

MySQL 8.3 Reference Manual

Including MySQL NDB Cluster 8.3

Abstract

This is the MySQL Reference Manual. It documents MySQL 8.3 (8.3.0), as well as NDB Cluster 8.3 (8.3.0-ndb-8.3.0), respectively. It may include documentation of features of MySQL versions that have not yet been released. For information about which versions have been released, see the [MySQL 8.3 Release Notes](#).

MySQL 8.3 features. This manual describes features that are not included in every edition of MySQL 8.3; such features may not be included in the edition of MySQL 8.3 licensed to you. If you have any questions about the features included in your edition of MySQL 8.3, refer to your MySQL 8.3 license agreement or contact your Oracle sales representative.

For notes detailing the changes in each release, see the [MySQL 8.3 Release Notes](#).

For legal information, including licensing information, see the [Preface and Legal Notices](#).

For help with using MySQL, please visit the [MySQL Forums](#), where you can discuss your issues with other MySQL users.

Table of Contents

Preface and Legal Notices	xxvii
1 General Information	1
1.1 About This Manual	2
1.2 Overview of the MySQL Database Management System	4
1.2.1 What is MySQL?	4
1.2.2 The Main Features of MySQL	5
1.2.3 History of MySQL	8
1.3 What Is New in MySQL 8.3	8
1.4 Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 8.3	14
1.5 How to Report Bugs or Problems	17
1.6 MySQL Standards Compliance	21
1.6.1 MySQL Extensions to Standard SQL	22
1.6.2 MySQL Differences from Standard SQL	25
1.6.3 How MySQL Deals with Constraints	28
2 Installing MySQL	31
2.1 General Installation Guidance	33
2.1.1 Supported Platforms	33
2.1.2 Which MySQL Version and Distribution to Install	33
2.1.3 How to Get MySQL	34
2.1.4 Verifying Package Integrity Using MD5 Checksums or GnuPG	35
2.1.5 Installation Layouts	50
2.1.6 Compiler-Specific Build Characteristics	50
2.2 Installing MySQL on Unix/Linux Using Generic Binaries	50
2.3 Installing MySQL on Microsoft Windows	53
2.3.1 Choosing an Installation Package	55
2.3.2 Configuration: Using MySQL Configurator	57
2.3.3 Configuration: Manually	62
2.3.4 Troubleshooting a Microsoft Windows MySQL Server Installation	70
2.3.5 Windows Postinstallation Procedures	71
2.3.6 Windows Platform Restrictions	73
2.4 Installing MySQL on macOS	75
2.4.1 General Notes on Installing MySQL on macOS	75
2.4.2 Installing MySQL on macOS Using Native Packages	76
2.4.3 Installing and Using the MySQL Launch Daemon	79
2.4.4 Installing and Using the MySQL Preference Pane	82
2.5 Installing MySQL on Linux	87
2.5.1 Installing MySQL on Linux Using the MySQL Yum Repository	88
2.5.2 Installing MySQL on Linux Using the MySQL APT Repository	93
2.5.3 Using the MySQL SLES Repository	102
2.5.4 Installing MySQL on Linux Using RPM Packages from Oracle	108
2.5.5 Installing MySQL on Linux Using Debian Packages from Oracle	112
2.5.6 Deploying MySQL on Linux with Docker Containers	114
2.5.7 Installing MySQL on Linux from the Native Software Repositories	126
2.5.8 Installing MySQL on Linux with Juju	128
2.5.9 Managing MySQL Server with systemd	128
2.6 Installing MySQL Using Unbreakable Linux Network (ULN)	133
2.7 Installing MySQL on Solaris	134
2.7.1 Installing MySQL on Solaris Using a Solaris PKG	134
2.8 Installing MySQL from Source	135
2.8.1 Source Installation Methods	136
2.8.2 Source Installation Prerequisites	136
2.8.3 MySQL Layout for Source Installation	137
2.8.4 Installing MySQL Using a Standard Source Distribution	138
2.8.5 Installing MySQL Using a Development Source Tree	142

2.8.6 Configuring SSL Library Support	143
2.8.7 MySQL Source-Configuration Options	144
2.8.8 Dealing with Problems Compiling MySQL	169
2.8.9 MySQL Configuration and Third-Party Tools	170
2.8.10 Generating MySQL Doxygen Documentation Content	170
2.9 Postinstallation Setup and Testing	171
2.9.1 Initializing the Data Directory	172
2.9.2 Starting the Server	177
2.9.3 Testing the Server	180
2.9.4 Securing the Initial MySQL Account	182
2.9.5 Starting and Stopping MySQL Automatically	183
2.10 Perl Installation Notes	184
2.10.1 Installing Perl on Unix	185
2.10.2 Installing ActiveState Perl on Windows	186
2.10.3 Problems Using the Perl DBI/DBD Interface	186
3 Upgrading MySQL	189
3.1 Before You Begin	189
3.2 Upgrade Paths	190
3.3 Upgrade Best Practices	191
3.4 What the MySQL Upgrade Process Upgrades	194
3.5 Changes in MySQL 8.3	196
3.6 Preparing Your Installation for Upgrade	196
3.7 Upgrading MySQL Binary or Package-based Installations on Unix/Linux	199
3.8 Upgrading MySQL with the MySQL Yum Repository	203
3.9 Upgrading MySQL with the MySQL APT Repository	204
3.10 Upgrading MySQL with the MySQL SLES Repository	204
3.11 Upgrading MySQL on Windows	205
3.12 Upgrading a Docker Installation of MySQL	206
3.13 Upgrade Troubleshooting	206
3.14 Rebuilding or Repairing Tables or Indexes	206
3.15 Copying MySQL Databases to Another Machine	208
4 Downgrading MySQL	211
5 Tutorial	213
5.1 Connecting to and Disconnecting from the Server	213
5.2 Entering Queries	214
5.3 Creating and Using a Database	217
5.3.1 Creating and Selecting a Database	218
5.3.2 Creating a Table	219
5.3.3 Loading Data into a Table	220
5.3.4 Retrieving Information from a Table	221
5.4 Getting Information About Databases and Tables	234
5.5 Using mysql in Batch Mode	235
5.6 Examples of Common Queries	236
5.6.1 The Maximum Value for a Column	237
5.6.2 The Row Holding the Maximum of a Certain Column	237
5.6.3 Maximum of Column per Group	237
5.6.4 The Rows Holding the Group-wise Maximum of a Certain Column	238
5.6.5 Using User-Defined Variables	239
5.6.6 Using Foreign Keys	239
5.6.7 Searching on Two Keys	241
5.6.8 Calculating Visits Per Day	241
5.6.9 Using AUTO_INCREMENT	242
5.7 Using MySQL with Apache	244
6 MySQL Programs	247
6.1 Overview of MySQL Programs	248
6.2 Using MySQL Programs	251
6.2.1 Invoking MySQL Programs	251
6.2.2 Specifying Program Options	252

6.2.3	Command Options for Connecting to the Server	266
6.2.4	Connecting to the MySQL Server Using Command Options	278
6.2.5	Connecting to the Server Using URI-Like Strings or Key-Value Pairs	281
6.2.6	Connecting to the Server Using DNS SRV Records	288
6.2.7	Connection Transport Protocols	289
6.2.8	Connection Compression Control	291
6.2.9	Setting Environment Variables	294
6.3	Server and Server-Startup Programs	295
6.3.1	mysqld — The MySQL Server	295
6.3.2	mysqld_safe — MySQL Server Startup Script	296
6.3.3	mysql.server — MySQL Server Startup Script	304
6.3.4	mysqld_multi — Manage Multiple MySQL Servers	306
6.4	Installation-Related Programs	311
6.4.1	comp_err — Compile MySQL Error Message File	311
6.4.2	mysql_secure_installation — Improve MySQL Installation Security	314
6.4.3	mysql_ssl_rsa_setup — Create SSL/RSA Files	319
6.4.4	mysql_tzinfo_to_sql — Load the Time Zone Tables	322
6.4.5	mysql_upgrade — Deprecated; Performs No Tasks and Exits with Status 0	323
6.5	Client Programs	323
6.5.1	mysql — The MySQL Command-Line Client	323
6.5.2	mysqladmin — A MySQL Server Administration Program	367
6.5.3	mysqlcheck — A Table Maintenance Program	383
6.5.4	mysqldump — A Database Backup Program	397
6.5.5	mysqlimport — A Data Import Program	435
6.5.6	mysqlpump — A Database Backup Program	448
6.5.7	mysqlshow — Display Database, Table, and Column Information	473
6.5.8	mysqlslap — A Load Emulation Client	485
6.6	Administrative and Utility Programs	502
6.6.1	ibd2sdi — InnoDB Tablespace SDI Extraction Utility	502
6.6.2	innochecksum — Offline InnoDB File Checksum Utility	507
6.6.3	myisam_ftdump — Display Full-Text Index information	513
6.6.4	myisamchk — MyISAM Table-Maintenance Utility	515
6.6.5	myisamlog — Display MyISAM Log File Contents	534
6.6.6	myisampack — Generate Compressed, Read-Only MyISAM Tables	535
6.6.7	mysql_config_editor — MySQL Configuration Utility	541
6.6.8	mysql_migrate_keyring — Keyring Key Migration Utility	548
6.6.9	mysqlbinlog — Utility for Processing Binary Log Files	557
6.6.10	mysqldumpslow — Summarize Slow Query Log Files	587
6.7	Program Development Utilities	590
6.7.1	mysql_config — Display Options for Compiling Clients	590
6.7.2	my_print_defaults — Display Options from Option Files	591
6.8	Miscellaneous Programs	593
6.8.1	lz4_decompress — Decompress mysqlpump LZ4-Compressed Output	593
6.8.2	perror — Display MySQL Error Message Information	593
6.8.3	zlib_decompress — Decompress mysqlpump ZLIB-Compressed Output	594
6.9	Environment Variables	594
6.10	Unix Signal Handling in MySQL	597
7	MySQL Server Administration	599
7.1	The MySQL Server	600
7.1.1	Configuring the Server	601
7.1.2	Server Configuration Defaults	602
7.1.3	Server Configuration Validation	602
7.1.4	Server Option, System Variable, and Status Variable Reference	603
7.1.5	Server System Variable Reference	652
7.1.6	Server Status Variable Reference	677
7.1.7	Server Command Options	695
7.1.8	Server System Variables	722
7.1.9	Using System Variables	878

7.1.10 Server Status Variables	909
7.1.11 Server SQL Modes	934
7.1.12 Connection Management	946
7.1.13 IPv6 Support	953
7.1.14 Network Namespace Support	957
7.1.15 MySQL Server Time Zone Support	962
7.1.16 Resource Groups	967
7.1.17 Server-Side Help Support	971
7.1.18 Server Tracking of Client Session State	972
7.1.19 The Server Shutdown Process	975
7.2 The MySQL Data Directory	976
7.3 The mysql System Schema	977
7.4 MySQL Server Logs	982
7.4.1 Selecting General Query Log and Slow Query Log Output Destinations	983
7.4.2 The Error Log	985
7.4.3 The General Query Log	1006
7.4.4 The Binary Log	1008
7.4.5 The Slow Query Log	1024
7.4.6 Server Log Maintenance	1027
7.5 MySQL Components	1029
7.5.1 Installing and Uninstalling Components	1030
7.5.2 Obtaining Component Information	1030
7.5.3 Error Log Components	1030
7.5.4 Query Attribute Components	1033
7.5.5 Scheduler Component	1033
7.6 MySQL Server Plugins	1034
7.6.1 Installing and Uninstalling Plugins	1035
7.6.2 Obtaining Server Plugin Information	1039
7.6.3 MySQL Enterprise Thread Pool	1040
7.6.4 The Rewriter Query Rewrite Plugin	1047
7.6.5 The ddl_rewriter Plugin	1055
7.6.6 Version Tokens	1058
7.6.7 The Clone Plugin	1069
7.6.8 The Keyring Proxy Bridge Plugin	1093
7.6.9 MySQL Plugin Services	1093
7.7 MySQL Server Loadable Functions	1100
7.7.1 Installing and Uninstalling Loadable Functions	1101
7.7.2 Obtaining Information About Loadable Functions	1103
7.8 Running Multiple MySQL Instances on One Machine	1103
7.8.1 Setting Up Multiple Data Directories	1104
7.8.2 Running Multiple MySQL Instances on Windows	1105
7.8.3 Running Multiple MySQL Instances on Unix	1108
7.8.4 Using Client Programs in a Multiple-Server Environment	1109
7.9 Debugging MySQL	1110
7.9.1 Debugging a MySQL Server	1110
7.9.2 Debugging a MySQL Client	1115
7.9.3 The LOCK_ORDER Tool	1116
7.9.4 The DBUG Package	1121
8 Security	1125
8.1 General Security Issues	1126
8.1.1 Security Guidelines	1126
8.1.2 Keeping Passwords Secure	1128
8.1.3 Making MySQL Secure Against Attackers	1131
8.1.4 Security-Related mysqld Options and Variables	1132
8.1.5 How to Run MySQL as a Normal User	1133
8.1.6 Security Considerations for LOAD DATA LOCAL	1134
8.1.7 Client Programming Security Guidelines	1137
8.2 Access Control and Account Management	1139

8.2.1 Account User Names and Passwords	1140
8.2.2 Privileges Provided by MySQL	1141
8.2.3 Grant Tables	1161
8.2.4 Specifying Account Names	1171
8.2.5 Specifying Role Names	1173
8.2.6 Access Control, Stage 1: Connection Verification	1174
8.2.7 Access Control, Stage 2: Request Verification	1177
8.2.8 Adding Accounts, Assigning Privileges, and Dropping Accounts	1179
8.2.9 Reserved Accounts	1182
8.2.10 Using Roles	1182
8.2.11 Account Categories	1189
8.2.12 Privilege Restriction Using Partial Revokes	1193
8.2.13 When Privilege Changes Take Effect	1199
8.2.14 Assigning Account Passwords	1200
8.2.15 Password Management	1201
8.2.16 Server Handling of Expired Passwords	1212
8.2.17 Pluggable Authentication	1214
8.2.18 Multifactor Authentication	1219
8.2.19 Proxy Users	1223
8.2.20 Account Locking	1231
8.2.21 Setting Account Resource Limits	1231
8.2.22 Troubleshooting Problems Connecting to MySQL	1233
8.2.23 SQL-Based Account Activity Auditing	1237
8.3 Using Encrypted Connections	1239
8.3.1 Configuring MySQL to Use Encrypted Connections	1240
8.3.2 Encrypted Connection TLS Protocols and Ciphers	1248
8.3.3 Creating SSL and RSA Certificates and Keys	1257
8.3.4 Connecting to MySQL Remotely from Windows with SSH	1265
8.3.5 Reusing SSL Sessions	1266
8.4 Security Components and Plugins	1269
8.4.1 Authentication Plugins	1269
8.4.2 The Connection-Control Plugins	1369
8.4.3 The Password Validation Component	1375
8.4.4 The MySQL Keyring	1387
8.4.5 MySQL Enterprise Audit	1457
8.4.6 The Audit Message Component	1543
8.4.7 MySQL Enterprise Firewall	1545
8.5 MySQL Enterprise Data Masking and De-Identification	1574
8.5.1 Data-Masking Components Versus the Data-Masking Plugin	1576
8.5.2 MySQL Enterprise Data Masking and De-Identification Components	1576
8.5.3 MySQL Enterprise Data Masking and De-Identification Plugin	1602
8.6 MySQL Enterprise Encryption	1618
8.6.1 MySQL Enterprise Encryption Installation and Upgrading	1619
8.6.2 Configuring MySQL Enterprise Encryption	1622
8.6.3 MySQL Enterprise Encryption Usage and Examples	1623
8.6.4 MySQL Enterprise Encryption Function Reference	1625
8.6.5 MySQL Enterprise Encryption Component Function Descriptions	1625
8.6.6 MySQL Enterprise Encryption Legacy Function Descriptions	1629
8.7 SELinux	1634
8.7.1 Check if SELinux is Enabled	1634
8.7.2 Changing the SELinux Mode	1635
8.7.3 MySQL Server SELinux Policies	1635
8.7.4 SELinux File Context	1635
8.7.5 SELinux TCP Port Context	1637
8.7.6 Troubleshooting SELinux	1638
8.8 FIPS Support	1639
9 Backup and Recovery	1643
9.1 Backup and Recovery Types	1644

9.2 Database Backup Methods	1647
9.3 Example Backup and Recovery Strategy	1649
9.3.1 Establishing a Backup Policy	1649
9.3.2 Using Backups for Recovery	1651
9.3.3 Backup Strategy Summary	1652
9.4 Using mysqldump for Backups	1652
9.4.1 Dumping Data in SQL Format with mysqldump	1653
9.4.2 Reloading SQL-Format Backups	1654
9.4.3 Dumping Data in Delimited-Text Format with mysqldump	1654
9.4.4 Reloading Delimited-Text Format Backups	1655
9.4.5 mysqldump Tips	1656
9.5 Point-in-Time (Incremental) Recovery	1658
9.5.1 Point-in-Time Recovery Using Binary Log	1658
9.5.2 Point-in-Time Recovery Using Event Positions	1659
9.6 MyISAM Table Maintenance and Crash Recovery	1661
9.6.1 Using myisamchk for Crash Recovery	1661
9.6.2 How to Check MyISAM Tables for Errors	1662
9.6.3 How to Repair MyISAM Tables	1663
9.6.4 MyISAM Table Optimization	1665
9.6.5 Setting Up a MyISAM Table Maintenance Schedule	1665
10 Optimization	1667
10.1 Optimization Overview	1668
10.2 Optimizing SQL Statements	1670
10.2.1 Optimizing SELECT Statements	1670
10.2.2 Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions	1721
10.2.3 Optimizing INFORMATION_SCHEMA Queries	1734
10.2.4 Optimizing Performance Schema Queries	1737
10.2.5 Optimizing Data Change Statements	1739
10.2.6 Optimizing Database Privileges	1740
10.2.7 Other Optimization Tips	1740
10.3 Optimization and Indexes	1741
10.3.1 How MySQL Uses Indexes	1741
10.3.2 Primary Key Optimization	1742
10.3.3 SPATIAL Index Optimization	1742
10.3.4 Foreign Key Optimization	1743
10.3.5 Column Indexes	1743
10.3.6 Multiple-Column Indexes	1744
10.3.7 Verifying Index Usage	1746
10.3.8 InnoDB and MyISAM Index Statistics Collection	1746
10.3.9 Comparison of B-Tree and Hash Indexes	1747
10.3.10 Use of Index Extensions	1749
10.3.11 Optimizer Use of Generated Column Indexes	1751
10.3.12 Invisible Indexes	1752
10.3.13 Descending Indexes	1754
10.3.14 Indexed Lookups from TIMESTAMP Columns	1756
10.4 Optimizing Database Structure	1758
10.4.1 Optimizing Data Size	1758
10.4.2 Optimizing MySQL Data Types	1760
10.4.3 Optimizing for Many Tables	1761
10.4.4 Internal Temporary Table Use in MySQL	1762
10.4.5 Limits on Number of Databases and Tables	1766
10.4.6 Limits on Table Size	1766
10.4.7 Limits on Table Column Count and Row Size	1767
10.5 Optimizing for InnoDB Tables	1770
10.5.1 Optimizing Storage Layout for InnoDB Tables	1770
10.5.2 Optimizing InnoDB Transaction Management	1770
10.5.3 Optimizing InnoDB Read-Only Transactions	1772

10.5.4 Optimizing InnoDB Redo Logging	1772
10.5.5 Bulk Data Loading for InnoDB Tables	1773
10.5.6 Optimizing InnoDB Queries	1775
10.5.7 Optimizing InnoDB DDL Operations	1775
10.5.8 Optimizing InnoDB Disk I/O	1776
10.5.9 Optimizing InnoDB Configuration Variables	1780
10.5.10 Optimizing InnoDB for Systems with Many Tables	1781
10.6 Optimizing for MyISAM Tables	1781
10.6.1 Optimizing MyISAM Queries	1781
10.6.2 Bulk Data Loading for MyISAM Tables	1782
10.6.3 Optimizing REPAIR TABLE Statements	1784
10.7 Optimizing for MEMORY Tables	1785
10.8 Understanding the Query Execution Plan	1785
10.8.1 Optimizing Queries with EXPLAIN	1785
10.8.2 EXPLAIN Output Format	1786
10.8.3 Extended EXPLAIN Output Format	1800
10.8.4 Obtaining Execution Plan Information for a Named Connection	1802
10.8.5 Estimating Query Performance	1802
10.9 Controlling the Query Optimizer	1803
10.9.1 Controlling Query Plan Evaluation	1803
10.9.2 Switchable Optimizations	1804
10.9.3 Optimizer Hints	1814
10.9.4 Index Hints	1828
10.9.5 The Optimizer Cost Model	1830
10.9.6 Optimizer Statistics	1834
10.10 Buffering and Caching	1837
10.10.1 InnoDB Buffer Pool Optimization	1837
10.10.2 The MyISAM Key Cache	1837
10.10.3 Caching of Prepared Statements and Stored Programs	1841
10.11 Optimizing Locking Operations	1843
10.11.1 Internal Locking Methods	1843
10.11.2 Table Locking Issues	1845
10.11.3 Concurrent Inserts	1847
10.11.4 Metadata Locking	1847
10.11.5 External Locking	1850
10.12 Optimizing the MySQL Server	1851
10.12.1 Optimizing Disk I/O	1851
10.12.2 Using Symbolic Links	1853
10.12.3 Optimizing Memory Use	1856
10.13 Measuring Performance (Benchmarking)	1862
10.13.1 Measuring the Speed of Expressions and Functions	1863
10.13.2 Using Your Own Benchmarks	1863
10.13.3 Measuring Performance with performance_schema	1863
10.14 Examining Server Thread (Process) Information	1864
10.14.1 Accessing the Process List	1864
10.14.2 Thread Command Values	1866
10.14.3 General Thread States	1868
10.14.4 Replication Source Thread States	1874
10.14.5 Replication I/O (Receiver) Thread States	1875
10.14.6 Replication SQL Thread States	1876
10.14.7 Replication Connection Thread States	1878
10.14.8 NDB Cluster Thread States	1878
10.14.9 Event Scheduler Thread States	1879
11 Language Structure	1881
11.1 Literal Values	1881
11.1.1 String Literals	1881
11.1.2 Numeric Literals	1884
11.1.3 Date and Time Literals	1884

11.1.4 Hexadecimal Literals	1889
11.1.5 Bit-Value Literals	1891
11.1.6 Boolean Literals	1893
11.1.7 NULL Values	1893
11.2 Schema Object Names	1893
11.2.1 Identifier Length Limits	1895
11.2.2 Identifier Qualifiers	1896
11.2.3 Identifier Case Sensitivity	1897
11.2.4 Mapping of Identifiers to File Names	1899
11.2.5 Function Name Parsing and Resolution	1901
11.3 Keywords and Reserved Words	1904
11.4 User-Defined Variables	1934
11.5 Expressions	1937
11.6 Query Attributes	1941
11.7 Comments	1944
12 Character Sets, Collations, Unicode	1947
12.1 Character Sets and Collations in General	1948
12.2 Character Sets and Collations in MySQL	1949
12.2.1 Character Set Repertoire	1951
12.2.2 UTF-8 for Metadata	1953
12.3 Specifying Character Sets and Collations	1954
12.3.1 Collation Naming Conventions	1954
12.3.2 Server Character Set and Collation	1955
12.3.3 Database Character Set and Collation	1956
12.3.4 Table Character Set and Collation	1957
12.3.5 Column Character Set and Collation	1957
12.3.6 Character String Literal Character Set and Collation	1959
12.3.7 The National Character Set	1960
12.3.8 Character Set Introducers	1961
12.3.9 Examples of Character Set and Collation Assignment	1963
12.3.10 Compatibility with Other DBMSs	1964
12.4 Connection Character Sets and Collations	1964
12.5 Configuring Application Character Set and Collation	1969
12.6 Error Message Character Set	1971
12.7 Column Character Set Conversion	1972
12.8 Collation Issues	1973
12.8.1 Using COLLATE in SQL Statements	1973
12.8.2 COLLATE Clause Precedence	1974
12.8.3 Character Set and Collation Compatibility	1974
12.8.4 Collation Coercibility in Expressions	1974
12.8.5 The binary Collation Compared to _bin Collations	1975
12.8.6 Examples of the Effect of Collation	1978
12.8.7 Using Collation in INFORMATION_SCHEMA Searches	1979
12.9 Unicode Support	1981
12.9.1 The utf8mb4 Character Set (4-Byte UTF-8 Unicode Encoding)	1983
12.9.2 The utf8mb3 Character Set (3-Byte UTF-8 Unicode Encoding)	1984
12.9.3 The utf8 Character Set (Deprecated alias for utf8mb3)	1984
12.9.4 The ucs2 Character Set (UCS-2 Unicode Encoding)	1985
12.9.5 The utf16 Character Set (UTF-16 Unicode Encoding)	1985
12.9.6 The utf16le Character Set (UTF-16LE Unicode Encoding)	1986
12.9.7 The utf32 Character Set (UTF-32 Unicode Encoding)	1986
12.9.8 Converting Between 3-Byte and 4-Byte Unicode Character Sets	1986
12.10 Supported Character Sets and Collations	1989
12.10.1 Unicode Character Sets	1989
12.10.2 West European Character Sets	1997
12.10.3 Central European Character Sets	1998
12.10.4 South European and Middle East Character Sets	1999
12.10.5 Baltic Character Sets	2000

12.10.6 Cyrillic Character Sets	2000
12.10.7 Asian Character Sets	2001
12.10.8 The Binary Character Set	2005
12.11 Restrictions on Character Sets	2006
12.12 Setting the Error Message Language	2006
12.13 Adding a Character Set	2007
12.13.1 Character Definition Arrays	2009
12.13.2 String Collating Support for Complex Character Sets	2010
12.13.3 Multi-Byte Character Support for Complex Character Sets	2010
12.14 Adding a Collation to a Character Set	2010
12.14.1 Collation Implementation Types	2011
12.14.2 Choosing a Collation ID	2014
12.14.3 Adding a Simple Collation to an 8-Bit Character Set	2015
12.14.4 Adding a UCA Collation to a Unicode Character Set	2016
12.15 Character Set Configuration	2022
12.16 MySQL Server Locale Support	2023
13 Data Types	2029
13.1 Numeric Data Types	2030
13.1.1 Numeric Data Type Syntax	2030
13.1.2 Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT	2034
13.1.3 Fixed-Point Types (Exact Value) - DECIMAL, NUMERIC	2034
13.1.4 Floating-Point Types (Approximate Value) - FLOAT, DOUBLE	2035
13.1.5 Bit-Value Type - BIT	2035
13.1.6 Numeric Type Attributes	2035
13.1.7 Out-of-Range and Overflow Handling	2037
13.2 Date and Time Data Types	2038
13.2.1 Date and Time Data Type Syntax	2039
13.2.2 The DATE, DATETIME, and TIMESTAMP Types	2041
13.2.3 The TIME Type	2043
13.2.4 The YEAR Type	2043
13.2.5 Automatic Initialization and Updating for TIMESTAMP and DATETIME	2044
13.2.6 Fractional Seconds in Time Values	2047
13.2.7 What Calendar Is Used By MySQL?	2048
13.2.8 Conversion Between Date and Time Types	2049
13.2.9 2-Digit Years in Dates	2050
13.3 String Data Types	2050
13.3.1 String Data Type Syntax	2050
13.3.2 The CHAR and VARCHAR Types	2054
13.3.3 The BINARY and VARBINARY Types	2055
13.3.4 The BLOB and TEXT Types	2056
13.3.5 The ENUM Type	2058
13.3.6 The SET Type	2061
13.4 Spatial Data Types	2063
13.4.1 Spatial Data Types	2065
13.4.2 The OpenGIS Geometry Model	2066
13.4.3 Supported Spatial Data Formats	2071
13.4.4 Geometry Well-Formedness and Validity	2074
13.4.5 Spatial Reference System Support	2075
13.4.6 Creating Spatial Columns	2076
13.4.7 Populating Spatial Columns	2076
13.4.8 Fetching Spatial Data	2077
13.4.9 Optimizing Spatial Analysis	2078
13.4.10 Creating Spatial Indexes	2078
13.4.11 Using Spatial Indexes	2079
13.5 The JSON Data Type	2081
13.6 Data Type Default Values	2096
13.7 Data Type Storage Requirements	2098

13.8	Choosing the Right Type for a Column	2103
13.9	Using Data Types from Other Database Engines	2103
14	Functions and Operators	2105
14.1	Built-In Function and Operator Reference	2107
14.2	Loadable Function Reference	2124

19.5.3	Upgrading a Replication Topology	3599
19.5.4	Troubleshooting Replication	3601

19.5.5 How to Report Replication Bugs or Problems	3602
20 Group Replication	3605
20.1 Group Replication Background	3606
20.1.1 Replication Technologies	3607
20.1.2 Group Replication Use Cases	3610
20.1.3 Multi-Primary and Single-Primary Modes	3611
20.1.4 Group Replication Services	3615
20.1.5 Group Replication Plugin Architecture	3617
20.2 Getting Started	3619
20.2.1 Deploying Group Replication in Single-Primary Mode	3619
20.2.2 Deploying Group Replication Locally	3631
20.3 Requirements and Limitations	3632
20.3.1 Group Replication Requirements	3632
20.3.2 Group Replication Limitations	3635
20.4 Monitoring Group Replication	3637
20.4.1 GTIDs and Group Replication	3638
20.4.2 Group Replication Server States	3639
20.4.3 The replication_group_members Table	3640
20.4.4 The replication_group_member_stats Table	3641
20.5 Group Replication Operations	3641
20.5.1 Configuring an Online Group	3641
20.5.2 Restarting a Group	3647
20.5.3 Transaction Consistency Guarantees	3649
20.5.4 Distributed Recovery	3655
20.5.5 Support For IPv6 And For Mixed IPv6 And IPv4 Groups	3670
20.5.6 Using MySQL Enterprise Backup with Group Replication	3671
20.6 Group Replication Security	3678
20.6.1 Communication Stack for Connection Security Management	3678
20.6.2 Securing Group Communication Connections with Secure Socket Layer (SSL) .	3680
20.6.3 Securing Distributed Recovery Connections	3683
20.6.4 Group Replication IP Address Permissions	3687
20.7 Group Replication Performance and Troubleshooting	3689
20.7.1 Fine Tuning the Group Communication Thread	3690
20.7.2 Flow Control	3690
20.7.3 Single Consensus Leader	3692
20.7.4 Message Compression	3692
20.7.5 Message Fragmentation	3694
20.7.6 XCom Cache Management	3695
20.7.7 Responses to Failure Detection and Network Partitioning	3696
20.7.8 Handling a Network Partition and Loss of Quorum	3702
20.7.9 Monitoring Group Replication Memory Usage with Performance Schema Memory Instrumentation	3707
20.8 Upgrading Group Replication	3716
20.8.1 Combining Different Member Versions in a Group	3716
20.8.2 Group Replication Offline Upgrade	3718
20.8.3 Group Replication Online Upgrade	3718
20.9 Group Replication Variables	3722
20.9.1 Group Replication System Variables	3724
20.9.2 Group Replication Status Variables	3766
20.10 Frequently Asked Questions	3768
21 MySQL Shell	3773
22 Using MySQL as a Document Store	3775
22.1 Interfaces to a MySQL Document Store	3776
22.2 Document Store Concepts	3776
22.3 JavaScript Quick-Start Guide: MySQL Shell for Document Store	3777
22.3.1 MySQL Shell	3778
22.3.2 Download and Import world_x Database	3779
22.3.3 Documents and Collections	3780

22.3.4	Relational Tables	3790
22.3.5	Documents in Tables	3796
22.4	Python Quick-Start Guide: MySQL Shell for Document Store	3797
22.4.1	MySQL Shell	3797
22.4.2	Download and Import world_x Database	3799
22.4.3	Documents and Collections	3799
22.4.4	Relational Tables	3810
22.4.5	Documents in Tables	3816
22.5	X Plugin	3817
22.5.1	Checking X Plugin Installation	3817
22.5.2	Disabling X Plugin	3817
22.5.3	Using Encrypted Connections with X Plugin	3817
22.5.4	Using X Plugin with the Caching SHA-2 Authentication Plugin	3818
22.5.5	Connection Compression with X Plugin	3819
22.5.6	X Plugin Options and Variables	3822
22.5.7	Monitoring X Plugin	3842
23	InnoDB Cluster	3845
24	InnoDB ReplicaSet	3847
25	MySQL NDB Cluster 8.3	3849
25.1	General Information	3851
25.2	NDB Cluster Overview	3853
25.2.1	NDB Cluster Core Concepts	3854
25.2.2	NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions	3857
25.2.3	NDB Cluster Hardware, Software, and Networking Requirements	3860
25.2.4	What is New in MySQL NDB Cluster 8.3	3861
25.2.5	Options, Variables, and Parameters Added, Deprecated or Removed in NDB 8.3	3864
25.2.6	MySQL Server Using InnoDB Compared with NDB Cluster	3864
25.2.7	Known Limitations of NDB Cluster	3867
25.3	NDB Cluster Installation	3878
25.3.1	Installation of NDB Cluster on Linux	3881
25.3.2	Installing NDB Cluster on Windows	3889
25.3.3	Initial Configuration of NDB Cluster	3897
25.3.4	Initial Startup of NDB Cluster	3899
25.3.5	NDB Cluster Example with Tables and Data	3899
25.3.6	Safe Shutdown and Restart of NDB Cluster	3903
25.3.7	Upgrading and Downgrading NDB Cluster	3903
25.4	Configuration of NDB Cluster	3904
25.4.1	Quick Test Setup of NDB Cluster	3905
25.4.2	Overview of NDB Cluster Configuration Parameters, Options, and Variables	3907
25.4.3	NDB Cluster Configuration Files	3928
25.4.4	Using High-Speed Interconnects with NDB Cluster	4130
25.5	NDB Cluster Programs	4130
25.5.1	ndbd — The NDB Cluster Data Node Daemon	4130
25.5.2	ndbinfo_select_all — Select From ndbinfo Tables	4142
25.5.3	ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)	4147
25.5.4	ndb_mgmd — The NDB Cluster Management Server Daemon	4148
25.5.5	ndb_mgm — The NDB Cluster Management Client	4160
25.5.6	ndb_blob_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables	4166
25.5.7	ndb_config — Extract NDB Cluster Configuration Information	4173
25.5.8	ndb_delete_all — Delete All Rows from an NDB Table	4186
25.5.9	ndb_desc — Describe NDB Tables	4191
25.5.10	ndb_drop_index — Drop Index from an NDB Table	4202
25.5.11	ndb_drop_table — Drop an NDB Table	4207
25.5.12	ndb_error_reporter — NDB Error-Reporting Utility	4212
25.5.13	ndb_import — Import CSV Data Into NDB	4213
25.5.14	ndb_index_stat — NDB Index Statistics Utility	4230

25.5.15	ndb_move_data — NDB Data Copy Utility	4239
25.5.16	ndb_perror — Obtain NDB Error Message Information	4245
25.5.17	ndb_print_backup_file — Print NDB Backup File Contents	4248
25.5.18	ndb_print_file — Print NDB Disk Data File Contents	4253
25.5.19	ndb_print_frag_file — Print NDB Fragment List File Contents	4254
25.5.20	ndb_print_schema_file — Print NDB Schema File Contents	4255
25.5.21	ndb_print_sys_file — Print NDB System File Contents	4255
25.5.22	ndb_redo_log_reader — Check and Print Content of Cluster Redo Log	4256
25.5.23	ndb_restore — Restore an NDB Cluster Backup	4259
25.5.24	ndb_secretsfile_reader — Obtain Key Information from an Encrypted NDB Data File	4285
25.5.25	ndb_select_all — Print Rows from an NDB Table	4288
25.5.26	ndb_select_count — Print Row Counts for NDB Tables	4295
25.5.27	ndb_show_tables — Display List of NDB Tables	4300
25.5.28	ndb_sign_keys — Create, Sign, and Manage TLS Keys and Certificates for NDB Cluster	4305
25.5.29	ndb_size.pl — NDBCLUSTER Size Requirement Estimator	4315
25.5.30	ndb_top — View CPU usage information for NDB threads	4318
25.5.31	ndb_waiter — Wait for NDB Cluster to Reach a Given Status	4323
25.5.32	ndbxfrm — Compress, Decompress, Encrypt, and Decrypt Files Created by NDB Cluster	4330
25.6	Management of NDB Cluster	4336
25.6.1	Commands in the NDB Cluster Management Client	4337
25.6.2	NDB Cluster Log Messages	4344
25.6.3	Event Reports Generated in NDB Cluster	4362
25.6.4	Summary of NDB Cluster Start Phases	4374
25.6.5	Performing a Rolling Restart of an NDB Cluster	4376
25.6.6	NDB Cluster Single User Mode	4378
25.6.7	Adding NDB Cluster Data Nodes Online	4379
25.6.8	Online Backup of NDB Cluster	4389
25.6.9	Importing Data Into MySQL Cluster	4395
25.6.10	MySQL Server Usage for NDB Cluster	4396

26	Partitioning	4581

26.1 Overview of Partitioning in MySQL	4582
26.2 Partitioning Types	4585
26.2.1 RANGE Partitioning	4586
26.2.2 LIST Partitioning	4590
26.2.3 COLUMNS Partitioning	4593
26.2.4 HASH Partitioning	4600
26.2.5 KEY Partitioning	4603
26.2.6 Subpartitioning	4604
26.2.7 How MySQL Partitioning Handles NULL	4606
26.3 Partition Management	4610
26.3.1 Management of RANGE and LIST Partitions	4611
26.3.2 Management of HASH and KEY Partitions	4617
26.3.3 Exchanging Partitions and Subpartitions with Tables	4618
26.3.4 Maintenance of Partitions	4625
26.3.5 Obtaining Information About Partitions	4626
26.4 Partition Pruning	4628
26.5 Partition Selection	4631
26.6 Restrictions and Limitations on Partitioning	4637
26.6.1 Partitioning Keys, Primary Keys, and Unique Keys	4643
26.6.2 Partitioning Limitations Relating to Storage Engines	4646
26.6.3 Partitioning Limitations Relating to Functions	4647
27 Stored Objects	4649
27.1 Defining Stored Programs	4650
27.2 Using Stored Routines	4651
27.2.1 Stored Routine Syntax	4652
27.2.2 Stored Routines and MySQL Privileges	4652
27.2.3 Stored Routine Metadata	4653
27.2.4 Stored Procedures, Functions, Triggers, and LAST_INSERT_ID()	4653
27.3 Using Triggers	4653
27.3.1 Trigger Syntax and Examples	4654
27.3.2 Trigger Metadata	4658
27.4 Using the Event Scheduler	4658
27.4.1 Event Scheduler Overview	4659
27.4.2 Event Scheduler Configuration	4659
27.4.3 Event Syntax	4662
27.4.4 Event Metadata	4662
27.4.5 Event Scheduler Status	4663
27.4.6 The Event Scheduler and MySQL Privileges	4663
27.5 Using Views	4666
27.5.1 View Syntax	4666
27.5.2 View Processing Algorithms	4666
27.5.3 Updatable and Insertable Views	4668
27.5.4 The View WITH CHECK OPTION Clause	4670
27.5.5 View Metadata	4671
27.6 Stored Object Access Control	4671
27.7 Stored Program Binary Logging	4675
27.8 Restrictions on Stored Programs	4681
27.9 Restrictions on Views	4685
28 INFORMATION_SCHEMA Tables	4687

Preface and Legal Notices

This is the Reference Manual for the MySQL Database System, for the 8.3.0 Innovation release. For license information, see the [Legal Notices](#).

This manual is not intended for use with older versions of the MySQL software due to the many functional and other differences between MySQL 8.3 and previous versions. If you are using an earlier release of the MySQL software, please refer to the appropriate manual. For example, [MySQL 8.0 Reference Manual](#) covers the 8.0 bugfix series of MySQL software releases.

Licensing information—MySQL 8.3. This product may include third-party software, used under license. If you are using a *Commercial* release of MySQL 8.3, see the [MySQL 8.3 Commercial Release License Information User Manual](#) for licensing information, including licensing information relating to third-party software that may be included in this Commercial release. If you are using a *Community* release of MySQL 8.3, see the [MySQL 8.3 Community Release License Information User Manual](#) for licensing information, including licensing information relating to third-party software that may be included in this Community release.

Licensing information—MySQL NDB Cluster 8.3. This product may include third-party software, used under license. If you are using a *Commercial* release of MySQL NDB Cluster 8.3, see the [MySQL NDB Cluster 8.3 Commercial Release License Information User Manual](#) for licensing information, including licensing information relating to third-party software that may be included in this Commercial release. If you are using a *Community* release of MySQL NDB Cluster 8.3, see the [MySQL NDB Cluster 8.3 Community Release License Information User Manual](#) for licensing information, including licensing information relating to third-party software that may be included in this Community release.

Legal Notices

Copyright © 1997, 2024, Oracle and/or its affiliates.

License Restrictions

This software and related documentation are provided under a license agreement containing restrictions on use and disclosure and are protected by intellectual property laws. Except as expressly permitted in your license agreement or allowed by law, you may not use, copy, reproduce, translate, broadcast, modify, license, transmit, distribute, exhibit, perform, publish, or display any part, in any form, or by any means. Reverse engineering, disassembly, or decompilation of this software, unless required by law for interoperability, is prohibited.

Warranty Disclaimer

The information contained herein is subject to change without notice and is not warranted to be error-free. If you find any errors, please report them to us in writing.

Restricted Rights Notice

If this is software, software documentation, data (as defined in the Federal Acquisition Regulation), or related documentation that is delivered to the U.S. Government or anyone licensing it on behalf of the U.S. Government, then the following notice is applicable:

U.S. GOVERNMENT END USERS: Oracle programs (including any operating system, integrated software, any programs embedded, installed, or activated on delivered hardware, and modifications of such programs) and Oracle computer documentation or other Oracle data delivered to or accessed by U.S. Government end users are "commercial computer software," "commercial computer software documentation," or "limited rights data" pursuant to the applicable Federal Acquisition Regulation and agency-specific supplemental regulations. As such, the use, reproduction, duplication, release, display, disclosure, modification, preparation of derivative works, and/or adaptation of i) Oracle programs (including any operating system, integrated software, any programs embedded, installed, or activated on delivered hardware, and modifications of such programs), ii) Oracle computer documentation and/

or iii) other Oracle data, is subject to the rights and limitations specified in the license contained in the applicable contract. The terms governing the U.S. Government's use of Oracle cloud services are defined by the applicable contract for such services. No other rights are granted to the U.S. Government.

Hazardous Applications Notice

This software or hardware is developed for general use in a variety of information management applications. It is not developed or intended for use in any inherently dangerous applications, including applications that may create a risk of personal injury. If you use this software or hardware in dangerous applications, then you shall be responsible to take all appropriate fail-safe, backup, redundancy, and other measures to ensure its safe use. Oracle Corporation and its affiliates disclaim any liability for any damages caused by use of this software or hardware in dangerous applications.

Trademark Notice

Oracle, Java, MySQL, and NetSuite are registered trademarks of Oracle and/or its affiliates. Other names may be trademarks of their respective owners.

Intel and Intel Inside are trademarks or registered trademarks of Intel Corporation. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. AMD, Epyc, and the AMD logo are trademarks or registered trademarks of Advanced Micro Devices. UNIX is a registered trademark of The Open Group.

Third-Party Content, Products, and Services Disclaimer

This software or hardware and documentation may provide access to or information about content, products, and services from third parties. Oracle Corporation and its affiliates are not responsible for and expressly disclaim all warranties of any kind with respect to third-party content, products, and services unless otherwise set forth in an applicable agreement between you and Oracle. Oracle Corporation and its affiliates will not be responsible for any loss, costs, or damages incurred due to your access to or use of third-party content, products, or services, except as set forth in an applicable agreement between you and Oracle.

Use of This Documentation

This documentation is NOT distributed under a GPL license. Use of this documentation is subject to the following terms:

You may create a printed copy of this documentation solely for your own personal use. Conversion to other formats is allowed as long as the actual content is not altered or edited in any way. You shall not publish or distribute this documentation in any form or on any media, except if you distribute the documentation in a manner similar to how Oracle disseminates it (that is, electronically for download on a Web site with the software) or on a CD-ROM or similar medium, provided however that the documentation is disseminated together with the software on the same medium. Any other use, such as any dissemination of printed copies or use of this documentation, in whole or in part, in another publication, requires the prior written consent from an authorized representative of Oracle. Oracle and/or its affiliates reserve any and all rights to this documentation not expressly granted above.

Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc>.

Access to Oracle Support for Accessibility

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit

<http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info> or visit <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs> if you are hearing impaired.

Chapter 1 General Information

Table of Contents

1.1 About This Manual	2
1.2 Overview of the MySQL Database Management System	4
1.2.1 What is MySQL?	4
1.2.2 The Main Features of MySQL	5
1.2.3 History of MySQL	8
1.3 What Is New in MySQL 8.3	8
1.4 Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 8.3	14
1.5 How to Report Bugs or Problems	17
1.6 MySQL Standards Compliance	21
1.6.1 MySQL Extensions to Standard SQL	22
1.6.2 MySQL Differences from Standard SQL	25
1.6.3 How MySQL Deals with Constraints	28

The MySQL software delivers a very fast, multithreaded, multi-user, and robust SQL (Structured Query Language) database server. MySQL Server is intended for mission-critical, heavy-load production systems as well as for embedding into mass-deployed software. Oracle is a registered trademark of Oracle Corporation and/or its affiliates. MySQL is a trademark of Oracle Corporation and/or its affiliates, and shall not be used by Customer without Oracle's express written authorization. Other names may be trademarks of their respective owners.

The MySQL software is Dual Licensed. Users can choose to use the MySQL software as an Open Source product under the terms of the GNU General Public License (<http://www.fsf.org/licenses/>) or can purchase a standard commercial license from Oracle. See <http://www.mysql.com/company/legal/licensing/> for more information on our licensing policies.

The following list describes some sections of particular interest in this manual:

- For a discussion of MySQL Database Server capabilities, see [Section 1.2.2, “The Main Features of MySQL”](#).
- For an overview of new MySQL features, see [Section 1.3, “What Is New in MySQL 8.3”](#). For information about the changes in each version, see the [Release Notes](#).
- For installation instructions, see [Chapter 2, *Installing MySQL*](#). For information about upgrading MySQL, see [Chapter 3, *Upgrading MySQL*](#).
- For a tutorial introduction to the MySQL Database Server, see [Chapter 5, *Tutorial*](#).
- For information about configuring and administering MySQL Server, see [Chapter 7, *MySQL Server Administration*](#).
- For information about security in MySQL, see [Chapter 8, *Security*](#).
- For information about setting up replication servers, see [Chapter 19, *Replication*](#).
- For information about MySQL Enterprise, the commercial MySQL release with advanced features and management tools, see [Chapter 32, *MySQL Enterprise Edition*](#).
- For answers to a number of questions that are often asked concerning the MySQL Database Server and its capabilities, see [Appendix A, *MySQL 8.3 Frequently Asked Questions*](#).
- For a history of new features and bug fixes, see the [Release Notes](#).

**Important**

To report problems or bugs, please use the instructions at [Section 1.5, “How to Report Bugs or Problems”](#). If you find a security bug in MySQL Server, please let us know immediately by sending an email message to [<secalert_us@oracle.com>](mailto:secalert_us@oracle.com). *Exception:* Support customers should report all problems, including security bugs, to Oracle Support.

1.1 About This Manual

This is the Reference Manual for the MySQL Database System, version 8.3, through release 8.3.0. Differences between minor versions of MySQL 8.3 are noted in the present text with reference to release numbers (8.3.x). For license information, see the [Legal Notices](#).

This manual is not intended for use with older versions of the MySQL software due to the many functional and other differences between MySQL 8.3 and previous versions. If you are using an earlier release of the MySQL software, please refer to the appropriate manual. For example, [MySQL 8.2 Reference Manual](#) covers the 8.2 series of MySQL software releases.

Because this manual serves as a reference, it does not provide general instruction on SQL or relational database concepts. It also does not teach you how to use your operating system or command-line interpreter.

The MySQL Database Software is under constant development, and the Reference Manual is updated frequently as well. The most recent version of the manual is available online in searchable form at <https://dev.mysql.com/doc/>. Other formats also are available there, including downloadable HTML and PDF versions.

The source code for MySQL itself contains internal documentation written using Doxygen. The generated Doxygen content is available from <https://dev.mysql.com/doc/index-other.html>. It is also possible to generate this content locally from a MySQL source distribution using the instructions at [Section 2.8.10, “Generating MySQL Doxygen Documentation Content”](#).

If you have questions about using MySQL, join the [MySQL Community Slack](#). If you have suggestions concerning additions or corrections to the manual itself, please send them to the <http://www.mysql.com/company/contact/>.

Typographical and Syntax Conventions

This manual uses certain typographical conventions:

- *Text in this style* is used for SQL statements; database, table, and column names; program listings and source code; and environment variables. Example: “To reload the grant tables, use the `FLUSH PRIVILEGES` statement.”
- *Text in this style* indicates input that you type in examples.
- *Text in this style* indicates the names of executable programs and scripts, examples being `mysql` (the MySQL command-line client program) and `mysqld` (the MySQL server executable).
- *Text in this style* is used for variable input for which you should substitute a value of your own choosing.
- *Text in this style* is used for emphasis.
- **Text in this style** is used in table headings and to convey especially strong emphasis.
- *Text in this style* is used to indicate a program option that affects how the program is executed, or that supplies information that is needed for the program to function in a certain way. *Example:* “The `--host` option (short form `-h`) tells the `mysql` client program the hostname or IP address of the MySQL server that it should connect to”.

- File names and directory names are written like this: “The global `my.cnf` file is located in the `/etc` directory.”
- Character sequences are written like this: “To specify a wildcard, use the ‘`%`’ character.”

When commands or statements are prefixed by a prompt, we use these:

```
$> type a command here
#> type a command as root here
C:\> type a command here (Windows only)
mysql> type a mysql statement here
```

Commands are issued in your command interpreter. On Unix, this is typically a program such as `sh`, `csh`, or `bash`. On Windows, the equivalent program is `command.com` or `cmd.exe`, typically run in a console window. Statements prefixed by `mysql` are issued in the `mysql` command-line client.

Note

When you enter a command or statement shown in an example, do not type the prompt shown in the example.

In some areas different systems may be distinguished from each other to show that commands should be executed in two different environments. For example, while working with replication the commands might be prefixed with `source` and `replica`:

```
source> type a mysql statement on the replication source here
replica> type a mysql statement on the replica here
```

Database, table, and column names must often be substituted into statements. To indicate that such substitution is necessary, this manual uses `db_name`, `tbl_name`, and `col_name`. For example, you might see a statement like this:

```
mysql> SELECT col_name FROM db_name.tbl_name;
```

This means that if you were to enter a similar statement, you would supply your own database, table, and column names, perhaps like this:

```
mysql> SELECT author_name FROM biblio_db.author_list;
```

SQL keywords are not case-sensitive and may be written in any lettercase. This manual uses uppercase.

In syntax descriptions, square brackets (“`[`” and “`]`”) indicate optional words or clauses. For example, in the following statement, `IF EXISTS` is optional:

```
DROP TABLE [IF EXISTS] tbl_name
```

When a syntax element consists of a number of alternatives, the alternatives are separated by vertical bars (“`|`”). When one member from a set of choices *may* be chosen, the alternatives are listed within square brackets (“`[`” and “`]`”):

```
TRIM([[BOTH | LEADING | TRAILING] [remstr] FROM] str)
```

When one member from a set of choices *must* be chosen, the alternatives are listed within braces (“`{`” and “`}`”):

```
{DESCRIBE | DESC} tbl_name [col_name | wild]
```

An ellipsis (`...`) indicates the omission of a section of a statement, typically to provide a shorter version of more complex syntax. For example, `SELECT ... INTO OUTFILE` is shorthand for the form of `SELECT` statement that has an `INTO OUTFILE` clause following other parts of the statement.

An ellipsis can also indicate that the preceding syntax element of a statement may be repeated. In the following example, multiple `reset_option` values may be given, with each of those after the first preceded by commas:

```
RESET reset_option [,reset_option] ...
```

Commands for setting shell variables are shown using Bourne shell syntax. For example, the sequence to set the `CC` environment variable and run the `configure` command looks like this in Bourne shell syntax:

```
$> CC=gcc ./configure
```

If you are using `csh` or `tcsh`, you must issue commands somewhat differently:

```
$> setenv CC gcc
$> ./configure
```

Manual Authorship

The Reference Manual source files are written in DocBook XML format. The HTML version and other formats are produced automatically, primarily using the DocBook XSL stylesheets. For information about DocBook, see <http://docbook.org/>

This manual was originally written by David Axmark and Michael “Monty” Widenius. It is maintained by the MySQL Documentation Team, consisting of Edward Gilmore, Stefan Hinz, David Hollis, Philip Olson, Daniel So, and Jon Stephens.

1.2 Overview of the MySQL Database Management System

1.2.1 What is MySQL?

MySQL, the most popular Open Source SQL database management system, is developed, distributed, and supported by Oracle Corporation.

The MySQL website (<http://www.mysql.com/>) provides the latest information about MySQL software.

- **MySQL is a database management system.**

A database is a structured collection of data. It may be anything from a simple shopping list to a picture gallery or the vast amounts of information in a corporate network. To add, access, and process data stored in a computer database, you need a database management system such as MySQL Server. Since computers are very good at handling large amounts of data, database management systems play a central role in computing, as standalone utilities, or as parts of other applications.

- **MySQL databases are relational.**

A relational database stores data in separate tables rather than putting all the data in one big storeroom. The database structures are organized into physical files optimized for speed. The logical model, with objects such as databases, tables, views, rows, and columns, offers a flexible programming environment. You set up rules governing the relationships between different data fields, such as one-to-one, one-to-many, unique, required or optional, and “pointers” between different tables. The database enforces these rules, so that with a well-designed database, your application never sees inconsistent, duplicate, orphan, out-of-date, or missing data.

The SQL part of “MySQL” stands for “Structured Query Language”. SQL is the most common standardized language used to access databases. Depending on your programming environment, you might enter SQL directly (for example, to generate reports), embed SQL statements into code written in another language, or use a language-specific API that hides the SQL syntax.

SQL is defined by the ANSI/ISO SQL Standard. The SQL standard has been evolving since 1986 and several versions exist. In this manual, “SQL-92” refers to the standard released in 1992, “SQL:1999” refers to the standard released in 1999, and “SQL:2003” refers to the current version of the standard. We use the phrase “the SQL standard” to mean the current version of the SQL Standard at any time.

- **MySQL software is Open Source.**

Open Source means that it is possible for anyone to use and modify the software. Anybody can download the MySQL software from the Internet and use it without paying anything. If you wish, you may study the source code and change it to suit your needs. The MySQL software uses the GPL (GNU General Public License), <http://www.fsf.org/licenses/>, to define what you may and may not do with the software in different situations. If you feel uncomfortable with the GPL or need to embed MySQL code into a commercial application, you can buy a commercially licensed version from us. See the MySQL Licensing Overview for more information (<http://www.mysql.com/company/legal/licensing/>).

- **The MySQL Database Server is very fast, reliable, scalable, and easy to use.**

If that is what you are looking for, you should give it a try. MySQL Server can run comfortably on a desktop or laptop, alongside your other applications, web servers, and so on, requiring little or no attention. If you dedicate an entire machine to MySQL, you can adjust the settings to take advantage of all the memory, CPU power, and I/O capacity available. MySQL can also scale up to clusters of machines, networked together.

MySQL Server was originally developed to handle large databases much faster than existing solutions and has been successfully used in highly demanding production environments for several years. Although under constant development, MySQL Server today offers a rich and useful set of functions. Its connectivity, speed, and security make MySQL Server highly suited for accessing databases on the Internet.

- **MySQL Server works in client/server or embedded systems.**

The MySQL Database Software is a client/server system that consists of a multithreaded SQL server that supports different back ends, several different client programs and libraries, administrative tools, and a wide range of application programming interfaces (APIs).

We also provide MySQL Server as an embedded multithreaded library that you can link into your application to get a smaller, faster, easier-to-manage standalone product.

- **A large amount of contributed MySQL software is available.**

MySQL Server has a practical set of features developed in close cooperation with our users. It is very likely that your favorite application or language supports the MySQL Database Server.

- **MySQL HeatWave.**

MySQL HeatWave is a fully managed database service, powered by the HeatWave in-memory query accelerator. It is the only cloud service that combines transactions, real-time analytics across data warehouses and data lakes, and machine learning in one MySQL Database; without the complexity, latency, risks, and cost of ETL duplication. It is available on OCI, AWS, and Azure. Learn more at: <https://www.oracle.com/mysql/>.

The official way to pronounce “MySQL” is “My Ess Que Ell” (not “my sequel”), but we do not mind if you pronounce it as “my sequel” or in some other localized way.

1.2.2 The Main Features of MySQL

This section describes some of the important characteristics of the MySQL Database Software. In most respects, the roadmap applies to all versions of MySQL. For information about features as they are introduced into MySQL on a series-specific basis, see the “In a Nutshell” section of the appropriate Manual:

- MySQL 8.0: [What Is New in MySQL 8.0](#)
- MySQL 5.7: [What Is New in MySQL 5.7](#)

Internals and Portability

- Written in C and C++.
- Tested with a broad range of different compilers.
- Works on many different platforms. See <https://www.mysql.com/support/supportedplatforms/database.html>.
- For portability, configured using CMake.
- Tested with Purify (a commercial memory leakage detector) as well as with Valgrind, a GPL tool (<https://valgrind.org/>).
- Uses multi-layered server design with independent modules.
- Designed to be fully multithreaded using kernel threads, to easily use multiple CPUs if they are available.
- Provides transactional and nontransactional storage engines.
- Uses very fast B-tree disk tables (MyISAM) with index compression.
- Designed to make it relatively easy to add other storage engines. This is useful if you want to provide an SQL interface for an in-house database.
- Uses a very fast thread-based memory allocation system.
- Executes very fast joins using an optimized nested-loop join.
- Implements in-memory hash tables, which are used as temporary tables.
- Implements SQL functions using a highly optimized class library that should be as fast as possible. Usually there is no memory allocation at all after query initialization.
- Provides the server as a separate program for use in a client/server networked environment.

Data Types

- Many data types: signed/unsigned integers 1, 2, 3, 4, and 8 bytes long, FLOAT, DOUBLE, CHAR, VARCHAR, BINARY, VARBINARY, TEXT, BLOB, DATE, TIME, DATETIME, TIMESTAMP, YEAR, SET, ENUM, and OpenGIS spatial types. See [Chapter 13, Data Types](#).
- Fixed-length and variable-length string types.

Statements and Functions

- Full operator and function support in the SELECT list and WHERE clause of queries. For example:

```
mysql> SELECT CONCAT(first_name, ' ', last_name)
-> FROM citizen
-> WHERE income/dependents > 10000 AND age > 30;
```

- Full support for SQL GROUP BY and ORDER BY clauses. Support for group functions (COUNT(), AVG(), STD(), SUM(), MAX(), MIN(), and GROUP_CONCAT()).
- Support for LEFT OUTER JOIN and RIGHT OUTER JOIN with both standard SQL and ODBC syntax.
- Support for aliases on tables and columns as required by standard SQL.
- Support for DELETE, INSERT, REPLACE, and UPDATE to return the number of rows that were changed (affected), or to return the number of rows matched instead by setting a flag when connecting to the server.

- Support for MySQL-specific [SHOW](#) statements that retrieve information about databases, storage engines, tables, and indexes. Support for the [INFORMATION_SCHEMA](#) database, implemented according to standard SQL.
- An [EXPLAIN](#) statement to show how the optimizer resolves a query.
- Independence of function names from table or column names. For example, [ABS](#) is a valid column name. The only restriction is that for a function call, no spaces are permitted between the function name and the “(” that follows it. See [Section 11.3, “Keywords and Reserved Words”](#).
- You can refer to tables from different databases in the same statement.

Security

- A privilege and password system that is very flexible and secure, and that enables host-based verification.
- Password security by encryption of all password traffic when you connect to a server.

Scalability and Limits

- Support for large databases. We use MySQL Server with databases that contain 50 million records. We also know of users who use MySQL Server with 200,000 tables and about 5,000,000,000 rows.
- Support for up to 64 indexes per table. Each index may consist of 1 to 16 columns or parts of columns. The maximum index width for [InnoDB](#) tables is either 767 bytes or 3072 bytes. See [Section 17.21, “InnoDB Limits”](#). The maximum index width for [MyISAM](#) tables is 1000 bytes. See [Section 18.2, “The MyISAM Storage Engine”](#). An index may use a prefix of a column for [CHAR](#), [VARCHAR](#), [BLOB](#), or [TEXT](#) column types.

Connectivity

- Clients can connect to MySQL Server using several protocols:
 - Clients can connect using TCP/IP sockets on any platform.
 - On Windows systems, clients can connect using named pipes if the server is started with the [named_pipe](#) system variable enabled. Windows servers also support shared-memory connections if started with the [shared_memory](#) system variable enabled. Clients can connect through shared memory by using the [--protocol=memory](#) option.
 - On Unix systems, clients can connect using Unix domain socket files.
- MySQL client programs can be written in many languages. A client library written in C is available for clients written in C or C++, or for any language that provides C bindings.
- APIs for C, C++, Eiffel, Java, Perl, PHP, Python, Ruby, and Tcl are available, enabling MySQL clients to be written in many languages. See [Chapter 31, Connectors and APIs](#).
- The Connector/ODBC (MyODBC) interface provides MySQL support for client programs that use ODBC (Open Database Connectivity) connections. For example, you can use MS Access to connect to your MySQL server. Clients can be run on Windows or Unix. Connector/ODBC source is available. All ODBC 2.5 functions are supported, as are many others. See [MySQL Connector/ODBC Developer Guide](#).
- The Connector/J interface provides MySQL support for Java client programs that use JDBC connections. Clients can be run on Windows or Unix. Connector/J source is available. See [MySQL Connector/J 8.1 Developer Guide](#).
- MySQL Connector/NET enables developers to easily create .NET applications that require secure, high-performance data connectivity with MySQL. It implements the required ADO.NET interfaces and

integrates into ADO.NET aware tools. Developers can build applications using their choice of .NET languages. MySQL Connector/NET is a fully managed ADO.NET driver written in 100% pure C#. See [MySQL Connector/NET Developer Guide](#).

Localization

- The server can provide error messages to clients in many languages. See [Section 12.12, “Setting the Error Message Language”](#).
- Full support for several different character sets, including `latin1` (cp1252), `german`, `big5`, `ujis`, several Unicode character sets, and more. For example, the Scandinavian characters “å”, “ä” and “ö” are permitted in table and column names.
- All data is saved in the chosen character set.
- Sorting and comparisons are done according to the default character set and collation. It is possible to change this when the MySQL server is started (see [Section 12.3.2, “Server Character Set and Collation”](#)). To see an example of very advanced sorting, look at the Czech sorting code. MySQL Server supports many different character sets that can be specified at compile time and runtime.
- The server time zone can be changed dynamically, and individual clients can specify their own time zone. See [Section 7.1.15, “MySQL Server Time Zone Support”](#).

Clients and Tools

- MySQL includes several client and utility programs. These include both command-line programs such as `mysqldump` and `mysqladmin`, and graphical programs such as [MySQL Workbench](#).
- MySQL Server has built-in support for SQL statements to check, optimize, and repair tables. These statements are available from the command line through the `mysqlcheck` client. MySQL also includes `myisamchk`, a very fast command-line utility for performing these operations on `MyISAM` tables. See [Chapter 6, MySQL Programs](#).
- MySQL programs can be invoked with the `--help` or `-?` option to obtain online assistance.

1.2.3 History of MySQL

We started out with the intention of using the `mSQL` database system to connect to our tables using our own fast low-level (ISAM) routines. However, after some testing, we came to the conclusion that `mSQL` was not fast enough or flexible enough for our needs. This resulted in a new SQL interface to our database but with almost the same API interface as `mSQL`. This API was designed to enable third-party code that was written for use with `mSQL` to be ported easily for use with MySQL.

MySQL is named after co-founder Monty Widenius's daughter, My.

The name of the MySQL Dolphin (our logo) is “Sakila,” which was chosen from a huge list of names suggested by users in our “Name the Dolphin” contest. The winning name was submitted by Ambrose Twebaze, an Open Source software developer from Eswatini (formerly Swaziland), Africa. According to Ambrose, the feminine name Sakila has its roots in SiSwati, the local language of Eswatini. Sakila is also the name of a town in Arusha, Tanzania, near Ambrose's country of origin, Uganda.

1.3 What Is New in MySQL 8.3

This section summarizes what has been added to, deprecated in, and removed from MySQL 8.3. A companion section lists MySQL server options and variables that have been added, deprecated, or removed in MySQL 8.3; see [Section 1.4, “Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 8.3”](#).

- [Features Added in MySQL 8.3](#)
- [Features Deprecated in MySQL 8.3](#)

- [Features Removed in MySQL 8.3](#)

Features Added in MySQL 8.3

The following features have been added to MySQL 8.3:

- **MySQL Replication: tagged GTIDs.** The format of global transaction identifiers (GTIDs) used in MySQL Replication and Group Replication has been extended to enable identification of groups of transactions, making it possible to assign a unique name to the GTIDs which belong to a specific group of transactions. For example, transactions containing data operations can easily be distinguished from those arising from administrative operations simply by comparing their GTIDs.

The new GTID format is `UUID:TAG:NUMBER`, where `TAG` is a string of up to 8 characters, which is enabled by setting the value of the `gtid_next` system variable to `AUTOMATIC:TAG`, added in this release (see the description of the variable for tag format and other information). This tag persists for all transactions originating in the current session (unless changed using `SET gtid_next`), and is applied at commit time for such transactions, or, when using Group Replication, at certification time. It is also possible to set `gtid_next` to `UUID:TAG:NUMBER` to set the UUID of a single transaction to an arbitrary value, along with assigning it a custom tag. The assignments of `UUID` and `NUMBER` are otherwise unchanged from previous MySQL releases. In either case, the user is responsible for making sure that the tag is unique to a given replication topology.

The original `UUID:NUMBER` format for GTIDs continues to be supported unchanged, as implemented in previous versions of MySQL; changes to existing replication setups using GTIDs are not required.

Setting `gtid_next` to `AUTOMATIC:TAG` or `UUID:TAG:NUMBER` requires a new `TRANSACTION_GTID_TAG` privilege which is added in this release; this is true both on the originating server as well as for the `PRIVILEGE_CHECKS_APPLIER` for the replica applier thread. This also means that an administrator can now restrict the use of `SET @gtid_next=AUTOMATIC:TAG` or `UUID:TAG:NUMBER` to a desired set of MySQL users or roles so that only those users related to a given data or operational domain can commit new transactions with assigned tags.

Note

When upgrading from a previous version of MySQL to MySQL 8.3, any user accounts or roles which already have the `BINLOG_ADMIN` privilege are automatically granted the `TRANSACTION_GTID_TAG` privilege.

The built-in functions `GTID_SUBSET()`, `GTID_SUBTRACT()`, and `WAIT_FOR_EXECUTED_GTID_SET()` are compatible with tagged GTIDs.

For more information, see the descriptions of the `gtid_next` system variable and the `TRANSACTION_GTID_TAG` privilege, as well as [Section 19.1.4, “Changing GTID Mode on Online Servers”](#).

- **EXPLAIN FORMAT=JSON format versioning.** It is now possible to choose between 2 versions of the JSON output format used by `EXPLAIN FORMAT=JSON` statements using the `explain_json_format_version` server system variable introduced in this release. Setting this variable to `1` causes the server to use Version 1, which is the linear format which was always used for output from such statements in MySQL 8.2 and earlier. This is the default value and format in MySQL 8.3. Setting `explain_json_format_version` to `2` causes the Version 2 format to be used; this JSON output format is based on access paths, and is intended to provide better compatibility with future versions of the MySQL Optimizer.

See [Obtaining Execution Plan Information](#), for more information and examples.

- **DDL and DCL statement tracking for `group_replication_set_as_primary()`.** `group_replication_set_as_primary()` now waits for the following statements to complete before a new primary is elected:

- ALTER DATABASE
- ALTER FUNCTION
- ALTER INSTANCE
- ALTER PROCEDURE
- ALTER SERVER
- ALTER TABLESPACE
- ALTER USER
- ALTER VIEW
- CREATE DATABASE
- CREATE FUNCTION
- CREATE PROCEDURE
- CREATE ROLE
- CREATE SERVER
- CREATE SPATIAL REFERENCE SYSTEM
- CREATE TABLESPACE
- CREATE TRIGGER
- CREATE USER
- CREATE VIEW
- DROP DATABASE
- DROP FUNCTION
- DROP PROCEDURE
- DROP ROLE
- DROP SERVER
- DROP SPATIAL REFERENCE SYSTEM
- DROP TABLESPACE
- DROP TRIGGER
- DROP USER
- DROP VIEW
- GRANT
- RENAME TABLE
- REVOKE

These are in addition to those statements added in MySQL 8.1 or otherwise already supported in this regard. For more information, including a listing of all such statements supported in MySQL 8.3, see the description of the `group_replication_set_as_primary()` function.

- **SASL-based LDAP authentication on Windows.** On Microsoft Windows, the server plugin for SASL-based LDAP authentication is now supported. This means that Windows clients can now use GSSAPI/Kerberos for authenticating with the `authentication_ldap_sasl_client` plugin.

For more information, see [SASL-Based LDAP Authentication](#).

- **Change in `binlog_transaction_dependency_tracking` default value.** The `binlog_transaction_dependency_tracking` server system variable was deprecated in MySQL 8.2.0. In preparation for the eventual removal of this variable, its default value is now `WRITESET`. There are no plans to replace this variable or its functionality, which is expected later to be made internal to the server.
- **WITH_LD CMake option.** Define whether to use the `llvm lld` or `mold` linker, otherwise use the standard linker. `WITH_LD` also replaces the `USE_LD_LLD` CMake option that was removed in MySQL 8.3.0.
- **MySQL Enterprise Data Masking and De-Identification.** Data-masking components added support for specifying a dedicated schema to store the related internal table and masking functions. Previously, the `mysql` system schema provided the only storage option. The new `component_masking.masking_database` read-only variable enables setting and persisting an alternative schema name at server startup.
- **Thread pool plugin connection information.** Added thread pool connection information to the MySQL Performance Schema, as follows:
 - Added a `tp_connections` table, with information about each thread pool connection.
 - Added the following columns to the `tp_thread_state` table: `TIME_OF_ATTACH`, `MARKED_STALLED`, `STATE`, `EVENT_COUNT`, `ACCUMULATED_EVENT_TIME`, `EXEC_COUNT`, and `ACCUMULATED_EXEC_TIME`
 - Added the following columns to the `tp_thread_group_state` table: `EFFECTIVE_MAX_TRANSACTIONS_LIMIT`, `NUM_QUERY_THREADS`, `TIME_OF_LAST_THREAD_CREATION`, `NUM_CONNECT_HANDLER_THREAD_IN_SLEEP`, `THREADS_BOUND_TO_TRANSACTION`, `QUERY_THREADS_COUNT`, and `TIME_OF_EARLIEST_CON_EXPIRE`.

For more information, see [Section 7.6.3, “MySQL Enterprise Thread Pool”](#), and [Section 29.12.16, “Performance Schema Thread Pool Tables”](#).

- **Information Schema `PROCESSLIST` table usage.** Although the `INFORMATION_SCHEMA.PROCESSLIST` table was deprecated in MySQL 8.0.35 and 8.2.0, interest remains in tracking its usage. This release adds two system status variables providing information about accesses to the `PROCESSLIST` table, listed here:
 - `Deprecated_use_i_s_processlist_count` provides a count of the number of references to the `PROCESSLIST` table in queries since the server was last started.
 - `Deprecated_use_i_s_processlist_last_timestamp` stores the time the `PROCESSLIST` table was last accessed. This is a timestamp value (number of microseconds since the Unix Epoch).

- **Flushing of data masking dictionaries.** The MySQL Enterprise Data Masking and De-Identification component now includes the ability to flush the data on the secondary or replica into memory. This can be done in either of the ways described here:
 - A flush can be performed by the user at any time using the `masking_dictionaries_flush()` function added in this release.
 - The component can be configured to flush the memory periodically, leveraging the Scheduler component, by setting the new `component_masking.dictionaries_flush_interval_seconds` system variable to an appropriate value.

For more information, see [Section 8.5, “MySQL Enterprise Data Masking and De-Identification”](#), and the descriptions of these items.

Features Deprecated in MySQL 8.3

The following features are deprecated in MySQL 8.3 and may be removed in a future series. Where alternatives are shown, applications should be updated to use them.

For applications that use features deprecated in MySQL 8.3 that have been removed in a later MySQL version, statements may fail when replicated from a MySQL 8.3 source to a replica running a later version, or may have different effects on source and replica. To avoid such problems, applications that use features deprecated in 8.3 should be revised to avoid them and use alternatives when possible.

- **Group Replication recovery metadata.** Group Replication recovery no longer depends on writing of view change events to the binary log to mark changes in group membership; instead, when all members of a group are MySQL version 8.3.0 or later, members share compressed recovery metadata, and no such event is logged (or assigned a GTID) when a new member joins the group.

