** value is stored using a 3-byte length prefix that indicates the number of bytes in the value.

- **LONGTEXT** [CHARACTER SET `charset_name`][COLLATE `collation_name`]

A **TEXT** column with a maximum length of 4,294,967,295 or 4GB \(2^{32} - 1\) bytes. The effective maximum length of **LONGBLOB** columns depends on the configured maximum packet size in the client/server protocol and available memory. Each **LONGBLOB** value is stored using a 4-byte length prefix that indicates the number of bytes in the value.

- **LONGTEXT** [CHARACTER SET `charset_name`][COLLATE `collation_name`]

A **TEXT** column with a maximum length of 4,294,967,295 or 4GB \(2^{32} - 1\) characters. The effective maximum length of **LONGTEXT** columns also depends on the configured maximum packet size in the client/server protocol and available memory. Each **LONGTEXT** value is stored using a 4-byte length prefix that indicates the number of bytes in the value.

- **ENUM('value1','value2',...)** [CHARACTER SET `charset_name`][COLLATE `collation_name`]

An enumeration. A string object that can have only one value, chosen from the list of values `'value1', 'value2', ..., NULL` or the special ``` error value. **ENUM** values are represented internally as integers.

An **ENUM** column can have a maximum of 65,535 distinct elements.

The maximum supported length of an individual **ENUM** element is \(M \leq 255\) and \((M \times w) \leq 1020\), where \(M\) is the element literal length and \(w\) is the number of bytes required for the maximum-length character in the character set.

- **SET('value1','value2',...)** [CHARACTER SET `charset_name`][COLLATE `collation_name`]

A set. A string object that can have zero or more values, each of which must be chosen from the list of values `'value1', 'value2', ...` **SET** values are represented internally as integers.

A **SET** column can have a maximum of 64 distinct members.

The maximum supported length of an individual **SET** element is \(M \leq 255\) and \((M \times w) \leq 1020\), where \(M\) is the element literal length and \(w\) is the number of bytes required for the maximum-length character in the character set.

### 11.3.2 The CHAR and VARCHAR Types

The **CHAR** and **VARCHAR** types are similar, but differ in the way they are stored and retrieved. They also differ in maximum length and in whether trailing spaces are retained.

The **CHAR** and **VARCHAR** types are declared with a length that indicates the maximum number of characters you want to store. For example, **CHAR(30)** can hold up to 30 characters.
The length of a `CHAR` column is fixed to the length that you declare when you create the table. The length can be any value from 0 to 255. When `CHAR` values are stored, they are right-padded with spaces to the specified length. When `CHAR` values are retrieved, trailing spaces are removed unless the `PAD_CHAR_TO_FULL_LENGTH` SQL mode is enabled.

Values in `VARCHAR` columns are variable-length strings. The length can be specified as a value from 0 to 65,535. The effective maximum length of a `VARCHAR` is subject to the maximum row size (65,535 bytes, which is shared among all columns) and the character set used. See Section 8.4.7, “Limits on Table Column Count and Row Size”.

In contrast to `CHAR`, `VARCHAR` values are stored as a 1-byte or 2-byte length prefix plus data. The length prefix indicates the number of bytes in the value. A column uses one length byte if values require no more than 255 bytes, two length bytes if values may require more than 255 bytes.

If strict SQL mode is not enabled and you assign a value to a `CHAR` or `VARCHAR` column that exceeds the column’s maximum length, the value is truncated to fit and a warning is generated. For truncation of non-space characters, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See Section 5.1.11, “Server SQL Modes”.

For `VARCHAR` columns, trailing spaces in excess of the column length are truncated prior to insertion and a warning is generated, regardless of the SQL mode in use. For `CHAR` columns, truncation of excess trailing spaces from inserted values is performed silently regardless of the SQL mode.

`VARCHAR` values are not padded when they are stored. Trailing spaces are retained when values are stored and retrieved, in conformance with standard SQL.

The following table illustrates the differences between `CHAR` and `VARCHAR` by showing the result of storing various string values into `CHAR(4)` and `VARCHAR(4)` columns (assuming that the column uses a single-byte character set such as `latin1`).

<table>
<thead>
<tr>
<th>Value</th>
<th><code>CHAR(4)</code> Storage Required</th>
<th><code>VARCHAR(4)</code> Storage Required</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>'</code></td>
<td>4 bytes</td>
<td>1 byte</td>
</tr>
<tr>
<td><code>'ab'</code></td>
<td>4 bytes</td>
<td>3 bytes</td>
</tr>
<tr>
<td><code>'abcd'</code></td>
<td>4 bytes</td>
<td>5 bytes</td>
</tr>
<tr>
<td><code>'abcdefghijklmnopqrstuvwxyz'</code></td>
<td>4 bytes</td>
<td>5 bytes</td>
</tr>
</tbody>
</table>

The values shown as stored in the last row of the table apply only when not using strict SQL mode; if strict mode is enabled, values that exceed the column length are not stored, and an error results.

`InnoDB` encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

If a given value is stored into the `CHAR(4)` and `VARCHAR(4)` columns, the values retrieved from the columns are not always the same because trailing spaces are removed from `CHAR` columns upon retrieval. The following example illustrates this difference:

```sql
mysql> CREATE TABLE vc (v VARCHAR(4), c CHAR(4));
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO vc VALUES ('ab ', 'ab ');  
Query OK, 1 row affected (0.00 sec)

mysql> SELECT CONCAT('(', v, ')'), CONCAT('(', c, ')') FROM vc;
+---------------------+---------------------+
| (, ab )             | (, ab )             |
| (, ab )             | (, ab )             |
```

2174
Values in `CHAR`, `VARCHAR`, and `TEXT` columns are sorted and compared according to the character set collation assigned to the column.

MySQL collations have a pad attribute of `PAD SPACE`, other than Unicode collations based on UCA 9.0.0 and higher, which have a pad attribute of `NO PAD` (see Section 10.10.1, “Unicode Character Sets”).

To determine the pad attribute for a collation, use the `INFORMATION_SCHEMA COLLATIONS` table, which has a `PAD_ATTRIBUTE` column.

For nonbinary strings (`CHAR`, `VARCHAR`, and `TEXT` values), the string collation pad attribute determines treatment in comparisons of trailing spaces at the end of strings. `NO PAD` collations treat trailing spaces as significant in comparisons, like any other character. `PAD SPACE` collations treat trailing spaces as insignificant in comparisons; strings are compared without regard to trailing spaces. See Trailing Space Handling in Comparisons. The server SQL mode has no effect on comparison behavior with respect to trailing spaces.

**Note**

For more information about MySQL character sets and collations, see Chapter 10, Character Sets, Collations, Unicode. For additional information about storage requirements, see Section 11.7, “Data Type Storage Requirements”.

For those cases where trailing pad characters are stripped or comparisons ignore them, if a column has an index that requires unique values, inserting into the column values that differ only in number of trailing pad characters results in a duplicate-key error. For example, if a table contains `'a'`, an attempt to store `'a '` causes a duplicate-key error.

### 11.3.3 The BINARY and VARBINARY Types

The `BINARY` and `VARBINARY` types are similar to `CHAR` and `VARCHAR`, except that they store binary strings rather than nonbinary strings. That is, they store byte strings rather than character strings. This means they have the `binary` character set and collation, and comparison and sorting are based on the numeric values of the bytes in the values.

The permissible maximum length is the same for `BINARY` and `VARBINARY` as it is for `CHAR` and `VARCHAR`, except that the length for `BINARY` and `VARBINARY` is measured in bytes rather than characters.

The `BINARY` and `VARBINARY` data types are distinct from the `CHAR BINARY` and `VARCHAR BINARY` data types. For the latter types, the `BINARY` attribute does not cause the column to be treated as a binary string column. Instead, it causes the binary (_bin) collation for the column character set (or the table default character set if no column character set is specified) to be used, and the column itself stores nonbinary character strings rather than binary byte strings. For example, if the default character set is `utf8mb4`, `CHAR(5) BINARY` is treated as `CHAR(5) CHARACTER SET utf8mb4 COLLATE utf8mb4_bin`. This differs from `BINARY(5)`, which stores 5-byte binary strings that have the `binary` character set and collation.

For information about the differences between the `binary` collation of the `binary` character set and the `_bin` collations of nonbinary character sets, see Section 10.8.5, “The binary Collation Compared to _bin Collations”.

If strict SQL mode is not enabled and you assign a value to a `BINARY` or `VARBINARY` column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For cases of
truncation, to cause an error to occur (rather than a warning) and suppress insertion of the value, use strict SQL mode. See Section 5.1.11, “Server SQL Modes”.

When BINARY values are stored, they are right-padded with the pad value to the specified length. The pad value is 0x00 (the zero byte). Values are right-padded with 0x00 for inserts, and no trailing bytes are removed for retrievals. All bytes are significant in comparisons, including ORDER BY and DISTINCT operations. 0x00 and space differ in comparisons, with 0x00 sorting before space.

Example: For a BINARY(3) column, 'a ' becomes 'a \0' when inserted. 'a\0' becomes 'a\0\0' when inserted. Both inserted values remain unchanged for retrievals.

For VARBINARY, there is no padding for inserts and no bytes are stripped for retrievals. All bytes are significant in comparisons, including ORDER BY and DISTINCT operations. 0x00 and space differ in comparisons, with 0x00 sorting before space.

For those cases where trailing pad bytes are stripped or comparisons ignore them, if a column has an index that requires unique values, inserting values into the column that differ only in number of trailing pad bytes results in a duplicate-key error. For example, if a table contains 'a', an attempt to store 'a\0' causes a duplicate-key error.

You should consider the preceding padding and stripping characteristics carefully if you plan to use the BINARY data type for storing binary data and you require that the value retrieved be exactly the same as the value stored. The following example illustrates how 0x00-padding of BINARY values affects column value comparisons:

```
mysql> CREATE TABLE t (c BINARY(3));
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET c = 'a';
Query OK, 1 row affected (0.01 sec)

mysql> SELECT HEX(c), c = 'a', c = 'a\0\0' from t;
+--------+---------+-------------+
| HEX(c) | c = 'a' | c = 'a\0\0' |
|--------+---------+-------------+
| 610000 |       0 |           1 |
+--------+---------+-------------+
1 row in set (0.09 sec)
```

If the value retrieved must be the same as the value specified for storage with no padding, it might be preferable to use VARBINARY or one of the BLOB data types instead.

```
Note
Within the mysql client, binary strings display using hexadecimal notation, depending on the value of the --binary-as-hex. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.
```

11.3.4 The BLOB and TEXT Types

A BLOB is a binary large object that can hold a variable amount of data. The four BLOB types are TINYBLOB, BLOB, MEDIUMBLOB, and LONGBLOB. These differ only in the maximum length of the values they can hold. The four TEXT types are TINYTEXT, TEXT, MEDIUMTEXT, and LONGTEXT. These correspond to the four BLOB types and have the same maximum lengths and storage requirements. See Section 11.7, “Data Type Storage Requirements”.

BLOB values are treated as binary strings (byte strings). They have the binary character set and collation, and comparison and sorting are based on the numeric values of the bytes in column values. TEXT values
The BLOB and TEXT Types

are treated as nonbinary strings (character strings). They have a character set other than binary, and values are sorted and compared based on the collation of the character set.

If strict SQL mode is not enabled and you assign a value to a BLOB or TEXT column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For truncation of nonspace characters, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See Section 5.1.11, “Server SQL Modes”.

Truncation of excess trailing spaces from values to be inserted into TEXT columns always generates a warning, regardless of the SQL mode.

For TEXT and BLOB columns, there is no padding on insert and no bytes are stripped on select.

If a TEXT column is indexed, index entry comparisons are space-padded at the end. This means that, if the index requires unique values, duplicate-key errors occur for values that differ only in the number of trailing spaces. For example, if a table contains 'a ', an attempt to store 'a ' causes a duplicate-key error. This is not true for BLOB columns.

In most respects, you can regard a BLOB column as a VARBINARY column that can be as large as you like. Similarly, you can regard a TEXT column as a VARCHAR column. BLOB and TEXT differ from VARBINARY and VARCHAR in the following ways:

• For indexes on BLOB and TEXT columns, you must specify an index prefix length. For CHAR and VARCHAR, a prefix length is optional. See Section 8.3.5, “Column Indexes”.

• BLOB and TEXT columns cannot have DEFAULT values.

If you use the BINARY attribute with a TEXT data type, the column is assigned the binary (_bin) collation of the column character set.

LONG and LONG VARCHAR map to the MEDIUMTEXT data type. This is a compatibility feature.

MySQL Connector/ODBC defines BLOB values as LONGVARBINARY and TEXT values as LONGVARCHAR.

Because BLOB and TEXT values can be extremely long, you might encounter some constraints in using them:

• Only the first max_sort_length bytes of the column are used when sorting. The default value of max_sort_length is 1024. You can make more bytes significant in sorting or grouping by increasing the value of max_sort_length at server startup or runtime. Any client can change the value of its session max_sort_length variable:

  mysql> SET max_sort_length = 2000;
  mysql> SELECT id, comment FROM t
  -> ORDER BY comment;

• Instances of BLOB or TEXT columns in the result of a query that is processed using a temporary table causes the server to use a table on disk rather than in memory because the MEMORY storage engine does not support those data types (see Section 8.4.4, “Internal Temporary Table Use in MySQL”). Use of disk incurs a performance penalty, so include BLOB or TEXT columns in the query result only if they are really needed. For example, avoid using SELECT *

• The maximum size of a BLOB or TEXT object is determined by its type, but the largest value you actually can transmit between the client and server is determined by the amount of available memory and the size of the communications buffers. You can change the message buffer size by changing the value of the max_allowed_packet variable, but you must do so for both the server and your client program. For example, both mysql and mysqldump enable you to change the client-side max_allowed_packet value. See Section 5.1.1, “Configuring the Server”, Section 4.5.1, “mysql — The MySQL Command-
The ENUM Type

Line Client”, and Section 4.5.4, “mysqldump — A Database Backup Program”. You may also want to
compare the packet sizes and the size of the data objects you are storing with the storage requirements,
see Section 11.7, “Data Type Storage Requirements”

Each BLOB or TEXT value is represented internally by a separately allocated object. This is in contrast to all
other data types, for which storage is allocated once per column when the table is opened.

In some cases, it may be desirable to store binary data such as media files in BLOB or TEXT columns.
You may find MySQL’s string handling functions useful for working with such data. See Section 12.8,
“String Functions and Operators”. For security and other reasons, it is usually preferable to do so using
application code rather than giving application users the FILE privilege. You can discuss specifics for
various languages and platforms in the MySQL Forums (http://forums.mysql.com/).

Note

Within the mysql client, binary strings display using hexadecimal notation,
depending on the value of the --binary-as-hex. For more information about that
option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

11.3.5 The ENUM Type

An ENUM is a string object with a value chosen from a list of permitted values that are enumerated explicitly
in the column specification at table creation time.

See Section 11.3.1, “String Data Type Syntax” for ENUM type syntax and length limits.

The ENUM type has these advantages:

• Compact data storage in situations where a column has a limited set of possible values. The strings you
  specify as input values are automatically encoded as numbers. See Section 11.7, “Data Type Storage
  Requirements” for storage requirements for the ENUM type.

• Readable queries and output. The numbers are translated back to the corresponding strings in query
  results.

and these potential issues to consider:

• If you make enumeration values that look like numbers, it is easy to mix up the literal values with their
  internal index numbers, as explained in Enumeration Limitations.

• Using ENUM columns in ORDER BY clauses requires extra care, as explained in Enumeration Sorting.

• Creating and Using ENUM Columns

• Index Values for Enumeration Literals

• Handling of Enumeration Literals

• Empty or NULL Enumeration Values

• Enumeration Sorting

• Enumeration Limitations

Creating and Using ENUM Columns

An enumeration value must be a quoted string literal. For example, you can create a table with an ENUM
column like this:
CREATE TABLE shirts (  
    name VARCHAR(40),  
    size ENUM('x-small', 'small', 'medium', 'large', 'x-large')  
);

INSERT INTO shirts (name, size) VALUES ('dress shirt','large'), ('t-shirt','medium'), ('polo shirt','small');

SELECT name, size FROM shirts WHERE size = 'medium';

<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
</tr>
</thead>
<tbody>
<tr>
<td>t-shirt</td>
<td>medium</td>
</tr>
</tbody>
</table>

UPDATE shirts SET size = 'small' WHERE size = 'large';

COMMIT;

Inserting 1 million rows into this table with a value of 'medium' would require 1 million bytes of storage, as opposed to 6 million bytes if you stored the actual string 'medium' in a VARCHAR column.

Index Values for Enumeration Literals

Each enumeration value has an index:

- The elements listed in the column specification are assigned index numbers, beginning with 1.
- The index value of the empty string error value is 0. This means that you can use the following SELECT statement to find rows into which invalid ENUM values were assigned:

  mysql> SELECT * FROM tbl_name WHERE enum_col=0;

- The index of the NULL value is NULL.
- The term “index” here refers to a position within the list of enumeration values. It has nothing to do with table indexes.

For example, a column specified as ENUM('Mercury', 'Venus', 'Earth') can have any of the values shown here. The index of each value is also shown.

<table>
<thead>
<tr>
<th>Value</th>
<th>Index</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>'</td>
<td>0</td>
</tr>
<tr>
<td>'Mercury'</td>
<td>1</td>
</tr>
<tr>
<td>'Venus'</td>
<td>2</td>
</tr>
<tr>
<td>'Earth'</td>
<td>3</td>
</tr>
</tbody>
</table>

An ENUM column can have a maximum of 65,535 distinct elements.

If you retrieve an ENUM value in a numeric context, the column value's index is returned. For example, you can retrieve numeric values from an ENUM column like this:

  mysql> SELECT enum_col+0 FROM tbl_name;

Functions such as SUM() or AVG() that expect a numeric argument cast the argument to a number if necessary. For ENUM values, the index number is used in the calculation.

Handling of Enumeration Literals

Trailing spaces are automatically deleted from ENUM member values in the table definition when a table is created.
The ENUM Type

When retrieved, values stored into an ENUM column are displayed using the lettercase that was used in the column definition. Note that ENUM columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase is taken into account when assigning values to the column.