Recovery metadata includes the GCS view ID, `GTID_SET` of certified transactions, and certification information, as well as a list of online members.

Since `View_change_log_event` no longer plays a role in recovery, the `group_replication_view_change_uuid` system variable is no longer needed, and so is now deprecated; expect its removal in a future MySQL release. You should be aware that no replacement or alternative for this variable or its functionality is planned, and develop your applications accordingly.

Features Removed in MySQL 8.3

The following items are obsolete and have been removed in MySQL 8.3. Where alternatives are shown, applications should be updated to use them.

For MySQL 8.2 applications that use features removed in MySQL 8.3, statements may fail when replicated from a MySQL 8.2 source to a MySQL 8.3 replica, or may have different effects on source and replica. To avoid such problems, applications that use features removed in MySQL 8.3 should be revised to avoid them and use alternatives when possible.

- **C API functions removed.** The following MySQL C API functions were deprecated in previous versions of MySQL, and have now been removed:
 - `mysql_kill()`: Use `mysql_real_query()` or `mysql_query()` to execute a `KILL` statement instead.
 - `mysql_list_fields()`: Use `mysql_real_query()` or `mysql_query()` to execute `SELECT * FROM table LIMIT 0` instead. (This is roughly equivalent to executing the statement in the `mysql` client after starting it with the `--column-type-info` option.)

The `char *def` member of the `MYSQL_FIELD` structure was used by this function only, and has also been removed.

- `mysql_list_processes()`: Use `mysql_real_query()` or `mysql_query()` to execute a `SHOW PROCESSLIST` statement instead.
- `mysql_refresh()`: Use `mysql_real_query()` or `mysql_query()` to execute a `FLUSH` statement instead.

Due to the removal of this function, the `mysqladmin flush-threads` command has also been removed.

- `mysql_reload()`: Use `mysql_real_query()` or `mysql_query()` to execute a `FLUSH PRIVILEGES` statement instead.
- `mysql_shutdown()`: Use `mysql_real_query()` or `mysql_query()` to execute a `SHUTDOWN` statement instead.

`mysql_shutdown()` was deprecated in MySQL 8.0; the remainder of the functions listed were deprecated in MySQL 5.7.11.

Due to these changes, the MySQL C API library version is raised from 22.1 to 23.0.

- **FLUSH HOSTS statement.** The `FLUSH HOSTS` statement, deprecated in MySQL 8.0.23, has been removed. To clear the host cache, issue `TRUNCATE TABLE performance_schema.host_cache` or `mysqladmin flush-hosts`.
- **Obsolete replication options and variables.** A number of options and variables relating to MySQL Replication were deprecated in previous versions of MySQL, and have been removed from MySQL 8.3. Attempting to use any of these now causes the server to raise a syntax error. These options and variables are listed here:
 - `--slave-rows-search-algorithms`: The algorithm used by the replication applier to look up table rows when applying updates or deletes is now always `HASH_SCAN`, `INDEX_SCAN`, and is no longer configurable by the user.
 - `log_bin_use_v1_events`: This allowed source servers running MySQL 5.7 and newer to replicate to earlier versions of MySQL which are no longer supported or maintained.
 - `--relay-log-info-file`, `--relay-log-info-repository`, `--master-info-file`, `--master-info-repository`: The use of files for the applier metadata repository and the connection metadata repository has been superseded by crash-safe tables, and is no longer supported. See [Section 19.2.4.2, “Replication Metadata Repositories”](#).
 - `transaction_write_set_extraction`
 - `group_replication_ip_whitelist`: Use `group_replication_ip_allowlist` instead.
 - `group_replication_primary_member`: No longer needed; check the `MEMBER_ROLE` column of the Performance Schema `replication_group_members` table instead.
- **--skip-host-cache server option.** This option has been removed; start the server with `--host-cache-size=0` instead. See [Section 7.1.12.3, “DNS Lookups and the Host Cache”](#).
- **--innodb and --skip-innodb server options.** These options have been removed. The `InnoDB` storage engine is always enabled, and it is not possible to disable it.
- **--character-set-client-handshake and --old-style-user-limits server options.** These options were formerly used for compatibility with very old versions of MySQL which are no longer supported or maintained, and thus no longer serve any useful purpose.

- **Obsolete CMake options.** The following options for compiling the server with CMake were obsolete and have been removed:
 - `USE_LD_LLD`: Use `WITH_LD=lld` instead.
 - `WITH_BOOST`, `DOWNLOAD_BOOST`, `DOWNLOAD_BOOST_TIMEOUT`: These options are no longer necessary; MySQL now includes and uses a bundled version of Boost when compiling from source.
- **GTID-based replication and `IGNORE_SERVER_IDS`.** When global transaction identifiers (GTIDs) are used for replication, transactions that have already been applied are automatically ignored. This means that `IGNORE_SERVER_IDS` is not compatible with GTID mode. If `gtid_mode` is `ON`, `CHANGE REPLICATION SOURCE TO` with a non-empty `IGNORE_SERVER_IDS` list is rejected with an error. Likewise, if any existing replication channel was created with a list of server IDs to be ignored, `SET gtid_mode=ON` is also rejected. Before starting GTID-based replication, check for and clear any ignored server ID lists on the servers involved; you can do this by checking the output from `SHOW REPLICA STATUS`. In such cases, you can clear the list by issuing `CHANGE REPLICATION SOURCE TO` with an empty list of server IDs, as shown here:

```
CHANGE REPLICATION SOURCE TO IGNORE_SERVER_IDS = ( );
```

See [Section 19.1.3.7, “Restrictions on Replication with GTIDs”](#), for more information.

- **Binary log transaction dependency tracking and logging format.** Using writeset information for conflict detection has been found to cause issues with dependency tracking; for this reason, we now limit the usage of writesets for conflict checks to when row-based logging is in effect.

This means that, beginning with this release, if `binlog_transaction_dependency_tracking` is set to `WRITESET` or `WRITESET_SESSION`, `binlog_format` must be `ROW`; `MIXED` is no longer supported in such cases.

1.4 Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 8.3

- [Options and Variables Introduced in MySQL 8.3](#)
- [Options and Variables Deprecated in MySQL 8.3](#)
- [Options and Variables Removed in MySQL 8.3](#)

This section lists server variables, status variables, and options that were added for the first time, have been deprecated, or have been removed in MySQL 8.3.

Options and Variables Introduced in MySQL 8.3

The following system variables, status variables, and server options have been added in MySQL 8.3.

- `Deprecated_use_i_s_processlist_count`: Number of times Information Schema processlist table has been accessed. Added in MySQL 8.3.0.
- `Deprecated_use_i_s_processlist_last_timestamp`: Time of most recent access to Information Schema processlist table (timestamp). Added in MySQL 8.3.0.
- `component_masking.dictionaries_flush_interval_seconds`: How long for scheduler to wait until attempting to schedule next execution, in seconds. Added in MySQL 8.3.0.
- `component_masking.masking_database`: Database to use for masking dictionaries. Added in MySQL 8.3.0.
- `telemetry.metrics_reader_frequency_1`: . Added in MySQL 8.3.0.

- `telemetry.metrics_reader_frequency_1`: . Added in MySQL 8.3.0.
- `telemetry.metrics_reader_frequency_1`: . Added in MySQL 8.3.0.
- `telemetry.otel_exporter_otlp_metrics_certificates`: The trusted certificate to use when verifying a server's TLS credentials. Added in MySQL 8.3.0.
- `telemetry.otel_exporter_otlp_metrics_cipher`: TLS cipher to use for metrics (TLS 1.2). Added in MySQL 8.3.0.
- `telemetry.otel_exporter_otlp_metrics_cipher_suite`: TLS cipher to use for metrics (TLS 1.3). Added in MySQL 8.3.0.
- `telemetry.otel_exporter_otlp_metrics_client_certificates`: Client certificate/chain trust for clients private key in PEM format. Added in MySQL 8.3.0.
- `telemetry.otel_exporter_otlp_metrics_client_key`: Client's private key in PEM format. Added in MySQL 8.3.0.
- `telemetry.otel_exporter_otlp_metrics_compression`: Compression used by exporter. Added in MySQL 8.3.0.
- `telemetry.otel_exporter_otlp_metrics_endpoint`: Metrics endpoint URL. Added in MySQL 8.3.0.
- `telemetry.otel_exporter_otlp_metrics_headers`: Key-value pairs to be used as headers associated with HTTP requests. Added in MySQL 8.3.0.
- `telemetry.otel_exporter_otlp_metrics_max_tls`: Maximum TLS version to use for metrics. Added in MySQL 8.3.0.
- `telemetry.otel_exporter_otlp_metrics_min_tls`: Minimum TLS version to use for metrics. Added in MySQL 8.3.0.
- `telemetry.otel_exporter_otlp_metrics_protocol`: Specifies the OTLP transport protocol. Added in MySQL 8.3.0.
- `telemetry.otel_exporter_otlp_metrics_timeout`: Time OLTP exporter waits for each batch export. Added in MySQL 8.3.0.
- `telemetry.otel_exporter_otlp_traces_cipher`: TLS cipher to use for traces (TLS 1.2). Added in MySQL 8.3.0.
- `telemetry.otel_exporter_otlp_traces_cipher_suite`: TLS cipher to use for traces (TLS 1.3). Added in MySQL 8.3.0.
- `telemetry.otel_exporter_otlp_traces_max_tls`: Maximum TLS version to use for traces. Added in MySQL 8.3.0.
- `telemetry.otel_exporter_otlp_traces_min_tls`: Minimum TLS version to use for traces. Added in MySQL 8.3.0.

Options and Variables Deprecated in MySQL 8.3

The following system variables, status variables, and options have been deprecated in MySQL 8.3.

- `group_replication_view_change_uuid`: UUID for view change event GTIDs. Deprecated in MySQL 8.3.0.

Options and Variables Removed in MySQL 8.3

The following system variables, status variables, and options have been removed in MySQL 8.3.

- `Replica_rows_last_search_algorithm_used`: Search algorithm most recently used by this replica to locate rows for row-based replication (index, table, or hash scan). Removed in MySQL 8.3.0.
- `character-set-client-handshake`: Do not ignore client side character set value sent during handshake. Removed in MySQL 8.3.0.
- `daemon_memcached_enable_binlog`: . Removed in MySQL 8.3.0.
- `daemon_memcached_engine_lib_name`: Shared library implementing InnoDB memcached plugin. Removed in MySQL 8.3.0.
- `daemon_memcached_engine_lib_path`: Directory which contains shared library implementing InnoDB memcached plugin. Removed in MySQL 8.3.0.
- `daemon_memcached_option`: Space-separated options which are passed to underlying memcached daemon on startup. Removed in MySQL 8.3.0.
- `daemon_memcached_r_batch_size`: Specifies how many memcached read operations to perform before doing COMMIT to start new transaction. Removed in MySQL 8.3.0.
- `daemon_memcached_w_batch_size`: Specifies how many memcached write operations to perform before doing COMMIT to start new transaction. Removed in MySQL 8.3.0.
- `group_replication_ip_whitelist`: List of hosts permitted to connect to group. Removed in MySQL 8.3.0.
- `group_replication_primary_member`: Primary member UUID when group operates in single-primary mode. Empty string if group is operating in multi-primary mode. Removed in MySQL 8.3.0.
- `innodb`: Enable InnoDB (if this version of MySQL supports it). Removed in MySQL 8.3.0.
- `innodb_api_bk_commit_interval`: How often to auto-commit idle connections which use InnoDB memcached interface, in seconds. Removed in MySQL 8.3.0.
- `innodb_api_disable_rowlock`: . Removed in MySQL 8.3.0.
- `innodb_api_enable_binlog`: Allows use of InnoDB memcached plugin with MySQL binary log. Removed in MySQL 8.3.0.
- `innodb_api_enable_md1`: Locks table used by InnoDB memcached plugin, so that it cannot be dropped or altered by DDL through SQL interface. Removed in MySQL 8.3.0.
- `innodb_api_trx_level`: Allows control of transaction isolation level on queries processed by memcached interface. Removed in MySQL 8.3.0.
- `log_bin_use_v1_row_events`: Whether server is using version 1 binary log row events. Removed in MySQL 8.3.0.
- `master-info-file`: Location and name of file that remembers source and where I/O replication thread is in source's binary log. Removed in MySQL 8.3.0.
- `master_info_repository`: Whether to write connection metadata repository, containing source information and replication I/O thread location in source's binary log, to file or table. Removed in MySQL 8.3.0.
- `old-style-user-limits`: Enable old-style user limits (before 5.0.3, user resources were counted per each user+host vs. per account). Removed in MySQL 8.3.0.
- `relay_log_info_file`: File name for applier metadata repository in which replica records information about relay logs. Removed in MySQL 8.3.0.
- `relay_log_info_repository`: Whether to write location of replication SQL thread in relay logs to file or table. Removed in MySQL 8.3.0.

- `skip-character-set-client-handshake`: Ignore client side character set value sent during handshake. Removed in MySQL 8.3.0.
- `skip-host-cache`: Do not cache host names. Removed in MySQL 8.3.0.
- `slave_rows_search_algorithms`: Determines search algorithms used for replica update batching. Any 2 or 3 from this list: INDEX_SEARCH, TABLE_SCAN, HASH_SCAN. Removed in MySQL 8.3.0.
- `transaction_write_set_extraction`: Defines algorithm used to hash writes extracted during transaction. Removed in MySQL 8.3.0.

1.5 How to Report Bugs or Problems

Before posting a bug report about a problem, please try to verify that it is a bug and that it has not been reported already:

- Start by searching the MySQL online manual at <https://dev.mysql.com/doc/>. We try to keep the manual up to date by updating it frequently with solutions to newly found problems. In addition, the release notes accompanying the manual can be particularly useful since it is quite possible that a newer version contains a solution to your problem. The release notes are available at the location just given for the manual.
- If you get a parse error for an SQL statement, please check your syntax closely. If you cannot find something wrong with it, it is extremely likely that your current version of MySQL Server doesn't support the syntax you are using. If you are using the current version and the manual doesn't cover the syntax that you are using, MySQL Server doesn't support your statement.

If the manual covers the syntax you are using, but you have an older version of MySQL Server, you should check the MySQL change history to see when the syntax was implemented. In this case, you have the option of upgrading to a newer version of MySQL Server.

- For solutions to some common problems, see [Section B.3, “Problems and Common Errors”](#).
- Search the bugs database at <http://bugs.mysql.com/> to see whether the bug has been reported and fixed.
- You can also use <http://www.mysql.com/search/> to search all the Web pages (including the manual) that are located at the MySQL website.

If you cannot find an answer in the manual, the bugs database, or the mailing list archives, check with your local MySQL expert. If you still cannot find an answer to your question, please use the following guidelines for reporting the bug.

The normal way to report bugs is to visit <http://bugs.mysql.com/>, which is the address for our bugs database. This database is public and can be browsed and searched by anyone. If you log in to the system, you can enter new reports.

Bugs posted in the bugs database at <http://bugs.mysql.com/> that are corrected for a given release are noted in the release notes.

If you find a security bug in MySQL Server, please let us know immediately by sending an email message to [<secalert_us@oracle.com>](mailto:secalert_us@oracle.com). Exception: Support customers should report all problems, including security bugs, to Oracle Support at <http://support.oracle.com/>.

To discuss problems with other users, you can use the [MySQL Community Slack](#).

Writing a good bug report takes patience, but doing it right the first time saves time both for us and for yourself. A good bug report, containing a full test case for the bug, makes it very likely that we will fix the bug in the next release. This section helps you write your report correctly so that you do not waste

your time doing things that may not help us much or at all. Please read this section carefully and make sure that all the information described here is included in your report.

Preferably, you should test the problem using the latest production or development version of MySQL Server before posting. Anyone should be able to repeat the bug by just using `mysql test < script_file` on your test case or by running the shell or Perl script that you include in the bug report. Any bug that we are able to repeat has a high chance of being fixed in the next MySQL release.

It is most helpful when a good description of the problem is included in the bug report. That is, give a good example of everything you did that led to the problem and describe, in exact detail, the problem itself. The best reports are those that include a full example showing how to reproduce the bug or problem. See [Section 7.9, “Debugging MySQL”](#).

Remember that it is possible for us to respond to a report containing too much information, but not to one containing too little. People often omit facts because they think they know the cause of a problem and assume that some details do not matter. A good principle to follow is that if you are in doubt about stating something, state it. It is faster and less troublesome to write a couple more lines in your report than to wait longer for the answer if we must ask you to provide information that was missing from the initial report.

The most common errors made in bug reports are (a) not including the version number of the MySQL distribution that you use, and (b) not fully describing the platform on which the MySQL server is installed (including the platform type and version number). These are highly relevant pieces of information, and in 99 cases out of 100, the bug report is useless without them. Very often we get questions like, “Why doesn’t this work for me?” Then we find that the feature requested wasn’t implemented in that MySQL version, or that a bug described in a report has been fixed in newer MySQL versions. Errors often are platform-dependent. In such cases, it is next to impossible for us to fix anything without knowing the operating system and the version number of the platform.

If you compiled MySQL from source, remember also to provide information about your compiler if it is related to the problem. Often people find bugs in compilers and think the problem is MySQL-related. Most compilers are under development all the time and become better version by version. To determine whether your problem depends on your compiler, we need to know what compiler you used. Note that every compiling problem should be regarded as a bug and reported accordingly.

If a program produces an error message, it is very important to include the message in your report. If we try to search for something from the archives, it is better that the error message reported exactly matches the one that the program produces. (Even the lettercase should be observed.) It is best to copy and paste the entire error message into your report. You should never try to reproduce the message from memory.

If you have a problem with Connector/ODBC (MyODBC), please try to generate a trace file and send it with your report. See [How to Report Connector/ODBC Problems or Bugs](#).

If your report includes long query output lines from test cases that you run with the `mysql` command-line tool, you can make the output more readable by using the `--vertical` option or the `\G` statement terminator. The [EXPLAIN SELECT](#) example later in this section demonstrates the use of `\G`.

Please include the following information in your report:

- The version number of the MySQL distribution you are using (for example, MySQL 5.7.10). You can find out which version you are running by executing `mysqladmin version`. The `mysqladmin` program can be found in the `bin` directory under your MySQL installation directory.
- The manufacturer and model of the machine on which you experience the problem.
- The operating system name and version. If you work with Windows, you can usually get the name and version number by double-clicking your My Computer icon and pulling down the “Help/About Windows” menu. For most Unix-like operating systems, you can get this information by executing the command `uname -a`.

- Sometimes the amount of memory (real and virtual) is relevant. If in doubt, include these values.
- The contents of the `docs/INFO_BIN` file from your MySQL installation. This file contains information about how MySQL was configured and compiled.
- If you are using a source distribution of the MySQL software, include the name and version number of the compiler that you used. If you have a binary distribution, include the distribution name.
- If the problem occurs during compilation, include the exact error messages and also a few lines of context around the offending code in the file where the error occurs.
- If `mysqld` died, you should also report the statement that caused `mysqld` to unexpectedly exit. You can usually get this information by running `mysqld` with query logging enabled, and then looking in the log after `mysqld` exits. See [Section 7.9, “Debugging MySQL”](#).
- If a database table is related to the problem, include the output from the `SHOW CREATE TABLE db_name.tbl_name` statement in the bug report. This is a very easy way to get the definition of any table in a database. The information helps us create a situation matching the one that you have experienced.
- The SQL mode in effect when the problem occurred can be significant, so please report the value of the `sql_mode` system variable. For stored procedure, stored function, and trigger objects, the relevant `sql_mode` value is the one in effect when the object was created. For a stored procedure or function, the `SHOW CREATE PROCEDURE` or `SHOW CREATE FUNCTION` statement shows the relevant SQL mode, or you can query `INFORMATION_SCHEMA` for the information:

```
SELECT ROUTINE_SCHEMA, ROUTINE_NAME, SQL_MODE
FROM INFORMATION_SCHEMA.ROUTINES;
```

For triggers, you can use this statement:

```
SELECT EVENT_OBJECT_SCHEMA, EVENT_OBJECT_TABLE, TRIGGER_NAME, SQL_MODE
FROM INFORMATION_SCHEMA.TRIGGERS;
```

- For performance-related bugs or problems with `SELECT` statements, you should always include the output of `EXPLAIN SELECT ...`, and at least the number of rows that the `SELECT` statement produces. You should also include the output from `SHOW CREATE TABLE tbl_name` for each table that is involved. The more information you provide about your situation, the more likely it is that someone can help you.

The following is an example of a very good bug report. The statements are run using the `mysql` command-line tool. Note the use of the `\G` statement terminator for statements that would otherwise provide very long output lines that are difficult to read.

```
mysql> SHOW VARIABLES;
mysql> SHOW COLUMNS FROM ... \G
      <output from SHOW COLUMNS>
mysql> EXPLAIN SELECT ... \G
      <output from EXPLAIN>
mysql> FLUSH STATUS;
mysql> SELECT ...;
      <A short version of the output from SELECT,
      including the time taken to run the query>
mysql> SHOW STATUS;
      <output from SHOW STATUS>
```

- If a bug or problem occurs while running `mysqld`, try to provide an input script that reproduces the anomaly. This script should include any necessary source files. The more closely the script can reproduce your situation, the better. If you can make a reproducible test case, you should upload it to be attached to the bug report.

If you cannot provide a script, you should at least include the output from `mysqladmin variables extended-status processlist` in your report to provide some information on how your system is performing.

- If you cannot produce a test case with only a few rows, or if the test table is too big to be included in the bug report (more than 10 rows), you should dump your tables using `mysqldump` and create a `README` file that describes your problem. Create a compressed archive of your files using `tar` and `gzip` or `zip`. After you initiate a bug report for our bugs database at <http://bugs.mysql.com/>, click the Files tab in the bug report for instructions on uploading the archive to the bugs database.
- If you believe that the MySQL server produces a strange result from a statement, include not only the result, but also your opinion of what the result should be, and an explanation describing the basis for your opinion.
- When you provide an example of the problem, it is better to use the table names, variable names, and so forth that exist in your actual situation than to come up with new names. The problem could be related to the name of a table or variable. These cases are rare, perhaps, but it is better to be safe than sorry. After all, it should be easier for you to provide an example that uses your actual situation, and it is by all means better for us. If you have data that you do not want to be visible to others in the bug report, you can upload it using the Files tab as previously described. If the information is really top secret and you do not want to show it even to us, go ahead and provide an example using other names, but please regard this as the last choice.
- Include all the options given to the relevant programs, if possible. For example, indicate the options that you use when you start the `mysqld` server, as well as the options that you use to run any MySQL client programs. The options to programs such as `mysqld` and `mysql`, and to the `configure` script, are often key to resolving problems and are very relevant. It is never a bad idea to include them. If your problem involves a program written in a language such as Perl or PHP, please include the language processor's version number, as well as the version for any modules that the program uses. For example, if you have a Perl script that uses the `DBI` and `DBD: :mysql` modules, include the version numbers for Perl, `DBI`, and `DBD: :mysql`.
- If your question is related to the privilege system, please include the output of `mysqladmin reload`, and all the error messages you get when trying to connect. When you test your privileges, you should execute `mysqladmin reload version` and try to connect with the program that gives you trouble.
- If you have a patch for a bug, do include it. But do not assume that the patch is all we need, or that we can use it, if you do not provide some necessary information such as test cases showing the bug that your patch fixes. We might find problems with your patch or we might not understand it at all. If so, we cannot use it.

If we cannot verify the exact purpose of the patch, we will not use it. Test cases help us here. Show that the patch handles all the situations that may occur. If we find a borderline case (even a rare one) where the patch will not work, it may be useless.

- Guesses about what the bug is, why it occurs, or what it depends on are usually wrong. Even the MySQL team cannot guess such things without first using a debugger to determine the real cause of a bug.
- Indicate in your bug report that you have checked the reference manual and mail archive so that others know you have tried to solve the problem yourself.
- If your data appears corrupt or you get errors when you access a particular table, first check your tables with `CHECK TABLE`. If that statement reports any errors:
 - The `InnoDB` crash recovery mechanism handles cleanup when the server is restarted after being killed, so in typical operation there is no need to “repair” tables. If you encounter an error with `InnoDB` tables, restart the server and see whether the problem persists, or whether the error affected only cached data in memory. If data is corrupted on disk, consider restarting with the `innodb_force_recovery` option enabled so that you can dump the affected tables.
 - For non-transactional tables, try to repair them with `REPAIR TABLE` or with `myisamchk`. See [Chapter 7, MySQL Server Administration](#).

If you are running Windows, please verify the value of `lower_case_table_names` using the `SHOW VARIABLES LIKE 'lower_case_table_names'` statement. This variable affects how the server handles lettercase of database and table names. Its effect for a given value should be as described in [Section 11.2.3, “Identifier Case Sensitivity”](#).

- If you often get corrupted tables, you should try to find out when and why this happens. In this case, the error log in the MySQL data directory may contain some information about what happened. (This is the file with the `.err` suffix in the name.) See [Section 7.4.2, “The Error Log”](#). Please include any relevant information from this file in your bug report. Normally `mysqld` should *never* corrupt a table if nothing killed it in the middle of an update. If you can find the cause of `mysqld` dying, it is much easier for us to provide you with a fix for the problem. See [Section B.3.1, “How to Determine What Is Causing a Problem”](#).
- If possible, download and install the most recent version of MySQL Server and check whether it solves your problem. All versions of the MySQL software are thoroughly tested and should work without problems. We believe in making everything as backward-compatible as possible, and you should be able to switch MySQL versions without difficulty. See [Section 2.1.2, “Which MySQL Version and Distribution to Install”](#).

1.6 MySQL Standards Compliance

This section describes how MySQL relates to the ANSI/ISO SQL standards. MySQL Server has many extensions to the SQL standard, and here you can find out what they are and how to use them. You can also find information about functionality missing from MySQL Server, and how to work around some of the differences.

The SQL standard has been evolving since 1986 and several versions exist. In this manual, “SQL-92” refers to the standard released in 1992. “SQL:1999”, “SQL:2003”, “SQL:2008”, and “SQL:2011” refer to the versions of the standard released in the corresponding years, with the last being the most recent version. We use the phrase “the SQL standard” or “standard SQL” to mean the current version of the SQL Standard at any time.

One of our main goals with the product is to continue to work toward compliance with the SQL standard, but without sacrificing speed or reliability. We are not afraid to add extensions to SQL or support for non-SQL features if this greatly increases the usability of MySQL Server for a large segment of our user base. The `HANDLER` interface is an example of this strategy. See [Section 15.2.5, “HANDLER Statement”](#).

We continue to support transactional and nontransactional databases to satisfy both mission-critical 24/7 usage and heavy Web or logging usage.

MySQL Server was originally designed to work with medium-sized databases (10-100 million rows, or about 100MB per table) on small computer systems. Today MySQL Server handles terabyte-sized databases.

We are not targeting real-time support, although MySQL replication capabilities offer significant functionality.

MySQL supports ODBC levels 0 to 3.51.

MySQL supports high-availability database clustering using the `NDBCLUSTER` storage engine. See [Chapter 25, MySQL NDB Cluster 8.3](#).

We implement XML functionality which supports most of the W3C XPath standard. See [Section 14.11, “XML Functions”](#).

MySQL supports a native JSON data type as defined by RFC 7159, and based on the ECMAScript standard (ECMA-262). See [Section 13.5, “The JSON Data Type”](#). MySQL also implements a subset

of the SQL/JSON functions specified by a pre-publication draft of the SQL:2016 standard; see [Section 14.17, “JSON Functions”](#), for more information.

Selecting SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients, depending on the value of the `sql_mode` system variable. DBAs can set the global SQL mode to match site server operating requirements, and each application can set its session SQL mode to its own requirements.

Modes affect the SQL syntax MySQL supports and the data validation checks it performs. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

For more information on setting the SQL mode, see [Section 7.1.11, “Server SQL Modes”](#).

Running MySQL in ANSI Mode

To run MySQL Server in ANSI mode, start `mysqld` with the `--ansi` option. Running the server in ANSI mode is the same as starting it with the following options:

```
--transaction-isolation=SERIALIZABLE --sql-mode=ANSI
```

To achieve the same effect at runtime, execute these two statements:

```
SET GLOBAL TRANSACTION ISOLATION LEVEL SERIALIZABLE;  
SET GLOBAL sql_mode = 'ANSI';
```

You can see that setting the `sql_mode` system variable to `'ANSI'` enables all SQL mode options that are relevant for ANSI mode as follows:

```
mysql> SET GLOBAL sql_mode='ANSI';  
mysql> SELECT @@GLOBAL.sql_mode;  
-> 'REAL_AS_FLOAT,PIPES_AS_CONCAT,ANSI_QUOTES,IGNORE_SPACE,ANSI'
```

Running the server in ANSI mode with `--ansi` is not quite the same as setting the SQL mode to `'ANSI'` because the `--ansi` option also sets the transaction isolation level.

See [Section 7.1.7, “Server Command Options”](#).

1.6.1 MySQL Extensions to Standard SQL

MySQL Server supports some extensions that you are not likely to find in other SQL DBMSs. Be warned that if you use them, your code is most likely not portable to other SQL servers. In some cases, you can write code that includes MySQL extensions, but is still portable, by using comments of the following form:

```
/*! MySQL-specific code */
```

In this case, MySQL Server parses and executes the code within the comment as it would any other SQL statement, but other SQL servers should ignore the extensions. For example, MySQL Server recognizes the `STRAIGHT_JOIN` keyword in the following statement, but other servers should not:

```
SELECT /*! STRAIGHT_JOIN */ col1 FROM table1,table2 WHERE ...
```

If you add a version number after the `!` character, the syntax within the comment is executed only if the MySQL version is greater than or equal to the specified version number. The `KEY_BLOCK_SIZE` clause in the following comment is executed only by servers from MySQL 5.1.10 or higher:

```
CREATE TABLE t1(a INT, KEY (a)) /*!50110 KEY_BLOCK_SIZE=1024 */;
```

The following descriptions list MySQL extensions, organized by category.

- Organization of data on disk

MySQL Server maps each database to a directory under the MySQL data directory, and maps tables within a database to file names in the database directory. Consequently, database and table names are case-sensitive in MySQL Server on operating systems that have case-sensitive file names (such as most Unix systems). See [Section 11.2.3, “Identifier Case Sensitivity”](#).

- General language syntax

- By default, strings can be enclosed by " as well as '. If the `ANSI_QUOTES` SQL mode is enabled, strings can be enclosed only by ' and the server interprets strings enclosed by " as identifiers.
- \ is the escape character in strings.
- In SQL statements, you can access tables from different databases with the `db_name.tbl_name` syntax. Some SQL servers provide the same functionality but call this `User space`. MySQL Server doesn't support tablespaces such as used in statements like this: `CREATE TABLE ralph.my_table ... IN my_tablespace.`

- SQL statement syntax

- The `ANALYZE TABLE`, `CHECK TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements.
- The `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE` statements. See [Section 15.1.12, “CREATE DATABASE Statement”](#), [Section 15.1.24, “DROP DATABASE Statement”](#), and [Section 15.1.2, “ALTER DATABASE Statement”](#).
- The `DO` statement.
- `EXPLAIN SELECT` to obtain a description of how tables are processed by the query optimizer.
- The `FLUSH` and `RESET` statements.
- The `SET` statement. See [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#).
- The `SHOW` statement. See [Section 15.7.7, “SHOW Statements”](#). The information produced by many of the MySQL-specific `SHOW` statements can be obtained in more standard fashion by using `SELECT` to query `INFORMATION_SCHEMA`. See [Chapter 28, `INFORMATION_SCHEMA` Tables](#).
- Use of `LOAD DATA`. In many cases, this syntax is compatible with Oracle `LOAD DATA`. See [Section 15.2.9, “LOAD DATA Statement”](#).
- Use of `RENAME TABLE`. See [Section 15.1.36, “RENAME TABLE Statement”](#).
- Use of `REPLACE` instead of `DELETE` plus `INSERT`. See [Section 15.2.12, “REPLACE Statement”](#).
- Use of `CHANGE col_name`, `DROP col_name`, or `DROP INDEX`, `IGNORE` or `RENAME` in `ALTER TABLE` statements. Use of multiple `ADD`, `ALTER`, `DROP`, or `CHANGE` clauses in an `ALTER TABLE` statement. See [Section 15.1.9, “ALTER TABLE Statement”](#).
- Use of index names, indexes on a prefix of a column, and use of `INDEX` or `KEY` in `CREATE TABLE` statements. See [Section 15.1.20, “CREATE TABLE Statement”](#).
- Use of `TEMPORARY` or `IF NOT EXISTS` with `CREATE TABLE`.
- Use of `IF EXISTS` with `DROP TABLE` and `DROP DATABASE`.
- The capability of dropping multiple tables with a single `DROP TABLE` statement.
- The `ORDER BY` and `LIMIT` clauses of the `UPDATE` and `DELETE` statements.
- `INSERT INTO tbl_name SET col_name = ...` syntax.

- The `DELAYED` clause of the `INSERT` and `REPLACE` statements.
- The `LOW_PRIORITY` clause of the `INSERT`, `REPLACE`, `DELETE`, and `UPDATE` statements.
- Use of `INTO OUTFILE` or `INTO DUMPFILE` in `SELECT` statements. See [Section 15.2.13, “SELECT Statement”](#).
- Options such as `STRAIGHT_JOIN` or `SQL_SMALL_RESULT` in `SELECT` statements.
- You don't need to name all selected columns in the `GROUP BY` clause. This gives better performance for some very specific, but quite normal queries. See [Section 14.19, “Aggregate Functions”](#).
- You can specify `ASC` and `DESC` with `GROUP BY`, not just with `ORDER BY`.
- The ability to set variables in a statement with the `:=` assignment operator. See [Section 11.4, “User-Defined Variables”](#).
- Data types
 - The `MEDIUMINT`, `SET`, and `ENUM` data types, and the various `BLOB` and `TEXT` data types.
 - The `AUTO_INCREMENT`, `BINARY`, `NULL`, `UNSIGNED`, and `ZEROFILL` data type attributes.
- Functions and operators
 - To make it easier for users who migrate from other SQL environments, MySQL Server supports aliases for many functions. For example, all string functions support both standard SQL syntax and ODBC syntax.
 - MySQL Server understands the `||` and `&&` operators to mean logical OR and AND, as in the C programming language. In MySQL Server, `||` and `OR` are synonyms, as are `&&` and `AND`. Because of this nice syntax, MySQL Server doesn't support the standard SQL `||` operator for string concatenation; use `CONCAT()` instead. Because `CONCAT()` takes any number of arguments, it is easy to convert use of the `||` operator to MySQL Server.
 - Use of `COUNT(DISTINCT value_list)` where `value_list` has more than one element.
 - String comparisons are case-insensitive by default, with sort ordering determined by the collation of the current character set, which is `utf8mb4` by default. To perform case-sensitive comparisons instead, you should declare your columns with the `BINARY` attribute or use the `BINARY` cast, which causes comparisons to be done using the underlying character code values rather than a lexical ordering.
 - The `%` operator is a synonym for `MOD()`. That is, `N % M` is equivalent to `MOD(N,M)`. `%` is supported for C programmers and for compatibility with PostgreSQL.
 - The `=`, `<>`, `<=`, `<`, `>=`, `>`, `<<`, `>>`, `<=>`, `AND`, `OR`, or `LIKE` operators may be used in expressions in the output column list (to the left of the `FROM`) in `SELECT` statements. For example:

```
mysql> SELECT col1=1 AND col2=2 FROM my_table;
```
 - The `LAST_INSERT_ID()` function returns the most recent `AUTO_INCREMENT` value. See [Section 14.15, “Information Functions”](#).
 - `LIKE` is permitted on numeric values.
 - The `REGEXP` and `NOT REGEXP` extended regular expression operators.
 - `CONCAT()` or `CHAR()` with one argument or more than two arguments. (In MySQL Server, these functions can take a variable number of arguments.)

- The `BIT_COUNT()`, `CASE`, `ELT()`, `FROM_DAYS()`, `FORMAT()`, `IF()`, `MD5()`, `PERIOD_ADD()`, `PERIOD_DIFF()`, `TO_DAYS()`, and `WEEKDAY()` functions.
- Use of `TRIM()` to trim substrings. Standard SQL supports removal of single characters only.
- The `GROUP BY` functions `STD()`, `BIT_OR()`, `BIT_AND()`, `BIT_XOR()`, and `GROUP_CONCAT()`. See [Section 14.19, “Aggregate Functions”](#).

1.6.2 MySQL Differences from Standard SQL

We try to make MySQL Server follow the ANSI SQL standard and the ODBC SQL standard, but MySQL Server performs operations differently in some cases:

- There are several differences between the MySQL and standard SQL privilege systems. For example, in MySQL, privileges for a table are not automatically revoked when you delete a table. You must explicitly issue a `REVOKE` statement to revoke privileges for a table. For more information, see [Section 15.7.1.8, “REVOKE Statement”](#).
- The `CAST()` function does not support cast to `REAL` or `BIGINT`. See [Section 14.10, “Cast Functions and Operators”](#).

1.6.2.1 SELECT INTO TABLE Differences

MySQL Server doesn't support the `SELECT ... INTO TABLE` Sybase SQL extension. Instead, MySQL Server supports the `INSERT INTO ... SELECT` standard SQL syntax, which is basically the same thing. See [Section 15.2.7.1, “INSERT ... SELECT Statement”](#). For example:

```
INSERT INTO tbl_temp2 (fld_id)
  SELECT tbl_temp1.fld_order_id
  FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

Alternatively, you can use `SELECT ... INTO OUTFILE` or `CREATE TABLE ... SELECT`.

You can use `SELECT ... INTO` with user-defined variables. The same syntax can also be used inside stored routines using cursors and local variables. See [Section 15.2.13.1, “SELECT ... INTO Statement”](#).

1.6.2.2 UPDATE Differences

If you access a column from the table to be updated in an expression, `UPDATE` uses the current value of the column. The second assignment in the following statement sets `col2` to the current (updated) `col1` value, not the original `col1` value. The result is that `col1` and `col2` have the same value. This behavior differs from standard SQL.

```
UPDATE t1 SET col1 = col1 + 1, col2 = col1;
```

1.6.2.3 FOREIGN KEY Constraint Differences

The MySQL implementation of foreign key constraints differs from the SQL standard in the following key respects:

- If there are several rows in the parent table with the same referenced key value, `InnoDB` performs a foreign key check as if the other parent rows with the same key value do not exist. For example, if you define a `RESTRICT` type constraint, and there is a child row with several parent rows, `InnoDB` does not permit the deletion of any of the parent rows.
- If `ON UPDATE CASCADE` or `ON UPDATE SET NULL` recurses to update the *same table* it has previously updated during the same cascade, it acts like `RESTRICT`. This means that you cannot use self-referential `ON UPDATE CASCADE` or `ON UPDATE SET NULL` operations. This is to prevent infinite loops resulting from cascaded updates. A self-referential `ON DELETE SET NULL`, on the

other hand, is possible, as is a self-referential `ON DELETE CASCADE`. Cascading operations may not be nested more than 15 levels deep.

- In an SQL statement that inserts, deletes, or updates many rows, foreign key constraints (like unique constraints) are checked row-by-row. When performing foreign key checks, `InnoDB` sets shared row-level locks on child or parent records that it must examine. MySQL checks foreign key constraints immediately; the check is not deferred to transaction commit. According to the SQL standard, the default behavior should be deferred checking. That is, constraints are only checked after the *entire SQL statement* has been processed. This means that it is not possible to delete a row that refers to itself using a foreign key.
- No storage engine, including `InnoDB`, recognizes or enforces the `MATCH` clause used in referential-integrity constraint definitions. Use of an explicit `MATCH` clause does not have the specified effect, and it causes `ON DELETE` and `ON UPDATE` clauses to be ignored. Specifying the `MATCH` should be avoided.

The `MATCH` clause in the SQL standard controls how `NULL` values in a composite (multiple-column) foreign key are handled when comparing to a primary key in the referenced table. MySQL essentially implements the semantics defined by `MATCH SIMPLE`, which permits a foreign key to be all or partially `NULL`. In that case, a (child table) row containing such a foreign key can be inserted even though it does not match any row in the referenced (parent) table. (It is possible to implement other semantics using triggers.)

- MySQL requires that the referenced columns be indexed for performance reasons. However, MySQL does not enforce a requirement that the referenced columns be `UNIQUE` or be declared `NOT NULL`.

A `FOREIGN KEY` constraint that references a non-`UNIQUE` key is not standard SQL but rather an `InnoDB` extension. The `NDB` storage engine, on the other hand, requires an explicit unique key (or primary key) on any column referenced as a foreign key.

The handling of foreign key references to nonunique keys or keys that contain `NULL` values is not well defined for operations such as `UPDATE` or `DELETE CASCADE`. You are advised to use foreign keys that reference only `UNIQUE` (including `PRIMARY`) and `NOT NULL` keys.

- For storage engines that do not support foreign keys (such as `MyISAM`), MySQL Server parses and ignores foreign key specifications.
- MySQL parses but ignores “inline `REFERENCES` specifications” (as defined in the SQL standard) where the references are defined as part of the column specification. MySQL accepts `REFERENCES` clauses only when specified as part of a separate `FOREIGN KEY` specification.

Defining a column to use a `REFERENCES tbl_name(col_name)` clause has no actual effect and serves only as a memo or comment to you that the column which you are currently defining is intended to refer to a column in another table. It is important to realize when using this syntax that:

- MySQL does not perform any sort of check to make sure that `col_name` actually exists in `tbl_name` (or even that `tbl_name` itself exists).
- MySQL does not perform any sort of action on `tbl_name` such as deleting rows in response to actions taken on rows in the table which you are defining; in other words, this syntax induces no `ON DELETE` or `ON UPDATE` behavior whatsoever. (Although you can write an `ON DELETE` or `ON UPDATE` clause as part of the `REFERENCES` clause, it is also ignored.)
- This syntax creates a *column*; it does **not** create any sort of index or key.

You can use a column so created as a join column, as shown here:

```
CREATE TABLE person (  
  id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,  
  name CHAR(60) NOT NULL,  
  PRIMARY KEY (id)  
);
```

```

CREATE TABLE shirt (
  id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
  style ENUM('t-shirt', 'polo', 'dress') NOT NULL,
  color ENUM('red', 'blue', 'orange', 'white', 'black') NOT NULL,
  owner SMALLINT UNSIGNED NOT NULL REFERENCES person(id),
  PRIMARY KEY (id)
);

INSERT INTO person VALUES (NULL, 'Antonio Paz');

SELECT @last := LAST_INSERT_ID();

INSERT INTO shirt VALUES
(NULL, 'polo', 'blue', @last),
(NULL, 'dress', 'white', @last),
(NULL, 't-shirt', 'blue', @last);

INSERT INTO person VALUES (NULL, 'Lilliana Angelovska');

SELECT @last := LAST_INSERT_ID();

INSERT INTO shirt VALUES
(NULL, 'dress', 'orange', @last),
(NULL, 'polo', 'red', @last),
(NULL, 'dress', 'blue', @last),
(NULL, 't-shirt', 'white', @last);

SELECT * FROM person;
+----+-----+
| id | name                |
+----+-----+
|  1 | Antonio Paz         |
|  2 | Lilliana Angelovska |
+----+-----+

SELECT * FROM shirt;
+----+-----+-----+-----+
| id | style  | color  | owner |
+----+-----+-----+-----+
|  1 | polo   | blue   | 1     |
|  2 | dress  | white  | 1     |
|  3 | t-shirt| blue   | 1     |
|  4 | dress  | orange | 2     |
|  5 | polo   | red    | 2     |
|  6 | dress  | blue   | 2     |
|  7 | t-shirt| white  | 2     |
+----+-----+-----+-----+

SELECT s.* FROM person p INNER JOIN shirt s
  ON s.owner = p.id
 WHERE p.name LIKE 'Lilliana%'
    AND s.color <> 'white';

+----+-----+-----+-----+
| id | style  | color  | owner |
+----+-----+-----+-----+
|  4 | dress  | orange | 2     |
|  5 | polo   | red    | 2     |
|  6 | dress  | blue   | 2     |
+----+-----+-----+-----+

```

When used in this fashion, the [REFERENCES](#) clause is not displayed in the output of [SHOW CREATE TABLE](#) or [DESCRIBE](#):

```

SHOW CREATE TABLE shirt\G
***** 1. row *****
Table: shirt
Create Table: CREATE TABLE `shirt` (
  `id` smallint(5) unsigned NOT NULL auto_increment,
  `style` enum('t-shirt','polo','dress') NOT NULL,

```

```
`color` enum('red','blue','orange','white','black') NOT NULL,
`owner` smallint(5) unsigned NOT NULL,
PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
```

For information about foreign key constraints, see [Section 15.1.20.5, “FOREIGN KEY Constraints”](#).

1.6.2.4 '--' as the Start of a Comment

Standard SQL uses the C syntax `/* this is a comment */` for comments, and MySQL Server supports this syntax as well. MySQL also support extensions to this syntax that enable MySQL-specific SQL to be embedded in the comment; see [Section 11.7, “Comments”](#).

MySQL Server also uses `#` as the start comment character. This is nonstandard.

Standard SQL also uses “`--`” as a start-comment sequence. MySQL Server supports a variant of the `--` comment style; the `--` start-comment sequence is accepted as such, but must be followed by a whitespace character such as a space or newline. The space is intended to prevent problems with generated SQL queries that use constructs such as the following, which updates the balance to reflect a charge:

```
UPDATE account SET balance=balance-charge
WHERE account_id=user_id
```

Consider what happens when `charge` has a negative value such as `-1`, which might be the case when an amount is credited to the account. In this case, the generated statement looks like this:

```
UPDATE account SET balance=balance--1
WHERE account_id=5752;
```

`balance--1` is valid standard SQL, but `--` is interpreted as the start of a comment, and part of the expression is discarded. The result is a statement that has a completely different meaning than intended:

```
UPDATE account SET balance=balance
WHERE account_id=5752;
```

This statement produces no change in value at all. To keep this from happening, MySQL requires a whitespace character following the `--` for it to be recognized as a start-comment sequence in MySQL Server, so that an expression such as `balance--1` is always safe to use.

1.6.3 How MySQL Deals with Constraints

MySQL enables you to work both with transactional tables that permit rollback and with nontransactional tables that do not. Because of this, constraint handling is a bit different in MySQL than in other DBMSs. We must handle the case when you have inserted or updated a lot of rows in a nontransactional table for which changes cannot be rolled back when an error occurs.

The basic philosophy is that MySQL Server tries to produce an error for anything that it can detect while parsing a statement to be executed, and tries to recover from any errors that occur while executing the statement. We do this in most cases, but not yet for all.

The options MySQL has when an error occurs are to stop the statement in the middle or to recover as well as possible from the problem and continue. By default, the server follows the latter course. This means, for example, that the server may coerce invalid values to the closest valid values.

Several SQL mode options are available to provide greater control over handling of bad data values and whether to continue statement execution or abort when errors occur. Using these options, you can configure MySQL Server to act in a more traditional fashion that is like other DBMSs that reject improper input. The SQL mode can be set globally at server startup to affect all clients. Individual clients can set the SQL mode at runtime, which enables each client to select the behavior most appropriate for its requirements. See [Section 7.1.11, “Server SQL Modes”](#).

The following sections describe how MySQL Server handles different types of constraints.

1.6.3.1 PRIMARY KEY and UNIQUE Index Constraints

Normally, errors occur for data-change statements (such as `INSERT` or `UPDATE`) that would violate primary-key, unique-key, or foreign-key constraints. If you are using a transactional storage engine such as `InnoDB`, MySQL automatically rolls back the statement. If you are using a nontransactional storage engine, MySQL stops processing the statement at the row for which the error occurred and leaves any remaining rows unprocessed.

MySQL supports an `IGNORE` keyword for `INSERT`, `UPDATE`, and so forth. If you use it, MySQL ignores primary-key or unique-key violations and continues processing with the next row. See the section for the statement that you are using ([Section 15.2.7, “INSERT Statement”](#), [Section 15.2.17, “UPDATE Statement”](#), and so forth).

You can get information about the number of rows actually inserted or updated with the `mysql_info()` C API function. You can also use the `SHOW WARNINGS` statement. See `mysql_info()`, and [Section 15.7.7.44, “SHOW WARNINGS Statement”](#).

`InnoDB` and `NDB` tables support foreign keys. See [Section 1.6.3.2, “FOREIGN KEY Constraints”](#).

1.6.3.2 FOREIGN KEY Constraints

Foreign keys let you cross-reference related data across tables, and [foreign key constraints](#) help keep this spread-out data consistent.

MySQL supports `ON UPDATE` and `ON DELETE` foreign key references in `CREATE TABLE` and `ALTER TABLE` statements. The available referential actions are `RESTRICT`, `CASCADE`, `SET NULL`, and `NO ACTION` (the default).

`SET DEFAULT` is also supported by the MySQL Server but is currently rejected as invalid by `InnoDB`. Since MySQL does not support deferred constraint checking, `NO ACTION` is treated as `RESTRICT`. For the exact syntax supported by MySQL for foreign keys, see [Section 15.1.20.5, “FOREIGN KEY Constraints”](#).

`MATCH FULL`, `MATCH PARTIAL`, and `MATCH SIMPLE` are allowed, but their use should be avoided, as they cause the MySQL Server to ignore any `ON DELETE` or `ON UPDATE` clause used in the same statement. `MATCH` options do not have any other effect in MySQL, which in effect enforces `MATCH SIMPLE` semantics full-time.

MySQL requires that foreign key columns be indexed; if you create a table with a foreign key constraint but no index on a given column, an index is created.

You can obtain information about foreign keys from the Information Schema `KEY_COLUMN_USAGE` table. An example of a query against this table is shown here:

```
mysql> SELECT TABLE_SCHEMA, TABLE_NAME, COLUMN_NAME, CONSTRAINT_NAME
> FROM INFORMATION_SCHEMA.KEY_COLUMN_USAGE
> WHERE REFERENCED_TABLE_SCHEMA IS NOT NULL;
```

TABLE_SCHEMA	TABLE_NAME	COLUMN_NAME	CONSTRAINT_NAME
fk1	myuser	myuser_id	f
fk1	product_order	customer_id	f2
fk1	product_order	product_id	f1

```
3 rows in set (0.01 sec)
```

Information about foreign keys on `InnoDB` tables can also be found in the `INNODB_FOREIGN` and `INNODB_FOREIGN_COLS` tables, in the `INFORMATION_SCHEMA` database.

`InnoDB` and `NDB` tables support foreign keys.

1.6.3.3 Enforced Constraints on Invalid Data

By default, MySQL 8.0 rejects invalid or improper data values and aborts the statement in which they occur. It is possible to alter this behavior to be more forgiving of invalid values, such that the server coerces them to valid ones for data entry, by disabling strict SQL mode (see [Section 7.1.11, “Server SQL Modes”](#)), but this is not recommended.

Older versions of MySQL employed the forgiving behavior by default; for a description of this behavior, see [Constraints on Invalid Data](#).

1.6.3.4 ENUM and SET Constraints

[ENUM](#) and [SET](#) columns provide an efficient way to define columns that can contain only a given set of values. See [Section 13.3.5, “The ENUM Type”](#), and [Section 13.3.6, “The SET Type”](#).

Unless strict mode is disabled (not recommended, but see [Section 7.1.11, “Server SQL Modes”](#)), the definition of a [ENUM](#) or [SET](#) column acts as a constraint on values entered into the column. An error occurs for values that do not satisfy these conditions:

- An [ENUM](#) value must be one of those listed in the column definition, or the internal numeric equivalent thereof. The value cannot be the error value (that is, 0 or the empty string). For a column defined as `ENUM('a', 'b', 'c')`, values such as `'`, `'d'`, or `'ax'` are invalid and are rejected.
- A [SET](#) value must be the empty string or a value consisting only of the values listed in the column definition separated by commas. For a column defined as `SET('a', 'b', 'c')`, values such as `'d'` or `'a,b,c,d'` are invalid and are rejected.

Errors for invalid values can be suppressed in strict mode if you use `INSERT IGNORE` or `UPDATE IGNORE`. In this case, a warning is generated rather than an error. For [ENUM](#), the value is inserted as the error member (0). For [SET](#), the value is inserted as given except that any invalid substrings are deleted. For example, `'a,x,b,y'` results in a value of `'a,b'`.

Chapter 2 Installing MySQL

2.10.2 Installing ActiveState Perl on Windows	186
2.10.3 Problems Using the Perl DBI/DBD Interface	186

This chapter describes how to obtain and install MySQL. A summary of the procedure follows and later sections provide the details. If you plan to upgrade an existing version of MySQL to a newer version rather than install MySQL for the first time, see [Chapter 3, *Upgrading MySQL*](#), for information about upgrade procedures and about issues that you should consider before upgrading.

If you are interested in migrating to MySQL from another database system, see [Section A.8, “MySQL 8.3 FAQ: Migration”](#), which contains answers to some common questions concerning migration issues.

Installation of MySQL generally follows the steps outlined here:

1. **Determine whether MySQL runs and is supported on your platform.**

Please note that not all platforms are equally suitable for running MySQL, and that not all platforms on which MySQL is known to run are officially supported by Oracle Corporation. For information about those platforms that are officially supported, see <https://www.mysql.com/support/supportedplatforms/database.html> on the MySQL website.

2. **Choose which track to install.**

MySQL offers a bugfix track (such as MySQL 8.0), and an innovation track (today it's MySQL 8.3) and each track addresses different use cases. Both tracks are considered production-ready and include bug fixes, while innovation releases also include new features and potential for modified behavior.

A bugfix track upgrade includes point releases, such as MySQL 8.0.*x* upgrading to 8.0.*y*, while innovation track releases typically only have minor releases, such as MySQL 8.3.0 upgrading to 9.0.0. However, an innovation track does have the occasional point release.

3. **Choose which distribution to install.**

Several versions of MySQL are available, and most are available in several distribution formats. You can choose from pre-packaged distributions containing binary (precompiled) programs or source code. When in doubt, use a binary distribution. Oracle also provides access to the MySQL source code for those who want to see recent developments and test new code. To determine which version and type of distribution you should use, see [Section 2.1.2, “Which MySQL Version and Distribution to Install”](#).

4. **Download the distribution that you want to install.**

For instructions, see [Section 2.1.3, “How to Get MySQL”](#). To verify the integrity of the distribution, use the instructions in [Section 2.1.4, “Verifying Package Integrity Using MD5 Checksums or GnuPG”](#).

5. **Install the distribution.**

To install MySQL from a binary distribution, use the instructions in [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#). Alternatively, use the [Secure Deployment Guide](#), which provides procedures for deploying a generic binary distribution of MySQL Enterprise Edition Server with features for managing the security of your MySQL installation.

To install MySQL from a source distribution or from the current development source tree, use the instructions in [Section 2.8, “Installing MySQL from Source”](#).

6. **Perform any necessary postinstallation setup.**

After installing MySQL, see [Section 2.9, “Postinstallation Setup and Testing”](#) for information about making sure the MySQL server is working properly. Also refer to the information provided

in [Section 2.9.4, “Securing the Initial MySQL Account”](#). This section describes how to secure the initial MySQL `root` user account, *which has no password* until you assign one. The section applies whether you install MySQL using a binary or source distribution.

7. If you want to run the MySQL benchmark scripts, Perl support for MySQL must be available. See [Section 2.10, “Perl Installation Notes”](#).

Instructions for installing MySQL on different platforms and environments is available on a platform by platform basis:

- **Unix, Linux**

For instructions on installing MySQL on most Linux and Unix platforms using a generic binary (for example, a `.tar.gz` package), see [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#).

For information on building MySQL entirely from the source code distributions or the source code repositories, see [Section 2.8, “Installing MySQL from Source”](#)

For specific platform help on installation, configuration, and building from source see the corresponding platform section:

- Linux, including notes on distribution specific methods, see [Section 2.5, “Installing MySQL on Linux”](#).
- IBM AIX, see [Section 2.7, “Installing MySQL on Solaris”](#).

- **Microsoft Windows**

For instructions on installing MySQL on Microsoft Windows, using either the MSI installer or Zipped binary, see [Section 2.3, “Installing MySQL on Microsoft Windows”](#).

For details and instructions on building MySQL from source code, see [Section 2.8, “Installing MySQL from Source”](#).

- **macOS**

For installation on macOS, including using both the binary package and native PKG formats, see [Section 2.4, “Installing MySQL on macOS”](#).

For information on making use of an macOS Launch Daemon to automatically start and stop MySQL, see [Section 2.4.3, “Installing and Using the MySQL Launch Daemon”](#).

For information on the MySQL Preference Pane, see [Section 2.4.4, “Installing and Using the MySQL Preference Pane”](#).

2.1 General Installation Guidance

The immediately following sections contain the information necessary to choose, download, and verify your distribution. The instructions in later sections of the chapter describe how to install the distribution that you choose. For binary distributions, see the instructions at [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#) or the corresponding section for your platform if available. To build MySQL from source, use the instructions in [Section 2.8, “Installing MySQL from Source”](#).

2.1.1 Supported Platforms

MySQL platform support evolves over time; please refer to <https://www.mysql.com/support/supportedplatforms/database.html> for the latest updates.

2.1.2 Which MySQL Version and Distribution to Install

When preparing to install MySQL, decide which version and distribution format (binary or source) to use.

First, decide whether to install from a bugfix series like MySQL 8.0, or use an innovation release like MySQL 8.3. Both tracks include bug fixes while an innovation release includes the newest features. Both bugfix and innovation releases are meant for production use.

The naming scheme in MySQL 8.3 uses release names that consist of three numbers and an optional suffix (for example, **mysql-8.3.0**). The numbers within the release name are interpreted as follows:

- The first number (**8**) is the major version number.
- The second number (**3**) is the minor version number. Taken together, the major and minor numbers constitute the release series number. The series number describes the stable feature set.
- The third number (**0**) is the version number within the release series. This is incremented for each new bugfix release; for an innovation release, it will likely always be 0. For a bugfix series such as MySQL 8.0, the most recent version within the series is the best choice.

After choosing which MySQL version to install, decide which distribution format to install for your operating system. For most use cases, a binary distribution is the right choice. Binary distributions are available in native format for many platforms, such as RPM packages for Linux or DMG packages for macOS. Distributions are also available in more generic formats such as Zip archives or compressed `tar` files. On Windows, you might use an MSI to install a binary distribution.

Under some circumstances, it may be preferable to install MySQL from a source distribution:

- You want to install MySQL at some explicit location. The standard binary distributions are ready to run at any installation location, but you might require even more flexibility to place MySQL components where you want.
- You want to configure `mysqld` with features that might not be included in the standard binary distributions. Here is a list of the most common extra options used to ensure feature availability:
 - `-DWITH_LIBWRAP=1` for TCP wrappers support.
 - `-DWITH_ZLIB={system|bundled}` for features that depend on compression
 - `-DWITH_DEBUG=1` for debugging support

For additional information, see [Section 2.8.7, “MySQL Source-Configuration Options”](#).

- You want to configure `mysqld` without some features that are included in the standard binary distributions.
- You want to read or modify the C and C++ code that makes up MySQL. For this purpose, obtain a source distribution.
- Source distributions contain more tests and examples than binary distributions.

2.1.3 How to Get MySQL

Check our downloads page at <https://dev.mysql.com/downloads/> for information about the current version of MySQL and for downloading instructions.

For RPM-based Linux platforms that use Yum as their package management system, MySQL can be installed using the [MySQL Yum Repository](#). See [Section 2.5.1, “Installing MySQL on Linux Using the MySQL Yum Repository”](#) for details.

For Debian-based Linux platforms, MySQL can be installed using the [MySQL APT Repository](#). See [Section 2.5.2, “Installing MySQL on Linux Using the MySQL APT Repository”](#) for details.

For SUSE Linux Enterprise Server (SLES) platforms, MySQL can be installed using the [MySQL SLES Repository](#). See [Section 2.5.3, “Using the MySQL SLES Repository”](#) for details.

To obtain the latest development source, see [Section 2.8.5, “Installing MySQL Using a Development Source Tree”](#).

2.1.4 Verifying Package Integrity Using MD5 Checksums or GnuPG

After downloading the MySQL package that suits your needs and before attempting to install it, make sure that it is intact and has not been tampered with. There are three means of integrity checking:

- MD5 checksums
- Cryptographic signatures using [GnuPG](#), the GNU Privacy Guard
- For RPM packages, the built-in RPM integrity verification mechanism

The following sections describe how to use these methods.

If you notice that the MD5 checksum or GPG signatures do not match, first try to download the respective package one more time, perhaps from another mirror site.

2.1.4.1 Verifying the MD5 Checksum

After you have downloaded a MySQL package, you should make sure that its MD5 checksum matches the one provided on the MySQL download pages. Each package has an individual checksum that you can verify against the package that you downloaded. The correct MD5 checksum is listed on the downloads page for each MySQL product; you should compare it against the MD5 checksum of the file (product) that you download.

Each operating system and setup offers its own version of tools for checking the MD5 checksum. Typically the command is named `md5sum`, or it may be named `md5`, and some operating systems do not ship it at all. On Linux, it is part of the **GNU Text Utilities** package, which is available for a wide range of platforms. You can also download the source code from <http://www.gnu.org/software/textutils/>. If you have OpenSSL installed, you can use the command `openssl md5 package_name` instead. A Windows implementation of the `md5` command line utility is available from <http://www.fourmilab.ch/md5/>. `winMd5Sum` is a graphical MD5 checking tool that can be obtained from <http://www.nullriver.com/index/products/winmd5sum>. Our Microsoft Windows examples assume the name `md5.exe`.

Linux and Microsoft Windows examples:

```
$> md5sum mysql-standard-8.3.0-linux-i686.tar.gz
aaab65abbec64d5e907dcd41b8699945  mysql-standard-8.3.0-linux-i686.tar.gz

$> md5.exe mysql-installer-community-8.3.0.msi
aaab65abbec64d5e907dcd41b8699945  mysql-installer-community-8.3.0.msi
```

You should verify that the resulting checksum (the string of hexadecimal digits) matches the one displayed on the download page immediately below the respective package.

Note

Make sure to verify the checksum of the *archive file* (for example, the `.zip`, `.tar.gz`, or `.msi` file) and not of the files that are contained inside of the archive. In other words, verify the file before extracting its contents.

2.1.4.2 Signature Checking Using GnuPG

Another method of verifying the integrity and authenticity of a package is to use cryptographic signatures. This is more reliable than using [MD5 checksums](#), but requires more work.

We sign MySQL downloadable packages with [GnuPG](#) (GNU Privacy Guard). [GnuPG](#) is an Open Source alternative to the well-known Pretty Good Privacy ([PGP](#)) by Phil Zimmermann. Most Linux distributions

ship with [GnuPG](#) installed by default. Otherwise, see <http://www.gnupg.org/> for more information about [GnuPG](#) and how to obtain and install it.

To verify the signature for a specific package, you first need to obtain a copy of our public GPG build key, which you can download from <http://pgp.mit.edu/>. The key that you want to obtain is named mysql-build@oss.oracle.com. The keyID for MySQL 8.0.36 packages and higher, and MySQL 8.3.0 and higher, is [A8D3785C](#). After obtaining this key, you should compare it with the key following value before using it verify MySQL packages. Alternatively, you can copy and paste the key directly from the text below.

Note

The public GPG build key for earlier MySQL release packages (keyID [5072E1F5](#) or [3A79BD29](#)), see [Section 2.1.4.5, “GPG Public Build Key for Archived Packages”](#).

=h5nH
-----END PGP PUBLIC KEY BLOCK-----
```

To import the build key into your personal public GPG keyring, use `gpg --import`. For example, if you have saved the key in a file named `mysql_pubkey.asc`, the import command looks like this:

```
$> gpg --import mysql_pubkey.asc
gpg: key B7B3B788A8D3785C: public key "MySQL Release Engineering
<mysql-build@oss.oracle.com>" imported
gpg: Total number processed: 1
gpg:             imported: 1
```

You can also download the key from the public keyserver using the public key id, [A8D3785C](#):

```
$> gpg --recv-keys A8D3785C
gpg: requesting key A8D3785C from hkp server keys.gnupg.net
gpg: key A8D3785C: "MySQL Release Engineering <mysql-build@oss.oracle.com>"
1 new user ID
gpg: key A8D3785C: "MySQL Release Engineering <mysql-build@oss.oracle.com>"
53 new signatures
gpg: no ultimately trusted keys found
gpg: Total number processed: 1
gpg:             new user IDs: 1
gpg:             new signatures: 53
```

If you want to import the key into your RPM configuration to validate RPM install packages, you should be able to import the key directly:

```
$> rpm --import mysql_pubkey.asc
```

If you experience problems or require RPM specific information, see [Section 2.1.4.4, “Signature Checking Using RPM”](#).

After you have downloaded and imported the public build key, download your desired MySQL package and the corresponding signature, which also is available from the download page. The signature file has the same name as the distribution file with an `.asc` extension, as shown by the examples in the following table.

Table 2.1 MySQL Package and Signature Files for Source files

File Type	File Name
Distribution file	<code>mysql-standard-8.3.0-linux-i686.tar.gz</code>
Signature file	<code>mysql-standard-8.3.0-linux-i686.tar.gz.asc</code>

Make sure that both files are stored in the same directory and then run the following command to verify the signature for the distribution file:

```
$> gpg --verify package_name.asc
```

If the downloaded package is valid, you should see a `Good signature` message similar to this:

```
$> gpg --verify mysql-standard-8.3.0-linux-i686.tar.gz.asc
gpg: Signature made Fri 13 Oct 2023 01:53:29 AM PDT
gpg:             using RSA key 859BE8D7C586F538430B19C2467B942D3A79BD29
gpg: Good signature from "MySQL Release Engineering <mysql-build@oss.oracle.com>"
```

The `Good signature` message indicates that the file signature is valid, when compared to the signature listed on our site. But you might also see warnings, like so:

```
$> gpg --verify mysql-standard-8.3.0-linux-i686.tar.gz.asc
gpg: Signature made Fri 13 Oct 2023 01:53:29 AM PDT
gpg:             using RSA key 859BE8D7C586F538430B19C2467B942D3A79BD29
gpg: Good signature from "MySQL Release Engineering <mysql-build@oss.oracle.com>"
gpg: WARNING: This key is not certified with a trusted signature!
gpg:             There is no indication that the signature belongs to the owner.
Primary key fingerprint: 859B E8D7 C586 F538 430B 19C2 467B 942D 3A79 BD29
```

That is normal, as they depend on your setup and configuration. Here are explanations for these warnings:

- *gpg: no ultimately trusted keys found*: This means that the specific key is not "ultimately trusted" by you or your web of trust, which is okay for the purposes of verifying file signatures.
- *WARNING: This key is not certified with a trusted signature! There is no indication that the signature belongs to the owner.*: This refers to your level of trust in your belief that you possess our real public key. This is a personal decision. Ideally, a MySQL developer would hand you the key in person, but more commonly, you downloaded it. Was the download tampered with? Probably not, but this decision is up to you. Setting up a web of trust is one method for trusting them.

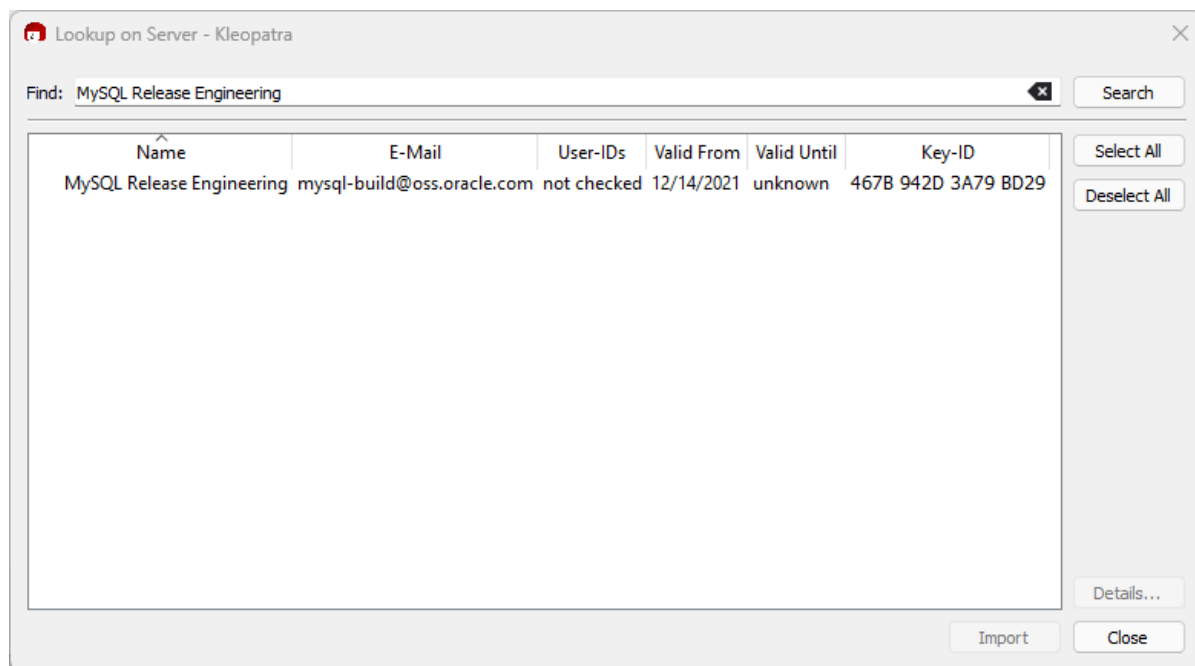

See the GPG documentation for more information on how to work with public keys.

2.1.4.3 Signature Checking Using Gpg4win for Windows

The [Section 2.1.4.2, "Signature Checking Using GnuPG"](#) section describes how to verify MySQL downloads using GPG. That guide also applies to Microsoft Windows, but another option is to use a GUI tool like [Gpg4win](#). You may use a different tool but our examples are based on Gpg4win, and utilize its bundled [Kleopatra](#) GUI.

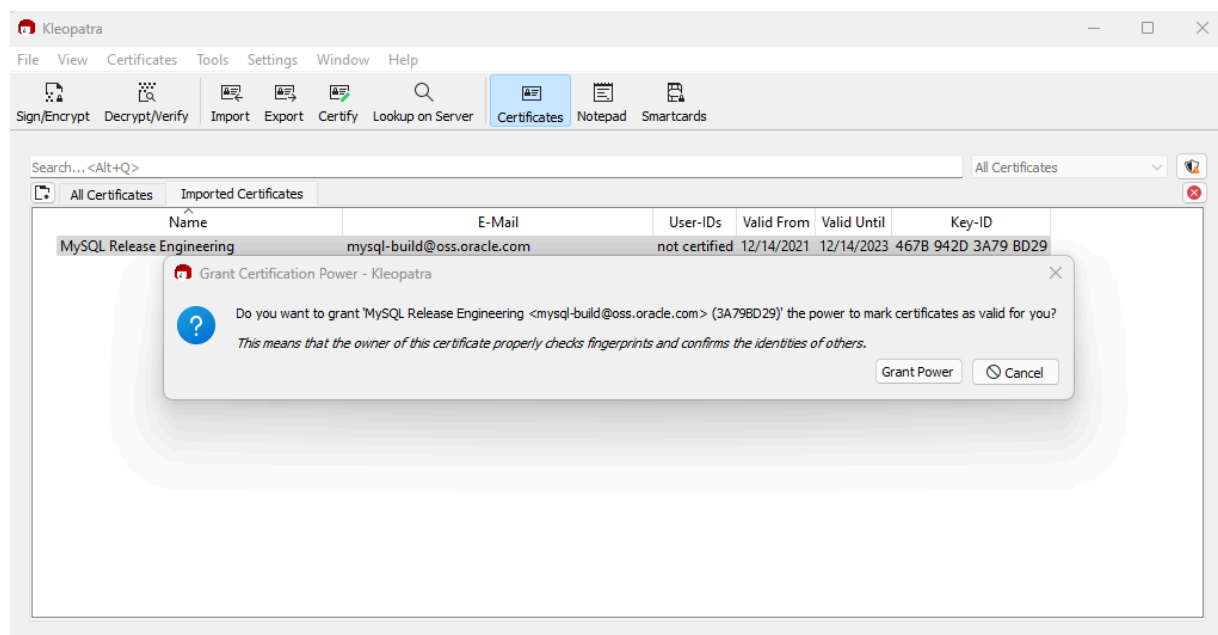

Download and install Gpg4win, load Kleopatra, and add the MySQL Release Engineering certificate. Do this by clicking **File, Lookup on Server**. Type "Mysql Release Engineering" into the search box and press **Search**.

Figure 2.1 Kleopatra: Lookup on Server Wizard: Finding a Certificate

Select the "MySQL Release Engineering" certificate. The Key-ID must reference "3A79 BD29", or choose **Details...** to confirm the certificate is valid. Now, import it by clicking **Import**. When the import dialog is displayed, choose **Okay**, and this certificate should now be listed under the **Imported Certificates** tab.

Next, grant trust to the certificate. Select our certificate, then from the main menu select **Certificates, Change Certification Power**, and click **Grant Power**.

Figure 2.2 Kleopatra: Grant Certification Power for MySQL Release Engineering

Next, verify the downloaded MySQL package file. This requires files for both the packaged file, and the signature. The signature file must have the same name as the packaged file but with an appended `.asc` extension, as shown by the example in the following table. The signature is linked to on the downloads page for each MySQL product. You must create the `.asc` file with this signature.

Table 2.2 MySQL Package and Signature Files for MySQL Server MSI for Microsoft Windows

File Type	File Name
Distribution file	<code>mysql-8.3.0-winx64.msi</code>
Signature file	<code>mysql-8.3.0-winx64.msi.asc</code>

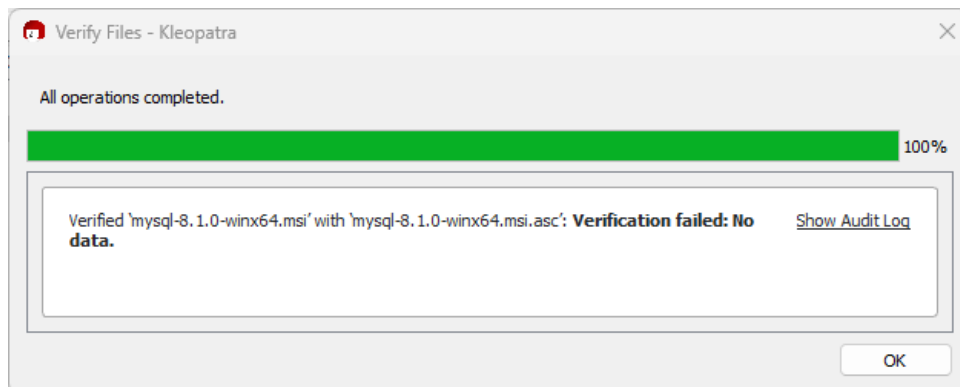

Make sure that both files are stored in the same directory and then run the following command to verify the signature for the distribution file. Load the dialog from **File, Decrypt/Verify Files...**, and then choose the `.asc` file.

The two most common results look like the following figures; and although the "The data could not be verified." warning looks problematic, the file check passed with success. For additional information on what this warning means, click **Show Audit Log** and compare it to [Section 2.1.4.2, "Signature Checking Using GnuPG"](#). You may now execute the MSI file.

Figure 2.3 Kleopatra: the Decrypt and Verify Results Dialog: Success

Seeing an error such as `Verification failed: No Data.` means the file is invalid. Do not execute the MSI file if you see this error.

Figure 2.4 Kleopatra: the Decrypt and Verify Results Dialog: Bad

2.1.4.4 Signature Checking Using RPM

For RPM packages, there is no separate signature. RPM packages have a built-in GPG signature and MD5 checksum. You can verify a package by running the following command:

```
$> rpm --checksig package_name.rpm
```

Example:

```
$> rpm --checksig mysql-community-server-8.3.0-1.el8.x86_64.rpm
mysql-community-server-8.3.0-1.el8.x86_64.rpm: digests signatures OK
```

Note

If you are using RPM 4.1 and it complains about `(GPG) NOT OK (MISSING KEYS: GPG#a8d3785c)`, even though you have imported the MySQL public build key into your own GPG keyring, you need to import the key into the RPM keyring first. RPM 4.1 no longer uses your personal GPG keyring (or GPG itself). Rather, RPM maintains a separate keyring because it is a system-wide application and a user's GPG public keyring is a user-specific file. To import the MySQL public key into the RPM keyring, first obtain the key, then use `rpm --import` to import the key. For example:

```
$> gpg --export -a a8d3785c > a8d3785c.asc
$> rpm --import a8d3785c.asc
```

Alternatively, `rpm` also supports loading the key directly from a URL:

```
$> rpm --import https://repo.mysql.com/RPM-GPG-KEY-mysql-2023
```

You can also obtain the MySQL public key from this manual page: [Section 2.1.4.2, "Signature Checking Using GnuPG"](#).

2.1.4.5 GPG Public Build Key for Archived Packages

The following GPG public build key (keyID `3A79BD29`) can be used to verify the authenticity and integrity of MySQL packages versions 8.0.28 through 8.0.35, 8.1.0, and 8.2.0. For signature checking instructions, see [Section 2.1.4.2, "Signature Checking Using GnuPG"](#). It expired on December 14, 2023.

GPG Public Build Key for MySQL 8.0.28 through 8.0.35, and 8.1.0/8.2.0 Packages

2.1.5 Installation Layouts

The installation layout differs for different installation types (for example, native packages, binary tarballs, and source tarballs), which can lead to confusion when managing different systems or using different installation sources. The individual layouts are given in the corresponding installation type or platform chapter, as described following. Note that the layout of installations from vendors other than Oracle may differ from these layouts.

- [MySQL Installation Layout on Microsoft Windows](#)
- [Section 2.8.3, “MySQL Layout for Source Installation”](#)
- [Table 2.3, “MySQL Installation Layout for Generic Unix/Linux Binary Package”](#)
- [Table 2.11, “MySQL Installation Layout for Linux RPM Packages from the MySQL Developer Zone”](#)
- [Table 2.6, “MySQL Installation Layout on macOS”](#)

2.1.6 Compiler-Specific Build Characteristics

In some cases, the compiler used to build MySQL affects the features available for use. The notes in this section apply for binary distributions provided by Oracle Corporation or that you compile yourself from source.

icc (Intel C++ Compiler) Builds

A server built with `icc` has these characteristics:

- SSL support is not included.

2.2 Installing MySQL on Unix/Linux Using Generic Binaries

Oracle provides a set of binary distributions of MySQL. These include generic binary distributions in the form of compressed `tar` files (files with a `.tar.xz` extension) for a number of platforms, and binaries in platform-specific package formats for selected platforms.

This section covers the installation of MySQL from a compressed `tar` file binary distribution on Unix/Linux platforms. For Linux-generic binary distribution installation instructions with a focus on MySQL security features, refer to the [Secure Deployment Guide](#). For other platform-specific binary package formats, see the other platform-specific sections in this manual. For example, for Windows distributions, see [Section 2.3, “Installing MySQL on Microsoft Windows”](#). See [Section 2.1.3, “How to Get MySQL”](#) on how to obtain MySQL in different distribution formats.

MySQL compressed `tar` file binary distributions have names of the form `mysql-VERSION-OS.tar.xz`, where `VERSION` is a number (for example, `8.3.0`), and `OS` indicates the type of operating system for which the distribution is intended (for example, `pc-linux-i686` or `winx64`).

There is also a “minimal install” version of the MySQL compressed `tar` file for the Linux generic binary distribution, which has a name of the form `mysql-VERSION-OS-GLIBCVER-ARCH-minimal.tar.xz`. The minimal install distribution excludes debug binaries and is stripped of debug symbols, making it significantly smaller than the regular binary distribution. If you choose to install the minimal install distribution, remember to adjust for the difference in file name format in the instructions that follow.

Warnings

- If you have previously installed MySQL using your operating system native package management system, such as Yum or APT, you may experience problems installing using a native binary. Make sure your previous MySQL installation has been removed entirely (using your package management system), and that any additional files, such as old versions of your data files, have also been removed. You should also check for configuration files such as `/etc/my.cnf` or the `/etc/mysql` directory and delete them.

For information about replacing third-party packages with official MySQL packages, see the related [APT guide](#) or [Yum guide](#).

- MySQL has a dependency on the `libaio` library. Data directory initialization and subsequent server startup steps fail if this library is not installed locally. If necessary, install it using the appropriate package manager. For example, on Yum-based systems:

```
$> yum search libaio # search for info
$> yum install libaio # install library
```

Or, on APT-based systems:

```
$> apt-cache search libaio # search for info
$> apt-get install libaio1 # install library
```

- **Oracle Linux 8 / Red Hat 8 (EL8):** These platforms by default do not install the file `/lib64/libtinfo.so.5`, which is required by the MySQL client `bin/mysql` for packages `mysql-VERSION-el7-x86_64.tar.gz` and `mysql-VERSION-linux-glibc2.12-x86_64.tar.xz`. To work around this issue, install the `ncurses-compat-libs` package:

```
$> yum install ncurses-compat-libs
```

To install a compressed `tar` file binary distribution, unpack it at the installation location you choose (typically `/usr/local/mysql`). This creates the directories shown in the following table.

Table 2.3 MySQL Installation Layout for Generic Unix/Linux Binary Package

Directory	Contents of Directory
<code>bin</code>	<code>mysqld</code> server, client and utility programs
<code>docs</code>	MySQL manual in Info format
<code>man</code>	Unix manual pages
<code>include</code>	Include (header) files
<code>lib</code>	Libraries
<code>share</code>	Error messages, dictionary, and SQL for database installation
<code>support-files</code>	Miscellaneous support files

Debug versions of the `mysqld` binary are available as `mysqld-debug`. To compile your own debug version of MySQL from a source distribution, use the appropriate configuration options to enable debugging support. See [Section 2.8, “Installing MySQL from Source”](#).

To install and use a MySQL binary distribution, the command sequence looks like this:

```
$> groupadd mysql
$> useradd -r -g mysql -s /bin/false mysql
$> cd /usr/local
$> tar xvf /path/to/mysql-VERSION-OS.tar.xz
$> ln -s full-path-to-mysql-VERSION-OS mysql
$> cd mysql
$> mkdir mysql-files
$> chown mysql:mysql mysql-files
$> chmod 750 mysql-files
$> bin/mysqld --initialize --user=mysql
$> bin/mysql_ssl_rsa_setup
$> bin/mysqld_safe --user=mysql &
# Next command is optional
$> cp support-files/mysql.server /etc/init.d/mysql.server
```

Note

This procedure assumes that you have `root` (administrator) access to your system. Alternatively, you can prefix each command using the `sudo` (Linux) or `pfexec` (Solaris) command.

The `mysql-files` directory provides a convenient location to use as the value for the `secure_file_priv` system variable, which limits import and export operations to a specific directory. See [Section 7.1.8, “Server System Variables”](#).

A more detailed version of the preceding description for installing a binary distribution follows.

Create a mysql User and Group

If your system does not already have a user and group to use for running `mysqld`, you may need to create them. The following commands add the `mysql` group and the `mysql` user. You might want to call the user and group something else instead of `mysql`. If so, substitute the appropriate name in the following instructions. The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix/Linux, or they may have different names such as `adduser` and `addgroup`.

```
$> groupadd mysql
$> useradd -r -g mysql -s /bin/false mysql
```

Note

Because the user is required only for ownership purposes, not login purposes, the `useradd` command uses the `-r` and `-s /bin/false` options to create a user that does not have login permissions to your server host. Omit these options if your `useradd` does not support them.

Obtain and Unpack the Distribution

Pick the directory under which you want to unpack the distribution and change location into it. The example here unpacks the distribution under `/usr/local`. The instructions, therefore, assume that you have permission to create files and directories in `/usr/local`. If that directory is protected, you must perform the installation as `root`.

```
$> cd /usr/local
```

Obtain a distribution file using the instructions in [Section 2.1.3, “How to Get MySQL”](#). For a given release, binary distributions for all platforms are built from the same MySQL source distribution.

Unpack the distribution, which creates the installation directory. `tar` can uncompress and unpack the distribution if it has `z` option support:

```
$> tar xvf /path/to/mysql-VERSION-OS.tar.xz
```

The `tar` command creates a directory named `mysql-VERSION-OS`.

To install MySQL from a compressed `tar` file binary distribution, your system must have GNU `xz Utils` to uncompress the distribution and a reasonable `tar` to unpack it.

GNU `tar` is known to work. The standard `tar` provided with some operating systems is not able to unpack the long file names in the MySQL distribution. You should download and install GNU `tar`, or if available, use a preinstalled version of GNU `tar`. Usually this is available as `gnutar`, `gtar`, or as `tar` within a GNU or Free Software directory, such as `/usr/sfw/bin` or `/usr/local/bin`. GNU `tar` is available from <http://www.gnu.org/software/tar/>.

If your `tar` does not support the `xz` format then use the `xz` command to unpack the distribution and `tar` to unpack it. Replace the preceding `tar` command with the following alternative command to uncompress and extract the distribution:

```
$> xz -dc /path/to/mysql-VERSION-OS.tar.xz | tar x
```

Next, create a symbolic link to the installation directory created by `tar`:

```
$> ln -s full-path-to-mysql-VERSION-OS mysql
```

The `ln` command makes a symbolic link to the installation directory. This enables you to refer more easily to it as `/usr/local/mysql`. To avoid having to type the path name of client programs always when you are working with MySQL, you can add the `/usr/local/mysql/bin` directory to your `PATH` variable:

```
$> export PATH=$PATH:/usr/local/mysql/bin
```

Perform Postinstallation Setup

The remainder of the installation process involves setting distribution ownership and access permissions, initializing the data directory, starting the MySQL server, and setting up the configuration file. For instructions, see [Section 2.9, “Postinstallation Setup and Testing”](#).

2.3 Installing MySQL on Microsoft Windows

MySQL is available for Microsoft Windows 64-bit operating systems only. For supported Windows platform information, see <https://www.mysql.com/support/supportedplatforms/database.html>.

There are different methods to install MySQL on Microsoft Windows: the MSI, the standard binary distribution (packaged as a compressed file) containing all of the necessary files that you unpack, and source files to compile MySQL yourself. For related information, see [Section 2.3.1, “Choosing an Installation Package”](#).

Note

MySQL 8.3 Server requires the Microsoft Visual C++ 2019 Redistributable Package to run on Windows platforms. Users should make sure the package has been installed on the system before installing the server. The package is available at the [Microsoft Download Center](#). Additionally, MySQL debug binaries require Visual Studio 2019.

Recommended MSI Installation Method

The simplest and recommended method is to download the MSI and let it install MySQL Server, and then use the MySQL Configurator it installs to configure MySQL:

1. Download the MSI from <https://dev.mysql.com/downloads/> and execute it. This installs the MySQL server, an associated MySQL Configurator application, and it adds related MySQL items to the Microsoft Windows Start menu under the `MySQL` group.
2. Upon completion, the installation wizard prompts to execute [MySQL Configurator](#). Execute it now (recommended) or later, or instead choose to manually configure MySQL.

**Note**

The MySQL server won't start until it's configured; it's recommended to execute the bundled MySQL Configurator immediately after the MSI.

MySQL is now installed. If you used MySQL Configurator to configure MySQL as a Windows service, then Windows automatically starts the MySQL server every time you restart the system. Also, the MSI installs the MySQL Configurator application on the local host, which you can use later to reconfigure MySQL server. It and other MySQL start up menu items were added by the MSI.

MySQL Installation Layout on Microsoft Windows

For MySQL 8.3 on Windows, the default installation directory is `C:\Program Files\MySQL\MySQL Server 8.3` for installations using the MSI, although the MSI **Custom** setup type allows using a different location. If you use the ZIP archive method to install MySQL, install it there are elsewhere, such as `C:\mysql`. Regardless, the layout of the subdirectories remains the same.

All of the files are located within this parent directory using the structure shown in the following table.

Table 2.4 Default MySQL Installation Layout for Microsoft Windows

Directory	Contents of Directory	Notes
<code>bin</code>	<code>mysqld</code> server, client, and utility programs	
<code>%PROGRAMDATA%\MySQL\MySQL Server 8.3\</code>	Log files, databases	The Windows system variable <code>%PROGRAMDATA%</code> defaults to <code>C:\ProgramData</code> .
<code>docs</code>	Release documentation	With the MSI, use the Custom type to include this optional component.
<code>include</code>	Include (header) files	
<code>lib</code>	Libraries	
<code>share</code>	Miscellaneous support files, including error messages, character set files, sample configuration files, SQL for database installation	

Additional Installation Information

By default, MySQL Configurator sets up the MySQL server as a Windows service. By using a service, you can monitor and control the operation of the server through the standard Windows service management tools. For related information about manually setting up the Windows service, see [Section 2.3.3.8, “Starting MySQL as a Windows Service”](#).

To accommodate the `RESTART` statement, the MySQL server forks when run as a service or standalone, to enable a monitor process to supervise the server process. In this case, there are two `mysqld` processes. If `RESTART` capability is not required, the server can be started with the `--no-monitor` option. See [Section 15.7.8.8, “RESTART Statement”](#).

Generally, you should install MySQL on Windows using an account that has administrator rights. Otherwise, you may encounter problems with certain operations such as editing the `PATH` environment variable or accessing the [Service Control Manager](#). When installed, MySQL does not need to be executed using a user with Administrator privileges.

For a list of limitations on the use of MySQL on the Windows platform, see [Section 2.3.6, “Windows Platform Restrictions”](#).

In addition to the MySQL Server package, you may need or want additional components to use MySQL with your application or development environment. These include, but are not limited to:

- To connect to the MySQL server using ODBC, you must have a Connector/ODBC driver. For more information, including installation and configuration instructions, see [MySQL Connector/ODBC Developer Guide](#).
- To use MySQL server with .NET applications, you must have the Connector/.NET driver. For more information, including installation and configuration instructions, see [MySQL Connector/.NET Developer Guide](#).

MySQL distributions for Windows can be downloaded from <https://dev.mysql.com/downloads/>. See [Section 2.1.3, “How to Get MySQL”](#).

MySQL for Windows is available in several distribution formats, detailed here. Generally speaking, you should use the MSI to install MySQL server and MySQL Configurator to configure it. The MSI is simpler to use than the compressed file, and you need no additional tools to get MySQL up and running. MySQL Configurator automatically configures MySQL Server, creates an options file, starts the server, enables you to create default user accounts, and more. For more information on choosing a package, see [Section 2.3.1, “Choosing an Installation Package”](#).

**Note**

Before MySQL 8.1, an application named MySQL Installer included functionality now present in MySQL Configurator. The MySQL Installer both installed and configured MySQL products but it does not exist as of MySQL 8.1.

MySQL on Windows Considerations

- **Large Table Support**

If you need tables with a size larger than 4GB, install MySQL on an NTFS or newer file system. Do not forget to use `MAX_ROWS` and `AVG_ROW_LENGTH` when you create tables. See [Section 15.1.20, “CREATE TABLE Statement”](#).

- **MySQL and Virus Checking Software**

Virus-scanning software such as Norton/Symantec Anti-Virus on directories containing MySQL data and temporary tables can cause issues, both in terms of the performance of MySQL and the virus-scanning software misidentifying the contents of the files as containing spam. This is due to the fingerprinting mechanism used by the virus-scanning software, and the way in which MySQL rapidly updates different files, which may be identified as a potential security risk.

After installing MySQL Server, it is recommended that you disable virus scanning on the main directory (`datadir`) used to store your MySQL table data. There is usually a system built into the virus-scanning software to enable specific directories to be ignored.

In addition, by default, MySQL creates temporary files in the standard Windows temporary directory. To prevent the temporary files also being scanned, configure a separate temporary directory for MySQL temporary files and add this directory to the virus scanning exclusion list. To do this, add a configuration option for the `tmpdir` parameter to your `my.ini` configuration file. For more information, see [Section 2.3.3.2, “Creating an Option File”](#).

2.3.1 Choosing an Installation Package

For MySQL 8.3, there are multiple installation package formats to choose from when installing MySQL on Windows. The package formats described in this section are:

- [MySQL Installation MSI](#)
- [MySQL noinstall ZIP Archives](#)

- [MySQL Docker Images](#)

MySQL Installation MSI

This package has a file name similar to `mysql-community-8.3.0.msi` or `mysql-commercial-8.3.0.msi`, and installs MySQL server along with MySQL Configurator. The MSI includes a MySQL Configurator application that is recommended for most users to set up, configure, and reconfigure the MySQL server.

The MSI and MySQL Configurator operate on all MySQL supported versions of Windows (see <https://www.mysql.com/support/supportedplatforms/database.html>). For instructions on how to configure MySQL using MySQL Configurator, see [Section 2.3.2, “Configuration: Using MySQL Configurator”](#).

MySQL noinstall ZIP Archives

These packages contain the files found in the complete MySQL Server installation package, with the exception of the GUI. This format does not include an automated installer, but does include MySQL Configurator to configure the MySQL server.

The `noinstall` ZIP archives are split into two separate compressed files. The main package is named `mysql-VERSION-winx64.zip`. This contains the components needed to use MySQL on your system. The optional MySQL test suite, MySQL benchmark suite, and debugging binaries/information components (including PDB files) are in a separate compressed file named `mysql-VERSION-winx64-debug-test.zip`.

Program Database (PDB) files (with file name extension `pdb`) provide information for debugging your MySQL installation in the event of a problem. These files are included in ZIP Archive distributions (but not MSI distributions) of MySQL.

To install MySQL by extracting the Zip archive rather than use the MSI, consider the following:

1. If you are upgrading from a previous version please refer to [Section 3.11, “Upgrading MySQL on Windows”](#), before beginning the upgrade process.
2. Make sure that you are logged in as a user with administrator privileges.
3. Choose an installation location. Traditionally, the MySQL server is installed in `C:\mysql`. If you do not install MySQL at `C:\mysql`, you must specify the path to the install directory during startup or in an option file. See [Section 2.3.3.2, “Creating an Option File”](#).

Note

The MSI installs MySQL under `C:\Program Files\MySQL\MySQL Server 8.3\`.

4. Extract the install archive to the chosen installation location using your preferred file-compression tool. Some tools may extract the archive to a folder within your chosen installation location. If this occurs, you can move the contents of the subfolder into the chosen installation location.
5. Configure the MySQL server using either MySQL Configurator (recommended) or [Section 2.3.3, “Configuration: Manually”](#).

MySQL Docker Images

For information on using the MySQL Docker images provided by Oracle on Windows platform, see [Section 2.5.6.3, “Deploying MySQL on Windows and Other Non-Linux Platforms with Docker”](#).

Warning

The MySQL Docker images provided by Oracle are built specifically for Linux platforms. Other platforms are not supported, and users running the MySQL Docker images from Oracle on them are doing so at their own risk.

2.3.2 Configuration: Using MySQL Configurator

MySQL Configurator is a standalone application designed to ease the complexity of configuring a MySQL server to run MySQL on Microsoft Windows. It is bundled with the MySQL server, in both the MSI and standalone Zip archive.

Methods to Start MySQL Configurator

MySQL Configurator can both configure and reconfigure MySQL server; and the methods to start MySQL Configurator are:

- The MySQL server MSI prompts to execute MySQL Configurator immediately after it installs the MySQL server.
- From the Start Menu: the MSI creates a MySQL Configurator start menu item.
- From the command line: the `mysql-configurator.exe` executable is located in the same directory as `mysqld.exe` and other MySQL binaries installed with the MySQL server.

Typically this location is in `C:\Program Files\MySQL\MySQL Server X.Y\bin` if installed via the MSI, or a custom directory for the Zip archive.

2.3.2.1 MySQL Server Configuration with MySQL Configurator

MySQL Configurator performs the initial configuration, a reconfiguration, and also functions as part of the uninstallation process.

Note

Full permissions are granted to the user executing MySQL Configurator to all generated files, such as `my.ini`. This does not apply to files and directories for specific products, such as the MySQL server data directory in `%ProgramData%` that is owned by `SYSTEM`.

MySQL Configurator performs the configuration of the MySQL server. For example:

- It creates the configuration file (`my.ini`) that is used to configure the MySQL server. The values written to this file are influenced by choices you make during the installation process. Some definitions are host dependent.
- By default, a Windows service for the MySQL server is added.
- Provides default installation and data paths for MySQL server.
- It can optionally create MySQL server user accounts with configurable permissions based on general roles, such as DB Administrator, DB Designer, and Backup Admin.
- Checking **Show Advanced Options** enables additional **Logging Options** to be set. This includes defining custom file paths for the error log, general log, slow query log (including the configuration of seconds it requires to execute a query), and the binary log.

The sections that follow describe the server configuration options that apply to MySQL server on Windows. The server version you installed will determine which steps and options you can configure. Configuring MySQL server may include some or all of the steps.

MySQL Server Installations

MySQL Configurator adds an upgrade option if it finds an existing MySQL Server installation is discovered. It offers two options:

Note

This upgrade functionality was added in MySQL 8.3.0.

In-Place Upgrade of an Existing MySQL Server Installation

This replaces the existing MySQL server installation as part of the upgrade process which may also upgrade the data schema. Upon success, the existing MySQL server installation is removed from the system.

Note

The existing MySQL server instance must be running for the in-place upgrade option to function.

While MySQL Configurator may attempt (and succeed) to perform an in-place upgrade for other scenarios, the following table lists the scenarios officially supported by the configurator:

Table 2.5 Supported Upgrade Paths

A supported upgrade scenario	Description
8.0.35+ to 8.1	From 8.0.35 or higher to the first MySQL 8 Innovation release.
8.0.35+ to 8.4	From 8.0.35 or higher to the MySQL next LTS release.
8.X to 8.Y where $Y = X + 1$	From an Innovation release to the next consecutive Innovation release.
8.3 to 8.4	From the last MySQL 8 Innovation release to the next MySQL 8 LTS release.
8.4.X to 8.4.Y where $Y > X$	From within the same LTS release.
8.4.X to 9.0.0	From an LTS release to the first consecutive Innovation release.
8.4 to 9.7	From an LTS release to the next consecutive LTS release.

This dialogue prompts for the protocol (default: TCP/IP), port (default: 3306), and root password for the existing installation. Execute connect and then review and confirm the MySQL instance's information (such as version, paths, and configuration file) before proceeding with the upgrade.

This upgrade may replace the file paths. For example, "MySQL Server 8.2\Data\" changes to "MySQL Server 8.3\Data\" when upgrading 8.2 to 8.3.

This upgrade functionality also provides these additional options: "Backup Data" allows running `mysqldump` before performing the upgrade, and "Server File Permissions" to optionally customize file permissions.

Add a Separate MySQL Server Installation

Configure a standard side-by-side installation with the new MySQL server installation. This means having multiple MySQL server installations installed and running on the system.

Type and Networking

- Server Configuration Type

Choose the MySQL server configuration type that describes your setup. This setting defines the amount of system resources (memory) to assign to your MySQL server instance.

- **Development:** A computer that hosts many other applications, and typically this is your personal workstation. This setting configures MySQL to use the least amount of memory.
- **Server:** Several other applications are expected to run on this computer, such as a web server. The Server setting configures MySQL to use a medium amount of memory.

- **Dedicated:** A computer that is dedicated to running the MySQL server. Because no other major applications run on this server, this setting configures MySQL to use the majority of available memory.
- **Manual:** Prevents MySQL Configurator from attempting to optimize the server installation, and instead, sets the default values to the server variables included in the `my.ini` configuration file. With the **Manual** type selected, MySQL Configurator uses the default value of 16M for the `tmp_table_size` variable assignment.
- **Connectivity**

Connectivity options control how the connection to MySQL is made. Options include:

- **TCP/IP:** This option is selected by default. You may disable TCP/IP Networking to permit local host connections only. With the TCP/IP connection option selected, you can modify the following items:
 - **Port** for classic MySQL protocol connections. The default value is `3306`.
 - **X Protocol Port** defaults to `33060`
 - **Open Windows Firewall port for network access**, which is selected by default for TCP/IP connections.

If a port number is in use already, you will see the error icon () next to the default value and **Next** is disabled until you provide a new port number.

- **Named Pipe:** Enable and define the pipe name, similar to setting the `named_pipe` system variable. The default name is `MySQL`.

When you select **Named Pipe** connectivity, and then proceed to the next step, you are prompted to set the level of access control granted to client software on named-pipe connections. Some clients require only minimum access control for communication, while other clients require full access to the named pipe.

You can set the level of access control based on the Windows user (or users) running the client as follows:

- **Minimum access to all users (RECOMMENDED).** This level is enabled by default because it is the most secure.
- **Full access to members of a local group.** If the minimum-access option is too restrictive for the client software, use this option to reduce the number of users who have full access on the named pipe. The group must be established on Windows before you can select it from the list. Membership in this group should be limited and managed. Windows requires a newly added member to first log out and then log in again to join a local group.
- **Full access to all users (NOT RECOMMENDED).** This option is less secure and should be set only when other safeguards are implemented.
- **Shared Memory:** Enable and define the memory name, similar to setting the `shared_memory` system variable. The default name is `MySQL`.
- **Advanced Configuration**

Check **Show Advanced and Logging Options** to set custom logging and advanced options in later steps. The Logging Options step enables you to define custom file paths for the error log, general log, slow query log (including the configuration of seconds it requires to execute a query), and the

binary log. The Advanced Options step enables you to set the unique server ID required when binary logging is enabled in a replication topology.

- MySQL Enterprise Firewall (Enterprise Edition only)

The **Enable MySQL Enterprise Firewall** check box is deselected by default. Select this option to enable a security list that offers protection against certain types of attacks. Additional post-installation configuration is required (see [Section 8.4.7, “MySQL Enterprise Firewall”](#)).

Accounts and Roles

- Root Account Password

Assigning a root password is required and you will be asked for it when reconfiguring with MySQL Configurator in the future. Password strength is evaluated when you repeat the password in the box provided. For descriptive information regarding password requirements or status, move your mouse

pointer over the information icon () when it appears.

- MySQL User Accounts (Optional)

Click **Add User** or **Edit User** to create or modify MySQL user accounts with predefined roles. Next, enter the required account credentials:

- **User Name:** MySQL user names can be up to 32 characters long.
- **Host:** Select `localhost` for local connections only or `<All Hosts (%)>` when remote connections to the server are required.
- **Role:** Each predefined role, such as `DB Admin`, is configured with its own set of privileges. For example, the `DB Admin` role has more privileges than the `DB Designer` role. The **Role** drop-down list contains a description of each role.
- **Password:** Password strength assessment is performed while you type the password. Passwords must be confirmed. MySQL permits a blank or empty password (considered to be insecure).

MySQL Configurator Commercial Release Only: MySQL Enterprise Edition for Windows, a commercial product, also supports an authentication method that performs external authentication on Windows. Accounts authenticated by the Windows operating system can access the MySQL server without providing an additional password.

To create a new MySQL account that uses Windows authentication, enter the user name and then select a value for **Host** and **Role**. Click **Windows** authentication to enable the `authentication_windows` plugin. In the Windows Security Tokens area, enter a token for each Windows user (or group) who can authenticate with the MySQL user name. MySQL accounts can include security tokens for both local Windows users and Windows users that belong to a domain. Multiple security tokens are separated by the semicolon character (`;`) and use the following format for local and domain accounts:

- Local account

Enter the simple Windows user name as the security token for each local user or group; for example, `finley;jeffrey;admin`.

- Domain account

Use standard Windows syntax (`domain\domainuser`) or MySQL syntax (`domain\domainuser`) to enter Windows domain users and groups.

For domain accounts, you may need to use the credentials of an administrator within the domain if the account running MySQL Configurator lacks the permissions to query the Active Directory. If

this is the case, select **Validate Active Directory users with** to activate the domain administrator credentials.

Windows authentication permits you to test all of the security tokens each time you add or modify a token. Click **Test Security Tokens** to validate (or revalidate) each token. Invalid tokens generate a descriptive error message along with a red **x** icon and red token text. When all tokens resolve as valid (green text without an **x** icon), you can click **OK** to save the changes.

Windows Service

On the Windows platform, MySQL server can run as a named service managed by the operating system and be configured to start up automatically when Windows starts. Alternatively, you can configure MySQL server to run as an executable program that requires manual configuration.

- **Configure MySQL server as a Windows service** (Selected by default.)

When the default configuration option is selected, you can also select the following:

- **Windows Service Name**

Defaults to MySQL_{XY} where XY is 81 for MySQL 8.1.

- **Start the MySQL Server at System Startup**

When selected (default), the service startup type is set to Automatic; otherwise, the startup type is set to Manual.

- **Run Windows Service as**

When **Standard System Account** is selected (default), the service logs on as Network Service.

The **Custom User** option must have privileges to log on to Microsoft Windows as a service. The **Next** button will be disabled until this user is configured with the required privileges.

A custom user account is configured in Windows by searching for "local security policy" in the Start menu. In the Local Security Policy window, select **Local Policies, User Rights Assignment**, and then **Log On As A Service** to open the property dialog. Click **Add User or Group** to add the custom user and then click **OK** in each dialog to save the changes.

Server File Permissions

Optionally, permissions set on the folders and files located at `C:\ProgramData\MySQL\MySQL Server X.Y\Data` can be managed during the server configuration operation. You have the following options:

- MySQL Configurator can configure the folders and files with full control granted exclusively to the user running the Windows service, if applicable, and to the Administrators group.

All other groups and users are denied access. This is the default option.

- Have MySQL Configurator use a configuration option similar to the one just described, but also have MySQL Configurator show which users could have full control.

You are then able to decide if a group or user should be given full control. If not, you can move the qualified members from this list to a second list that restricts all access.

- Have MySQL Configurator skip making file-permission changes during the configuration operation.

If you select this option, you are responsible for securing the `Data` folder and its related files manually after the server configuration finishes.

Logging Options

This step is available if the **Show Advanced Configuration** check box was selected during the **Type and Networking** step. To enable this step now, click **Back** to return to the **Type and Networking** step and select the check box.

Advanced configuration options are related to the following MySQL log files:

- [Error Log](#)
- [General Log](#)
- [Slow Query Log](#)
- [Binary Log](#)

Advanced Options

This step is available if the **Show Advanced Configuration** check box was selected during the **Type and Networking** step. To enable this step now, click **Back** to return to the **Type and Networking** step and select the check box.

The advanced-configuration options include:

- **Server ID**

Set the unique identifier used in a replication topology. If binary logging is enabled, you must specify a server ID. The default ID value depends on the server version. For more information, see the description of the [server_id](#) system variable.

- **Table Names Case**

These options only apply to the initial configuration of the MySQL server.

- Lower Case

Sets the [lower_case_table_names](#) option value to 1 (default), in which table names are stored in lowercase on disk and comparisons are not case-sensitive.

- Preserve Given Case

Sets the [lower_case_table_names](#) option value to 2, in which table names are stored as given but compared in lowercase.

Sample Databases

Optionally install sample databases that include test data to help develop applications with MySQL. The options include the [sakila](#) and [world](#) databases.

Apply Configuration

All configuration settings are applied to the MySQL server when you click **Execute**. Use the **Configuration Steps** tab to follow the progress of each action; the icon for each toggles from white to green (with a check mark) on success. Otherwise, the process stops and displays an error message if an individual action times out. Click the **Log** tab to view the log.

2.3.3 Configuration: Manually

These instructions apply to those *not* using the MySQL Configurator application to configure and set up the MySQL server; or for manually making additional changes. Using MySQL Configurator is recommended.

2.3.3.1 Extracting the Install Archive

To install MySQL manually, do the following:

1. If you are upgrading from a previous version then refer to [Section 3.11, “Upgrading MySQL on Windows”](#) before beginning the upgrade process.
2. Make sure that you are logged in as a user with administrator privileges.
3. Choose an installation location. Traditionally, the MySQL server is installed in `C:\mysql`. If you do not install MySQL at `C:\mysql`, you must specify the path to the install directory during startup or in an option file. See [Section 2.3.3.2, “Creating an Option File”](#).

Note

The MSI installs MySQL under `C:\Program Files\MySQL\MySQL Server 8.3`.

4. Extract the install archive to the chosen installation location using your preferred file-compression tool. Some tools may extract the archive to a folder within your chosen installation location. If this occurs, you can move the contents of the subfolder into the chosen installation location.

2.3.3.2 Creating an Option File

If you need to specify startup options when you run the server, you can indicate them on the command line or place them in an option file. For options that are used every time the server starts, you may find it most convenient to use an option file to specify your MySQL configuration. This is particularly true under the following circumstances:

- The installation or data directory locations are different from the default locations (`C:\Program Files\MySQL\MySQL Server 8.3` and `C:\Program Files\MySQL\MySQL Server 8.3\data`).
- You need to tune the server settings, such as memory, cache, or InnoDB configuration information.

When the MySQL server starts on Windows, it looks for option files in several locations, such as the Windows directory, `C:\`, and the MySQL installation directory (for the full list of locations, see [Section 6.2.2.2, “Using Option Files”](#)). The Windows directory typically is named something like `C:\WINDOWS`. You can determine its exact location from the value of the `WINDIR` environment variable using the following command:

```
C:\> echo %WINDIR%
```

MySQL looks for options in each location first in the `my.ini` file, and then in the `my.cnf` file. However, to avoid confusion, it is best if you use only one file. If your PC uses a boot loader where `C:` is not the boot drive, your only option is to use the `my.ini` file. Whichever option file you use, it must be a plain text file.

Note

When using MySQL Configurator to configure MySQL Server, it creates the `my.ini` at the default location, and the user executing MySQL Configurator is granted full permissions to this new `my.ini` file.

In other words, be sure that the MySQL Server user has permission to read the `my.ini` file.

You can also make use of the example option files included with your MySQL distribution; see [Section 7.1.2, “Server Configuration Defaults”](#).

An option file can be created and modified with any text editor, such as Notepad. For example, if MySQL is installed in `E:\mysql` and the data directory is in `E:\mydata\data`, you can create an option file containing a `[mysqld]` section to specify values for the `basedir` and `datadir` options:

```
[mysqld]
# set basedir to your installation path
basedir=E:/mysql
# set datadir to the location of your data directory
datadir=E:/mydata/data
```

Microsoft Windows path names are specified in option files using (forward) slashes rather than backslashes. If you do use backslashes, double them:

```
[mysqld]
# set basedir to your installation path
basedir=E:\\mysql
# set datadir to the location of your data directory
datadir=E:\\mydata\\data
```

The rules for use of backslash in option file values are given in [Section 6.2.2.2, “Using Option Files”](#).

The ZIP archive does not include a `data` directory. To initialize a MySQL installation by creating the data directory and populating the tables in the mysql system database, initialize MySQL using either `--initialize` or `--initialize-insecure`. For additional information, see [Section 2.9.1, “Initializing the Data Directory”](#).

If you would like to use a data directory in a different location, you should copy the entire contents of the `data` directory to the new location. For example, if you want to use `E:\\mydata` as the data directory instead, you must do two things:

1. Move the entire `data` directory and all of its contents from the default location (for example `C:\\Program Files\\MySQL\\MySQL Server 8.3\\data`) to `E:\\mydata`.
2. Use a `--datadir` option to specify the new data directory location each time you start the server.

2.3.3.3 Selecting a MySQL Server Type

The following table shows the available servers for Windows in MySQL 8.3.

Binary	Description
<code>mysqld</code>	Optimized binary with named-pipe support
<code>mysqld-debug</code>	Like <code>mysqld</code> , but compiled with full debugging and automatic memory allocation checking

Each of the servers in a distribution support the same set of storage engines. The `SHOW ENGINES` statement displays which engines a given server supports.

All Windows MySQL 8.3 servers have support for symbolic linking of database directories.

MySQL supports TCP/IP on all Windows platforms. MySQL servers on Windows also support named pipes, if you start the server with the `named_pipe` system variable enabled. It is necessary to enable this variable explicitly because some users have experienced problems with shutting down the MySQL server when named pipes were used. The default is to use TCP/IP regardless of platform because named pipes are slower than TCP/IP in many Windows configurations.

2.3.3.4 Initializing the Data Directory

If you installed MySQL using the `noinstall` package, no data directory is included. To initialize the data directory, use the instructions at [Section 2.9.1, “Initializing the Data Directory”](#).

2.3.3.5 Starting the Server for the First Time

This section gives a general overview of starting the MySQL server. The following sections provide more specific information for starting the MySQL server from the command line or as a Windows service.

The information here applies primarily if you installed MySQL using the `noinstall` version, or if you wish to configure and test MySQL manually rather than using MySQL Configurator.

The examples in these sections assume that MySQL is installed under the default location of `C:\Program Files\MySQL\MySQL Server 8.3`. Adjust the path names shown in the examples if you have MySQL installed in a different location.

Clients have two options. They can use TCP/IP, or they can use a named pipe if the server supports named-pipe connections.

MySQL for Windows also supports shared-memory connections if the server is started with the `shared_memory` system variable enabled. Clients can connect through shared memory by using the `--protocol=MEMORY` option.

For information about which server binary to run, see [Section 2.3.3.3, “Selecting a MySQL Server Type”](#).

Testing is best done from a command prompt in a console window (or “DOS window”). In this way you can have the server display status messages in the window where they are easy to see. If something is wrong with your configuration, these messages make it easier for you to identify and fix any problems.

Note

The database must be initialized before MySQL can be started. For additional information about the initialization process, see [Section 2.9.1, “Initializing the Data Directory”](#).

To start the server, enter this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.3\bin\mysqld" --console
```

You should see messages similar to those following as it starts (the path names and sizes may differ). The `ready for connections` messages indicate that the server is ready to service client connections.

```
[Server] C:\mysql\bin\mysqld.exe (mysqld 8.0.30) starting as process 21236
[InnoDB] InnoDB initialization has started.
[InnoDB] InnoDB initialization has ended.
[Server] CA certificate ca.pem is self signed.
[Server] Channel mysql_main configured to support TLS.
Encrypted connections are now supported for this channel.
[Server] X Plugin ready for connections. Bind-address: '::' port: 33060
[Server] C:\mysql\bin\mysqld.exe: ready for connections.
Version: '8.0.30' socket: '' port: 3306 MySQL Community Server - GPL.
```

You can now open a new console window in which to run client programs.

If you omit the `--console` option, the server writes diagnostic output to the error log in the data directory (`C:\Program Files\MySQL\MySQL Server 8.3\data` by default). The error log is the file with the `.err` extension, and may be set using the `--log-error` option.

Note

The initial `root` account in the MySQL grant tables has no password. After starting the server, you should set up a password for it using the instructions in [Section 2.9.4, “Securing the Initial MySQL Account”](#).

2.3.3.6 Starting MySQL from the Windows Command Line

The MySQL server can be started manually from the command line. This can be done on any version of Windows.

To start the `mysqld` server from the command line, you should start a console window (or “DOS window”) and enter this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.3\bin\mysqld"
```

The path to `mysqld` may vary depending on the install location of MySQL on your system.

You can stop the MySQL server by executing this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.3\bin\mysqladmin" -u root shutdown
```

Note

If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

This command invokes the MySQL administrative utility `mysqladmin` to connect to the server and tell it to shut down. The command connects as the MySQL `root` user, which is the default administrative account in the MySQL grant system.

Note

Users in the MySQL grant system are wholly independent from any operating system users under Microsoft Windows.

If `mysqld` doesn't start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. By default, the error log is located in the `C:\Program Files\MySQL\MySQL Server 8.3\data` directory. It is the file with a suffix of `.err`, or may be specified by passing in the `--log-error` option. Alternatively, you can try to start the server with the `--console` option; in this case, the server may display some useful information on the screen to help solve the problem.

The last option is to start `mysqld` with the `--standalone` and `--debug` options. In this case, `mysqld` writes a log file `C:\mysqld.trace` that should contain the reason why `mysqld` doesn't start. See [Section 7.9.4, "The DBUG Package"](#).

Use `mysqld --verbose --help` to display all the options that `mysqld` supports.

2.3.3.7 Customizing the PATH for MySQL Tools

Warning

You must exercise great care when editing your system `PATH` by hand; accidental deletion or modification of any portion of the existing `PATH` value can leave you with a malfunctioning or even unusable system.

To make it easier to invoke MySQL programs, you can add the path name of the MySQL `bin` directory to your Windows system `PATH` environment variable:

- On the Windows desktop, right-click the **My Computer** icon, and select **Properties**.
- Next select the **Advanced** tab from the **System Properties** menu that appears, and click the **Environment Variables** button.
- Under **System Variables**, select **Path**, and then click the **Edit** button. The **Edit System Variable** dialogue should appear.
- Place your cursor at the end of the text appearing in the space marked **Variable Value**. (Use the **End** key to ensure that your cursor is positioned at the very end of the text in this space.) Then enter the complete path name of your MySQL `bin` directory (for example, `C:\Program Files\MySQL\MySQL Server 8.3\bin`)

Note

There must be a semicolon separating this path from any values present in this field.

Dismiss this dialogue, and each dialogue in turn, by clicking **OK** until all of the dialogues that were opened have been dismissed. The new `PATH` value should now be available to any new command

shell you open, allowing you to invoke any MySQL executable program by typing its name at the DOS prompt from any directory on the system, without having to supply the path. This includes the servers, the `mysql` client, and all MySQL command-line utilities such as `mysqladmin` and `mysqldump`.

You should not add the MySQL `bin` directory to your Windows `PATH` if you are running multiple MySQL servers on the same machine.

2.3.3.8 Starting MySQL as a Windows Service

On Windows, the recommended way to run MySQL is to install it as a Windows service, so that MySQL starts and stops automatically when Windows starts and stops. A MySQL server installed as a service can also be controlled from the command line using `NET` commands, or with the graphical `Services` utility. Generally, to install MySQL as a Windows service you should be logged in using an account that has administrator rights.

The `Services` utility (the Windows `Service Control Manager`) can be found in the Windows Control Panel. To avoid conflicts, it is advisable to close the `Services` utility while performing server installation or removal operations from the command line.

Installing the service

Before installing MySQL as a Windows service, you should first stop the current server if it is running by using the following command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.3\bin\mysqladmin"
      -u root shutdown
```

Note

If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

This command invokes the MySQL administrative utility `mysqladmin` to connect to the server and tell it to shut down. The command connects as the MySQL `root` user, which is the default administrative account in the MySQL grant system.

Note

Users in the MySQL grant system are wholly independent from any operating system users under Windows.

Install the server as a service using this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.3\bin\mysqld" --install
```

The service-installation command does not start the server. Instructions for that are given later in this section.

To make it easier to invoke MySQL programs, you can add the path name of the MySQL `bin` directory to your Windows system `PATH` environment variable:

- On the Windows desktop, right-click the **My Computer** icon, and select **Properties**.
- Next select the **Advanced** tab from the **System Properties** menu that appears, and click the **Environment Variables** button.
- Under **System Variables**, select **Path**, and then click the **Edit** button. The **Edit System Variable** dialogue should appear.
- Place your cursor at the end of the text appearing in the space marked **Variable Value**. (Use the **End** key to ensure that your cursor is positioned at the very end of the text in this space.) Then enter

the complete path name of your MySQL `bin` directory (for example, `C:\Program Files\MySQL\MySQL Server 8.3\bin`), and there should be a semicolon separating this path from any values present in this field. Dismiss this dialogue, and each dialogue in turn, by clicking **OK** until all of the dialogues that were opened have been dismissed. You should now be able to invoke any MySQL executable program by typing its name at the DOS prompt from any directory on the system, without having to supply the path. This includes the servers, the `mysql` client, and all MySQL command-line utilities such as `mysqladmin` and `mysqldump`.

You should not add the MySQL `bin` directory to your Windows `PATH` if you are running multiple MySQL servers on the same machine.

Warning

You must exercise great care when editing your system `PATH` by hand; accidental deletion or modification of any portion of the existing `PATH` value can leave you with a malfunctioning or even unusable system.

The following additional arguments can be used when installing the service:

- You can specify a service name immediately following the `--install` option. The default service name is `MySQL`.
- If a service name is given, it can be followed by a single option. By convention, this should be `--defaults-file=file_name` to specify the name of an option file from which the server should read options when it starts.

The use of a single option other than `--defaults-file` is possible but discouraged. `--defaults-file` is more flexible because it enables you to specify multiple startup options for the server by placing them in the named option file.

- You can also specify a `--local-service` option following the service name. This causes the server to run using the `LocalService` Windows account that has limited system privileges. If both `--defaults-file` and `--local-service` are given following the service name, they can be in any order.

For a MySQL server that is installed as a Windows service, the following rules determine the service name and option files that the server uses:

- If the service-installation command specifies no service name or the default service name (`MySQL`) following the `--install` option, the server uses the service name of `MySQL` and reads options from the `[mysqld]` group in the standard option files.
- If the service-installation command specifies a service name other than `MySQL` following the `--install` option, the server uses that service name. It reads options from the `[mysqld]` group and the group that has the same name as the service in the standard option files. This enables you to use the `[mysqld]` group for options that should be used by all MySQL services, and an option group with the service name for use by the server installed with that service name.
- If the service-installation command specifies a `--defaults-file` option after the service name, the server reads options the same way as described in the previous item, except that it reads options only from the named file and ignores the standard option files.

As a more complex example, consider the following command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.3\bin\mysqld"
      --install MySQL --defaults-file=C:\my-opts.cnf
```

Here, the default service name (`MySQL`) is given after the `--install` option. If no `--defaults-file` option had been given, this command would have the effect of causing the server to read the `[mysqld]` group from the standard option files. However, because the `--defaults-file` option is present, the server reads options from the `[mysqld]` option group, and only from the named file.

**Note**

On Windows, if the server is started with the `--defaults-file` and `--install` options, `--install` must be first. Otherwise, `mysqld.exe` attempts to start the MySQL server.

You can also specify options as Start parameters in the Windows [Services](#) utility before you start the MySQL service.

Finally, before trying to start the MySQL service, make sure the user variables `%TEMP%` and `%TMP%` (and also `%TMPDIR%`, if it has ever been set) for the operating system user who is to run the service are pointing to a folder to which the user has write access. The default user for running the MySQL service is `LocalSystem`, and the default value for its `%TEMP%` and `%TMP%` is `C:\Windows\Temp`, a directory `LocalSystem` has write access to by default. However, if there are any changes to that default setup (for example, changes to the user who runs the service or to the mentioned user variables, or the `--tmpdir` option has been used to put the temporary directory somewhere else), the MySQL service might fail to run because write access to the temporary directory has not been granted to the proper user.

Starting the service

After a MySQL server instance has been installed as a service, Windows starts the service automatically whenever Windows starts. The service also can be started immediately from the [Services](#) utility, or by using an `sc start mysql_service_name` or `NET START mysql_service_name` command. `SC` and `NET` commands are not case-sensitive.

When run as a service, `mysqld` has no access to a console window, so no messages can be seen there. If `mysqld` does not start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. The error log is located in the MySQL data directory (for example, `C:\Program Files\MySQL\MySQL Server 8.3\data`). It is the file with a suffix of `.err`.

When a MySQL server has been installed as a service, and the service is running, Windows stops the service automatically when Windows shuts down. The server also can be stopped manually using the [Services](#) utility, the `sc stop mysql_service_name` command, the `NET STOP mysql_service_name` command, or the `mysqladmin shutdown` command.

You also have the choice of installing the server as a manual service if you do not wish for the service to be started automatically during the boot process. To do this, use the `--install-manual` option rather than the `--install` option:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.3\bin\mysqld" --install-manual
```

Removing the service

To remove a server that is installed as a service, first stop it if it is running by executing `SC STOP mysql_service_name` or `NET STOP mysql_service_name`. Then use `SC DELETE mysql_service_name` to remove it:

```
C:\> SC DELETE mysql
```

Alternatively, use the `mysqld --remove` option to remove the service.

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.3\bin\mysqld" --remove
```

If `mysqld` is not running as a service, you can start it from the command line. For instructions, see [Section 2.3.3.6, “Starting MySQL from the Windows Command Line”](#).

If you encounter difficulties during installation, see [Section 2.3.4, “Troubleshooting a Microsoft Windows MySQL Server Installation”](#).

For more information about stopping or removing a Windows service, see [Section 7.8.2.2, “Starting Multiple MySQL Instances as Windows Services”](#).

2.3.3.9 Testing The MySQL Installation

You can test whether the MySQL server is working by executing any of the following commands:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.3\bin\mysqlshow"
C:\> "C:\Program Files\MySQL\MySQL Server 8.3\bin\mysqlshow" -u root mysql
C:\> "C:\Program Files\MySQL\MySQL Server 8.3\bin\mysqladmin" version status proc
C:\> "C:\Program Files\MySQL\MySQL Server 8.3\bin\mysql" test
```

If `mysqld` is slow to respond to TCP/IP connections from client programs, there is probably a problem with your DNS. In this case, start `mysqld` with the `skip_name_resolve` system variable enabled and use only `localhost` and IP addresses in the `Host` column of the MySQL grant tables. (Be sure that an account exists that specifies an IP address or you may not be able to connect.)

You can force a MySQL client to use a named-pipe connection rather than TCP/IP by specifying the `--pipe` or `--protocol=PIPE` option, or by specifying `.` (period) as the host name. Use the `--socket` option to specify the name of the pipe if you do not want to use the default pipe name.

If you have set a password for the `root` account, deleted the anonymous account, or created a new user account, then to connect to the MySQL server you must use the appropriate `-u` and `-p` options with the commands shown previously. See [Section 6.2.4, “Connecting to the MySQL Server Using Command Options”](#).

For more information about `mysqlshow`, see [Section 6.5.7, “mysqlshow — Display Database, Table, and Column Information”](#).

2.3.4 Troubleshooting a Microsoft Windows MySQL Server Installation

When installing and running MySQL for the first time, you may encounter certain errors that prevent the MySQL server from starting. This section helps you diagnose and correct some of these errors.

Your first resource when troubleshooting server issues is the [error log](#). The MySQL server uses the error log to record information relevant to the error that prevents the server from starting. The error log is located in the [data directory](#) specified in your `my.ini` file. The default data directory location is `C:\Program Files\MySQL\MySQL Server 8.3\data`, or `C:\ProgramData\MySQL` on Windows 7 and Windows Server 2008. The `C:\ProgramData` directory is hidden by default. You need to change your folder options to see the directory and contents. For more information on the error log and understanding the content, see [Section 7.4.2, “The Error Log”](#).

For information regarding possible errors, also consult the console messages displayed when the MySQL service is starting. Use the `SC START mysqld_service_name` or `NET START mysqld_service_name` command from the command line after installing `mysqld` as a service to see any error messages regarding the starting of the MySQL server as a service. See [Section 2.3.3.8, “Starting MySQL as a Windows Service”](#).

The following examples show other common error messages you might encounter when installing MySQL and starting the server for the first time:

- If the MySQL server cannot find the `mysql` privileges database or other critical files, it displays these messages:

```
System error 1067 has occurred.
Fatal error: Can't open and lock privilege tables:
Table 'mysql.user' doesn't exist
```

These messages often occur when the MySQL base or data directories are installed in different locations than the default locations (`C:\Program Files\MySQL\MySQL Server 8.3` and `C:\Program Files\MySQL\MySQL Server 8.3\data`, respectively).

This situation can occur when MySQL is upgraded and installed to a new location, but the configuration file is not updated to reflect the new location. In addition, old and new configuration files might conflict. Be sure to delete or rename any old configuration files when upgrading MySQL.

If you have installed MySQL to a directory other than `C:\Program Files\MySQL\MySQL Server 8.3`, ensure that the MySQL server is aware of this through the use of a configuration (`my.ini`) file. Put the `my.ini` file in your Windows directory, typically `C:\WINDOWS`. To determine its exact location from the value of the `WINDIR` environment variable, issue the following command from the command prompt:

```
C:\> echo %WINDIR%
```

You can create or modify an option file with any text editor, such as Notepad. For example, if MySQL is installed in `E:\mysql` and the data directory is `D:\MySQLdata`, you can create the option file and set up a `[mysqld]` section to specify values for the `basedir` and `datadir` options:

```
[mysqld]
# set basedir to your installation path
basedir=E:/mysql
# set datadir to the location of your data directory
datadir=D:/MySQLdata
```

Microsoft Windows path names are specified in option files using (forward) slashes rather than backslashes. If you do use backslashes, double them:

```
[mysqld]
# set basedir to your installation path
basedir=C:\\Program Files\\MySQL\\MySQL Server 8.3
# set datadir to the location of your data directory
datadir=D:\\MySQLdata
```

The rules for use of backslash in option file values are given in [Section 6.2.2.2, “Using Option Files”](#).

If you change the `datadir` value in your MySQL configuration file, you must move the contents of the existing MySQL data directory before restarting the MySQL server.

See [Section 2.3.3.2, “Creating an Option File”](#).

- If you reinstall or upgrade MySQL without first stopping and removing the existing MySQL service, and then configure MySQL using MySQL Configurator, you might see this error:

```
Error: Cannot create Windows service for MySql. Error: 0
```

This occurs when the Configuration Wizard tries to install the service and finds an existing service with the same name.

One solution to this problem is to choose a service name other than `mysql` when using the configuration wizard. This enables the new service to be installed correctly, but leaves the outdated service in place. Although this is harmless, it is best to remove old services that are no longer in use.

To permanently remove the old `mysql` service, execute the following command as a user with administrative privileges, on the command line:

```
C:\> SC DELETE mysql
[SC] DeleteService SUCCESS
```

If the `SC` utility is not available for your version of Windows, download the `delsrv` utility from <http://www.microsoft.com/windows2000/techinfo/reskit/tools/existing/delsrv-o.asp> and use the `delsrv mysql` syntax.

2.3.5 Windows Postinstallation Procedures

GUI tools exist that perform most of the tasks described in this section, including:

- **MySQL Configurator:** Used to configure the MySQL server.
- **MySQL Workbench:** Manages the MySQL server and edits SQL statements.

If necessary, initialize the data directory and create the MySQL grant tables. Windows installation operations performed by MySQL Configurator can initialize the data directory automatically. For installation from a ZIP Archive package, initialize the data directory as described at [Section 2.9.1, “Initializing the Data Directory”](#).

Regarding passwords, if you configured MySQL using the MySQL Configurator, you may have already assigned a password to the initial `root` account. (See [Section 2.3.2, “Configuration: Using MySQL Configurator”](#).) Otherwise, use the password-assignment procedure given in [Section 2.9.4, “Securing the Initial MySQL Account”](#).

Before assigning a password, you might want to try running some client programs to make sure that you can connect to the server and that it is operating properly. Make sure that the server is running (see [Section 2.3.3.5, “Starting the Server for the First Time”](#)). You can also set up a MySQL service that runs automatically when Windows starts (see [Section 2.3.3.8, “Starting MySQL as a Windows Service”](#)).

These instructions assume that your current location is the MySQL installation directory and that it has a `bin` subdirectory containing the MySQL programs used here. If that is not true, adjust the command path names accordingly.

If you installed MySQL using the MSI, the default installation directory is `C:\Program Files\MySQL\MySQL Server 8.3`:

```
C:\> cd "C:\Program Files\MySQL\MySQL Server 8.3"
```

A common installation location for installation from a ZIP archive is `C:\mysql`:

```
C:\> cd C:\mysql
```

Alternatively, add the `bin` directory to your `PATH` environment variable setting. That enables your command interpreter to find MySQL programs properly, so that you can run a program by typing only its name, not its path name. See [Section 2.3.3.7, “Customizing the PATH for MySQL Tools”](#).

With the server running, issue the following commands to verify that you can retrieve information from the server. The output should be similar to that shown here.

Use `mysqlshow` to see what databases exist:

```
C:\> bin\mysqlshow
+-----+
| Databases |
+-----+
| information_schema |
| mysql |
| performance_schema |
| sys |
+-----+
```

The list of installed databases may vary, but always includes at least `mysql` and `information_schema`.

The preceding command (and commands for other MySQL programs such as `mysql`) may not work if the correct MySQL account does not exist. For example, the program may fail with an error, or you may not be able to view all databases. If you configured MySQL using MySQL Configurator, the `root` user is created automatically with the password you supplied. In this case, you should use the `-u root` and `-p` options. (You must use those options if you have already secured the initial MySQL accounts.) With `-p`, the client program prompts for the `root` password. For example:

```
C:\> bin\mysqlshow -u root -p
Enter password: (enter root password here)
+-----+
| Databases |
+-----+
| information_schema |
| mysql |
+-----+
```

```
| performance_schema |
| sys                 |
+-----+
```

If you specify a database name, `mysqlshow` displays a list of the tables within the database:

```
C:\> bin\mysqlshow mysql
Database: mysql
+-----+
| Tables |
+-----+
| columns_priv |
| component |
| db |
| default_roles |
| engine_cost |
| func |
| general_log |
| global_grants |
| gtid_executed |
| help_category |
| help_keyword |
| help_relation |
| help_topic |
| innodb_index_stats |
| innodb_table_stats |
| ndb_binlog_index |
| password_history |
| plugin |
| procs_priv |
| proxies_priv |
| role_edges |
| server_cost |
| servers |
| slave_master_info |
| slave_relay_log_info |
| slave_worker_info |
| slow_log |
| tables_priv |
| time_zone |
| time_zone_leap_second |
| time_zone_name |
| time_zone_transition |
| time_zone_transition_type |
| user |
+-----+
```

Use the `mysql` program to select information from a table in the `mysql` database:

```
C:\> bin\mysql -e "SELECT User, Host, plugin FROM mysql.user" mysql
+-----+
| User | Host      | plugin |
+-----+
| root | localhost | caching_sha2_password |
+-----+
```

For more information about `mysql` and `mysqlshow`, see [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#), and [Section 6.5.7, “mysqlshow — Display Database, Table, and Column Information”](#).

2.3.6 Windows Platform Restrictions

The following restrictions apply to use of MySQL on the Windows platform:

- **Process memory**

On Windows 32-bit platforms, it is not possible by default to use more than 2GB of RAM within a single process, including MySQL. This is because the physical address limit on Windows 32-bit is 4GB and the default setting within Windows is to split the virtual address space between kernel (2GB) and user/applications (2GB).

Some versions of Windows have a boot time setting to enable larger applications by reducing the kernel application. Alternatively, to use more than 2GB, use a 64-bit version of Windows.

- **File system aliases**

When using `MyISAM` tables, you cannot use aliases within Windows link to the data files on another volume and then link back to the main MySQL `datadir` location.

This facility is often used to move the data and index files to a RAID or other fast solution.

- **Limited number of ports**

Windows systems have about 4,000 ports available for client connections, and after a connection on a port closes, it takes two to four minutes before the port can be reused. In situations where clients connect to and disconnect from the server at a high rate, it is possible for all available ports to be used up before closed ports become available again. If this happens, the MySQL server appears to be unresponsive even though it is running. Ports may be used by other applications running on the machine as well, in which case the number of ports available to MySQL is lower.

For more information about this problem, see <https://support.microsoft.com/kb/196271>.

- **DATA DIRECTORY and INDEX DIRECTORY**

The `DATA DIRECTORY` clause of the `CREATE TABLE` statement is supported on Windows for `InnoDB` tables only, as described in [Section 17.6.1.2, “Creating Tables Externally”](#). For `MyISAM` and other storage engines, the `DATA DIRECTORY` and `INDEX DIRECTORY` clauses for `CREATE TABLE` are ignored on Windows and any other platforms with a nonfunctional `realpath()` call.

- **DROP DATABASE**

You cannot drop a database that is in use by another session.

- **Case-insensitive names**

File names are not case-sensitive on Windows, so MySQL database and table names are also not case-sensitive on Windows. The only restriction is that database and table names must be specified using the same case throughout a given statement. See [Section 11.2.3, “Identifier Case Sensitivity”](#).

- **Directory and file names**

On Windows, MySQL Server supports only directory and file names that are compatible with the current ANSI code pages. For example, the following Japanese directory name does not work in the Western locale (code page 1252):

```
datadir="C:/私たちのプロジェクトのデータ"
```

The same limitation applies to directory and file names referred to in SQL statements, such as the data file path name in `LOAD DATA`.

- **The \ path name separator character**

Path name components in Windows are separated by the `\` character, which is also the escape character in MySQL. If you are using `LOAD DATA` or `SELECT ... INTO OUTFILE`, use Unix-style file names with `/` characters:

```
mysql> LOAD DATA INFILE 'C:/tmp/skr.txt' INTO TABLE skr;  
mysql> SELECT * INTO OUTFILE 'C:/tmp/skr.txt' FROM skr;
```

Alternatively, you must double the `\` character:

```
mysql> LOAD DATA INFILE 'C:\\tmp\\skr.txt' INTO TABLE skr;  
mysql> SELECT * INTO OUTFILE 'C:\\tmp\\skr.txt' FROM skr;
```

- **Problems with pipes**

Pipes do not work reliably from the Windows command-line prompt. If the pipe includes the character `^Z / CHAR(24)`, Windows thinks that it has encountered end-of-file and aborts the program.

This is mainly a problem when you try to apply a binary log as follows:

```
C:\> mysqlbinlog binary_log_file | mysql --user=root
```

If you have a problem applying the log and suspect that it is because of a `^Z / CHAR(24)` character, you can use the following workaround:

```
C:\> mysqlbinlog binary_log_file --result-file=/tmp/bin.sql
C:\> mysql --user=root --execute "source /tmp/bin.sql"
```

The latter command also can be used to reliably read any SQL file that may contain binary data.

2.4 Installing MySQL on macOS

For a list of macOS versions that the MySQL server supports, see <https://www.mysql.com/support/supportedplatforms/database.html>.

MySQL for macOS is available in a number of different forms:

- **Native Package Installer**, which uses the native macOS installer (DMG) to walk you through the installation of MySQL. For more information, see [Section 2.4.2, “Installing MySQL on macOS Using Native Packages”](#). You can use the package installer with macOS. The user you use to perform the installation must have administrator privileges.
- **Compressed TAR archive**, which uses a file packaged using the Unix `tar` and `gzip` commands. To use this method, you need to open a `Terminal` window. You do not need administrator privileges using this method; you can install the MySQL server anywhere using this method. For more information on using this method, you can use the generic instructions for using a tarball, [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#).

In addition to the core installation, the Package Installer also includes [Section 2.4.3, “Installing and Using the MySQL Launch Daemon”](#) and [Section 2.4.4, “Installing and Using the MySQL Preference Pane”](#) to simplify the management of your installation.

For additional information on using MySQL on macOS, see [Section 2.4.1, “General Notes on Installing MySQL on macOS”](#).

2.4.1 General Notes on Installing MySQL on macOS

You should keep the following issues and notes in mind:

- **Other MySQL installations:** The installation procedure does not recognize MySQL installations by package managers such as Homebrew. The installation and upgrade process is for MySQL packages provided by us. If other installations are present, then consider stopping them before executing this installer to avoid port conflicts.

Homebrew: For example, if you installed MySQL Server using Homebrew to its default location then the MySQL installer installs to a different location and won't upgrade the version from Homebrew. In this scenario you would end up with multiple MySQL installations that, by default, attempt to use the same ports. Stop the other MySQL Server instances before running this installer, such as executing `brew services stop mysql` to stop the Homebrew's MySQL service.

- **Launchd:** A launchd daemon is installed that alters MySQL configuration options. Consider editing it if needed, see the documentation below for additional information. Also, macOS 10.10 removed startup item support in favor of launchd daemons. The optional MySQL preference pane under macOS **System Preferences** uses the launchd daemon.

- **Users:** You may need (or want) to create a specific `mysql` user to own the MySQL directory and data. You can do this through the [Directory Utility](#), and the `mysql` user should already exist. For use in single user mode, an entry for `_mysql` (note the underscore prefix) should already exist within the system `/etc/passwd` file.
- **Data:** Because the MySQL package installer installs the MySQL contents into a version and platform specific directory, you can use this to upgrade and migrate your database between versions. You need either to copy the `data` directory from the old version to the new version, or to specify an alternative `datadir` value to set location of the data directory. By default, the MySQL directories are installed under `/usr/local/`.
- **Aliases:** You might want to add aliases to your shell's resource file to make it easier to access commonly used programs such as `mysql` and `mysqladmin` from the command line. The syntax for `bash` is:

```
alias mysql=/usr/local/mysql/bin/mysql
alias mysqladmin=/usr/local/mysql/bin/mysqladmin
```

For `tcsh`, use:

```
alias mysql /usr/local/mysql/bin/mysql
alias mysqladmin /usr/local/mysql/bin/mysqladmin
```

Even better, add `/usr/local/mysql/bin` to your `PATH` environment variable. You can do this by modifying the appropriate startup file for your shell. For more information, see [Section 6.2.1, “Invoking MySQL Programs”](#).

- **Removing:** After you have copied over the MySQL database files from the previous installation and have successfully started the new server, you should consider removing the old installation files to save disk space. Additionally, you should also remove older versions of the Package Receipt directories located in `/Library/Receipts/mysql-VERSION.pkg`.

2.4.2 Installing MySQL on macOS Using Native Packages

The package is located inside a disk image (`.dmg`) file that you first need to mount by double-clicking its icon in the Finder. It should then mount the image and display its contents.

Note

Before proceeding with the installation, be sure to stop all running MySQL server instances by using either the MySQL Manager Application (on macOS Server), the preference pane, or `mysqladmin shutdown` on the command line.

To install MySQL using the package installer:

1. Download the disk image (`.dmg`) file (the community version is available [here](#)) that contains the MySQL package installer. Double-click the file to mount the disk image and see its contents.

Double-click the MySQL installer package from the disk. It is named according to the version of MySQL you have downloaded. For example, for MySQL server 8.3.0 it might be named `mysql-8.3.0-macos-10.13-x86_64.pkg`.

2. The initial wizard introduction screen references the MySQL server version to install. Click **Continue** to begin the installation.

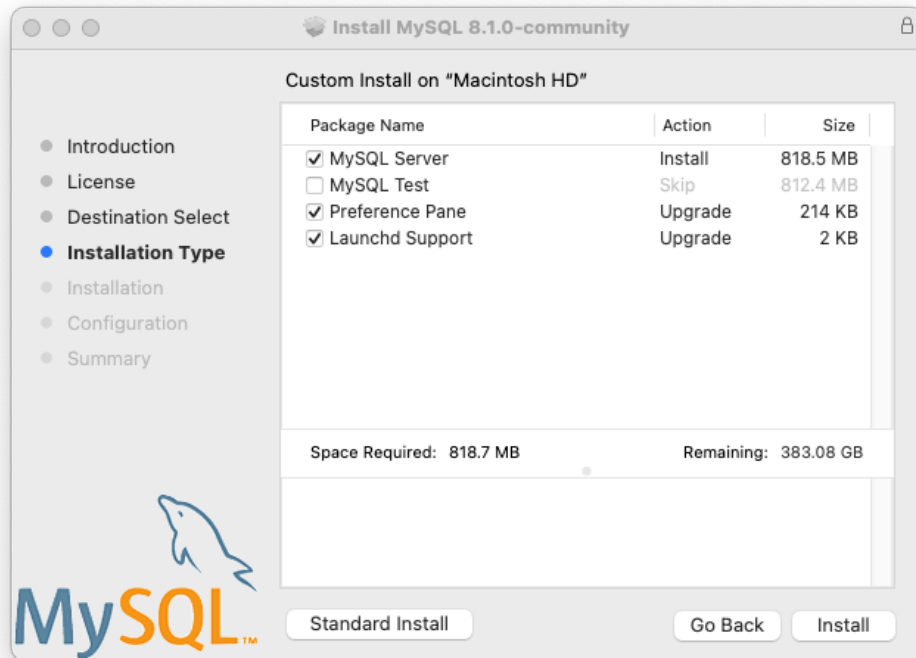

The MySQL community edition shows a copy of the relevant GNU General Public License. Click **Continue** and then **Agree** to continue.

3. From the **Installation Type** page you can either click **Install** to execute the installation wizard using all defaults, click **Customize** to alter which components to install (MySQL server, MySQL Test, Preference Pane, Launchd Support -- all but MySQL Test are enabled by default).

**Note**

Although the **Change Install Location** option is visible, the installation location cannot be changed.

Figure 2.5 MySQL Package Installer Wizard: Customize

4. Click **Install** to install MySQL Server. The installation process ends here if upgrading a current MySQL Server installation, otherwise follow the wizard's additional configuration steps for your new MySQL Server installation.
5. After a successful new MySQL Server installation, complete the configuration steps by choosing the default encryption type for passwords, define the root password, and also enable (or disable) MySQL server at startup.

- The default MySQL 8.3 password mechanism is `caching_sha2_password` (Strong), and this step allows you to change it to `mysql_native_password` (Legacy).

Figure 2.6 MySQL Package Installer Wizard: Choose a Password Encryption Type

Choosing the legacy password mechanism, which is deprecated, alters the generated launchd file to set `--default_authentication_plugin=mysql_native_password` under `ProgramArguments`. Choosing strong password encryption does not set `--default_authentication_plugin` because the default MySQL Server value is used, which is `caching_sha2_password`.

- Define a password for the root user, and also toggle whether MySQL Server should start after the configuration step is complete.
- Summary** is the final step and references a successful and complete MySQL Server installation. **Close** the wizard.

MySQL server is now installed. If you chose to not start MySQL, then use either `launchctl` from the command line or start MySQL by clicking "Start" using the MySQL preference pane. For additional information, see [Section 2.4.3, "Installing and Using the MySQL Launch Daemon"](#), and [Section 2.4.4, "Installing and Using the MySQL Preference Pane"](#). Use the MySQL Preference Pane or `launchd` to configure MySQL to automatically start at bootup.

When installing using the package installer, the files are installed into a directory within `/usr/local` matching the name of the installation version and platform. For example, the installer file `mysql-8.3.0-macos10.15-x86_64.dmg` installs MySQL into `/usr/local/mysql-8.3.0-macos10.15-x86_64/` with a symlink to `/usr/local/mysql`. The following table shows the layout of this MySQL installation directory.

Note

The macOS installation process does not create nor install a sample `my.cnf` MySQL configuration file.

Table 2.6 MySQL Installation Layout on macOS

Directory	Contents of Directory
<code>bin</code>	<code>mysqld</code> server, client and utility programs
<code>data</code>	Log files, databases, where <code>/usr/local/mysql/data/mysqld.local.err</code> is the default error log
<code>docs</code>	Helper documents, like the Release Notes and build information
<code>include</code>	Include (header) files
<code>lib</code>	Libraries
<code>man</code>	Unix manual pages
<code>mysql-test</code>	MySQL test suite ('MySQL Test' is disabled by default during the installation process when using the installer package (DMG))
<code>share</code>	Miscellaneous support files, including error messages, <code>dictionary.txt</code> , and rewriter SQL
<code>support-files</code>	Support scripts, such as <code>mysqld_multi.server</code> , <code>mysql.server</code> , and <code>mysql-log-rotate</code> .
<code>/tmp/mysql.sock</code>	Location of the MySQL Unix socket

2.4.3 Installing and Using the MySQL Launch Daemon

macOS uses launch daemons to automatically start, stop, and manage processes and applications such as MySQL.

By default, the installation package (DMG) on macOS installs a launchd file named `/Library/LaunchDaemons/com.oracle.oss.mysql.mysqld.plist` that contains a plist definition similar to:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plist PUBLIC "-//Apple Computer//DTD PLIST 1.0//EN" "http://www.apple.com/DTDs/PropertyList-1.0.dtd">
<plist version="1.0">
<dict>
  <key>Label</key>          <string>com.oracle.oss.mysql.mysqld</string>
  <key>ProcessType</key>    <string>Interactive</string>
  <key>Disabled</key>       <false/>
  <key>RunAtLoad</key>      <true/>
  <key>KeepAlive</key>      <true/>
  <key>SessionCreate</key>  <true/>
  <key>LaunchOnlyOnce</key> <false/>
  <key>UserName</key>       <string>_mysql</string>
  <key>GroupName</key>      <string>_mysql</string>
  <key>ExitTimeOut</key>    <integer>600</integer>
  <key>Program</key>        <string>/usr/local/mysql/bin/mysqld</string>
  <key>ProgramArguments</key>
    <array>
      <string>/usr/local/mysql/bin/mysqld</string>
      <string>--user=_mysql</string>
      <string>--basedir=/usr/local/mysql</string>
      <string>--datadir=/usr/local/mysql/data</string>
      <string>--plugin-dir=/usr/local/mysql/lib/plugin</string>
      <string>--log-error=/usr/local/mysql/data/mysqld.local.err</string>
      <string>--pid-file=/usr/local/mysql/data/mysqld.local.pid</string>
      <string>--keyring-file-data=/usr/local/mysql/keyring/keyring</string>
      <string>--early-plugin-load=keyring_file=keyring_file.so</string>
    </array>
  <key>WorkingDirectory</key> <string>/usr/local/mysql</string>
</dict>
</plist>
```

```
</dict>
</plist>
```

Note

Some users report that adding a plist DOCTYPE declaration causes the launchd operation to fail, despite it passing the lint check. We suspect it's a copy-n-paste error. The md5 checksum of a file containing the above snippet is *d925f05f6d1b6ee5ce5451b596d6baed*.