If you store a number into an ENUM column, the number is treated as the index into the possible values, and the value stored is the enumeration member with that index. (However, this does not work with LOAD DATA, which treats all input as strings.) If the numeric value is quoted, it is still interpreted as an index if there is no matching string in the list of enumeration values. For these reasons, it is not advisable to define an ENUM column with enumeration values that look like numbers, because this can easily become confusing. For example, the following column has enumeration members with string values of '0', '1', and '2', but numeric index values of 1, 2, and 3:

```sql
numbers ENUM('0','1','2')
```

If you store 2, it is interpreted as an index value, and becomes '1' (the value with index 2). If you store '2', it matches an enumeration value, so it is stored as '2'. If you store '3', it does not match any enumeration value, so it is treated as an index and becomes '2' (the value with index 3).

```sql
mysql> INSERT INTO t (numbers) VALUES(2),('2'),('3');
mysql> SELECT * FROM t;
+---------+
| numbers |
+---------+
| 1       |
| 2       |
| 2       |
+---------+
```

To determine all possible values for an ENUM column, use SHOW COLUMNS FROM tbl_name LIKE 'enum_col' and parse the ENUM definition in the Type column of the output.

In the C API, ENUM values are returned as strings. For information about using result set metadata to distinguish them from other strings, see C API Basic Data Structures.

Empty or NULL Enumeration Values

An enumeration value can also be the empty string ('') or NULL under certain circumstances:

- If you insert an invalid value into an ENUM (that is, a string not present in the list of permitted values), the empty string is inserted instead as a special error value. This string can be distinguished from a “normal” empty string by the fact that this string has the numeric value 0. See Index Values for Enumeration Literals for details about the numeric indexes for the enumeration values.

  If strict SQL mode is enabled, attempts to insert invalid ENUM values result in an error.

- If an ENUM column is declared to permit NULL, the NULL value is a valid value for the column, and the default value is NULL. If an ENUM column is declared NOT NULL, its default value is the first element of the list of permitted values.

Enumeration Sorting

ENUM values are sorted based on their index numbers, which depend on the order in which the enumeration members were listed in the column specification. For example, 'b' sorts before 'a' for ENUM('b', 'a'). The empty string sorts before nonempty strings, and NULL values sort before all other enumeration values.

To prevent unexpected results when using the ORDER BY clause on an ENUM column, use one of these techniques:
• Specify the `ENUM` list in alphabetic order.
• Make sure that the column is sorted lexically rather than by index number by coding `ORDER BY CAST(col AS CHAR)` or `ORDER BY CONCAT(col)`.

Enumeration Limitations

An enumeration value cannot be an expression, even one that evaluates to a string value.

For example, this `CREATE TABLE` statement does *not* work because the `CONCAT` function cannot be used to construct an enumeration value:

```sql
CREATE TABLE sizes (  
    size ENUM('small', CONCAT('med','ium'), 'large')
);
```

You also cannot employ a user variable as an enumeration value. This pair of statements do *not* work:

```sql
SET @mysize = 'medium';
CREATE TABLE sizes (  
    size ENUM('small', @mysize, 'large')
);
```

We strongly recommend that you do *not* use numbers as enumeration values, because it does not save on storage over the appropriate `TINYINT` or `SMALLINT` type, and it is easy to mix up the strings and the underlying number values (which might not be the same) if you quote the `ENUM` values incorrectly. If you do use a number as an enumeration value, always enclose it in quotation marks. If the quotation marks are omitted, the number is regarded as an index. See Handling of Enumeration Literals to see how even a quoted number could be mistakenly used as a numeric index value.

Duplicate values in the definition cause a warning, or an error if strict SQL mode is enabled.

11.3.6 The SET Type

A `SET` is a string object that can have zero or more values, each of which must be chosen from a list of permitted values specified when the table is created. `SET` column values that consist of multiple set members are specified with members separated by commas (,). A consequence of this is that `SET` member values should not themselves contain commas.

For example, a column specified as `SET('one', 'two') NOT NULL` can have any of these values:

```
''  
'one'  
'two'  
'one,two'
```

A `SET` column can have a maximum of 64 distinct members.

Duplicate values in the definition cause a warning, or an error if strict SQL mode is enabled.

Trailing spaces are automatically deleted from `SET` member values in the table definition when a table is created.

See String Type Storage Requirements for storage requirements for the `SET` type.

See Section 11.3.1, “String Data Type Syntax” for `SET` type syntax and length limits.
When retrieved, values stored in a `SET` column are displayed using the lettercase that was used in the column definition. Note that `SET` columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase is taken into account when assigning values to the column.

MySQL stores `SET` values numerically, with the low-order bit of the stored value corresponding to the first set member. If you retrieve a `SET` value in a numeric context, the value retrieved has bits set corresponding to the set members that make up the column value. For example, you can retrieve numeric values from a `SET` column like this:

```
mysql> SELECT set_col+0 FROM tbl_name;
```

If a number is stored into a `SET` column, the bits that are set in the binary representation of the number determine the set members in the column value. For a column specified as `SET('a', 'b', 'c', 'd')`, the members have the following decimal and binary values.

<table>
<thead>
<tr>
<th>SET Member</th>
<th>Decimal Value</th>
<th>Binary Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'a'</td>
<td>1</td>
<td>0001</td>
</tr>
<tr>
<td>'b'</td>
<td>2</td>
<td>0010</td>
</tr>
<tr>
<td>'c'</td>
<td>4</td>
<td>0100</td>
</tr>
<tr>
<td>'d'</td>
<td>8</td>
<td>1000</td>
</tr>
</tbody>
</table>

If you assign a value of 9 to this column, that is 1001 in binary, so the first and fourth `SET` value members 'a' and 'd' are selected and the resulting value is 'a,d'.

For a value containing more than one `SET` element, it does not matter what order the elements are listed in when you insert the value. It also does not matter how many times a given element is listed in the value. When the value is retrieved later, each element in the value appears once, with elements listed according to the order in which they were specified at table creation time. Suppose that a column is specified as `SET('a','b','c','d')`:

```
mysql> CREATE TABLE myset (col SET('a', 'b', 'c', 'd'));
```

If you insert the values 'a,d', 'd,a', 'a,d,d', 'a,d,a', and 'd,a,d':

```
mysql> INSERT INTO myset (col) VALUES
                -> ('a,d'), ('d,a'), ('a,d,a'), ('a,d,d'), ('d,a,d');
```

Then all these values appear as 'a,d' when retrieved:

```
mysql> SELECT col FROM myset;
```

If you set a `SET` column to an unsupported value, the value is ignored and a warning is issued:

```
mysql> INSERT INTO myset (col) VALUES ('a,d,d,s');
```

```
mysql> SHOW WARNINGS;
```
If strict SQL mode is enabled, attempts to insert invalid SET values result in an error.

SET values are sorted numerically. NULL values sort before non-NULL SET values.

Functions such as SUM() or AVG() that expect a numeric argument cast the argument to a number if necessary. For SET values, the cast operation causes the numeric value to be used.

Normally, you search for SET values using the FIND_IN_SET() function or the LIKE operator:

```sql
mysql> SELECT * FROM myset;
+------+
| col  |
+------+
| a,d  |
| a,d  |
| a,d  |
| a,d  |
| a,d  |
| a,d  |
+------+
6 rows in set (0.01 sec)
```

The first statement finds rows where `set_col` contains the `value` set member. The second is similar, but not the same: It finds rows where `set_col` contains `value` anywhere, even as a substring of another set member.

The following statements also are permitted:

```sql
mysql> SELECT * FROM tbl_name WHERE set_col & 1;
mysql> SELECT * FROM tbl_name WHERE set_col = 'val1,val2';
```

The first of these statements looks for values containing the first set member. The second looks for an exact match. Be careful with comparisons of the second type. Comparing set values to 'val1,val2' returns different results than comparing values to 'val2,val1'. You should specify the values in the same order they are listed in the column definition.

To determine all possible values for a SET column, use SHOW COLUMNS FROM `tbl_name` LIKE `set_col` and parse the SET definition in the Type column of the output.

In the C API, SET values are returned as strings. For information about using result set metadata to distinguish them from other strings, see C API Basic Data Structures.

### 11.4 Spatial Data Types

The Open Geospatial Consortium (OGC) is an international consortium of more than 250 companies, agencies, and universities participating in the development of publicly available conceptual solutions that can be useful with all kinds of applications that manage spatial data.

The Open Geospatial Consortium publishes the OpenGIS® Implementation Standard for Geographic information - Simple feature access - Part 2: SQL option, a document that proposes several conceptual...
ways for extending an SQL RDBMS to support spatial data. This specification is available from the OGC website at http://www.opengeospatial.org/standards/sfs.

Following the OGC specification, MySQL implements spatial extensions as a subset of the SQL with Geometry Types environment. This term refers to an SQL environment that has been extended with a set of geometry types. A geometry-valued SQL column is implemented as a column that has a geometry type. The specification describes a set of SQL geometry types, as well as functions on those types to create and analyze geometry values.

MySQL spatial extensions enable the generation, storage, and analysis of geographic features:

- Data types for representing spatial values
- Functions for manipulating spatial values
- Spatial indexing for improved access times to spatial columns

The spatial data types and functions are available for MyISAM, InnoDB, NDB, and ARCHIVE tables. For indexing spatial columns, MyISAM and InnoDB support both SPATIAL and non-SPATIAL indexes. The other storage engines support non-SPATIAL indexes, as described in Section 13.1.15, “CREATE INDEX Statement”.

A geographic feature is anything in the world that has a location. A feature can be:

- An entity. For example, a mountain, a pond, a city.
- A space. For example, town district, the tropics.
- A definable location. For example, a crossroad, as a particular place where two streets intersect.

Some documents use the term geospatial feature to refer to geographic features.

Geometry is another word that denotes a geographic feature. Originally the word geometry meant measurement of the earth. Another meaning comes from cartography, referring to the geometric features that cartographers use to map the world.

The discussion here considers these terms synonymous: geographic feature, geospatial feature, feature, or geometry. The term most commonly used is geometry, defined as a point or an aggregate of points representing anything in the world that has a location.

The following material covers these topics:

- The spatial data types implemented in MySQL model
- The basis of the spatial extensions in the OpenGIS geometry model
- Data formats for representing spatial data
- How to use spatial data in MySQL
- Use of indexing for spatial data
- MySQL differences from the OpenGIS specification

For information about functions that operate on spatial data, see Section 12.16, “Spatial Analysis Functions”.
Additional Resources

These standards are important for the MySQL implementation of spatial operations:

• SQL/MM Part 3: Spatial.

• The grammar for spatial reference system (SRS) definitions is based on the grammar defined in OpenGIS Implementation Specification: Coordinate Transformation Services, Revision 1.00, OGC 01-009, January 12, 2001, Section 7.2. This specification is available at http://www.opengeospatial.org/standards/ct. For differences from that specification in SRS definitions as implemented in MySQL, see Section 13.1.19, “CREATE SPATIAL REFERENCE SYSTEM Statement”.

If you have questions or concerns about the use of the spatial extensions to MySQL, you can discuss them in the GIS forum: https://forums.mysql.com/list.php?23.

11.4.1 Spatial Data Types

MySQL has spatial data types that correspond to OpenGIS classes. The basis for these types is described in Section 11.4.2, “The OpenGIS Geometry Model”.

Some spatial data types hold single geometry values:

• GEOMETRY
• POINT
• LINestring
• POLYGON

GEOMETRY can store geometry values of any type. The other single-value types (POINT, LINestring, and POLYGON) restrict their values to a particular geometry type.

The other spatial data types hold collections of values:

• MULTIPOINT
• MULTILINestring
• MULTIPOLYGON
• GEOMETRYCOLLECTION

GEOMETRYCOLLECTION can store a collection of objects of any type. The other collection types (MULTIPOINT, MULTILINestring, and MULTIPOLYGON) restrict collection members to those having a particular geometry type.

Example: To create a table named geom that has a column named g that can store values of any geometry type, use this statement:
Columns with a spatial data type can have an `SRID` attribute, to explicitly indicate the spatial reference system (SRS) for values stored in the column. For example:

```sql
CREATE TABLE geom (p POINT SRID 0,
g GEOMETRY NOT NULL SRID 4326);
```

`SPATIAL` indexes can be created on spatial columns if they are `NOT NULL` and have a specific SRID, so if you plan to index the column, declare it with the `NOT NULL` and `SRID` attributes:

```sql
CREATE TABLE geom (g GEOMETRY NOT NULL SRID 4326);
```

`InnoDB` tables permit `SRID` values for Cartesian and geographic SRSs. `MyISAM` tables permit `SRID` values for Cartesian SRSs. The `SRID` attribute makes a spatial column SRID-restricted, which has these implications:

- The column can contain only values with the given SRID. Attempts to insert values with a different SRID produce an error.
- The optimizer can use `SPATIAL` indexes on the column. See Section 8.3.3, “SPATIAL Index Optimization”.

Spatial columns with no `SRID` attribute are not SRID-restricted and accept values with any SRID. However, the optimizer cannot use `SPATIAL` indexes on them until the column definition is modified to include an `SRID` attribute, which may require that the column contents first be modified so that all values have the same SRID.

For other examples showing how to use spatial data types in MySQL, see Section 11.4.6, “Creating Spatial Columns”. For information about spatial reference systems, see Section 11.4.5, “Spatial Reference System Support”.

### 11.4.2 The OpenGIS Geometry Model

The set of geometry types proposed by OGC's SQL with Geometry Types environment is based on the OpenGIS Geometry Model. In this model, each geometric object has the following general properties:

- It is associated with a spatial reference system, which describes the coordinate space in which the object is defined.
- It belongs to some geometry class.

#### 11.4.2.1 The Geometry Class Hierarchy

The geometry classes define a hierarchy as follows:

- `Geometry` (noninstantiable)
  - `Point` (instantiable)
  - `Curve` (noninstantiable)
    - `LineString` (instantiable)
    - `Line`
• LinearRing
• Surface (noninstantiable)
• Polygon (instantiable)
• GeometryCollection (instantiable)
• MultiPoint (instantiable)
• MultiCurve (noninstantiable)
  • MultiLineString (instantiable)
• MultiSurface (noninstantiable)
• MultiPolygon (instantiable)

It is not possible to create objects in noninstantiable classes. It is possible to create objects in instantiable classes. All classes have properties, and instantiable classes may also have assertions (rules that define valid class instances).

Geometry is the base class. It is an abstract class. The instantiable subclasses of Geometry are restricted to zero-, one-, and two-dimensional geometric objects that exist in two-dimensional coordinate space. All instantiable geometry classes are defined so that valid instances of a geometry class are topologically closed (that is, all defined geometries include their boundary).

The base Geometry class has subclasses for Point, Curve, Surface, and GeometryCollection:

• Point represents zero-dimensional objects.

• Curve represents one-dimensional objects, and has subclass LineString, with sub-subclasses Line and LinearRing.

• Surface is designed for two-dimensional objects and has subclass Polygon.

• GeometryCollection has specialized zero-, one-, and two-dimensional collection classes named MultiPoint, MultiLineString, and MultiPolygon for modeling geometries corresponding to collections of Points, LineStrings, and Polygons, respectively. MultiCurve and MultiSurface are introduced as abstract superclasses that generalize the collection interfaces to handle Curves and Surfaces.

Geometry, Curve, Surface, MultiCurve, and MultiSurface are defined as noninstantiable classes. They define a common set of methods for their subclasses and are included for extensibility.

Point, LineString, Polygon, GeometryCollection, MultiPoint, MultiLineString, and MultiPolygon are instantiable classes.

11.4.2.2 Geometry Class

Geometry is the root class of the hierarchy. It is a noninstantiable class but has a number of properties, described in the following list, that are common to all geometry values created from any of the Geometry subclasses. Particular subclasses have their own specific properties, described later.

Geometry Properties

A geometry value has the following properties:
The OpenGIS Geometry Model

- Its **type**. Each geometry belongs to one of the instantiable classes in the hierarchy.

- Its **SRID**, or spatial reference identifier. This value identifies the geometry's associated spatial reference system that describes the coordinate space in which the geometry object is defined.

  In MySQL, the SRID value is an integer associated with the geometry value. The maximum usable SRID value is $2^{32} - 1$. If a larger value is given, only the lower 32 bits are used.

  SRID 0 represents an infinite flat Cartesian plane with no units assigned to its axes. To ensure SRID 0 behavior, create geometry values using SRID 0. SRID 0 is the default for new geometry values if no SRID is specified.

  For computations on multiple geometry values, all values must have the same SRID or an error occurs.

- Its **coordinates** in its spatial reference system, represented as double-precision (8-byte) numbers.
  All nonempty geometries include at least one pair of (X,Y) coordinates. Empty geometries contain no coordinates.

  Coordinates are related to the SRID. For example, in different coordinate systems, the distance between two objects may differ even when objects have the same coordinates, because the distance on the planar coordinate system and the distance on the geodetic system (coordinates on the Earth's surface) are different things.

- Its **interior**, **boundary**, and **exterior**.

  Every geometry occupies some position in space. The exterior of a geometry is all space not occupied by the geometry. The interior is the space occupied by the geometry. The boundary is the interface between the geometry's interior and exterior.

- Its **MBR** (minimum bounding rectangle), or envelope. This is the bounding geometry, formed by the minimum and maximum (X,Y) coordinates:

  ```
  (MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY)
  ```

- Whether the value is **simple** or **nonsimple**. Geometry values of types (LineString, MultiPoint, MultiLineString) are either simple or nonsimple. Each type determines its own assertions for being simple or nonsimple.

- Whether the value is **closed** or **not closed**. Geometry values of types (LineString, MultiString) are either closed or not closed. Each type determines its own assertions for being closed or not closed.

- Whether the value is **empty** or **nonempty**. A geometry is empty if it does not have any points. Exterior, interior, and boundary of an empty geometry are not defined (that is, they are represented by a NULL value). An empty geometry is defined to be always simple and has an area of 0.

- Its **dimension**. A geometry can have a dimension of −1, 0, 1, or 2:

  - −1 for an empty geometry.
  - 0 for a geometry with no length and no area.
  - 1 for a geometry with nonzero length and zero area.
  - 2 for a geometry with nonzero area.

  *Point* objects have a dimension of zero. *LineString* objects have a dimension of 1. *Polygon* objects have a dimension of 2. The dimensions of *MultiPoint*, *MultiLineString*, and *MultiPolygon* objects are the same as the dimensions of the elements they consist of.
11.4.2.3 Point Class

A Point is a geometry that represents a single location in coordinate space.

Point Examples
- Imagine a large-scale map of the world with many cities. A Point object could represent each city.
- On a city map, a Point object could represent a bus stop.

Point Properties
- X-coordinate value.
- Y-coordinate value.
- Point is defined as a zero-dimensional geometry.
- The boundary of a Point is the empty set.

11.4.2.4 Curve Class

A Curve is a one-dimensional geometry, usually represented by a sequence of points. Particular subclasses of Curve define the type of interpolation between points. Curve is a noninstantiable class.