To enable the launchd service, you can either:

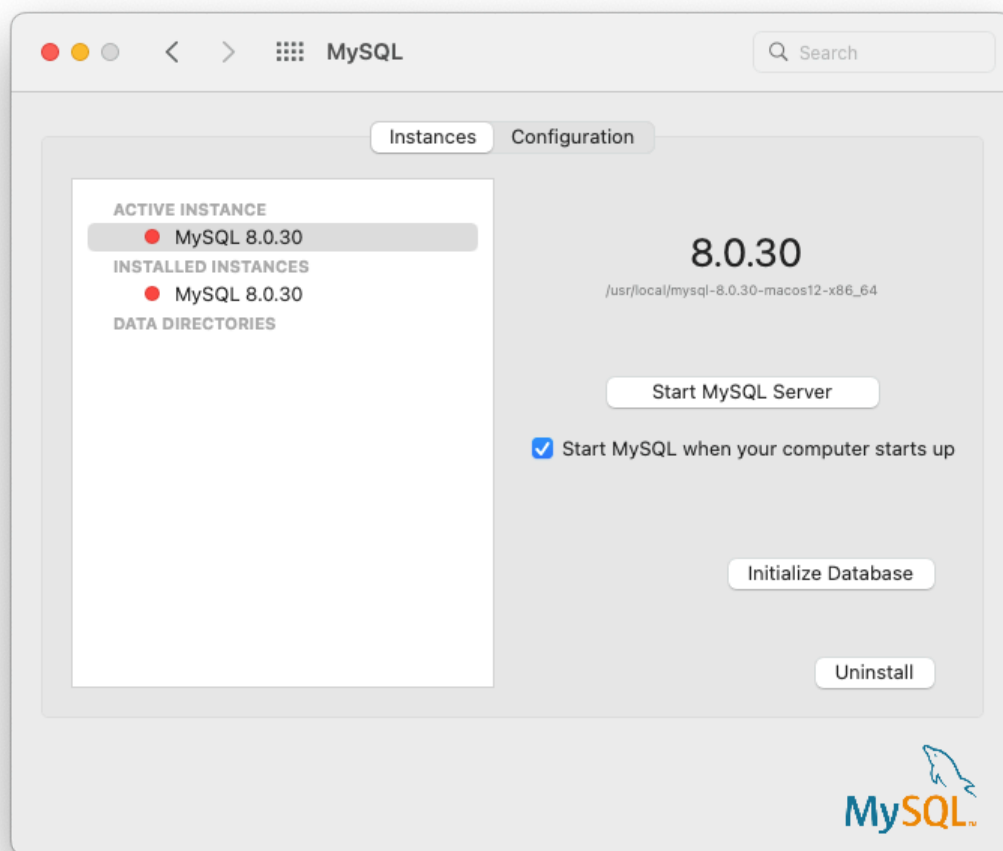

- Open macOS system preferences and select the MySQL preference panel, and then execute **Start MySQL Server**.

Figure 2.7 MySQL Preference Pane: Location

The **Instances** page includes an option to start or stop MySQL, and **Initialize Database** recreates the `data/` directory. **Uninstall** uninstalls MySQL Server and optionally the MySQL preference panel and launchd information.

Figure 2.8 MySQL Preference Pane: Instances

- Or, manually load the launchd file.

```
$> cd /Library/LaunchDaemons
$> sudo launchctl load -F com.oracle.oss.mysql.mysqld.plist
```

- To configure MySQL to automatically start at bootup, you can:

```
$> sudo launchctl load -w com.oracle.oss.mysql.mysqld.plist
```

Note

When upgrading MySQL server, the launchd installation process removes the old startup items that were installed with MySQL server 5.7.7 and below.

Upgrading also replaces your existing launchd file named `com.oracle.oss.mysql.mysqld.plist`.

Additional launchd related information:

- The plist entries override `my.cnf` entries, because they are passed in as command line arguments. For additional information about passing in program options, see [Section 6.2.2, “Specifying Program Options”](#).
- The **ProgramArguments** section defines the command line options that are passed into the program, which is the `mysqld` binary in this case.

- The default plist definition is written with less sophisticated use cases in mind. For more complicated setups, you may want to remove some of the arguments and instead rely on a MySQL configuration file, such as [my.cnf](#).
- If you edit the plist file, then uncheck the installer option when reinstalling or upgrading MySQL. Otherwise, your edited plist file is overwritten, and all edits are lost.

Because the default plist definition defines several **ProgramArguments**, you might remove most of these arguments and instead rely upon your [my.cnf](#) MySQL configuration file to define them. For example:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plist PUBLIC "-//Apple Computer//DTD PLIST 1.0//EN" "http://www.apple.com/DTDs/PropertyList-1.0.dtd" >
<plist version="1.0">
<dict>
    <key>Label</key>                <string>com.oracle.oss.mysql.mysqld</string>
    <key>ProcessType</key>          <string>Interactive</string>
    <key>Disabled</key>              <false/>
    <key>RunAtLoad</key>             <true/>
    <key>KeepAlive</key>            <true/>
    <key>SessionCreate</key>         <true/>
    <key>LaunchOnlyOnce</key>        <false/>
    <key>UserName</key>              <string>_mysql</string>
    <key>GroupName</key>            <string>_mysql</string>
    <key>ExitTimeOut</key>          <integer>600</integer>
    <key>Program</key>              <string>/usr/local/mysql/bin/mysqld</string>
    <key>ProgramArguments</key>
        <array>
            <string>/usr/local/mysql/bin/mysqld</string>
            <string>--user=_mysql</string>
            <string>--basedir=/usr/local/mysql</string>
            <string>--datadir=/usr/local/mysql/data</string>
            <string>--plugin-dir=/usr/local/mysql/lib/plugin</string>
            <string>--log-error=/usr/local/mysql/data/mysqld.local.err</string>
            <string>--pid-file=/usr/local/mysql/data/mysqld.local.pid</string>
            <string>--keyring-file-data=/usr/local/mysql/keyring/keyring</string>
            <string>--early-plugin-load=keyring_file=keyring_file.so</string>
        </array>
    <key>WorkingDirectory</key>    <string>/usr/local/mysql</string>
</dict>
</plist>
```

In this case, the [basedir](#), [datadir](#), [plugin_dir](#), [log_error](#), [pid_file](#), [keyring_file_data](#), and [--early-plugin-load](#) options were removed from the default plist *ProgramArguments* definition, which you might have defined in [my.cnf](#) instead.

2.4.4 Installing and Using the MySQL Preference Pane

The MySQL Installation Package includes a MySQL preference pane that enables you to start, stop, and control automated startup during boot of your MySQL installation.

This preference pane is installed by default, and is listed under your system's *System Preferences* window.

Figure 2.9 MySQL Preference Pane: Location

The MySQL preference pane is installed with the same DMG file that installs MySQL Server. Typically it is installed with MySQL Server but it can be installed by itself too.

To install the MySQL preference pane:

1. Go through the process of installing the MySQL server, as described in the documentation at [Section 2.4.2, "Installing MySQL on macOS Using Native Packages"](#).
2. Click **Customize** at the **Installation Type** step. The "Preference Pane" option is listed there and enabled by default; make sure it is not deselected. The other options, such as MySQL Server, can be selected or deselected.

Figure 2.10 MySQL Package Installer Wizard: Customize

3. Complete the installation process.

**Note**

The MySQL preference pane only starts and stops MySQL installation installed from the MySQL package installation that have been installed in the default location.

Once the MySQL preference pane has been installed, you can control your MySQL server instance using this preference pane.

The **Instances** page includes an option to start or stop MySQL, and **Initialize Database** recreates the `data/` directory. **Uninstall** uninstalls MySQL Server and optionally the MySQL preference panel and launchd information.

Figure 2.11 MySQL Preference Pane: Instances

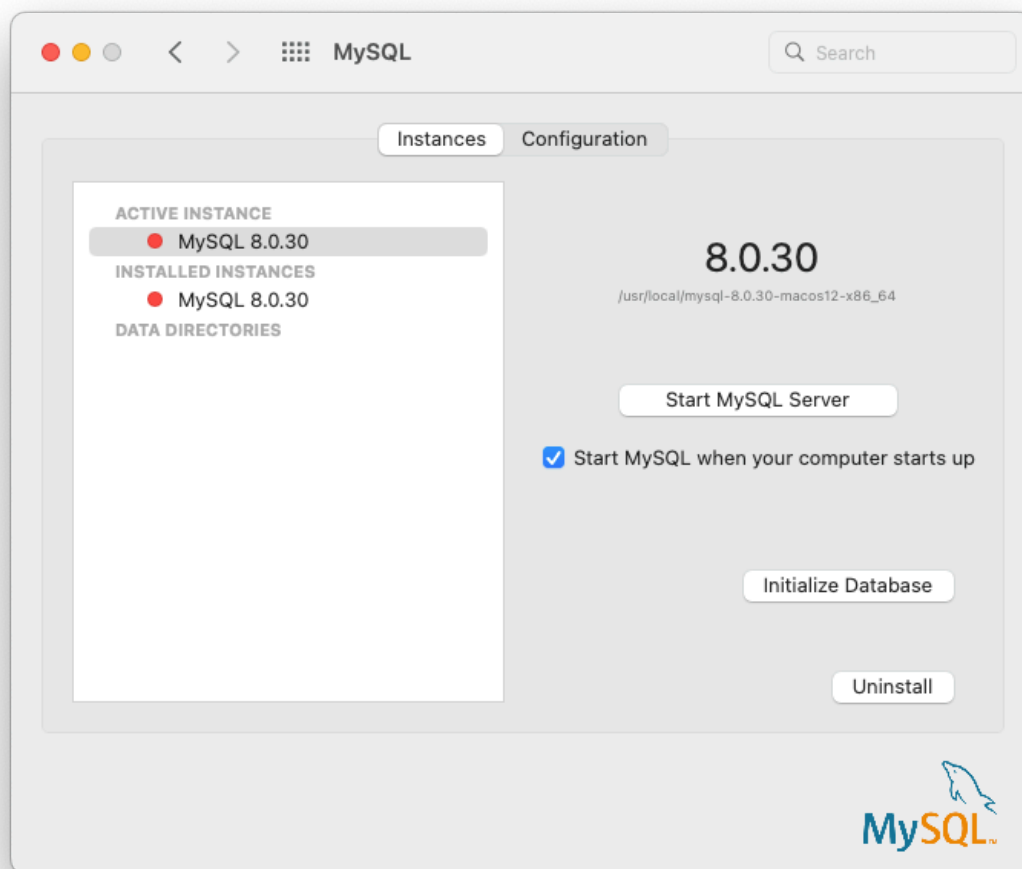

Figure 2.12 MySQL Preference Pane: Initialize Database

The dialog box is titled "Initialize Database". It contains the following text: "Create a new data directory for the selected MySQL instance. If a data directory already exists, it will be deleted." Below this, it says "Please enter a password for the database 'root' user:" followed by a password input field with ten dots and a show/hide icon. There are three radio button options: "Use Strong Password Encryption" (selected), "Use Legacy Password Encryption", and "Load configuration file". Each option has a descriptive paragraph. At the bottom right are "Cancel" and "OK" buttons.

Initialize Database

Create a new data directory for the selected MySQL instance.
If a data directory already exists, it will be deleted.

Please enter a password for the database "root" user:

••••••••••

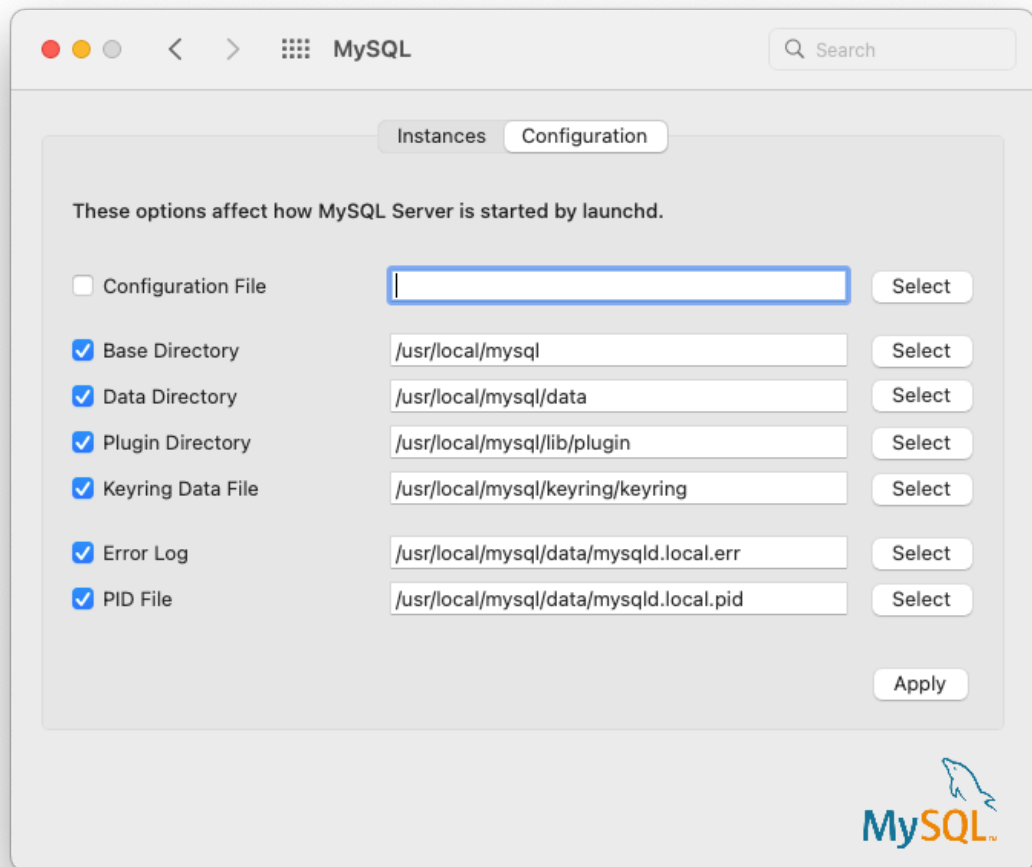

☒ **Use Strong Password Encryption**
MySQL 8 supports a newer, stronger authentication method. All new installations should use this method, but older connectors and clients may be unable to connect.

☐ **Use Legacy Password Encryption**
The legacy authentication method should only be used when compatibility with MySQL 5.x connectors or clients is required.

☐ **Load configuration file**
If a configuration file has been specified, allow mysqld to load it during initialization. Please note that plugin-specific options may prevent the initialization from completing successfully.

Cancel OK

The **Configuration** page shows MySQL Server options including the path to the MySQL configuration file.

Figure 2.13 MySQL Preference Pane: Configuration

The MySQL Preference Pane shows the current status of the MySQL server, showing **stopped** (in red) if the server is not running and **running** (in green) if the server has already been started. The preference pane also shows the current setting for whether the MySQL server has been set to start automatically.

2.5 Installing MySQL on Linux

Linux supports a number of different solutions for installing MySQL. We recommend that you use one of the distributions from Oracle, for which several methods for installation are available:

Table 2.7 Linux Installation Methods and Information

Type	Setup Method	Additional Information
Apt	Enable the MySQL Apt repository	Documentation
Yum	Enable the MySQL Yum repository	Documentation
Zypper	Enable the MySQL SLES repository	Documentation
RPM	Download a specific package	Documentation
DEB	Download a specific package	Documentation
Generic	Download a generic package	Documentation

Type	Setup Method	Additional Information
Source	Compile from source	Documentation
Docker	Use the Oracle Container Registry . You can also use My Oracle Support for the MySQL Enterprise Edition.	Documentation
Oracle Unbreakable Linux Network	Use ULN channels	Documentation

As an alternative, you can use the package manager on your system to automatically download and install MySQL with packages from the native software repositories of your Linux distribution. These native packages are often several versions behind the currently available release. You are also normally unable to install innovation releases, since these are not usually made available in the native repositories. For more information on using the native package installers, see [Section 2.5.7, “Installing MySQL on Linux from the Native Software Repositories”](#).

Note

For many Linux installations, you want to set up MySQL to be started automatically when your machine starts. Many of the native package installations perform this operation for you, but for source, binary and RPM solutions you may need to set this up separately. The required script, `mysql.server`, can be found in the `support-files` directory under the MySQL installation directory or in a MySQL source tree. You can install it as `/etc/init.d/mysql` for automatic MySQL startup and shutdown. See [Section 6.3.3, “mysql.server — MySQL Server Startup Script”](#).

2.5.1 Installing MySQL on Linux Using the MySQL Yum Repository

The [MySQL Yum repository](#) for Oracle Linux, Red Hat Enterprise Linux, CentOS, and Fedora provides RPM packages for installing the MySQL server, client, MySQL Workbench, MySQL Utilities, MySQL Router, MySQL Shell, Connector/ODBC, Connector/Python and so on (not all packages are available for all the distributions; see [Installing Additional MySQL Products and Components with Yum](#) for details).

Before You Start

As a popular, open-source software, MySQL, in its original or re-packaged form, is widely installed on many systems from various sources, including different software download sites, software repositories, and so on. The following instructions assume that MySQL is not already installed on your system using a third-party-distributed RPM package; if that is not the case, follow the instructions given in [Section 3.8, “Upgrading MySQL with the MySQL Yum Repository”](#) or [Replacing a Third-Party Distribution of MySQL Using the MySQL Yum Repository](#).

Note

Repository setup RPM file names begin with `mysql80-community` to highlight the default active MySQL subrepository, which is MySQL 8.0 today. They also install subrepositories for the MySQL innovation track, which allows installing and upgrading the MySQL 8.3 innovation release.

Steps for a Fresh Installation of MySQL

Follow these steps to choose and install the latest MySQL products:

Adding the MySQL Yum Repository

Add the MySQL Yum repository to your system's repository list. This is typically a one-time operation that's performed by installing the RPM provided by MySQL. Follow these steps:

- Download it from the MySQL Yum Repository page (<https://dev.mysql.com/downloads/repo/yum/>) in the MySQL Developer Zone.
- Select and download the release package for your platform.
- Install the downloaded release package. The package file format is:

```
mysql80-community-release-{platform}-{version-number}.noarch.rpm
```

- mysql80*: Indicates the MySQL version that's enabled by default. In this case, MySQL 8.0 is enabled by default and MySQL 8.3 (the innovation track) is available but disabled by default.
- {platform}*: The platform code, such as el7, el8, el9, fc37, fc38, or fc39. The 'el' represents Enterprise Linux, 'fc' for Fedora, and it ends with the platform's base version number.
- {version-number}*: Version of the MySQL repository configuration RPM as they do receive occasional updates.

Install the RPM you downloaded for your system, for example:

```
$> sudo yum localinstall mysql80-community-release-{platform}-{version-number}.noarch.rpm
```

The installation command adds the MySQL Yum repository to your system's repository list and downloads the GnuPG key to check the integrity of the software packages. See [Section 2.1.4.2, “Signature Checking Using GnuPG”](#) for details on GnuPG key checking.

You can check that the MySQL Yum repository has been successfully added and enabled by the following command (for dnf-enabled systems, replace *yum* in the command with *dnf*):

```
$> yum repolist enabled | grep mysql.*-community
```

Example output:

```
mysql-connectors-community      MySQL Connectors Community
mysql-tools-community          MySQL Tools Community
mysql80-community              MySQL 8.0 Community Server
```

This also demonstrates that the latest bugfix or LTS MySQL version is enabled by default. Methods to choose a different release series, such as the innovation track (which today is 8.3), are described below.

Note

Once the MySQL Yum repository is enabled on your system, any system-wide update by the *yum update* command (or *dnf upgrade* for dnf-enabled systems) upgrades MySQL packages on your system and replaces any native third-party packages, if Yum finds replacements for them in the MySQL Yum repository; see [Section 3.8, “Upgrading MySQL with the MySQL Yum Repository”](#), for a discussion on some possible effects of that on your system, see [Upgrading the Shared Client Libraries](#).

Selecting a Release Series

When using the MySQL Yum repository, the latest bugfix series (currently MySQL 8.0) is selected for installation by default. If this is what you want, you can skip to the next step, [Installing MySQL](#).

Within the MySQL Yum repository, each MySQL Community Server release series is hosted in a different subrepository. The subrepository for the latest bugfix series (currently MySQL 8.0) is enabled by default, and the subrepositories for all other series' (for example, the MySQL

Innovation series) are disabled by default. Use this command to see all available MySQL-related subrepositories (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
$> yum repolist all | grep mysql
```

Example output:

```
mysql-connectors-community          MySQL Connectors Community   enabled
mysql-connectors-community-debuginfo MySQL Connectors Community - disabled
mysql-connectors-community-source   MySQL Connectors Community - disabled
mysql-innovation-community          MySQL Innovation Release Com disabled
mysql-innovation-community-debuginfo MySQL Innovation Release Com disabled
mysql-innovation-community-source   MySQL Innovation Release Com disabled
mysql-tools-community              MySQL Tools Community        enabled
mysql-tools-community-debuginfo     MySQL Tools Community - Debu disabled
mysql-tools-community-source        MySQL Tools Community - Sour disabled
mysql-tools-innovation-community    MySQL Tools Innovation Commu disabled
mysql-tools-innovation-community-debuginfo MySQL Tools Innovation Commu disabled
mysql-tools-innovation-community-source MySQL Tools Innovation Commu disabled
mysql80-community                  MySQL 8.0 Community Server   enabled
mysql80-community-debuginfo         MySQL 8.0 Community Server - disabled
mysql80-community-source            MySQL 8.0 Community Server - disabled
```

To install the latest release from a specific series other than the latest bugfix series, disable the bug subrepository for the latest bugfix series and enable the subrepository for the specific series before running the installation command. If your platform supports the `yum-config-manager` or `dnf config-manager` command, you can do that by issuing the following commands to disable the subrepository for the 8.0 series and enable the one for the innovation track:

```
$> sudo yum-config-manager --disable mysql80-community
$> sudo yum-config-manager --enable mysql-innovation-community
```

For dnf-enabled platforms:

```
$> sudo dnf config-manager --disable mysql80-community
$> sudo dnf config-manager --enable mysql-innovation-community
```

Instead of using the config-manager commands you can manually edit the `/etc/yum.repos.d/mysql-community.repo` file by toggling the `enabled` option. For example, a typical default entry for EL8:

```
[mysql80-community]
name=MySQL 8.0 Community Server
baseurl=http://repo.mysql.com/yum/mysql-8.0-community/el/8/$basearch/
enabled=1
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-mysql-2023
       file:///etc/pki/rpm-gpg/RPM-GPG-KEY-mysql-2022
```

Find the entry for the subrepository you want to configure and edit the `enabled` option. Specify `enabled=0` to disable a subrepository or `enabled=1` to enable a subrepository. For example, to install from the MySQL innovation track, make sure you have `enabled=0` for the MySQL 8.0 subrepository entries and have `enabled=1` for the innovation entries:

```
[mysql-innovation-community]
name=MySQL Innovation Release Community Server
baseurl=http://repo.mysql.com/yum/mysql-innovation-community/el/8/$basearch
enabled=1
gpgcheck=1
```

```
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-mysql-2023
```

You should only enable subrepository for one release series at any time.

Verify that the correct subrepositories have been enabled and disabled by running the following command and checking its output (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
$> yum repolist enabled | grep mysql
```

Disabling the Default MySQL Module

(EL8 systems only) EL8-based systems such as RHEL8 and Oracle Linux 8 include a MySQL module that is enabled by default. Unless this module is disabled, it masks packages provided by MySQL repositories. To disable the included module and make the MySQL repository packages visible, use the following command (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
$> sudo yum module disable mysql
```

Installing MySQL

Install MySQL by the following command (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
$> sudo yum install mysql-community-server
```

This installs the package for MySQL server (`mysql-community-server`) and also packages for the components required to run the server, including packages for the client (`mysql-community-client`), the common error messages and character sets for client and server (`mysql-community-common`), and the shared client libraries (`mysql-community-libs`).

Starting the MySQL Server

Start the MySQL server with the following command:

```
$> systemctl start mysqld
```

You can check the status of the MySQL server with the following command:

```
$> systemctl status mysqld
```

If the operating system is systemd enabled, standard `systemctl` (or alternatively, `service` with the arguments reversed) commands such as `stop`, `start`, `status`, and `restart` should be used to manage the MySQL server service. The `mysqld` service is enabled by default, and it starts at system reboot. See [Section 2.5.9, “Managing MySQL Server with systemd”](#) for additional information.

At the initial start up of the server, the following happens, given that the data directory of the server is empty:

- The server is initialized.
- SSL certificate and key files are generated in the data directory.
- `validate_password` is installed and enabled.
- A superuser account `'root'@'localhost'` is created. A password for the superuser is set and stored in the error log file. To reveal it, use the following command:

```
$> sudo grep 'temporary password' /var/log/mysqld.log
```

Change the root password as soon as possible by logging in with the generated, temporary password and set a custom password for the superuser account:

```
$> mysql -uroot -p
```

```
mysql> ALTER USER 'root'@'localhost' IDENTIFIED BY 'MyNewPass4!';
```

Note

`validate_password` is installed by default. The default password policy implemented by `validate_password` requires that passwords contain at least one uppercase letter, one lowercase letter, one digit, and one special character, and that the total password length is at least 8 characters.

For more information on the postinstallation procedures, see [Section 2.9, “Postinstallation Setup and Testing”](#).

Note

Compatibility Information for EL7-based platforms: The following RPM packages from the native software repositories of the platforms are incompatible with the package from the MySQL Yum repository that installs the MySQL server. Once you have installed MySQL using the MySQL Yum repository, you cannot install these packages (and vice versa).

- `akonadi-mysql`

Installing Additional MySQL Products and Components with Yum

You can use Yum to install and manage individual components of MySQL. Some of these components are hosted in sub-repositories of the MySQL Yum repository: for example, the MySQL Connectors are to be found in the MySQL Connectors Community sub-repository, and the MySQL Workbench in MySQL Tools Community. You can use the following command to list the packages for all the MySQL components available for your platform from the MySQL Yum repository (for `dnf`-enabled systems, replace `yum` in the command with `dnf`):

```
$> sudo yum --disablerepo=* --enablerepo='mysql*-community*' list available
```

Install any packages of your choice with the following command, replacing `package-name` with name of the package (for `dnf`-enabled systems, replace `yum` in the command with `dnf`):

```
$> sudo yum install package-name
```

For example, to install MySQL Workbench on Fedora:

```
$> sudo dnf install mysql-workbench-community
```

To install the shared client libraries (for `dnf`-enabled systems, replace `yum` in the command with `dnf`):

```
$> sudo yum install mysql-community-libs
```

Platform Specific Notes

ARM Support

ARM 64-bit (aarch64) is supported on Oracle Linux 7 and requires the Oracle Linux 7 Software Collections Repository (`ol7_software_collections`). For example, to install the server:

```
$> yum-config-manager --enable ol7_software_collections
$> yum install mysql-community-server
```

Updating MySQL with Yum

Besides installation, you can also perform updates for MySQL products and components using the MySQL Yum repository. See [Section 3.8, “Upgrading MySQL with the MySQL Yum Repository”](#) for details.

Replacing a Third-Party Distribution of MySQL Using the MySQL Yum Repository

To replace third-party distributions of MySQL that were installed from the supported Linux platforms' native software repositories with the latest bug release (from the MySQL 8.0 series currently) from the MySQL Yum repository, follow these steps:

Replacing a Native Third-Party Distribution of MySQL

If you have installed a third-party distribution of MySQL from a native software repository (that is, a software repository provided by your own Linux distribution), follow these steps:

Backing Up Your Database

To avoid loss of data, always back up your database before trying to replace your MySQL installation using the MySQL Yum repository. See [Chapter 9, Backup and Recovery](#), on how to back up your database.

Adding the MySQL Yum Repository

Add the MySQL Yum repository to your system's repository list by following the instructions given in [Adding the MySQL Yum Repository](#).

Replacing the Native Third-Party Distribution by a Yum Update or a DNF Upgrade

By design, the MySQL Yum repository replaces your native, third-party MySQL with the latest bugfix release from the MySQL Yum repository when you perform a `yum update` command (or `dnf upgrade` for dnf-enabled systems) on the system, or a `yum update mysql-server` (or `dnf upgrade mysql-server` for dnf-enabled systems).

After updating MySQL using the Yum repository, applications compiled with older versions of the shared client libraries should continue to work. However, *if you want to recompile applications and dynamically link them with the updated libraries*, see [Upgrading the Shared Client Libraries](#), for some special considerations.

Note

For EL7-based platforms: See [Compatibility Information for EL7-based platforms \[92\]](#).

2.5.2 Installing MySQL on Linux Using the MySQL APT Repository

Steps for a Fresh Installation of MySQL

Note

The following instructions assume that no versions of MySQL (whether distributed by Oracle or other parties) have already been installed on your system; if that is not the case, follow the instructions given in [Replacing a Native Distribution of MySQL Using the MySQL APT Repository](#) or [Replacing a MySQL Server Installed by a Direct deb Package Download](#) instead.

Adding the MySQL Yum Repository. First, add the MySQL APT repository to your system's software repository list. Follow these steps:

1. Go to the download page for the MySQL APT repository at <https://dev.mysql.com/downloads/repo/apt/>.
2. Select and download the release package for your Linux distribution.

Although this is not required for each update, it does update MySQL repository information to include the current information. For example, `mysql-apt-config_0.8.26-1_all.deb` is the

first APT repository configuration file that adds the innovation release track that begins with MySQL 8.1.

3. Install the downloaded release package with the following command, replacing `version-specific-package-name` with the name of the downloaded package (preceded by its path, if you are not running the command inside the folder where the package is):

```
$> sudo dpkg -i /PATH/version-specific-package-name.deb
```

For example, for version `w.x.y-z` of the package, the command is:

```
$> sudo dpkg -i mysql-apt-config_w.x.y-z_all.deb
```

Note that the same package works on all supported Debian and Ubuntu platforms.

4. During the installation of the package, you will be asked to choose the versions of the MySQL server and other components (for example, the MySQL Workbench) that you want to install. If you are not sure which version to choose, do not change the default options selected for you. You can also choose **none** if you do not want a particular component to be installed. After making the choices for all components, choose **Ok** to finish the configuration and installation of the release package.

Note

The innovation track, which begins with MySQL 8.1, includes "-innovation-" in the component name.

You can always change your choices for the versions later; see [Selecting a Major Release Version](#) for instructions.

5. Update package information from the MySQL APT repository with the following command (*this step is mandatory*):

```
$> sudo apt-get update
```

Instead of using the release package, you can also add and configure the MySQL APT repository manually; see [Appendix A: Adding and Configuring the MySQL APT Repository Manually](#) for details.

Note

Once the MySQL APT repository is enabled on your system, you will no longer be able to install any MySQL packages from your platform's native software repositories until the MySQL APT repository is disabled.

Note

Once the MySQL APT repository is enabled on your system, any system-wide upgrade by the `apt-get upgrade` command will automatically upgrade the MySQL packages on your system and also replace any native MySQL packages you installed from your Linux distribution's software repository, if APT finds replacements for them from within the MySQL APT repository.

Selecting a Major Release Version

By default, all installations and upgrades for your MySQL server and the other required components come from the release series of the major version you have selected during the installation of the configuration package (see [Adding the MySQL Yum Repository](#)). However, you can switch to another supported major release series at any time by reconfiguring the configuration package you have installed. Use the following command:

```
$> sudo dpkg-reconfigure mysql-apt-config
```

A dialogue box then asks you to choose the major release version you want. Make your selection and choose **Ok**. After returning to the command prompt, update package information from the MySQL APT repository with this command:

```
$> sudo apt-get update
```

The latest version in the selected series will then be installed when you use the `apt-get install` command next time.

You can use the same method to change the version for any other MySQL component you want to install with the MySQL APT repository.

Installing MySQL with APT

Install MySQL by the following command:

```
$> sudo apt-get install mysql-server
```

This installs the package for the MySQL server, as well as the packages for the client and for the database common files.

During the installation, you are asked to supply a password for the root user for your MySQL installation.

Important

Make sure you remember the root password you set. Users who want to set a password later can leave the **password** field blank in the dialogue box and just press **Ok**; in that case, root access to the server will be authenticated by [Section 8.4.1.10, “Socket Peer-Credential Pluggable Authentication”](#) for connections using a Unix socket file. You can set the root password later using the program `mysql_secure_installation`.

Starting and Stopping the MySQL Server

The MySQL server is started automatically after installation. You can check the status of the MySQL server with the following command:

```
$> systemctl status mysql
```

If the operating system is systemd enabled, standard `systemctl` (or alternatively, `service` with the arguments reversed) commands such as `stop`, `start`, `status`, and `restart` should be used to manage the MySQL server service. The `mysql` service is enabled by default, and it starts at system reboot. See [Section 2.5.9, “Managing MySQL Server with systemd”](#) for additional information.

Note

A few third-party native repository packages that have dependencies on the native MySQL packages may not work with the MySQL APT repository packages and should not be used together with them; these include `akonadi-backend-mysql`, `handlersocket-mysql-5.5`, and `zoneminder`.

Installing Additional MySQL Products and Components with APT

You can use APT to install individual components of MySQL from the MySQL APT repository. Assuming you already have the MySQL APT repository on your system's repository list (see [Adding the MySQL Yum Repository](#) for instructions), first, use the following command to get the latest package information from the MySQL APT repository:

```
$> sudo apt-get update
```

Install any packages of your choice with the following command, replacing `package-name` with name of the package to install:

```
$> sudo apt-get install package-name
```

For example, to install the MySQL Workbench:

```
$> sudo apt-get install mysql-workbench-community
```

To install the shared client libraries:

```
$> sudo apt-get install libmysqlclient21
```

Installing MySQL from Source with the MySQL APT Repository

Note

This feature is only supported on 64-bit systems.

You can download the source code for MySQL and build it using the MySQL APT Repository:

1. Add the MySQL APT repository to your system's repository list and choose the major release series you want (see [Adding the MySQL Yum Repository](#) for instructions).
2. Update package information from the MySQL APT repository with the following command (*this step is mandatory*):

```
$> sudo apt-get update
```

3. Install packages that the build process depends on:

```
$> sudo apt-get build-dep mysql-server
```

4. Download the source code for the major components of MySQL and then build them (run this command in the folder in which you want the downloaded files and the builds to be located):

```
$> apt-get source -b mysql-server
```

`deb` packages for installing the various MySQL components are created.

5. Pick the `deb` packages for the MySQL components you need and install them with the command:

```
$> sudo dpkg -i package-name.deb
```

Notice that dependency relationships exist among the MySQL packages. For a basic installation of the MySQL server, install the database common files package, the client package, the client metapackage, the server package, and the server metapackage (in that order) with the following steps:

- Preconfigure the MySQL server package with the following command:

```
$> sudo dpkg-preconfigure mysql-community-server_version-and-platform-specific-part.deb
```

You will be asked to provide a password for the root user for your MySQL installation; see important information on root password given in [Installing MySQL with APT](#) above. You might also be asked other questions regarding the installation.

- Install the required packages with a single command:

```
$> sudo dpkg -i mysql-{common,community-client,client,community-server,server}*.deb
```

- If you are being warned of unmet dependencies by `dpkg`, you can fix them using `apt-get`:

```
sudo apt-get -f install
```

Here are where the files are installed on the system:

- All configuration files (like `my.cnf`) are under `/etc/mysql`
- All binaries, libraries, headers, etc., are under `/usr/bin` and `/usr/sbin`
- The data directory is under `/var/lib/mysql`

See also information given in [Starting and Stopping the MySQL Server](#).

Upgrading MySQL with the MySQL APT Repository

Notes

- Before performing any upgrade to MySQL, follow carefully the instructions in [Chapter 3, Upgrading MySQL](#). Among other instructions discussed there, *it is especially important to back up your database before the upgrade*.
- The following instructions assume that MySQL has been installed on your system using the MySQL APT repository; if that is not the case, follow the instructions given in [Replacing a Native Distribution of MySQL Using the MySQL APT Repository](#) or [Replacing a MySQL Server Installed by a Direct deb Package Download](#) instead. Also notice that you cannot use the MySQL APT repository to upgrade a distribution of MySQL that you have installed from a nonnative software repository (for example, from MariaDB or Percona).

Use the MySQL APT repository to perform an in-place upgrade for your MySQL installation (that is, replacing the old version and then running the new version using the old data files) by following these steps:

1. Make sure you already have the MySQL APT repository on your system's repository list (see [Adding the MySQL Yum Repository](#) for instructions).
2. Make sure you have the most up-to-date package information on the MySQL APT repository by running:

```
$> sudo apt-get update
```

3. Note that, by default, the MySQL APT repository will update MySQL to the release series you have selected when you were [adding the MySQL APT repository to your system](#). If you want to upgrade to another release series, select it by following the steps given in [Selecting a Major Release Version](#).

As a general rule, to upgrade from one release series to another, go to the next series rather than skipping a series. For example, if you are currently running MySQL 5.6 and wish to upgrade to a newer series, upgrade to MySQL 5.7 first before upgrading to 8.0.

Important

- For important information about upgrading from MySQL 5.6 to 5.7, see [Upgrading from MySQL 5.6 to 5.7](#).
- For important information about upgrading from MySQL 5.7 to 8.0, see [Upgrading from MySQL 5.7 to 8.0](#).
- In-place downgrading of MySQL is not supported by the MySQL APT repository. Follow the instructions in [Chapter 4, Downgrading MySQL](#).

- Upgrade MySQL by the following command:

```
$> sudo apt-get install mysql-server
```

The MySQL server, client, and the database common files are upgraded if newer versions are available. To upgrade any other MySQL package, use the same `apt-get install` command and supply the name for the package you want to upgrade:

```
$> sudo apt-get install package-name
```

To see the names of the packages you have installed from the MySQL APT repository, use the following command:

```
$> dpkg -l | grep mysql | grep ii
```

Note

If you perform a system-wide upgrade using `apt-get upgrade`, only the MySQL library and development packages are upgraded with newer versions (if available). To upgrade other components including the server, client, test suite, etc., use the `apt-get install` command.

- The MySQL server always restarts after an update by APT. Prior to MySQL 8.0.16, run `mysql_upgrade` after the server restarts to check and possibly resolve any incompatibilities between the old data and the upgraded software. `mysql_upgrade` also performs other functions; see [Section 6.4.5, “mysql_upgrade — Deprecated; Performs No Tasks and Exits with Status 0”](#) for details. As of MySQL 8.0.16, this step is not required, as the server performs all tasks previously handled by `mysql_upgrade`.

Replacing a Native Distribution of MySQL Using the MySQL APT Repository

Variants and forks of MySQL are distributed by different parties through their own software repositories or download sites. You can replace a native distribution of MySQL installed from your Linux platform's software repository with a distribution from the MySQL APT repository in a few steps.

Note

The MySQL APT repository can only replace distributions of MySQL maintained and distributed by Debian or Ubuntu. It cannot replace any MySQL forks found either inside or outside of the distributions' native repositories. To replace such MySQL forks, you have to uninstall them first before you install MySQL using the MySQL APT repository. Follow the instructions for uninstallation from the forks' distributors and, before you proceed, make sure you back up your data and you know how to restore them to a new server.

Warning

A few third-party native repository packages that have dependencies on the native MySQL packages may not work with the MySQL APT repository packages and should not be used together with them; these include `akonadi-backend-mysql`, `handlersocket-mysql-5.5`, and `zoneminder`.

Backing Up Your Database

To avoid loss of data, always back up your database before trying to replace your MySQL installation using the MySQL APT repository. See [Chapter 9, Backup and Recovery](#) for instructions.

Adding the MySQL APT Repository and Selecting a Release Series

Add the MySQL APT repository to your system's repository list and select the release series you want by following the instructions given in [Adding the MySQL Yum Repository](#).

Replacing the Native Distribution by an APT Update

By design, the MySQL APT repository replaces your native distribution of MySQL when you perform upgrades on the MySQL packages. To perform the upgrades, follow the same instructions given in [Step 4 in Upgrading MySQL with the MySQL APT Repository](#).

Warning

Once the native distribution of MySQL has been replaced using the MySQL APT repository, purging the old MySQL packages from the native repository using the `apt-get purge`, `apt-get remove --purge`, or `dpkg -P` command might impact the newly installed MySQL server in various ways. Therefore, *do not purge the old MySQL packages from the native repository packages*.

Replacing a MySQL Server Installed by a Direct deb Package Download

`deb` packages from MySQL for installing the MySQL server and its components can either be downloaded from the [MySQL Developer Zone's MySQL Download page](#) or from the MySQL APT repository. The `deb` packages from the two sources are different, and they install and configure MySQL in different ways.

If you have installed MySQL with the MySQL Developer Zone's `deb` packages and now want to replace the installation using the ones from the MySQL APT repository, follow these steps:

1. Back up your database. See [Chapter 9, Backup and Recovery](#) for instructions.
2. Follow the steps given previously for [adding the MySQL APT repository](#).
3. Remove the old installation of MySQL by running:

```
$> sudo dpkg -P mysql
```

4. Install MySQL from the MySQL APT repository:

```
$> sudo apt-get install mysql-server
```

5. If needed, restore the data on the new MySQL installation. See [Chapter 9, Backup and Recovery](#) for instructions.

Removing MySQL with APT

To uninstall the MySQL server and the related components that have been installed using the MySQL APT repository, first, remove the MySQL server using the following command:

```
$> sudo apt-get remove mysql-server
```

Then, remove any other software that was installed automatically with the MySQL server:

```
$> sudo apt-get autoremove
```

To uninstall other components, use the following command, replacing `package-name` with the name of the package of the component you want to remove:

```
$> sudo apt-get remove package-name
```

To see a list of packages you have installed from the MySQL APT repository, use the following command:

```
$> dpkg -l | grep mysql | grep ii
```

Special Notes on Upgrading the Shared Client Libraries

You can install the shared client libraries from MySQL APT repository by the following command (see [Installing Additional MySQL Products and Components with APT](#) for more details):

```
$> sudo apt-get install libmysqlclient21
```

If you already have the shared client libraries installed from your Linux platform's software repository, it can be updated by the MySQL APT repository with its own package by using the same command (see [Replacing the Native Distribution by an APT Update](#) for more details).

After updating MySQL using the APT repository, applications compiled with older versions of the shared client libraries should continue to work.

If you recompile applications and dynamically link them with the updated libraries: as typical with new versions of shared libraries, any applications compiled using the updated, newer shared libraries might require those updated libraries on systems where the applications are deployed. If those libraries are not in place, the applications requiring the shared libraries might fail. Therefore, it is recommended that the packages for the shared libraries from MySQL be deployed on those systems. You can do this by adding the MySQL APT repository to the systems (see [Adding the MySQL Yum Repository](#)) and installing the latest shared client libraries using the command given at the beginning of this section.

Installing MySQL NDB Cluster Using the APT Repository

Notes

- The MySQL APT repository supports installation of MySQL NDB Cluster on Debian and Ubuntu systems. For methods to install NDB Cluster on other Debian-based systems, see [Installing NDB Cluster Using .deb Files](#).
- If you already have the MySQL server or MySQL NDB Cluster installed on your system, make sure it is stopped and you have your data and configuration files backed up before proceeding.

Adding the MySQL APT Repository for MySQL NDB Cluster

Follow the steps in [Adding the MySQL Yum Repository](#) to add the MySQL APT repository to your system's repository list. During the installation process of the configuration package, when you are asked which MySQL product you want to configure, choose "MySQL Server & Cluster"; when asked which version you wish to receive, choose "mysql-cluster-*x.y*." After returning to the command prompt, go to Step 2 below.

If you already have the configuration package installed on your system, make sure it is up-to-date by running the following command:

```
$> sudo apt-get install mysql-apt-config
```

Then, use the same method described in [Selecting a Major Release Version](#) to select MySQL NDB Cluster for installation. When you are asked which MySQL product you want to configure, choose "MySQL Server & Cluster"; when asked which version you wish to receive, choose "mysql-cluster-*x.y*." After returning to the command prompt, update package information from the MySQL APT repository with this command:

```
$> sudo apt-get update
```

Installing MySQL NDB Cluster

For a minimal installation of MySQL NDB Cluster, follow these steps:

- Install the components for SQL nodes:

```
$> sudo apt-get install mysql-cluster-community-server
```

You will be asked to provide a password for the root user for your SQL node; see important information on the root password given in [Installing MySQL with APT](#) above. You might also be asked other questions regarding the installation.

- Install the executables for management nodes:

```
$> sudo apt-get install mysql-cluster-community-management-server
```

- Install the executables for data nodes:

```
$> sudo apt-get install mysql-cluster-community-data-node
```

Configuring and Starting MySQL NDB Cluster

See [Section 25.3.3, “Initial Configuration of NDB Cluster”](#) on how to configure MySQL NDB Cluster and [Section 25.3.4, “Initial Startup of NDB Cluster”](#) on how to start it for the first time. When following those instructions, adjust them according to the following details regarding the SQL nodes of your NDB Cluster installation:

- All configuration files (like `my.cnf`) are under `/etc/mysql`
- All binaries, libraries, headers, etc., are under `/usr/bin` and `/usr/sbin`
- The data directory is `/var/lib/mysql`

Installing Additional MySQL NDB Cluster Products and Components

You can use APT to install individual components and additional products of MySQL NDB Cluster from the MySQL APT repository. To do that, assuming you already have the MySQL APT repository on your system's repository list (see [Adding the MySQL Yum Repository for MySQL NDB Cluster](#)), follow the same steps given in [Installing Additional MySQL Products and Components with APT](#).

Note

Known issue: Currently, not all components required for running the MySQL NDB Cluster test suite are installed automatically when you install the test suite package (`mysql-cluster-community-test`). Install the following packages with `apt-get install` before you run the test suite:

- `mysql-cluster-community-auto-installer`
- `mysql-cluster-community-management-server`
- `mysql-cluster-community-data-node`
- `mysql-cluster-community-memcached`
- `mysql-cluster-community-java`
- `ndbclient-dev`

Appendix A: Adding and Configuring the MySQL APT Repository Manually

Here are the steps for adding manually the MySQL APT repository to your system's software repository list and configuring it, without using the release packages provided by MySQL:

- Download the MySQL GPG Public key (see [Section 2.1.4.2, “Signature Checking Using GnuPG”](#) on how to do that) and save it to a file, without adding any spaces or special characters. Then, add the key to your system's GPG keyring with the following command:

```
$> sudo apt-key add path/to/signature-file
```

- Alternatively, you can download the GPG key to your APT keyring directly using the `apt-key` utility:

```
$> sudo apt-key adv --keyserver pgp.mit.edu --recv-keys 3A79BD29
```

**Note**

The KeyID for MySQL 8.0.28 release packages and higher is [3A79BD29](#), as shown above. For earlier MySQL releases, the keyID is [5072E1F5](#). Using an incorrect key can cause a key verification error.

- Create a file named `/etc/apt/sources.list.d/mysql.list`, and put into it repository entries in the following format (this is not a command to execute):

```
deb http://repo.mysql.com/apt/{debian|ubuntu}/ {buster|bionic} {mysql-5.7|mysql-8.0|workbench-8.0|connector-python-8.0}
```

Pick the relevant options for your repository set up:

- Choose “debian” or “ubuntu” according to your platform.
- Choose the appropriate version name for the version of your system; examples include “bullseye” (for Debian 11) and “jammy” (for Ubuntu 22.04).
- For installing MySQL server, client, and database common files, choose “mysql-5.7” or “mysql-8.0” according to the MySQL version you want. To switch to another release series later, come back and adjust the entry with your new choice.

**Note**

If you already have a version of MySQL installed on your system, do not choose a lower version at this step, or it might result in an unsupported downgrade operation.

- For installing components like MySQL Workbench or MySQL Connector/Python, create a single entry for each of them, specifying respectively “workbench-8.0” or “connector-python-8.0” at the end of each entry.

For example, on the Ubuntu 18.04 platform use these lines in your `mysql.list` files to install MySQL 8.0 and MySQL Connector/Python from the MySQL APT repository:

```
deb http://repo.mysql.com/apt/ubuntu/ bionic mysql-8.0
deb http://repo.mysql.com/apt/ubuntu/ bionic connector-python-8.0
```

- Use the following command to get the most up-to-date package information from the MySQL APT repository:

```
$> sudo apt-get update
```

You have configured your system to use the MySQL APT repository and are now ready to continue with [Installing MySQL with APT](#) or [Installing Additional MySQL Products and Components with APT](#).

2.5.3 Using the MySQL SLES Repository

Adding the MySQL SLES Repository

The MySQL SLES repository provides RPM packages for installing and managing the MySQL server, client, and other components on SUSE Enterprise Linux Server.

Add or update the official MySQL SLES repository for your system's repository list:

**Note**

The “[mysql180](#)” in the repository file name indicates that the MySQL 8.0 series is enabled by default, but it also includes the optional “Innovation” track that starts with MySQL 8.1.

New MySQL Repository Installation

If the MySQL repository is not yet present on the system then:

1. Go to the download page for MySQL SLES repository at <https://dev.mysql.com/downloads/repo/suse/>.
2. Select and download the release package for your SLES version.
3. Install the downloaded release package with the following command, replacing *package-name* with the name of the downloaded package:

```
$> sudo rpm -Uvh package-name.rpm
```

For example, to install the SLES 15 package where *#* indicates the release number within a version such as *15-1*:

```
$> sudo rpm -Uvh mysql80-community-release-sl15-#.noarch.rpm
```

Update an Existing MySQL Repository Installation

If an older version is already present then update it:

```
$> sudo zypper update mysql80-community-release
```

- Although this is not required for each MySQL release, it does update MySQL repository information to include the current information. For example, *mysql80-community-release-sl15-7.noarch.rpm* is the first SUSE 15 repository configuration file that adds the innovation release track that begins with MySQL 8.1. series.

Selecting a Release Series

Within the MySQL SLES repository, different release series of the MySQL Community Server are hosted in different subrepositories. The subrepository for the latest bugfix series (currently MySQL 8.0) is enabled by default, and the subrepositories for all other series are disabled. Use this command to see all of the subrepositories in the MySQL SLES repository, and to see which of them are enabled or disabled:

```
$> zypper repos | grep mysql.*community
```

The innovation track is available for SLES 15 as of MySQL 8.1, with entries such as *mysql-innovation-community*.

To install the latest release from a specific series, before running the installation command, make sure that the subrepository for the series you want is enabled and the subrepositories for other series are disabled. For example, on SLES 15, to disable the subrepositories for MySQL 8.0 server and tools, which are enabled by default, use the following:

```
$> sudo zypper modifyrepo -d mysql80-community
$> sudo zypper modifyrepo -d mysql-tools-community
```

Then, enable the subrepositories for the release series you want. For example, to enable the Innovation track on SLES 15:

```
$> sudo zypper modifyrepo -e mysql-innovation-community
$> sudo zypper modifyrepo -e mysql-tools-innovation-community
```

You should only enable a subrepository for one release series at any time.

Verify that the correct subrepositories have been enabled by running the following command and checking its output:

```
$> zypper repos -E | grep mysql.*community
```

```
7 | mysql-connectors-community | MySQL Connectors Community | Yes | (r ) Ye
```

10	mysql-innovation-community	MySQL Innovation Release Community Server	Yes	(r) Yes
16	mysql-tools-innovation-community	MySQL Tools Innovation Community	Yes	(p) Yes

After that, use the following command to refresh the repository information for the enabled subrepository:

```
$> sudo zypper refresh
```

Installing MySQL with Zypper

With the official MySQL repository enabled, install MySQL Server:

```
$> sudo zypper install mysql-community-server
```

This installs the package for the MySQL server, as well as other required packages.

Starting the MySQL Server

Start the MySQL server with the following command:

```
$> systemctl start mysql
```

You can check the status of the MySQL server with the following command:

```
$> systemctl status mysql
```

If the operating system is systemd enabled, standard `systemctl` (or alternatively, `service` with the arguments reversed) commands such as `stop`, `start`, `status`, and `restart` should be used to manage the MySQL server service. The `mysql` service is enabled by default, and it starts at system reboot. See [Section 2.5.9, “Managing MySQL Server with systemd”](#) for additional information.

MySQL Server Initialization: When the server is started for the first time, the server is initialized, and the following happens (if the data directory of the server is empty when the initialization process begins):

- The SSL certificate and key files are generated in the data directory.
- The [validate_password plugin](#) is installed and enabled.
- A superuser account '`root`'@'`localhost`' is created. A password for the superuser is set and stored in the error log file. To reveal it, use the following command:

```
$> sudo grep 'temporary password' /var/log/mysql/mysqld.log
```

Change the root password as soon as possible by logging in with the generated, temporary password and set a custom password for the superuser account:

```
$> mysql -uroot -p
```

```
mysql> ALTER USER 'root'@'localhost' IDENTIFIED BY 'MyNewPass4!';
```

Note

MySQL's [validate_password](#) plugin is installed by default. This will require that passwords contain at least one uppercase letter, one lowercase letter, one digit, and one special character, and that the total password length is at least 8 characters.

You can stop the MySQL Server with the following command:

```
$> sudo systemctl stop mysql
```

Installing Additional MySQL Products and Components

You can install more components of MySQL. List subrepositories in the MySQL SLES repository with the following command:

```
$> zypper repos | grep mysql.*community
```

Use the following command to list the packages for the MySQL components available for a certain subrepository, changing *subrepo-name* to the name of the subrepository you are interested in :

```
$> zypper packages subrepo-name
```

Install any packages of your choice with the following command, replacing *package-name* with name of the package (you might need to enable first the subrepository for the package, using the same method for selecting a subrepository for a specific release series outlined in [Selecting a Release Series](#)):

```
$> sudo zypper install package-name
```

For example, to install the MySQL benchmark suite from the subrepository for the release series you have already enabled:

```
$> sudo zypper install mysql-community-bench
```

Upgrading MySQL with the MySQL SLES Repository

Note

- Before performing any update to MySQL, follow carefully the instructions in [Chapter 3, Upgrading MySQL](#). Among other instructions discussed there, it is especially important to back up your database before the update.

Use the MySQL SLES repository to perform an in-place update (that is, replacing the old version of the server and then running the new version using the old data files) for your MySQL installation by following these steps (they assume you have installed MySQL with the MySQL SLES repository; if that is not the case, following the instructions in [Replacing MySQL Installed by an RPM from Other Sources](#) instead):

Selecting^{1a} Target Series

During an update operation, by default, the MySQL SLES repository updates MySQL to the latest version in the release series you have chosen during installation (see [Selecting a Release Series](#) for details), which means. For example, a bugfix series installation, such as 8.0, will *not* update to an innovation series, such as 8.3. To update to another release series, you need to first disable the subrepository for the series that has been selected (by default, or by yourself) and enable the subrepository for your target series. To do that, follow the general instructions given in [Selecting a Release Series](#).

As a general rule, to upgrade from one release series to another, go to the next series rather than skipping a series.

Important

- For important information about upgrading from MySQL 5.7 to 8.0, see [Upgrading from MySQL 5.7 to 8.0](#).
- For important information about upgrading from MySQL 8.0 to an innovation series, see [Upgrading from MySQL 8.0 to 8.3](#).
- In-place downgrading of MySQL is not supported by the MySQL SLES repository. Follow the instructions in [Chapter 4, Downgrading MySQL](#).

Upgrading MySQL

Upgrade MySQL and its components by the following command:

```
$> sudo zypper update mysql-community-server
```

Alternatively, you can update MySQL by telling Zypper to update everything on your system (this might take considerably more time):

```
$> sudo zypper update
```

You can also update a specific component only. Use the following command to list all the installed packages from the MySQL SLES repository:

```
$> zypper packages -i | grep mysql-.*community
```

After identifying the package name of the component of your choice, update the package with the following command, replacing *package-name* with the name of the package:

```
$> sudo zypper update package-name
```

Replacing MySQL Installed by an RPM from Other Sources

RPMs for installing the MySQL Community Server and its components can be downloaded from MySQL either from the [MySQL Developer Zone](#), from the native software repository of SLES, or from the MySQL SLES repository. The RPMs from the those sources might be different, and they might install and configure MySQL in different ways.

If you have installed MySQL with RPMs from the MySQL Developer Zone or the native software repository of SLES and want to replace the installation using the RPM from the MySQL SLES repository, follow these steps:

1. Back up your database to avoid data loss. See [Chapter 9, Backup and Recovery](#) on how to do that.
2. Stop your MySQL Server, if it is running. If the server is running as a service, you can stop it with the following command:

```
$> systemctl stop mysql
```

3. Follow the steps given for [Adding the MySQL SLES Repository](#).
4. Follow the steps given for [Selecting a Release Series](#).
5. Follow the steps given for [Installing MySQL with Zypper](#). You will be asked if you want to replace the old packages with the new ones; for example:

```
Problem: mysql-community-server-5.6.22-2.sles11.x86_64 requires mysql-community-client = 5.6.22-2.sles11.x86_64
but this requirement cannot be provided by available providers:
mysql-community-client-5.6.22-2.sles11.x86_64[mysql56-community]
Solution 1: replacement of mysql-client-5.5.31-0.7.10.x86_64 with mysql-community-client-5.6.22-2.sles11.x86_64
Solution 2: do not install mysql-community-server-5.6.22-2.sles11.x86_64
Solution 3: break mysql-community-server-5.6.22-2.sles11.x86_64 by ignoring some of its dependencies
Choose from above solutions by number or cancel [1/2/3/c] (c)
```

Choose the “replacement” option (“Solution 1” in the example) to finish your installation from the MySQL SLES repository.

Installing MySQL NDB Cluster Using the SLES Repository

- The following instructions assume that neither the MySQL Server nor MySQL NDB Cluster has already been installed on your system; if that is not the case, remove the MySQL Server or MySQL NDB Cluster, including all its executables, libraries, configuration files, log files, and data directories, before you continue. However there is no need to remove the release package you might have used to enable the MySQL SLES repository on your system.
- The NDB Cluster Auto-Installer package has a dependency on the [python2-crypto](#) and [python-paramiko](#) packages. Zypper can take care of this dependency if the Python repository has been enabled on your system.

Selecting the MySQL NDB Cluster Subrepository

Within the MySQL SLES repository, the MySQL Community Server and MySQL NDB Cluster are hosted in different subrepositories. By default, the subrepository for the latest bugfix series of the MySQL Server is enabled and the subrepository for MySQL NDB Cluster is disabled. To install NDB Cluster, disable the subrepository for the MySQL Server and enable the subrepository for NDB Cluster. For example, disable the subrepository for MySQL 8.0, which is enabled by default, with the following command:

```
$> sudo zypper modifyrepo -d mysql80-community
```

Then, enable the subrepository for MySQL NDB Cluster:

```
$> sudo zypper modifyrepo -e mysql-cluster-8.0-community
```

Verify that the correct subrepositories have been enabled by running the following command and checking its output:

```
$> zypper repos -E | grep mysql.*community
10 | mysql-cluster-8.0-community | MySQL Cluster 8.0 Community | Yes | No
```

After that, use the following command to refresh the repository information for the enabled subrepository:

```
$> sudo zypper refresh
```

Installing MySQL NDB Cluster

For a minimal installation of MySQL NDB Cluster, follow these steps:

- Install the components for SQL nodes:

```
$> sudo zypper install mysql-cluster-community-server
```

After the installation is completed, start and initialize the SQL node by following the steps given in [Starting the MySQL Server](#).

If you choose to initialize the data directory manually using the `mysqld --initialize` command (see [Section 2.9.1, “Initializing the Data Directory”](#) for details), a `root` password is going to be generated and stored in the SQL node's error log; see [Starting the MySQL Server](#) for how to find the password, and for a few things you need to know about it.

- Install the executables for management nodes:

```
$> sudo zypper install mysql-cluster-community-management-server
```

- Install the executables for data nodes:

```
$> sudo zypper install mysql-cluster-community-data-node
```

To install more NDB Cluster components, see [Installing Additional MySQL Products and Components](#).

See [Section 25.3.3, “Initial Configuration of NDB Cluster”](#) on how to configure MySQL NDB Cluster and [Section 25.3.4, “Initial Startup of NDB Cluster”](#) on how to start it for the first time.

Installing Additional MySQL NDB Cluster Products and Components

You can use Zypper to install individual components and additional products of MySQL NDB Cluster from the MySQL SLES repository. To do that, assuming you already have the MySQL SLES repository on your system's repository list (if not, follow Step 1 and 2 of [Installing MySQL NDB Cluster Using the SLES Repository](#)), follow the same steps given in [Installing Additional MySQL NDB Cluster Products and Components](#).

**Note**

Known issue: Currently, not all components required for running the MySQL NDB Cluster test suite are installed automatically when you install the test suite package (`mysql-cluster-community-test`). Install the following packages with `zypper install` before you run the test suite:

- `mysql-cluster-community-auto-installer`
- `mysql-cluster-community-management-server`
- `mysql-cluster-community-data-node`
- `mysql-cluster-community-memcached`
- `mysql-cluster-community-java`
- `mysql-cluster-community-ndbclient-devel`

2.5.4 Installing MySQL on Linux Using RPM Packages from Oracle

The recommended way to install MySQL on RPM-based Linux distributions is by using the RPM packages provided by Oracle. There are two sources for obtaining them, for the Community Edition of MySQL:

- From the MySQL software repositories:
 - The MySQL Yum repository (see [Section 2.5.1, “Installing MySQL on Linux Using the MySQL Yum Repository”](#) for details).
 - The MySQL SLES repository (see [Section 2.5.3, “Using the MySQL SLES Repository”](#) for details).
- From the [Download MySQL Community Server](#) page in the [MySQL Developer Zone](#).

**Note**

RPM distributions of MySQL are also provided by other vendors. Be aware that they may differ from those built by Oracle in features, capabilities, and conventions (including communication setup), and that the installation instructions in this manual do not necessarily apply to them. The vendor's instructions should be consulted instead.

MySQL RPM Packages

Table 2.8 RPM Packages for MySQL Community Edition

Package Name	Summary
<code>mysql-community-client</code>	MySQL client applications and tools
<code>mysql-community-client-plugins</code>	Shared plugins for MySQL client applications
<code>mysql-community-common</code>	Common files for server and client libraries
<code>mysql-community-devel</code>	Development header files and libraries for MySQL database client applications
<code>mysql-community-embedded-compat</code>	MySQL server as an embedded library with compatibility for applications using version 18 of the library
<code>mysql-community-icu-data-files</code>	MySQL packaging of ICU data files needed by MySQL regular expressions
<code>mysql-community-libs</code>	Shared libraries for MySQL database client applications

Package Name	Summary
<code>mysql-community-libs-compat</code>	Shared compatibility libraries for previous MySQL installations; only present if previous MySQL versions are supported by the platform
<code>mysql-community-server</code>	Database server and related tools
<code>mysql-community-server-debug</code>	Debug server and plugin binaries
<code>mysql-community-test</code>	Test suite for the MySQL server
<code>mysql-community</code>	The source code RPM looks similar to <code>mysql-community-8.3.0-1.el7.src.rpm</code> , depending on selected OS
Additional <code>*debuginfo*</code> RPMs	There are several <code>debuginfo</code> packages: <code>mysql-community-client-debuginfo</code> , <code>mysql-community-libs-debuginfo</code> , <code>mysql-community-server-debuginfo</code> , <code>mysql-community-server-debuginfo</code> , and <code>mysql-community-test-debuginfo</code> .

Table 2.9 RPM Packages for the MySQL Enterprise Edition

Package Name	Summary
<code>mysql-commercial-backup</code>	MySQL Enterprise Backup
<code>mysql-commercial-client</code>	MySQL client applications and tools
<code>mysql-commercial-client-plugins</code>	Shared plugins for MySQL client applications
<code>mysql-commercial-common</code>	Common files for server and client libraries
<code>mysql-commercial-devel</code>	Development header files and libraries for MySQL database client applications
<code>mysql-commercial-embedded-compat</code>	MySQL server as an embedded library with compatibility for applications using version 18 of the library
<code>mysql-commercial-icu-data-files</code>	MySQL packaging of ICU data files needed by MySQL regular expressions
<code>mysql-commercial-libs</code>	Shared libraries for MySQL database client applications
<code>mysql-commercial-libs-compat</code>	Shared compatibility libraries for previous MySQL installations; only present if previous MySQL versions are supported by the platform. The version of the libraries matches the version of the libraries installed by default by the distribution you are using.
<code>mysql-commercial-server</code>	Database server and related tools
<code>mysql-commercial-test</code>	Test suite for the MySQL server
Additional <code>*debuginfo*</code> RPMs	There are several <code>debuginfo</code> packages: <code>mysql-commercial-client-debuginfo</code> , <code>mysql-commercial-libs-debuginfo</code> , <code>mysql-commercial-server-debuginfo</code> , <code>mysql-commercial-server-debuginfo</code> , and <code>mysql-commercial-test-debuginfo</code> .

The full names for the RPMs have the following syntax:

```
packagename-version-distribution-arch.rpm
```

The *distribution* and *arch* values indicate the Linux distribution and the processor type for which the package was built. See the table below for lists of the distribution identifiers:

Table 2.10 MySQL Linux RPM Package Distribution Identifiers

Distribution Value	Intended Use
el{ <i>version</i> } where { <i>version</i> } is the major Enterprise Linux version, such as el8	EL6 (8.0), EL7, EL8, and EL9-based platforms (for example, the corresponding versions of Oracle Linux, Red Hat Enterprise Linux, and CentOS)
fc{ <i>version</i> } where { <i>version</i> } is the major Fedora version, such as fc37	Fedora 38 and 39
sl5	SUSE Linux Enterprise Server 15

To see all files in an RPM package (for example, `mysql-community-server`), use the following command:

```
$> rpm -qpl mysql-community-server-version-distribution-arch.rpm
```

The discussion in the rest of this section applies only to an installation process using the RPM packages directly downloaded from Oracle, instead of through a MySQL repository.

Dependency relationships exist among some of the packages. If you plan to install many of the packages, you may wish to download the RPM bundle `tar` file instead, which contains all the RPM packages listed above, so that you need not download them separately.

In most cases, you need to install the `mysql-community-server`, `mysql-community-client`, `mysql-community-client-plugins`, `mysql-community-libs`, `mysql-community-icu-data-files`, `mysql-community-common`, and `mysql-community-libs-compat` packages to get a functional, standard MySQL installation. To perform such a standard, basic installation, go to the folder that contains all those packages (and, preferably, no other RPM packages with similar names), and issue the following command:

```
$> sudo yum install mysql-community-{server,client,client-plugins,icu-data-files,common,libs}-*
```

Replace `yum` with `zypper` for SLES, and with `dnf` for Fedora.

While it is much preferable to use a high-level package management tool like `yum` to install the packages, users who prefer direct `rpm` commands can replace the `yum install` command with the `rpm -Uvh` command; however, using `rpm -Uvh` instead makes the installation process more prone to failure, due to potential dependency issues the installation process might run into.

To install only the client programs, you can skip `mysql-community-server` in your list of packages to install; issue the following command:

```
$> sudo yum install mysql-community-{client,client-plugins,common,libs}-*
```

Replace `yum` with `zypper` for SLES, and with `dnf` for Fedora.

A standard installation of MySQL using the RPM packages result in files and resources created under the system directories, shown in the following table.

Table 2.11 MySQL Installation Layout for Linux RPM Packages from the MySQL Developer Zone

Files or Resources	Location
Client programs and scripts	<code>/usr/bin</code>
<code>mysqld</code> server	<code>/usr/sbin</code>
Configuration file	<code>/etc/my.cnf</code>
Data directory	<code>/var/lib/mysql</code>
Error log file	For RHEL, Oracle Linux, CentOS or Fedora platforms: <code>/var/log/mysqld.log</code> For SLES: <code>/var/log/mysql/mysqld.log</code>
Value of <code>secure_file_priv</code>	<code>/var/lib/mysql-files</code>

Files or Resources	Location
System V init script	For RHEL, Oracle Linux, CentOS or Fedora platforms: <code>/etc/init.d/mysqld</code> For SLES: <code>/etc/init.d/mysql</code>
Systemd service	For RHEL, Oracle Linux, CentOS or Fedora platforms: <code>mysqld</code> For SLES: <code>mysql</code>
Pid file	<code>/var/run/mysql/mysqld.pid</code>
Socket	<code>/var/lib/mysql/mysql.sock</code>
Keyring directory	<code>/var/lib/mysql-keyring</code>
Unix manual pages	<code>/usr/share/man</code>
Include (header) files	<code>/usr/include/mysql</code>
Libraries	<code>/usr/lib/mysql</code>
Miscellaneous support files (for example, error messages, and character set files)	<code>/usr/share/mysql</code>

The installation also creates a user named `mysql` and a group named `mysql` on the system.

Notes

- The `mysql` user is created using the `-r` and `-s /bin/false` options of the `useradd` command, so that it does not have login permissions to your server host (see [Creating the mysql User and Group](#) for details). To switch to the `mysql` user on your OS, use the `--shell=/bin/bash` option for the `su` command:

```
su - mysql --shell=/bin/bash
```

- Installation of previous versions of MySQL using older packages might have created a configuration file named `/usr/my.cnf`. It is highly recommended that you examine the contents of the file and migrate the desired settings inside to the file `/etc/my.cnf` file, then remove `/usr/my.cnf`.

MySQL is NOT automatically started at the end of the installation process. For Red Hat Enterprise Linux, Oracle Linux, CentOS, and Fedora systems, use the following command to start MySQL:

```
$> systemctl start mysqld
```

For SLES systems, the command is the same, but the service name is different:

```
$> systemctl start mysql
```

If the operating system is systemd enabled, standard `systemctl` (or alternatively, `service` with the arguments reversed) commands such as `stop`, `start`, `status`, and `restart` should be used to manage the MySQL server service. The `mysqld` service is enabled by default, and it starts at system reboot. Notice that certain things might work differently on systemd platforms: for example, changing the location of the data directory might cause issues. See [Section 2.5.9, “Managing MySQL Server with systemd”](#) for additional information.

During an upgrade installation using RPM and DEB packages, if the MySQL server is running when the upgrade occurs then the MySQL server is stopped, the upgrade occurs, and the MySQL server is restarted. One exception: if the edition also changes during an upgrade (such as community to commercial, or vice-versa), then MySQL server is not restarted.

At the initial start up of the server, the following happens, given that the data directory of the server is empty:

- The server is initialized.
- An SSL certificate and key files are generated in the data directory.
- `validate_password` is installed and enabled.
- A superuser account '`root`'@'`localhost`' is created. A password for the superuser is set and stored in the error log file. To reveal it, use the following command for RHEL, Oracle Linux, CentOS, and Fedora systems:

```
$> sudo grep 'temporary password' /var/log/mysqld.log
```

Use the following command for SLES systems:

```
$> sudo grep 'temporary password' /var/log/mysql/mysqld.log
```

The next step is to log in with the generated, temporary password and set a custom password for the superuser account:

```
$> mysql -uroot -p
```

```
mysql> ALTER USER 'root'@'localhost' IDENTIFIED BY 'MyNewPass4!';
```

Note

`validate_password` is installed by default. The default password policy implemented by `validate_password` requires that passwords contain at least one uppercase letter, one lowercase letter, one digit, and one special character, and that the total password length is at least 8 characters.

If something goes wrong during installation, you might find debug information in the error log file `/var/log/mysqld.log`.

For some Linux distributions, it might be necessary to increase the limit on number of file descriptors available to `mysqld`. See [Section B.3.2.16, “File Not Found and Similar Errors”](#)

Installing Client Libraries from Multiple MySQL Versions. It is possible to install multiple client library versions, such as for the case that you want to maintain compatibility with older applications linked against previous libraries. To install an older client library, use the `--oldpackage` option with `rpm`. For example, to install `mysql-community-libs-5.5` on an EL6 system that has `libmysqlclient.21` from MySQL 8.0, use a command like this:

```
$> rpm --oldpackage -ivh mysql-community-libs-5.5.50-2.el6.x86_64.rpm
```

Debug Package. A special variant of MySQL Server compiled with the [debug package](#) has been included in the server RPM packages. It performs debugging and memory allocation checks and produces a trace file when the server is running. To use that debug version, start MySQL with `/usr/sbin/mysqld-debug`, instead of starting it as a service or with `/usr/sbin/mysqld`. See [Section 7.9.4, “The DEBUG Package”](#) for the debug options you can use.

Note

The default plugin directory is `/usr/lib64/mysql/plugin/debug` and is configurable with `plugin_dir`.

Rebuilding RPMs from source SRPMs. Source code SRPM packages for MySQL are available for download. They can be used as-is to rebuild the MySQL RPMs with the standard `rpmbuild` tool chain.

2.5.5 Installing MySQL on Linux Using Debian Packages from Oracle

Oracle provides Debian packages for installing MySQL on Debian or Debian-like Linux systems. The packages are available through two different channels:

- The [MySQL APT Repository](#). This is the preferred method for installing MySQL on Debian-like systems, as it provides a simple and convenient way to install and update MySQL products. For details, see [Section 2.5.2, “Installing MySQL on Linux Using the MySQL APT Repository”](#).
- The [MySQL Developer Zone's Download Area](#). For details, see [Section 2.1.3, “How to Get MySQL”](#). The following are some information on the Debian packages available there and the instructions for installing them:
- Various Debian packages are provided in the MySQL Developer Zone for installing different components of MySQL on the current Debian and Ubuntu platforms. The preferred method is to use the tarball bundle, which contains the packages needed for a basic setup of MySQL. The tarball bundles have names in the format of `mysql-server_MVER-DVER_CPU.deb-bundle.tar`. *MVER* is the MySQL version and *DVER* is the Linux distribution version. The *CPU* value indicates the processor type or family for which the package is built, as shown in the following table:

Table 2.12 MySQL Debian and Ubuntu Installation Packages CPU Identifiers

<i>CPU</i> Value	Intended Processor Type or Family
i386	Pentium processor or better, 32 bit
amd64	64-bit x86 processor

- After downloading the tarball, unpack it with the following command:

```
$> tar -xvf mysql-server_MVER-DVER_CPU.deb-bundle.tar
```

- You may need to install the `libaio` library if it is not already present on your system:

```
$> sudo apt-get install libaio1
```

- Preconfigure the MySQL server package with the following command:

```
$> sudo dpkg-preconfigure mysql-community-server_*.deb
```

You are asked to provide a password for the root user for your MySQL installation. You might also be asked other questions regarding the installation.

Important

Make sure you remember the root password you set. Users who want to set a password later can leave the **password** field blank in the dialogue box and just press **OK**; in that case, root access to the server is authenticated using the [MySQL Socket Peer-Credential Authentication Plugin](#) for connections using a Unix socket file. You can set the root password later using `mysql_secure_installation`.

- For a basic installation of the MySQL server, install the database common files package, the client package, the client metapackage, the server package, and the server metapackage (in that order); you can do that with a single command:

```
$> sudo dpkg -i mysql-{common,community-client-plugins,community-client-core,community-client,client,c
```

There are also packages with `server-core` and `client-core` in the package names. These contain binaries only and are installed automatically by the standard packages. Installing them by themselves does not result in a functioning MySQL setup.

If you are being warned of unmet dependencies by `dpkg` (such as `libmecab2`), you can fix them using `apt-get`:

```
sudo apt-get -f install
```

Here are where the files are installed on the system:

- All configuration files (like `my.cnf`) are under `/etc/mysql`
- All binaries, libraries, headers, etc., are under `/usr/bin` and `/usr/sbin`
- The data directory is under `/var/lib/mysql`

Note

Debian distributions of MySQL are also provided by other vendors. Be aware that they may differ from those built by Oracle in features, capabilities, and conventions (including communication setup), and that the instructions in this manual do not necessarily apply to installing them. The vendor's instructions should be consulted instead.

2.5.6 Deploying MySQL on Linux with Docker Containers

This section explains how to deploy MySQL Server using Docker containers.

While the `docker` client is used in the following instructions for demonstration purposes, in general, the MySQL container images provided by Oracle work with any container tools that are compliant with the [OCI 1.0 specification](#).

Warning

Before deploying MySQL with Docker containers, make sure you understand the security risks of running containers and mitigate them properly.

2.5.6.1 Basic Steps for MySQL Server Deployment with Docker

Warning

The MySQL Docker images maintained by the MySQL team are built specifically for Linux platforms. Other platforms are not supported, and users using these MySQL Docker images on them are doing so at their own risk. See [the discussion here](#) for some known limitations for running these containers on non-Linux operating systems.

- [Downloading a MySQL Server Docker Image](#)
- [Starting a MySQL Server Instance](#)
- [Connecting to MySQL Server from within the Container](#)
- [Container Shell Access](#)

- [Stopping and Deleting a MySQL Container](#)
- [Upgrading a MySQL Server Container](#)
- [More Topics on Deploying MySQL Server with Docker](#)

Downloading a MySQL Server Docker Image

Important

For users of MySQL Enterprise Edition: A subscription is required to use the Docker images for MySQL Enterprise Edition. Subscriptions work by a Bring Your Own License model; see [How to Buy MySQL Products and Services](#) for details.

Downloading the server image in a separate step is not strictly necessary; however, performing this step before you create your Docker container ensures your local image is up to date. To download the MySQL Community Edition image from the [Oracle Container Registry \(OCR\)](#), run this command:

```
docker pull container-registry.oracle.com/mysql/community-server:tag
```

The `tag` is the label for the image version you want to pull (for example, `8.0`, or `8.3`, or `latest`). If `:tag` is omitted, the `latest` label is used, and the image for the latest GA release (which is the latest innovation release) of MySQL Community Server is downloaded.

To download the MySQL Enterprise Edition image from the OCR, you need to first accept the license agreement on the OCR and log in to the container repository with your Docker client. Follow these steps:

- Visit the OCR at <https://container-registry.oracle.com/> and choose **MySQL**.
- Under the list of MySQL repositories, choose `enterprise-server`.
- If you have not signed in to the OCR yet, click the **Sign in** button on the right of the page, and then enter your Oracle account credentials when prompted to.
- Follow the instructions on the right of the page to accept the license agreement.
- Log in to the OCR with your container client using, for example, the `docker login` command:

```
# docker login container-registry.oracle.com
Username: Oracle-Account-ID
Password: password
Login successful.
```

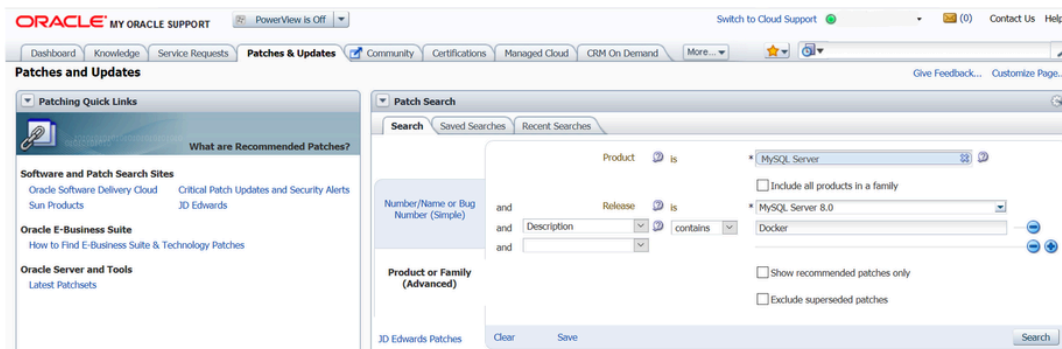

Download the Docker image for MySQL Enterprise Edition from the OCR with this command:

```
docker pull container-registry.oracle.com/mysql/enterprise-server:tag
```

To download the MySQL Enterprise Edition image from [My Oracle Support](#) website, go onto the website, sign in to your Oracle account, and perform these steps once you are on the landing page:

- Select the **Patches and Updates** tab.
- Go to the **Patch Search** region and, on the **Search** tab, switch to the **Product or Family (Advanced)** subtab.
- Enter “MySQL Server” for the **Product** field, and the desired version number in the **Release** field.
- Use the dropdowns for additional filters to select **Description—contains**, and enter “Docker” in the text field.

The following figure shows the search settings for the MySQL Enterprise Edition image for MySQL Server 8.0:

- Click the **Search** button and, from the result list, select the version you want, and click the **Download** button.
- In the **File Download** dialogue box that appears, click and download the `.zip` file for the Docker image.

Unzip the downloaded `.zip` archive to obtain the tarball inside (`mysql-enterprise-server-version.tar`), and then load the image by running this command:

```
docker load -i mysql-enterprise-server-version.tar
```

You can list downloaded Docker images with this command:

```
$> docker images
```

REPOSITORY	TAG	IMAGE ID	CREATED	SIZE
container-registry.oracle.com/mysql/community-server	latest	1d9c2219ff69	2 months ago	496MB

Starting a MySQL Server Instance

To start a new Docker container for a MySQL Server, use the following command:

```
docker run --name=container_name --restart on-failure -d image_name:tag
```

`image_name` is the name of the image to be used to start the container; see [Downloading a MySQL Server Docker Image](#) for more information.

The `--name` option, for supplying a custom name for your server container, is optional; if no container name is supplied, a random one is generated.

The `--restart` option is for configuring the [restart policy](#) for your container; it should be set to the value `on-failure`, to enable support for server restart within a client session (which happens, for example, when the [RESTART](#) statement is executed by a client or during the [configuration of an InnoDB cluster instance](#)). With the support for restart enabled, issuing a restart within a client session causes the server and the container to stop and then restart.

For example, to start a new Docker container for the MySQL Community Server, use this command:

```
docker run --name=mysql11 --restart on-failure -d container-registry.oracle.com/mysql/community-server:latest
```

To start a new Docker container for the MySQL Enterprise Server with a Docker image downloaded from the OCR, use this command:

```
docker run --name=mysql11 --restart on-failure -d container-registry.oracle.com/mysql/enterprise-server:latest
```

To start a new Docker container for the MySQL Enterprise Server with a Docker image downloaded from My Oracle Support, use this command:

```
docker run --name=mysql11 --restart on-failure -d mysql/enterprise-server:latest
```

If the Docker image of the specified name and tag has not been downloaded by an earlier `docker pull` or `docker run` command, the image is now downloaded. Initialization for the container begins,

and the container appears in the list of running containers when you run the `docker ps` command. For example:

```
$> docker ps
CONTAINER ID   IMAGE                                     COMMAND
4cd4129b3211   container-registry.oracle.com/mysql/community-server:latest   "/entrypoint.sh mysql..."
```

The container initialization might take some time. When the server is ready for use, the `STATUS` of the container in the output of the `docker ps` command changes from `(health: starting)` to `(healthy)`.

The `-d` option used in the `docker run` command above makes the container run in the background. Use this command to monitor the output from the container:

```
docker logs mysql1
```

Once initialization is finished, the command's output is going to contain the random password generated for the root user; check the password with, for example, this command:

```
$> docker logs mysql1 2>&1 | grep GENERATED
GENERATED ROOT PASSWORD: Axegh3kAJyDLaRuBemecis&EShOs
```

Connecting to MySQL Server from within the Container

Once the server is ready, you can run the `mysql` client within the MySQL Server container you just started, and connect it to the MySQL Server. Use the `docker exec -it` command to start a `mysql` client inside the Docker container you have started, like the following:

```
docker exec -it mysql1 mysql -uroot -p
```

When asked, enter the generated root password (see the last step in [Starting a MySQL Server Instance](#) above on how to find the password). Because the `MYSQL_ONETIME_PASSWORD` option is true by default, after you have connected a `mysql` client to the server, you must reset the server root password by issuing this statement:

```
mysql> ALTER USER 'root'@'localhost' IDENTIFIED BY 'password';
```

Substitute `password` with the password of your choice. Once the password is reset, the server is ready for use.

Container Shell Access

To have shell access to your MySQL Server container, use the `docker exec -it` command to start a bash shell inside the container:

```
$> docker exec -it mysql1 bash
bash-4.2#
```

You can then run Linux commands inside the container. For example, to view contents in the server's data directory inside the container, use this command:

```
bash-4.2# ls /var/lib/mysql
auto.cnf      ca.pem      client-key.pem  ib_logfile0  ibdata1  mysql      mysql.sock.lock  private_key
ca-key.pem    client-cert.pem  ib_buffer_pool  ib_logfile1  ibtmp1   mysql.sock  performance_schema  pub...
```

Stopping and Deleting a MySQL Container

To stop the MySQL Server container we have created, use this command:

```
docker stop mysql1
```

`docker stop` sends a `SIGTERM` signal to the `mysqld` process, so that the server is shut down gracefully.

Also notice that when the main process of a container (`mysqld` in the case of a MySQL Server container) is stopped, the Docker container stops automatically.

To start the MySQL Server container again:

```
docker start mysql1
```

To stop and start again the MySQL Server container with a single command:

```
docker restart mysql1
```

To delete the MySQL container, stop it first, and then use the `docker rm` command:

```
docker stop mysql1
```

```
docker rm mysql1
```

If you want the [Docker volume for the server's data directory](#) to be deleted at the same time, add the `-v` option to the `docker rm` command.

Upgrading a MySQL Server Container

Important

- Before performing any upgrade to MySQL, follow carefully the instructions in [Chapter 3, Upgrading MySQL](#). Among other instructions discussed there, it is especially important to back up your database before the upgrade.
- The instructions in this section require that the server's data and configuration have been persisted on the host. See [Persisting Data and Configuration Changes](#) for details.

Follow these steps to upgrade a Docker installation of MySQL 8.0 to 8.3:

- Stop the MySQL 8.0 server (container name is `mysql80` in this example):

```
docker stop mysql80
```

- Download the MySQL 8.3 Server Docker image. See instructions in [Downloading a MySQL Server Docker Image](#). Make sure you use the right tag for MySQL 8.3.
- Start a new MySQL 8.3 Docker container (named `mysql83` in this example) with the old server data and configuration (with proper modifications if needed—see [Chapter 3, Upgrading MySQL](#)) that have been persisted on the host (by [bind-mounting](#) in this example). For the MySQL Community Server, run this command:

```
docker run --name=mysql83 \
  --mount type=bind,src=/path-on-host-machine/my.cnf,dst=/etc/my.cnf \
  --mount type=bind,src=/path-on-host-machine/datadir,dst=/var/lib/mysql \
  -d container-registry.oracle.com/mysql/community-server:8.3
```

If needed, adjust `container-registry.oracle.com/mysql/community-server` to the correct image name—for example, replace it with `container-registry.oracle.com/mysql/enterprise-server` for MySQL Enterprise Edition images downloaded from the OCR, or `mysql/enterprise-server` for MySQL Enterprise Edition images downloaded from My Oracle Support.

- Wait for the server to finish startup. You can check the status of the server using the `docker ps` command (see [Starting a MySQL Server Instance](#) for how to do that).

Follow the same steps for upgrading within the 8.3 series (that is, from release 8.3.x to 8.3.y): stop the original container, and start a new one with a newer image on the old server data and configuration. If you used the 8.3 or the `latest` tag when starting your original container and there is now a new

MySQL 8.3 release you want to upgrade to it, you must first pull the image for the new release with the command:

```
docker pull container-registry.oracle.com/mysql/community-server:8.3
```

You can then upgrade by starting a *new* container with the same tag on the old data and configuration (adjust the image name if you are using the MySQL Enterprise Edition; see [Downloading a MySQL Server Docker Image](#)):

```
docker run --name=mysql83new \
  --mount type=bind,src=/path-on-host-machine/my.cnf,dst=/etc/my.cnf \
  --mount type=bind,src=/path-on-host-machine/datadir,dst=/var/lib/mysql \
  -d container-registry.oracle.com/mysql/community-server:8.3
```

More Topics on Deploying MySQL Server with Docker

For more topics on deploying MySQL Server with Docker like server configuration, persisting data and configuration, server error log, and container environment variables, see [Section 2.5.6.2, “More Topics on Deploying MySQL Server with Docker”](#).

2.5.6.2 More Topics on Deploying MySQL Server with Docker

Note

Most of the following sample commands have `container-registry.oracle.com/mysql/community-server` as the Docker image being used (like with the `docker pull` and `docker run` commands); change that if your image is from another repository—for example, replace it with `container-registry.oracle.com/mysql/enterprise-server` for MySQL Enterprise Edition images downloaded from the Oracle Container Registry (OCR), or `mysql/enterprise-server` for MySQL Enterprise Edition images downloaded from [My Oracle Support](#).

- [The Optimized MySQL Installation for Docker](#)
- [Configuring the MySQL Server](#)
- [Persisting Data and Configuration Changes](#)
- [Running Additional Initialization Scripts](#)
- [Connect to MySQL from an Application in Another Docker Container](#)
- [Server Error Log](#)
- [Using MySQL Enterprise Backup with Docker](#)
- [Using mysqldump with Docker](#)
- [Known Issues](#)
- [Docker Environment Variables](#)

The Optimized MySQL Installation for Docker

Docker images for MySQL are optimized for code size, which means they only include crucial components that are expected to be relevant for the majority of users who run MySQL instances in Docker containers. A MySQL Docker installation is different from a common, non-Docker installation in the following aspects:

- Only a limited number of binaries are included.
- All binaries are stripped; they contain no debug information.

Warning

Any software updates or installations users perform to the Docker container (including those for MySQL components) may conflict with the optimized MySQL installation created by the Docker image. Oracle does not provide support for MySQL products running in such an altered container, or a container created from an altered Docker image.

Configuring the MySQL Server

When you start the MySQL Docker container, you can pass configuration options to the server through the `docker run` command. For example:

```
docker run --name mysql1 -d container-registry.oracle.com/mysql/community-server:tag --character-set-server=
```

The command starts the MySQL Server with `utf8mb4` as the default character set and `utf8mb4_col` as the default collation for databases.

Another way to configure the MySQL Server is to prepare a configuration file and mount it at the location of the server configuration file inside the container. See [Persisting Data and Configuration Changes](#) for details.

Persisting Data and Configuration Changes

Docker containers are in principle ephemeral, and any data or configuration are expected to be lost if the container is deleted or corrupted (see discussions [here](#)). [Docker volumes](#) provides a mechanism to persist data created inside a Docker container. At its initialization, the MySQL Server container creates a Docker volume for the server data directory. The JSON output from the `docker inspect` command on the container includes a `Mount` key, whose value provides information on the data directory volume:

```
$> docker inspect mysql1
...
  "Mounts": [
    {
      "Type": "volume",
      "Name": "4f2d463cfc4bdd4baebcb098c97d7da3337195ed2c6572bc0b89f7e845d27652",
      "Source": "/var/lib/docker/volumes/4f2d463cfc4bdd4baebcb098c97d7da3337195ed2c6572bc0b89f7e845d27652/_data",
      "Destination": "/var/lib/mysql",
      "Driver": "local",
      "Mode": "",
      "RW": true,
      "Propagation": ""
    }
  ],
  ...
```

The output shows that the source directory `/var/lib/docker/volumes/4f2d463cfc4bdd4baebcb098c97d7da3337195ed2c6572bc0b89f7e845d27652/_data`, in which data is persisted on the host, has been mounted at `/var/lib/mysql`, the server data directory inside the container.

Another way to preserve data is to [bind-mount](#) a host directory using the `--mount` option when creating the container. The same technique can be used to persist the configuration of the server. The following command creates a MySQL Server container and bind-mounts both the data directory and the server configuration file:

```
docker run --name=mysql1 \
--mount type=bind,src=/path-on-host-machine/my.cnf,dst=/etc/my.cnf \
--mount type=bind,src=/path-on-host-machine/datadir,dst=/var/lib/mysql \
-d container-registry.oracle.com/mysql/community-server:tag
```

The command mounts `path-on-host-machine/my.cnf` at `/etc/my.cnf` (the server configuration file inside the container), and `path-on-host-machine/datadir` at `/var/lib/mysql` (the data directory inside the container). The following conditions must be met for the bind-mounting to work:

- The configuration file `path-on-host-machine/my.cnf` must already exist, and it must contain the specification for starting the server by the user `mysql`:

```
[mysqld]
user=mysql
```

You can also include other server configuration options in the file.

- The data directory `path-on-host-machine/datadir` must already exist. For server initialization to happen, the directory must be empty. You can also mount a directory prepopulated with data and start the server with it; however, you must make sure you start the Docker container with the same configuration as the server that created the data, and any host files or directories required are mounted when starting the container.

Running Additional Initialization Scripts

If there are any `.sh` or `.sql` scripts you want to run on the database immediately after it has been created, you can put them into a host directory and then mount the directory at `/docker-entrypoint-initdb.d/` inside the container. For example:

```
docker run --name=mysql1 \
--mount type=bind,src=/path-on-host-machine/scripts/,dst=/docker-entrypoint-initdb.d/ \
-d container-registry.oracle.com/mysql/community-server:tag
```

Connect to MySQL from an Application in Another Docker Container

By setting up a Docker network, you can allow multiple Docker containers to communicate with each other, so that a client application in another Docker container can access the MySQL Server in the server container. First, create a Docker network:

```
docker network create my-custom-net
```

Then, when you are creating and starting the server and the client containers, use the `--network` option to put them on network you created. For example:

```
docker run --name=mysql1 --network=my-custom-net -d container-registry.oracle.com/mysql/community-server:tag
```

```
docker run --name=myapp1 --network=my-custom-net -d myapp
```

The `myapp1` container can then connect to the `mysql1` container with the `mysql1` hostname and vice versa, as Docker automatically sets up a DNS for the given container names. In the following example, we run the `mysql` client from inside the `myapp1` container to connect to host `mysql1` in its own container:

```
docker exec -it myapp1 mysql --host=mysql1 --user=myuser --password
```

For other networking techniques for containers, see the [Docker container networking](#) section in the Docker Documentation.

Server Error Log

When the MySQL Server is first started with your server container, a [server error log](#) is NOT generated if either of the following conditions is true:

- A server configuration file from the host has been mounted, but the file does not contain the system variable `log_error` (see [Persisting Data and Configuration Changes](#) on bind-mounting a server configuration file).
- A server configuration file from the host has not been mounted, but the Docker environment variable `MYSQL_LOG_CONSOLE` is `true` (which is the variable's default state for MySQL 8.3 server containers). The MySQL Server's error log is then redirected to `stderr`, so that the error log goes

into the Docker container's log and is viewable using the `docker logs mysqld-container` command.

To make MySQL Server generate an error log when either of the two conditions is true, use the `--log-error` option to [configure the server](#) to generate the error log at a specific location inside the container. To persist the error log, mount a host file at the location of the error log inside the container as explained in [Persisting Data and Configuration Changes](#). However, you must make sure your MySQL Server inside its container has write access to the mounted host file.

Using MySQL Enterprise Backup with Docker

[MySQL Enterprise Backup](#) is a commercially-licensed backup utility for MySQL Server, available with [MySQL Enterprise Edition](#). MySQL Enterprise Backup is included in the Docker installation of MySQL Enterprise Edition.

In the following example, we assume that you already have a MySQL Server running in a Docker container (see [Section 2.5.6.1, “Basic Steps for MySQL Server Deployment with Docker”](#) on how to start a MySQL Server instance with Docker). For MySQL Enterprise Backup to back up the MySQL Server, it must have access to the server's data directory. This can be achieved by, for example, [binding a host directory on the data directory of the MySQL Server](#) when you start the server:

```
docker run --name=mysqlserver \
--mount type=bind,src=/path-on-host-machine/datadir/,dst=/var/lib/mysql \
-d mysql/enterprise-server:8.3
```

With this command, the MySQL Server is started with a Docker image of the MySQL Enterprise Edition, and the host directory `/path-on-host-machine/datadir/` has been mounted onto the server's data directory (`/var/lib/mysql`) inside the server container. We also assume that, after the server has been started, the required privileges have also been set up for MySQL Enterprise Backup to access the server (see [Grant MySQL Privileges to Backup Administrator](#), for details). Use the following steps to back up and restore a MySQL Server instance.

To back up a MySQL Server instance running in a Docker container using MySQL Enterprise Backup with Docker, follow the steps listed here:

1. On the same host where the MySQL Server container is running, start another container with an image of MySQL Enterprise Edition to perform a back up with the MySQL Enterprise Backup command `backup-to-image`. Provide access to the server's data directory using the bind mount we created in the last step. Also, mount a host directory (`/path-on-host-machine/backups/` in this example) onto the storage folder for backups in the container (`/data/backups` in the example) to persist the backups we are creating. Here is a sample command for this step, in which MySQL Enterprise Backup is started with a Docker image downloaded from [My Oracle Support](#):

```
$> docker run \
--mount type=bind,src=/path-on-host-machine/datadir/,dst=/var/lib/mysql \
--mount type=bind,src=/path-on-host-machine/backups/,dst=/data/backups \
--rm mysql/enterprise-server:8.3 \
mysqlbackup -umysqlbackup -ppassword --backup-dir=/tmp/backup-tmp --with-timestamp \
--backup-image=/data/backups/db.mbi backup-to-image
```

It is important to check the end of the output by `mysqlbackup` to make sure the backup has been completed successfully.

2. The container exits once the backup job is finished and, with the `--rm` option used to start it, it is removed after it exits. An image backup has been created, and can be found in the host directory mounted in the last step for storing backups, as shown here:

```
$> ls /tmp/backups
db.mbi
```

To restore a MySQL Server instance in a Docker container using MySQL Enterprise Backup with Docker, follow the steps listed here:

1. Stop the MySQL Server container, which also stops the MySQL Server running inside:

```
docker stop mysqlserver
```

2. On the host, delete all contents in the bind mount for the MySQL Server data directory:

```
rm -rf /path-on-host-machine/datadir/*
```

3. Start a container with an image of MySQL Enterprise Edition to perform the restore with the MySQL Enterprise Backup command `copy-back-and-apply-log`. Bind-mount the server's data directory and the storage folder for the backups, like what we did when we backed up the server:

```
$> docker run \
--mount type=bind,src=/path-on-host-machine/datadir/,dst=/var/lib/mysql \
--mount type=bind,src=/path-on-host-machine/backups/,dst=/data/backups \
--rm mysql/enterprise-server:8.3 \
mysqlbackup --backup-dir=/tmp/backup-tmp --with-timestamp \
--datadir=/var/lib/mysql --backup-image=/data/backups/db.mbi copy-back-and-apply-log

mysqlbackup completed OK! with 3 warnings
```

The container exits with the message "mysqlbackup completed OK!" once the backup job is finished and, with the `--rm` option used when starting it, it is removed after it exits.

4. Restart the server container, which also restarts the restored server, using the following command:

```
docker restart mysqlserver
```

Or, start a new MySQL Server on the restored data directory, as shown here:

```
docker run --name=mysqlserver2 \
--mount type=bind,src=/path-on-host-machine/datadir/,dst=/var/lib/mysql \
-d mysql/enterprise-server:8.3
```

Log on to the server to check that the server is running with the restored data.

Using `mysqldump` with Docker

Besides [using MySQL Enterprise Backup to back up a MySQL Server running in a Docker container](#), you can perform a logical backup of your server by using the `mysqldump` utility, run inside a Docker container.

The following instructions assume that you already have a MySQL Server running in a Docker container and, when the container was first started, a host directory `/path-on-host-machine/datadir/` has been mounted onto the server's data directory `/var/lib/mysql` (see [bind-mounting a host directory on the data directory of the MySQL Server](#) for details), which contains the Unix socket file by which `mysqldump` and `mysql` can connect to the server. We also assume that, after the server has been started, a user with the proper privileges (`admin` in this example) has been created, with which `mysqldump` can access the server. Use the following steps to back up and restore MySQL Server data:

Backing up MySQL Server data using `mysqldump` with Docker.

1. On the same host where the MySQL Server container is running, start another container with an image of MySQL Server to perform a backup with the `mysqldump` utility (see documentation of the utility for its functionality, options, and limitations). Provide access to the server's data directory by bind mounting `/path-on-host-machine/datadir/`. Also, mount a host directory (`/path-on-host-machine/backups/` in this example) onto a storage folder for backups inside the container (`/data/backups` is used in this example) to persist the backups you are creating. Here is a sample command for backing up all databases on the server using this setup:

```
$> docker run --entrypoint "/bin/sh" \
--mount type=bind,src=/path-on-host-machine/datadir/,dst=/var/lib/mysql \
--mount type=bind,src=/path-on-host-machine/backups/,dst=/data/backups \
```

```
--rm container-registry.oracle.com/mysql/community-server:8.3 \
-c "mysqldump -uadmin --password='password' --all-databases > /data/backups/all-databases.sql"
```

In the command, the `--entrypoint` option is used so that the system shell is invoked after the container is started, and the `-c` option is used to specify the `mysqldump` command to be run in the shell, whose output is redirected to the file `all-databases.sql` in the backup directory.

2. The container exits once the backup job is finished and, with the `--rm` option used to start it, it is removed after it exits. A logical backup been created, and can be found in the host directory mounted for storing the backup, as shown here:

```
$> ls /path-on-host-machine/backups/
all-databases.sql
```

Restoring MySQL Server data using `mysqldump` with Docker.

1. Make sure you have a MySQL Server running in a container, onto which you want your backed-up data to be restored.
2. Start a container with an image of MySQL Server to perform the restore with a `mysql` client. Bind-mount the server's data directory, as well as the storage folder that contains your backup:

```
$> docker run \
--mount type=bind,src=/path-on-host-machine/datadir/,dst=/var/lib/mysql \
--mount type=bind,src=/path-on-host-machine/backups/,dst=/data/backups \
--rm container-registry.oracle.com/mysql/community-server:8.3 \
mysql -uadmin --password='password' -e "source /data/backups/all-databases.sql"
```

The container exits once the backup job is finished and, with the `--rm` option used when starting it, it is removed after it exits.

3. Log on to the server to check that the restored data is now on the server.

Known Issues

- When using the server system variable `audit_log_file` to configure the audit log file name, use the `loose` option modifier with it; otherwise, Docker cannot start the server.

Docker Environment Variables

When you create a MySQL Server container, you can configure the MySQL instance by using the `--env` option (short form `-e`) and specifying one or more environment variables. No server initialization is performed if the mounted data directory is not empty, in which case setting any of these variables has no effect (see [Persisting Data and Configuration Changes](#)), and no existing contents of the directory, including server settings, are modified during container startup.

Environment variables which can be used to configure a MySQL instance are listed here:

- The boolean variables including `MYSQL_RANDOM_ROOT_PASSWORD`, `MYSQL_ONETIME_PASSWORD`, `MYSQL_ALLOW_EMPTY_PASSWORD`, and `MYSQL_LOG_CONSOLE` are made true by setting them with any strings of nonzero lengths. Therefore, setting them to, for example, "0", "false", or "no" does not make them false, but actually makes them true. This is a known issue.
- `MYSQL_RANDOM_ROOT_PASSWORD`: When this variable is true (which is its default state, unless `MYSQL_ROOT_PASSWORD` is set or `MYSQL_ALLOW_EMPTY_PASSWORD` is set to true), a random password for the server's root user is generated when the Docker container is started. The password is printed to `stdout` of the container and can be found by looking at the container's log (see [Starting a MySQL Server Instance](#)).
- `MYSQL_ONETIME_PASSWORD`: When the variable is true (which is its default state, unless `MYSQL_ROOT_PASSWORD` is set or `MYSQL_ALLOW_EMPTY_PASSWORD` is set to true), the root user's password is set as expired and must be changed before MySQL can be used normally.

- **MYSQL_DATABASE**: This variable allows you to specify the name of a database to be created on image startup. If a user name and a password are supplied with **MYSQL_USER** and **MYSQL_PASSWORD**, the user is created and granted superuser access to this database (corresponding to **GRANT ALL**). The specified database is created by a **CREATE DATABASE IF NOT EXIST** statement, so that the variable has no effect if the database already exists.
- **MYSQL_USER**, **MYSQL_PASSWORD**: These variables are used in conjunction to create a user and set that user's password, and the user is granted superuser permissions for the database specified by the **MYSQL_DATABASE** variable. Both **MYSQL_USER** and **MYSQL_PASSWORD** are required for a user to be created—if any of the two variables is not set, the other is ignored. If both variables are set but **MYSQL_DATABASE** is not, the user is created without any privileges.

**Note**

There is no need to use this mechanism to create the root superuser, which is created by default with the password set by either one of the mechanisms discussed in the descriptions for **MYSQL_ROOT_PASSWORD** and **MYSQL_RANDOM_ROOT_PASSWORD**, unless **MYSQL_ALLOW_EMPTY_PASSWORD** is true.

- **MYSQL_ROOT_HOST**: By default, MySQL creates the 'root'@'localhost' account. This account can only be connected to from inside the container as described in [Connecting to MySQL Server from within the Container](#). To allow root connections from other hosts, set this environment variable. For example, the value **172.17.0.1**, which is the default Docker gateway IP, allows connections from the host machine that runs the container. The option accepts only one entry, but wildcards are allowed (for example, **MYSQL_ROOT_HOST=172.*.*.*** or **MYSQL_ROOT_HOST=%**).
- **MYSQL_LOG_CONSOLE**: When the variable is true (which is its default state for MySQL 8.3 server containers), the MySQL Server's error log is redirected to **stderr**, so that the error log goes into the Docker container's log and is viewable using the `docker logs mysqld-container` command.

**Note**

The variable has no effect if a server configuration file from the host has been mounted (see [Persisting Data and Configuration Changes](#) on bind-mounting a configuration file).

- **MYSQL_ROOT_PASSWORD**: This variable specifies a password that is set for the MySQL root account.

**Warning**

Setting the MySQL root user password on the command line is insecure. As an alternative to specifying the password explicitly, you can set the variable with a container file path for a password file, and then mount a file from your host that contains the password at the container file path. This is still not very secure, as the location of the password file is still exposed. It is preferable to use the default settings of **MYSQL_RANDOM_ROOT_PASSWORD** and **MYSQL_ONETIME_PASSWORD** both being true.

- **MYSQL_ALLOW_EMPTY_PASSWORD**. Set it to true to allow the container to be started with a blank password for the root user.

**Warning**

Setting this variable to true is insecure, because it is going to leave your MySQL instance completely unprotected, allowing anyone to gain complete superuser access. It is preferable to use the default settings of **MYSQL_RANDOM_ROOT_PASSWORD** and **MYSQL_ONETIME_PASSWORD** both being true.

2.5.6.3 Deploying MySQL on Windows and Other Non-Linux Platforms with Docker

**Warning**

The MySQL Docker images provided by Oracle are built specifically for Linux platforms. Other platforms are not supported, and users running the MySQL Docker images from Oracle on them are doing so at their own risk. This section discusses some known issues for the images when used on non-Linux platforms.

Known Issues for using the MySQL Server Docker images from Oracle on Windows include:

- If you are bind-mounting on the container's MySQL data directory (see [Persisting Data and Configuration Changes](#) for details), you have to set the location of the server socket file with the `--socket` option to somewhere outside of the MySQL data directory; otherwise, the server fails to start. This is because the way Docker for Windows handles file mounting does not allow a host file from being bind-mounted on the socket file.

2.5.7 Installing MySQL on Linux from the Native Software Repositories

Many Linux distributions include a version of the MySQL server, client tools, and development components in their native software repositories and can be installed with the platforms' standard package management systems. This section provides basic instructions for installing MySQL using those package management systems.

**Important**

Native packages are often several versions behind the currently available release. You are also normally unable to install development milestone releases (DMRs), since these are not usually made available in the native repositories. Before proceeding, we recommend that you check out the other installation options described in [Section 2.5, "Installing MySQL on Linux"](#).

Distribution specific instructions are shown below:

- **Red Hat Linux, Fedora, CentOS**

**Note**

For a number of Linux distributions, you can install MySQL using the MySQL Yum repository instead of the platform's native software repository. See [Section 2.5.1, "Installing MySQL on Linux Using the MySQL Yum Repository"](#) for details.

For Red Hat and similar distributions, the MySQL distribution is divided into a number of separate packages, `mysql` for the client tools, `mysql-server` for the server and associated tools, and `mysql-libs` for the libraries. The libraries are required if you want to provide connectivity from different languages and environments such as Perl, Python and others.

To install, use the `yum` command to specify the packages that you want to install. For example:

```
#> yum install mysql mysql-server mysql-libs mysql-server
Loaded plugins: presto, refresh-packagekit

Complete!

```

MySQL and the MySQL server should now be installed. A sample configuration file is installed into `/etc/my.cnf`. To start the MySQL server use `systemctl`:

```
$> systemctl start mysqld
```

The database tables are automatically created for you, if they do not already exist. You should, however, run `mysql_secure_installation` to set the root passwords on your server.

- **Debian, Ubuntu, Kubuntu**

Note

For supported Debian and Ubuntu versions, MySQL can be installed using the [MySQL APT Repository](#) instead of the platform's native software repository. See [Section 2.5.2, "Installing MySQL on Linux Using the MySQL APT Repository"](#) for details.

On Debian and related distributions, there are two packages for MySQL in their software repositories, `mysql-client` and `mysql-server`, for the client and server components respectively. You should specify an explicit version, for example `mysql-client-5.1`, to ensure that you install the version of MySQL that you want.

To download and install, including any dependencies, use the `apt-get` command, specifying the packages that you want to install.

**Note**

Before installing, make sure that you update your `apt-get` index files to ensure you are downloading the latest available version.

**Note**

The `apt-get` command installs a number of packages, including the MySQL server, in order to provide the typical tools and application environment. This can mean that you install a large number of packages in addition to the main MySQL package.

During installation, the initial database is created, and you are prompted for the MySQL root password (and confirmation). A configuration file is created in `/etc/mysql/my.cnf`. An init script is created in `/etc/init.d/mysql`.

The server should already be started. You can manually start and stop the server using:

```
#> service mysql [start|stop]
```

The service is automatically added to the 2, 3 and 4 run levels, with stop scripts in the single, shutdown and restart levels.

2.5.8 Installing MySQL on Linux with Juju

The Juju deployment framework supports easy installation and configuration of MySQL servers. For instructions, see <https://jujucharms.com/mysql/>.

2.5.9 Managing MySQL Server with systemd

If you install MySQL using an RPM or Debian package on the following Linux platforms, server startup and shutdown is managed by systemd:

- RPM package platforms:
 - Enterprise Linux variants version 7 and higher
 - SUSE Linux Enterprise Server 12 and higher
 - Fedora 29 and higher
- Debian family platforms:
 - Debian platforms
 - Ubuntu platforms

If you install MySQL from a generic binary distribution on a platform that uses systemd, you can manually configure systemd support for MySQL following the instructions provided in the post-installation setup section of the [MySQL 8.0 Secure Deployment Guide](#).

If you install MySQL from a source distribution on a platform that uses systemd, obtain systemd support for MySQL by configuring the distribution using the `-DWITH_SYSTEMD=1` CMake option. See [Section 2.8.7, “MySQL Source-Configuration Options”](#).

The following discussion covers these topics:

- [Overview of systemd](#)

- [Configuring systemd for MySQL](#)
- [Configuring Multiple MySQL Instances Using systemd](#)
- [Migrating from mysqld_safe to systemd](#)

**Note**

On platforms for which systemd support for MySQL is installed, scripts such as `mysqld_safe` and the System V initialization script are unnecessary and are not installed. For example, `mysqld_safe` can handle server restarts, but systemd provides the same capability, and does so in a manner consistent with management of other services rather than by using an application-specific program.

One implication of the non-use of `mysqld_safe` on platforms that use systemd for server management is that use of `[mysqld_safe]` or `[safe_mysqld]` sections in option files is not supported and might lead to unexpected behavior.

Because systemd has the capability of managing multiple MySQL instances on platforms for which systemd support for MySQL is installed, `mysqld_multi` and `mysqld_multi.server` are unnecessary and are not installed.

Overview of systemd

systemd provides automatic MySQL server startup and shutdown. It also enables manual server management using the `systemctl` command. For example:

```
$> systemctl {start/stop/restart/status} mysqld
```

Alternatively, use the `service` command (with the arguments reversed), which is compatible with System V systems:

```
$> service mysqld {start/stop/restart/status}
```

**Note**

For the `systemctl` command (and the alternative `service` command), if the MySQL service name is not `mysqld` then use the appropriate name. For example, use `mysql` rather than `mysqld` on Debian-based and SLES systems.

Support for systemd includes these files:

- `mysqld.service` (RPM platforms), `mysql.service` (Debian platforms): systemd service unit configuration file, with details about the MySQL service.
- `mysqld@.service` (RPM platforms), `mysql@.service` (Debian platforms): Like `mysqld.service` or `mysql.service`, but used for managing multiple MySQL instances.
- `mysqld.tmpfiles.d`: File containing information to support the `tmpfiles` feature. This file is installed under the name `mysql.conf`.
- `mysqld_pre_systemd` (RPM platforms), `mysql-system-start` (Debian platforms): Support script for the unit file. This script assists in creating the error log file only if the log location matches a pattern (`/var/log/mysql*.log` for RPM platforms, `/var/log/mysql/*.log` for Debian platforms). In other cases, the error log directory must be writable or the error log must be present and writable for the user running the `mysqld` process.

Configuring systemd for MySQL

To add or change systemd options for MySQL, these methods are available:

- Use a localized systemd configuration file.

- Arrange for systemd to set environment variables for the MySQL server process.
- Set the `MYSQLD_OPTS` systemd variable.

To use a localized systemd configuration file, create the `/etc/systemd/system/mysql.service.d` directory if it does not exist. In that directory, create a file that contains a `[Service]` section listing the desired settings. For example:

```
[Service]
LimitNOFILE=max_open_files
Nice=nice_level
LimitCore=core_file_limit
Environment="LD_PRELOAD=/path/to/malloc/library"
Environment="TZ=time_zone_setting"
```

The discussion here uses `override.conf` as the name of this file. Newer versions of systemd support the following command, which opens an editor and permits you to edit the file:

```
systemctl edit mysqld # RPM platforms
systemctl edit mysql  # Debian platforms
```

Whenever you create or change `override.conf`, reload the systemd configuration, then tell systemd to restart the MySQL service:

```
systemctl daemon-reload
systemctl restart mysqld # RPM platforms
systemctl restart mysql  # Debian platforms
```

With systemd, the `override.conf` configuration method must be used for certain parameters, rather than settings in a `[mysqld]`, `[mysqld_safe]`, or `[safe_mysqld]` group in a MySQL option file:

- For some parameters, `override.conf` must be used because systemd itself must know their values and it cannot read MySQL option files to get them.
- Parameters that specify values otherwise settable only using options known to `mysqld_safe` must be specified using systemd because there is no corresponding `mysqld` parameter.

For additional information about using systemd rather than `mysqld_safe`, see [Migrating from mysqld_safe to systemd](#).

You can set the following parameters in `override.conf`:

- To set the number of file descriptors available to the MySQL server, use `LimitNOFILE` in `override.conf` rather than the `open_files_limit` system variable for `mysqld` or `--open-files-limit` option for `mysqld_safe`.
- To set the maximum core file size, use `LimitCore` in `override.conf` rather than the `--core-file-size` option for `mysqld_safe`.
- To set the scheduling priority for the MySQL server, use `Nice` in `override.conf` rather than the `--nice` option for `mysqld_safe`.

Some MySQL parameters are configured using environment variables:

- `LD_PRELOAD`: Set this variable if the MySQL server should use a specific memory-allocation library.
- `NOTIFY_SOCKET`: This environment variable specifies the socket that `mysqld` uses to communicate notification of startup completion and service status change with systemd. It is set by systemd when the `mysqld` service is started. The `mysqld` service reads the variable setting and writes to the defined location.

In MySQL 8.3, `mysqld` uses the `Type=notify` process startup type. (`Type=forking` was used in MySQL 5.7.) With `Type=notify`, systemd automatically configures a socket file and exports the path to the `NOTIFY_SOCKET` environment variable.

- `TZ`: Set this variable to specify the default time zone for the server.

There are multiple ways to specify environment variable values for use by the MySQL server process managed by systemd:

- Use `Environment` lines in the `override.conf` file. For the syntax, see the example in the preceding discussion that describes how to use this file.
- Specify the values in the `/etc/sysconfig/mysql` file (create the file if it does not exist). Assign values using the following syntax:

```
LD_PRELOAD=/path/to/malloc/library
TZ=time_zone_setting
```

After modifying `/etc/sysconfig/mysql`, restart the server to make the changes effective:

```
systemctl restart mysqld # RPM platforms
systemctl restart mysql  # Debian platforms
```

To specify options for `mysqld` without modifying systemd configuration files directly, set or unset the `MYSQLD_OPTS` systemd variable. For example:

```
systemctl set-environment MYSQLD_OPTS="--general_log=1"
systemctl unset-environment MYSQLD_OPTS
```

`MYSQLD_OPTS` can also be set in the `/etc/sysconfig/mysql` file.

After modifying the systemd environment, restart the server to make the changes effective:

```
systemctl restart mysqld # RPM platforms
systemctl restart mysql  # Debian platforms
```

For platforms that use systemd, the data directory is initialized if empty at server startup. This might be a problem if the data directory is a remote mount that has temporarily disappeared: The mount point would appear to be an empty data directory, which then would be initialized as a new data directory. To suppress this automatic initialization behavior, specify the following line in the `/etc/sysconfig/mysql` file (create the file if it does not exist):

```
NO_INIT=true
```

Configuring Multiple MySQL Instances Using systemd

This section describes how to configure systemd for multiple instances of MySQL.

Note

Because systemd has the capability of managing multiple MySQL instances on platforms for which systemd support is installed, `mysqld_multi` and `mysqld_multi.server` are unnecessary and are not installed.

To use multiple-instance capability, modify the `my.cnf` option file to include configuration of key options for each instance. These file locations are typical:

- `/etc/my.cnf` or `/etc/mysql/my.cnf` (RPM platforms)
- `/etc/mysql/mysql.conf.d/mysqld.cnf` (Debian platforms)

For example, to manage two instances named `replica01` and `replica02`, add something like this to the option file:

RPM platforms:

```
[mysqld@replica01]
datadir=/var/lib/mysql-replica01
socket=/var/lib/mysql-replica01/mysql.sock
port=3307
log-error=/var/log/mysqld-replica01.log
```

```
[mysqld@replica02]
datadir=/var/lib/mysql-replica02
socket=/var/lib/mysql-replica02/mysql.sock
port=3308
log-error=/var/log/mysqld-replica02.log
```

Debian platforms:

```
[mysqld@replica01]
datadir=/var/lib/mysql-replica01
socket=/var/lib/mysql-replica01/mysql.sock
port=3307
log-error=/var/log/mysql/replica01.log

[mysqld@replica02]
datadir=/var/lib/mysql-replica02
socket=/var/lib/mysql-replica02/mysql.sock
port=3308
log-error=/var/log/mysql/replica02.log
```

The replica names shown here use `@` as the delimiter because that is the only delimiter supported by `systemd`.

Instances then are managed by normal `systemd` commands, such as:

```
systemctl start mysqld@replica01
systemctl start mysqld@replica02
```

To enable instances to run at boot time, do this:

```
systemctl enable mysqld@replica01
systemctl enable mysqld@replica02
```

Use of wildcards is also supported. For example, this command displays the status of all replica instances:

```
systemctl status 'mysqld@replica*'
```

For management of multiple MySQL instances on the same machine, `systemd` automatically uses a different unit file:

- `mysqld@.service` rather than `mysqld.service` (RPM platforms)
- `mysql@.service` rather than `mysql.service` (Debian platforms)

In the unit file, `%I` and `%i` reference the parameter passed in after the `@` marker and are used to manage the specific instance. For a command such as this:

```
systemctl start mysqld@replica01
```

`systemd` starts the server using a command such as this:

```
mysqld --defaults-group-suffix=%I ...
```

The result is that the `[server]`, `[mysqld]`, and `[mysqld@replica01]` option groups are read and used for that instance of the service.

Note

On Debian platforms, AppArmor prevents the server from reading or writing `/var/lib/mysql-replica*`, or anything other than the default locations. To address this, you must customize or disable the profile in `/etc/apparmor.d/usr.sbin.mysqld`.

Note

On Debian platforms, the packaging scripts for MySQL uninstallation cannot currently handle `mysqld@` instances. Before removing or upgrading the package, you must stop any extra instances manually first.

Migrating from `mysqld_safe` to `systemd`

Because `mysqld_safe` is not installed on platforms that use `systemd` to manage MySQL, options previously specified for that program (for example, in an `[mysqld_safe]` or `[safe_mysqld]` option group) must be specified another way:

- Some `mysqld_safe` options are also understood by `mysqld` and can be moved from the `[mysqld_safe]` or `[safe_mysqld]` option group to the `[mysqld]` group. This does *not* include `--pid-file`, `--open-files-limit`, or `--nice`. To specify those options, use the `override.conf` `systemd` file, described previously.

Note

On `systemd` platforms, use of `[mysqld_safe]` and `[safe_mysqld]` option groups is not supported and may lead to unexpected behavior.

- For some `mysqld_safe` options, there are alternative `mysqld` procedures. For example, the `mysqld_safe` option for enabling `syslog` logging is `--syslog`, which is deprecated. To write error log output to the system log, use the instructions at [Section 7.4.2.8, “Error Logging to the System Log”](#).
- `mysqld_safe` options not understood by `mysqld` can be specified in `override.conf` or environment variables. For example, with `mysqld_safe`, if the server should use a specific memory allocation library, this is specified using the `--malloc-lib` option. For installations that manage the server with `systemd`, arrange to set the `LD_PRELOAD` environment variable instead, as described previously.

2.6 Installing MySQL Using Unbreakable Linux Network (ULN)

Linux supports a number of different solutions for installing MySQL, covered in [Section 2.5, “Installing MySQL on Linux”](#). One of the methods, covered in this section, is installing from Oracle's Unbreakable Linux Network (ULN). You can find information about Oracle Linux and ULN under <http://linux.oracle.com/>.

To use ULN, you need to obtain a ULN login and register the machine used for installation with ULN. This is described in detail in the [ULN FAQ](#). The page also describes how to install and update packages.

Both Community and Commercial packages are supported, and each offers three MySQL channels:

- Server:** MySQL Server
- Connectors:** MySQL Connector/C++, MySQL Connector/J, MySQL Connector/ODBC, and MySQL Connector/Python.
- Tools:** MySQL Router, MySQL Shell, and MySQL Workbench

The Community channels are available to all ULN users.

Accessing commercial MySQL ULN packages at linux.oracle.com requires you to provide a CSI with a valid commercial license for MySQL (Enterprise or Standard). As of this writing, valid purchases are 60944, 60945, 64911, and 64912. The appropriate CSI makes commercial MySQL subscription channels available in your ULN GUI interface.

Once MySQL has been installed using ULN, you can find information on starting and stopping the server, and more, at [Section 2.5.7, “Installing MySQL on Linux from the Native Software Repositories”](#), particularly under [Section 2.5.4, “Installing MySQL on Linux Using RPM Packages from Oracle”](#).

If you are changing your package source to use ULN and not changing which build of MySQL you are using, then back up your data, remove your existing binaries, and replace them with those from ULN. If a change of build is involved, we recommend the backup be a dump (`mysqldump` or `mysqlpump` or from [MySQL Shell's backup utility](#)) just in case you need to rebuild your data after the new binaries

are in place. If this shift to ULN crosses a version boundary, consult this section before proceeding: [Chapter 3, Upgrading MySQL](#).

2.7 Installing MySQL on Solaris

Note

MySQL 8.3 supports Solaris 11.4 and higher

MySQL on Solaris is available in a number of different formats.

- For information on installing using the native Solaris PKG format, see [Section 2.7.1, “Installing MySQL on Solaris Using a Solaris PKG”](#).
- To use a standard `tar` binary installation, use the notes provided in [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#). Check the notes and hints at the end of this section for Solaris specific notes that you may need before or after installation.

To obtain a binary MySQL distribution for Solaris in tarball or PKG format, <https://dev.mysql.com/downloads/mysql/8.3.html>.

Additional notes to be aware of when installing and using MySQL on Solaris:

- If you want to use MySQL with the `mysql` user and group, use the `groupadd` and `useradd` commands:

```
groupadd mysql
useradd -g mysql -s /bin/false mysql
```

- If you install MySQL using a binary tarball distribution on Solaris, because the Solaris `tar` cannot handle long file names, use GNU `tar` (`gtar`) to unpack the distribution. If you do not have GNU `tar` on your system, install it with the following command:

```
pkg install archiver/gnu-tar
```

- You should mount any file systems on which you intend to store `InnoDB` files with the `forcedirectio` option. (By default mounting is done without this option.) Failing to do so causes a significant drop in performance when using the `InnoDB` storage engine on this platform.
- If you would like MySQL to start automatically, you can copy `support-files/mysql.server` to `/etc/init.d` and create a symbolic link to it named `/etc/rc3.d/S99mysql.server`.
- If too many processes try to connect very rapidly to `mysqld`, you should see this error in the MySQL log:

```
Error in accept: Protocol error
```

You might try starting the server with the `--back_log=50` option as a workaround for this.

- To configure the generation of core files on Solaris you should use the `coreadm` command. Because of the security implications of generating a core on a `setuid()` application, by default, Solaris does not support core files on `setuid()` programs. However, you can modify this behavior using `coreadm`. If you enable `setuid()` core files for the current user, they are generated using mode 600 and are owned by the superuser.

2.7.1 Installing MySQL on Solaris Using a Solaris PKG

You can install MySQL on Solaris using a binary package of the native Solaris PKG format instead of the binary tarball distribution.

To use this package, download the corresponding `mysql-VERSION-solaris11-PLATFORM.pkg.gz` file, then uncompress it. For example:

```
$> gunzip mysql-8.3.0-solaris11-x86_64.pkg.gz
```

To install a new package, use `pkgadd` and follow the onscreen prompts. You must have root privileges to perform this operation:

```
$> pkgadd -d mysql-8.3.0-solaris11-x86_64.pkg

The following packages are available:
  1  mysql      MySQL Community Server (GPL)
                        (i86pc) 8.3.0

Select package(s) you wish to process (or 'all' to process
all packages). (default: all) [?,??,q]:
```

The PKG installer installs all of the files and tools needed, and then initializes your database if one does not exist. To complete the installation, you should set the root password for MySQL as provided in the instructions at the end of the installation. Alternatively, you can run the `mysql_secure_installation` script that comes with the installation.

By default, the PKG package installs MySQL under the root path `/opt/mysql`. You can change only the installation root path when using `pkgadd`, which can be used to install MySQL in a different Solaris zone. If you need to install in a specific directory, use a binary `tar` file distribution.

The `pkg` installer copies a suitable startup script for MySQL into `/etc/init.d/mysql`. To enable MySQL to startup and shutdown automatically, you should create a link between this file and the init script directories. For example, to ensure safe startup and shutdown of MySQL you could use the following commands to add the right links:

```
$> ln /etc/init.d/mysql /etc/rc3.d/S91mysql
$> ln /etc/init.d/mysql /etc/rc0.d/K02mysql
```

To remove MySQL, the installed package name is `mysql`. You can use this in combination with the `pkgrm` command to remove the installation.

To upgrade when using the Solaris package file format, you must remove the existing installation before installing the updated package. Removal of the package does not delete the existing database information, only the server, binaries and support files. The typical upgrade sequence is therefore:

```
$> mysqladmin shutdown
$> pkgrm mysql
$> pkgadd -d mysql-8.3.0-solaris11-x86_64.pkg
$> mysql_safe &
```

You should check the notes in [Chapter 3, Upgrading MySQL](#) before performing any upgrade.

2.8 Installing MySQL from Source

Building MySQL from the source code enables you to customize build parameters, compiler optimizations, and installation location. For a list of systems on which MySQL is known to run, see <https://www.mysql.com/support/supportedplatforms/database.html>.

Before you proceed with an installation from source, check whether Oracle produces a precompiled binary distribution for your platform and whether it works for you. We put a great deal of effort into ensuring that our binaries are built with the best possible options for optimal performance. Instructions for installing binary distributions are available in [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#).

If you are interested in building MySQL from a source distribution using build options the same as or similar to those used by Oracle to produce binary distributions on your platform, obtain a binary distribution, unpack it, and look in the `docs/INFO_BIN` file, which contains information about how that MySQL distribution was configured and compiled.

Warning

Building MySQL with nonstandard options may lead to reduced functionality, performance, or security.

The MySQL source code contains internal documentation written using Doxygen. The generated Doxygen content is available at <https://dev.mysql.com/doc/index-other.html>. It is also possible to generate this content locally from a MySQL source distribution using the instructions at [Section 2.8.10, “Generating MySQL Doxygen Documentation Content”](#).

2.8.1 Source Installation Methods

There are two methods for installing MySQL from source:

- Use a standard MySQL source distribution. To obtain a standard distribution, see [Section 2.1.3, “How to Get MySQL”](#). For instructions on building from a standard distribution, see [Section 2.8.4, “Installing MySQL Using a Standard Source Distribution”](#).

Standard distributions are available as compressed `tar` files, Zip archives, or RPM packages. Distribution files have names of the form `mysql-VERSION.tar.gz`, `mysql-VERSION.zip`, or `mysql-VERSION.rpm`, where `VERSION` is a number like `8.3.0`. File names for source distributions can be distinguished from those for precompiled binary distributions in that source distribution names are generic and include no platform name, whereas binary distribution names include a platform name indicating the type of system for which the distribution is intended (for example, `pc-linux-i686` or `winx64`).

- Use a MySQL development tree. For information on building from one of the development trees, see [Section 2.8.5, “Installing MySQL Using a Development Source Tree”](#).

2.8.2 Source Installation Prerequisites

Installation of MySQL from source requires several development tools. Some of these tools are needed no matter whether you use a standard source distribution or a development source tree. Other tool requirements depend on which installation method you use.

To install MySQL from source, the following system requirements must be satisfied, regardless of installation method:

- `CMake`, which is used as the build framework on all platforms. `CMake` can be downloaded from <http://www.cmake.org>.
- A good `make` program. Although some platforms come with their own `make` implementations, it is highly recommended that you use GNU `make` 3.75 or later. It may already be available on your system as `gmake`. GNU `make` is available from <http://www.gnu.org/software/make/>.

On Unix-like systems, including Linux, you can check your system's version of `make` like this:

```
$> make --version
GNU Make 4.2.1
```

- MySQL 8.3 source code permits use of C++17 features. To enable the necessary level of C++17 support across all supported platforms, the following minimum compiler versions apply:
 - Linux: GCC 10 or Clang 12
 - macOS: XCode 10
 - Solaris: GCC 10
 - Windows: Visual Studio 2019
- The MySQL C API requires a C++ or C99 compiler to compile.
- An SSL library is required for support of encrypted connections, entropy for random number generation, and other encryption-related operations. By default, the build uses the OpenSSL library installed on the host system. To specify the library explicitly, use the `WITH_SSL` option when you invoke `CMake`. For additional information, see [Section 2.8.6, “Configuring SSL Library Support”](#).

- The [Boost C++ libraries](#) are required to build MySQL (but not to use it). In MySQL 8.3 and later, these libraries are always bundled with the MySQL source.
- The [ncurses](#) library.
- Sufficient free memory. If you encounter build errors such as [internal compiler error](#) when compiling large source files, it may be that you have too little memory. If compiling on a virtual machine, try increasing the memory allocation.
- Perl is needed if you intend to run test scripts. Most Unix-like systems include Perl. For Windows, you can use [ActiveState Perl](#) or [Strawberry Perl](#).

To install MySQL from a standard source distribution, one of the following tools is required to unpack the distribution file:

- For a [.tar.gz](#) compressed [tar](#) file: GNU [gunzip](#) to uncompress the distribution and a reasonable [tar](#) to unpack it. If your [tar](#) program supports the [z](#) option, it can both uncompress and unpack the file.

GNU [tar](#) is known to work. The standard [tar](#) provided with some operating systems is not able to unpack the long file names in the MySQL distribution. You should download and install GNU [tar](#), or if available, use a preinstalled version of GNU [tar](#). Usually this is available as [gnutar](#), [gtar](#), or as [tar](#) within a GNU or Free Software directory, such as [/usr/sfw/bin](#) or [/usr/local/bin](#). GNU [tar](#) is available from <https://www.gnu.org/software/tar/>.

- For a [.zip](#) Zip archive: [WinZip](#) or another tool that can read [.zip](#) files.
- For an [.rpm](#) RPM package: The [rpmbuild](#) program used to build the distribution unpacks it.

To install MySQL from a development source tree, the following additional tools are required:

- The Git revision control system is required to obtain the development source code. [GitHub Help](#) provides instructions for downloading and installing Git on different platforms.
- [bison](#) 2.1 or later, available from <http://www.gnu.org/software/bison/>. (Version 1 is no longer supported.) Use the latest version of [bison](#) where possible; if you experience problems, upgrade to a later version, rather than revert to an earlier one.

[bison](#) is available from <http://www.gnu.org/software/bison/>. [bison](#) for Windows can be downloaded from <http://gnuwin32.sourceforge.net/packages/bison.htm>. Download the package labeled “Complete package, excluding sources”. On Windows, the default location for [bison](#) is the [C:\Program Files\GnuWin32](#) directory. Some utilities may fail to find [bison](#) because of the space in the directory name. Also, Visual Studio may simply hang if there are spaces in the path. You can resolve these problems by installing into a directory that does not contain a space (for example [C:\GnuWin32](#)).

- On Solaris Express, [m4](#) must be installed in addition to [bison](#). [m4](#) is available from <http://www.gnu.org/software/m4/>.

**Note**

If you have to install any programs, modify your [PATH](#) environment variable to include any directories in which the programs are located. See [Section 6.2.9, “Setting Environment Variables”](#).

If you run into problems and need to file a bug report, please use the instructions in [Section 1.5, “How to Report Bugs or Problems”](#).

2.8.3 MySQL Layout for Source Installation

By default, when you install MySQL after compiling it from source, the installation step installs files under [/usr/local/mysql](#). The component locations under the installation directory are the same as for binary distributions. See [Table 2.3, “MySQL Installation Layout for Generic Unix/Linux Binary](#)

[Package](#)", and [MySQL Installation Layout on Microsoft Windows](#). To configure installation locations different from the defaults, use the options described at [Section 2.8.7, "MySQL Source-Configuration Options"](#).

2.8.4 Installing MySQL Using a Standard Source Distribution

To install MySQL from a standard source distribution:

1. Verify that your system satisfies the tool requirements listed at [Section 2.8.2, "Source Installation Prerequisites"](#).
2. Obtain a distribution file using the instructions in [Section 2.1.3, "How to Get MySQL"](#).
3. Configure, build, and install the distribution using the instructions in this section.
4. Perform postinstallation procedures using the instructions in [Section 2.9, "Postinstallation Setup and Testing"](#).

MySQL uses [CMake](#) as the build framework on all platforms. The instructions given here should enable you to produce a working installation. For additional information on using [CMake](#) to build MySQL, see [How to Build MySQL Server with CMake](#).

If you start from a source RPM, use the following command to make a binary RPM that you can install. If you do not have `rpmbuild`, use `rpm` instead.

```
$> rpmbuild --rebuild --clean MySQL-VERSION.src.rpm
```

The result is one or more binary RPM packages that you install as indicated in [Section 2.5.4, "Installing MySQL on Linux Using RPM Packages from Oracle"](#).

The sequence for installation from a compressed `tar` file or Zip archive source distribution is similar to the process for installing from a generic binary distribution (see [Section 2.2, "Installing MySQL on Unix/Linux Using Generic Binaries"](#)), except that it is used on all platforms and includes steps to configure and compile the distribution. For example, with a compressed `tar` file source distribution on Unix, the basic installation command sequence looks like this:

```
# Preconfiguration setup
$> groupadd mysql
$> useradd -r -g mysql -s /bin/false mysql
# Beginning of source-build specific instructions
$> tar zxvf mysql-VERSION.tar.gz
$> cd mysql-VERSION
$> mkdir bld
$> cd bld
$> cmake ..
$> make
$> make install
# End of source-build specific instructions
# Postinstallation setup
$> cd /usr/local/mysql
$> mkdir mysql-files
$> chown mysql:mysql mysql-files
$> chmod 750 mysql-files
$> bin/mysqld --initialize --user=mysql
$> bin/mysql_ssl_rsa_setup
$> bin/mysqld_safe --user=mysql &
# Next command is optional
$> cp support-files/mysql.server /etc/init.d/mysql.server
```

A more detailed version of the source-build specific instructions is shown following.

Note

The procedure shown here does not set up any passwords for MySQL accounts. After following the procedure, proceed to [Section 2.9, "Postinstallation Setup and Testing"](#), for postinstallation setup and testing.

- [Perform Preconfiguration Setup](#)
- [Obtain and Unpack the Distribution](#)
- [Configure the Distribution](#)
- [Build the Distribution](#)
- [Install the Distribution](#)
- [Perform Postinstallation Setup](#)

Perform Preconfiguration Setup

On Unix, set up the `mysql` user that owns the database directory and that should be used to run and execute the MySQL server, and the group to which this user belongs. For details, see [Create a mysql User and Group](#). Then perform the following steps as the `mysql` user, except as noted.

Obtain and Unpack the Distribution

Pick the directory under which you want to unpack the distribution and change location into it.

Obtain a distribution file using the instructions in [Section 2.1.3, "How to Get MySQL"](#).

Unpack the distribution into the current directory:

- To unpack a compressed `tar` file, `tar` can decompress and unpack the distribution if it has `z` option support:

```
$> tar zxvf mysql-VERSION.tar.gz
```

If your `tar` does not have `z` option support, use `gunzip` to decompress the distribution and `tar` to unpack it:

```
$> gunzip < mysql-VERSION.tar.gz | tar xvf -
```

Alternatively, `CMake` can decompress and unpack the distribution:

```
$> cmake -E tar zxvf mysql-VERSION.tar.gz
```

- To unpack a Zip archive, use [WinZip](#) or another tool that can read `.zip` files.

Unpacking the distribution file creates a directory named `mysql-VERSION`.

Configure the Distribution

Change location into the top-level directory of the unpacked distribution:

```
$> cd mysql-VERSION
```

Build outside of the source tree to keep the tree clean. If the top-level source directory is named `mysql-src` under your current working directory, you can build in a directory named `build` at the same level. Create the directory and go there:

```
$> mkdir bld
$> cd bld
```

Configure the build directory. The minimum configuration command includes no options to override configuration defaults:

```
$> cmake ../mysql-src
```

The build directory need not be outside the source tree. For example, you can build in a directory named `build` under the top-level source tree. To do this, starting with `mysql-src` as your current working directory, create the directory `build` and then go there:

```
$> mkdir build
$> cd build
```

Configure the build directory. The minimum configuration command includes no options to override configuration defaults:

```
$> cmake ..
```

If you have multiple source trees at the same level (for example, to build multiple versions of MySQL), the second strategy can be advantageous. The first strategy places all build directories at the same level, which requires that you choose a unique name for each. With the second strategy, you can use the same name for the build directory within each source tree. The following instructions assume this second strategy.

On Windows, specify the development environment. For example, the following commands configure MySQL for 32-bit or 64-bit builds, respectively:

```
$> cmake .. -G "Visual Studio 12 2013"
$> cmake .. -G "Visual Studio 12 2013 Win64"
```

On macOS, to use the Xcode IDE:

```
$> cmake .. -G Xcode
```

When you run `Cmake`, you might want to add options to the command line. Here are some examples:

- `-DBUILD_CONFIG=mysql_release`: Configure the source with the same build options used by Oracle to produce binary distributions for official MySQL releases.
- `-DCMAKE_INSTALL_PREFIX=dir_name`: Configure the distribution for installation under a particular location.
- `-DCPACK_MONOLITHIC_INSTALL=1`: Cause `make package` to generate a single installation file rather than multiple files.
- `-DWITH_DEBUG=1`: Build the distribution with debugging support.

For a more extensive list of options, see [Section 2.8.7, “MySQL Source-Configuration Options”](#).

To list the configuration options, use one of the following commands:

```
$> cmake .. -L # overview
$> cmake .. -LH # overview with help text
$> cmake .. -LAH # all params with help text
$> cmake .. # interactive display
```

If `CMake` fails, you might need to reconfigure by running it again with different options. If you do reconfigure, take note of the following:

- If `CMake` is run after it has previously been run, it may use information that was gathered during its previous invocation. This information is stored in `CMakeCache.txt`. When `CMake` starts, it looks for that file and reads its contents if it exists, on the assumption that the information is still correct. That assumption is invalid when you reconfigure.
- Each time you run `CMake`, you must run `make` again to recompile. However, you may want to remove old object files from previous builds first because they were compiled using different configuration options.

To prevent old object files or configuration information from being used, run these commands in the build directory on Unix before re-running `CMake`:

```
$> make clean
$> rm CMakeCache.txt
```

Or, on Windows:

```
$> devenv MySQL.sln /clean
$> del CMakeCache.txt
```

Before asking on the [MySQL Community Slack](#), check the files in the `CMakeFiles` directory for useful information about the failure. To file a bug report, please use the instructions in [Section 1.5, “How to Report Bugs or Problems”](#).

Build the Distribution

On Unix:

```
$> make
$> make VERBOSE=1
```

The second command sets `VERBOSE` to show the commands for each compiled source.

Use `gmake` instead on systems where you are using GNU `make` and it has been installed as `gmake`.

On Windows:

```
$> devenv MySQL.sln /build RelWithDebInfo
```

If you have gotten to the compilation stage, but the distribution does not build, see [Section 2.8.8, “Dealing with Problems Compiling MySQL”](#), for help. If that does not solve the problem, please enter it into our bugs database using the instructions given in [Section 1.5, “How to Report Bugs or Problems”](#). If you have installed the latest versions of the required tools, and they crash trying to process our configuration files, please report that also. However, if you get a `command not found` error or a similar problem for required tools, do not report it. Instead, make sure that all the required tools are installed and that your `PATH` variable is set correctly so that your shell can find them.

Install the Distribution

On Unix:

```
$> make install
```

This installs the files under the configured installation directory (by default, `/usr/local/mysql`). You might need to run the command as `root`.

To install in a specific directory, add a `DESTDIR` parameter to the command line:

```
$> make install DESTDIR="/opt/mysql"
```

Alternatively, generate installation package files that you can install where you like:

```
$> make package
```

This operation produces one or more `.tar.gz` files that can be installed like generic binary distribution packages. See [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#). If you run `CMake` with `-DCPACK_MONOLITHIC_INSTALL=1`, the operation produces a single file. Otherwise, it produces multiple files.

On Windows, generate the data directory, then create a `.zip` archive installation package:

```
$> devenv MySQL.sln /build RelWithDebInfo /project initial_database
$> devenv MySQL.sln /build RelWithDebInfo /project package
```

You can install the resulting `.zip` archive where you like. See [Section 2.3.3, “Configuration: Manually”](#).

Perform Postinstallation Setup

The remainder of the installation process involves setting up the configuration file, creating the core databases, and starting the MySQL server. For instructions, see [Section 2.9, “Postinstallation Setup and Testing”](#).

**Note**

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in [Section 2.9, “Postinstallation Setup and Testing”](#).

2.8.5 Installing MySQL Using a Development Source Tree

This section describes how to install MySQL from the latest development source code, which is hosted on [GitHub](#). To obtain the MySQL Server source code from this repository hosting service, you can set up a local MySQL Git repository.

On [GitHub](#), MySQL Server and other MySQL projects are found on the [MySQL](#) page. The MySQL Server project is a single repository that contains branches for several MySQL series.

- [Prerequisites for Installing from Development Source](#)
- [Setting Up a MySQL Git Repository](#)

Prerequisites for Installing from Development Source

To install MySQL from a development source tree, your system must satisfy the tool requirements listed at [Section 2.8.2, “Source Installation Prerequisites”](#).

Setting Up a MySQL Git Repository

To set up a MySQL Git repository on your machine:

1. Clone the MySQL Git repository to your machine. The following command clones the MySQL Git repository to a directory named `mysql-server`. The initial download may take some time to complete, depending on the speed of your connection.

```
$> git clone https://github.com/mysql/mysql-server.git
Cloning into 'mysql-server'...
remote: Counting objects: 1198513, done.
remote: Total 1198513 (delta 0), reused 0 (delta 0), pack-reused 1198513
Receiving objects: 100% (1198513/1198513), 1.01 GiB | 7.44 MiB/s, done.
Resolving deltas: 100% (993200/993200), done.
Checking connectivity... done.
Checking out files: 100% (25510/25510), done.
```

2. When the clone operation completes, the contents of your local MySQL Git repository appear similar to the following:

```
~> cd mysql-server
~/mysql-server> ls
client          extra           mysql           storage
cmake           include        packaging       strings
CMakeLists.txt  INSTALL       plugin         support-files
components      libbinlogevents  README        testclients
config.h.cmake  libchangestreams  router        unittest
configure.cmake libmysql        run_doxygen.cmake  utilities
Docs            libservices     scripts        VERSION
Doxyfile-ignored LICENSE       share         vio
Doxyfile.in     man           sql           win
doxygen_resources mysql-test     sql-common
```

3. Use the `git branch -r` command to view the remote tracking branches for the MySQL repository.

```
~/mysql-server> git branch -r
origin/5.7
origin/8.0
origin/HEAD -> origin/trunk
origin/cluster-7.4
origin/cluster-7.5
```

```
origin/cluster-7.6
origin/trunk
```

4. To view the branch that is checked out in your local repository, issue the `git branch` command. When you clone the MySQL Git repository, the latest MySQL branch is checked out automatically. The asterisk identifies the active branch.

```
~/mysql-server$ git branch
* trunk
```

5. To check out an earlier MySQL branch, run the `git checkout` command, specifying the branch name. For example, to check out the MySQL 8.0 branch:

```
~/mysql-server$ git checkout 8.0
Checking out files: 100% (9600/9600), done.
Branch 8.0 set up to track remote branch 8.0 from origin.
Switched to a new branch '8.0'
```

6. To obtain changes made after your initial setup of the MySQL Git repository, switch to the branch you want to update and issue the `git pull` command:

```
~/mysql-server$ git checkout trunk
~/mysql-server$ git pull
```

To examine the commit history, use the `git log` command:

```
~/mysql-server$ git log
```

You can also browse commit history and source code on the GitHub [MySQL](#) site.

If you see changes or code that you have a question about, ask on [MySQL Community Slack](#).

7. After you have cloned the MySQL Git repository and have checked out the branch you want to build, you can build MySQL Server from the source code. Instructions are provided in [Section 2.8.4, “Installing MySQL Using a Standard Source Distribution”](#), except that you skip the part about obtaining and unpacking the distribution.

Be careful about installing a build from a distribution source tree on a production machine. The installation command may overwrite your live release installation. If you already have MySQL installed and do not want to overwrite it, run `CMake` with values for the `CMAKE_INSTALL_PREFIX`, `MYSQL_TCP_PORT`, and `MYSQL_UNIX_ADDR` options different from those used by your production server. For additional information about preventing multiple servers from interfering with each other, see [Section 7.8, “Running Multiple MySQL Instances on One Machine”](#).

Play hard with your new installation. For example, try to make new features crash. Start by running `make test`. See [The MySQL Test Suite](#).

2.8.6 Configuring SSL Library Support

An SSL library is required for support of encrypted connections, entropy for random number generation, and other encryption-related operations.

If you compile MySQL from a source distribution, `CMake` configures the distribution to use the installed OpenSSL library by default.

To compile using OpenSSL, use this procedure:

1. Ensure that OpenSSL 1.0.1 or newer is installed on your system. If the installed OpenSSL version is older than 1.0.1, `CMake` produces an error at MySQL configuration time. If it is necessary to obtain OpenSSL, visit <http://www.openssl.org>.
2. The `WITH_SSL` `CMake` option determines which SSL library to use for compiling MySQL (see [Section 2.8.7, “MySQL Source-Configuration Options”](#)). The default is `-DWITH_SSL=system`, which uses OpenSSL. To make this explicit, specify that option. For example:

```
cmake . -DWITH_SSL=system
```

That command configures the distribution to use the installed OpenSSL library. Alternatively, to explicitly specify the path name to the OpenSSL installation, use the following syntax. This can be useful if you have multiple versions of OpenSSL installed, to prevent [CMake](#) from choosing the wrong one:

```
cmake . -DWITH_SSL=path_name
```

Alternative OpenSSL system packages are supported by using `WITH_SSL=openssl11` on EL7 or `WITH_SSL=openssl13` on EL8. Authentication plugins, such as LDAP and Kerberos, are disabled since they do not support these alternative versions of OpenSSL.

3. Compile and install the distribution.

To check whether a `mysqld` server supports encrypted connections, examine the value of the `have_ssl` system variable:

```
mysql> SHOW VARIABLES LIKE 'have_ssl';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| have_ssl      | YES   |
+-----+-----+
```

If the value is `YES`, the server supports encrypted connections. If the value is `DISABLED`, the server is capable of supporting encrypted connections but was not started with the appropriate `--ssl-xxx` options to enable encrypted connections to be used; see [Section 8.3.1, “Configuring MySQL to Use Encrypted Connections”](#).

2.8.7 MySQL Source-Configuration Options

The [CMake](#) program provides a great deal of control over how you configure a MySQL source distribution. Typically, you do this using options on the [CMake](#) command line. For information about options supported by [CMake](#), run either of these commands in the top-level source directory:

```
$> cmake . -LH
$> ccmake .
```

You can also affect [CMake](#) using certain environment variables. See [Section 6.9, “Environment Variables”](#).

For boolean options, the value may be specified as `1` or `ON` to enable the option, or as `0` or `OFF` to disable the option.

Many options configure compile-time defaults that can be overridden at server startup. For example, the `CMAKE_INSTALL_PREFIX`, `MYSQL_TCP_PORT`, and `MYSQL_UNIX_ADDR` options that configure the default installation base directory location, TCP/IP port number, and Unix socket file can be changed at server startup with the `--basedir`, `--port`, and `--socket` options for `mysqld`. Where applicable, configuration option descriptions indicate the corresponding `mysqld` startup option.

The following sections provide more information about [CMake](#) options.

- [CMake Option Reference](#)
- [General Options](#)
- [Installation Layout Options](#)
- [Storage Engine Options](#)
- [Feature Options](#)
- [Compiler Flags](#)

- [CMake Options for Compiling NDB Cluster](#)

CMake Option Reference

The following table shows the available CMake options. In the `Default` column, `PREFIX` stands for the value of the `CMAKE_INSTALL_PREFIX` option, which specifies the installation base directory. This value is used as the parent location for several of the installation subdirectories.

Table 2.13 MySQL Source-Configuration Option Reference (CMake)

Formats	Description	Default
<code>ADD_GDB_INDEX</code>	Whether to enable generation of .gdb_index section in binaries	
<code>BUILD_CONFIG</code>	Use same build options as official releases	
<code>BUNDLE_RUNTIME_LIBRARIES</code>	Bundle runtime libraries with server MSI and Zip packages for Windows	<code>OFF</code>
<code>CMAKE_BUILD_TYPE</code>	Type of build to produce	<code>RelWithDebInfo</code>
<code>CMAKE_CXX_FLAGS</code>	Flags for C++ Compiler	
<code>CMAKE_C_FLAGS</code>	Flags for C Compiler	
<code>CMAKE_INSTALL_PREFIX</code>	Installation base directory	<code>/usr/local/mysql</code>
<code>COMPILATION_COMMENT</code>	Comment about compilation environment	
<code>COMPILATION_COMMENT_SERVER</code>	Comment about compilation environment for use by mysqld	
<code>COMPRESS_DEBUG_SECTIONS</code>	Compress debug sections of binary executables	<code>OFF</code>
<code>CPACK_MONOLITHIC_INSTALL</code>	Whether package build produces single file	<code>OFF</code>
<code>DEFAULT_CHARSET</code>	The default server character set	<code>utf8mb4</code>
<code>DEFAULT_COLLATION</code>	The default server collation	<code>utf8mb4_0900_ai_ci</code>
<code>DISABLE_PSI_COND</code>	Exclude Performance Schema condition instrumentation	<code>OFF</code>
<code>DISABLE_PSI_DATA_LOCK</code>	Exclude the performance schema data lock instrumentation	<code>OFF</code>
<code>DISABLE_PSI_ERROR</code>	Exclude the performance schema server error instrumentation	<code>OFF</code>
<code>DISABLE_PSI_FILE</code>	Exclude Performance Schema file instrumentation	<code>OFF</code>
<code>DISABLE_PSI_IDLE</code>	Exclude Performance Schema idle instrumentation	<code>OFF</code>
<code>DISABLE_PSI_MEMORY</code>	Exclude Performance Schema memory instrumentation	<code>OFF</code>
<code>DISABLE_PSI_METADATA</code>	Exclude Performance Schema metadata instrumentation	<code>OFF</code>
<code>DISABLE_PSI_MUTEX</code>	Exclude Performance Schema mutex instrumentation	<code>OFF</code>

Formats	Description	Default
<code>DISABLE_PSI_PS</code>	Exclude the performance schema prepared statements	<code>OFF</code>
<code>DISABLE_PSI_RWLOCK</code>	Exclude Performance Schema rwlock instrumentation	<code>OFF</code>
<code>DISABLE_PSI_SOCKET</code>	Exclude Performance Schema socket instrumentation	<code>OFF</code>
<code>DISABLE_PSI_SP</code>	Exclude Performance Schema stored program instrumentation	<code>OFF</code>
<code>DISABLE_PSI_STAGE</code>	Exclude Performance Schema stage instrumentation	<code>OFF</code>
<code>DISABLE_PSI_STATEMENT</code>	Exclude Performance Schema statement instrumentation	<code>OFF</code>
<code>DISABLE_PSI_STATEMENT_DIGEST</code>	Exclude Performance Schema statements_digest instrumentation	<code>OFF</code>
<code>DISABLE_PSI_TABLE</code>	Exclude Performance Schema table instrumentation	<code>OFF</code>
<code>DISABLE_PSI_THREAD</code>	Exclude the performance schema thread instrumentation	<code>OFF</code>
<code>DISABLE_PSI_TRANSACTION</code>	Exclude the performance schema transaction instrumentation	<code>OFF</code>
<code>ENABLED_LOCAL_INFILE</code>	Whether to enable LOCAL for LOAD DATA	<code>OFF</code>
<code>ENABLED_PROFILING</code>	Whether to enable query profiling code	<code>ON</code>
<code>ENABLE_EXPERIMENTAL_SYSVAR</code>	Whether to enable experimental InnoDB system variables	<code>OFF</code>
<code>ENABLE_GCOV</code>	Whether to include gcov support	
<code>ENABLE_GPROF</code>	Enable gprof (optimized Linux builds only)	<code>OFF</code>
<code>FORCE_COLORED_OUTPUT</code>	Whether to colorize compiler output	<code>OFF</code>
<code>FORCE_INSOURCE_BUILD</code>	Whether to force an in-source build	<code>OFF</code>
<code>FORCE_UNSUPPORTED_COMPILER</code>	Whether to permit unsupported compilers	<code>OFF</code>
<code>FPROFILE_GENERATE</code>	Whether to generate profile guided optimization data	<code>OFF</code>
<code>FPROFILE_USE</code>	Whether to use profile guided optimization data	<code>OFF</code>
<code>HAVE_PSI_MEMORY_INTERFACE</code>	Enable performance schema memory tracing module for memory allocation functions used in dynamic storage of over-aligned types	<code>OFF</code>

Formats	Description	Default
IGNORE_AIO_CHECK	With -DBUILD_CONFIG=mysql_release, ignore libaio check	OFF
INSTALL_BINDIR	User executables directory	PREFIX/bin
INSTALL_DOCDIR	Documentation directory	PREFIX/docs
INSTALL_DOCREADMEDIR	README file directory	PREFIX
INSTALL_INCLUDEDIR	Header file directory	PREFIX/include
INSTALL_INFODIR	Info file directory	PREFIX/docs
INSTALL_LAYOUT	Select predefined installation layout	STANDALONE
INSTALL_LIBDIR	Library file directory	PREFIX/lib
INSTALL_MANDIR	Manual page directory	PREFIX/man
INSTALL_MYSQLKEYRINGDIR	Directory for keyring_file plugin data file	platform specific
INSTALL_MYSQLSHAREDIR	Shared data directory	PREFIX/share
INSTALL_MYSQLTESTDIR	mysql-test directory	PREFIX/mysql-test
INSTALL_PKGCONFIGDIR	Directory for mysqlclient.pc pkg-config file	INSTALL_LIBDIR/pkgconfig
INSTALL_PLUGINDIR	Plugin directory	PREFIX/lib/plugin
INSTALL_PRIV_LIBDIR	Installation private library directory	
INSTALL_SBINDIR	Server executable directory	PREFIX/bin
INSTALL_SECURE_FILE_PRIVDIR	secure_file_priv default value	platform specific
INSTALL_SHAREDIR	aclocal/mysql.m4 installation directory	PREFIX/share
INSTALL_STATIC_LIBRARIES	Whether to install static libraries	ON
INSTALL_SUPPORTFILESDIR	Extra support files directory	PREFIX/support-files
LINK_RANDOMIZE	Whether to randomize order of symbols in mysqld binary	OFF
LINK_RANDOMIZE_SEED	Seed value for LINK_RANDOMIZE option	mysql
MAX_INDEXES	Maximum indexes per table	64
MSVC_CPPCHECK	Enable MSVC code analysis.	ON
MUTEX_TYPE	InnoDB mutex type	event
MYSQLX_TCP_PORT	TCP/IP port number used by X Plugin	33060
MYSQLX_UNIX_ADDR	Unix socket file used by X Plugin	/tmp/mysqlx.sock
MYSQL_DATADIR	Data directory	
MYSQL_MAINTAINER_MODE	Whether to enable MySQL maintainer-specific development environment	OFF
MYSQL_PROJECT_NAME	Windows/macOS project name	MySQL
MYSQL_TCP_PORT	TCP/IP port number	3306
MYSQL_UNIX_ADDR	Unix socket file	/tmp/mysql.sock

Formats	Description	Default
<code>NDB_UTILS_LINK_DYNAMIC</code>	Cause NDB tools to be dynamically linked to ndbclient	
<code>ODBC_INCLUDES</code>	ODBC includes directory	
<code>ODBC_LIB_DIR</code>	ODBC library directory	
<code>OPTIMIZER_TRACE</code>	Whether to support optimizer tracing	
<code>OPTIMIZE_SANITIZER_BUILDS</code>	Whether to optimize sanitizer builds	<code>ON</code>
<code>REPRODUCIBLE_BUILD</code>	Take extra care to create a build result independent of build location and time	
<code>SHOW_SUPPRESSED_COMPILER_WARNINGS</code>	Whether to show suppressed compiler warnings and not fail with -Werror.	<code>OFF</code>
<code>SYSCONFDIR</code>	Option file directory	
<code>SYSTEMD_PID_DIR</code>	Directory for PID file under systemd	<code>/var/run/mysqld</code>
<code>SYSTEMD_SERVICE_NAME</code>	Name of MySQL service under systemd	<code>mysqld</code>
<code>TMPDIR</code>	tmpdir default value	
<code>WIN_DEBUG_NO_INLINE</code>	Whether to disable function inlining	<code>OFF</code>
<code>WITHOUT_SERVER</code>	Do not build the server	<code>OFF</code>
<code>WITHOUT_XXX_STORAGE_ENGINE</code>	Exclude storage engine xxx from build	
<code>WITH_ANT</code>	Path to Ant for building GCS Java wrapper	
<code>WITH_ASAN</code>	Enable AddressSanitizer	<code>OFF</code>
<code>WITH_ASAN_SCOPE</code>	Enable AddressSanitizer - fsanitize-address-use-after-scope Clang flag	<code>OFF</code>
<code>WITH_AUTHENTICATION_CLIENT</code>	Enabled automatically if any corresponding server authentication plugins are built	
<code>WITH_AUTHENTICATION_LDAP</code>	Whether to report error if LDAP authentication plugins cannot be built	<code>OFF</code>
<code>WITH_AUTHENTICATION_PAM</code>	Build PAM authentication plugin	<code>OFF</code>
<code>WITH_AWS_SDK</code>	Location of Amazon Web Services software development kit	
<code>WITH_BUILD_ID</code>	On Linux systems, generate a unique build ID	<code>ON</code>
<code>WITH_CLASSPATH</code>	Classpath to use when building MySQL Cluster Connector for Java. Default is an empty string.	

Formats	Description	Default
WITH_CLIENT_PROTOCOL_TRACING	Build client-side protocol tracing framework	ON
WITH_CURL	Location of curl library	
WITH_DEBUG	Whether to include debugging support	OFF
WITH_DEFAULT_COMPILER_OPTIONS	Whether to use default compiler options	ON
WITH_DEVELOPER_ENTITLEMENTS	Whether to add the 'get-task-allow' entitlement to all executables on macOS to generate a core dump in the event of an unexpected server halt	OFF
WITH_EDITLINE	Which libedit/editline library to use	bundled
WITH_ERROR_INSERT	Enable error injection in the NDB storage engine. Should not be used for building binaries intended for production.	OFF
WITH_FIDO	Type of FIDO library support	bundled
WITH_ICU	Type of ICU support	bundled
WITH_INNOODB_EXTRA_DEBUG	Whether to include extra debugging support for InnoDB.	OFF
WITH_JEMALLOC	Whether to link with -ljemalloc	OFF
WITH_KEYRING_TEST	Build the keyring test program	OFF
WITH_LD	Whether to use the LLVM lld or mold linker	
WITH_LIBEVENT	Which libevent library to use	bundled
WITH_LIBWRAP	Whether to include libwrap (TCP wrappers) support	OFF
WITH_LOCK_ORDER	Whether to enable LOCK_ORDER tooling	OFF
WITH_LSAN	Whether to run LeakSanitizer, without AddressSanitizer	OFF
WITH_LTO	Enable link-time optimizer	OFF
WITH_LZ4	Type of LZ4 library support	bundled
WITH_MECAB	Compiles MeCab	
WITH_MSAN	Enable MemorySanitizer	OFF
WITH_MSCRT_DEBUG	Enable Visual Studio CRT memory leak tracing	OFF
WITH_MYSQLX	Whether to disable X Protocol	ON
WITH_NDB	Build MySQL NDB Cluster	OFF
WITH_NDBAPI_EXAMPLES	Build API example programs	OFF
WITH_NDBCLUSTER	Build the NDB storage engine	OFF
WITH_NDBCLUSTER_STORAGE_ENGINE	For internal use; may not work as expected in all	ON

Formats	Description	Default
	circumstances; users should employ WITH_NDBCLUSTER instead	
WITH_NDBMTD	Build multithreaded data node.	ON
WITH_NDB_DEBUG	Produce a debug build for testing or troubleshooting.	OFF
WITH_NDB_JAVA	Enable building of Java and ClusterJ support. Enabled by default. Supported in MySQL Cluster only.	ON
WITH_NDB_PORT	Default port used by a management server built with this option. If this option was not used to build it, the management server's default port is 1186.	[none]
WITH_NDB_TEST	Include NDB API test programs.	OFF
WITH_NDB_TLS_SEARCH_PATH	Default path used by NDB programs to search for TLS certificate and key files.	\$HOME/ndb-tls
WITH_NUMA	Set NUMA memory allocation policy	
WITH_PACKAGE_FLAGS	For flags typically used for RPM/DEB packages, whether to add them to standalone builds on those platforms	
WITH_PROTOBUF	Which Protocol Buffers package to use	bundled
WITH_RAPID	Whether to build rapid development cycle plugins	ON
WITH_RAPIDJSON	Type of RapidJSON support	bundled
WITH_ROUTER	Whether to build MySQL Router	ON
WITH_SHOW_PARSE_TREE	Support for SHOW PARSE_TREE debugging statement	
WITH_SSL	Type of SSL support	system
WITH_SYSTEMD	Enable installation of systemd support files	OFF
WITH_SYSTEMD_DEBUG	Enable additional systemd debug information	OFF
WITH_SYSTEM_LIBS	Set system value of library options not set explicitly	OFF
WITH_TCMALLOC	Whether to link with -ltcmalloc	OFF
WITH_TEST_TRACE_PLUGIN	Build test protocol trace plugin	OFF
WITH_TSAN	Enable ThreadSanitizer	OFF
WITH_UBSAN	Enable Undefined Behavior Sanitizer	OFF
WITH_UNIT_TESTS	Compile MySQL with unit tests	ON

Formats	Description	Default
<code>WITH_UNIXODBC</code>	Enable unixODBC support	<code>OFF</code>
<code>WITH_VALGRIND</code>	Whether to compile in Valgrind header files	<code>OFF</code>
<code>WITH_WIN_JEMALLOC</code>	Path to directory containing jemalloc.dll	
<code>WITH_ZLIB</code>	Type of zlib support	<code>bundled</code>
<code>WITH_ZSTD</code>	Type of zstd support	<code>bundled</code>
<code>WITH_XXX_STORAGE_ENGINE</code>	Compile storage engine xxx statically into server	

General Options

- `-DBUILD_CONFIG=mysql_release`

This option configures a source distribution with the same build options used by Oracle to produce binary distributions for official MySQL releases.

- `-DWITH_BUILD_ID=bool`

On Linux systems, generates a unique build ID which is used as the value of the `build_id` system variable and written to the MySQL server log on startup. Set this option to `OFF` to disable this feature.

This option has no effect on platforms other than Linux.

- `-DBUNDLE_RUNTIME_LIBRARIES=bool`

Whether to bundle runtime libraries with server MSI and Zip packages for Windows.

- `-DCMAKE_BUILD_TYPE=type`

The type of build to produce:

- `RelWithDebInfo`: Enable optimizations and generate debugging information. This is the default MySQL build type.
- `Release`: Enable optimizations but omit debugging information to reduce the build size.
- `Debug`: Disable optimizations and generate debugging information. This build type is also used if the `WITH_DEBUG` option is enabled. That is, `-DWITH_DEBUG=1` has the same effect as `-DCMAKE_BUILD_TYPE=Debug`.

The option values `None` and `MinSizeRel` are not supported.

- `-DCPACK_MONOLITHIC_INSTALL=bool`

This option affects whether the `make package` operation produces multiple installation package files or a single file. If disabled, the operation produces multiple installation package files, which may be useful if you want to install only a subset of a full MySQL installation. If enabled, it produces a single file for installing everything.

- `-DFORCE_INSOURCE_BUILD=bool`

Defines whether to force an in-source build. Out-of-source builds are recommended, as they permit multiple builds from the same source, and cleanup can be performed quickly by removing the build directory. To force an in-source build, invoke `CMake` with `-DFORCE_INSOURCE_BUILD=ON`.

- `-DFORCE_COLORED_OUTPUT=bool`

Defines whether to enable colored compiler output for `gcc` and `clang` when compiling on the command line. Defaults to `OFF`.

Installation Layout Options

The `CMAKE_INSTALL_PREFIX` option indicates the base installation directory. Other options with names of the form `INSTALL_XXX` that indicate component locations are interpreted relative to the prefix and their values are relative pathnames. Their values should not include the prefix.

- `-DCMAKE_INSTALL_PREFIX=dir_name`

The installation base directory.

This value can be set at server startup using the `--basedir` option.

- `-DINSTALL_BINDIR=dir_name`

Where to install user programs.

- `-DINSTALL_DOCDIR=dir_name`

Where to install documentation.

- `-DINSTALL_DOCREADMEDIR=dir_name`

Where to install `README` files.

- `-DINSTALL_INCLUDEDIR=dir_name`

Where to install header files.

- `-DINSTALL_INFODIR=dir_name`

Where to install Info files.

- `-DINSTALL_LAYOUT=name`

Select a predefined installation layout:

- `STANDALONE`: Same layout as used for `.tar.gz` and `.zip` packages. This is the default.
- `RPM`: Layout similar to RPM packages.
- `SVR4`: Solaris package layout.
- `DEB`: DEB package layout (experimental).

You can select a predefined layout but modify individual component installation locations by specifying other options. For example:

```
cmake . -DINSTALL_LAYOUT=SVR4 -DMYSQL_DATADIR=/var/mysql/data
```

The `INSTALL_LAYOUT` value determines the default value of the `secure_file_priv`, `keyring_encrypted_file_data`, and `keyring_file_data` system variables. See the descriptions of those variables in [Section 7.1.8, “Server System Variables”](#), and [Section 8.4.4.19, “Keyring System Variables”](#).

- `-DINSTALL_LIBDIR=dir_name`

Where to install library files.

- `-DINSTALL_MANDIR=dir_name`

Where to install manual pages.

- `-DINSTALL_MYSQLKEYRINGDIR=dir_path`

The default directory to use as the location of the `keyring_file` plugin data file. The default value is platform specific and depends on the value of the `INSTALL_LAYOUT` CMake option; see the description of the `keyring_file_data` system variable in [Section 7.1.8, “Server System Variables”](#).

- `-DINSTALL_MYSQLSHAREDIR=dir_name`

Where to install shared data files.

- `-DINSTALL_MYSQLTESTDIR=dir_name`

Where to install the `mysql-test` directory. To suppress installation of this directory, explicitly set the option to the empty value (`-DINSTALL_MYSQLTESTDIR=`).

- `-DINSTALL_PKGCONFIGDIR=dir_name`

The directory in which to install the `mysqlclient.pc` file for use by `pkg-config`. The default value is `INSTALL_LIBDIR/pkgconfig`, unless `INSTALL_LIBDIR` ends with `/mysql`, in which case that is removed first.

- `-DINSTALL_PLUGINDIR=dir_name`

The location of the plugin directory.

This value can be set at server startup with the `--plugin_dir` option.

- `-DINSTALL_PRIV_LIBDIR=dir_name`

The location of the dynamic library directory.

Default location. For RPM builds, this is `/usr/lib64/mysql/private/`, for DEB it is `/usr/lib/mysql/private/`, and for TAR it is `lib/private/`.

Protobuf. Because this is a private location, the loader (such as `ld-linux.so` on Linux) may not find the `libprotobuf.so` files without help. To guide the loader, `RPATH=$ORIGIN/../../$INSTALL_PRIV_LIBDIR` is added to `mysqld` and `mysqlxtest`. This works for most cases but when using the [Resource Group](#) feature, `mysqld` is `setsuid`, and the loader ignores any `RPATH` which contains `$ORIGIN`. To overcome this, an explicit full path to the directory is set in the DEB and RPM versions of `mysqld`, since the target destination is known. For tarball installs, patching of `mysqld` with a tool like `patchelf` is required.

- `-DINSTALL_SBINDIR=dir_name`

Where to install the `mysqld` server.

- `-DINSTALL_SECURE_FILE_PRIVDIR=dir_name`

The default value for the `secure_file_priv` system variable. The default value is platform specific and depends on the value of the `INSTALL_LAYOUT` CMake option; see the description of the `secure_file_priv` system variable in [Section 7.1.8, “Server System Variables”](#).

- `-DINSTALL_SHAREDIR=dir_name`

Where to install `aclocal/mysql.m4`.

- `-DINSTALL_STATIC_LIBRARIES=bool`

Whether to install static libraries. The default is `ON`. If set to `OFF`, these library files are not installed: `libmysqlclient.a`, `libmysqldservices.a`.

- `-DINSTALL_SUPPORTFILES_DIR=dir_name`

Where to install extra support files.

- `-DLINK_RANDOMIZE=bool`

Whether to randomize the order of symbols in the `mysqld` binary. The default is `OFF`. This option should be enabled only for debugging purposes.

- `-DLINK_RANDOMIZE_SEED=val`

Seed value for the `LINK_RANDOMIZE` option. The value is a string. The default is `mysql`, an arbitrary choice.

- `-DMYSQL_DATADIR=dir_name`

The location of the MySQL data directory.

This value can be set at server startup with the `--datadir` option.

- `-DODBC_INCLUDES=dir_name`

The location of the ODBC includes directory, which may be used while configuring Connector/ODBC.

- `-DODBC_LIB_DIR=dir_name`

The location of the ODBC library directory, which may be used while configuring Connector/ODBC.

- `-DSYSCONFDIR=dir_name`

The default `my.cnf` option file directory.

This location cannot be set at server startup, but you can start the server with a given option file using the `--defaults-file=file_name` option, where `file_name` is the full path name to the file.

- `-DSYSTEMD_PID_DIR=dir_name`

The name of the directory in which to create the PID file when MySQL is managed by `systemd`. The default is `/var/run/mysqld`; this might be changed implicitly according to the `INSTALL_LAYOUT` value.

This option is ignored unless `WITH_SYSTEMD` is enabled.

- `-DSYSTEMD_SERVICE_NAME=name`

The name of the MySQL service to use when MySQL is managed by `systemd`. The default is `mysqld`; this might be changed implicitly according to the `INSTALL_LAYOUT` value.

This option is ignored unless `WITH_SYSTEMD` is enabled.

- `-DTMPDIR=dir_name`

The default location to use for the `tmpdir` system variable. If unspecified, the value defaults to `P_tmpdir` in `<stdio.h>`.

Storage Engine Options

Storage engines are built as plugins. You can build a plugin as a static module (compiled into the server) or a dynamic module (built as a dynamic library that must be installed into the server using the `INSTALL PLUGIN` statement or the `--plugin-load` option before it can be used). Some plugins might not support static or dynamic building.

The `InnoDB`, `MyISAM`, `MERGE`, `MEMORY`, and `CSV` engines are mandatory (always compiled into the server) and need not be installed explicitly.

To compile a storage engine statically into the server, use `-DWITH_engine_STORAGE_ENGINE=1`. Some permissible *engine* values are `ARCHIVE`, `BLACKHOLE`, `EXAMPLE`, and `FEDERATED`. Examples:

```
-DWITH_ARCHIVE_STORAGE_ENGINE=1
-DWITH_BLACKHOLE_STORAGE_ENGINE=1
```

To build MySQL with support for NDB Cluster, use the `WITH_NDB` option.

Note

It is not possible to compile without Performance Schema support. If it is desired to compile without particular types of instrumentation, that can be done with the following `CMake` options:

```
DISABLE_PSI_COND
DISABLE_PSI_DATA_LOCK
DISABLE_PSI_ERROR
DISABLE_PSI_FILE
DISABLE_PSI_IDLE
DISABLE_PSI_MEMORY
DISABLE_PSI_METADATA
DISABLE_PSI_MUTEX
DISABLE_PSI_PS
DISABLE_PSI_RWLOCK
DISABLE_PSI_SOCKET
DISABLE_PSI_SP
DISABLE_PSI_STAGE
DISABLE_PSI_STATEMENT
DISABLE_PSI_STATEMENT_DIGEST
DISABLE_PSI_TABLE
DISABLE_PSI_THREAD
DISABLE_PSI_TRANSACTION
```

For example, to compile without mutex instrumentation, configure MySQL using `-DDISABLE_PSI_MUTEX=1`.

To exclude a storage engine from the build, use `-DWITH_engine_STORAGE_ENGINE=0`. Examples:

```
-DWITH_ARCHIVE_STORAGE_ENGINE=0
-DWITH_EXAMPLE_STORAGE_ENGINE=0
-DWITH_FEDERATED_STORAGE_ENGINE=0
```

It is also possible to exclude a storage engine from the build using `-DWITHOUT_engine_STORAGE_ENGINE=1` (but `-DWITH_engine_STORAGE_ENGINE=0` is preferred). Examples:

```
-DWITHOUT_ARCHIVE_STORAGE_ENGINE=1
-DWITHOUT_EXAMPLE_STORAGE_ENGINE=1
-DWITHOUT_FEDERATED_STORAGE_ENGINE=1
```

If neither `-DWITH_engine_STORAGE_ENGINE` nor `-DWITHOUT_engine_STORAGE_ENGINE` are specified for a given storage engine, the engine is built as a shared module, or excluded if it cannot be built as a shared module.

Feature Options

- `-DADD_GDB_INDEX=bool`

This option determines whether to enable generation of a `.gdb_index` section in binaries, which makes loading them in a debugger faster. The option is disabled by default. `lld` linker is used, and is disabled by It has no effect if a linker other than `lld` or GNU `gold` is used.

- `-DCOMPILATION_COMMENT=string`

A descriptive comment about the compilation environment. While `mysqld` uses `COMPILATION_COMMENT_SERVER`, other programs use `COMPILATION_COMMENT`.

- `-DCOMPRESS_DEBUG_SECTIONS=bool`

Whether to compress the debug sections of binary executables (Linux only). Compressing executable debug sections saves space at the cost of extra CPU time during the build process.

The default is `OFF`. If this option is not set explicitly but the `COMPRESS_DEBUG_SECTIONS` environment variable is set, the option takes its value from that variable.

- `-DCOMPILATION_COMMENT_SERVER=string`

A descriptive comment about the compilation environment for use by `mysqld` (for example, to set the `version_comment` system variable). Programs other than the server use `COMPILATION_COMMENT`.

- `-DDEFAULT_CHARSET=charset_name`

The server character set. By default, MySQL uses the `utf8mb4` character set.

`charset_name` may be one of `binary`, `armscii8`, `ascii`, `big5`, `cp1250`, `cp1251`, `cp1256`, `cp1257`, `cp850`, `cp852`, `cp866`, `cp932`, `dec8`, `eucjpms`, `euckr`, `gb2312`, `gbk`, `geostd8`, `greek`, `hebrew`, `hp8`, `keybcs2`, `koi8r`, `koi8u`, `latin1`, `latin2`, `latin5`, `latin7`, `macce`, `macroman`, `sjis`, `swe7`, `tis620`, `ucs2`, `ujis`, `utf8mb3`, `utf8mb4`, `utf16`, `utf16le`, `utf32`.

This value can be set at server startup with the `--character-set-server` option.

- `-DDEFAULT_COLLATION=collation_name`

The server collation. By default, MySQL uses `utf8mb4_0900_ai_ci`. Use the `SHOW COLLATION` statement to determine which collations are available for each character set.

This value can be set at server startup with the `--collation_server` option.

- `-DDISABLE_PSI_COND=bool`

Whether to exclude the Performance Schema condition instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_FILE=bool`

Whether to exclude the Performance Schema file instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_IDLE=bool`

Whether to exclude the Performance Schema idle instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_MEMORY=bool`

Whether to exclude the Performance Schema memory instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_METADATA=bool`

Whether to exclude the Performance Schema metadata instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_MUTEX=bool`

Whether to exclude the Performance Schema mutex instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_RWLOCK=bool`

Whether to exclude the Performance Schema rwlock instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_SOCKET=bool`

Whether to exclude the Performance Schema socket instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_SP=bool`

Whether to exclude the Performance Schema stored program instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_STAGE=bool`

Whether to exclude the Performance Schema stage instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_STATEMENT=bool`

Whether to exclude the Performance Schema statement instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_STATEMENT_DIGEST=bool`

Whether to exclude the Performance Schema statement digest instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_TABLE=bool`

Whether to exclude the Performance Schema table instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_PS=bool`

Exclude the Performance Schema prepared statements instances instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_THREAD=bool`

Exclude the Performance Schema thread instrumentation. The default is `OFF` (include).

Only disable threads when building without any instrumentation, because other instrumentations have a dependency on threads.

- `-DDISABLE_PSI_TRANSACTION=bool`

Exclude the Performance Schema transaction instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_DATA_LOCK=bool`

Exclude the performance schema data lock instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_ERROR=bool`

Exclude the performance schema server error instrumentation. The default is `OFF` (include).

- `-DENABLE_EXPERIMENTAL_SYSVARS=bool`

Whether to enable experimental `InnoDB` system variables. Experimental system variables are intended for those engaged in MySQL development, should only be used in a development or test environment, and may be removed without notice in a future MySQL release. For information

about experimental system variables, refer to `/storage/innobase/handler/ha_innodb.cc` in the MySQL source tree. Experimental system variables can be identified by searching for “`PLUGIN_VAR_EXPERIMENTAL`”.

- `-DWITHOUT_SERVER=bool`

Whether to build without MySQL Server. The default is OFF, which does build the server.

This is considered an experimental option; it is preferred to build with the server.

- `-DENABLE_GCOV=bool`

Whether to include `gcov` support (Linux only).

- `-DENABLE_GPROF=bool`

Whether to enable `gprof` (optimized Linux builds only).

- `-DENABLED_LOCAL_INFILE=bool`

This option controls the compiled-in default `LOCAL` capability for the MySQL client library. Clients that make no explicit arrangements therefore have `LOCAL` capability disabled or enabled according to the `ENABLED_LOCAL_INFILE` setting specified at MySQL build time.

By default, the client library in MySQL binary distributions is compiled with `ENABLED_LOCAL_INFILE` disabled. If you compile MySQL from source, configure it with `ENABLED_LOCAL_INFILE` disabled or enabled based on whether clients that make no explicit arrangements should have `LOCAL` capability disabled or enabled, respectively.

`ENABLED_LOCAL_INFILE` controls the default for client-side `LOCAL` capability. For the server, the `local_infile` system variable controls server-side `LOCAL` capability. To explicitly cause the server to refuse or permit `LOAD DATA LOCAL` statements (regardless of how client programs and libraries are configured at build time or runtime), start `mysqld` with `--local-infile` disabled or enabled, respectively. `local_infile` can also be set at runtime. See [Section 8.1.6, “Security Considerations for LOAD DATA LOCAL”](#).

- `-DENABLED_PROFILING=bool`

Whether to enable query profiling code (for the `SHOW PROFILE` and `SHOW PROFILES` statements).

- `-DFORCE_UNSUPPORTED_COMPILER=bool`

By default, `CMake` checks for minimum versions of [supported compilers](#); to disable this check, use `-DFORCE_UNSUPPORTED_COMPILER=ON`.

- `-DSHOW_SUPPRESSED_COMPILER_WARNINGS=bool`

Show suppressed compiler warnings, and do so without failing with `-Werror`. Defaults to OFF.

- `-DFPROFILE_GENERATE=bool`

Whether to generate profile guided optimization (PGO) data. This option is available for experimenting with PGO with GCC. See `cmake/fprofile.cmake` in the MySQL source distribution for information about using `FPROFILE_GENERATE` and `FPROFILE_USE`. These options have been tested with GCC 8 and 9.

- `-DFPROFILE_USE=bool`

Whether to use profile guided optimization (PGO) data. This option is available for experimenting with PGO with GCC. See the `cmake/fprofile.cmake` file in a MySQL source distribution for information about using `FPROFILE_GENERATE` and `FPROFILE_USE`. These options have been tested with GCC 8 and 9.

Enabling `FPROFILE_USE` also enables `WITH_LTO`.

- `-DHAVE_PSI_MEMORY_INTERFACE=bool`

Whether to enable the performance schema memory tracing module for memory allocation functions (`ut::aligned_name` library functions) used in dynamic storage of over-aligned types.

- `-DIGNORE_AIO_CHECK=bool`

If the `-DBUILD_CONFIG=mysql_release` option is given on Linux, the `libaio` library must be linked in by default. If you do not have `libaio` or do not want to install it, you can suppress the check for it by specifying `-DIGNORE_AIO_CHECK=1`.

- `-DMAX_INDEXES=num`

The maximum number of indexes per table. The default is 64. The maximum is 255. Values smaller than 64 are ignored and the default of 64 is used.

- `-DMYSQL_MAINTAINER_MODE=bool`

Whether to enable a MySQL maintainer-specific development environment. If enabled, this option causes compiler warnings to become errors.

- `-DWITH_DEVELOPER_ENTITLEMENTS=bool`

Whether to add the `get-task-allow` entitlement to all executables to generate a core dump in the event of an unexpected server halt.

On macOS 11+, core dumps are limited to processes with the `com.apple.security.get-task-allow` entitlement, which this CMake option enables. The entitlement allows other processes to attach and read/modify the processes memory, and allows `--core-file` to function as expected.

- `-DMUTEX_TYPE=type`

The mutex type used by `InnoDB`. Options include:

- `event`: Use event mutexes. This is the default value and the original `InnoDB` mutex implementation.
- `sys`: Use POSIX mutexes on UNIX systems. Use `CRITICAL_SECTION` objects on Windows, if available.
- `futex`: Use Linux futexes instead of condition variables to schedule waiting threads.

- `-DMYSQLX_TCP_PORT=port_num`

The port number on which X Plugin listens for TCP/IP connections. The default is 33060.

This value can be set at server startup with the `mysqlx_port` system variable.

- `-DMYSQLX_UNIX_ADDR=file_name`

The Unix socket file path on which the server listens for X Plugin socket connections. This must be an absolute path name. The default is `/tmp/mysqlx.sock`.

This value can be set at server startup with the `mysqlx_port` system variable.

- `-DMYSQL_PROJECT_NAME=name`

For Windows or macOS, the project name to incorporate into the project file name.

- `-DMYSQL_TCP_PORT=port_num`

The port number on which the server listens for TCP/IP connections. The default is 3306.

This value can be set at server startup with the `--port` option.

- `-DMYSQL_UNIX_ADDR=file_name`

The Unix socket file path on which the server listens for socket connections. This must be an absolute path name. The default is `/tmp/mysql.sock`.

This value can be set at server startup with the `--socket` option.

- `-DOPTIMIZER_TRACE=bool`

Whether to support optimizer tracing. See [MySQL Internals: Tracing the Optimizer](#).

- `-DREPRODUCIBLE_BUILD=bool`

For builds on Linux systems, this option controls whether to take extra care to create a build result independent of build location and time.

This option defaults to `ON` for `RelWithDebInfo` builds.

- `-DWITH_LD=string`

`CMake` uses the standard linker by default. Optionally pass in `lld` or `gold` to specify an alternative linker. `gold` must be version 2 or newer.

This option can be used on Linux-based systems other than Enterprise Linux, which always uses the `ld` linker.

Note

Previously, the option `USE_LD_LLD` could be used to enable (the default) or disable explicitly the LLVM `lld` linker for Clang. In MySQL 8.3, `USE_LD_LLD` has been removed.

- `-DWIN_DEBUG_NO_INLINE=bool`

Whether to disable function inlining on Windows. The default is `OFF` (inlining enabled).

- `-DWITH_ANT=path_name`

Set the path to Ant, required when building GCS Java wrapper. Set `WITH_ANT` to the path of a directory where the Ant tarball or unpacked archive is saved. When `WITH_ANT` is not set, or is set with the special value `system`, the build process assumes a binary `ant` exists in `$PATH`.

- `-DWITH_ASAN=bool`

Whether to enable the AddressSanitizer, for compilers that support it. The default is `OFF`.

- `-DWITH_ASAN_SCOPE=bool`

Whether to enable the AddressSanitizer `-fsanitize-address-use-after-scope` Clang flag for use-after-scope detection. The default is off. To use this option, `-DWITH_ASAN` must also be enabled.

- `-DWITH_AUTHENTICATION_CLIENT_PLUGINS=bool`

This option is enabled automatically if any corresponding server authentication plugins are built. Its value thus depends on other `CMake` options and it should not be set explicitly.

- `-DWITH_AUTHENTICATION_LDAP=bool`

Whether to report an error if the LDAP authentication plugins cannot be built:

- If this option is disabled (the default), the LDAP plugins are built if the required header files and libraries are found. If they are not, [CMake](#) displays a note about it.
 - If this option is enabled, a failure to find the required header file and libraries causes CMake to produce an error, preventing the server from being built.
- `-DWITH_AUTHENTICATION_PAM=bool`

Whether to build the PAM authentication plugin, for source trees that include this plugin. (See [Section 8.4.1.5, “PAM Pluggable Authentication”](#).) If this option is specified and the plugin cannot be compiled, the build fails.

- `-DWITH_AWS_SDK=path_name`

The location of the Amazon Web Services software development kit.

- `-DWITH_CLIENT_PROTOCOL_TRACING=bool`

Whether to build the client-side protocol tracing framework into the client library. By default, this option is enabled.

For information about writing protocol trace client plugins, see [Writing Protocol Trace Plugins](#).

See also the `WITH_TEST_TRACE_PLUGIN` option.

- `-DWITH_CURL=curl_type`

The location of the `curl` library. `curl_type` can be `system` (use the system `curl` library), a path name to the `curl` library, `no|off|none` to disable curl support, or `bundled` to use the bundled curl distribution in `extra/curl/`.

- `-DWITH_DEBUG=bool`

Whether to include debugging support.

Configuring MySQL with debugging support enables you to use the `--debug="d,parser_debug"` option when you start the server. This causes the Bison parser that is used to process SQL statements to dump a parser trace to the server's standard error output. Typically, this output is written to the error log.

Sync debug checking for the [InnoDB](#) storage engine is defined under `UNIV_DEBUG` and is available when debugging support is compiled in using the `WITH_DEBUG` option. When debugging support is compiled in, the `innodb_sync_debug` configuration option can be used to enable or disable [InnoDB](#) sync debug checking.

Enabling `WITH_DEBUG` also enables Debug Sync. This facility is used for testing and debugging. When compiled in, Debug Sync is disabled by default at runtime. To enable it, start `mysqld` with the `--debug-sync-timeout=N` option, where `N` is a timeout value greater than 0. (The default value is 0, which disables Debug Sync.) `N` becomes the default timeout for individual synchronization points.

Sync debug checking for the [InnoDB](#) storage engine is available when debugging support is compiled in using the `WITH_DEBUG` option.

For a description of the Debug Sync facility and how to use synchronization points, see [MySQL Internals: Test Synchronization](#).

- `-DWITH_EDITLINE=value`

Which `libedit/editline` library to use. The permitted values are `bundled` (the default) and `system`.

- `-DWITH_FIDO=fido_type`

The `authentication_fido` authentication plugin is implemented using a FIDO library (see [Section 8.4.1.12, “FIDO Pluggable Authentication”](#)). The `WITH_FIDO` option indicates the source of FIDO support:

- `bundled`: Use the FIDO library bundled with the distribution. This is the default.

MySQL includes `fido2` version 1.8.0.

- `system`: Use the system FIDO library.

`WITH_FIDO` is disabled (set to `none`) if all authentication plugins are disabled.

- `-DWITH_ICU={icu_type|path_name}`

MySQL uses International Components for Unicode (ICU) to support regular expression operations. The `WITH_ICU` option indicates the type of ICU support to include or the path name to the ICU installation to use.

- `icu_type` can be one of the following values:

- `bundled`: Use the ICU library bundled with the distribution. This is the default, and is the only supported option for Windows.

- `system`: Use the system ICU library.

- `path_name` is the path name to the ICU installation to use. This can be preferable to using the `icu_type` value of `system` because it can prevent CMake from detecting and using an older or incorrect ICU version installed on the system. (Another permitted way to do the same thing is to set `WITH_ICU` to `system` and set the `CMAKE_PREFIX_PATH` option to `path_name`.)

- `-DWITH_INNODB_EXTRA_DEBUG=bool`

Whether to include extra InnoDB debugging support.

Enabling `WITH_INNODB_EXTRA_DEBUG` turns on extra InnoDB debug checks. This option can only be enabled when `WITH_DEBUG` is enabled.

- `-DWITH_JEMALLOC=bool`

Whether to link with `-ljemalloc`. If enabled, built-in `malloc()`, `calloc()`, `realloc()`, and `free()` routines are disabled. The default is `OFF`.

`WITH_JEMALLOC` and `WITH_TCMALLOC` are mutually exclusive.

- `-DWITH_WIN_JEMALLOC=string`

On Windows, pass in a path to a directory containing `jemalloc.dll` to enable `jemalloc` functionality. The build system copies `jemalloc.dll` to the same directory as `mysqld.exe` and/or `mysqld-debug.exe` and utilizes it for memory management operations. Standard memory functions are used if `jemalloc.dll` is not found or does not export the required functions. An INFORMATION level log message records whether or not `jemalloc` is found and used.

This option is enabled for official MySQL binaries for Windows.

- `-DWITH_KEYRING_TEST=bool`

Whether to build the test program that accompanies the `keyring_file` plugin. The default is `OFF`. Test file source code is located in the `plugin/keyring/keyring-test` directory.

- `-DWITH_LIBEVENT=string`

Which `libevent` library to use. Permitted values are `bundled` (default) and `system`. If `system` is specified and no system `libevent` library can be found, an error occurs regardless, and the bundled `libevent` is not used.

The `libevent` library is required by `InnoDB` memcached, X Plugin, and MySQL Router.

- `-DWITH_LIBWRAP=bool`

Whether to include `libwrap` (TCP wrappers) support.

- `-DWITH_LOCK_ORDER=bool`

Whether to enable `LOCK_ORDER` tooling. By default, this option is disabled and server builds contain no tooling. If tooling is enabled, the `LOCK_ORDER` tool is available and can be used as described in [Section 7.9.3, “The LOCK_ORDER Tool”](#).

**Note**

With the `WITH_LOCK_ORDER` option enabled, MySQL builds require the `flex` program.

- `-DWITH_LSAN=bool`

Whether to run LeakSanitizer, without AddressSanitizer. The default is `OFF`.

- `-DWITH_LTO=bool`

Whether to enable the link-time optimizer, if the compiler supports it. The default is `OFF` unless `FPROFILE_USE` is enabled.

- `-DWITH_LZ4=lz4_type`

The `WITH_LZ4` option indicates the source of `zlib` support:

- `bundled`: Use the `lz4` library bundled with the distribution. This is the default.
- `system`: Use the system `lz4` library. If `WITH_LZ4` is set to this value, the `lz4_decompress` utility is not built. In this case, the system `lz4` command can be used instead.
- `-DWITH_MECAB={disabled|system|path_name}`

Use this option to compile the MeCab parser. If you have installed MeCab to its default installation directory, set `-DWITH_MECAB=system`. The `system` option applies to MeCab installations performed from source or from binaries using a native package management utility. If you installed MeCab to a custom installation directory, specify the path to the MeCab installation, for example, `-DWITH_MECAB=/opt/mecab`. If the `system` option does not work, specifying the MeCab installation path should work in all cases.

For related information, see [Section 14.9.9, “MeCab Full-Text Parser Plugin”](#).

- `-DWITH_MSAN=bool`

Whether to enable MemorySanitizer, for compilers that support it. The default is off.

For this option to have an effect if enabled, all libraries linked to MySQL must also have been compiled with the option enabled.

- `-DWITH_MSRTC_DEBUG=bool`

Whether to enable Visual Studio CRT memory leak tracing. The default is `OFF`.

- `-DMSVC_CPPCHECK=bool`

Whether to enable MSVC code analysis. The default is `ON`.

- `-DWITH_MYSQLX=bool`

Whether to build with support for X Plugin. The default is `ON`. See [Chapter 22, Using MySQL as a Document Store](#).

- `-DWITH_NUMA=bool`

Explicitly set the NUMA memory allocation policy. `CMake` sets the default `WITH_NUMA` value based on whether the current platform has `NUMA` support. For platforms without `NUMA` support, `CMake` behaves as follows:

- With no `NUMA` option (the normal case), `CMake` continues normally, producing only this warning:
`NUMA library missing or required version not available.`
- With `-DWITH_NUMA=ON`, `CMake` aborts with this error: `NUMA library missing or required version not available.`

- `-DWITH_PACKAGE_FLAGS=bool`

For flags typically used for RPM and Debian packages, whether to add them to standalone builds on those platforms. The default is `ON` for nondebug builds.

- `-DWITH_PROTOBUF=protobuf_type`

Which Protocol Buffers package to use. `protobuf_type` can be one of the following values:

- `bundled`: Use the package bundled with the distribution. This is the default. Optionally use `INSTALL_PRIV_LIBDIR` to modify the dynamic Protobuf library directory.
- `system`: Use the package installed on the system.

Other values are ignored, with a fallback to `bundled`.

- `-DWITH_RAPID=bool`

Whether to build the rapid development cycle plugins. When enabled, a `rapid` directory is created in the build tree containing these plugins. When disabled, no `rapid` directory is created in the build tree. The default is `ON`, unless the `rapid` directory is removed from the source tree, in which case the default becomes `OFF`.

- `-DWITH_RAPIDJSON=rapidjson_type`

The type of RapidJSON library support to include. `rapidjson_type` can be one of the following values:

- `bundled`: Use the RapidJSON library bundled with the distribution. This is the default.
- `system`: Use the system RapidJSON library. Version 1.1.0 or later is required.

- `-DWITH_ROUTER=bool`

Whether to build MySQL Router. The default is `ON`.

- `-DWITH_SSL={ssl_type|path_name}`

For support of encrypted connections, entropy for random number generation, and other encryption-related operations, MySQL must be built using an SSL library. This option specifies which SSL library to use.

- `ssl_type` can be one of the following values:

- `system`: Use the system OpenSSL library. This is the default.

On macOS and Windows, using `system` configures MySQL to build as if CMake was invoked with `path_name` points to a manually installed OpenSSL library. This is because they do not have system SSL libraries. On macOS, `brew install openssl` installs to `/usr/local/opt/openssl` so that `system` can find it. On Windows, it checks `%ProgramFiles%/OpenSSL`, `%ProgramFiles%/OpenSSL-Win32`, `%ProgramFiles%/OpenSSL-Win64`, `C:/OpenSSL`, `C:/OpenSSL-Win32`, and `C:/OpenSSL-Win64`.

- `yes`: This is a synonym for `system`.
 - `opensslversion`: Use an alternate OpenSSL system package such as `openssl11` on EL7, or `openssl3` (or `openssl3-fips`) on EL8.

Authentication plugins, such as LDAP and Kerberos, are disabled as they do not support these alternative versions of OpenSSL.

- `path_name` is the path name to the OpenSSL installation to use. This can be preferable to using the `ssl_type` value `system` because it can prevent CMake from detecting and using an older or incorrect OpenSSL version installed on the system. (Another permitted way to do the same thing is to set `WITH_SSL` to `system` and set the `CMAKE_PREFIX_PATH` option to `path_name`.)

For additional information about configuring the SSL library, see [Section 2.8.6, “Configuring SSL Library Support”](#).

- `-DWITH_SHOW_PARSE_TREE=bool`

Enables support for `SHOW PARSE_TREE` in the server, used in development and debugging only. Not used for release builds or supported in production.

- `-DWITH_SYSTEMD=bool`

Whether to enable installation of `systemd` support files. By default, this option is disabled. When enabled, `systemd` support files are installed, and scripts such as `mysqld_safe` and the System V initialization script are not installed. On platforms where `systemd` is not available, enabling `WITH_SYSTEMD` results in an error from CMake.

When the server was built using this option, MySQL includes all `systemd` messages in the server's error log (see [Section 7.4.2, “The Error Log”](#)).

For more information about using `systemd`, see [Section 2.5.9, “Managing MySQL Server with systemd”](#). That section also includes information about specifying options otherwise specified in `[mysqld_safe]` option groups. Because `mysqld_safe` is not installed when `systemd` is used, such options must be specified another way.

- `-DWITH_SYSTEM_LIBS=bool`

This option serves as an “umbrella” option to set the `system` value of any of the following CMake options that are not set explicitly: `WITH_CURL`, `WITH_EDITLINE`, `WITH_FIDO`, `WITH_ICU`, `WITH_LIBEVENT`, `WITH_LZ4`, `WITH_LZMA`, `WITH_PROTOBUF`, `WITH_RE2`, `WITH_SSL`, `WITH_ZLIB`, `WITH_ZSTD`.

- `-DWITH_SYSTEMD_DEBUG=bool`

Whether to produce additional `systemd` debugging information, for platforms on which `systemd` is used to run MySQL. The default is `OFF`.

- `-DWITH_TCMALLOC=bool`

Whether to link with `-ltcmalloc`. If enabled, built-in `malloc()`, `calloc()`, `realloc()`, and `free()` routines are disabled. The default is `OFF`.

`WITH_TCMALLOC` and `WITH_JEMALLOC` are mutually exclusive.

- `-DWITH_TEST_TRACE_PLUGIN=bool`

Whether to build the test protocol trace client plugin (see [Using the Test Protocol Trace Plugin](#)). By default, this option is disabled. Enabling this option has no effect unless the `WITH_CLIENT_PROTOCOL_TRACING` option is enabled. If MySQL is configured with both options enabled, the `libmysqlclient` client library is built with the test protocol trace plugin built in, and all the standard MySQL clients load the plugin. However, even when the test plugin is enabled, it has no effect by default. Control over the plugin is afforded using environment variables; see [Using the Test Protocol Trace Plugin](#).

**Note**

Do *not* enable the `WITH_TEST_TRACE_PLUGIN` option if you want to use your own protocol trace plugins because only one such plugin can be loaded at a time and an error occurs for attempts to load a second one. If you have already built MySQL with the test protocol trace plugin enabled to see how it works, you must rebuild MySQL without it before you can use your own plugins.

For information about writing trace plugins, see [Writing Protocol Trace Plugins](#).

- `-DWITH_TSAN=bool`

Whether to enable the ThreadSanitizer, for compilers that support it. The default is off.

- `-DWITH_UBSAN=bool`

Whether to enable the Undefined Behavior Sanitizer, for compilers that support it. The default is off.

- `-DWITH_UNIT_TESTS={ON|OFF}`

If enabled, compile MySQL with unit tests. The default is `ON` unless the server is not being compiled.

- `-DWITH_UNIXODBC=1`

Enables unixODBC support, for Connector/ODBC.

- `-DWITH_VALGRIND=bool`

Whether to compile in the Valgrind header files, which exposes the Valgrind API to MySQL code. The default is `OFF`.

To generate a Valgrind-aware debug build, `-DWITH_VALGRIND=1` normally is combined with `-DWITH_DEBUG=1`. See [Building Debug Configurations](#).

- `-DWITH_ZLIB=zlib_type`

Some features require that the server be built with compression library support, such as the `COMPRESS()` and `UNCOMPRESS()` functions, and compression of the client/server protocol. The `WITH_ZLIB` option indicates the source of `zlib` support:

The minimum supported version of `zlib` is 1.2.13.

- `bundled`: Use the `zlib` library bundled with the distribution. This is the default.
- `system`: Use the system `zlib` library. If `WITH_ZLIB` is set to this value, the `zlib_decompress` utility is not built. In this case, the system `openssl zlib` command can be used instead.
- `-DWITH_ZSTD=zstd_type`

Connection compression using the `zstd` algorithm (see [Section 6.2.8, “Connection Compression Control”](#)) requires that the server be built with `zstd` library support. The `WITH_ZSTD` option indicates the source of `zstd` support:

- `bundled`: Use the `zstd` library bundled with the distribution. This is the default.
- `system`: Use the system `zstd` library.

Compiler Flags

- `-DCMAKE_C_FLAGS="flags"`

Flags for the C compiler.

- `-DCMAKE_CXX_FLAGS="flags"`

Flags for the C++ compiler.

- `-DWITH_DEFAULT_COMPILER_OPTIONS=bool`

Whether to use the flags from `cmake/build_configurations/compiler_options.cmake`.

Note

All optimization flags are carefully chosen and tested by the MySQL build team. Overriding them can lead to unexpected results and is done at your own risk.

- `-DOPTIMIZE_SANITIZER_BUILDS=bool`

Whether to add `-O1 -fno-inline` to sanitizer builds. The default is `ON`.

To specify your own C and C++ compiler flags, for flags that do not affect optimization, use the `CMAKE_C_FLAGS` and `CMAKE_CXX_FLAGS` CMake options.

When providing your own compiler flags, you might want to specify `CMAKE_BUILD_TYPE` as well.

For example, to create a 32-bit release build on a 64-bit Linux machine, do this:

```
$> mkdir build
$> cd build
$> cmake .. -DCMAKE_C_FLAGS=-m32 \
-DMAKE_CXX_FLAGS=-m32 \
-DMAKE_BUILD_TYPE=RelWithDebInfo
```

If you set flags that affect optimization (`-Onumber`), you must set the `CMAKE_C_FLAGS_build_type` and/or `CMAKE_CXX_FLAGS_build_type` options, where `build_type` corresponds to the `CMAKE_BUILD_TYPE` value. To specify a different optimization for the default build type (`RelWithDebInfo`) set the `CMAKE_C_FLAGS_RELWITHDEBINFO` and `CMAKE_CXX_FLAGS_RELWITHDEBINFO` options. For example, to compile on Linux with `-O3` and with debug symbols, do this:

```
$> cmake .. -DCMAKE_C_FLAGS_RELWITHDEBINFO="-O3 -g" \
-DMAKE_CXX_FLAGS_RELWITHDEBINFO="-O3 -g"
```

CMake Options for Compiling NDB Cluster

The following options are for use when building the MySQL sources with NDB Cluster support.

- `-DNDB_UTILS_LINK_DYNAMIC={ON|OFF}`

Controls whether NDB utilities such as `ndb_drop_table` are linked with `ndbclient` statically (`OFF`) or dynamically (`ON`); `OFF` (static linking) is the default. Normally static linking is used when building these to avoid problems with `LD_LIBRARY_PATH`, or when multiple versions of `ndbclient` are installed. This option is intended for creating Docker images and possibly other cases in which the target environment is subject to precise control and it is desirable to reduce image size.

- `-DWITH_CLASSPATH=path`

Sets the classpath for building MySQL NDB Cluster Connector for Java. The default is empty. This option is ignored if `-DWITH_NDB_JAVA=OFF` is used.

- `-DWITH_ERROR_INSERT={ON|OFF}`

Enables error injection in the `NDB` kernel. For testing only; not intended for use in building production binaries. The default is `OFF`.

- `-DWITH_NDB={ON|OFF}`

Build MySQL NDB Cluster; build the NDB plugin and all NDB Cluster programs.

- `-DWITH_NDBAPI_EXAMPLES={ON|OFF}`

Build NDB API example programs in `storage/ndb/ndbapi-examples/`. See [NDB API Examples](#), for information about these.

- `-DWITH_NDBCLUSTER_STORAGE_ENGINE={ON|OFF}`

Controls (only) whether the `ndbcluster` plugin is included in the build; `WITH_NDB` enables this option automatically, so it is recommended that you use `WITH_NDB` instead.

- `-DWITH_NDBCLUSTER={ON|OFF}`

Build and link in support for the `NDB` storage engine in `mysqld`.

This option is deprecated and subject to eventual removal; use `WITH_NDB` instead.

- `-DWITH_NDBMTD={ON|OFF}`

Build the multithreaded data node executable `ndbmt.d`. The default is `ON`.

- `-DWITH_NDB_DEBUG={ON|OFF}`

Enable building the debug versions of the NDB Cluster binaries. This is `OFF` by default.

- `-DWITH_NDB_JAVA={ON|OFF}`

Enable building NDB Cluster with Java support, including support for ClusterJ (see [MySQL NDB Cluster Connector for Java](#)).

This option is `ON` by default. If you do not wish to compile NDB Cluster with Java support, you must disable it explicitly by specifying `-DWITH_NDB_JAVA=OFF` when running `CMake`. Otherwise, if Java cannot be found, configuration of the build fails.

- `-DWITH_NDB_PORT=port`

Causes the NDB Cluster management server (`ndb_mgmd`) that is built to use this `port` by default. If this option is unset, the resulting management server tries to use port 1186 by default.

- `-DWITH_NDB_TEST={ON|OFF}`

If enabled, include a set of NDB API test programs. The default is `OFF`.

- `-DWITH_NDB_TLS_SEARCH_PATH=path`

Set the default path searched by `ndb_sign_keys` and other NDB programs for TLS certificate and key files.

The default for Windows platforms is `$HOMEDIR/ndb-tls`; for other platforms, such as Linux, it is `$HOME/ndb-tls`.

2.8.8 Dealing with Problems Compiling MySQL

The solution to many problems involves reconfiguring. If you do reconfigure, take note of the following:

- If `CMake` is run after it has previously been run, it may use information that was gathered during its previous invocation. This information is stored in `CMakeCache.txt`. When `CMake` starts, it looks for that file and reads its contents if it exists, on the assumption that the information is still correct. That assumption is invalid when you reconfigure.
- Each time you run `CMake`, you must run `make` again to recompile. However, you may want to remove old object files from previous builds first because they were compiled using different configuration options.

To prevent old object files or configuration information from being used, run the following commands before re-running `CMake`:

On Unix:

```
$> make clean
$> rm CMakeCache.txt
```

On Windows:

```
$> devenv MySQL.sln /clean
$> del CMakeCache.txt
```

If you build outside of the source tree, remove and recreate your build directory before re-running `CMake`. For instructions on building outside of the source tree, see [How to Build MySQL Server with CMake](#).

On some systems, warnings may occur due to differences in system include files. The following list describes other problems that have been found to occur most often when compiling MySQL:

- To define which C and C++ compilers to use, you can define the `CC` and `CXX` environment variables. For example:

```
$> CC=gcc
$> CXX=g++
$> export CC CXX
```

While this can be done on the command line, as just shown, you may prefer to define these values in a build script, in which case the `export` command is not needed.

To specify your own C and C++ compiler flags, use the `CMAKE_C_FLAGS` and `CMAKE_CXX_FLAGS` CMake options. See [Compiler Flags](#).

To see what flags you might need to specify, invoke `mysql_config` with the `--cflags` and `--cxxflags` options.

- To see what commands are executed during the compile stage, after using `CMake` to configure MySQL, run `make VERBOSE=1` rather than just `make`.

- If compilation fails, check whether the `MYSQL_MAINTAINER_MODE` option is enabled. This mode causes compiler warnings to become errors, so disabling it may enable compilation to proceed.
- If your compile fails with errors such as any of the following, you must upgrade your version of `make` to GNU `make`:

```
make: Fatal error in reader: Makefile, line 18:
Badly formed macro assignment
```

Or:

```
make: file `Makefile' line 18: Must be a separator (:
```

Or:

```
pthread.h: No such file or directory
```

Solaris and FreeBSD are known to have troublesome `make` programs.

GNU `make` 3.75 is known to work.

- The `sql_yacc.cc` file is generated from `sql_yacc.yy`. Normally, the build process does not need to create `sql_yacc.cc` because MySQL comes with a pregenerated copy. However, if you do need to re-create it, you might encounter this error:

```
"sql_yacc.yy", line xxx fatal: default action causes potential...
```

This is a sign that your version of `yacc` is deficient. You probably need to install a recent version of `bison` (the GNU version of `yacc`) and use that instead.

Versions of `bison` older than 1.75 may report this error:

```
sql_yacc.yy:#####: fatal error: maximum table size (32767) exceeded
```

The maximum table size is not actually exceeded; the error is caused by bugs in older versions of `bison`.

For information about acquiring or updating tools, see the system requirements in [Section 2.8](#), "Installing MySQL from Source".

2.8.9 MySQL Configuration and Third-Party Tools

Third-party tools that need to determine the MySQL version from the MySQL source can read the `MYSQL_VERSION` file in the top-level source directory. The file lists the pieces of the version separately. For example, if the version is MySQL 8.3.0, the file looks like this:

```
MYSQL_VERSION_MAJOR=8
MYSQL_VERSION_MINOR=3
MYSQL_VERSION_PATCH=0
MYSQL_VERSION_EXTRA="INNOVATION"
```

To construct a five-digit number from the version components, use this formula:

```
MYSQL_VERSION_MAJOR*10000 + MYSQL_VERSION_MINOR*100 + MYSQL_VERSION_PATCH
```

2.8.10 Generating MySQL Doxygen Documentation Content

The MySQL source code contains internal documentation written using Doxygen. The generated Doxygen content is available at <https://dev.mysql.com/doc/index-other.html>. It is also possible to generate this content locally from a MySQL source distribution using the following procedure:

1. Install `doxygen` 1.9.2 or later. Distributions are available here at <http://www.doxygen.nl/>.

After installing `doxygen`, verify the version number:

```
$> doxygen --version
1.9.2
```

2. Install [PlantUML](#).

When you install PlantUML on Windows (tested on Windows 10), you must run it at least once as administrator so it creates the registry keys. Open an administrator console and run this command:

```
$> java -jar path-to-plantuml.jar
```

The command should open a GUI window and return no errors on the console.

3. Set the `PLANTUML_JAR_PATH` environment to the location where you installed PlantUML. For example:

```
$> export PLANTUML_JAR_PATH=path-to-plantuml.jar
```

4. Install the [Graphviz](#) `dot` command.

After installing Graphviz, verify `dot` availability. For example:

```
$> which dot
/usr/bin/dot

$> dot -v
dot - graphviz version 2.40.1 (20161225.0304)
```

5. Change location to the top-level directory of your MySQL source distribution and do the following:

First, execute `cmake`:

```
$> cd mysql-source-directory
$> mkdir build
$> cd build
$> cmake ..
```

Next, generate the `doxygen` documentation:

```
$> make doxygen
```

Inspect the error log, which is available in the `doxyerror.log` file in the top-level directory. Assuming that the build executed successfully, view the generated output using a browser. For example:

```
$> firefox doxygen/html/index.html
```

2.9 Postinstallation Setup and Testing

This section discusses tasks that you should perform after installing MySQL:

- If necessary, initialize the data directory and create the MySQL grant tables. For some MySQL installation methods, data directory initialization may be done for you automatically:
 - Windows installation operations performed by the MSI installer and MySQL Configurator.
 - Installation on Linux using a server RPM or Debian distribution from Oracle.
 - Installation using the native packaging system on many platforms, including Debian Linux, Ubuntu Linux, Gentoo Linux, and others.
 - Installation on macOS using a DMG distribution.

For other platforms and installation types, you must initialize the data directory manually. These include installation from generic binary and source distributions on Unix and Unix-like system, and

installation from a ZIP Archive package on Windows. For instructions, see [Section 2.9.1, “Initializing the Data Directory”](#).

- Start the server and make sure that it can be accessed. For instructions, see [Section 2.9.2, “Starting the Server”](#), and [Section 2.9.3, “Testing the Server”](#).
- Assign passwords to the initial `root` account in the grant tables, if that was not already done during data directory initialization. Passwords prevent unauthorized access to the MySQL server. For instructions, see [Section 2.9.4, “Securing the Initial MySQL Account”](#).
- Optionally, arrange for the server to start and stop automatically when your system starts and stops. For instructions, see [Section 2.9.5, “Starting and Stopping MySQL Automatically”](#).
- Optionally, populate time zone tables to enable recognition of named time zones. For instructions, see [Section 7.1.15, “MySQL Server Time Zone Support”](#).

When you are ready to create additional user accounts, you can find information on the MySQL access control system and account management in [Section 8.2, “Access Control and Account Management”](#).

2.9.1 Initializing the Data Directory

After MySQL is installed, the data directory must be initialized, including the tables in the `mysql` system schema:

- For some MySQL installation methods, data directory initialization is automatic, as described in [Section 2.9, “Postinstallation Setup and Testing”](#).
- For other installation methods, you must initialize the data directory manually. These include installation from generic binary and source distributions on Unix and Unix-like systems, and installation from a ZIP Archive package on Windows.

This section describes how to initialize the data directory manually for MySQL installation methods for which data directory initialization is not automatic. For some suggested commands that enable testing whether the server is accessible and working properly, see [Section 2.9.3, “Testing the Server”](#).

Note

The default authentication plugin is `caching_sha2_password`, and the `'root'@'localhost'` administrative account uses `caching_sha2_password` by default. The default authentication plugin before MySQL 8.0 was `mysql_native_password`, which is deprecated.

- [Data Directory Initialization Overview](#)
- [Data Directory Initialization Procedure](#)
- [Server Actions During Data Directory Initialization](#)
- [Post-Initialization root Password Assignment](#)

Data Directory Initialization Overview

In the examples shown here, the server is intended to run under the user ID of the `mysql` login account. Either create the account if it does not exist (see [Create a mysql User and Group](#)), or substitute the name of a different existing login account that you plan to use for running the server.

1. Change location to the top-level directory of your MySQL installation, which is typically `/usr/local/mysql` (adjust the path name for your system as necessary):

```
cd /usr/local/mysql
```

Within this directory you can find several files and subdirectories, including the `bin` subdirectory that contains the server, as well as client and utility programs.

- The `secure_file_priv` system variable limits import and export operations to a specific directory. Create a directory whose location can be specified as the value of that variable:

```
mkdir mysql-files
```

Grant directory user and group ownership to the `mysql` user and `mysql` group, and set the directory permissions appropriately:

```
chown mysql:mysql mysql-files
chmod 750 mysql-files
```

- Use the server to initialize the data directory, including the `mysql` schema containing the initial MySQL grant tables that determine how users are permitted to connect to the server. For example:

```
bin/mysqld --initialize --user=mysql
```

For important information about the command, especially regarding command options you might use, see [Data Directory Initialization Procedure](#). For details about how the server performs initialization, see [Server Actions During Data Directory Initialization](#).

Typically, data directory initialization need be done only after you first install MySQL. (For upgrades to an existing installation, perform the upgrade procedure instead; see [Chapter 3, Upgrading MySQL](#).) However, the command that initializes the data directory does not overwrite any existing `mysql` schema tables, so it is safe to run in any circumstances.

- If you want to deploy the server with automatic support for secure connections, use the `mysql_ssl_rsa_setup` utility to create default SSL and RSA files:

```
bin/mysql_ssl_rsa_setup
```

For more information, see [Section 6.4.3, “mysql_ssl_rsa_setup — Create SSL/RSA Files”](#).

Note

The `mysql_ssl_rsa_setup` utility is deprecated.

- In the absence of any option files, the server starts with its default settings. (See [Section 7.1.2, “Server Configuration Defaults”](#).) To explicitly specify options that the MySQL server should use at startup, put them in an option file such as `/etc/my.cnf` or `/etc/mysql/my.cnf`. (See [Section 6.2.2.2, “Using Option Files”](#).) For example, you can use an option file to set the `secure_file_priv` system variable.
- To arrange for MySQL to start without manual intervention at system boot time, see [Section 2.9.5, “Starting and Stopping MySQL Automatically”](#).
- Data directory initialization creates time zone tables in the `mysql` schema but does not populate them. To do so, use the instructions in [Section 7.1.15, “MySQL Server Time Zone Support”](#).

Data Directory Initialization Procedure

Change location to the top-level directory of your MySQL installation, which is typically `/usr/local/mysql` (adjust the path name for your system as necessary):