Curve Properties
- A Curve has the coordinates of its points.
- A Curve is defined as a one-dimensional geometry.
- A Curve is simple if it does not pass through the same point twice, with the exception that a curve can still be simple if the start and end points are the same.
- A Curve is closed if its start point is equal to its endpoint.
- The boundary of a closed Curve is empty.
- The boundary of a nonclosed Curve consists of its two endpoints.
- A Curve that is simple and closed is a LinearRing.

11.4.2.5 LineString Class

A LineString is a Curve with linear interpolation between points.

LineString Examples
- On a world map, LineString objects could represent rivers.
- In a city map, LineString objects could represent streets.

LineString Properties
- A LineString has coordinates of segments, defined by each consecutive pair of points.
- A LineString is a Line if it consists of exactly two points.
- A LineString is a LinearRing if it is both closed and simple.
11.4.2.6 Surface Class

A **Surface** is a two-dimensional geometry. It is a noninstantiable class. Its only instantiable subclass is **Polygon**.

**Surface Properties**

- A **Surface** is defined as a two-dimensional geometry.
- The OpenGIS specification defines a simple **Surface** as a geometry that consists of a single “patch” that is associated with a single exterior boundary and zero or more interior boundaries.
- The boundary of a simple **Surface** is the set of closed curves corresponding to its exterior and interior boundaries.

11.4.2.7 Polygon Class

A **Polygon** is a planar **Surface** representing a multisided geometry. It is defined by a single exterior boundary and zero or more interior boundaries, where each interior boundary defines a hole in the **Polygon**.

**Polygon Examples**

- On a region map, **Polygon** objects could represent forests, districts, and so on.

**Polygon Assertions**

- The boundary of a **Polygon** consists of a set of **LinearRing** objects (that is, **LineString** objects that are both simple and closed) that make up its exterior and interior boundaries.
- A **Polygon** has no rings that cross. The rings in the boundary of a **Polygon** may intersect at a **Point**, but only as a tangent.
- A **Polygon** has no lines, spikes, or punctures.
- A **Polygon** has an interior that is a connected point set.
- A **Polygon** may have holes. The exterior of a **Polygon** with holes is not connected. Each hole defines a connected component of the exterior.

The preceding assertions make a **Polygon** a simple geometry.

11.4.2.8 GeometryCollection Class

A **GeomCollection** is a geometry that is a collection of zero or more geometries of any class.

**GeomCollection** and **GeometryCollection** are synonymous, with **GeomCollection** the preferred type name.

All the elements in a geometry collection must be in the same spatial reference system (that is, in the same coordinate system). There are no other constraints on the elements of a geometry collection, although the subclasses of **GeomCollection** described in the following sections may restrict membership. Restrictions may be based on:

- Element type (for example, a **MultiPoint** may contain only **Point** elements)
- Dimension
• Constraints on the degree of spatial overlap between elements

11.4.2.9 MultiPoint Class

A **MultiPoint** is a geometry collection composed of **Point** elements. The points are not connected or ordered in any way.

**MultiPoint Examples**

• On a world map, a **MultiPoint** could represent a chain of small islands.
• On a city map, a **MultiPoint** could represent the outlets for a ticket office.

**MultiPoint Properties**

• A **MultiPoint** is a zero-dimensional geometry.
• A **MultiPoint** is simple if no two of its **Point** values are equal (have identical coordinate values).
• The boundary of a **MultiPoint** is the empty set.

11.4.2.10 MultiCurve Class

A **MultiCurve** is a geometry collection composed of **Curve** elements. **MultiCurve** is a noninstantiable class.

**MultiCurve Properties**

• A **MultiCurve** is a one-dimensional geometry.
• A **MultiCurve** is simple if and only if all of its elements are simple; the only intersections between any two elements occur at points that are on the boundaries of both elements.
• A **MultiCurve** boundary is obtained by applying the “mod 2 union rule” (also known as the “odd-even rule”): A point is in the boundary of a **MultiCurve** if it is in the boundaries of an odd number of **Curve** elements.
• A **MultiCurve** is closed if all of its elements are closed.
• The boundary of a closed **MultiCurve** is always empty.

11.4.2.11 MultiLineString Class

A **MultiLineString** is a **MultiCurve** geometry collection composed of **LineString** elements.

**MultiLineString Examples**

• On a region map, a **MultiLineString** could represent a river system or a highway system.

11.4.2.12 MultiSurface Class

A **MultiSurface** is a geometry collection composed of surface elements. **MultiSurface** is a noninstantiable class. Its only instantiable subclass is **MultiPolygon**.

**MultiSurface Assertions**

• Surfaces within a **MultiSurface** have no interiors that intersect.
• Surfaces within a **MultiSurface** have boundaries that intersect at most at a finite number of points.

### 11.4.2.13 MultiPolygon Class

A **MultiPolygon** is a **MultiSurface** object composed of **Polygon** elements.

**MultiPolygon Examples**

• On a region map, a **MultiPolygon** could represent a system of lakes.

**MultiPolygon Assertions**

• A **MultiPolygon** has no two **Polygon** elements with interiors that intersect.

• A **MultiPolygon** has no two **Polygon** elements that cross (crossing is also forbidden by the previous assertion), or that touch at an infinite number of points.

• A **MultiPolygon** may not have cut lines, spikes, or punctures. A **MultiPolygon** is a regular, closed point set.

• A **MultiPolygon** that has more than one **Polygon** has an interior that is not connected. The number of connected components of the interior of a **MultiPolygon** is equal to the number of **Polygon** values in the **MultiPolygon**.

**MultiPolygon Properties**

• A **MultiPolygon** is a two-dimensional geometry.

• A **MultiPolygon** boundary is a set of closed curves (**LineString** values) corresponding to the boundaries of its **Polygon** elements.

• Each **Curve** in the boundary of the **MultiPolygon** is in the boundary of exactly one **Polygon** element.

• Every **Curve** in the boundary of an **Polygon** element is in the boundary of the **MultiPolygon**.

### 11.4.3 Supported Spatial Data Formats

Two standard spatial data formats are used to represent geometry objects in queries:

• Well-Known Text (WKT) format

• Well-Known Binary (WKB) format

Internally, MySQL stores geometry values in a format that is not identical to either WKT or WKB format. (Internal format is like WKB but with an initial 4 bytes to indicate the SRID.)

There are functions available to convert between different data formats; see Section 12.16.6, "Geometry Format Conversion Functions".

The following sections describe the spatial data formats MySQL uses:

• Well-Known Text (WKT) Format

• Well-Known Binary (WKB) Format

• Internal Geometry Storage Format

**Well-Known Text (WKT) Format**
The Well-Known Text (WKT) representation of geometry values is designed for exchanging geometry data in ASCII form. The OpenGIS specification provides a Backus-Naur grammar that specifies the formal production rules for writing WKT values (see Section 11.4, “Spatial Data Types”).

Examples of WKT representations of geometry objects:

- A **Point**:
  
  ```
  POINT(15 20)
  ```

  The point coordinates are specified with no separating comma. This differs from the syntax for the SQL `Point()` function, which requires a comma between the coordinates. Take care to use the syntax appropriate to the context of a given spatial operation. For example, the following statements both use `ST_X()` to extract the X-coordinate from a `Point` object. The first produces the object directly using the `Point()` function. The second uses a WKT representation converted to a `Point` with `ST_GeomFromText()`.

  ```
  mysql> SELECT ST_X(Point(15, 20));
  +---------------------+
  | ST_X(POINT(15, 20)) |
  +---------------------+
  |                  15 |
  +---------------------+
  mysql> SELECT ST_X(ST_GeomFromText('POINT(15 20)'));
  +---------------------------------------+
  | ST_X(ST_GeomFromText('POINT(15 20)')) |
  +---------------------------------------+
  |                                    15 |
  +---------------------------------------+
  ```

- A **LineString** with four points:
  
  ```
  LINESTRING(0 0, 10 10, 20 25, 50 60)
  ```

  The point coordinate pairs are separated by commas.

- A **Polygon** with one exterior ring and one interior ring:
  
  ```
  POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))
  ```

- A **MultiPoint** with three **Point** values:
  
  ```
  MULTIPOLYGON((0 0, 20 20, 60 60))
  ```

Spatial functions such as `ST_MPointFromText()` and `ST_GeomFromText()` that accept WKT-format representations of `MultiPoint` values permit individual points within values to be surrounded by parentheses. For example, both of the following function calls are valid:

- `ST_MPointFromText('MULTIPOINT (1 1, 2 2, 3 3)')`
- `ST_MPointFromText('MULTIPOINT ((1 1), (2 2), (3 3))')`

- A **MultiLineString** with two **LineString** values:
  
  ```
  MULTILINESTRING((10 10, 20 20), (15 15, 30 15))
  ```

- A **MultiPolygon** with two **Polygon** values:
  
  ```
  MULTIPOLYGON(((0 0,10 0,10,0 10,0 0)),((5 5,7 5,7 7,5 7, 5 5)))
  ```

- A **GeometryCollection** consisting of two **Point** values and one **LineString**:

  ```

  ```
Well-Known Binary (WKB) Format

The Well-Known Binary (WKB) representation of geometric values is used for exchanging geometry data as binary streams represented by BLOB values containing geometric WKB information. This format is defined by the OpenGIS specification (see Section 11.4, “Spatial Data Types”). It is also defined in the ISO SQL/MM Part 3: Spatial standard.

WKB uses 1-byte unsigned integers, 4-byte unsigned integers, and 8-byte double-precision numbers (IEEE 754 format). A byte is eight bits.

For example, a WKB value that corresponds to POINT(1 -1) consists of this sequence of 21 bytes, each represented by two hexadecimal digits:

```
0101000000000000000000F03F000000000000F0BF
```

The sequence consists of the components shown in the following table.

<table>
<thead>
<tr>
<th>Component</th>
<th>Size</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Byte order</td>
<td>1 byte</td>
<td>01</td>
</tr>
<tr>
<td>WKB type</td>
<td>4 bytes</td>
<td>01000000</td>
</tr>
<tr>
<td>X coordinate</td>
<td>8 bytes</td>
<td>0000000000F03F0000000000F0BF</td>
</tr>
<tr>
<td>Y coordinate</td>
<td>8 bytes</td>
<td>00000000000F0BF</td>
</tr>
</tbody>
</table>

Component representation is as follows:

- The byte order indicator is either 1 or 0 to signify little-endian or big-endian storage. The little-endian and big-endian byte orders are also known as Network Data Representation (NDR) and External Data Representation (XDR), respectively.

- The WKB type is a code that indicates the geometry type. MySQL uses values from 1 through 7 to indicate Point, LineString, Polygon, MultiPoint, MultiLineString, MultiPolygon, and GeometryCollection.

- A Point value has X and Y coordinates, each represented as a double-precision value.

WKB values for more complex geometry values have more complex data structures, as detailed in the OpenGIS specification.

Internal Geometry Storage Format

MySQL stores geometry values using 4 bytes to indicate the SRID followed by the WKB representation of the value. For a description of WKB format, see Well-Known Binary (WKB) Format.

For the WKB part, these MySQL-specific considerations apply:

- The byte-order indicator byte is 1 because MySQL stores geometries as little-endian values.

- MySQL supports geometry types of Point, LineString, Polygon, MultiPoint, MultiLineString, MultiPolygon, and GeometryCollection. Other geometry types are not supported.

- Only GeometryCollection can be empty. Such a value is stored with 0 elements.
Geometry Well-Formedness and Validity

- Polygon rings can be specified both clockwise and counterclockwise. MySQL flips the rings automatically when reading data.

Cartesian coordinates are stored in the length unit of the spatial reference system, with X values in the X coordinates and Y values in the Y coordinates. Axis directions are those specified by the spatial reference system.

Geographic coordinates are stored in the angle unit of the spatial reference system, with longitudes in the X coordinates and latitudes in the Y coordinates. Axis directions and the meridian are those specified by the spatial reference system.

The `LENGTH()` function returns the space in bytes required for value storage. Example:

```sql
mysql> SET @g = ST_GeomFromText('POINT(1 -1)');
mysql> SELECT LENGTH(@g);
+------------+
| LENGTH(@g) |
+------------+
|         25 |
+------------+
mysql> SELECT HEX(@g);
+----------------------------------------------------+
| HEX(@g)                                            |
+----------------------------------------------------+
| 0000000000101000000000000000000000000000000000000F0BF |
+----------------------------------------------------+
```

The value length is 25 bytes, made up of these components (as can be seen from the hexadecimal value):

- 4 bytes for integer SRID (0)
- 1 byte for integer byte order (1 = little-endian)
- 4 bytes for integer type information (1 = `Point`)
- 8 bytes for double-precision X coordinate (1)
- 8 bytes for double-precision Y coordinate (−1)

11.4.4 Geometry Well-Formedness and Validity

For geometry values, MySQL distinguishes between the concepts of syntactically well-formed and geometrically valid.

A geometry is syntactically well-formed if it satisfies conditions such as those in this (nonexhaustive) list:

- Linestrings have at least two points
- Polygons have at least one ring
- Polygon rings are closed (first and last points the same)
- Polygon rings have at least 4 points (minimum polygon is a triangle with first and last points the same)
- Collections are not empty (except `GeometryCollection`)

A geometry is geometrically valid if it is syntactically well-formed and satisfies conditions such as those in this (nonexhaustive) list:

- Polygons are not self-intersecting
• Polygon interior rings are inside the exterior ring
• Multipolygons do not have overlapping polygons

Spatial functions fail if a geometry is not syntactically well-formed. Spatial import functions that parse WKT or WKB values raise an error for attempts to create a geometry that is not syntactically well-formed. Syntactic well-formedness is also checked for attempts to store geometries into tables.

It is permitted to insert, select, and update geometrically invalid geometries, but they must be syntactically well-formed. Due to the computational expense, MySQL does not check explicitly for geometric validity. Spatial computations may detect some cases of invalid geometries and raise an error, but they may also return an undefined result without detecting the invalidity. Applications that require geometrically-valid geometries should check them using the \texttt{ST_IsValid()} function.

### 11.4.5 Spatial Reference System Support

A spatial reference system (SRS) for spatial data is a coordinate-based system for geographic locations.

There are different types of spatial reference systems:

• A projected SRS is a projection of a globe onto a flat surface; that is, a flat map. For example, a light bulb inside a globe that shines on a paper cylinder surrounding the globe projects a map onto the paper. The result is georeferenced: Each point maps to a place on the globe. The coordinate system on that plane is Cartesian using a length unit (meters, feet, and so forth), rather than degrees of longitude and latitude.

The globes in this case are ellipsoids; that is, flattened spheres. Earth is a bit shorter in its North-South axis than its East-West axis, so a slightly flattened sphere is more correct, but perfect spheres permit faster calculations.

• A geographic SRS is a nonprojected SRS representing longitude-latitude (or latitude-longitude) coordinates on an ellipsoid, in any angular unit.

• The SRS denoted in MySQL by SRID 0 represents an infinite flat Cartesian plane with no units assigned to its axes. Unlike projected SRSs, it is not georeferenced and it does not necessarily represent Earth. It is an abstract plane that can be used for anything. SRID 0 is the default SRID for spatial data in MySQL.

MySQL maintains information about available spatial reference systems for spatial data in the data dictionary table \texttt{mysql.st_spatial_reference_systems}, which can store entries for projected and geographic SRSs. This data dictionary table is invisible, but SRS entry contents are available through the \texttt{INFORMATION_SCHEMA.ST_SPATIAL_REFERENCE_SYSTEMS} table, implemented as a view on \texttt{mysql.st_spatial_reference_systems} (see Section 26.3.36, “The \texttt{INFORMATION_SCHEMA.ST_SPATIAL_REFERENCE_SYSTEMS} Table”).

The following example shows what an SRS entry looks like:

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.ST_SPATIAL_REFERENCE_SYSTEMS WHERE SRS_ID = 4326;
```

```
************************************ 1. row ************************************
 SRS_NAME: WGS 84
 SRS_ID: 4326
 ORGANIZATION: EPSG
 ORGANIZATION_COORDSYS_ID: 4326
 DEFINITION: GEOGCS["WGS 84",DATUM["World Geodetic System 1984", SPHEROID["WGS 84",6378137,298.257223563, AUTHORITY["EPSG","7030"]],AUTHORITY["EPSG","6326"]], PRIMEM["Greenwich",0,AUTHORITY["EPSG","8901"]],
```
UNIT["degree",0.017453292519943278, 
AUTHORITY["EPSG","9122"], 
AXIS["Lat",NORTH],AXIS["Long",EAST], 
AUTHORITY["EPSG","4326"]

DESCRIPTION:

This entry describes the SRS used for GPS systems. It has the name (SRS_NAME) WGS 84 and the ID (SRS_ID) 4326, which is the ID used by the European Petroleum Survey Group (EPSG).

SRS definitions in the DEFINITION column are WKT values, represented as specified in the Open Geospatial Consortium document OGC 12-063r5.

SRS_ID values represent the same kind of values as the SRID of geometry values or passed as the SRID argument to spatial functions. SRID 0 (the unitless Cartesian plane) is special. It is always a legal spatial reference system ID and can be used in any computations on spatial data that depend on SRID values.

For computations on multiple geometry values, all values must have the same SRID or an error occurs.

SRS definition parsing occurs on demand when definitions are needed by GIS functions.Parsed definitions are stored in the data dictionary cache to enable reuse and avoid incurring parsing overhead for every statement that needs SRS information.

To enable manipulation of SRS entries stored in the data dictionary, MySQL provides these SQL statements:

• CREATE SPATIAL REFERENCE SYSTEM: See Section 13.1.19, "CREATE SPATIAL REFERENCE SYSTEM Statement". The description for this statement includes additional information about SRS components.

• DROP SPATIAL REFERENCE SYSTEM: See Section 13.1.31, "DROP SPATIAL REFERENCE SYSTEM Statement".

### 11.4.6 Creating Spatial Columns

MySQL provides a standard way of creating spatial columns for geometry types, for example, with CREATE TABLE or ALTER TABLE. Spatial columns are supported for MyISAM, InnoDB, NDB, and ARCHIVE tables. See also the notes about spatial indexes under Section 11.4.10, “Creating Spatial Indexes”.

Columns with a spatial data type can have an SRID attribute, to explicitly indicate the spatial reference system (SRS) for values stored in the column. For implications of an SRID-restricted column, see Section 11.4.1, “Spatial Data Types”.

• Use the CREATE TABLE statement to create a table with a spatial column:

```sql
CREATE TABLE geom (g GEOMETRY);
```

• Use the ALTER TABLE statement to add or drop a spatial column to or from an existing table:

```sql
ALTER TABLE geom ADD pt POINT;
ALTER TABLE geom DROP pt;
```

### 11.4.7 Populating Spatial Columns

After you have created spatial columns, you can populate them with spatial data.

Values should be stored in internal geometry format, but you can convert them to that format from either Well-Known Text (WKT) or Well-Known Binary (WKB) format. The following examples demonstrate how to insert geometry values into a table by converting WKT values to internal geometry format:
• Perform the conversion directly in the `INSERT` statement:

```
INSERT INTO geom VALUES (ST_GeomFromText('POINT(1 1)'));
SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (ST_GeomFromText(@g));
```

• Perform the conversion prior to the `INSERT`:

```
SET @g = ST_GeomFromText('POINT(1 1)');
INSERT INTO geom VALUES (@g);
```

The following examples insert more complex geometries into the table:

```
SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (ST_GeomFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5, 5 5))';
INSERT INTO geom VALUES (ST_GeomFromText(@g));

SET @g = 'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1,2 2,3,4 4))';
INSERT INTO geom VALUES (ST_GeomFromText(@g));
```

The preceding examples use `ST_GeomFromText()` to create geometry values. You can also use type-specific functions:

```
SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (ST_PointFromText(@g));

SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (ST_LineStringFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5, 5 5))';
INSERT INTO geom VALUES (ST_PolygonFromText(@g));

SET @g = 'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1,2 2,3,4 4))';
INSERT INTO geom VALUES (ST_GeomCollFromText(@g));
```

A client application program that wants to use WKB representations of geometry values is responsible for sending correctly formed WKB in queries to the server. There are several ways to satisfy this requirement. For example:

• Inserting a `POINT(1 1)` value with hex literal syntax:

```
INSERT INTO geom VALUES (ST_GeomFromWKB(X'01010000000000000000FFFF03F'));
```

• An ODBC application can send a WKB representation, binding it to a placeholder using an argument of `BLOB` type:

```
INSERT INTO geom VALUES (ST_GeomFromWKB(?))
```

Other programming interfaces may support a similar placeholder mechanism.

• In a C program, you can escape a binary value using `mysql_real_escape_string_quote()` and include the result in a query string that is sent to the server. See `mysql_real_escape_string_quote()`.

### 11.4.8 Fetching Spatial Data

Geometry values stored in a table can be fetched in internal format. You can also convert them to WKT or WKB format.
• Fetching spatial data in internal format:

Fetching geometry values using internal format can be useful in table-to-table transfers:

```sql
CREATE TABLE geom2 (g GEOMETRY) SELECT g FROM geom;
```

• Fetching spatial data in WKT format:

The `ST_AsText()` function converts a geometry from internal format to a WKT string.

```sql
SELECT ST_AsText(g) FROM geom;
```

• Fetching spatial data in WKB format:

The `ST_AsBinary()` function converts a geometry from internal format to a `BLOB` containing the WKB value.

```sql
SELECT ST_AsBinary(g) FROM geom;
```

### 11.4.9 Optimizing Spatial Analysis

For **MyISAM** and **InnoDB** tables, search operations in columns containing spatial data can be optimized using **SPATIAL** indexes. The most typical operations are:

- Point queries that search for all objects that contain a given point
- Region queries that search for all objects that overlap a given region

MySQL uses **R-Trees with quadratic splitting** for **SPATIAL** indexes on spatial columns. A **SPATIAL** index is built using the minimum bounding rectangle (MBR) of a geometry. For most geometries, the MBR is a minimum rectangle that surrounds the geometries. For a horizontal or a vertical linestring, the MBR is a rectangle degenerated into the linestring. For a point, the MBR is a rectangle degenerated into the point.

It is also possible to create normal indexes on spatial columns. In a non-**SPATIAL** index, you must declare a prefix for any spatial column except for **POINT** columns.

**MyISAM** and **InnoDB** support both **SPATIAL** and non-**SPATIAL** indexes. Other storage engines support non-**SPATIAL** indexes, as described in Section 13.1.15, “CREATE INDEX Statement”.

### 11.4.10 Creating Spatial Indexes

For **InnoDB** and **MyISAM** tables, MySQL can create spatial indexes using syntax similar to that for creating regular indexes, but using the **SPATIAL** keyword. Columns in spatial indexes must be declared **NOT NULL**.

The following examples demonstrate how to create spatial indexes:

- With **CREATE TABLE**:

  ```sql
  CREATE TABLE geom (g GEOMETRY NOT NULL SRID 4326, SPATIAL INDEX(g));
  ```

- With **ALTER TABLE**:

  ```sql
  CREATE TABLE geom (g GEOMETRY NOT NULL SRID 4326);
  ALTER TABLE geom ADD SPATIAL INDEX(g);
  ```

- With **CREATE INDEX**:

  ```sql
  CREATE TABLE geom (g GEOMETRY NOT NULL SRID 4326);
  CREATE SPATIAL INDEX g ON geom (g);
  ```
**Using Spatial Indexes**

**SPATIAL INDEX** creates an R-tree index. For storage engines that support nonspatial indexing of spatial columns, the engine creates a B-tree index. A B-tree index on spatial values is useful for exact-value lookups, but not for range scans.

The optimizer can use spatial indexes defined on columns that are SRID-restricted. For more information, see Section 11.4.1, “Spatial Data Types”, and Section 8.3.3, “SPATIAL Index Optimization”.

For more information on indexing spatial columns, see Section 13.1.15, “CREATE INDEX Statement”.

To drop spatial indexes, use `ALTER TABLE` or `DROP INDEX`:

- With `ALTER TABLE`:
  ```sql
  ALTER TABLE geom DROP INDEX g;
  ```
- With `DROP INDEX`:
  ```sql
  DROP INDEX g ON geom;
  ```

Example: Suppose that a table `geom` contains more than 32,000 geometries, which are stored in the column `g` of type `GEOMETRY`. The table also has an `AUTO_INCREMENT` column `fid` for storing object ID values.

```sql
mysql> DESCRIBE geom;
+-------+----------+------+-----+---------+----------------+
| Field | Type     | Null | Key | Default | Extra          |
+-------+----------+------+-----+---------+----------------+
| fid   | int(11)  |      | PRI | NULL    | auto_increment |
| g     | geometry |      |     |         |                |
+-------+----------+------+-----+---------+----------------+
2 rows in set (0.00 sec)
```

```sql
mysql> SELECT COUNT(*) FROM geom;
+----------+
| count(*) |
+----------+
|    32376 |
+----------+
1 row in set (0.00 sec)
```

To add a spatial index on the column `g`, use this statement:

```sql
mysql> ALTER TABLE geom ADD SPATIAL INDEX(g);
Query OK, 32376 rows affected (4.05 sec)
```

### 11.4.11 Using Spatial Indexes

The optimizer investigates whether available spatial indexes can be involved in the search for queries that use a function such as `MBRContains()` or `MBRWithin()` in the `WHERE` clause. The following query finds all objects that are in the given rectangle:

```sql
mysql> SET @poly =
  -> 'Polygon((30000 15000,
      31000 15000,
      31000 16000,
      30000 16000,
      30000 15000))';
mysql> SELECT fid,ST_AsText(g) FROM geom WHERE
  -> MBRContains(ST_GeomFromText(@poly),g);  
<table>
<thead>
<tr>
<th>fid</th>
<th>ST_AsText(g)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

2200
Use EXPLAIN to check the way this query is executed:

```sql
mysql> SET @poly = 
  -> 'Polygon((30000 15000,
            31000 15000,
            31000 16000,
            30000 16000,
            30000 15000))';

mysql> EXPLAIN SELECT fid,ST_AsText(g) FROM geom WHERE 
  -> MBRContains(ST_GeomFromText(@poly),g)\G
```

```
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: geom
type: range
possible_keys: g
key: g
key_len: 32
ref: NULL
rows: 50
Extra: Using where
```

Check what would happen without a spatial index:

```sql
mysql> SET @poly = 
  -> 'Polygon((30000 15000,
            31000 15000,
            31000 16000,
            30000 16000,
            30000 15000))';

mysql> EXPLAIN SELECT fid,ST_AsText(g) FROM geom IGNORE INDEX (g) WHERE 
  -> MBRContains(ST_GeomFromText(@poly),g)\G
```

```
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: geom
type: ALL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: 32376
Extra: Using where
```
11.5 The JSON Data Type

- Creating JSON Values
- Normalization, Merging, and Autowrapping of JSON Values
- Searching and Modifying JSON Values
- JSON Path Syntax
- Comparison and Ordering of JSON Values
- Converting between JSON and non-JSON values
- Aggregation of JSON Values

MySQL supports a native JSON data type defined by RFC 7159 that enables efficient access to data in JSON (JavaScript Object Notation) documents. The JSON data type provides these advantages over storing JSON-format strings in a string column:

- Automatic validation of JSON documents stored in JSON columns. Invalid documents produce an error.
- Optimized storage format. JSON documents stored in JSON columns are converted to an internal format that permits quick read access to document elements. When the server later must read a JSON value
Partial Updates of JSON Values

stored in this binary format, the value need not be parsed from a text representation. The binary format is structured to enable the server to look up subobjects or nested values directly by key or array index without reading all values before or after them in the document.

MySQL 8.2 also supports the JSON Merge Patch format defined in RFC 7396, using the JSON_MERGE_PATCH() function. See the description of this function, as well as Normalization, Merging, and Autowrapping of JSON Values, for examples and further information.

Note

This discussion uses JSON in monotype to indicate specifically the JSON data type and “JSON” in regular font to indicate JSON data in general.

The space required to store a JSON document is roughly the same as for LONGBLOB or LONGTEXT; see Section 11.7, “Data Type Storage Requirements”, for more information. It is important to keep in mind that the size of any JSON document stored in a JSON column is limited to the value of the max_allowed_packet system variable. (When the server is manipulating a JSON value internally in memory, it can be larger than this; the limit applies when the server stores it.) You can obtain the amount of space required to store a JSON document using the JSON_STORAGE_SIZE() function; note that for a JSON column, the storage size—and thus the value returned by this function—is that used by the column prior to any partial updates that may have been performed on it (see the discussion of the JSON partial update optimization later in this section).

Along with the JSON data type, a set of SQL functions is available to enable operations on JSON values, such as creation, manipulation, and searching. The following discussion shows examples of these operations. For details about individual functions, see Section 12.17, “JSON Functions”.

A set of spatial functions for operating on GeoJSON values is also available. See Section 12.16.11, “Spatial GeoJSON Functions”.

JSON columns, like columns of other binary types, are not indexed directly; instead, you can create an index on a generated column that extracts a scalar value from the JSON column. See Indexing a Generated Column to Provide a JSON Column Index, for a detailed example.

The MySQL optimizer also looks for compatible indexes on virtual columns that match JSON expressions.

The InnoDB storage engine supports multi-valued indexes on JSON arrays. See Multi-Valued Indexes.

MySQL NDB Cluster supports JSON columns and MySQL JSON functions, including creation of an index on a column generated from a JSON column as a workaround for being unable to index a JSON column. A maximum of 3 JSON columns per NDB table is supported.

Partial Updates of JSON Values

In MySQL 8.2, the optimizer can perform a partial, in-place update of a JSON column instead of removing the old document and writing the new document in its entirety to the column. This optimization can be performed for an update that meets the following conditions:

• The column being updated was declared as JSON.

• The UPDATE statement uses any of the three functions JSON_SET(), JSON_REPLACE(), or JSON_REMOVE() to update the column. A direct assignment of the column value (for example, UPDATE mytable SET jcol = '{"a": 10, "b": 25}') cannot be performed as a partial update.

Updates of multiple JSON columns in a single UPDATE statement can be optimized in this fashion; MySQL can perform partial updates of only those columns whose values are updated using the three functions just listed.
Creating JSON Values

- The input column and the target column must be the same column; a statement such as `UPDATE mytable SET jcol1 = JSON_SET(jcol2, '\$.a', 100)` cannot be performed as a partial update.

  The update can use nested calls to any of the functions listed in the previous item, in any combination, as long as the input and target columns are the same.

- All changes replace existing array or object values with new ones, and do not add any new elements to the parent object or array.

- The value being replaced must be at least as large as the replacement value. In other words, the new value cannot be any larger than the old one.

  A possible exception to this requirement occurs when a previous partial update has left sufficient space for the larger value. You can use the function `JSON_STORAGE_FREE()` to see how much space has been freed by any partial updates of a JSON column.

  Such partial updates can be written to the binary log using a compact format that saves space; this can be enabled by setting the `binlog_row_value_options` system variable to `PARTIAL_JSON`.

  It is important to distinguish the partial update of a JSON column value stored in a table from writing the partial update of a row to the binary log. It is possible for the complete update of a JSON column to be recorded in the binary log as a partial update. This can happen when either (or both) of the last two conditions from the previous list is not met but the other conditions are satisfied.

  See also the description of `binlog_row_value_options`.

The next few sections provide basic information regarding the creation and manipulation of JSON values.

Creating JSON Values

A JSON array contains a list of values separated by commas and enclosed within `[]` characters:

- `"abc", 10, null, true, false`

A JSON object contains a set of key-value pairs separated by commas and enclosed within `{` and `}` characters:

- `"k1": "value", "k2": 10`

As the examples illustrate, JSON arrays and objects can contain scalar values that are strings or numbers, the JSON null literal, or the JSON boolean true or false literals. Keys in JSON objects must be strings. Temporal (date, time, or datetime) scalar values are also permitted:

Nesting is permitted within JSON array elements and JSON object key values:

- `[99, {"id": "HK500", "cost": 75.99}, {"hot", "cold"}]`
- `{"k1": "value", "k2": [10, 20]}`

You can also obtain JSON values from a number of functions supplied by MySQL for this purpose (see Section 12.17.2, “Functions That Create JSON Values”) as well as by casting values of other types to the JSON type using `CAST(value AS JSON)` (see Converting between JSON and non-JSON values). The next several paragraphs describe how MySQL handles JSON values provided as input.

In MySQL, JSON values are written as strings. MySQL parses any string used in a context that requires a JSON value, and produces an error if it is not valid as JSON. These contexts include inserting a value
Creating JSON Values

into a column that has the JSON data type and passing an argument to a function that expects a JSON
value (usually shown as json_doc or json_val in the documentation for MySQL JSON functions), as the
following examples demonstrate:
• Attempting to insert a value into a JSON column succeeds if the value is a valid JSON value, but fails if it
is not:
mysql> CREATE TABLE t1 (jdoc JSON);
Query OK, 0 rows affected (0.20 sec)
mysql> INSERT INTO t1 VALUES('{"key1": "value1", "key2": "value2"}');
Query OK, 1 row affected (0.01 sec)
mysql> INSERT INTO t1 VALUES('[1, 2,');
ERROR 3140 (22032) at line 2: Invalid JSON text:
"Invalid value." at position 6 in value (or column) '[1, 2,'.

Positions for “at position N” in such error messages are 0-based, but should be considered rough
indications of where the problem in a value actually occurs.
• The JSON_TYPE() function expects a JSON argument and attempts to parse it into a JSON value. It
returns the value's JSON type if it is valid and produces an error otherwise:
mysql> SELECT JSON_TYPE('["a", "b", 1]');
+----------------------------+
| JSON_TYPE('["a", "b", 1]') |
+----------------------------+
| ARRAY
|
+----------------------------+
mysql> SELECT JSON_TYPE('"hello"');
+----------------------+
| JSON_TYPE('"hello"') |
+----------------------+
| STRING
|
+----------------------+
mysql> SELECT JSON_TYPE('hello');
ERROR 3146 (22032): Invalid data type for JSON data in argument 1
to function json_type; a JSON string or JSON type is required.

MySQL handles strings used in JSON context using the utf8mb4 character set and utf8mb4_bin
collation. Strings in other character sets are converted to utf8mb4 as necessary. (For strings in the
ascii or utf8mb3 character sets, no conversion is needed because ascii and utf8mb3 are subsets of
utf8mb4.)
As an alternative to writing JSON values using literal strings, functions exist for composing JSON values
from component elements. JSON_ARRAY() takes a (possibly empty) list of values and returns a JSON
array containing those values:
mysql> SELECT JSON_ARRAY('a', 1, NOW());
+----------------------------------------+
| JSON_ARRAY('a', 1, NOW())
|
+----------------------------------------+
| ["a", 1, "2015-07-27 09:43:47.000000"] |
+----------------------------------------+

JSON_OBJECT() takes a (possibly empty) list of key-value pairs and returns a JSON object containing
those pairs:
mysql> SELECT JSON_OBJECT('key1', 1, 'key2', 'abc');
+---------------------------------------+
| JSON_OBJECT('key1', 1, 'key2', 'abc') |

2205


Creating JSON Values

JSON_MERGE_PRESERVE() takes two or more JSON documents and returns the combined result:

```sql
mysql> SELECT JSON_MERGE_PRESERVE('["a", 1]', '{"key": "value"}');
+-----------------------------------------------------+
| JSON_MERGE_PRESERVE('["a", 1]', '{"key": "value"}') |
| 
| ["a", 1, {"key": "value"}]                          |
+-----------------------------------------------------+
1 row in set (0.00 sec)
```

For information about the merging rules, see Normalization, Merging, and Autowrapping of JSON Values.

(MySQL also supports JSON_MERGE_PATCH(), which has somewhat different behavior. See JSON_MERGE_PATCH() compared with JSON_MERGE_PRESERVE(), for information about the differences between these two functions.)

JSON values can be assigned to user-defined variables:

```sql
mysql> SET @j = JSON_OBJECT('key', 'value');
mysql> SELECT @j;
+------------------+
| @j               |
+------------------+
| {"key": "value"} |
+------------------+
```

However, user-defined variables cannot be of JSON data type, so although @j in the preceding example looks like a JSON value and has the same character set and collation as a JSON value, it does not have the JSON data type. Instead, the result from JSON_OBJECT() is converted to a string when assigned to the variable.