```
cd /usr/local/mysql
```

To initialize the data directory, invoke `mysqld` with the `--initialize` or `--initialize-insecure` option, depending on whether you want the server to generate a random initial password for the `'root'@'localhost'` account, or to create that account with no password:

- Use `--initialize` for “secure by default” installation (that is, including generation of a random initial `root` password). In this case, the password is marked as expired and you must choose a new one.

- With `--initialize-insecure`, no `root` password is generated. This is insecure; it is assumed that you intend to assign a password to the account in a timely fashion before putting the server into production use.

For instructions on assigning a new '`root`'@'`localhost`' password, see [Post-Initialization root Password Assignment](#).

Note

The server writes any messages (including any initial password) to its standard error output. This may be redirected to the error log, so look there if you do not see the messages on your screen. For information about the error log, including where it is located, see [Section 7.4.2, “The Error Log”](#).

On Windows, use the `--console` option to direct messages to the console.

On Unix and Unix-like systems, it is important for the database directories and files to be owned by the `mysql` login account so that the server has read and write access to them when you run it later. To ensure this, start `mysqld` from the system `root` account and include the `--user` option as shown here:

```
bin/mysqld --initialize --user=mysql
bin/mysqld --initialize-insecure --user=mysql
```

Alternatively, execute `mysqld` while logged in as `mysql`, in which case you can omit the `--user` option from the command.

On Windows, use one of these commands:

```
bin\mysqld --initialize --console
bin\mysqld --initialize-insecure --console
```

Note

Data directory initialization might fail if required system libraries are missing. For example, you might see an error like this:

```
bin/mysqld: error while loading shared libraries:
libnuma.so.1: cannot open shared object file:
No such file or directory
```

If this happens, you must install the missing libraries manually or with your system's package manager. Then retry the data directory initialization command.

It might be necessary to specify other options such as `--basedir` or `--datadir` if `mysqld` cannot identify the correct locations for the installation directory or data directory. For example (enter the command on a single line):

```
bin/mysqld --initialize --user=mysql
--basedir=/opt/mysql/mysql
--datadir=/opt/mysql/mysql/data
```

Alternatively, put the relevant option settings in an option file and pass the name of that file to `mysqld`. For Unix and Unix-like systems, suppose that the option file name is `/opt/mysql/mysql/etc/my.cnf`. Put these lines in the file:

```
[mysqld]
basedir=/opt/mysql/mysql
datadir=/opt/mysql/mysql/data
```

Then invoke `mysqld` as follows (enter the command on a single line, with the `--defaults-file` option first):

```
bin/mysqld --defaults-file=/opt/mysql/mysql/etc/my.cnf
--initialize --user=mysql
```

On Windows, suppose that `C:\my.ini` contains these lines:

```
[mysqld]
basedir=C:\\Program Files\\MySQL\\MySQL Server 8.3
datadir=D:\\MySQLdata
```

Then invoke `mysqld` as follows (again, you should enter the command on a single line, with the `--defaults-file` option first):

```
bin\\mysqld --defaults-file=C:\\my.ini
--initialize --console
```

Important

When initializing the data directory, you should not specify any options other than those used for setting directory locations such as `--basedir` or `--datadir`, and the `--user` option if needed. Options to be employed by the MySQL server during normal use can be set when restarting it following initialization. See the description of the `--initialize` option for further information.

Server Actions During Data Directory Initialization

Note

The data directory initialization sequence performed by the server does not substitute for the actions performed by `mysql_secure_installation` and `mysql_ssl_rsa_setup`. See [Section 6.4.2, “mysql_secure_installation — Improve MySQL Installation Security”](#), and [Section 6.4.3, “mysql_ssl_rsa_setup — Create SSL/RSA Files”](#).

When invoked with the `--initialize` or `--initialize-insecure` option, `mysqld` performs the following actions during the data directory initialization sequence:

1. The server checks for the existence of the data directory as follows:
 - If no data directory exists, the server creates it.
 - If the data directory exists but is not empty (that is, it contains files or subdirectories), the server exits after producing an error message:

```
[ERROR] --initialize specified but the data directory exists. Aborting.
```

In this case, remove or rename the data directory and try again.

An existing data directory is permitted to be nonempty if every entry has a name that begins with a period (.).

2. Within the data directory, the server creates the `mysql` system schema and its tables, including the data dictionary tables, grant tables, time zone tables, and server-side help tables. See [Section 7.3, “The mysql System Schema”](#).
3. The server initializes the `system tablespace` and related data structures needed to manage `InnoDB` tables.

Note

After `mysqld` sets up the `InnoDB system tablespace`, certain changes to tablespace characteristics require setting up a whole new `instance`. Qualifying changes include the file name of the first file in the system tablespace and the number of undo logs. If you do not want to use the default values, make sure that the settings for the `innodb_data_file_path` and `innodb_log_file_size`

configuration parameters are in place in the MySQL [configuration file](#) before running `mysqld`. Also make sure to specify as necessary other parameters that affect the creation and location of InnoDB files, such as `innodb_data_home_dir` and `innodb_log_group_home_dir`.

If those options are in your configuration file but that file is not in a location that MySQL reads by default, specify the file location using the `--defaults-extra-file` option when you run `mysqld`.

4. The server creates a `'root'@'localhost'` superuser account and other reserved accounts (see [Section 8.2.9, “Reserved Accounts”](#)). Some reserved accounts are locked and cannot be used by clients, but `'root'@'localhost'` is intended for administrative use and you should assign it a password.

Server actions with respect to a password for the `'root'@'localhost'` account depend on how you invoke it:

- With `--initialize` but not `--initialize-insecure`, the server generates a random password, marks it as expired, and writes a message displaying the password:

```
[Warning] A temporary password is generated for root@localhost:
iTag*AfrH5ej
```

- With `--initialize-insecure`, (either with or without `--initialize` because `--initialize-insecure` implies `--initialize`), the server does not generate a password or mark it expired, and writes a warning message:

```
[Warning] root@localhost is created with an empty password ! Please
consider switching off the --initialize-insecure option.
```

For instructions on assigning a new `'root'@'localhost'` password, see [Post-Initialization root Password Assignment](#).

5. The server populates the server-side help tables used for the `HELP` statement (see [Section 15.8.3, “HELP Statement”](#)). The server does not populate the time zone tables. To do so manually, see [Section 7.1.15, “MySQL Server Time Zone Support”](#).
6. If the `init_file` system variable was given to name a file of SQL statements, the server executes the statements in the file. This option enables you to perform custom bootstrapping sequences.

When the server operates in bootstrap mode, some functionality is unavailable that limits the statements permitted in the file. These include statements that relate to account management (such as `CREATE USER` or `GRANT`), replication, and global transaction identifiers.

7. The server exits.

Post-Initialization root Password Assignment

After you initialize the data directory by starting the server with `--initialize` or `--initialize-insecure`, start the server normally (that is, without either of those options) and assign the `'root'@'localhost'` account a new password:

1. Start the server. For instructions, see [Section 2.9.2, “Starting the Server”](#).
2. Connect to the server:
 - If you used `--initialize` but not `--initialize-insecure` to initialize the data directory, connect to the server as `root`:

```
mysql -u root -p
```

Then, at the password prompt, enter the random password that the server generated during the initialization sequence:

```
Enter password: (enter the random root password here)
```

Look in the server error log if you do not know this password.

- If you used `--initialize-insecure` to initialize the data directory, connect to the server as `root` without a password:

```
mysql -u root --skip-password
```

3. After connecting, use an `ALTER USER` statement to assign a new `root` password:

```
ALTER USER 'root'@'localhost' IDENTIFIED BY 'root-password';
```

See also [Section 2.9.4, “Securing the Initial MySQL Account”](#).

Note

Attempts to connect to the host `127.0.0.1` normally resolve to the `localhost` account. However, this fails if the server is run with `skip_name_resolve` enabled. If you plan to do that, make sure that an account exists that can accept a connection. For example, to be able to connect as `root` using `--host=127.0.0.1` or `--host=:1`, create these accounts:

```
CREATE USER 'root'@'127.0.0.1' IDENTIFIED BY 'root-password';
CREATE USER 'root'@':1' IDENTIFIED BY 'root-password';
```

It is possible to put those statements in a file to be executed using the `init_file` system variable, as discussed in [Server Actions During Data Directory Initialization](#).

2.9.2 Starting the Server

This section describes how start the server on Unix and Unix-like systems. (For Windows, see [Section 2.3.3.5, “Starting the Server for the First Time”](#).) For some suggested commands that you can use to test whether the server is accessible and working properly, see [Section 2.9.3, “Testing the Server”](#).

Start the MySQL server like this if your installation includes `mysqld_safe`:

```
$> bin/mysqld_safe --user=mysql &
```

Note

For Linux systems on which MySQL is installed using RPM packages, server startup and shutdown is managed using `systemd` rather than `mysqld_safe`, and `mysqld_safe` is not installed. See [Section 2.5.9, “Managing MySQL Server with systemd”](#).

Start the server like this if your installation includes `systemd` support:

```
$> systemctl start mysqld
```

Substitute the appropriate service name if it differs from `mysqld` (for example, `mysql` on SLES systems).

It is important that the MySQL server be run using an unprivileged (non-`root`) login account. To ensure this, run `mysqld_safe` as `root` and include the `--user` option as shown. Otherwise, you should execute the program while logged in as `mysql`, in which case you can omit the `--user` option from the command.

For further instructions for running MySQL as an unprivileged user, see [Section 8.1.5, “How to Run MySQL as a Normal User”](#).

If the command fails immediately and prints `mysqld ended`, look for information in the error log (which by default is the `host_name.err` file in the data directory).

If the server is unable to access the data directory it starts or read the grant tables in the `mysql` schema, it writes a message to its error log. Such problems can occur if you neglected to create the grant tables by initializing the data directory before proceeding to this step, or if you ran the command that initializes the data directory without the `--user` option. Remove the `data` directory and run the command with the `--user` option.

If you have other problems starting the server, see [Section 2.9.2.1, “Troubleshooting Problems Starting the MySQL Server”](#). For more information about `mysqld_safe`, see [Section 6.3.2, “mysqld_safe — MySQL Server Startup Script”](#). For more information about systemd support, see [Section 2.5.9, “Managing MySQL Server with systemd”](#).

2.9.2.1 Troubleshooting Problems Starting the MySQL Server

This section provides troubleshooting suggestions for problems starting the server. For additional suggestions for Windows systems, see [Section 2.3.4, “Troubleshooting a Microsoft Windows MySQL Server Installation”](#).

If you have problems starting the server, here are some things to try:

- Check the [error log](#) to see why the server does not start. Log files are located in the [data directory](#) (typically `C:\Program Files\MySQL\MySQL Server 8.3\data` on Windows, `/usr/local/mysql/data` for a Unix/Linux binary distribution, and `/usr/local/var` for a Unix/Linux source distribution). Look in the data directory for files with names of the form `host_name.err` and `host_name.log`, where `host_name` is the name of your server host. Then examine the last few lines of these files. Use `tail` to display them:

```
$> tail host_name.err
$> tail host_name.log
```

- Specify any special options needed by the storage engines you are using. You can create a `my.cnf` file and specify startup options for the engines that you plan to use. If you are going to use storage engines that support transactional tables ([InnoDB](#), [NDB](#)), be sure that you have them configured the way you want before starting the server. If you are using [InnoDB](#) tables, see [Section 17.8, “InnoDB Configuration”](#) for guidelines and [Section 17.14, “InnoDB Startup Options and System Variables”](#) for option syntax.

Although storage engines use default values for options that you omit, Oracle recommends that you review the available options and specify explicit values for any options whose defaults are not appropriate for your installation.

- Make sure that the server knows where to find the [data directory](#). The `mysqld` server uses this directory as its current directory. This is where it expects to find databases and where it expects to write log files. The server also writes the pid (process ID) file in the data directory.

The default data directory location is hardcoded when the server is compiled. To determine what the default path settings are, invoke `mysqld` with the `--verbose` and `--help` options. If the data directory is located somewhere else on your system, specify that location with the `--datadir` option to `mysqld` or `mysqld_safe`, on the command line or in an option file. Otherwise, the server does not work properly. As an alternative to the `--datadir` option, you can specify `mysqld` the location of the base directory under which MySQL is installed with the `--basedir`, and `mysqld` looks for the `data` directory there.

To check the effect of specifying path options, invoke `mysqld` with those options followed by the `--verbose` and `--help` options. For example, if you change location to the directory where `mysqld` is installed and then run the following command, it shows the effect of starting the server with a base directory of `/usr/local`:

```
$> ./mysqld --basedir=/usr/local --verbose --help
```

You can specify other options such as `--datadir` as well, but `--verbose` and `--help` must be the last options.

Once you determine the path settings you want, start the server without `--verbose` and `--help`.

If `mysqld` is currently running, you can find out what path settings it is using by executing this command:

```
$> mysqladmin variables
```

Or:

```
$> mysqladmin -h host_name variables
```

`host_name` is the name of the MySQL server host.

- Make sure that the server can access the [data directory](#). The ownership and permissions of the data directory and its contents must allow the server to read and modify them.

If you get `Errcode 13` (which means `Permission denied`) when starting `mysqld`, this means that the privileges of the data directory or its contents do not permit server access. In this case, you change the permissions for the involved files and directories so that the server has the right to use them. You can also start the server as `root`, but this raises security issues and should be avoided.

Change location to the data directory and check the ownership of the data directory and its contents to make sure the server has access. For example, if the data directory is `/usr/local/mysql/var`, use this command:

```
$> ls -la /usr/local/mysql/var
```

If the data directory or its files or subdirectories are not owned by the login account that you use for running the server, change their ownership to that account. If the account is named `mysql`, use these commands:

```
$> chown -R mysql /usr/local/mysql/var
$> chgrp -R mysql /usr/local/mysql/var
```

Even with correct ownership, MySQL might fail to start up if there is other security software running on your system that manages application access to various parts of the file system. In this case, reconfigure that software to enable `mysqld` to access the directories it uses during normal operation.

- Verify that the network interfaces the server wants to use are available.

If either of the following errors occur, it means that some other program (perhaps another `mysqld` server) is using the TCP/IP port or Unix socket file that `mysqld` is trying to use:

```
Can't start server: Bind on TCP/IP port: Address already in use
Can't start server: Bind on unix socket...
```

Use `ps` to determine whether you have another `mysqld` server running. If so, shut down the server before starting `mysqld` again. (If another server is running, and you really want to run multiple servers, you can find information about how to do so in [Section 7.8, "Running Multiple MySQL Instances on One Machine"](#).)

If no other server is running, execute the command `telnet your_host_name tcp_ip_port_number`. (The default MySQL port number is 3306.) Then press Enter a couple of times. If you do not get an error message like `telnet: Unable to connect to remote host: Connection refused`, some other program is using the TCP/IP port that `mysqld` is trying to use. Track down what program this is and disable it, or tell `mysqld` to listen to a different port with

the `--port` option. In this case, specify the same non-default port number for client programs when connecting to the server using TCP/IP.

Another reason the port might be inaccessible is that you have a firewall running that blocks connections to it. If so, modify the firewall settings to permit access to the port.

If the server starts but you cannot connect to it, make sure that you have an entry in `/etc/hosts` that looks like this:

```
127.0.0.1      localhost
```

- If you cannot get `mysqld` to start, try to make a trace file to find the problem by using the `--debug` option. See [Section 7.9.4, “The DEBUG Package”](#).

2.9.3 Testing the Server

After the data directory is initialized and you have started the server, perform some simple tests to make sure that it works satisfactorily. This section assumes that your current location is the MySQL installation directory and that it has a `bin` subdirectory containing the MySQL programs used here. If that is not true, adjust the command path names accordingly.

Alternatively, add the `bin` directory to your `PATH` environment variable setting. That enables your shell (command interpreter) to find MySQL programs properly, so that you can run a program by typing only its name, not its path name. See [Section 6.2.9, “Setting Environment Variables”](#).

Use `mysqladmin` to verify that the server is running. The following commands provide simple tests to check whether the server is up and responding to connections:

```
$> bin/mysqladmin version
$> bin/mysqladmin variables
```

If you cannot connect to the server, specify a `-u root` option to connect as `root`. If you have assigned a password for the `root` account already, you'll also need to specify `-p` on the command line and enter the password when prompted. For example:

```
$> bin/mysqladmin -u root -p version
Enter password: (enter root password here)
```

The output from `mysqladmin version` varies slightly depending on your platform and version of MySQL, but should be similar to that shown here:

```
$> bin/mysqladmin version
mysqladmin  Ver 14.12 Distrib 8.3.0, for pc-linux-gnu on i686
...

Server version          8.3.0
Protocol version        10
Connection              Localhost via UNIX socket
UNIX socket             /var/lib/mysql/mysql.sock
Uptime:                 14 days 5 hours 5 min 21 sec

Threads: 1  Questions: 366  Slow queries: 0
Opens: 0  Flush tables: 1  Open tables: 19
Queries per second avg: 0.000
```

To see what else you can do with `mysqladmin`, invoke it with the `--help` option.

Verify that you can shut down the server (include a `-p` option if the `root` account has a password already):

```
$> bin/mysqladmin -u root shutdown
```

Verify that you can start the server again. Do this by using `mysqld_safe` or by invoking `mysqld` directly. For example:

```
$> bin/mysqld_safe --user=mysql &
```

If `mysqld_safe` fails, see [Section 2.9.2.1](#), “Troubleshooting Problems Starting the MySQL Server”.

Run some simple tests to verify that you can retrieve information from the server. The output should be similar to that shown here.

Use `mysqlshow` to see what databases exist:

```
$> bin/mysqlshow
+-----+
|      Databases      |
+-----+
| information_schema |
| mysql              |
| performance_schema |
| sys                |
+-----+
```

The list of installed databases may vary, but always includes at least `mysql` and `information_schema`.

If you specify a database name, `mysqlshow` displays a list of the tables within the database:

```
$> bin/mysqlshow mysql
Database: mysql
+-----+
|      Tables      |
+-----+
| columns_priv      |
| component         |
| db                |
| default_roles     |
| engine_cost       |
| func              |
| general_log       |
| global_grants     |
| gtid_executed     |
| help_category     |
| help_keyword      |
| help_relation     |
| help_topic        |
| innodb_index_stats |
| innodb_table_stats |
| ndb_binlog_index  |
| password_history  |
| plugin            |
| procs_priv        |
| proxies_priv      |
| role_edges        |
| server_cost       |
| servers           |
| slave_master_info  |
| slave_relay_log_info |
| slave_worker_info |
| slow_log          |
| tables_priv       |
| time_zone         |
| time_zone_leap_second |
| time_zone_name    |
| time_zone_transition |
| time_zone_transition_type |
| user              |
+-----+
```

Use the `mysql` program to select information from a table in the `mysql` schema:

```
$> bin/mysql -e "SELECT User, Host, plugin FROM mysql.user" mysql
+-----+
+-----+
```

User	Host	plugin
root	localhost	caching_sha2_password

At this point, your server is running and you can access it. To tighten security if you have not yet assigned a password to the initial account, follow the instructions in [Section 2.9.4, “Securing the Initial MySQL Account”](#).

For more information about `mysql`, `mysqladmin`, and `mysqlshow`, see [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#), [Section 6.5.2, “mysqladmin — A MySQL Server Administration Program”](#), and [Section 6.5.7, “mysqlshow — Display Database, Table, and Column Information”](#).

2.9.4 Securing the Initial MySQL Account

The MySQL installation process involves initializing the data directory, including the grant tables in the `mysql` system schema that define MySQL accounts. For details, see [Section 2.9.1, “Initializing the Data Directory”](#).

This section describes how to assign a password to the initial `root` account created during the MySQL installation procedure, if you have not already done so.

Note

Alternative means for performing the process described in this section:

- On Windows, you can perform the process during installation with MySQL Configurator (see [Section 2.3.2, “Configuration: Using MySQL Configurator”](#)).
- On all platforms, the MySQL distribution includes `mysql_secure_installation`, a command-line utility that automates much of the process of securing a MySQL installation.
- On all platforms, MySQL Workbench is available and offers the ability to manage user accounts (see [Chapter 33, MySQL Workbench](#)).

A password may already be assigned to the initial account under these circumstances:

- On Windows, installations performed using the MSI installer and MySQL Configurator give you the option of assigning a password.
- Installation using the macOS installer generates an initial random password, which the installer displays to the user in a dialog box.
- Installation using RPM packages generates an initial random password, which is written to the server error log.
- Installations using Debian packages give you the option of assigning a password.
- For data directory initialization performed manually using `mysqld --initialize`, `mysqld` generates an initial random password, marks it expired, and writes it to the server error log. See [Section 2.9.1, “Initializing the Data Directory”](#).

The `mysql.user` grant table defines the initial MySQL user account and its access privileges. Installation of MySQL creates only a '`root`'@'`localhost`' superuser account that has all privileges and can do anything. If the `root` account has an empty password, your MySQL installation is unprotected: Anyone can connect to the MySQL server as `root` *without a password* and be granted all privileges.

The '`root`'@'`localhost`' account also has a row in the `mysql.proxies_priv` table that enables granting the `PROXY` privilege for '`'@'`', that is, for all users and all hosts. This enables `root` to set

up proxy users, as well as to delegate to other accounts the authority to set up proxy users. See [Section 8.2.19, “Proxy Users”](#).

To assign a password for the initial MySQL `root` account, use the following procedure. Replace `root-password` in the examples with the password that you want to use.

Start the server if it is not running. For instructions, see [Section 2.9.2, “Starting the Server”](#).

The initial `root` account may or may not have a password. Choose whichever of the following procedures applies:

- If the `root` account exists with an initial random password that has been expired, connect to the server as `root` using that password, then choose a new password. This is the case if the data directory was initialized using `mysqld --initialize`, either manually or using an installer that does not give you the option of specifying a password during the install operation. Because the password exists, you must use it to connect to the server. But because the password is expired, you cannot use the account for any purpose other than to choose a new password, until you do choose one.

1. If you do not know the initial random password, look in the server error log.
2. Connect to the server as `root` using the password:

```
$> mysql -u root -p
Enter password: (enter the random root password here)
```

3. Choose a new password to replace the random password:

```
mysql> ALTER USER 'root'@'localhost' IDENTIFIED BY 'root-password';
```

- If the `root` account exists but has no password, connect to the server as `root` using no password, then assign a password. This is the case if you initialized the data directory using `mysqld --initialize-insecure`.

1. Connect to the server as `root` using no password:

```
$> mysql -u root --skip-password
```

2. Assign a password:

```
mysql> ALTER USER 'root'@'localhost' IDENTIFIED BY 'root-password';
```

After assigning the `root` account a password, you must supply that password whenever you connect to the server using the account. For example, to connect to the server using the `mysql` client, use this command:

```
$> mysql -u root -p
Enter password: (enter root password here)
```

To shut down the server with `mysqladmin`, use this command:

```
$> mysqladmin -u root -p shutdown
Enter password: (enter root password here)
```

Note

For additional information about setting passwords, see [Section 8.2.14, “Assigning Account Passwords”](#). If you forget your `root` password after setting it, see [Section B.3.3.2, “How to Reset the Root Password”](#).

To set up additional accounts, see [Section 8.2.8, “Adding Accounts, Assigning Privileges, and Dropping Accounts”](#).

2.9.5 Starting and Stopping MySQL Automatically

This section discusses methods for starting and stopping the MySQL server.

Generally, you start the `mysqld` server in one of these ways:

- Invoke `mysqld` directly. This works on any platform.
- On Windows, you can set up a MySQL service that runs automatically when Windows starts. See [Section 2.3.3.8, “Starting MySQL as a Windows Service”](#).
- On Unix and Unix-like systems, you can invoke `mysqld_safe`, which tries to determine the proper options for `mysqld` and then runs it with those options. See [Section 6.3.2, “mysqld_safe — MySQL Server Startup Script”](#).
- On Linux systems that support systemd, you can use it to control the server. See [Section 2.5.9, “Managing MySQL Server with systemd”](#).
- On systems that use System V-style run directories (that is, `/etc/init.d` and run-level specific directories), invoke `mysql.server`. This script is used primarily at system startup and shutdown. It usually is installed under the name `mysql`. The `mysql.server` script starts the server by invoking `mysqld_safe`. See [Section 6.3.3, “mysql.server — MySQL Server Startup Script”](#).
- On macOS, install a launchd daemon to enable automatic MySQL startup at system startup. The daemon starts the server by invoking `mysqld_safe`. For details, see [Section 2.4.3, “Installing and Using the MySQL Launch Daemon”](#). A MySQL Preference Pane also provides control for starting and stopping MySQL through the System Preferences. See [Section 2.4.4, “Installing and Using the MySQL Preference Pane”](#).
- On Solaris, use the service management framework (SMF) system to initiate and control MySQL startup.

systemd, the `mysqld_safe` and `mysql.server` scripts, Solaris SMF, and the macOS Startup Item (or MySQL Preference Pane) can be used to start the server manually, or automatically at system startup time. systemd, `mysql.server`, and the Startup Item also can be used to stop the server.

The following table shows which option groups the server and startup scripts read from option files.

Table 2.14 MySQL Startup Scripts and Supported Server Option Groups

Script	Option Groups
<code>mysqld</code>	<code>[mysqld]</code> , <code>[server]</code> , <code>[mysqld-major_version]</code>
<code>mysqld_safe</code>	<code>[mysqld]</code> , <code>[server]</code> , <code>[mysqld_safe]</code>
<code>mysql.server</code>	<code>[mysqld]</code> , <code>[mysql.server]</code> , <code>[server]</code>

`[mysqld-major_version]` means that groups with names like `[mysqld-8.2]` and `[mysqld-8.3]` are read by servers having versions 8.2.x, 8.3.x, and so forth. This feature can be used to specify options that can be read only by servers within a given release series.

For backward compatibility, `mysql.server` also reads the `[mysql_server]` group and `mysqld_safe` also reads the `[safe_mysqld]` group. To be current, you should update your option files to use the `[mysql.server]` and `[mysqld_safe]` groups instead.

For more information on MySQL configuration files and their structure and contents, see [Section 6.2.2.2, “Using Option Files”](#).

2.10 Perl Installation Notes

The Perl `DBI` module provides a generic interface for database access. You can write a `DBI` script that works with many different database engines without change. To use `DBI`, you must install the `DBI`

module, as well as a DataBase Driver (DBD) module for each type of database server you want to access. For MySQL, this driver is the `DBD::mysql` module.

Note

Perl support is not included with MySQL distributions. You can obtain the necessary modules from <http://search.cpan.org> for Unix, or by using the ActiveState `ppm` program on Windows. The following sections describe how to do this.

The `DBI/DBD` interface requires Perl 5.6.0, and 5.6.1 or later is preferred. *DBI does not work* if you have an older version of Perl. You should use `DBD::mysql` 4.009 or higher. Although earlier versions are available, they do not support the full functionality of MySQL 8.3.

2.10.1 Installing Perl on Unix

MySQL Perl support requires that you have installed MySQL client programming support (libraries and header files). Most installation methods install the necessary files. If you install MySQL from RPM files on Linux, be sure to install the developer RPM as well. The client programs are in the client RPM, but client programming support is in the developer RPM.

The files you need for Perl support can be obtained from the CPAN (Comprehensive Perl Archive Network) at <http://search.cpan.org>.

The easiest way to install Perl modules on Unix is to use the `CPAN` module. For example:

```
$> perl -MCPAN -e shell
cpan> install DBI
cpan> install DBD::mysql
```

The `DBD::mysql` installation runs a number of tests. These tests attempt to connect to the local MySQL server using the default user name and password. (The default user name is your login name on Unix, and `ODBC` on Windows. The default password is “no password.”) If you cannot connect to the server with those values (for example, if your account has a password), the tests fail. You can use `force install DBD::mysql` to ignore the failed tests.

`DBI` requires the `Data::Dumper` module. It may be installed; if not, you should install it before installing `DBI`.

It is also possible to download the module distributions in the form of compressed `tar` archives and build the modules manually. For example, to unpack and build a `DBI` distribution, use a procedure such as this:

1. Unpack the distribution into the current directory:

```
$> gunzip < DBI-VERSION.tar.gz | tar xvf -
```

This command creates a directory named `DBI-VERSION`.

2. Change location into the top-level directory of the unpacked distribution:

```
$> cd DBI-VERSION
```

3. Build the distribution and compile everything:

```
$> perl Makefile.PL
$> make
$> make test
$> make install
```

The `make test` command is important because it verifies that the module is working. Note that when you run that command during the `DBD::mysql` installation to exercise the interface code, the MySQL server must be running or the test fails.

It is a good idea to rebuild and reinstall the `DBD::mysql` distribution whenever you install a new release of MySQL. This ensures that the latest versions of the MySQL client libraries are installed correctly.

If you do not have access rights to install Perl modules in the system directory or if you want to install local Perl modules, the following reference may be useful: <http://learn.perl.org/faq/perlfaq8.html#How-do-I-keep-my-own-module-library-directory->

2.10.2 Installing ActiveState Perl on Windows

On Windows, you should do the following to install the MySQL `DBD` module with ActiveState Perl:

1. Get ActiveState Perl from <http://www.activestate.com/Products/ActivePerl/> and install it.
2. Open a console window.
3. If necessary, set the `HTTP_proxy` variable. For example, you might try a setting like this:

```
C:\> set HTTP_proxy=my.proxy.com:3128
```

4. Start the PPM program:

```
C:\> C:\perl\bin\ppm.pl
```

5. If you have not previously done so, install `DBI`:

```
ppm> install DBI
```

6. If this succeeds, run the following command:

```
ppm> install DBD-mysql
```

This procedure should work with ActiveState Perl 5.6 or higher.

If you cannot get the procedure to work, you should install the ODBC driver instead and connect to the MySQL server through ODBC:

```
use DBI;
$dbh= DBI->connect("DBI:ODBC:$dsn",$user,$password) ||
die "Got error $DBI::errstr when connecting to $dsn\n";
```

2.10.3 Problems Using the Perl DBI/DBD Interface

If Perl reports that it cannot find the `../mysql/mysql.so` module, the problem is probably that Perl cannot locate the `libmysqlclient.so` shared library. You should be able to fix this problem by one of the following methods:

- Copy `libmysqlclient.so` to the directory where your other shared libraries are located (probably `/usr/lib` or `/lib`).
- Modify the `-L` options used to compile `DBD::mysql` to reflect the actual location of `libmysqlclient.so`.
- On Linux, you can add the path name of the directory where `libmysqlclient.so` is located to the `/etc/ld.so.conf` file.
- Add the path name of the directory where `libmysqlclient.so` is located to the `LD_RUN_PATH` environment variable. Some systems use `LD_LIBRARY_PATH` instead.

Note that you may also need to modify the `-L` options if there are other libraries that the linker fails to find. For example, if the linker cannot find `libc` because it is in `/lib` and the link command specifies `-L/usr/lib`, change the `-L` option to `-L/lib` or add `-L/lib` to the existing link command.

If you get the following errors from `DBD:mysql`, you are probably using `gcc` (or using an old binary compiled with `gcc`):

```
/usr/bin/perl: can't resolve symbol '__moddi3'
/usr/bin/perl: can't resolve symbol '__divdi3'
```

Add `-L/usr/lib/gcc-lib/... -lgcc` to the link command when the `mysql.so` library gets built (check the output from `make` for `mysql.so` when you compile the Perl client). The `-L` option should specify the path name of the directory where `libgcc.a` is located on your system.

Another cause of this problem may be that Perl and MySQL are not both compiled with `gcc`. In this case, you can solve the mismatch by compiling both with `gcc`.

3.13 Upgrade Troubleshooting	206
3.14 Rebuilding or Repairing Tables or Indexes	206
3.15 Copying MySQL Databases to Another Machine	208

This chapter describes the steps to upgrade a MySQL installation.

Upgrading is a common procedure, as you pick up bug fixes within the same MySQL release series or significant features between major MySQL releases. You perform this procedure first on some test systems to make sure everything works smoothly, and then on the production systems.

Note

In the following discussion, MySQL commands that must be run using a MySQL account with administrative privileges include `-u root` on the command line to specify the MySQL `root` user. Commands that require a password for `root` also include a `-p` option. Because `-p` is followed by no option value, such commands prompt for the password. Type the password when prompted and press Enter.

SQL statements can be executed using the `mysql` command-line client (connect as `root` to ensure that you have the necessary privileges).

3.1 Before You Begin

Review the information in this section before upgrading. Perform any recommended actions.

- Understand what may occur during an upgrade. See [Section 3.4, “What the MySQL Upgrade Process Upgrades”](#).
- Protect your data by creating a backup. The backup should include the `mysql` system database, which contains the MySQL data dictionary tables and system tables. See [Section 9.2, “Database Backup Methods”](#).

Important

Downgrade from MySQL 8.3 to MySQL 8.2, or from a MySQL 8.3 release to a previous MySQL 8.3 release, is not supported. The only supported alternative is to restore a backup taken *before* upgrading. It is therefore imperative that you back up your data before starting the upgrade process.

- Review [Section 3.2, “Upgrade Paths”](#) to ensure that your intended upgrade path is supported.
- Review [Section 3.5, “Changes in MySQL 8.3”](#) for changes that you should be aware of before upgrading. Some changes may require action.
- Review [Section 1.3, “What Is New in MySQL 8.3”](#) for deprecated and removed features. An upgrade may require changes with respect to those features if you use any of them.
- Review [Section 1.4, “Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 8.3”](#). If you use deprecated or removed variables, an upgrade may require configuration changes.
- Review the [Release Notes](#) for information about fixes, changes, and new features.
- If you use replication, review [Section 19.5.3, “Upgrading a Replication Topology”](#).
- Review [Section 3.3, “Upgrade Best Practices”](#) and plan accordingly.
- Upgrade procedures vary by platform and how the initial installation was performed. Use the procedure that applies to your current MySQL installation:
 - For binary and package-based installations on non-Windows platforms, refer to [Section 3.7, “Upgrading MySQL Binary or Package-based Installations on Unix/Linux”](#).

**Note**

For supported Linux distributions, the preferred method for upgrading package-based installations is to use the MySQL software repositories (MySQL Yum Repository, MySQL APT Repository, and MySQL SLES Repository).

- For installations on an Enterprise Linux platform or Fedora using the MySQL Yum Repository, refer to [Section 3.8, “Upgrading MySQL with the MySQL Yum Repository”](#).
- For installations on Ubuntu using the MySQL APT repository, refer to [Section 3.9, “Upgrading MySQL with the MySQL APT Repository”](#).
- For installations on SLES using the MySQL SLES repository, refer to [Section 3.10, “Upgrading MySQL with the MySQL SLES Repository”](#).
- For installations performed using Docker, refer to [Section 3.12, “Upgrading a Docker Installation of MySQL”](#).
- For installations on Windows, refer to [Section 3.11, “Upgrading MySQL on Windows”](#).
- If your MySQL installation contains a large amount of data that might take a long time to convert after an in-place upgrade, it may be useful to create a test instance for assessing the conversions that are required and the work involved to perform them. To create a test instance, make a copy of your MySQL instance that contains the `mysql` database and other databases without the data. Run the upgrade procedure on the test instance to assess the work involved to perform the actual data conversion.
- Rebuilding and reinstalling MySQL language interfaces is recommended when you install or upgrade to a new release of MySQL. This applies to MySQL interfaces such as PHP `mysql` extensions and the Perl `DBD::mysql` module.

3.2 Upgrade Paths

**Notes**

- Make sure you understand [the release model for MySQL innovation and long-term support \(LTS\) versions](#) before you proceed with an upgrade.

- Monthly Rapid Updates (MRUs) and hotfixes also count as "releases" in the following discussions.
- It is necessary to upgrade to the latest innovation releases (for example, from MySQL 8.2 to 8.3) regularly to keep up with the latest bug fixes and security patches.
- We use "8.4.x LTS" as an example for an LTS release *only for illustrative purposes*.

The supported upgrade paths for MySQL Server are listed in [Table 3.1, "Upgrade Paths for MySQL Server"](#) below:

Table 3.1 Upgrade Paths for MySQL Server

Upgrade Path	Path Examples	Upgrade Methods	Notes
Within an LTS or bugfix release series	8.0.34 to 8.0.36 8.4.x LTS to 8.4.x+1 LTS	in-place upgrade , logical upgrade , asynchronous replication , MySQL Clone	
From an LTS or bugfix release to the next LTS or bugfix release	8.0.34 to 8.4.x LTS	in-place upgrade , logical upgrade , asynchronous replication , MySQL Clone	
From an LTS or bugfix release to an innovation release <i>before the next LTS series</i>	8.0.34 to 8.3.0	in-place upgrade , logical upgrade , asynchronous replication	
From an innovation release series to another one <i>before the next LTS series</i>	8.1.0 to 8.3.0	in-place upgrade , logical upgrade , asynchronous replication	
From MySQL 5.7 to an LTS or Innovation release	MySQL 5.7 to 8.x	Upgrade first to a MySQL 8.0 bugfix release (8.0.34 or later), then to an innovation release	See upgrade paths for MySQL 8.0 for upgrade instructions for MySQL 5.7.

3.3 Upgrade Best Practices

MySQL supports upgrading between minor versions (within an LTS series) and to the next major version (across an LTS series). Upgrading provides the latest features, performance, and security fixes.

To prepare and help ensure that your upgrade to the latest MySQL release is successful, we recommend the following best practices:

- [Decide on Major or Minor Version for Upgrade](#)
- [Decide on Upgrade Type](#)

Decide on Major or Minor Version for Upgrade

The MySQL Release Model makes a distinction between LTS (Long Term Support) and Innovation Releases. LTS releases have 8+ years of support and are meant for production use. Innovation Releases provide users with the latest features and capabilities. Learn more about the [MySQL Release Model](#).

Performing a minor version upgrade is straightforward while major version upgrades require strategic planning and additional testing before the upgrade. This guide is especially useful for major version upgrades.

Decide on Upgrade Type

There are three main ways to upgrade MySQL, read the associated documentation to determine which type of upgrade is best suited for your situation.

- [An in-place upgrade](#): Replacing the MySQL Server packages.
- [A logical upgrade](#): exporting SQL from the old MySQL instance to the new.
- [A replication topology upgrade](#): account for each server's topology role.

Review Supported Platforms

If your current operating system is not supported by the new version of MySQL, then plan to upgrade the operating system as otherwise an in-place upgrade is not supported.

For a current list of supported platforms, see: <https://www.mysql.com/support/supportedplatforms/database.html>

Understand MySQL Server Changes

Each major version comes with new features, changes in behavior, deprecations, and removals. It is important to understand the impact of each of these to existing applications.

See: [Section 3.5, “Changes in MySQL 8.3”](#).

Run Upgrade Checker and Fix Incompatibilities

MySQL Shell's [Upgrade Checker Utility](#) detects incompatibilities between database versions that must be addressed before performing the upgrade. The `util.checkForServerUpgrade()` function verifies that MySQL server instances are ready to upgrade. Connect to the existing MySQL server and

select the MySQL Server version you plan to upgrade to for the utility to report issues to address prior to an upgrade. These include incompatibilities in data types, storage engines, and so on.

You are ready to upgrade when the upgrade checking utility no longer reports any issues.

Run Applications in a Test Environment

After completing the upgrade checker's requirements, next test your applications on the new target MySQL server. Check for errors and warnings in the MySQL error log and application logs.

Benchmark Applications and Workload Performance

We recommend benchmarking your own applications and workloads by comparing how they perform using the previous and new versions of MySQL. Usually, newer MySQL versions add features and improve performance but there are cases where an upgrade might run slower for specific queries. Possible issues resulting in performance regressions:

- Prior server configuration is not optimal for newer version
- Changes to data types
- Additional storage required by Multi-byte character set support
- Storage engines changes
- Dropped or changed indexes
- Stronger encryption
- Stronger authentication
- SQL optimizer changes
- Newer version of MySQL require additional memory
- Physical or Virtual Hardware is slower - compute or storage

For related information and potential mitigation techniques, see [Valid Performance Regressions](#).

Run Both MySQL Versions in Parallel

To minimize risk, it is best keep the current system running while running the upgraded system in parallel.

Run Final Test Upgrade

Practice and do a run though prior to upgrading your production server. Thoroughly test the upgrade procedures before upgrading a production system.

Check MySQL Backup

Check that the full backup exists and is viable before performing the upgrade.

Upgrade Production Server

You are ready to complete the upgrade.

Enterprise Support

If you're a MySQL Enterprise Edition customer, you can also contact the MySQL Support Team experts with any questions you may have.

3.4 What the MySQL Upgrade Process Upgrades

Installing a new version of MySQL may require upgrading these parts of the existing installation:

- The `mysql` system schema, which contains tables that store information required by the MySQL server as it runs (see [Section 7.3, “The mysql System Schema”](#)). `mysql` schema tables fall into two broad categories:
 - Data dictionary tables, which store database object metadata.
 - System tables (that is, the remaining non-data dictionary tables), which are used for other operational purposes.
- Other schemas, some of which are built in and may be considered “owned” by the server, and others which are not:
 - The `performance_schema`, `INFORMATION_SCHEMA`, `ndbinfo`, and `sys` schemas.
 - User schemas.

Two distinct version numbers are associated with parts of the installation that may require upgrading:

- The data dictionary version. This applies to the data dictionary tables.
- The server version, also known as the MySQL version. This applies to the system tables and objects in other schemas.

In both cases, the actual version applicable to the existing MySQL installation is stored in the data dictionary, and the current expected version is compiled into the new version of MySQL. When an actual version is lower than the current expected version, those parts of the installation associated with that version must be upgraded to the current version. If both versions indicate an upgrade is needed, the data dictionary upgrade must occur first.

As a reflection of the two distinct versions just mentioned, the upgrade occurs in two steps:

- Step 1: Data dictionary upgrade.

This step upgrades:

- The data dictionary tables in the `mysql` schema. If the actual data dictionary version is lower than the current expected version, the server creates data dictionary tables with updated definitions, copies persisted metadata to the new tables, atomically replaces the old tables with the new ones, and reinitializes the data dictionary.
- The Performance Schema, `INFORMATION_SCHEMA`, and `ndbinfo`.
- Step 2: Server upgrade.

This step comprises all other upgrade tasks. If the server version of the existing MySQL installation is lower than that of the new installed MySQL version, everything else must be upgraded:

- The system tables in the `mysql` schema (the remaining non-data dictionary tables).
- The `sys` schema.
- User schemas.

The data dictionary upgrade (step 1) is the responsibility of the server, which performs this task as necessary at startup unless invoked with an option that prevents it from doing so. The option is `--upgrade=NONE`.

If the data dictionary is out of date but the server is prevented from upgrading it, the server does not run, and exits with an error instead. For example:

```
[ERROR] [MY-013381] [Server] Server shutting down because upgrade is
required, yet prohibited by the command line option '--upgrade=NONE'.
[ERROR] [MY-010334] [Server] Failed to initialize DD Storage Engine
[ERROR] [MY-010020] [Server] Data Dictionary initialization failed.
```

The `--upgrade` server option controls whether and how the server performs an automatic upgrade at startup:

- With no option or with `--upgrade=AUTO`, the server upgrades anything it determines to be out of date (steps 1 and 2).
- With `--upgrade=NONE`, the server upgrades nothing (skips steps 1 and 2), but also exits with an error if the data dictionary must be upgraded. It is not possible to run the server with an out-of-date data dictionary; the server insists on either upgrading it or exiting.
- With `--upgrade=MINIMAL`, the server upgrades the data dictionary, the Performance Schema, and the `INFORMATION_SCHEMA`, if necessary (step 1). Note that following an upgrade with this option, Group Replication cannot be started, because system tables on which the replication internals depend are not updated, and reduced functionality might also be apparent in other areas.
- With `--upgrade=FORCE`, the server upgrades the data dictionary, the Performance Schema, and the `INFORMATION_SCHEMA`, if necessary (step 1), and forces an upgrade of everything else (step 2). Expect server startup to take longer with this option because the server checks all objects in all schemas.

`FORCE` is useful to force step 2 actions to be performed if the server thinks they are not necessary. One way that `FORCE` differs from `AUTO` is that with `FORCE`, the server re-creates system tables such as help tables or time zone tables if they are missing.

Additional notes about what occurs during upgrade step 2:

- Step 2 installs the `sys` schema if it is not installed, and upgrades it to the current version otherwise. An error occurs if a `sys` schema exists but has no `version` view, on the assumption that its absence indicates a user-created schema:

```
A sys schema exists with no sys.version view. If
you have a user created sys schema, this must be renamed for the
upgrade to succeed.
```

To upgrade in this case, remove or rename the existing `sys` schema first. Then perform the upgrade procedure again. (It may be necessary to force step 2.)

To prevent the `sys` schema check, start the server with the `--upgrade=NONE` or `--upgrade=MINIMAL` option.

- Step 2 upgrades the system tables to ensure that they have the current structure, and this includes the help tables but not the time zone tables. The procedure for loading time zone tables is platform dependent and requires decision making by the DBA, so it cannot be done automatically.
- When Step 2 is upgrading the system tables in the `mysql` schema, the column order in the primary key of the `mysql.db`, `mysql.tables_priv`, `mysql.columns_priv` and `mysql.procs_priv` tables is changed to place the host name and user name columns together. Placing the host name and user name together means that index lookup can be used, which improves performance for `CREATE USER`, `DROP USER`, and `RENAME USER` statements, and for ACL checks for multiple users with multiple privileges. Dropping and re-creating the index is necessary and might take some time if the system has a large number of users and privileges.
- Step 2 processes all tables in all user schemas as necessary. Table checking might take a long time to complete. Each table is locked and therefore unavailable to other sessions while it is being processed. Check and repair operations can be time-consuming, particularly for large tables. Table checking uses the `FOR UPGRADE` option of the `CHECK TABLE` statement. For details about what this option entails, see [Section 15.7.3.2, “CHECK TABLE Statement”](#).

To prevent table checking, start the server with the `--upgrade=NONE` or `--upgrade=MINIMAL` option.

To force table checking, start the server with the `--upgrade=FORCE` option.

- Step 2 saves the MySQL version number in a file named `mysql_upgrade_info` in the data directory.

To ignore the `mysql_upgrade_info` file and perform the check regardless, start the server with the `--upgrade=FORCE` option.

**Note**

The `mysql_upgrade_info` file is deprecated; expect it to be removed in a future version of MySQL.

- Step 2 marks all checked and repaired tables with the current MySQL version number. This ensures that the next time upgrade checking occurs with the same version of the server, it can be determined whether there is any need to check or repair a given table again.

3.5 Changes in MySQL 8.3

Before upgrading to MySQL 8.3, review the changes linked in this section to identify those that apply to your current MySQL installation and applications.

- [Overview of changes in MySQL 8.3.0](#)
- [Overview of changes in MySQL 8.2.0](#)
- [Overview of changes in MySQL 8.1.0](#)
- [MySQL 8.3.0 Release Notes](#)
- [MySQL 8.2.0 Release Notes](#)
- [MySQL 8.1.0 Release Notes](#)

3.6 Preparing Your Installation for Upgrade

Before upgrading to the latest MySQL 8.3 release, ensure the upgrade readiness of your current MySQL 8.2 or MySQL 8.0 server instance by performing the preliminary checks described below. The upgrade process may fail otherwise.

**Tip**

Consider using the [MySQL Shell upgrade checker utility](#) that enables you to verify whether MySQL server instances are ready for upgrade. You can select a target MySQL Server release to which you plan to upgrade, ranging from the MySQL Server 8.0.11 up to the MySQL Server release number that matches the current MySQL Shell release number. The upgrade checker utility carries out the automated checks that are relevant for the specified target release, and advises you of further relevant checks that you should make manually. The upgrade checker works for all GA releases of MySQL 5.7, 8.0, and 8.3. Installation instructions for MySQL Shell can be found [here](#).

Preliminary checks:

1. The following issues must not be present:
 - There must be no tables that use obsolete data types or functions.

- There must be no orphan `.frm` files.
- Triggers must not have a missing or empty definer or an invalid creation context (indicated by the `character_set_client`, `collation_connection`, `Database Collation` attributes displayed by `SHOW TRIGGERS` or the `INFORMATION_SCHEMA TRIGGERS` table). Any such triggers must be dumped and restored to fix the issue.

To check for these issues, execute this command:

```
mysqlcheck -u root -p --all-databases --check-upgrade
```

If `mysqlcheck` reports any errors, correct the issues.

2. There must be no partitioned tables that use a storage engine that does not have native partitioning support. To identify such tables, execute this query:

```
SELECT TABLE_SCHEMA, TABLE_NAME
FROM INFORMATION_SCHEMA.TABLES
WHERE ENGINE NOT IN ('innodb', 'ndbcluster')
AND CREATE_OPTIONS LIKE '%partitioned%';
```

Any table reported by the query must be altered to use `InnoDB` or be made nonpartitioned. To change a table storage engine to `InnoDB`, execute this statement:

```
ALTER TABLE table_name ENGINE = INNODB;
```

For information about converting `MyISAM` tables to `InnoDB`, see [Section 17.6.1.5, “Converting Tables from MyISAM to InnoDB”](#).

To make a partitioned table nonpartitioned, execute this statement:

```
ALTER TABLE table_name REMOVE PARTITIONING;
```

3. Some keywords may be reserved in MySQL 8.3 that were not reserved previously. See [Section 11.3, “Keywords and Reserved Words”](#). This can cause words previously used as identifiers to become illegal. To fix affected statements, use identifier quoting. See [Section 11.2, “Schema Object Names”](#).
4. There must be no tables in the MySQL 8.2 `mysql` system database that have the same name as a table used by the MySQL 8.3 data dictionary. To identify tables with those names, execute this query:

```
SELECT TABLE_SCHEMA, TABLE_NAME
FROM INFORMATION_SCHEMA.TABLES
WHERE LOWER(TABLE_SCHEMA) = 'mysql'
and LOWER(TABLE_NAME) IN
(
'catalogs',
'character_sets',
'check_constraints',
'collations',
'column_statistics',
'column_type_elements',
'columns',
'dd_properties',
'events',
'foreign_key_column_usage',
'foreign_keys',
'index_column_usage',
'index_partitions',
'index_stats',
'indexes',
'parameter_type_elements',
'parameters',
'resource_groups',
'routines',
```

```
'schemata',
'st_spatial_reference_systems',
'table_partition_values',
'table_partitions',
'table_stats',
'tables',
'tablespace_files',
'tablespace_files',
'triggers',
'view_routine_usage',
'view_table_usage'
);
```

Any tables reported by the query must be dropped or renamed (use [RENAME TABLE](#)). This may also entail changes to applications that use the affected tables.

5. There must be no tables that have foreign key constraint names longer than 64 characters. Use this query to identify tables with constraint names that are too long:

```
SELECT TABLE_SCHEMA, TABLE_NAME
FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_NAME IN
  (SELECT LEFT(SUBSTR(ID, INSTR(ID, '/')+1),
    INSTR(SUBSTR(ID, INSTR(ID, '/')+1), '_ibfk_')-1)
  FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN
  WHERE LENGTH(SUBSTR(ID, INSTR(ID, '/')+1))>64);
```

For a table with a constraint name that exceeds 64 characters, drop the constraint and add it back with constraint name that does not exceed 64 characters (use [ALTER TABLE](#)).

6. There must be no obsolete SQL modes defined by [sql_mode](#) system variable. Attempting to use an obsolete SQL mode prevents MySQL 8.3 from starting. Applications that use obsolete SQL modes should be revised to avoid them. For information about SQL modes removed in MySQL 8.3, see [Server Changes](#).
7. There must be no views with explicitly defined columns names that exceed 64 characters (views with column names up to 255 characters were permitted in MySQL 5.7). To avoid upgrade errors, such views should be altered before upgrading. Currently, the only method of identify views with column names that exceed 64 characters is to inspect the view definition using [SHOW CREATE VIEW](#). You can also inspect view definitions by querying the Information Schema [VIEWS](#) table.
8. There must be no tables or stored procedures with individual [ENUM](#) or [SET](#) column elements that exceed 255 characters or 1020 bytes in length. Prior to MySQL 8.3, the maximum combined length of [ENUM](#) or [SET](#) column elements was 64K. In MySQL 8.3, the maximum character length of an individual [ENUM](#) or [SET](#) column element is 255 characters, and the maximum byte length is 1020 bytes. (The 1020 byte limit supports multibyte character sets). Before upgrading to MySQL 8.0, modify any [ENUM](#) or [SET](#) column elements that exceed the new limits. Failing to do so causes the upgrade to fail with an error.
9. Your MySQL 8.2 installation must not use features that are not supported by MySQL 8.3. Any changes here are necessarily installation specific, but the following example illustrates the kind of thing to look for:

Some server startup options and system variables have been removed in MySQL 8.3. See [Features Removed in MySQL 8.3](#), and [Section 1.4, “Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 8.3”](#). If you use any of these, an upgrade requires configuration changes.

10. If you intend to change the [lower_case_table_names](#) setting to 1 at upgrade time, ensure that schema and table names are lowercase before upgrading. Otherwise, a failure could occur due to a schema or table name lettercase mismatch. You can use the following queries to check for schema and table names containing uppercase characters:

```
mysql> select TABLE_NAME, if(sha(TABLE_NAME) !=sha(lower(TABLE_NAME)), 'Yes', 'No') as UpperCase from inf
```

If `lower_case_table_names=1`, table and schema names are checked by the upgrade process to ensure that all characters are lowercase. If table or schema names are found to contain uppercase characters, the upgrade process fails with an error.

**Note**

Changing the `lower_case_table_names` setting at upgrade time is not recommended.

If upgrade to MySQL 8.3 fails due to any of the issues outlined above, the server reverts all changes to the data directory. In this case, remove all redo log files and restart the MySQL 8.2 server on the existing data directory to address the errors. The redo log files (`ib_logfile*`) reside in the MySQL data directory by default. After the errors are fixed, perform a slow shutdown (by setting `innodb_fast_shutdown=0`) before attempting the upgrade again.

3.7 Upgrading MySQL Binary or Package-based Installations on Unix/Linux

This section describes how to upgrade MySQL binary and package-based installations on Unix/Linux. In-place and logical upgrade methods are described.

- [In-Place Upgrade](#)
- [Logical Upgrade](#)
- [MySQL Cluster Upgrade](#)

In-Place Upgrade

An in-place upgrade involves shutting down the old MySQL server, replacing the old MySQL binaries or packages with the new ones, restarting MySQL on the existing data directory, and upgrading any remaining parts of the existing installation that require upgrading. For details about what may need upgrading, see [Section 3.4, “What the MySQL Upgrade Process Upgrades”](#).

**Note**

If you are upgrading an installation originally produced by installing multiple RPM packages, upgrade all the packages, not just some. For example, if you previously installed the server and client RPMs, do not upgrade just the server RPM.

For some Linux platforms, MySQL installation from RPM or Debian packages includes systemd support for managing MySQL server startup and shutdown. On these platforms, `mysqld_safe` is not installed. In such cases, use systemd for server startup and shutdown instead of the methods used in the following instructions. See [Section 2.5.9, “Managing MySQL Server with systemd”](#).

For upgrades to MySQL Cluster installations, see also [MySQL Cluster Upgrade](#).

To perform an in-place upgrade:

1. Review the information in [Section 3.1, “Before You Begin”](#).
2. Ensure the upgrade readiness of your installation by completing the preliminary checks in [Section 3.6, “Preparing Your Installation for Upgrade”](#).
3. If you use XA transactions with `InnoDB`, run `XA RECOVER` before upgrading to check for uncommitted XA transactions. If results are returned, either commit or rollback the XA transactions by issuing an `XA COMMIT` or `XA ROLLBACK` statement.

4. If you normally run your MySQL server configured with `innodb_fast_shutdown` set to 2 (cold shutdown), configure it to perform a fast or slow shutdown by executing either of these statements:

```
SET GLOBAL innodb_fast_shutdown = 1; -- fast shutdown
SET GLOBAL innodb_fast_shutdown = 0; -- slow shutdown
```

With a fast or slow shutdown, **InnoDB** leaves its undo logs and data files in a state that can be dealt with in case of file format differences between releases.

5. Shut down the old MySQL server. For example:

```
mysqladmin -u root -p shutdown
```

6. Upgrade the MySQL binaries or packages. If upgrading a binary installation, unpack the new MySQL binary distribution package. See [Obtain and Unpack the Distribution](#). For package-based installations, install the new packages.

7. Start the MySQL 8.3 server, using the existing data directory. For example:

```
mysqld_safe --user=mysql --datadir=/path/to/existing-datadir &
```

If there are encrypted **InnoDB** tablespaces, use the `--early-plugin-load` option to load the keyring plugin.

When you start the MySQL 8.3 server, it automatically detects whether data dictionary tables are present. If not, the server creates them in the data directory, populates them with metadata, and then proceeds with its normal startup sequence. During this process, the server upgrades metadata for all database objects, including databases, tablespaces, system and user tables, views, and stored programs (stored procedures and functions, triggers, and Event Scheduler events). The server also removes files that previously were used for metadata storage. For example, after upgrading from MySQL 8.2 to MySQL 8.3, you may notice that tables no longer have `.frm` files.

If this step fails, the server reverts all changes to the data directory. In this case, you should remove all redo log files, start your MySQL 8.2 server on the same data directory, and fix the cause of any errors. Then perform another slow shutdown of the 8.2 server and start the MySQL 8.3 server to try again.

8. In the previous step, the server upgrades the data dictionary as necessary, making any changes required in the `mysql` system database between MySQL 8.2 and MySQL 8.3, so that you can take advantage of new privileges or capabilities. It also brings the Performance Schema, `INFORMATION_SCHEMA`, and `sys` databases up to date for MySQL 8.3, and examines all user databases for incompatibilities with the current version of MySQL.

Note

The upgrade process does not upgrade the contents of the time zone tables. For upgrade instructions, see [Section 7.1.15, “MySQL Server Time Zone Support”](#).

Logical Upgrade

A logical upgrade involves exporting SQL from the old MySQL instance using a backup or export utility such as `mysqldump` or `mysqlpump`, installing the new MySQL server, and applying the SQL to your new MySQL instance. For details about what may need upgrading, see [Section 3.4, “What the MySQL Upgrade Process Upgrades”](#).

Note

For some Linux platforms, MySQL installation from RPM or Debian packages includes systemd support for managing MySQL server startup and shutdown. On these platforms, `mysqld_safe` is not installed. In such cases, use `systemd`

for server startup and shutdown instead of the methods used in the following instructions. See [Section 2.5.9, “Managing MySQL Server with systemd”](#).

Warning

Applying SQL extracted from a previous MySQL release to a new MySQL release may result in errors due to incompatibilities introduced by new, changed, deprecated, or removed features and capabilities. Consequently, SQL extracted from a previous MySQL release may require modification to enable a logical upgrade.

To identify incompatibilities before upgrading to the latest MySQL 8.3 release, perform the steps described in [Section 3.6, “Preparing Your Installation for Upgrade”](#).

To perform a logical upgrade:

1. Review the information in [Section 3.1, “Before You Begin”](#).
2. Export your existing data from the previous MySQL installation:

```
mysqldump -u root -p
--add-drop-table --routines --events
--all-databases --force > data-for-upgrade.sql
```

Note

Use the `--routines` and `--events` options with `mysqldump` (as shown above) if your databases include stored programs. The `--all-databases` option includes all databases in the dump, including the `mysql` database that holds the system tables.

Important

If you have tables that contain generated columns, use the `mysqldump` utility provided with MySQL 5.7.9 or higher to create your dump files. The `mysqldump` utility provided in earlier releases uses incorrect syntax for generated column definitions (Bug #20769542). You can use the Information Schema `COLUMNS` table to identify tables with generated columns.

3. Shut down the old MySQL server. For example:

```
mysqladmin -u root -p shutdown
```

4. Install MySQL 8.3. For installation instructions, see [Chapter 2, Installing MySQL](#).
5. Initialize a new data directory, as described in [Section 2.9.1, “Initializing the Data Directory”](#). For example:

```
mysqld --initialize --datadir=/path/to/8.3-datadir
```

Copy the temporary `'root'@'localhost'` password displayed to your screen or written to your error log for later use.

6. Start the MySQL 8.3 server, using the new data directory. For example:

```
mysqld_safe --user=mysql --datadir=/path/to/8.3-datadir &
```

7. Reset the `root` password:

```
$> mysql -u root -p
Enter password: **** <- enter temporary root password

mysql> ALTER USER USER() IDENTIFIED BY 'your new password';
```

8. Load the previously created dump file into the new MySQL server. For example:

```
mysql -u root -p --force < data-for-upgrade.sql
```

Note

It is not recommended to load a dump file when GTIDs are enabled on the server (`gtid_mode=ON`), if your dump file includes system tables. `mysqldump` issues DML instructions for the system tables which use the non-transactional MyISAM storage engine, and this combination is not permitted when GTIDs are enabled. Also be aware that loading a dump file from a server with GTIDs enabled, into another server with GTIDs enabled, causes different transaction identifiers to be generated.

9. Perform any remaining upgrade operations:

Shut down the server, then restart it with the `--upgrade=FORCE` option to perform the remaining upgrade tasks:

```
mysqldadmin -u root -p shutdown
mysqld_safe --user=mysql --datadir=/path/to/8.3-datadir --upgrade=FORCE &
```

Upon restart with `--upgrade=FORCE`, the server makes any changes required in the `mysql` system schema between MySQL 8.2 and MySQL 8.3, so that you can take advantage of new privileges or capabilities. It also brings the Performance Schema, `INFORMATION_SCHEMA`, and `sys` schema up to date for MySQL 8.3, and examines all user schemas for incompatibilities with the current version of MySQL.

Note

The upgrade process does not upgrade the contents of the time zone tables. For upgrade instructions, see [Section 7.1.15, “MySQL Server Time Zone Support”](#).

Note

Loading a dump file that contains a MySQL 5.7 `mysql` schema re-creates two tables that are no longer used: `event` and `proc`. (The corresponding MySQL 8.0 tables are `events` and `routines`, both of which are data dictionary tables and are protected.) After you are satisfied that the upgrade was successful, you can remove the `event` and `proc` tables by executing these SQL statements:

```
DROP TABLE mysql.event;
DROP TABLE mysql.proc;
```

MySQL Cluster Upgrade

The information in this section is an adjunct to the in-place upgrade procedure described in [In-Place Upgrade](#), for use if you are upgrading MySQL Cluster.

A MySQL Cluster upgrade can be performed as a regular rolling upgrade, following the usual three ordered steps:

1. Upgrade MGM nodes.
2. Upgrade data nodes one at a time.
3. Upgrade API nodes one at a time (including MySQL servers).

There are two steps to upgrading each individual `mysqld`:

1. Import the data dictionary.

Start the new server with the `--upgrade=MINIMAL` option to upgrade the data dictionary but not the system tables.

The MySQL server must be connected to `NDB` for this phase to complete. If any `NDB` or `NDBINFO` tables exist, and the server cannot connect to the cluster, it exits with an error message:

```
Failed to Populate DD tables.
```

2. Upgrade the system tables by restarting each individual `mysqld` without the `--upgrade=MINIMAL` option.

3.8 Upgrading MySQL with the MySQL Yum Repository

For supported Yum-based platforms (see [Section 2.5.1, “Installing MySQL on Linux Using the MySQL Yum Repository”](#), for a list), you can perform an in-place upgrade for MySQL (that is, replacing the old version and then running the new version using the old data files) with the MySQL Yum repository.

Notes

- An innovation series, such as MySQL 8.3, is in a separate track than a bugfix series, such as MySQL 8.0. The newest bugfix series is active by default.
- Before performing any update to MySQL, follow carefully the instructions in [Chapter 3, Upgrading MySQL](#). Among other instructions discussed there, it is especially important to back up your database before the update.
- The following instructions assume you have installed MySQL with the MySQL Yum repository or with an RPM package directly downloaded from [MySQL Developer Zone's MySQL Download page](#); if that is not the case, following the instructions in [Replacing a Third-Party Distribution of MySQL Using the MySQL Yum Repository](#).

Selecting a Target Series

By default, the MySQL Yum repository updates MySQL to the latest version in the release track you have chosen during installation (see [Selecting a Release Series](#) for details), which means, for example, a 5.7.x installation is *not* updated to a 8.0.x release automatically. To update to another release series, you must first disable the subrepository for the series that has been selected (by default, or by yourself) and enable the subrepository for your target series. To do that, see the general instructions given in [Selecting a Release Series](#) for editing the subrepository entries in the `/etc/yum.repos.d/mysql-community.repo` file.

As a general rule, to upgrade from one bugfix series to another, go to the next bugfix series rather than skipping a bugfix series. For example, if you are currently running MySQL 5.6 and wish to upgrade to MySQL 8.0, upgrade to MySQL 5.7 first before upgrading to MySQL 8.0. For additional details, see [Section 3.5, “Changes in MySQL 8.3”](#).

- For important information about upgrading from MySQL 5.6 to 5.7, see [Upgrading from MySQL 5.6 to 5.7](#).
- For important information about upgrading from MySQL 5.7 to 8.0, see [Upgrading from MySQL 5.7 to 8.0](#).
- In-place downgrading of MySQL is not supported by the MySQL Yum repository. Follow the instructions in [Chapter 4, Downgrading MySQL](#).

Upgrading MySQL

Upgrade MySQL components using standard yum (or dnf) commands, such as MySQL Server:

```
sudo yum update mysql-server
```

For platforms that are dnf-enabled:

```
sudo dnf upgrade mysql-server
```

Alternatively, you can update MySQL by telling Yum to update everything on your system, which might take considerably more time. For platforms that are not dnf-enabled:

```
sudo yum update
```

For platforms that are dnf-enabled:

```
sudo dnf upgrade
```

Note

The MySQL server always restarts after an update by Yum.

You can also update only a specific component. Use the following command to list all the installed packages for the MySQL components (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
sudo yum list installed | grep "^mysql"
```

After identifying the package name of the component of your choice, update the package with the following command, replacing `package-name` with the name of the package. For platforms that are not dnf-enabled:

```
sudo yum update package-name
```

For dnf-enabled platforms:

```
sudo dnf upgrade package-name
```

Upgrading the Shared Client Libraries

After updating MySQL using the Yum repository, applications compiled with older versions of the shared client libraries should continue to work.

If you recompile applications and dynamically link them with the updated libraries: As typical with new versions of shared libraries where there are differences or additions in symbol versioning between the newer and older libraries (for example, between the newer, standard 8.3 shared client libraries and some older—prior or variant—versions of the shared libraries shipped natively by the Linux distributions' software repositories, or from some other sources), any applications compiled using the updated, newer shared libraries require those updated libraries on systems where the applications are deployed. As expected, if those libraries are not in place, the applications requiring the shared libraries fail. For this reason, be sure to deploy the packages for the shared libraries from MySQL on those systems. To do this, add the MySQL Yum repository to the systems (see [Adding the MySQL Yum Repository](#)) and install the latest shared libraries using the instructions given in [Installing Additional MySQL Products and Components with Yum](#).

3.9 Upgrading MySQL with the MySQL APT Repository

On Debian and Ubuntu platforms, to perform an in-place upgrade of MySQL and its components, use the MySQL APT repository. See [Upgrading MySQL with the MySQL APT Repository](#) in [A Quick Guide to Using the MySQL APT Repository](#).

3.10 Upgrading MySQL with the MySQL SLES Repository

On the SUSE Linux Enterprise Server (SLES) platform, to perform an in-place upgrade of MySQL and its components, use the MySQL SLES repository. See [Upgrading MySQL with the MySQL SLES Repository](#) in [A Quick Guide to Using the MySQL SLES Repository](#).

3.11 Upgrading MySQL on Windows

To upgrade MySQL on Windows, either [download and execute the latest MySQL Server MSI](#) or [use the Windows ZIP archive distribution](#).

Note

Unlike MySQL 8.3, MySQL 8.0 uses MySQL Installer to install and upgrade MySQL Server along with most other MySQL products; but MySQL Installer is not available with MySQL 8.1 and higher. However, the configuration functionality used in MySQL Installer is available as of MySQL 8.1 using [Section 2.3.2, “Configuration: Using MySQL Configurator”](#) that's bundled with both the MSI and Zip archive.

Considering 8.3 is an innovation release, there likely won't be a 8.3 point release to upgrade to. Upgrading beyond MySQL 8.3 involves a new series number, such as 8.1 to 8.2, so it's especially important to always back up your current MySQL installation before performing an upgrade. See [Section 9.2, “Database Backup Methods”](#).

The approach you select depends on how the existing installation was performed. Before proceeding, review [Chapter 3, Upgrading MySQL](#) for additional information on upgrading MySQL that is not specific to Windows.

Upgrading MySQL with MSI

Download and execute the latest MSI. Although upgrading between release series is not directly supported, the "Custom Setup" option allows defining an installation location as otherwise the MSI installs to the standard location, such as `C:\Program Files\MySQL\MySQL Server 8.3\`.

Execute [MySQL Configurator](#) to configure your installation.

Upgrading MySQL Using the Windows ZIP Distribution

To perform an upgrade using the Windows ZIP archive distribution:

1. Download the latest Windows ZIP Archive distribution of MySQL from <https://dev.mysql.com/downloads/>.
2. If the server is running, stop it. If the server is installed as a service, stop the service with the following command from the command prompt:

```
C:\> SC STOP mysqld_service_name
```

Alternatively, use `NET STOP mysqld_service_name`.