Strings produced by converting JSON values have a character set of utf8mb4 and a collation of utf8mb4_bin:

```sql
mysql> SELECT CHARSET(@j), COLLATION(@j);
+-------------+---------------+
| CHARSET(@j) | COLLATION(@j) |
+-------------+---------------+
| utf8mb4     | utf8mb4_bin   |
+-------------+---------------+
```

Because utf8mb4_bin is a binary collation, comparison of JSON values is case-sensitive.

```sql
mysql> SELECT JSON_ARRAY('x') = JSON_ARRAY('X');
+-----------------------------------+
| JSON_ARRAY('x') = JSON_ARRAY('X') |
|                                 0 |
+-----------------------------------+
```

Case sensitivity also applies to the JSON null, true, and false literals, which always must be written in lowercase:

```sql
mysql> SELECT JSON_VALID('null'), JSON_VALID('Null'), JSON_VALID('NULL');
+--------------------+--------------------+--------------------+
| JSON_VALID('null') | JSON_VALID('Null') | JSON_VALID('NULL') |
+--------------------+--------------------+--------------------+
|                  1 |                  0 |                  0 |
+--------------------+--------------------+--------------------+
```

2206
Case sensitivity of the JSON literals differs from that of the SQL NULL, TRUE, and FALSE literals, which can be written in any lettercase:

```
mysql> SELECT ISNULL(null), ISNULL(Null), ISNULL(NULL);
+--------------+--------------+--------------+
| ISNULL(null) | ISNULL(Null) | ISNULL(NULL) |
+--------------+--------------+--------------+
|            1 |            1 |            1 |
+--------------+--------------+--------------+
```

Sometimes it may be necessary or desirable to insert quote characters (" or ") into a JSON document. Assume for this example that you want to insert some JSON objects containing strings representing sentences that state some facts about MySQL, each paired with an appropriate keyword, into a table created using the SQL statement shown here:

```
mysql> CREATE TABLE facts (sentence JSON);
```

Among these keyword-sentence pairs is this one:

```
mascot: The MySQL mascot is a dolphin named "Sakila".
```

One way to insert this as a JSON object into the facts table is to use the MySQL JSON_OBJECT() function. In this case, you must escape each quote character using a backslash, as shown here:

```
mysql> INSERT INTO facts VALUES
    > (JSON_OBJECT("mascot", "Our mascot is a dolphin named \"Sakila\"."));
```

This does not work in the same way if you insert the value as a JSON object literal, in which case, you must use the double backslash escape sequence, like this:

```
mysql> INSERT INTO facts VALUES
    > ('{"mascot": "Our mascot is a dolphin named \"Sakila\"."}');
```

Using the double backslash keeps MySQL from performing escape sequence processing, and instead causes it to pass the string literal to the storage engine for processing. After inserting the JSON object in either of the ways just shown, you can see that the backslashes are present in the JSON column value by doing a simple SELECT, like this:

```
mysql> SELECT sentence FROM facts;
```

To look up this particular sentence employing mascot as the key, you can use the column-path operator ->, as shown here:

```
mysql> SELECT col->"$.mascot" FROM qtest;
```
Normalization, Merging, and Autowrapping of JSON Values

When a string is parsed and found to be a valid JSON document, it is also normalized. This means that members with keys that duplicate a key found later in the document, reading from left to right, are discarded. The object value produced by the following `JSON_OBJECT()` call includes only the second `key1` element because that key name occurs earlier in the value, as shown here:

```sql
mysql> SELECT JSON_OBJECT('key1', 1, 'key2', 'abc', 'key1', 'def');
+------------------------------------------------------+
| JSON_OBJECT('key1', 1, 'key2', 'abc', 'key1', 'def') |
| {"key1": "def", "key2": "abc"}                     |
+------------------------------------------------------+
```

Normalization is also performed when values are inserted into JSON columns, as shown here:

```sql
mysql> CREATE TABLE t1 (c1 JSON);
mysql> INSERT INTO t1 VALUES
> ('{"x": 17, "x": "red"}'),
> ('{"x": 17, "x": "red", "x": [3, 5, 7]}');
mysql> SELECT c1 FROM t1;
+------------------+
| c1               |
| {"x": "red"}    |
| {"x": [3, 5, 7]} |
+------------------+
```

Note

The previous example does not work as shown if the `NO_BACKSLASH_ESCAPES` server SQL mode is enabled. If this mode is set, a single backslash instead of double backslashes can be used to insert the JSON object literal, and the backslashes are preserved. If you use the `JSON_OBJECT()` function when performing the insert and this mode is set, you must alternate single and double quotes, like this:

```sql
mysql> INSERT INTO facts VALUES
> (JSON_OBJECT('mascot', 'Our mascot is a dolphin named "Sakila".'));
```

See the description of the `JSON_UNQUOTE()` function for more information about the effects of this mode on escaped characters in JSON values.

Normalization, Merging, and Autowrapping of JSON Values

This leaves the backslashes intact, along with the surrounding quote marks. To display the desired value using `mascot` as the key, but without including the surrounding quote marks or any escapes, use the inline path operator `->>`, like this:

```sql
mysql> SELECT sentence->>>"$.mascot" FROM facts;
+-----------------------------------------+
| sentence->>>"$.mascot"                   |
| Our mascot is a dolphin named "Sakila". |
+-----------------------------------------+
```

2208
Normalization, Merging, and Autowrapping of JSON Values

This “last duplicate key wins” behavior is suggested by RFC 7159 and is implemented by most JavaScript
parsers. (Bug #86866, Bug #26369555)
MySQL discards extra whitespace between keys, values, or elements in the original JSON document, and
leaves (or inserts, when necessary) a single space following each comma (,) or colon (:) when displaying
it. This is done to enhance readability.
MySQL functions that produce JSON values (see Section 12.17.2, “Functions That Create JSON Values”)
always return normalized values.
To make lookups more efficient, MySQL also sorts the keys of a JSON object. You should be aware that
the result of this ordering is subject to change and not guaranteed to be consistent across releases.

Merging JSON Values
Two merging algorithms are supported, implemented by the functions JSON_MERGE_PRESERVE() and
JSON_MERGE_PATCH(). These differ in how they handle duplicate keys: JSON_MERGE_PRESERVE()
retains values for duplicate keys, while JSON_MERGE_PATCH() discards all but the last value. The next
few paragraphs explain how each of these two functions handles the merging of different combinations of
JSON documents (that is, of objects and arrays).
Merging arrays.
In contexts that combine multiple arrays, the arrays are merged into a single array.
JSON_MERGE_PRESERVE() does this by concatenating arrays named later to the end of the first array.
JSON_MERGE_PATCH() considers each argument as an array consisting of a single element (thus having
0 as its index) and then applies “last duplicate key wins” logic to select only the last argument. You can
compare the results shown by this query:
mysql> SELECT
->
JSON_MERGE_PRESERVE('[1, 2]', '["a", "b", "c"]', '[true, false]') AS Preserve,
->
JSON_MERGE_PATCH('[1, 2]', '["a", "b", "c"]', '[true, false]') AS Patch\G
*************************** 1. row ***************************
Preserve: [1, 2, "a", "b", "c", true, false]
Patch: [true, false]

Multiple objects when merged produce a single object. JSON_MERGE_PRESERVE() handles multiple
objects having the same key by combining all unique values for that key in an array; this array is then used
as the value for that key in the result. JSON_MERGE_PATCH() discards values for which duplicate keys are
found, working from left to right, so that the result contains only the last value for that key. The following
query illustrates the difference in the results for the duplicate key a:
mysql> SELECT
->
JSON_MERGE_PRESERVE('{"a": 1, "b": 2}', '{"c": 3, "a": 4}', '{"c": 5, "d": 3}') AS Preserve,
->
JSON_MERGE_PATCH('{"a": 3, "b": 2}', '{"c": 3, "a": 4}', '{"c": 5, "d": 3}') AS Patch\G
*************************** 1. row ***************************
Preserve: {"a": [1, 4], "b": 2, "c": [3, 5], "d": 3}
Patch: {"a": 4, "b": 2, "c": 5, "d": 3}

Nonarray values used in a context that requires an array value are autowrapped: The value is surrounded
by [ and ] characters to convert it to an array. In the following statement, each argument is autowrapped
as an array ([1], [2]). These are then merged to produce a single result array; as in the previous two
cases, JSON_MERGE_PRESERVE() combines values having the same key while JSON_MERGE_PATCH()
discards values for all duplicate keys except the last, as shown here:
mysql> SELECT
->
JSON_MERGE_PRESERVE('1', '2') AS Preserve,
->
JSON_MERGE_PATCH('1', '2') AS Patch\G
*************************** 1. row ***************************
Preserve: [1, 2]
Patch: 2

2209


Searching and Modifying JSON Values

Array and object values are merged by autowrapping the object as an array and merging the arrays
by combining values or by “last duplicate key wins” according to the choice of merging function
(JSON_MERGE_PRESERVE() or JSON_MERGE_PATCH(), respectively), as can be seen in this example:
mysql> SELECT
->
JSON_MERGE_PRESERVE('[10, 20]', '{"a": "x", "b": "y"}') AS Preserve,
->
JSON_MERGE_PATCH('[10, 20]', '{"a": "x", "b": "y"}') AS Patch\G
*************************** 1. row ***************************
Preserve: [10, 20, {"a": "x", "b": "y"}]
Patch: {"a": "x", "b": "y"}

Searching and Modifying JSON Values
A JSON path expression selects a value within a JSON document.
Path expressions are useful with functions that extract parts of or modify a JSON document, to specify
where within that document to operate. For example, the following query extracts from a JSON document
the value of the member with the name key:
mysql> SELECT JSON_EXTRACT('{"id": 14, "name": "Aztalan"}', '$.name');
+---------------------------------------------------------+
| JSON_EXTRACT('{"id": 14, "name": "Aztalan"}', '$.name') |
+---------------------------------------------------------+
| "Aztalan"
|
+---------------------------------------------------------+

Path syntax uses a leading $ character to represent the JSON document under consideration, optionally
followed by selectors that indicate successively more specific parts of the document:
• A period followed by a key name names the member in an object with the given key. The key name
must be specified within double quotation marks if the name without quotes is not legal within path
expressions (for example, if it contains a space).
• [N] appended to a path that selects an array names the value at position N within the array. Array
positions are integers beginning with zero. If path does not select an array value, path[0] evaluates to
the same value as path:
mysql> SELECT JSON_SET('"x"', '$[0]', 'a');
+------------------------------+
| JSON_SET('"x"', '$[0]', 'a') |
+------------------------------+
| "a"
|
+------------------------------+
1 row in set (0.00 sec)

• [M to N] specifies a subset or range of array values starting with the value at position M, and ending
with the value at position N.
last is supported as a synonym for the index of the rightmost array element. Relative addressing of
array elements is also supported. If path does not select an array value, path[last] evaluates to the
same value as path, as shown later in this section (see Rightmost array element).
• Paths can contain * or ** wildcards:
• .[*] evaluates to the values of all members in a JSON object.
• [*] evaluates to the values of all elements in a JSON array.
• prefix**suffix evaluates to all paths that begin with the named prefix and end with the named
suffix.

2210


• A path that does not exist in the document (evaluates to nonexistent data) evaluates to NULL.

Let $\$ refer to this JSON array with three elements:

\[
[3, \{"a": [5, 6], "b": 10\}, [99, 100]]
\]

Then:

• $\[0\]$ evaluates to 3.
• $\[1\]$ evaluates to $\{"a": [5, 6], "b": 10\}$.
• $\[2\]$ evaluates to [99, 100].
• $\[3\]$ evaluates to NULL (it refers to the fourth array element, which does not exist).

Because $\[1\]$ and $\[2\]$ evaluate to nonscalar values, they can be used as the basis for more-specific path expressions that select nested values. Examples:

• $\[1\].a$ evaluates to [5, 6].
• $\[1\].a[1]$ evaluates to 6.
• $\[1\].b$ evaluates to 10.
• $\[2\][0]$ evaluates to 99.

As mentioned previously, path components that name keys must be quoted if the unquoted key name is not legal in path expressions. Let $\$ refer to this value:

\[
{"a fish": "shark", "a bird": "sparrow"}
\]

The keys both contain a space and must be quoted:

• $\$.a fish$ evaluates to shark.
• $\$.a bird$ evaluates to sparrow.

Paths that use wildcards evaluate to an array that can contain multiple values:

\[
\text{mysql> } \text{SELECT JSON_EXTRACT('{"a": 1, "b": 2, "c": [3, 4, 5]}', '$.*');}
\]

\[
\begin{array}{c}
\text{| JSON_EXTRACT('{"a": 1, "b": 2, "c": [3, 4, 5]}', '$.*') |} \\
\text{| [1, 2, [3, 4, 5]] |}
\end{array}
\]

\[
\text{mysql> SELECT JSON_EXTRACT('{"a": 1, "b": 2, "c": [3, 4, 5]}', '$.c[*]');}
\]

\[
\begin{array}{c}
\text{| JSON_EXTRACT('{"a": 1, "b": 2, "c": [3, 4, 5]}', '$.c[*]') |} \\
\text{| [3, 4, 5] |}
\end{array}
\]

In the following example, the path $**.b$ evaluates to multiple paths ($.a.b$ and $.c.b$) and produces an array of the matching path values:

\[
\text{mysql> SELECT JSON_EXTRACT('{"a": {"b": 1}, "c": {"b": 2}}', '$**.b');}
\]

\[
\begin{array}{c}
\text{| JSON_EXTRACT('{"a": {"b": 1}, "c": {"b": 2}}', '$**.b') |} \\
\text{| [1, 2] |}
\end{array}
\]
Ranges from JSON arrays. You can use ranges with the `to` keyword to specify subsets of JSON arrays. For example, `$[1 to 3]` includes the second, third, and fourth elements of an array, as shown here:

```
mysql> SELECT JSON_EXTRACT('[1, 2, 3, 4, 5]', '$[1 to 3]');
+----------------------------------------------+
| JSON_EXTRACT('[1, 2, 3, 4, 5]', '$[1 to 3]') |
+----------------------------------------------+
| [2, 3, 4]                                    |
+----------------------------------------------+
1 row in set (0.00 sec)
```

The syntax is `M to N`, where `M` and `N` are, respectively, the first and last indexes of a range of elements from a JSON array. `N` must be greater than `M`; `M` must be greater than or equal to 0. Array elements are indexed beginning with 0.

You can use ranges in contexts where wildcards are supported.

Rightmost array element. The `last` keyword is supported as a synonym for the index of the last element in an array. Expressions of the form `last - N` can be used for relative addressing, and within range definitions, like this:

```
mysql> SELECT JSON_EXTRACT('[1, 2, 3, 4, 5]', '$[last-3 to last-1]');
+--------------------------------------------------------+
| JSON_EXTRACT('[1, 2, 3, 4, 5]', '$[last-3 to last-1]') |
+--------------------------------------------------------+
| [2, 3, 4]                                              |
+--------------------------------------------------------+
1 row in set (0.01 sec)
```

If the path is evaluated against a value that is not an array, the result of the evaluation is the same as if the value had been wrapped in a single-element array:

```
mysql> SELECT JSON_REPLACE('"Sakila"', '$[last]', 10);
+-----------------------------------------+
| JSON_REPLACE('"Sakila"', '$[last]', 10) |
+-----------------------------------------+
| 10                                      |
+-----------------------------------------+
1 row in set (0.00 sec)
```

You can use `column->path` with a JSON column identifier and JSON path expression as a synonym for `JSON_EXTRACT(column, path)`. See Section 12.17.3, “Functions That Search JSON Values”, for more information. See also Indexing a Generated Column to Provide a JSON Column Index.

Some functions take an existing JSON document, modify it in some way, and return the resulting modified document. Path expressions indicate where in the document to make changes. For example, the `JSON_SET()`, `JSON_INSERT()`, and `JSON_REPLACE()` functions each take a JSON document, plus one or more path-value pairs that describe where to modify the document and the values to use. The functions differ in how they handle existing and nonexistent values within the document.

Consider this document:

```
mysql> SET @j = '"a", {"b": [true, false], [10, 20]}';
```

`JSON_SET()` replaces values for paths that exist and adds values for paths that do not exist:

```
mysql> SELECT JSON_SET(@j, '$[1].b[0]', 1, '$[2][2]', 2);+
+-------------------------------------------+
| JSON_SET(@j, '$[1].b[0]', 1, '$[2][2]', 2) |
+-------------------------------------------+
1 row in set (0.00 sec)
```
In this case, the path $[1].b[0]$ selects an existing value (true), which is replaced with the value following the path argument (1). The path $[2][2]$ does not exist, so the corresponding value (2) is added to the value selected by $[2]$.

**JSON_INSERT()** adds new values but does not replace existing values:

```
SELECT JSON_INSERT(@j, '$[1].b[0]', 1, '$[2][2]', 2);
```

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

**JSON_REPLACE()** replaces existing values and ignores new values:

```
SELECT JSON_REPLACE(@j, '$[1].b[0]', 1, '$[2][2]', 2);
```

The paths have these effects:

- The first instance of $[1].b[1]$ matches false in the b element and removes it.
- The second instance of $[1].b[1]$ matches nothing: That element has already been removed, the path no longer exists, and has no effect.

**JSON Path Syntax**

Many of the JSON functions supported by MySQL and described elsewhere in this Manual (see Section 12.17, “JSON Functions”) require a path expression in order to identify a specific element in a JSON document. A path consists of the path's scope followed by one or more path legs. For paths used in MySQL JSON functions, the scope is always the document being searched or otherwise operated on, represented by a leading $ character. Path legs are separated by period characters (.). Cells in arrays are represented by [N], where N is a non-negative integer. Names of keys must be double-quoted strings or valid ECMAScript identifiers (see Identifier Names and Identifiers, in the ECMAScript Language Specification). Path expressions, like JSON text, should be encoded using the ascii, utf8mb3, or
Comparison and Ordering of JSON Values

utf8mb4 character set. Other character encodings are implicitly coerced to utf8mb4. The complete syntax is shown here:

```plaintext
pathExpression:  
    scope[(pathLeg)*]

pathLeg:  
    member | arrayLocation | doubleAsterisk

member:  
    period ( keyName | asterisk )

arrayLocation:  
    leftBracket ( nonNegativeInteger | asterisk ) rightBracket

keyName:  
    ESIdentifier | doubleQuotedString

doubleAsterisk:  
    '**'

period:  
    '.

asterisk:  
    '*'

leftBracket:  
    '['

rightBracket:  
    ']'
```

As noted previously, in MySQL, the scope of the path is always the document being operated on, represented as $. You can use ' $ ' as a synonym for the document in JSON path expressions.

**Note**

Some implementations support column references for scopes of JSON paths; MySQL 8.2 does not support these.

The wildcard * and ** tokens are used as follows:

- . * represents the values of all members in the object.
- [ * ] represents the values of all cells in the array.
- [prefix]**suffix represents all paths beginning with prefix and ending with suffix. prefix is optional, while suffix is required; in other words, a path may not end in **.

In addition, a path may not contain the sequence ***.

For path syntax examples, see the descriptions of the various JSON functions that take paths as arguments, such as JSON_CONTAINS_PATH(), JSON_SET(), and JSON_REPLACE(). For examples which include the use of the * and ** wildcards, see the description of the JSON_SEARCH() function.

MySQL also supports range notation for subsets of JSON arrays using the to keyword (such as $[2 to 10]), as well as the last keyword as a synonym for the rightmost element of an array. See Searching and Modifying JSON Values, for more information and examples.

**Comparison and Ordering of JSON Values**

JSON values can be compared using the =, <, <=, >, >=, <>, ! =, and <=> operators.
Comparison and Ordering of JSON Values

The following comparison operators and functions are not yet supported with JSON values:

- BETWEEN
- IN()
- GREATEST()
- LEAST()

A workaround for the comparison operators and functions just listed is to cast JSON values to a native MySQL numeric or string data type so they have a consistent non-JSON scalar type.

Comparison of JSON values takes place at two levels. The first level of comparison is based on the JSON types of the compared values. If the types differ, the comparison result is determined solely by which type has higher precedence. If the two values have the same JSON type, a second level of comparison occurs using type-specific rules.

The following list shows the precedences of JSON types, from highest precedence to the lowest. (The type names are those returned by the `JSON_TYPE()` function.) Types shown together on a line have the same precedence. Any value having a JSON type listed earlier in the list compares greater than any value having a JSON type listed later in the list.

<table>
<thead>
<tr>
<th>BLOB</th>
<th>BIT</th>
<th>OPAQUE</th>
<th>DATETIME</th>
<th>TIME</th>
<th>DATE</th>
<th>BOOLEAN</th>
<th>ARRAY</th>
<th>OBJECT</th>
<th>STRING</th>
<th>INTEGER, DOUBLE</th>
<th>NULL</th>
</tr>
</thead>
</table>

For JSON values of the same precedence, the comparison rules are type specific:

- **BLOB**

  The first \( N \) bytes of the two values are compared, where \( N \) is the number of bytes in the shorter value. If the first \( N \) bytes of the two values are identical, the shorter value is ordered before the longer value.

- **BIT**

  Same rules as for BLOB.

- **OPAQUE**

  Same rules as for BLOB. OPAQUE values are values that are not classified as one of the other types.

- **DATETIME**

  A value that represents an earlier point in time is ordered before a value that represents a later point in time. If two values originally come from the MySQL DATETIME and TIMESTAMP types, respectively, they are equal if they represent the same point in time.

- **TIME**

  The smaller of two time values is ordered before the larger one.
Comparison and Ordering of JSON Values

- **DATE**
  The earlier date is ordered before the more recent date.

- **ARRAY**
  Two JSON arrays are equal if they have the same length and values in corresponding positions in the arrays are equal.
  If the arrays are not equal, their order is determined by the elements in the first position where there is a difference. The array with the smaller value in that position is ordered first. If all values of the shorter array are equal to the corresponding values in the longer array, the shorter array is ordered first.

  Example:
  
  ```json
  [] < ["a"] < ["ab"] < ["ab", "cd", "ef"] < ["ab", "ef"]
  ```

- **BOOLEAN**
  The JSON false literal is less than the JSON true literal.

- **OBJECT**
  Two JSON objects are equal if they have the same set of keys, and each key has the same value in both objects.

  Example:
  
  ```json
  {"a": 1, "b": 2} = {"b": 2, "a": 1}
  ```
  The order of two objects that are not equal is unspecified but deterministic.

- **STRING**
  Strings are ordered lexically on the first $N$ bytes of the utf8mb4 representation of the two strings being compared, where $N$ is the length of the shorter string. If the first $N$ bytes of the two strings are identical, the shorter string is considered smaller than the longer string.

  Example:
  
  ```text
  "a" < "ab" < "b" < "bc"
  ```
  This ordering is equivalent to the ordering of SQL strings with collation utf8mb4_bin. Because utf8mb4_bin is a binary collation, comparison of JSON values is case-sensitive:

  ```text
  "A" < "a"
  ```

- **INTEGER, DOUBLE**
  JSON values can contain exact-value numbers and approximate-value numbers. For a general discussion of these types of numbers, see Section 9.1.2, "Numeric Literals".

  The rules for comparing native MySQL numeric types are discussed in Section 12.3, "Type Conversion in Expression Evaluation", but the rules for comparing numbers within JSON values differ somewhat:

  - In a comparison between two columns that use the native MySQL INT and DOUBLE numeric types, respectively, it is known that all comparisons involve an integer and a double, so the integer is converted to double for all rows. That is, exact-value numbers are converted to approximate-value numbers.
On the other hand, if the query compares two JSON columns containing numbers, it cannot be known in advance whether numbers are integer or double. To provide the most consistent behavior across all rows, MySQL converts approximate-value numbers to exact-value numbers. The resulting ordering is consistent and does not lose precision for the exact-value numbers. For example, given the scalars 9223372036854775805, 9223372036854775806, 9223372036854775807 and 9.223372036854776e18, the order is such as this:

```
9223372036854775805 < 9223372036854775806 < 9223372036854775807
< 9.223372036854776e18 = 9223372036854776000 < 9223372036854776001
```

Were JSON comparisons to use the non-JSON numeric comparison rules, inconsistent ordering could occur. The usual MySQL comparison rules for numbers yield these orderings:

- Integer comparison:
  
  ```
  9223372036854775805 < 9223372036854775806 < 9223372036854775807
  (not defined for 9.223372036854776e18)
  ```

- Double comparison:
  
  ```
  9223372036854775805 = 9223372036854775806 = 9223372036854775807 = 9.223372036854776e18
  ```

For comparison of any JSON value to SQL NULL, the result is UNKNOWN.

For comparison of JSON and non-JSON values, the non-JSON value is converted to JSON according to the rules in the following table, then the values compared as described previously.

**Converting between JSON and non-JSON values**

The following table provides a summary of the rules that MySQL follows when casting between JSON values and values of other types:

<table>
<thead>
<tr>
<th>other type</th>
<th>CAST(other type AS JSON)</th>
<th>CAST(JSON AS other type)</th>
</tr>
</thead>
<tbody>
<tr>
<td>JSON</td>
<td>No change</td>
<td>No change</td>
</tr>
<tr>

<th>CAST(JSON AS other type)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>type. Otherwise, returns NULL and produces a warning.</td>
</tr>
</tbody>
</table>

**ORDER BY** and **GROUP BY** for JSON values works according to these principles:

- Ordering of scalar JSON values uses the same rules as in the preceding discussion.

- For ascending sorts, SQL NULL orders before all JSON values, including the JSON null literal; for descending sorts, SQL NULL orders after all JSON values, including the JSON null literal.

- Sort keys for JSON values are bound by the value of the **max_sort_length** system variable, so keys that differ only after the first **max_sort_length** bytes compare as equal.

- Sorting of nonscalar values is not currently supported and a warning occurs.

For sorting, it can be beneficial to cast a JSON scalar to some other native MySQL type. For example, if a column named *jdoc* contains JSON objects having a member consisting of an *id* key and a nonnegative value, use this expression to sort by *id* values:

```
ORDER BY CAST(JSON_EXTRACT(jdoc, '$.id') AS UNSIGNED)
```

If there happens to be a generated column defined to use the same expression as in the **ORDER BY**, the MySQL optimizer recognizes that and considers using the index for the query execution plan. See Section 8.3.11, “Optimizer Use of Generated Column Indexes”.

**Aggregation of JSON Values**

For aggregation of JSON values, SQL NULL values are ignored as for other data types. Non-NULL values are converted to a numeric type and aggregated, except for **MIN()**, **MAX()**, and **GROUP_CONCAT()**. The conversion to number should produce a meaningful result for JSON values that are numeric scalars, although (depending on the values) truncation and loss of precision may occur. Conversion to number of other JSON values may not produce a meaningful result.

### 11.6 Data Type Default Values

Data type specifications can have explicit or implicit default values.

A **DEFAULT value** clause in a data type specification explicitly indicates a default value for a column. Examples:

```
CREATE TABLE t1 (  
i INT DEFAULT -1,  
c VARCHAR(10) DEFAULT '',  
price DOUBLE(16,2) DEFAULT 0.00  
);
```

**SERIAL DEFAULT VALUE** is a special case. In the definition of an integer column, it is an alias for **NOT NULL AUTO_INCREMENT UNIQUE**.

Some aspects of explicit **DEFAULT clause** handling are version dependent, as described following:

- **Explicit Default Handling**
- **Implicit Default Handling**
Explicit Default Handling

The default value specified in a `DEFAULT` clause can be a literal constant or an expression. With one exception, enclose expression default values within parentheses to distinguish them from literal constant default values. Examples:

```sql
CREATE TABLE t1 (  
    -- literal defaults  
    i INT         DEFAULT 0,  
    c VARCHAR(10) DEFAULT '',  
    -- expression defaults  
    f FLOAT       DEFAULT (RAND() * RAND()),  
    b BINARY(16)  DEFAULT (UUID_TO_BIN(UUID())),  
    d DATE        DEFAULT (CURRENT_DATE + INTERVAL 1 YEAR),  
    p POINT       DEFAULT (Point(0,0)),  
    j JSON        DEFAULT (JSON_ARRAY())
);  
```

The exception is that, for `TIMESTAMP` and `DATETIME` columns, you can specify the `CURRENT_TIMESTAMP` function as the default, without enclosing parentheses. See Section 11.2.5, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”.

The `BLOB`, `TEXT`, `GEOMETRY`, and `JSON` data types can be assigned a default value only if the value is written as an expression, even if the expression value is a literal:

- This is permitted (literal default specified as expression):
  ```sql
  CREATE TABLE t2 (b BLOB DEFAULT ('abc'));
  ```

- This produces an error (literal default not specified as expression):
  ```sql
  CREATE TABLE t2 (b BLOB DEFAULT 'abc');
  ```

Expression default values must adhere to the following rules. An error occurs if an expression contains disallowed constructs.

- Literals, built-in functions (both deterministic and nondeterministic), and operators are permitted.
- Subqueries, parameters, variables, stored functions, and loadable functions are not permitted.
- An expression default value cannot depend on a column that has the `AUTO_INCREMENT` attribute.
- An expression default value for one column can refer to other table columns, with the exception that references to generated columns or columns with expression default values must be to columns that occur earlier in the table definition. That is, expression default values cannot contain forward references to generated columns or columns with expression default values.

The ordering constraint also applies to the use of `ALTER TABLE` to reorder table columns. If the resulting table would have an expression default value that contains a forward reference to a generated column or column with an expression default value, the statement fails.

**Note**

If any component of an expression default value depends on the SQL mode, different results may occur for different uses of the table unless the SQL mode is the same during all uses.

For `CREATE TABLE ... LIKE` and `CREATE TABLE ... SELECT`, the destination table preserves expression default values from the original table.
If an expression default value refers to a nondeterministic function, any statement that causes the expression to be evaluated is unsafe for statement-based replication. This includes statements such as `INSERT` and `UPDATE`. In this situation, if binary logging is disabled, the statement is executed as normal. If binary logging is enabled and `binlog_format` is set to `STATEMENT`, the statement is logged and executed but a warning message is written to the error log, because replicas might diverge. When `binlog_format` is set to `MIXED` or `ROW`, the statement is executed as normal.

When inserting a new row, the default value for a column with an expression default can be inserted either by omitting the column name or by specifying the column as `DEFAULT` (just as for columns with literal defaults):

```sql
mysql> CREATE TABLE t4 (uid BINARY(16) DEFAULT (UUID_TO_BIN(UUID())))
mysql> INSERT INTO t4 () VALUES();
mysql> INSERT INTO t4 () VALUES(DEFAULT);
mysql> SELECT BIN_TO_UUID(uid) AS uid FROM t4;
```

```
+--------------------------------------+
| uid                                  |
+--------------------------------------+
| f1109174-94c9-11e8-971d-3bf1095aa633 |
| f110cf9a-94c9-11e8-971d-3bf1095aa633 |
+--------------------------------------+
```

However, the use of `DEFAULT(col_name)` to specify the default value for a named column is permitted only for columns that have a literal default value, not for columns that have an expression default value.

Not all storage engines permit expression default values. For those that do not, an `ER_UNSUPPORTED_ACTION_ON_DEFAULT_VAL_GENERATED` error occurs.

If a default value evaluates to a data type that differs from the declared column type, implicit coercion to the declared type occurs according to the usual MySQL type-conversion rules. See Section 12.3, “Type Conversion in Expression Evaluation”.

**Implicit Default Handling**

If a data type specification includes no explicit `DEFAULT` value, MySQL determines the default value as follows:

- If the column can take `NULL` as a value, the column is defined with an explicit `DEFAULT NULL` clause.
- If the column cannot take `NULL` as a value, MySQL defines the column with no explicit `DEFAULT` clause.

For data entry into a `NOT NULL` column that has no explicit `DEFAULT` clause, if an `INSERT` or `REPLACE` statement includes no value for the column, or an `UPDATE` statement sets the column to `NULL`, MySQL handles the column according to the SQL mode in effect at the time:

- If strict SQL mode is enabled, an error occurs for transactional tables and the statement is rolled back. For nontransactional tables, an error occurs, but if this happens for the second or subsequent row of a multiple-row statement, the preceding rows are inserted.
- If strict mode is not enabled, MySQL sets the column to the implicit default value for the column data type.

Suppose that a table `t` is defined as follows:

```sql
CREATE TABLE t (i INT NOT NULL);
```

In this case, `i` has no explicit default, so in strict mode each of the following statements produce an error and no row is inserted. When not using strict mode, only the third statement produces an error; the implicit
default is inserted for the first two statements, but the third fails because `DEFAULT(i)` cannot produce a value:

```sql
INSERT INTO t VALUES();
INSERT INTO t VALUES(DEFAULT);
INSERT INTO t VALUES(DEFAULT(i));
```

See Section 5.1.11, “Server SQL Modes”.

For a given table, the `SHOW CREATE TABLE` statement displays which columns have an explicit `DEFAULT` clause.

Implicit defaults are defined as follows:

- For numeric types, the default is 0, with the exception that for integer or floating-point types declared with the `AUTO_INCREMENT` attribute, the default is the next value in the sequence.

- For date and time types other than `TIMESTAMP`, the default is the appropriate “zero” value for the type. This is also true for `TIMESTAMP` if the `explicit_defaults_for_timestamp` system variable is enabled (see Section 5.1.8, “Server System Variables”). Otherwise, for the first `TIMESTAMP` column in a table, the default value is the current date and time. See Section 11.2, “Date and Time Data Types”.

- For string types other than `ENUM`, the default value is the empty string. For `ENUM`, the default is the first enumeration value.

## 11.7 Data Type Storage Requirements

- InnoDB Table Storage Requirements
- NDB Table Storage Requirements
- Numeric Type Storage Requirements
- Date and Time Type Storage Requirements
- String Type Storage Requirements
- Spatial Type Storage Requirements
- JSON Type Storage Requirements

The storage requirements for table data on disk depend on several factors. Different storage engines represent data types and store raw data differently. Table data might be compressed, either for a column or an entire row, complicating the calculation of storage requirements for a table or column.

Despite differences in storage layout on disk, the internal MySQL APIs that communicate and exchange information about table rows use a consistent data structure that applies across all storage engines.

This section includes guidelines and information for the storage requirements for each data type supported by MySQL, including the internal format and size for storage engines that use a fixed-size representation for data types. Information is listed by category or storage engine.

The internal representation of a table has a maximum row size of 65,535 bytes, even if the storage engine is capable of supporting larger rows. This figure excludes `BLOB` or `TEXT` columns, which contribute only 9 to 12 bytes toward this size. For `BLOB` and `TEXT` data, the information is stored internally in a different area of memory than the row buffer. Different storage engines handle the allocation and storage of this data in different ways, according to the method they use for handling the corresponding types. For more
InnoDB Table Storage Requirements

Information, see Chapter 16, Alternative Storage Engines, and Section 8.4.7, “Limits on Table Column Count and Row Size”.

InnoDB Table Storage Requirements

See Section 15.10, “InnoDB Row Formats” for information about storage requirements for InnoDB tables.

NDB Table Storage Requirements

Important

NDB tables use 4-byte alignment; all NDB data storage is done in multiples of 4 bytes. Thus, a column value that would typically take 15 bytes requires 16 bytes in an NDB table. For example, in NDB tables, the TINYINT, SMALLINT, MEDIUMINT, and INTEGER (INT) column types each require 4 bytes storage per record due to the alignment factor.

Each BIT(M) column takes M bits of storage space. Although an individual BIT column is not 4-byte aligned, NDB reserves 4 bytes (32 bits) per row for the first 1-32 bits needed for BIT columns, then another 4 bytes for bits 33-64, and so on.

While a NULL itself does not require any storage space, NDB reserves 4 bytes per row if the table definition contains any columns allowing NULL, up to 32 NULL columns. (If an NDB Cluster table is defined with more than 32 NULL columns up to 64 NULL columns, then 8 bytes per row are reserved.)

Every table using the NDB storage engine requires a primary key; if you do not define a primary key, a “hidden” primary key is created by NDB. This hidden primary key consumes 31-35 bytes per table record.

You can use the ndb_size.pl Perl script to estimate NDB storage requirements. It connects to a current MySQL (not NDB Cluster) database and creates a report on how much space that database would require if it used the NDB storage engine. See Section 23.5.28, “ndb_size.pl — NDBCLUSTER Size Requirement Estimator” for more information.

Numeric Type Storage Requirements

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Storage Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>TINYINT</td>
<td>1 byte</td>
</tr>
<tr>
<td>SMALLINT</td>
<td>2 bytes</td>
</tr>
<tr>
<td>MEDIUMINT</td>
<td>3 bytes</td>
</tr>
<tr>
<td>INT, INTEGER</td>
<td>4 bytes</td>
</tr>
<tr>
<td>BIGINT</td>
<td>8 bytes</td>
</tr>
<tr>
<td>FLOAT(p)</td>
<td>4 bytes if 0 &lt;= p &lt;= 24, 8 bytes if 25 &lt;= p &lt;= 53</td>
</tr>
<tr>
<td>FLOAT</td>
<td>4 bytes</td>
</tr>
<tr>
<td>DOUBLE [PRECISION], REAL</td>
<td>8 bytes</td>
</tr>
<tr>
<td>DECIMAL (M, D), NUMERIC (M, D)</td>
<td>VARIES; SEE FOLLOWING DISCUSSION</td>
</tr>
<tr>
<td>BIT(M)</td>
<td>(M+7)/8 bytes</td>
</tr>
</tbody>
</table>

Values for DECIMAL (and NUMERIC) columns are represented using a binary format that packs nine decimal (base 10) digits into four bytes. Storage for the integer and fractional parts of each value are...
determined separately. Each multiple of nine digits requires four bytes, and the “leftover” digits require some fraction of four bytes. The storage required for excess digits is given by the following table.

<table>
<thead>
<tr>
<th>Leftover Digits</th>
<th>Number of Bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
</tr>
<tr>
<td>5</td>
<td>3</td>
</tr>
<tr>
<td>6</td>
<td>3</td>
</tr>
<tr>
<td>7</td>
<td>4</td>
</tr>
<tr>
<td>8</td>
<td>4</td>
</tr>
</tbody>
</table>

**Date and Time Type Storage Requirements**

For `TIME`, `DATETIME`, and `TIMESTAMP` columns, the storage required for tables created before MySQL 5.6.4 differs from tables created from 5.6.4 on. This is due to a change in 5.6.4 that permits these types to have a fractional part, which requires from 0 to 3 bytes.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Storage Required Before MySQL 5.6.4</th>
<th>Storage Required as of MySQL 5.6.4</th>
</tr>
</thead>
<tbody>
<tr>
<td>YEAR</td>
<td>1 byte</td>
<td>1 byte</td>
</tr>
<tr>
<td>DATE</td>
<td>3 bytes</td>
<td>3 bytes</td>
</tr>
<tr>
<td>TIME</td>
<td>3 bytes</td>
<td>3 bytes + fractional seconds storage</td>
</tr>
<tr>
<td>DATETIME</td>
<td>8 bytes</td>
<td>5 bytes + fractional seconds storage</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>4 bytes</td>
<td>4 bytes + fractional seconds storage</td>
</tr>
</tbody>
</table>

As of MySQL 5.6.4, storage for `YEAR` and `DATE` remains unchanged. However, `TIME`, `DATETIME`, and `TIMESTAMP` are represented differently. `DATETIME` is packed more efficiently, requiring 5 rather than 8 bytes for the nonfractional part, and all three parts have a fractional part that requires from 0 to 3 bytes, depending on the fractional seconds precision of stored values.

<table>
<thead>
<tr>
<th>Fractional Seconds Precision</th>
<th>Storage Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0 bytes</td>
</tr>
<tr>
<td>1, 2</td>
<td>1 byte</td>
</tr>
<tr>
<td>3, 4</td>
<td>2 bytes</td>
</tr>
<tr>
<td>5, 6</td>
<td>3 bytes</td>
</tr>
</tbody>
</table>

For example, `TIME(0)`, `TIME(2)`, `TIME(4)`, and `TIME(6)` use 3, 4, 5, and 6 bytes, respectively. `TIME` and `TIME(0)` are equivalent and require the same storage.

For details about internal representation of temporal values, see [MySQL Internals: Important Algorithms and Structures](#).
String Type Storage Requirements

In the following table, $M$ represents the declared column length in characters for nonbinary string types and bytes for binary string types. $L$ represents the actual length in bytes of a given string value.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Storage Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR($\textit{M}$)</td>
<td>The compact family of InnoDB row formats optimize storage for variable-length character sets. See COMPACT Row Format Storage Characteristics. Otherwise, $M \times w$ bytes, $0 \leq M \leq 255$, where $w$ is the number of bytes required for the maximum-length character in the character set.</td>
</tr>
<tr>
<td>BINARY($\textit{M}$)</td>
<td>$\textit{M}$ bytes, $0 \leq \textit{M} \leq 255$</td>
</tr>
<tr>
<td>VARCHAR($\textit{M}$), VARBINARY($\textit{M}$)</td>
<td>$L + 1$ bytes if column values require $0 - 255$ bytes, $L + 2$ bytes if values may require more than $255$ bytes</td>
</tr>
<tr>
<td>TINYBLOB, TINYTEXT</td>
<td>$L + 1$ bytes, where $L &lt; 2^8$</td>
</tr>
<tr>
<td>BLOB, TEXT</td>
<td>$L + 2$ bytes, where $L &lt; 2^{16}$</td>
</tr>
<tr>
<td>MEDIUMBLOB, MEDIUMTEXT</td>
<td>$L + 3$ bytes, where $L &lt; 2^{24}$</td>
</tr>
<tr>
<td>LONGBLOB, LONGTEXT</td>
<td>$L + 4$ bytes, where $L &lt; 2^{32}$</td>
</tr>
<tr>
<td>ENUM('value1','value2',...)</td>
<td>1 or 2 bytes, depending on the number of enumeration values (65,535 values maximum)</td>
</tr>
<tr>
<td>SET('value1','value2',...)</td>
<td>1, 2, 3, 4, or 8 bytes, depending on the number of set members (64 members maximum)</td>
</tr>
</tbody>
</table>

Variable-length string types are stored using a length prefix plus data. The length prefix requires from one to four bytes depending on the data type, and the value of the prefix is $L$ (the byte length of the string). For example, storage for a MEDIUMTEXT value requires $L$ bytes to store the value plus three bytes to store the length of the value.

To calculate the number of bytes used to store a particular CHAR, VARCHAR, or TEXT column value, you must take into account the character set used for that column and whether the value contains multibyte characters. In particular, when using a UTF-8 Unicode character set, you must keep in mind that not all characters use the same number of bytes. utf8mb3 and utf8mb4 character sets can require up to three and four bytes per character, respectively. For a breakdown of the storage used for different categories of utf8mb3 or utf8mb4 characters, see Section 10.9, “Unicode Support”.

VARCHAR, VARBINARY, and the BLOB and TEXT types are variable-length types. For each, the storage requirements depend on these factors:

- The actual length of the column value
- The column's maximum possible length
- The character set used for the column, because some character sets contain multibyte characters

For example, a VARCHAR(255) column can hold a string with a maximum length of 255 characters. Assuming that the column uses the latin1 character set (one byte per character), the actual storage required is the length of the string ($L$), plus one byte to record the length of the string. For the string 'abcd', $L$ is 4 and the storage requirement is five bytes. If the same column is instead declared to use the ucs2 double-byte character set, the storage requirement is 10 bytes: The length of 'abcd' is eight bytes.
and the column requires two bytes to store lengths because the maximum length is greater than 255 (up to 510 bytes).

The effective maximum number of bytes that can be stored in a `VARCHAR` or `VARBINARY` column is subject to the maximum row size of 65,535 bytes, which is shared among all columns. For a `VARCHAR` column that stores multibyte characters, the effective maximum number of characters is less. For example, `utf8mb4` characters can require up to four bytes per character, so a `VARCHAR` column that uses the `utf8mb4` character set can be declared to be a maximum of 16,383 characters. See Section 8.4.7, “Limits on Table Column Count and Row Size”.

InnoDB encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

The NDB storage engine supports variable-width columns. This means that a `VARCHAR` column in an NDB Cluster table requires the same amount of storage as would any other storage engine, with the exception that such values are 4-byte aligned. Thus, the string 'abcd' stored in a `VARCHAR(50)` column using the `latin1` character set requires 8 bytes (rather than 5 bytes for the same column value in a MyISAM table).

`TEXT`, `BLOB`, and `JSON` columns are implemented differently in the NDB storage engine, wherein each row in the column is made up of two separate parts. One of these is of fixed size (256 bytes for `TEXT` and `BLOB`, 4000 bytes for `JSON`), and is actually stored in the original table. The other consists of any data in excess of 256 bytes, which is stored in a hidden blob parts table. The size of the rows in this second table are determined by the exact type of the column, as shown in the following table:

<table>
<thead>
<tr>
<th>Type</th>
<th>Blob Part Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLOB, TEXT</td>
<td>2000</td>
</tr>
<tr>
<td>MEDIUMBLOB, MEDIUMTEXT</td>
<td>4000</td>
</tr>
<tr>
<td>LONGBLOB, LONGTEXT</td>
<td>13948</td>
</tr>
<tr>
<td>JSON</td>
<td>8100</td>
</tr>
</tbody>
</table>

This means that the size of a `TEXT` column is 256 if `size <= 256` (where `size` represents the size of the row); otherwise, the size is `256 + size + (2000 × (size − 256) % 2000)`.

No blob parts are stored separately by NDB for `TINYBLOB` or `TINYTEXT` column values.

You can increase the size of an NDB blob column's blob part to the maximum of 13948 using `NDB_COLUMN` in a column comment when creating or altering the parent table. NDB also supports setting the inline size for a `TEXT`, `BLOB`, or `JSON` column, using `NDB_TABLE` in a column comment. See `NDB_COLUMN Options`, for more information.

The size of an `ENUM` object is determined by the number of different enumeration values. One byte is used for enumerations with up to 255 possible values. Two bytes are used for enumerations having between 256 and 65,535 possible values. See Section 11.3.5, “The ENUM Type”.

The size of a `SET` object is determined by the number of different set members. If the set size is `N`, the object occupies `(N+7) / 8` bytes, rounded up to 1, 2, 3, 4, or 8 bytes. A `SET` can have a maximum of 64 members. See Section 11.3.6, “The SET Type”.

**Spatial Type Storage Requirements**

MySQL stores geometry values using 4 bytes to indicate the SRID followed by the WKB representation of the value. The `LENGTH()` function returns the space in bytes required for value storage.
For descriptions of WKB and internal storage formats for spatial values, see Section 11.4.3, “Supported Spatial Data Formats”.

### JSON Storage Requirements

In general, the storage requirement for a JSON column is approximately the same as for a LONGBLOB or LONGTEXT column; that is, the space consumed by a JSON document is roughly the same as it would be for the document's string representation stored in a column of one of these types. However, there is an overhead imposed by the binary encoding, including metadata and dictionaries needed for lookup, of the individual values stored in the JSON document. For example, a string stored in a JSON document requires 4 to 10 bytes additional storage, depending on the length of the string and the size of the object or array in which it is stored.

In addition, MySQL imposes a limit on the size of any JSON document stored in a JSON column such that it cannot be any larger than the value of max_allowed_packet.

### 11.8 Choosing the Right Type for a Column

For optimum storage, you should try to use the most precise type in all cases. For example, if an integer column is used for values in the range from 1 to 99999, MEDIUMINT UNSIGNED is the best type. Of the types that represent all the required values, this type uses the least amount of storage.

All basic calculations (+, -, *, and /) with DECIMAL columns are done with precision of 65 decimal (base 10) digits. See Section 11.1.1, “Numeric Data Type Syntax”.

If accuracy is not too important or if speed is the highest priority, the DOUBLE type may be good enough. For high precision, you can always convert to a fixed-point type stored in a BIGINT. This enables you to do all calculations with 64-bit integers and then convert results back to floating-point values as necessary.

### 11.9 Using Data Types from Other Database Engines

To facilitate the use of code written for SQL implementations from other vendors, MySQL maps data types as shown in the following table. These mappings make it easier to import table definitions from other database systems into MySQL.

<table>
<thead>
<tr>
<th>Other Vendor Type</th>
<th>MySQL Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOL</td>
<td>TINYINT</td>
</tr>
<tr>
<td>BOOLEAN</td>
<td>TINYINT</td>
</tr>
<tr>
<td>CHARACTER VARYING(M)</td>
<td>VARCHAR(M)</td>
</tr>
<tr>
<td>FIXED</td>
<td>DECIMAL</td>
</tr>
<tr>
<td>FLOAT4</td>
<td>FLOAT</td>
</tr>
<tr>
<td>FLOAT8</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>INT1</td>
<td>TINYINT</td>
</tr>
<tr>
<td>INT2</td>
<td>SMALLINT</td>
</tr>
<tr>
<td>INT3</td>
<td>MEDIUMINT</td>
</tr>
<tr>
<td>INT4</td>
<td>INT</td>
</tr>
<tr>
<td>INT8</td>
<td>BIGINT</td>
</tr>
<tr>
<td>LONG VARBINARY</td>
<td>MEDIUMBLOB</td>
</tr>
<tr>
<td>LONG VARCHAR</td>
<td>MEDIUMTEXT</td>
</tr>
</tbody>
</table>
Using Data Types from Other Database Engines

<table>
<thead>
<tr>
<th>Other Vendor Type</th>
<th>MySQL Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>LONG</td>
<td>MEDIUMTEXT</td>
</tr>
<tr>
<td>MIDDLEINT</td>
<td>MEDIUMINT</td>
</tr>
<tr>
<td>NUMERIC</td>
<td>DECIMAL</td>
</tr>
</tbody>
</table>

Data type mapping occurs at table creation time, after which the original type specifications are discarded. If you create a table with types used by other vendors and then issue a `DESCRIBE tbl_name` statement, MySQL reports the table structure using the equivalent MySQL types. For example:

```sql
mysql> CREATE TABLE t (a BOOL, b FLOAT8, c LONG VARCHAR, d NUMERIC);
Query OK, 0 rows affected (0.00 sec)

mysql> DESCRIBE t;
+-------+---------------+------+-----+---------+-------+
| Field | Type          | Null | Key | Default | Extra |
|-------+---------------+------+-----+---------+-------|
| a     | tinyint(1)    | YES  |     | NULL    |       |
| b     | double        | YES  |     | NULL    |       |
| c     | mediumtext    | YES  |     | NULL    |       |
| d     | decimal(10,0) | YES  |     | NULL    |       |
+-------+---------------+------+-----+---------+-------+
4 rows in set (0.01 sec)
```

</tbody>
</table>
Expressions can be used at several points in SQL statements, such as in the ORDER BY or HAVING clauses of SELECT statements, in the WHERE clause of a SELECT, DELETE, or UPDATE statement, or in SET statements. Expressions can be written using values from several sources, such as literal values, column values, NULL, variables, built-in functions and operators, loadable functions, and stored functions (a type of stored object).

This chapter describes the built-in functions and operators that are permitted for writing expressions in MySQL. For information about loadable functions and stored functions, see Section 5.7, “MySQL Server Loadable Functions”, and Section 25.2, “Using Stored Routines”. For the rules describing how the server interprets references to different kinds of functions, see Section 9.2.5, “Function Name Parsing and Resolution”.

An expression that contains NULL always produces a NULL value unless otherwise indicated in the documentation for a particular function or operator.

Note

By default, there must be no whitespace between a function name and the parenthesis following it. This helps the MySQL parser distinguish between function calls and references to tables or columns that happen to have the same name as a function. However, spaces around function arguments are permitted.
To tell the MySQL server to accept spaces after function names by starting it with the `--sql-mode=IGNORE_SPACE` option. (See Section 5.1.11, “Server SQL Modes”.) Individual client programs can request this behavior by using the CLIENT_IGNORE_SPACE option for `mysql_real_connect()`. In either case, all function names become reserved words.

For the sake of brevity, some examples in this chapter display the output from the `mysql` program in abbreviated form. Rather than showing examples in this format:

```
mysql> SELECT MOD(29, 9);
+-----------+
| mod(29,9) |
+-----------+
|      2    |
+-----------+
1 rows in set (0.00 sec)
```

This format is used instead:

```
mysql> SELECT MOD(29, 9);  
-> 2
```

### 12.1 Built-In Function and Operator Reference

The following table lists each built-in (native) function and operator and provides a short description of each one. For a table listing functions that are loadable at runtime, see Section 12.2, “Loadable Function Reference”.

**Table 12.1 Built-In Functions and Operators**

### 12.2 Loadable Function Reference

The following table lists each function that is loadable at runtime and provides a short description of each one. For a table listing built-in functions and operators, see Section 12.1, “Built-In Function and Operator Reference”

For general information about loadable functions, see Section 5.7, “MySQL Server Loadable Functions”.

#### Table 12.2 Loadable Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Deprecated</th>

</table>
### 12.3 Type Conversion in Expression Evaluation

When an operator is used with operands of different types, type conversion occurs to make the operands compatible. Some conversions occur implicitly. For example, MySQL automatically converts strings to numbers as necessary, and vice versa.

```sql
mysql> SELECT 1+'1';
-> 2
```

```sql
mysql> SELECT CONCAT(2, ' test');
-> '2 test'
```

It is also possible to convert a number to a string explicitly using the `CAST()` function. Conversion occurs implicitly with the `CONCAT()` function because it expects string arguments.

```sql
mysql> SELECT 38.8, CAST(38.8 AS CHAR);
-> 38.8, '38.8'
```

```sql
mysql> SELECT 38.8, CONCAT(38.8);
-> 38.8, '38.8'
```
See later in this section for information about the character set of implicit number-to-string conversions, and for modified rules that apply to CREATE TABLE ... SELECT statements.

The following rules describe how conversion occurs for comparison operations:

- If one or both arguments are NULL, the result of the comparison is NULL, except for the NULL-safe <=> equality comparison operator. For NULL <=> NULL, the result is true. No conversion is needed.
- If both arguments in a comparison operation are strings, they are compared as strings.
- If both arguments are integers, they are compared as integers.
- Hexadecimal values are treated as binary strings if not compared to a number.
- If one of the arguments is a TIMESTAMP or DATETIME column and the other argument is a constant, the constant is converted to a timestamp before the comparison is performed. This is done to be more ODBC-friendly. This is not done for the arguments to IN(). To be safe, always use complete datetime, date, or time strings when doing comparisons. For example, to achieve best results when using BETWEEN with date or time values, use CAST() to explicitly convert the values to the desired data type.

A single-row subquery from a table or tables is not considered a constant. For example, if a subquery returns an integer to be compared to a DATETIME value, the comparison is done as two integers. The integer is not converted to a temporal value. To compare the operands as DATETIME values, use CAST() to explicitly convert the subquery value to DATETIME.

- If one of the arguments is a decimal value, comparison depends on the other argument. The arguments are compared as decimal values if the other argument is a decimal or integer value, or as floating-point values if the other argument is a floating-point value.
- In all other cases, the arguments are compared as floating-point (double-precision) numbers. For example, a comparison of string and numeric operands takes place as a comparison of floating-point numbers.

For information about conversion of values from one temporal type to another, see Section 11.2.8, “Conversion Between Date and Time Types”.

Comparison of JSON values takes place at two levels. The first level of comparison is based on the JSON types of the compared values. If the types differ, the comparison result is determined solely by which type has higher precedence. If the two values have the same JSON type, a second level of comparison occurs using type-specific rules. For comparison of JSON and non-JSON values, the non-JSON value is converted to JSON and the values compared as JSON values. For details, see Comparison and Ordering of JSON Values.

The following examples illustrate conversion of strings to numbers for comparison operations:

```
mysql> SELECT 1 > '6x';
-> 0
mysql> SELECT 7 > '6x';
-> 1
mysql> SELECT 0 > 'x6';
-> 0
mysql> SELECT 0 = 'x6';
-> 1
```

For comparisons of a string column with a number, MySQL cannot use an index on the column to look up the value quickly. If str_col is an indexed string column, the index cannot be used when performing the lookup in the following statement:

```
SELECT * FROM tbl_name WHERE str_col=1;
```
Type Conversion in Expression Evaluation

The reason for this is that there are many different strings that may convert to the value 1, such as '1', '1', or '1a'.

Comparisons between floating-point numbers and large values of INTEGER type are approximate because the integer is converted to double-precision floating point before comparison, which is not capable of representing all 64-bit integers exactly. For example, the integer value $2^{53} + 1$ is not representable as a float, and is rounded to $2^{53}$ or $2^{53} + 2$ before a float comparison, depending on the platform.

To illustrate, only the first of the following comparisons compares equal values, but both comparisons return true (1):

```sql
mysql> SELECT '9223372036854775807' = 9223372036854775807;
-> 1
mysql> SELECT '9223372036854775807' = 9223372036854775806;
-> 1
```

When conversions from string to floating-point and from integer to floating-point occur, they do not necessarily occur the same way. The integer may be converted to floating-point by the CPU, whereas the string is converted digit by digit in an operation that involves floating-point multiplications. Also, results can be affected by factors such as computer architecture or the compiler version or optimization level. One way to avoid such problems is to use CAST() so that a value is not converted implicitly to a float-point number:

```sql
mysql> SELECT CAST('9223372036854775807' AS UNSIGNED) = 9223372036854775806;
-> 0
```

For more information about floating-point comparisons, see Section B.3.4.8, “Problems with Floating-Point Values”.

The server includes dtoa, a conversion library that provides the basis for improved conversion between string or DECIMAL values and approximate-value (FLOAT/DoubLe) numbers:

- Consistent conversion results across platforms, which eliminates, for example, Unix versus Windows conversion differences.
- Accurate representation of values in cases where results previously did not provide sufficient precision, such as for values close to IEEE limits.
- Conversion of numbers to string format with the best possible precision. The precision of dtoa is always the same or better than that of the standard C library functions.

Because the conversions produced by this library differ in some cases from non-dtoa results, the potential exists for incompatibilities in applications that rely on previous results. For example, applications that depend on a specific exact result from previous conversions might need adjustment to accommodate additional precision.

The dtoa library provides conversions with the following properties. \( D \) represents a value with a DECIMAL or string representation, and \( F \) represents a floating-point number in native binary (IEEE) format.

- \( F \rightarrow D \) conversion is done with the best possible precision, returning \( D \) as the shortest string that yields \( F \) when read back in and rounded to the nearest value in native binary format as specified by IEEE.
- \( D \rightarrow F \) conversion is done such that \( F \) is the nearest native binary number to the input decimal string \( D \).

These properties imply that \( F \rightarrow D \rightarrow F \) conversions are lossless unless \( F \) is \(-\text{inf}, +\text{inf}, \text{or NaN}\). The latter values are not supported because the SQL standard defines them as invalid values for FLOAT or DOUBLE.

For \( D \rightarrow F \) -> \( D \) conversions, a sufficient condition for losslessness is that \( D \) uses 15 or fewer digits of precision, is not a denormal value, \(-\text{inf}, +\text{inf}, \text{or Nan}\). In some cases, the conversion is lossless even if \( D \) has more than 15 digits of precision, but this is not always the case.
Explicit conversion of a numeric or temporal value to string produces a value that has a character set and collation determined by the character_set_connection and collation_connection system variables. (These variables commonly are set with SET NAMES. For information about connection character sets, see Section 10.4, "Connection Character Sets and Collations".)

This means that such a conversion results in a character (nonbinary) string (a CHAR, VARCHAR, or LONGTEXT value), except in the case that the connection character set is set to binary. In that case, the conversion result is a binary string (a BINARY, VARBINARY, or LONGBLOB value).

For integer expressions, the preceding remarks about expression evaluation apply somewhat differently for expression assignment; for example, in a statement such as this:

```sql
CREATE TABLE t SELECT integer_expr;
```

In this case, the table in the column resulting from the expression has type INT or BIGINT depending on the length of the integer expression. If the maximum length of the expression does not fit in an INT, BIGINT is used instead. The length is taken from the max_length value of the SELECT result set metadata (see C API Basic Data Structures). This means that you can force a BIGINT rather than INT by use of a sufficiently long expression:

```sql
CREATE TABLE t SELECT 000000000000000000000;
```

### 12.4 Operators

<td></td>
</tr>
</tbody>
</table>

### 12.4.1 Operator Precedence
Operator precedences are shown in the following list, from highest precedence to the lowest. Operators that are shown together on a line have the same precedence.

```
INTERVAL
BINARY, COLLATE
! (unary minus), ~ (unary bit inversion)
^,
*, /, DIV, %, MOD
-, +
<, >
=
| (comparison), <=>, >=, <=, <, <=>, !=, IS, LIKE, REGEXP, IN, MEMBER OF
BETWEEN, CASE, WHEN, THEN, ELSE
NOT
AND, &&
XOR
OR, ||
= (assignment), :=
```

The precedence of `=` depends on whether it is used as a comparison operator (`=`) or as an assignment operator (`:=`). When used as a comparison operator, it has the same precedence as `<=>, >=, <=, <, <=>, !=, IS, LIKE, REGEXP, IN`. When used as an assignment operator, it has the same precedence as `:=`. Section 13.7.6.1, “SET Syntax for Variable Assignment”, and Section 9.4, “User-Defined Variables”, explain how MySQL determines which interpretation of `=` should apply.

For operators that occur at the same precedence level within an expression, evaluation proceeds left to right, with the exception that assignments evaluate right to left.

The precedence and meaning of some operators depends on the SQL mode:

- By default, `||` is a logical OR operator. With `PIPES_AS_CONCAT` enabled, `||` is string concatenation, with a precedence between `^` and the unary operators.

- By default, `!` has a higher precedence than `NOT`. With `HIGH_NOT_PRECEDENCE` enabled, `!` and `NOT` have the same precedence.

See Section 5.1.11, “Server SQL Modes”.

The precedence of operators determines the order of evaluation of terms in an expression. To override this order and group terms explicitly, use parentheses. For example:

```
mysql> SELECT 1+2*3;
-> 7
mysql> SELECT (1+2)*3;
-> 9
```

### 12.4.2 Comparison Functions and Operators

<td>Negation of simple pattern matching</td>
</tr>
<tr>
<td><strong>STRCMP()</strong></td>
<td>Compare two strings</td>
</tr>
</tbody>
</table>

Comparison operations result in a value of 1 (TRUE), 0 (FALSE), or NULL. These operations work for both numbers and strings. Strings are automatically converted to numbers and numbers to strings as necessary.

The following relational comparison operators can be used to compare not only scalar operands, but row operands:

- `=  >  <  >=  <=  <>  !=`

The descriptions for those operators later in this section detail how they work with row operands. For additional examples of row comparisons in the context of row subqueries, see Section 13.2.15.5, “Row Subqueries”.

Some of the functions in this section return values other than 1 (TRUE), 0 (FALSE), or NULL. **LEAST()** and **GREATEST()** are examples of such functions; Section 12.3, “Type Conversion in Expression Evaluation”, describes the rules for comparison operations performed by these and similar functions for determining their return values.

---

**Note**

In previous versions of MySQL, when evaluating an expression containing **LEAST()** or **GREATEST()**, the server attempted to guess the context in which the function was used, and to coerce the function’s arguments to the data type of the
Comparison Functions and Operators

expression as a whole. For example, the arguments to \texttt{LEAST("11", "45", "2")} are evaluated and sorted as strings, so that this expression returns "11".

The function is executed using the arguments as provided, performing data type conversions to one or more of the arguments if and only if they are not all of the same type. Any type coercion mandated by an expression that makes use of the return value is now performed following function execution. This means that \texttt{LEAST("11", "45", "2") + 0} evaluates to "11" + 0 and thus to integer 11.

To convert a value to a specific type for comparison purposes, you can use the \texttt{CAST()} function. String values can be converted to a different character set using \texttt{CONVERT()}. See Section 12.10, "Cast Functions and Operators".

By default, string comparisons are not case-sensitive and use the current character set. The default is \texttt{utf8mb4}.

- \texttt{=}

  Equal:

  \begin{verbatim}
  mysql> SELECT 1 = 0;
  -> 0
  mysql> SELECT '0' = 0;
  -> 1
  mysql> SELECT '0.0' = 0;
  -> 1
  mysql> SELECT '0.01' = 0;
  -> 0
  mysql> SELECT '.01' = 0.01;
  -> 1
  \end{verbatim}

  For row comparisons, \((a, b) = (x, y)\) is equivalent to:

  \((a = x) \land (b = y)\)

- \texttt{<>}

  \texttt{NULL-safe equal}. This operator performs an equality comparison like the \texttt{=} operator, but returns \texttt{1} rather than \texttt{NULL} if both operands are \texttt{NULL}, and \texttt{0} rather than \texttt{NULL} if one operand is \texttt{NULL}.

  The \texttt{<>} operator is equivalent to the standard SQL \texttt{IS NOT DISTINCT FROM} operator.

  \begin{verbatim}
  mysql> SELECT 1 <=> 1, NULL <=> NULL, 1 <=> NULL;
  -> 1, 1, 0
  mysql> SELECT 1 = 1, NULL = NULL, 1 = NULL;
  -> 1, NULL, NULL
  \end{verbatim}

  For row comparisons, \((a, b) <> (x, y)\) is equivalent to:

  \((a <> x) \land (b <> y)\)

- \texttt{<>}, \texttt{!=}

  Not equal:

  \begin{verbatim}
  mysql> SELECT '.01' <> '0.01';
  -> 1
  mysql> SELECT .01 <> '0.01';
  -> 0
  mysql> SELECT 'zapp' <> 'zappp';
  -> 1
  \end{verbatim}
For row comparisons, \((a, b) <> (x, y)\) and \((a, b) != (x, y)\) are equivalent to:

\((a <> x) \text{ OR } (b <> y)\)

- \(<=\)

Less than or equal:

```sql
mysql> SELECT 0.1 <= 2;
-> 1
```

For row comparisons, \((a, b) <= (x, y)\) is equivalent to:

\((a < x) \text{ OR } ((a = x) \text{ AND } (b <= y))\)

- \(<\)

Less than:

```sql
mysql> SELECT 2 < 2;
-> 0
```

For row comparisons, \((a, b) < (x, y)\) is equivalent to:

\((a < x) \text{ OR } ((a = x) \text{ AND } (b < y))\)

- \(>=\)

Greater than or equal:

```sql
mysql> SELECT 2 >= 2;
-> 1
```

For row comparisons, \((a, b) >= (x, y)\) is equivalent to:

\((a > x) \text{ OR } ((a = x) \text{ AND } (b >= y))\)

- \(>\)

Greater than:

```sql
mysql> SELECT 2 > 2;
-> 0
```

For row comparisons, \((a, b) > (x, y)\) is equivalent to:

\((a > x) \text{ OR } ((a = x) \text{ AND } (b > y))\)

- \(\text{expr BETWEEN min AND max}\)

If \(\text{expr}\) is greater than or equal to \(\text{min}\) and \(\text{expr}\) is less than or equal to \(\text{max}\), BETWEEN returns 1, otherwise it returns 0. This is equivalent to the expression \((\text{min} <= \text{expr} \text{ AND } \text{expr} <= \text{max})\) if all the arguments are of the same type. Otherwise type conversion takes place according to the rules described in Section 12.3, “Type Conversion in Expression Evaluation”, but applied to all the three arguments.

```sql
mysql> SELECT 2 BETWEEN 1 AND 3, 2 BETWEEN 3 and 1;
-> 1, 0
mysql> SELECT 1 BETWEEN 2 AND 3;
-> 0
mysql> SELECT 'b' BETWEEN 'a' AND 'c';
```
Comparison Functions and Operators

For best results when using BETWEEN with date or time values, use CAST() to explicitly convert the values to the desired data type. Examples: If you compare a DATETIME to two DATE values, convert the DATE values to DATETIME values. If you use a string constant such as '2001-1-1' in a comparison to a DATE, cast the string to a DATE.

- expr NOT BETWEEN min AND max

  This is the same as NOT (expr BETWEEN min AND max).

- COALESCE(value,...)

  Returns the first non-NULL value in the list, or NULL if there are no non-NULL values.

  The return type of COALESCE() is the aggregated type of the argument types.

- GREATEST(value1,value2,...)

  With two or more arguments, returns the largest (maximum-valued) argument. The arguments are compared using the same rules as for LEAST().

- expr IN (value,...)

  Returns 1 (true) if expr is equal to any of the values in the IN() list, else returns 0 (false).

  Type conversion takes place according to the rules described in Section 12.3, “Type Conversion in Expression Evaluation”, applied to all the arguments. If no type conversion is needed for the values in the IN() list, they are all non-JSON constants of the same type, and expr can be compared to each of them as a value of the same type (possibly after type conversion), an optimization takes place. The values the list are sorted and the search for expr is done using a binary search, which makes the IN() operation very quick.

- IN() can be used to compare row constructors:
Comparison Functions and Operators

You should never mix quoted and unquoted values in an IN() list because the comparison rules for quoted values (such as strings) and unquoted values (such as numbers) differ. Mixing types may therefore lead to inconsistent results. For example, do not write an IN() expression like this:

```
SELECT val1 FROM tbl1 WHERE val1 IN (1,2,'a');
```

Instead, write it like this:

```
SELECT val1 FROM tbl1 WHERE val1 IN ('1','2','a');
```

Implicit type conversion may produce nonintuitive results:

```
mysql> SELECT 'a' IN (0), 0 IN ('b');
-> 1, 1
```

In both cases, the comparison values are converted to floating-point values, yielding 0.0 in each case, and a comparison result of 1 (true).

The number of values in the IN() list is only limited by the `max_allowed_packet` value.

To comply with the SQL standard, IN() returns NULL not only if the expression on the left hand side is NULL, but also if no match is found in the list and one of the expressions in the list is NULL.

IN() syntax can also be used to write certain types of subqueries. See Section 13.2.15.3, “Subqueries with ANY, IN, or SOME”.

- **expr NOT IN (value,...)**
  
  This is the same as NOT (expr IN (value,...)).

- **INTERVAL(N, N1, N2, N3,...)**
  
  Returns 0 if $N \leq N1$, 1 if $N \leq N2$ and so on, or -1 if $N$ is NULL. All arguments are treated as integers. It is required that $N1 \leq N2 \leq N3 \leq \ldots \leq Nn$ for this function to work correctly. This is because a binary search is used (very fast).

```
mysql> SELECT INTERVAL(23, 1, 15, 17, 30, 44, 200);
-> 3
mysql> SELECT INTERVAL(10, 1, 10, 100, 1000);
-> 2
mysql> SELECT INTERVAL(22, 23, 30, 44, 200);
-> 0
```

- **IS boolean_value**

  Tests a value against a boolean value, where boolean_value can be TRUE, FALSE, or UNKNOWN.

```
mysql> SELECT 1 IS TRUE, 0 IS FALSE, NULL IS UNKNOWN;
-> 1, 1, 1
```

- **IS NOT boolean_value**

  Tests a value against a boolean value, where boolean_value can be TRUE, FALSE, or UNKNOWN.

```
mysql> SELECT 1 IS NOT UNKNOWN, 0 IS NOT UNKNOWN, NULL IS NOT UNKNOWN;
-> 1, 1, 0
```

- **IS NULL**

  Tests whether a value is NULL.
Comparison Functions and Operators

mysql> SELECT 1 IS NULL, 0 IS NULL, NULL IS NULL;
-> 0, 0, 1

To work well with ODBC programs, MySQL supports the following extra features when using IS NULL:

• If sql_auto_is_null variable is set to 1, then after a statement that successfully inserts an automatically generated AUTO_INCREMENT value, you can find that value by issuing a statement of the following form:

```sql
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

If the statement returns a row, the value returned is the same as if you invoked the LAST_INSERT_ID() function. For details, including the return value after a multiple-row insert, see Section 12.15, “Information Functions”. If no AUTO_INCREMENT value was successfully inserted, the SELECT statement returns no row.

The behavior of retrieving an AUTO_INCREMENT value by using an IS NULL comparison can be disabled by setting sql_auto_is_null = 0. See Section 5.1.8, “Server System Variables”.

The default value of sql_auto_is_null is 0.

• For DATE and DATETIME columns that are declared as NOT NULL, you can find the special date '0000-00-00' by using a statement like this:

```sql
SELECT * FROM tbl_name WHERE date_column IS NULL
```

This is needed to get some ODBC applications to work because ODBC does not support a '0000-00-00' date value.

See Obtaining Auto-Increment Values, and the description for the FLAG_AUTO_IS_NULL option at Connector/ODBC Connection Parameters.

• IS NOT NULL

Tests whether a value is not NULL.

mysql> SELECT 1 IS NOT NULL, 0 IS NOT NULL, NULL IS NOT NULL;
-> 1, 1, 0

• ISNULL(expr)

If expr is NULL, ISNULL() returns 1, otherwise it returns 0.

mysql> SELECT ISNULL(1+1);
-> 0
mysql> SELECT ISNULL(1/0);
-> 1

ISNULL() can be used instead of = to test whether a value is NULL. (Comparing a value to NULL using = always yields NULL.)

The ISNULL() function shares some special behaviors with the IS NULL comparison operator. See the description of IS NULL.
• **LEAST(value1, value2,...)**

With two or more arguments, returns the smallest (minimum-valued) argument. The arguments are compared using the following rules:

- If any argument is **NULL**, the result is **NULL**. No comparison is needed.
- If all arguments are integer-valued, they are compared as integers.
- If at least one argument is double precision, they are compared as double-precision values. Otherwise, if at least one argument is a **DECIMAL** value, they are compared as **DECIMAL** values.
- If the arguments comprise a mix of numbers and strings, they are compared as strings.
- If any argument is a nonbinary (character) string, the arguments are compared as nonbinary strings.
- In all other cases, the arguments are compared as binary strings.

The return type of **LEAST()** is the aggregated type of the comparison argument types.

```sql
mysql> SELECT LEAST(2,0);
-> 0

mysql> SELECT LEAST(34.0,3.0,5.0,767.0);
-> 3.0

mysql> SELECT LEAST('B','A','C');
-> 'A'
```

### 12.4.3 Logical Operators

**Table 12.5 Logical Operators**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AND, &amp;&amp;</td>
<td>Logical AND</td>
</tr>
<tr>
<td>NOT, !</td>
<td>Negates value</td>
</tr>
<tr>
<td>OR,</td>
<td></td>
</tr>
<tr>
<td>XOR</td>
<td>Logical XOR</td>
</tr>
</tbody>
</table>

In SQL, all logical operators evaluate to **TRUE**, **FALSE**, or **NULL** (**UNKNOWN**). In MySQL, these are implemented as 1 (**TRUE**), 0 (**FALSE**), and **NULL**. Most of this is common to different SQL database servers, although some servers may return any nonzero value for **TRUE**.