If you are not running the MySQL server as a service, use `mysqladmin` to stop it. For example, before upgrading from MySQL 8.2 to 8.3, use `mysqladmin` from MySQL 8.2 as follows:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.2\bin\mysqladmin" -u root shutdown
```

Note

If the MySQL `root` user account has a password, invoke `mysqladmin` with the `-p` option and enter the password when prompted.

3. Extract the ZIP archive. You may either overwrite your existing MySQL installation (usually located at `C:\mysql`), or install it into a different directory, such as `C:\mysql8`. Overwriting the existing installation is recommended.
4. Restart the server. For example, use the `SC START mysqld_service_name` or `NET START mysqld_service_name` command if you run MySQL as a service, or invoke `mysqld` directly otherwise.
5. If you encounter errors, see [Section 2.3.4, “Troubleshooting a Microsoft Windows MySQL Server Installation”](#).

3.12 Upgrading a Docker Installation of MySQL

To upgrade a Docker installation of MySQL, refer to [Upgrading a MySQL Server Container](#).

3.13 Upgrade Troubleshooting

- A schema mismatch in a MySQL 8.2 instance between the `.frm` file of a table and the InnoDB data dictionary can cause an upgrade to MySQL 8.3 to fail. Such mismatches may be due to `.frm` file corruption. To address this issue, dump and restore affected tables before attempting the upgrade again.
- If problems occur, such as that the new `mysqld` server does not start, verify that you do not have an old `my.cnf` file from your previous installation. You can check this with the `--print-defaults` option (for example, `mysqld --print-defaults`). If this command displays anything other than the program name, you have an active `my.cnf` file that affects server or client operation.
- If, after an upgrade, you experience problems with compiled client programs, such as `Commands out of sync` or unexpected core dumps, you probably have used old header or library files when compiling your programs. In this case, check the date for your `mysql.h` file and `libmysqlclient.a` library to verify that they are from the new MySQL distribution. If not, recompile your programs with the new headers and libraries. Recompilation might also be necessary for programs compiled against the shared client library if the library major version number has changed (for example, from `libmysqlclient.so.20` to `libmysqlclient.so.21`).
- If you have created a loadable function with a given name and upgrade MySQL to a version that implements a new built-in function with the same name, the loadable function becomes inaccessible. To correct this, use `DROP FUNCTION` to drop the loadable function, and then use `CREATE FUNCTION` to re-create the loadable function with a different nonconflicting name. The same is true if the new version of MySQL implements a built-in function with the same name as an existing stored function. See [Section 11.2.5, “Function Name Parsing and Resolution”](#), for the rules describing how the server interprets references to different kinds of functions.
- If upgrade to MySQL 8.3 fails due to any of the issues outlined in [Section 3.6, “Preparing Your Installation for Upgrade”](#), the server reverts all changes to the data directory. In this case, remove all redo log files and restart the MySQL 8.2 server on the existing data directory to address the errors. The redo log files (`ib_logfile*`) reside in the MySQL data directory by default. After the errors are fixed, perform a slow shutdown (by setting `innodb_fast_shutdown=0`) before attempting the upgrade again.

3.14 Rebuilding or Repairing Tables or Indexes

This section describes how to rebuild or repair tables or indexes, which may be necessitated by:

- Changes to how MySQL handles data types or character sets. For example, an error in a collation might have been corrected, necessitating a table rebuild to update the indexes for character columns that use the collation.
- Required table repairs or upgrades reported by `CHECK TABLE` or `mysqlcheck`.

Methods for rebuilding a table include:

- [Dump and Reload Method](#)
- [ALTER TABLE Method](#)
- [REPAIR TABLE Method](#)

Dump and Reload Method

If you are rebuilding tables because a different version of MySQL cannot handle them after a binary (in-place) upgrade or downgrade, you must use the dump-and-reload method. Dump the tables *before* upgrading or downgrading using your original version of MySQL. Then reload the tables *after* upgrading or downgrading.

If you use the dump-and-reload method of rebuilding tables only for the purpose of rebuilding indexes, you can perform the dump either before or after upgrading or downgrading. Reloading still must be done afterward.

If you need to rebuild an [InnoDB](#) table because a [CHECK TABLE](#) operation indicates that a table upgrade is required, use [mysqldump](#) to create a dump file and [mysql](#) to reload the file. If the [CHECK TABLE](#) operation indicates that there is a corruption or causes [InnoDB](#) to fail, refer to [Section 17.20.3, “Forcing InnoDB Recovery”](#) for information about using the [innodb_force_recovery](#) option to restart [InnoDB](#). To understand the type of problem that [CHECK TABLE](#) may be encountering, refer to the [InnoDB](#) notes in [Section 15.7.3.2, “CHECK TABLE Statement”](#).

To rebuild a table by dumping and reloading it, use [mysqldump](#) to create a dump file and [mysql](#) to reload the file:

```
mysqldump db_name t1 > dump.sql
mysql db_name < dump.sql
```

To rebuild all the tables in a single database, specify the database name without any following table name:

```
mysqldump db_name > dump.sql
mysql db_name < dump.sql
```

To rebuild all tables in all databases, use the [--all-databases](#) option:

```
mysqldump --all-databases > dump.sql
mysql < dump.sql
```

ALTER TABLE Method

To rebuild a table with [ALTER TABLE](#), use a “null” alteration; that is, an [ALTER TABLE](#) statement that “changes” the table to use the storage engine that it already has. For example, if [t1](#) is an [InnoDB](#) table, use this statement:

```
ALTER TABLE t1 ENGINE = InnoDB;
```

If you are not sure which storage engine to specify in the [ALTER TABLE](#) statement, use [SHOW CREATE TABLE](#) to display the table definition.

REPAIR TABLE Method

The [REPAIR TABLE](#) method is only applicable to [MyISAM](#), [ARCHIVE](#), and [CSV](#) tables.

You can use [REPAIR TABLE](#) if the table checking operation indicates that there is a corruption or that an upgrade is required. For example, to repair a [MyISAM](#) table, use this statement:

```
REPAIR TABLE t1;
```

`mysqlcheck --repair` provides command-line access to the `REPAIR TABLE` statement. This can be a more convenient means of repairing tables because you can use the `--databases` or `--all-databases` option to repair all tables in specific databases or all databases, respectively:

```
mysqlcheck --repair --databases db_name ...
mysqlcheck --repair --all-databases
```

3.15 Copying MySQL Databases to Another Machine

In cases where you need to transfer databases between different architectures, you can use `mysqldump` to create a file containing SQL statements. You can then transfer the file to the other machine and feed it as input to the `mysql` client.

Use `mysqldump --help` to see what options are available.

Note

If GTIDs are in use on the server where you create the dump (`gtid_mode=ON`), by default, `mysqldump` includes the contents of the `gtid_executed` set in the dump to transfer these to the new machine. The results of this can vary depending on the MySQL Server versions involved. Check the description for `mysqldump's --set-gtid-purged` option to find what happens with the versions you are using, and how to change the behavior if the outcome of the default behavior is not suitable for your situation.

The easiest (although not the fastest) way to move a database between two machines is to run the following commands on the machine on which the database is located:

```
mysqladmin -h 'other_hostname' create db_name
mysqldump db_name | mysql -h 'other_hostname' db_name
```

If you want to copy a database from a remote machine over a slow network, you can use these commands:

```
mysqladmin create db_name
mysqldump -h 'other_hostname' --compress db_name | mysql db_name
```

You can also store the dump in a file, transfer the file to the target machine, and then load the file into the database there. For example, you can dump a database to a compressed file on the source machine like this:

```
mysqldump --quick db_name | gzip > db_name.gz
```

Transfer the file containing the database contents to the target machine and run these commands there:

```
mysqladmin create db_name
gunzip < db_name.gz | mysql db_name
```

You can also use `mysqldump` and `mysqlimport` to transfer the database. For large tables, this is much faster than simply using `mysqldump`. In the following commands, `DUMPDIR` represents the full path name of the directory you use to store the output from `mysqldump`.

First, create the directory for the output files and dump the database:

```
mkdir DUMPDIR
mysqldump --tab=DUMPDIR
db_name
```

Then transfer the files in the `DUMPDIR` directory to some corresponding directory on the target machine and load the files into MySQL there:

```
mysqladmin create db_name          # create database
cat DUMPDIR/*.sql | mysql db_name    # create tables in database
mysqlimport db_name
      DUMPDIR/*.txt    # load data into tables
```

Do not forget to copy the `mysql` database because that is where the grant tables are stored. You might have to run commands as the MySQL `root` user on the new machine until you have the `mysql` database in place.

After you import the `mysql` database on the new machine, execute `mysqladmin flush-privileges` so that the server reloads the grant table information.

Chapter 4 Downgrading MySQL

Notes

- Make sure you understand [the release model for MySQL innovation and long-term support \(LTS\) versions](#) before you proceed with a downgrade.
- Monthly Rapid Updates (MRUs) and hotfixes also count as "releases" in the following discussions.
- We use "8.4.x LTS" as an example for an LTS release and "8.3.0" as an example for a bugfix release *only for illustrative purposes*.

The supported downgrade paths for MySQL Server are listed in [Table 4.1, "Downgrade Paths for MySQL Server"](#) below:

Table 4.1 Downgrade Paths for MySQL Server

Downgrade Path	Path Examples	Downgrade Method
Within an LTS or bugfix release series	8.0.36 to 8.0.35 8.4.x+1 LTS to 8.4.x LTS	in-place downgrade MySQL Clone
From an LTS or bugfix release to the last LTS or bugfix release series	8.4.x LTS to 8.0.y	logical downgrade
From an LTS or bugfix release to an innovation release <i>after the last LTS series</i>	8.4.x LTS to 8.3.0	logical downgrade
From an innovation release series to another one <i>after the last LTS series</i>	8.3 to 8.2	logical downgrade

Downgrading to MySQL 5.7 or earlier is not supported.

Chapter 5 Tutorial

5.6.1 The Maximum Value for a Column	237
5.6.2 The Row Holding the Maximum of a Certain Column	237
5.6.3 Maximum of Column per Group	237
5.6.4 The Rows Holding the Group-wise Maximum of a Certain Column	238
5.6.5 Using User-Defined Variables	239
5.6.6 Using Foreign Keys	239
5.6.7 Searching on Two Keys	241
5.6.8 Calculating Visits Per Day	241
5.6.9 Using AUTO_INCREMENT	242
5.7 Using MySQL with Apache	244

This chapter provides a tutorial introduction to MySQL by showing how to use the `mysql` client program to create and use a simple database. `mysql` (sometimes referred to as the “terminal monitor” or just “monitor”) is an interactive program that enables you to connect to a MySQL server, run queries, and view the results. `mysql` may also be used in batch mode: you place your queries in a file beforehand, then tell `mysql` to execute the contents of the file. Both ways of using `mysql` are covered here.

To see a list of options provided by `mysql`, invoke it with the `--help` option:

```
$> mysql --help
```

This chapter assumes that `mysql` is installed on your machine and that a MySQL server is available to which you can connect. If this is not true, contact your MySQL administrator. (If *you* are the administrator, you need to consult the relevant portions of this manual, such as [Chapter 7, MySQL Server Administration](#).)

This chapter describes the entire process of setting up and using a database. If you are interested only in accessing an existing database, you may want to skip the sections that describe how to create the database and the tables it contains.

Because this chapter is tutorial in nature, many details are necessarily omitted. Consult the relevant sections of the manual for more information on the topics covered here.

5.1 Connecting to and Disconnecting from the Server

To connect to the server, you usually need to provide a MySQL user name when you invoke `mysql` and, most likely, a password. If the server runs on a machine other than the one where you log in, you must also specify a host name. Contact your administrator to find out what connection parameters you should use to connect (that is, what host, user name, and password to use). Once you know the proper parameters, you should be able to connect like this:

```
$> mysql -h host -u user -p
Enter password: *****
```

`host` and `user` represent the host name where your MySQL server is running and the user name of your MySQL account. Substitute appropriate values for your setup. The `*****` represents your password; enter it when `mysql` displays the `Enter password:` prompt.

If that works, you should see some introductory information followed by a `mysql>` prompt:

```
$> mysql -h host -u user -p
Enter password: *****
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 25338 to server version: 8.3.0-standard

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

The `mysql>` prompt tells you that `mysql` is ready for you to enter SQL statements.

If you are logging in on the same machine that MySQL is running on, you can omit the host, and simply use the following:

```
$> mysql -u user -p
```

If, when you attempt to log in, you get an error message such as `ERROR 2002 (HY000): Can't connect to local MySQL server through socket '/tmp/mysql.sock' (2)`, it means that the MySQL server daemon (Unix) or service (Windows) is not running. Consult the administrator or see the section of [Chapter 2, Installing MySQL](#) that is appropriate to your operating system.

For help with other problems often encountered when trying to log in, see [Section B.3.2, "Common Errors When Using MySQL Programs"](#).

Some MySQL installations permit users to connect as the anonymous (unnamed) user to the server running on the local host. If this is the case on your machine, you should be able to connect to that server by invoking `mysql` without any options:

```
$> mysql
```

After you have connected successfully, you can disconnect any time by typing `QUIT` (or `\q`) at the `mysql>` prompt:

```
mysql> QUIT
Bye
```

On Unix, you can also disconnect by pressing Control+D.

Most examples in the following sections assume that you are connected to the server. They indicate this by the `mysql>` prompt.

5.2 Entering Queries

Make sure that you are connected to the server, as discussed in the previous section. Doing so does not in itself select any database to work with, but that is okay. At this point, it is more important to find out a little about how to issue queries than to jump right in creating tables, loading data into them, and retrieving data from them. This section describes the basic principles of entering queries, using several queries you can try out to familiarize yourself with how `mysql` works.

Here is a simple query that asks the server to tell you its version number and the current date. Type it in as shown here following the `mysql>` prompt and press Enter:

```
mysql> SELECT VERSION(), CURRENT_DATE;
+-----+-----+
| VERSION() | CURRENT_DATE |
```

```
+-----+-----+
| 5.8.0-m17 | 2015-12-21 |
+-----+-----+
1 row in set (0.02 sec)
mysql>
```

This query illustrates several things about `mysql`:

- A query normally consists of an SQL statement followed by a semicolon. (There are some exceptions where a semicolon may be omitted. `QUIT`, mentioned earlier, is one of them. We'll get to others later.)
- When you issue a query, `mysql` sends it to the server for execution and displays the results, then prints another `mysql>` prompt to indicate that it is ready for another query.
- `mysql` displays query output in tabular form (rows and columns). The first row contains labels for the columns. The rows following are the query results. Normally, column labels are the names of the columns you fetch from database tables. If you're retrieving the value of an expression rather than a table column (as in the example just shown), `mysql` labels the column using the expression itself.
- `mysql` shows how many rows were returned and how long the query took to execute, which gives you a rough idea of server performance. These values are imprecise because they represent wall clock time (not CPU or machine time), and because they are affected by factors such as server load and network latency. (For brevity, the "rows in set" line is sometimes not shown in the remaining examples in this chapter.)

Keywords may be entered in any lettercase. The following queries are equivalent:

```
mysql> SELECT VERSION(), CURRENT_DATE;
mysql> select version(), current_date;
mysql> SeLeCt vErSiOn(), current_DATE;
```

Here is another query. It demonstrates that you can use `mysql` as a simple calculator:

```
mysql> SELECT SIN(PI()/4), (4+1)*5;
+-----+-----+
| SIN(PI()/4) | (4+1)*5 |
+-----+-----+
| 0.70710678118655 | 25 |
+-----+-----+
1 row in set (0.02 sec)
```

The queries shown thus far have been relatively short, single-line statements. You can even enter multiple statements on a single line. Just end each one with a semicolon:

```
mysql> SELECT VERSION(); SELECT NOW();
+-----+
| VERSION() |
+-----+
| 8.0.13 |
+-----+
1 row in set (0.00 sec)

+-----+
| NOW() |
+-----+
| 2018-08-24 00:56:40 |
+-----+
1 row in set (0.00 sec)
```

A query need not be given all on a single line, so lengthy queries that require several lines are not a problem. `mysql` determines where your statement ends by looking for the terminating semicolon, not by looking for the end of the input line. (In other words, `mysql` accepts free-format input: it collects input lines but does not execute them until it sees the semicolon.)

Here is a simple multiple-line statement:

```
mysql> SELECT
-> USER( )
-> ,
-> CURRENT_DATE;
+-----+-----+
| USER( ) | CURRENT_DATE |
+-----+-----+
| jon@localhost | 2018-08-24 |
+-----+-----+
```

In this example, notice how the prompt changes from `mysql>` to `->` after you enter the first line of a multiple-line query. This is how `mysql` indicates that it has not yet seen a complete statement and is waiting for the rest. The prompt is your friend, because it provides valuable feedback. If you use that feedback, you can always be aware of what `mysql` is waiting for.

If you decide you do not want to execute a query that you are in the process of entering, cancel it by typing `\c`:

```
mysql> SELECT
-> USER( )
-> \c
mysql>
```

Here, too, notice the prompt. It switches back to `mysql>` after you type `\c`, providing feedback to indicate that `mysql` is ready for a new query.

The following table shows each of the prompts you may see and summarizes what they mean about the state that `mysql` is in.

Prompt	Meaning
<code>mysql></code>	Ready for new query
<code>-></code>	Waiting for next line of multiple-line query
<code>'></code>	Waiting for next line, waiting for completion of a string that began with a single quote (')
<code>"></code>	Waiting for next line, waiting for completion of a string that began with a double quote (")
<code>`></code>	Waiting for next line, waiting for completion of an identifier that began with a backtick (`)
<code>/*></code>	Waiting for next line, waiting for completion of a comment that began with /*

Multiple-line statements commonly occur by accident when you intend to issue a query on a single line, but forget the terminating semicolon. In this case, `mysql` waits for more input:

```
mysql> SELECT USER()
->
```

If this happens to you (you think you've entered a statement but the only response is a `->` prompt), most likely `mysql` is waiting for the semicolon. If you don't notice what the prompt is telling you, you might sit there for a while before realizing what you need to do. Enter a semicolon to complete the statement, and `mysql` executes it:

```
mysql> SELECT USER()
-> ;
+-----+
| USER( ) |
+-----+
| jon@localhost |
+-----+
```

The `'>` and `">` prompts occur during string collection (another way of saying that MySQL is waiting for completion of a string). In MySQL, you can write strings surrounded by either `'` or `"` characters (for

example, 'hello' or "goodbye"), and `mysql` lets you enter strings that span multiple lines. When you see a `'>` or `">` prompt, it means that you have entered a line containing a string that begins with a ' or " quote character, but have not yet entered the matching quote that terminates the string. This often indicates that you have inadvertently left out a quote character. For example:

```
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;
'>
```

If you enter this `SELECT` statement, then press **Enter** and wait for the result, nothing happens. Instead of wondering why this query takes so long, notice the clue provided by the `'>` prompt. It tells you that `mysql` expects to see the rest of an unterminated string. (Do you see the error in the statement? The string `'Smith` is missing the second single quotation mark.)

At this point, what do you do? The simplest thing is to cancel the query. However, you cannot just type `\c` in this case, because `mysql` interprets it as part of the string that it is collecting. Instead, enter the closing quote character (so `mysql` knows you've finished the string), then type `\c`:

```
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;
'> '"'
mysql>
```

The prompt changes back to `mysql>`, indicating that `mysql` is ready for a new query.

The ``>` prompt is similar to the `'>` and `">` prompts, but indicates that you have begun but not completed a backtick-quoted identifier.

It is important to know what the `'>`, `">`, and ``>` prompts signify, because if you mistakenly enter an unterminated string, any further lines you type appear to be ignored by `mysql`—including a line containing `QUIT`. This can be quite confusing, especially if you do not know that you need to supply the terminating quote before you can cancel the current query.

Note

Multiline statements from this point on are written without the secondary (`->` or other) prompts, to make it easier to copy and paste the statements to try for yourself.

5.3 Creating and Using a Database

Once you know how to enter SQL statements, you are ready to access a database.

Suppose that you have several pets in your home (your menagerie) and you would like to keep track of various types of information about them. You can do so by creating tables to hold your data and loading them with the desired information. Then you can answer different sorts of questions about your animals by retrieving data from the tables. This section shows you how to perform the following operations:

- Create a database
- Create a table
- Load data into the table
- Retrieve data from the table in various ways
- Use multiple tables

The menagerie database is simple (deliberately), but it is not difficult to think of real-world situations in which a similar type of database might be used. For example, a database like this could be used by a farmer to keep track of livestock, or by a veterinarian to keep track of patient records. A menagerie distribution containing some of the queries and sample data used in the following sections can be

obtained from the MySQL website. It is available in both compressed `tar` file and Zip formats at <https://dev.mysql.com/doc/>.

Use the `SHOW` statement to find out what databases currently exist on the server:

```
mysql> SHOW DATABASES;
+-----+
| Database |
+-----+
| mysql    |
| test     |
| tmp      |
+-----+
```

The `mysql` database describes user access privileges. The `test` database often is available as a workspace for users to try things out.

The list of databases displayed by the statement may be different on your machine; `SHOW DATABASES` does not show databases that you have no privileges for if you do not have the `SHOW DATABASES` privilege. See [Section 15.7.7.15, “SHOW DATABASES Statement”](#).

If the `test` database exists, try to access it:

```
mysql> USE test
Database changed
```

`USE`, like `QUIT`, does not require a semicolon. (You can terminate such statements with a semicolon if you like; it does no harm.) The `USE` statement is special in another way, too: it must be given on a single line.

You can use the `test` database (if you have access to it) for the examples that follow, but anything you create in that database can be removed by anyone else with access to it. For this reason, you should probably ask your MySQL administrator for permission to use a database of your own. Suppose that you want to call yours `menagerie`. The administrator needs to execute a statement like this:

```
mysql> GRANT ALL ON menagerie.* TO 'your_mysql_name'@'your_client_host';
```

where `your_mysql_name` is the MySQL user name assigned to you and `your_client_host` is the host from which you connect to the server.

5.3.1 Creating and Selecting a Database

If the administrator creates your database for you when setting up your permissions, you can begin using it. Otherwise, you need to create it yourself:

```
mysql> CREATE DATABASE menagerie;
```

Under Unix, database names are case-sensitive (unlike SQL keywords), so you must always refer to your database as `menagerie`, not as `Menagerie`, `MENAGERIE`, or some other variant. This is also true for table names. (Under Windows, this restriction does not apply, although you must refer to databases and tables using the same lettercase throughout a given query. However, for a variety of reasons, the recommended best practice is always to use the same lettercase that was used when the database was created.)

Note

If you get an error such as `ERROR 1044 (42000): Access denied for user 'micah'@'localhost' to database 'menagerie'` when attempting to create a database, this means that your user account does not have the necessary privileges to do so. Discuss this with the administrator or see [Section 8.2, “Access Control and Account Management”](#).

Creating a database does not select it for use; you must do that explicitly. To make `menagerie` the current database, use this statement:

```
mysql> USE menagerie
Database changed
```

Your database needs to be created only once, but you must select it for use each time you begin a `mysql` session. You can do this by issuing a `USE` statement as shown in the example. Alternatively, you can select the database on the command line when you invoke `mysql`. Just specify its name after any connection parameters that you might need to provide. For example:

```
$> mysql -h host -u user -p menagerie
Enter password: *****
```

Important

`menagerie` in the command just shown is **not** your password. If you want to supply your password on the command line after the `-p` option, you must do so with no intervening space (for example, as `-ppassword`, not as `-p password`). However, putting your password on the command line is not recommended, because doing so exposes it to snooping by other users logged in on your machine.

Note

You can see at any time which database is currently selected using `SELECT DATABASE()`.

5.3.2 Creating a Table

Creating the database is the easy part, but at this point it is empty, as `SHOW TABLES` tells you:

```
mysql> SHOW TABLES;
Empty set (0.00 sec)
```

The harder part is deciding what the structure of your database should be: what tables you need and what columns should be in each of them.

You want a table that contains a record for each of your pets. This can be called the `pet` table, and it should contain, as a bare minimum, each animal's name. Because the name by itself is not very interesting, the table should contain other information. For example, if more than one person in your family keeps pets, you might want to list each animal's owner. You might also want to record some basic descriptive information such as species and sex.

How about age? That might be of interest, but it is not a good thing to store in a database. Age changes as time passes, which means you'd have to update your records often. Instead, it is better to store a fixed value such as date of birth. Then, whenever you need age, you can calculate it as the difference between the current date and the birth date. MySQL provides functions for doing date arithmetic, so this is not difficult. Storing birth date rather than age has other advantages, too:

- You can use the database for tasks such as generating reminders for upcoming pet birthdays. (If you think this type of query is somewhat silly, note that it is the same question you might ask in the context of a business database to identify clients to whom you need to send out birthday greetings in the current week or month, for that computer-assisted personal touch.)
- You can calculate age in relation to dates other than the current date. For example, if you store death date in the database, you can easily calculate how old a pet was when it died.

You can probably think of other types of information that would be useful in the `pet` table, but the ones identified so far are sufficient: name, owner, species, sex, birth, and death.

Use a `CREATE TABLE` statement to specify the layout of your table:

```
mysql> CREATE TABLE pet (name VARCHAR(20), owner VARCHAR(20),
species VARCHAR(20), sex CHAR(1), birth DATE, death DATE);
```

`VARCHAR` is a good choice for the `name`, `owner`, and `species` columns because the column values vary in length. The lengths in those column definitions need not all be the same, and need not be 20. You can normally pick any length from 1 to 65535, whatever seems most reasonable to you. If you make a poor choice and it turns out later that you need a longer field, MySQL provides an `ALTER TABLE` statement.

Several types of values can be chosen to represent sex in animal records, such as `'m'` and `'f'`, or perhaps `'male'` and `'female'`. It is simplest to use the single characters `'m'` and `'f'`.

The use of the `DATE` data type for the `birth` and `death` columns is a fairly obvious choice.

Once you have created a table, `SHOW TABLES` should produce some output:

```
mysql> SHOW TABLES;
+-----+
| Tables in menagerie |
+-----+
| pet                |
+-----+
```

To verify that your table was created the way you expected, use a `DESCRIBE` statement:

```
mysql> DESCRIBE pet;
+-----+-----+-----+-----+-----+-----+
| Field | Type      | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| name  | varchar(20) | YES  |     | NULL    |       |
| owner | varchar(20) | YES  |     | NULL    |       |
| species | varchar(20) | YES  |     | NULL    |       |
| sex   | char(1)     | YES  |     | NULL    |       |
| birth | date        | YES  |     | NULL    |       |
| death | date        | YES  |     | NULL    |       |
+-----+-----+-----+-----+-----+-----+
```

You can use `DESCRIBE` any time, for example, if you forget the names of the columns in your table or what types they have.

For more information about MySQL data types, see [Chapter 13, Data Types](#).

5.3.3 Loading Data into a Table

After creating your table, you need to populate it. The `LOAD DATA` and `INSERT` statements are useful for this.

Suppose that your pet records can be described as shown here. (Observe that MySQL expects dates in `'YYYY-MM-DD'` format; this may differ from what you are used to.)

name	owner	species	sex	birth	death
Fluffy	Harold	cat	f	1993-02-04	
Claws	Gwen	cat	m	1994-03-17	
Buffy	Harold	dog	f	1989-05-13	
Fang	Benny	dog	m	1990-08-27	
Bowser	Diane	dog	m	1979-08-31	1995-07-29
Chirpy	Gwen	bird	f	1998-09-11	
Whistler	Gwen	bird		1997-12-09	
Slim	Benny	snake	m	1996-04-29	

Because you are beginning with an empty table, an easy way to populate it is to create a text file containing a row for each of your animals, then load the contents of the file into the table with a single statement.

You could create a text file `pet.txt` containing one record per line, with values separated by tabs, and given in the order in which the columns were listed in the `CREATE TABLE` statement. For missing values (such as unknown sexes or death dates for animals that are still living), you can use `NULL` values. To represent these in your text file, use `\N` (backslash, capital-N). For example, the record for Whistler the bird would look like this (where the whitespace between values is a single tab character):

Whistler	Gwen	bird	\N	1997-12-09	\N
----------	------	------	----	------------	----

To load the text file `pet.txt` into the `pet` table, use this statement:

```
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet;
```

If you created the file on Windows with an editor that uses `\r\n` as a line terminator, you should use this statement instead:

```
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet
      LINES TERMINATED BY '\r\n';
```

(On an Apple machine running macOS, you would likely want to use `LINES TERMINATED BY '\r'`.)

You can specify the column value separator and end of line marker explicitly in the `LOAD DATA` statement if you wish, but the defaults are tab and linefeed. These are sufficient for the statement to read the file `pet.txt` properly.

If the statement fails, it is likely that your MySQL installation does not have local file capability enabled by default. See [Section 8.1.6, “Security Considerations for LOAD DATA LOCAL”](#), for information on how to change this.

When you want to add new records one at a time, the `INSERT` statement is useful. In its simplest form, you supply values for each column, in the order in which the columns were listed in the `CREATE TABLE` statement. Suppose that Diane gets a new hamster named “Puffball.” You could add a new record using an `INSERT` statement like this:

```
mysql> INSERT INTO pet
      VALUES ('Puffball','Diane','hamster','f','1999-03-30',NULL);
```

String and date values are specified as quoted strings here. Also, with `INSERT`, you can insert `NULL` directly to represent a missing value. You do not use `\N` like you do with `LOAD DATA`.

From this example, you should be able to see that there would be a lot more typing involved to load your records initially using several `INSERT` statements rather than a single `LOAD DATA` statement.

5.3.4 Retrieving Information from a Table

The `SELECT` statement is used to pull information from a table. The general form of the statement is:

```
SELECT what_to_select
FROM which_table
WHERE conditions_to_satisfy;
```

what_to_select indicates what you want to see. This can be a list of columns, or `*` to indicate “all columns.” *which_table* indicates the table from which you want to retrieve data. The `WHERE` clause is optional. If it is present, *conditions_to_satisfy* specifies one or more conditions that rows must satisfy to qualify for retrieval.

5.3.4.1 Selecting All Data

The simplest form of `SELECT` retrieves everything from a table:

```
mysql> SELECT * FROM pet;
+-----+-----+-----+-----+-----+-----+
| name  | owner | species | sex  | birth      | death      |
+-----+-----+-----+-----+-----+-----+
| Whistler | Gwen  | bird    |      | 1997-12-09 |             |
| Puffball | Diane | hamster | f    | 1999-03-30 |             |
```

Fluffy	Harold	cat	f	1993-02-04	NULL
Claws	Gwen	cat	m	1994-03-17	NULL
Buffy	Harold	dog	f	1989-05-13	NULL
Fang	Benny	dog	m	1990-08-27	NULL
Bowser	Diane	dog	m	1979-08-31	1995-07-29
Chirpy	Gwen	bird	f	1998-09-11	NULL
Whistler	Gwen	bird	NULL	1997-12-09	NULL
Slim	Benny	snake	m	1996-04-29	NULL
Puffball	Diane	hamster	f	1999-03-30	NULL

This form of `SELECT` uses `*`, which is shorthand for “select all columns.” This is useful if you want to review your entire table, for example, after you’ve just loaded it with your initial data set. For example, you may happen to think that the birth date for Bowser doesn’t seem quite right. Consulting your original pedigree papers, you find that the correct birth year should be 1989, not 1979.

There are at least two ways to fix this:

- Edit the file `pet.txt` to correct the error, then empty the table and reload it using `DELETE` and `LOAD DATA`:

```
mysql> DELETE FROM pet;
mysql> LOAD DATA LOCAL INFILE 'pet.txt' INTO TABLE pet;
```

However, if you do this, you must also re-enter the record for Puffball.

- Fix only the erroneous record with an `UPDATE` statement:

```
mysql> UPDATE pet SET birth = '1989-08-31' WHERE name = 'Bowser';
```

The `UPDATE` changes only the record in question and does not require you to reload the table.

There is an exception to the principle that `SELECT *` selects all columns. If a table contains invisible columns, `*` does not include them. For more information, see [Section 15.1.20.10, “Invisible Columns”](#).

5.3.4.2 Selecting Particular Rows

As shown in the preceding section, it is easy to retrieve an entire table. Just omit the `WHERE` clause from the `SELECT` statement. But typically you don’t want to see the entire table, particularly when it becomes large. Instead, you’re usually more interested in answering a particular question, in which case you specify some constraints on the information you want. Let’s look at some selection queries in terms of questions about your pets that they answer.

You can select only particular rows from your table. For example, if you want to verify the change that you made to Bowser’s birth date, select Bowser’s record like this:

```
mysql> SELECT * FROM pet WHERE name = 'Bowser';
+-----+-----+-----+-----+-----+-----+
| name | owner | species | sex | birth      | death      |
+-----+-----+-----+-----+-----+-----+
| Bowser | Diane | dog      | m   | 1989-08-31 | 1995-07-29 |
+-----+-----+-----+-----+-----+-----+
```

The output confirms that the year is correctly recorded as 1989, not 1979.

String comparisons normally are case-insensitive, so you can specify the name as `'bowser'`, `'BOWSER'`, and so forth. The query result is the same.

You can specify conditions on any column, not just `name`. For example, if you want to know which animals were born during or after 1998, test the `birth` column:

```
mysql> SELECT * FROM pet WHERE birth >= '1998-1-1';
+-----+-----+-----+-----+-----+-----+
| name | owner | species | sex | birth      | death      |
+-----+-----+-----+-----+-----+-----+
```

Chirpy	Gwen	bird	f	1998-09-11	NULL	
Puffball	Diane	hamster	f	1999-03-30	NULL	

You can combine conditions, for example, to locate female dogs:

```
mysql> SELECT * FROM pet WHERE species = 'dog' AND sex = 'f';
```

name	owner	species	sex	birth	death
Buffy	Harold	dog	f	1989-05-13	NULL

The preceding query uses the `AND` logical operator. There is also an `OR` operator:

```
mysql> SELECT * FROM pet WHERE species = 'snake' OR species = 'bird';
```

name	owner	species	sex	birth	death
Chirpy	Gwen	bird	f	1998-09-11	NULL
Whistler	Gwen	bird	NULL	1997-12-09	NULL
Slim	Benny	snake	m	1996-04-29	NULL

`AND` and `OR` may be intermixed, although `AND` has higher precedence than `OR`. If you use both operators, it is a good idea to use parentheses to indicate explicitly how conditions should be grouped:

```
mysql> SELECT * FROM pet WHERE (species = 'cat' AND sex = 'm')
OR (species = 'dog' AND sex = 'f');
```

name	owner	species	sex	birth	death
Claws	Gwen	cat	m	1994-03-17	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

5.3.4.3 Selecting Particular Columns

If you do not want to see entire rows from your table, just name the columns in which you are interested, separated by commas. For example, if you want to know when your animals were born, select the `name` and `birth` columns:

```
mysql> SELECT name, birth FROM pet;
```

name	birth
Fluffy	1993-02-04
Claws	1994-03-17
Buffy	1989-05-13
Fang	1990-08-27
Bowser	1989-08-31
Chirpy	1998-09-11
Whistler	1997-12-09
Slim	1996-04-29
Puffball	1999-03-30

To find out who owns pets, use this query:

```
mysql> SELECT owner FROM pet;
```

owner
Harold
Gwen
Harold
Benny
Diane
Gwen
Gwen

```
| Benny |
| Diane |
+-----+
```

Notice that the query simply retrieves the `owner` column from each record, and some of them appear more than once. To minimize the output, retrieve each unique output record just once by adding the keyword `DISTINCT`:

```
mysql> SELECT DISTINCT owner FROM pet;
+-----+
| owner |
+-----+
| Benny |
| Diane |
| Gwen  |
| Harold |
+-----+
```

You can use a `WHERE` clause to combine row selection with column selection. For example, to get birth dates for dogs and cats only, use this query:

```
mysql> SELECT name, species, birth FROM pet
      WHERE species = 'dog' OR species = 'cat';
+-----+-----+-----+
| name  | species | birth      |
+-----+-----+-----+
| Fluffy | cat     | 1993-02-04 |
| Claws  | cat     | 1994-03-17 |
| Buffy  | dog     | 1989-05-13 |
| Fang   | dog     | 1990-08-27 |
| Bowser | dog     | 1989-08-31 |
+-----+-----+-----+
```

5.3.4.4 Sorting Rows

You may have noticed in the preceding examples that the result rows are displayed in no particular order. It is often easier to examine query output when the rows are sorted in some meaningful way. To sort a result, use an `ORDER BY` clause.

Here are animal birthdays, sorted by date:

```
mysql> SELECT name, birth FROM pet ORDER BY birth;
+-----+-----+
| name  | birth      |
+-----+-----+
| Buffy  | 1989-05-13 |
| Bowser | 1989-08-31 |
| Fang   | 1990-08-27 |
| Fluffy  | 1993-02-04 |
| Claws  | 1994-03-17 |
| Slim   | 1996-04-29 |
| Whistler | 1997-12-09 |
| Chirpy  | 1998-09-11 |
| Puffball | 1999-03-30 |
+-----+-----+
```

On character type columns, sorting—like all other comparison operations—is normally performed in a case-insensitive fashion. This means that the order is undefined for columns that are identical except for their case. You can force a case-sensitive sort for a column by using `BINARY` like so: `ORDER BY BINARY col_name`.

The default sort order is ascending, with smallest values first. To sort in reverse (descending) order, add the `DESC` keyword to the name of the column you are sorting by:

```
mysql> SELECT name, birth FROM pet ORDER BY birth DESC;
+-----+-----+
| name  | birth      |
+-----+-----+
```

Puffball	1999-03-30
Chirpy	1998-09-11
Whistler	1997-12-09
Slim	1996-04-29
Claws	1994-03-17
Fluffy	1993-02-04
Fang	1990-08-27
Bowser	1989-08-31
Buffy	1989-05-13

You can sort on multiple columns, and you can sort different columns in different directions. For example, to sort by type of animal in ascending order, then by birth date within animal type in descending order (youngest animals first), use the following query:

```
mysql> SELECT name, species, birth FROM pet
        ORDER BY species, birth DESC;
```

name	species	birth
Chirpy	bird	1998-09-11
Whistler	bird	1997-12-09
Claws	cat	1994-03-17
Fluffy	cat	1993-02-04
Fang	dog	1990-08-27
Bowser	dog	1989-08-31
Buffy	dog	1989-05-13
Puffball	hamster	1999-03-30
Slim	snake	1996-04-29

The `DESC` keyword applies only to the column name immediately preceding it (`birth`); it does not affect the `species` column sort order.

5.3.4.5 Date Calculations

MySQL provides several functions that you can use to perform calculations on dates, for example, to calculate ages or extract parts of dates.

To determine how many years old each of your pets is, use the `TIMESTAMPDIFF()` function. Its arguments are the unit in which you want the result expressed, and the two dates for which to take the difference. The following query shows, for each pet, the birth date, the current date, and the age in years. An *alias* (`age`) is used to make the final output column label more meaningful.

```
mysql> SELECT name, birth, CURDATE(),
        TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
        FROM pet;
```

name	birth	CURDATE()	age
Fluffy	1993-02-04	2003-08-19	10
Claws	1994-03-17	2003-08-19	9
Buffy	1989-05-13	2003-08-19	14
Fang	1990-08-27	2003-08-19	12
Bowser	1989-08-31	2003-08-19	13
Chirpy	1998-09-11	2003-08-19	4
Whistler	1997-12-09	2003-08-19	5
Slim	1996-04-29	2003-08-19	7
Puffball	1999-03-30	2003-08-19	4

The query works, but the result could be scanned more easily if the rows were presented in some order. This can be done by adding an `ORDER BY name` clause to sort the output by name:

```
mysql> SELECT name, birth, CURDATE(),
        TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
        FROM pet ORDER BY name;
```

name	birth	CURDATE()	age
Bowser	1989-08-31	2003-08-19	13
Buffy	1989-05-13	2003-08-19	14
Chirpy	1998-09-11	2003-08-19	4
Claws	1994-03-17	2003-08-19	9
Fang	1990-08-27	2003-08-19	12
Fluffy	1993-02-04	2003-08-19	10
Puffball	1999-03-30	2003-08-19	4
Slim	1996-04-29	2003-08-19	7
Whistler	1997-12-09	2003-08-19	5

To sort the output by `age` rather than `name`, just use a different `ORDER BY` clause:

```
mysql> SELECT name, birth, CURDATE(),
        TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
        FROM pet ORDER BY age;
```

name	birth	CURDATE()	age
Chirpy	1998-09-11	2003-08-19	4
Puffball	1999-03-30	2003-08-19	4
Whistler	1997-12-09	2003-08-19	5
Slim	1996-04-29	2003-08-19	7
Claws	1994-03-17	2003-08-19	9
Fluffy	1993-02-04	2003-08-19	10
Fang	1990-08-27	2003-08-19	12
Bowser	1989-08-31	2003-08-19	13
Buffy	1989-05-13	2003-08-19	14

A similar query can be used to determine age at death for animals that have died. You determine which animals these are by checking whether the `death` value is `NULL`. Then, for those with non-`NULL` values, compute the difference between the `death` and `birth` values:

```
mysql> SELECT name, birth, death,
        TIMESTAMPDIFF(YEAR,birth,death) AS age
        FROM pet WHERE death IS NOT NULL ORDER BY age;
```

name	birth	death	age
Bowser	1989-08-31	1995-07-29	5

The query uses `death IS NOT NULL` rather than `death <> NULL` because `NULL` is a special value that cannot be compared using the usual comparison operators. This is discussed later. See [Section 5.3.4.6, “Working with NULL Values”](#).

What if you want to know which animals have birthdays next month? For this type of calculation, year and day are irrelevant; you simply want to extract the month part of the `birth` column. MySQL provides several functions for extracting parts of dates, such as `YEAR()`, `MONTH()`, and `DAYOFMONTH()`. `MONTH()` is the appropriate function here. To see how it works, run a simple query that displays the value of both `birth` and `MONTH(birth)`:

```
mysql> SELECT name, birth, MONTH(birth) FROM pet;
```

name	birth	MONTH(birth)
Fluffy	1993-02-04	2
Claws	1994-03-17	3
Buffy	1989-05-13	5
Fang	1990-08-27	8
Bowser	1989-08-31	8
Chirpy	1998-09-11	9
Whistler	1997-12-09	12
Slim	1996-04-29	4
Puffball	1999-03-30	3

Finding animals with birthdays in the upcoming month is also simple. Suppose that the current month is April. Then the month value is `4` and you can look for animals born in May (month `5`) like this:

```
mysql> SELECT name, birth FROM pet WHERE MONTH(birth) = 5;
+-----+-----+
| name | birth |
+-----+-----+
| Buffy | 1989-05-13 |
+-----+-----+
```

There is a small complication if the current month is December. You cannot merely add one to the month number (`12`) and look for animals born in month `13`, because there is no such month. Instead, you look for animals born in January (month `1`).

You can write the query so that it works no matter what the current month is, so that you do not have to use the number for a particular month. `DATE_ADD()` enables you to add a time interval to a given date. If you add a month to the value of `CURDATE()`, then extract the month part with `MONTH()`, the result produces the month in which to look for birthdays:

```
mysql> SELECT name, birth FROM pet
       WHERE MONTH(birth) = MONTH(DATE_ADD(CURDATE(),INTERVAL 1 MONTH));
```

A different way to accomplish the same task is to add `1` to get the next month after the current one after using the modulo function (`MOD`) to wrap the month value to `0` if it is currently `12`:

```
mysql> SELECT name, birth FROM pet
       WHERE MONTH(birth) = MOD(MONTH(CURDATE()), 12) + 1;
```

`MONTH()` returns a number between `1` and `12`. And `MOD(something,12)` returns a number between `0` and `11`. So the addition has to be after the `MOD()`, otherwise we would go from November (`11`) to January (`1`).

If a calculation uses invalid dates, the calculation fails and produces warnings:

```
mysql> SELECT '2018-10-31' + INTERVAL 1 DAY;
+-----+
| '2018-10-31' + INTERVAL 1 DAY |
+-----+
| 2018-11-01 |
+-----+
mysql> SELECT '2018-10-32' + INTERVAL 1 DAY;
+-----+
| '2018-10-32' + INTERVAL 1 DAY |
+-----+
| NULL |
+-----+
mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Incorrect datetime value: '2018-10-32' |
+-----+-----+-----+
```

5.3.4.6 Working with NULL Values

The `NULL` value can be surprising until you get used to it. Conceptually, `NULL` means “a missing unknown value” and it is treated somewhat differently from other values.

To test for `NULL`, use the `IS NULL` and `IS NOT NULL` operators, as shown here:

```
mysql> SELECT 1 IS NULL, 1 IS NOT NULL;
+-----+-----+
| 1 IS NULL | 1 IS NOT NULL |
+-----+-----+
| 0 | 1 |
+-----+-----+
```

You cannot use arithmetic comparison operators such as `=`, `<`, or `<>` to test for `NULL`. To demonstrate this for yourself, try the following query:

```
mysql> SELECT 1 = NULL, 1 <> NULL, 1 < NULL, 1 > NULL;
+-----+-----+-----+-----+
| 1 = NULL | 1 <> NULL | 1 < NULL | 1 > NULL |
+-----+-----+-----+-----+
|      NULL |      NULL |      NULL |      NULL |
+-----+-----+-----+-----+
```

Because the result of any arithmetic comparison with `NULL` is also `NULL`, you cannot obtain any meaningful results from such comparisons.

In MySQL, `0` or `NULL` means false and anything else means true. The default truth value from a boolean operation is `1`.

This special treatment of `NULL` is why, in the previous section, it was necessary to determine which animals are no longer alive using `death IS NOT NULL` instead of `death <> NULL`.

Two `NULL` values are regarded as equal in a `GROUP BY`.

When doing an `ORDER BY`, `NULL` values are presented first if you do `ORDER BY ... ASC` and last if you do `ORDER BY ... DESC`.

A common error when working with `NULL` is to assume that it is not possible to insert a zero or an empty string into a column defined as `NOT NULL`, but this is not the case. These are in fact values, whereas `NULL` means “not having a value.” You can test this easily enough by using `IS [NOT] NULL` as shown:

```
mysql> SELECT 0 IS NULL, 0 IS NOT NULL, '' IS NULL, '' IS NOT NULL;
+-----+-----+-----+-----+
| 0 IS NULL | 0 IS NOT NULL | '' IS NULL | '' IS NOT NULL |
+-----+-----+-----+-----+
|          0 |          1 |          0 |          1 |
+-----+-----+-----+-----+
```

Thus it is entirely possible to insert a zero or empty string into a `NOT NULL` column, as these are in fact `NOT NULL`. See [Section B.3.4.3, “Problems with NULL Values”](#).

5.3.4.7 Pattern Matching

MySQL provides standard SQL pattern matching as well as a form of pattern matching based on extended regular expressions similar to those used by Unix utilities such as `vi`, `grep`, and `sed`.

SQL pattern matching enables you to use `_` to match any single character and `%` to match an arbitrary number of characters (including zero characters). In MySQL, SQL patterns are case-insensitive by default. Some examples are shown here. Do not use `=` or `<>` when you use SQL patterns. Use the `LIKE` or `NOT LIKE` comparison operators instead.

To find names beginning with `b`:

```
mysql> SELECT * FROM pet WHERE name LIKE 'b%';
+-----+-----+-----+-----+-----+-----+
| name | owner | species | sex | birth | death |
+-----+-----+-----+-----+-----+-----+
| Buffy | Harold | dog | f | 1989-05-13 | NULL |
| Bowser | Diane | dog | m | 1989-08-31 | 1995-07-29 |
+-----+-----+-----+-----+-----+-----+
```

To find names ending with `fy`:

```
mysql> SELECT * FROM pet WHERE name LIKE '%fy';
+-----+-----+-----+-----+-----+-----+
```

name	owner	species	sex	birth	death
Fluffy	Harold	cat	f	1993-02-04	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

To find names containing a `w`:

```
mysql> SELECT * FROM pet WHERE name LIKE '%w%';
```

name	owner	species	sex	birth	death
Claws	Gwen	cat	m	1994-03-17	NULL
Bowser	Diane	dog	m	1989-08-31	1995-07-29
Whistler	Gwen	bird	NULL	1997-12-09	NULL

To find names containing exactly five characters, use five instances of the `_` pattern character:

```
mysql> SELECT * FROM pet WHERE name LIKE '_____';
```

name	owner	species	sex	birth	death
Claws	Gwen	cat	m	1994-03-17	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

The other type of pattern matching provided by MySQL uses extended regular expressions. When you test for a match for this type of pattern, use the `REGEXP_LIKE()` function (or the `REGEXP` or `RLIKE` operators, which are synonyms for `REGEXP_LIKE()`).

The following list describes some characteristics of extended regular expressions:

- `.` matches any single character.
- A character class `[...]` matches any character within the brackets. For example, `[abc]` matches `a`, `b`, or `c`. To name a range of characters, use a dash. `[a-z]` matches any letter, whereas `[0-9]` matches any digit.
- `*` matches zero or more instances of the thing preceding it. For example, `x*` matches any number of `x` characters, `[0-9]*` matches any number of digits, and `.*` matches any number of anything.
- A regular expression pattern match succeeds if the pattern matches anywhere in the value being tested. (This differs from a `LIKE` pattern match, which succeeds only if the pattern matches the entire value.)
- To anchor a pattern so that it must match the beginning or end of the value being tested, use `^` at the beginning or `$` at the end of the pattern.

To demonstrate how extended regular expressions work, the `LIKE` queries shown previously are rewritten here to use `REGEXP_LIKE()`.

To find names beginning with `b`, use `^` to match the beginning of the name:

```
mysql> SELECT * FROM pet WHERE REGEXP_LIKE(name, '^b');
```

name	owner	species	sex	birth	death
Buffy	Harold	dog	f	1989-05-13	NULL
Bowser	Diane	dog	m	1979-08-31	1995-07-29

To force a regular expression comparison to be case-sensitive, use a case-sensitive collation, or use the `BINARY` keyword to make one of the strings a binary string, or specify the `c` match-control character. Each of these queries matches only lowercase `b` at the beginning of a name:

```
SELECT * FROM pet WHERE REGEXP_LIKE(name, '^b' COLLATE utf8mb4_0900_as_cs);
```

```
SELECT * FROM pet WHERE REGEXP_LIKE(name, BINARY '^b');
SELECT * FROM pet WHERE REGEXP_LIKE(name, '^b', 'c');
```

To find names ending with `fy`, use `$` to match the end of the name:

```
mysql> SELECT * FROM pet WHERE REGEXP_LIKE(name, 'fy$');
+-----+-----+-----+-----+-----+-----+
| name   | owner | species | sex | birth      | death |
+-----+-----+-----+-----+-----+-----+
| Fluffy | Harold | cat     | f   | 1993-02-04 | NULL  |
| Buffy  | Harold | dog     | f   | 1989-05-13 | NULL  |
+-----+-----+-----+-----+-----+-----+
```

To find names containing a `w`, use this query:

```
mysql> SELECT * FROM pet WHERE REGEXP_LIKE(name, 'w');
+-----+-----+-----+-----+-----+-----+
| name   | owner | species | sex | birth      | death      |
+-----+-----+-----+-----+-----+-----+
| Claws  | Gwen  | cat     | m   | 1994-03-17 | NULL       |
| Bowser | Diane | dog     | m   | 1989-08-31 | 1995-07-29 |
| Whistler | Gwen | bird    | NULL | 1997-12-09 | NULL       |
+-----+-----+-----+-----+-----+-----+
```

Because a regular expression pattern matches if it occurs anywhere in the value, it is not necessary in the previous query to put a wildcard on either side of the pattern to get it to match the entire value as would be true with an SQL pattern.

To find names containing exactly five characters, use `^` and `$` to match the beginning and end of the name, and five instances of `.` in between:

```
mysql> SELECT * FROM pet WHERE REGEXP_LIKE(name, '^.....$');
+-----+-----+-----+-----+-----+-----+
| name   | owner | species | sex | birth      | death |
+-----+-----+-----+-----+-----+-----+
| Claws  | Gwen  | cat     | m   | 1994-03-17 | NULL   |
| Buffy  | Harold | dog     | f   | 1989-05-13 | NULL   |
+-----+-----+-----+-----+-----+-----+
```

You could also write the previous query using the `{n}` (“repeat-*n*-times”) operator:

```
mysql> SELECT * FROM pet WHERE REGEXP_LIKE(name, '^.{5}$');
+-----+-----+-----+-----+-----+-----+
| name   | owner | species | sex | birth      | death |
+-----+-----+-----+-----+-----+-----+
| Claws  | Gwen  | cat     | m   | 1994-03-17 | NULL   |
| Buffy  | Harold | dog     | f   | 1989-05-13 | NULL   |
+-----+-----+-----+-----+-----+-----+
```

For more information about the syntax for regular expressions, see [Section 14.8.2, “Regular Expressions”](#).

5.3.4.8 Counting Rows

Databases are often used to answer the question, “How often does a certain type of data occur in a table?” For example, you might want to know how many pets you have, or how many pets each owner has, or you might want to perform various kinds of census operations on your animals.

Counting the total number of animals you have is the same question as “How many rows are in the `pet` table?” because there is one record per pet. `COUNT(*)` counts the number of rows, so the query to count your animals looks like this:

```
mysql> SELECT COUNT(*) FROM pet;
+-----+
| COUNT(*) |
+-----+
|          9 |
+-----+
```

```
+-----+
```

Earlier, you retrieved the names of the people who owned pets. You can use `COUNT()` if you want to find out how many pets each owner has:

```
mysql> SELECT owner, COUNT(*) FROM pet GROUP BY owner;
```

```
+-----+-----+
| owner | COUNT(*) |
+-----+-----+
| Benny |        2 |
| Diane |        2 |
| Gwen  |        3 |
| Harold |        2 |
+-----+-----+
```

The preceding query uses `GROUP BY` to group all records for each `owner`. The use of `COUNT()` in conjunction with `GROUP BY` is useful for characterizing your data under various groupings. The following examples show different ways to perform animal census operations.

Number of animals per species:

```
mysql> SELECT species, COUNT(*) FROM pet GROUP BY species;
```

```
+-----+-----+
| species | COUNT(*) |
+-----+-----+
| bird    |        2 |
| cat     |        2 |
| dog     |        3 |
| hamster |        1 |
| snake   |        1 |
+-----+-----+
```

Number of animals per sex:

```
mysql> SELECT sex, COUNT(*) FROM pet GROUP BY sex;
```

```
+-----+-----+
| sex | COUNT(*) |
+-----+-----+
| NULL |        1 |
| f    |        4 |
| m    |        4 |
+-----+-----+
```

(In this output, `NULL` indicates that the sex is unknown.)

Number of animals per combination of species and sex:

```
mysql> SELECT species, sex, COUNT(*) FROM pet GROUP BY species, sex;
```

```
+-----+-----+-----+
| species | sex | COUNT(*) |
+-----+-----+-----+
| bird    | NULL |        1 |
| bird    | f    |        1 |
| cat     | f    |        1 |
| cat     | m    |        1 |
| dog     | f    |        1 |
| dog     | m    |        2 |
| hamster | f    |        1 |
| snake   | m    |        1 |
+-----+-----+-----+
```

You need not retrieve an entire table when you use `COUNT()`. For example, the previous query, when performed just on dogs and cats, looks like this:

```
mysql> SELECT species, sex, COUNT(*) FROM pet
       WHERE species = 'dog' OR species = 'cat'
       GROUP BY species, sex;
```

```
+-----+-----+-----+
| species | sex | COUNT(*) |
+-----+-----+-----+
```

cat	f	1
cat	m	1
dog	f	1
dog	m	2

Or, if you wanted the number of animals per sex only for animals whose sex is known:

```
mysql> SELECT species, sex, COUNT(*) FROM pet
        WHERE sex IS NOT NULL
        GROUP BY species, sex;
```

species	sex	COUNT(*)
bird	f	1
cat	f	1
cat	m	1
dog	f	1
dog	m	2
hamster	f	1
snake	m	1

If you name columns to select in addition to the `COUNT()` value, a `GROUP BY` clause should be present that names those same columns. Otherwise, the following occurs:

- If the `ONLY_FULL_GROUP_BY` SQL mode is enabled, an error occurs:

```
mysql> SET sql_mode = 'ONLY_FULL_GROUP_BY';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT owner, COUNT(*) FROM pet;
ERROR 1140 (42000): In aggregated query without GROUP BY, expression
#1 of SELECT list contains nonaggregated column 'menagerie.pet.owner';
this is incompatible with sql_mode=only_full_group_by
```

- If `ONLY_FULL_GROUP_BY` is not enabled, the query is processed by treating all rows as a single group, but the value selected for each named column is nondeterministic. The server is free to select the value from any row:

```
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT owner, COUNT(*) FROM pet;
+-----+-----+
| owner | COUNT(*) |
+-----+-----+
| Harold |      8 |
+-----+-----+
1 row in set (0.00 sec)
```

See also [Section 14.19.3, “MySQL Handling of GROUP BY”](#). See [Section 14.19.1, “Aggregate Function Descriptions”](#) for information about `COUNT(expr)` behavior and related optimizations.

5.3.4.9 Using More Than one Table

The `pet` table keeps track of which pets you have. If you want to record other information about them, such as events in their lives like visits to the vet or when litters are born, you need another table. What should this table look like? It needs to contain the following information:

- The pet name so that you know which animal each event pertains to.
- A date so that you know when the event occurred.
- A field to describe the event.
- An event type field, if you want to be able to categorize events.

Given these considerations, the `CREATE TABLE` statement for the `event` table might look like this:

```
mysql> CREATE TABLE event (name VARCHAR(20), date DATE,
                             type VARCHAR(15), remark VARCHAR(255));
```

As with the `pet` table, it is easiest to load the initial records by creating a tab-delimited text file containing the following information.

name	date	type	remark
Fluffy	1995-05-15	litter	4 kittens, 3 female, 1 male
Buffy	1993-06-23	litter	5 puppies, 2 female, 3 male
Buffy	1994-06-19	litter	3 puppies, 3 female
Chirpy	1999-03-21	vet	needed beak straightened
Slim	1997-08-03	vet	broken rib
Bowser	1991-10-12	kennel	
Fang	1991-10-12	kennel	
Fang	1998-08-28	birthday	Gave him a new chew toy
Claws	1998-03-17	birthday	Gave him a new flea collar
Whistler	1998-12-09	birthday	First birthday

Load the records like this:

```
mysql> LOAD DATA LOCAL INFILE 'event.txt' INTO TABLE event;
```

Based on what you have learned from the queries that you have run on the `pet` table, you should be able to perform retrievals on the records in the `event` table; the principles are the same. But when is the `event` table by itself insufficient to answer questions you might ask?

Suppose that you want to find out the ages at which each pet had its litters. We saw earlier how to calculate ages from two dates. The litter date of the mother is in the `event` table, but to calculate her age on that date you need her birth date, which is stored in the `pet` table. This means the query requires both tables:

```
mysql> SELECT pet.name,
               TIMESTAMPDIFF(YEAR,birth,date) AS age,
               remark
FROM pet INNER JOIN event
    ON pet.name = event.name
WHERE event.type = 'litter';
```

```
+-----+-----+-----+
| name | age | remark |
+-----+-----+-----+
| Fluffy | 2 | 4 kittens, 3 female, 1 male |
| Buffy | 4 | 5 puppies, 2 female, 3 male |
| Buffy | 5 | 3 puppies, 3 female |
+-----+-----+-----+
```

There are several things to note about this query:

- The `FROM` clause joins two tables because the query needs to pull information from both of them.
- When combining (joining) information from multiple tables, you need to specify how records in one table can be matched to records in the other. This is easy because they both have a `name` column. The query uses an `ON` clause to match up records in the two tables based on the `name` values.

The query uses an `INNER JOIN` to combine the tables. An `INNER JOIN` permits rows from either table to appear in the result if and only if both tables meet the conditions specified in the `ON` clause. In this example, the `ON` clause specifies that the `name` column in the `pet` table must match the `name` column in the `event` table. If a name appears in one table but not the other, the row does not appear in the result because the condition in the `ON` clause fails.

- Because the `name` column occurs in both tables, you must be specific about which table you mean when referring to the column. This is done by prepending the table name to the column name.

You need not have two different tables to perform a join. Sometimes it is useful to join a table to itself, if you want to compare records in a table to other records in that same table. For example, to find breeding pairs among your pets, you can join the `pet` table with itself to produce candidate pairs of live males and females of like species:

```
mysql> SELECT p1.name, p1.sex, p2.name, p2.sex, p1.species
      FROM pet AS p1 INNER JOIN pet AS p2
      ON p1.species = p2.species
      AND p1.sex = 'f' AND p1.death IS NULL
      AND p2.sex = 'm' AND p2.death IS NULL;
```

name	sex	name	sex	species
Fluffy	f	Claws	m	cat
Buffy	f	Fang	m	dog

In this query, we specify aliases for the table name to refer to the columns and keep straight which instance of the table each column reference is associated with.

5.4 Getting Information About Databases and Tables

What if you forget the name of a database or table, or what the structure of a given table is (for example, what its columns are called)? MySQL addresses this problem through several statements that provide information about the databases and tables it supports.

You have previously seen `SHOW DATABASES`, which lists the databases managed by the server. To find out which database is currently selected, use the `DATABASE()` function:

```
mysql> SELECT DATABASE();
```

DATABASE()
menagerie

If you have not yet selected any database, the result is `NULL`.

To find out what tables the default database contains (for example, when you are not sure about the name of a table), use this statement:

```
mysql> SHOW TABLES;
```

Tables_in_menagerie
event
pet

The name of the column in the output produced by this statement is always `Tables_in_db_name`, where `db_name` is the name of the database. See [Section 15.7.7.41, “SHOW TABLES Statement”](#), for more information.

If you want to find out about the structure of a table, the `DESCRIBE` statement is useful; it displays information about each of a table's columns:

```
mysql> DESCRIBE pet;
```

Field	Type	Null	Key	Default	Extra
name	varchar(20)	YES		NULL	
owner	varchar(20)	YES		NULL	
species	varchar(20)	YES		NULL	
sex	char(1)	YES		NULL	
birth	date	YES		NULL	
death	date	YES		NULL	

Field indicates the column name, **Type** is the data type for the column, **NULL** indicates whether the column can contain **NULL** values, **Key** indicates whether the column is indexed, and **Default** specifies the column's default value. **Extra** displays special information about columns: If a column was created with the **AUTO_INCREMENT** option, the value is **auto_increment** rather than empty.

DESC is a short form of **DESCRIBE**. See [Section 15.8.1, “DESCRIBE Statement”](#), for more information.

You can obtain the **CREATE TABLE** statement necessary to create an existing table using the **SHOW CREATE TABLE** statement. See [Section 15.7.7.11, “SHOW CREATE TABLE Statement”](#).

If you have indexes on a table, **SHOW INDEX FROM *tbl_name*** produces information about them. See [Section 15.7.7.23, “SHOW INDEX Statement”](#), for more about this statement.

5.5 Using mysql in Batch Mode

In the previous sections, you used **mysql** interactively to enter statements and view the results. You can also run **mysql** in batch mode. To do this, put the statements you want to run in a file, then tell **mysql** to read its input from the file:

```
$> mysql < batch-file
```

If you are running **mysql** under Windows and have some special characters in the file that cause problems, you can do this:

```
C:\> mysql -e "source batch-file"
```

If you need to specify connection parameters on the command line, the command might look like this:

```
$> mysql -h host -u user -p < batch-file
Enter password: *****
```

When you use **mysql** this way, you are creating a script file, then executing the script.

If you want the script to continue even if some of the statements in it produce errors, you should use the **--force** command-line option.

Why use a script? Here are a few reasons:

- If you run a query repeatedly (say, every day or every week), making it a script enables you to avoid retyping it each time you execute it.
- You can generate new queries from existing ones that are similar by copying and editing script files.
- Batch mode can also be useful while you're developing a query, particularly for multiple-line statements or multiple-statement sequences. If you make a mistake, you don't have to retype everything. Just edit your script to correct the error, then tell **mysql** to execute it again.
- If you have a query that produces a lot of output, you can run the output through a pager rather than watching it scroll off the top of your screen:

```
$> mysql < batch-file | more
```

- You can catch the output in a file for further processing:

```
$> mysql < batch-file > mysql.out
```

- You can distribute your script to other people so that they can also run the statements.
- Some situations do not allow for interactive use, for example, when you run a query from a [cron](#) job. In this case, you must use batch mode.

The default output format is different (more concise) when you run `mysql` in batch mode than when you use it interactively. For example, the output of `SELECT DISTINCT species FROM pet` looks like this when `mysql` is run interactively:

```
+-----+
| species |
+-----+
| bird    |
| cat     |
| dog     |
| hamster |
| snake   |
+-----+
```

In batch mode, the output looks like this instead:

```
species
bird
cat
dog
hamster
snake
```

If you want to get the interactive output format in batch mode, use `mysql -t`. To echo to the output the statements that are executed, use `mysql -v`.

You can also use scripts from the `mysql` prompt by using the `source` command or `\.` command:

```
mysql> source filename;
mysql> \. filename
```

See [Section 6.5.1.5, “Executing SQL Statements from a Text File”](#), for more information.

5.6 Examples of Common Queries

Here are examples of how to solve some common problems with MySQL.

Some of the examples use the table `shop` to hold the price of each article (item number) for certain traders (dealers). Supposing that each trader has a single fixed price per article, then (`article`, `dealer`) is a primary key for the records.

Start the command-line tool `mysql` and select a database:

```
$> mysql your-database-name
```

To create and populate the example table, use these statements:

```
CREATE TABLE shop (
  article INT UNSIGNED DEFAULT '0000' NOT NULL,
  dealer CHAR(20) DEFAULT '' NOT NULL,
  price DECIMAL(16,2) DEFAULT '0.00' NOT NULL,
  PRIMARY KEY(article, dealer));
INSERT INTO shop VALUES
  (1,'A',3.45),(1,'B',3.99),(2,'A',10.99),(3,'B',1.45),
  (3,'C',1.69),(3,'D',1.25),(4,'D',19.95);
```

After issuing the statements, the table should have the following contents:

```
SELECT * FROM shop ORDER BY article;
```

article	dealer	price
1	A	3.45
1	B	3.99
2	A	10.99
3	B	1.45
3	C	1.69
3	D	1.25
4	D	19.95

5.6.1 The Maximum Value for a Column

“What is the highest item number?”

```
SELECT MAX(article) AS article FROM shop;
```

article
4

5.6.2 The Row Holding the Maximum of a Certain Column

Task: Find the number, dealer, and price of the most expensive article.

This is easily done with a subquery:

```
SELECT article, dealer, price
FROM shop
WHERE price=(SELECT MAX(price) FROM shop);
```

article	dealer	price
0004	D	19.95

Another solution is to use a [LEFT JOIN](#), as shown here:

```
SELECT s1.article, s1.dealer, s1.price
FROM shop s1
LEFT JOIN shop s2 ON s1.price < s2.price
WHERE s2.article IS NULL;
```

You can also do this by sorting all rows descending by price and get only the first row using the MySQL-specific [LIMIT](#) clause, like this:

```
SELECT article, dealer, price
FROM shop
ORDER BY price DESC
LIMIT 1;
```

Note

If there were several most expensive articles, each with a price of 19.95, the [LIMIT](#) solution would show only one of them.

5.6.3 Maximum of Column per Group

Task: Find the highest price per article.

```
SELECT article, MAX(price) AS price
```

```
FROM shop
GROUP BY article
ORDER BY article;
```

article	price
0001	3.99
0002	10.99
0003	1.69
0004	19.95

5.6.4 The Rows Holding the Group-wise Maximum of a Certain Column

Task: For each article, find the dealer or dealers with the most expensive price.

This problem can be solved with a subquery like this one:

```
SELECT article, dealer, price
FROM shop s1
WHERE price=(SELECT MAX(s2.price)
              FROM shop s2
              WHERE s1.article = s2.article)
ORDER BY article;
```

article	dealer	price
0001	B	3.99
0002	A	10.99
0003	C	1.69
0004	D	19.95

The preceding example uses a correlated subquery, which can be inefficient (see [Section 15.2.15.7, “Correlated Subqueries”](#)). Other possibilities for solving the problem are to use an uncorrelated subquery in the `FROM` clause, a `LEFT JOIN`, or a common table expression with a window function.

Uncorrelated subquery:

```
SELECT s1.article, dealer, s1.price
FROM shop s1
JOIN (
  SELECT article, MAX(price) AS price
  FROM shop
  GROUP BY article) AS s2
ON s1.article = s2.article AND s1.price = s2.price
ORDER BY article;
```

`LEFT JOIN`:

```
SELECT s1.article, s1.dealer, s1.price
FROM shop s1
LEFT JOIN shop s2 ON s1.article = s2.article AND s1.price < s2.price
WHERE s2.article IS NULL
ORDER BY s1.article;
```

The `LEFT JOIN` works on the basis that when `s1.price` is at its maximum value, there is no `s2.price` with a greater value and thus the corresponding `s2.article` value is `NULL`. See [Section 15.2.13.2, “JOIN Clause”](#).

Common table expression with window function:

```
WITH s1 AS (
  SELECT article, dealer, price,
         RANK() OVER (PARTITION BY article
                      ORDER BY price DESC
                      ) AS `Rank`
```

```

    FROM shop
)
SELECT article, dealer, price
  FROM sl
 WHERE `Rank` = 1
ORDER BY article;

```

5.6.5 Using User-Defined Variables

You can employ MySQL user variables to remember results without having to store them in temporary variables in the client. (See [Section 11.4, “User-Defined Variables”](#).)

For example, to find the articles with the highest and lowest price you can do this:

```

mysql> SELECT @min_price:=MIN(price),@max_price:=MAX(price) FROM shop;
mysql> SELECT * FROM shop WHERE price=@min_price OR price=@max_price;
+-----+-----+-----+
| article | dealer | price |
+-----+-----+-----+
|    0003 | D      |  1.25 |
|    0004 | D      | 19.95 |
+-----+-----+-----+

```

Note

It is also possible to store the name of a database object such as a table or a column in a user variable and then to use this variable in an SQL statement; however, this requires the use of a prepared statement. See [Section 15.5, “Prepared Statements”](#), for more information.

5.6.6 Using Foreign Keys

MySQL supports foreign keys, which permit cross-referencing related data across tables, and foreign key constraints, which help keep the related data consistent.

A foreign key relationship involves a parent table that holds the initial column values, and a child table with column values that reference the parent column values. A foreign key constraint is defined on the child table.

This following example relates `parent` and `child` tables through a single-column foreign key and shows how a foreign key constraint enforces referential integrity.

Create the parent and child tables using the following SQL statements:

```

CREATE TABLE parent (
  id INT NOT NULL,
  PRIMARY KEY (id)
) ENGINE=INNODB;

CREATE TABLE child (
  id INT,
  parent_id INT,
  INDEX par_ind (parent_id),
  FOREIGN KEY (parent_id)
    REFERENCES parent(id)
) ENGINE=INNODB;

```

Insert a row into the parent table, like this:

```
mysql> INSERT INTO parent (id) VALUES ROW(1);
```

Verify that the data was inserted. You can do this simply by selecting all rows from `parent`, as shown here:

```
mysql> TABLE parent;
```

```
+-----+
| id |
+-----+
| 1 |
+-----+
```

Insert a row into the child table using the following SQL statement:

```
mysql> INSERT INTO child (id,parent_id) VALUES ROW(1,1);
```

The insert operation is successful because `parent_id` 1 is present in the parent table.

Insertion of a row into the child table with a `parent_id` value that is not present in the parent table is rejected with an error, as you can see here:

```
mysql> INSERT INTO child (id,parent_id) VALUES ROW(2,2);
ERROR 1452 (23000): Cannot add or update a child row: a foreign key constraint fails
(`test`.`child`, CONSTRAINT `child_ibfk_1` FOREIGN KEY (`parent_id`)
REFERENCES `parent` (`id`))
```

The operation fails because the specified `parent_id` value does not exist in the parent table.

Trying to delete the previously inserted row from the parent table also fails, as shown here:

```
mysql> DELETE FROM parent WHERE id VALUES = 1;
ERROR 1451 (23000): Cannot delete or update a parent row: a foreign key constraint fails
(`test`.`child`, CONSTRAINT `child_ibfk_1` FOREIGN KEY (`parent_id`)
REFERENCES `parent` (`id`))
```

This operation fails because the record in the child table contains the referenced id (`parent_id`) value.

When an operation affects a key value in the parent table that has matching rows in the child table, the result depends on the referential action specified by `ON UPDATE` and `ON DELETE` subclauses of the `FOREIGN KEY` clause. Omitting `ON DELETE` and `ON UPDATE` clauses (as in the current child table definition) is the same as specifying the `RESTRICT` option, which rejects operations that affect a key value in the parent table that has matching rows in the parent table.

To demonstrate `ON DELETE` and `ON UPDATE` referential actions, drop the child table and recreate it to include `ON UPDATE` and `ON DELETE` subclauses with the `CASCADE` option. The `CASCADE` option automatically deletes or updates matching rows in the child table when deleting or updating rows in the parent table.

```
DROP TABLE child;

CREATE TABLE child (
  id INT,
  parent_id INT,
  INDEX par_ind (parent_id),
  FOREIGN KEY (parent_id)
    REFERENCES parent(id)
    ON UPDATE CASCADE
    ON DELETE CASCADE
) ENGINE=INNODB;
```

Insert some rows into the child table using the statement shown here:

```
mysql> INSERT INTO child (id,parent_id) VALUES ROW(1,1), ROW(2,1), ROW(3,1);
```

Verify that the data was inserted, like this:

```
mysql> TABLE child;
+-----+-----+
| id | parent_id |
+-----+-----+
| 1 | 1 |
| 2 | 1 |
| 3 | 1 |
+-----+-----+
```

```
+-----+-----+
```

Update the ID in the parent table, changing it from 1 to 2, using the SQL statement shown here:

```
mysql> UPDATE parent SET id = 2 WHERE id = 1;
```

Verify that the update was successful by selecting all rows from the parent table, as shown here:

```
mysql> TABLE parent;
+-----+
| id |
+-----+
| 2 |
+-----+
```

Verify that the `ON UPDATE CASCADE` referential action updated the child table, like this:

```
mysql> TABLE child;
+-----+-----+
| id | parent_id |
+-----+-----+
| 1 | 2 |
| 2 | 2 |
| 3 | 2 |
+-----+-----+
```

To demonstrate the `ON DELETE CASCADE` referential action, delete records from the parent table where `parent_id = 2`; this deletes all records in the parent table.

```
mysql> DELETE FROM parent WHERE id = 2;
```

Because all records in the child table are associated with `parent_id = 2`, the `ON DELETE CASCADE` referential action removes all records from the child table, as shown here:

```
mysql> TABLE child;
Empty set (0.00 sec)
```

For more information about foreign key constraints, see [Section 15.1.20.5, “FOREIGN KEY Constraints”](#).

5.6.7 Searching on Two Keys

An `OR` using a single key is well optimized, as is the handling of `AND`.

The one tricky case is that of searching on two different keys combined with `OR`:

```
SELECT field1_index, field2_index FROM test_table
WHERE field1_index = '1' OR field2_index = '1'
```

This case is optimized. See [Section 10.2.1.3, “Index Merge Optimization”](#).

You can also solve the problem efficiently by using a `UNION` that combines the output of two separate `SELECT` statements. See [Section 15.2.18, “UNION Clause”](#).

Each `SELECT` searches only one key and can be optimized:

```
SELECT field1_index, field2_index
  FROM test_table WHERE field1_index = '1'
UNION
SELECT field1_index, field2_index
  FROM test_table WHERE field2_index = '1';
```

5.6.8 Calculating Visits Per Day

The following example shows how you can use the bit group functions to calculate the number of days per month a user has visited a Web page.

```
CREATE TABLE t1 (year YEAR, month INT UNSIGNED,
                  day INT UNSIGNED);
INSERT INTO t1 VALUES(2000,1,1),(2000,1,20),(2000,1,30),(2000,2,2),
                      (2000,2,23),(2000,2,23);
```

The example table contains year-month-day values representing visits by users to the page. To determine how many different days in each month these visits occur, use this query:

```
SELECT year,month,BIT_COUNT(BIT_OR(1<<day)) AS days FROM t1
GROUP BY year,month;
```

Which returns:

```
+-----+-----+-----+
| year | month | days |
+-----+-----+-----+
| 2000 |     1 |     3 |
| 2000 |     2 |     2 |
+-----+-----+-----+
```

The query calculates how many different days appear in the table for each year/month combination, with automatic removal of duplicate entries.

5.6.9 Using AUTO_INCREMENT

The [AUTO_INCREMENT](#) attribute can be used to generate a unique identity for new rows:

```
CREATE TABLE animals (
  id MEDIUMINT NOT NULL AUTO_INCREMENT,
  name CHAR(30) NOT NULL,
  PRIMARY KEY (id)
);

INSERT INTO animals (name) VALUES
  ('dog'),('cat'),('penguin'),
  ('lax'),('whale'),('ostrich');

SELECT * FROM animals;
```

Which returns:

```
+-----+-----+
| id | name |
+-----+-----+
| 1 | dog |
| 2 | cat |
| 3 | penguin |
| 4 | lax |
| 5 | whale |
| 6 | ostrich |
+-----+-----+
```

No value was specified for the [AUTO_INCREMENT](#) column, so MySQL assigned sequence numbers automatically. You can also explicitly assign 0 to the column to generate sequence numbers, unless the [NO_AUTO_VALUE_ON_ZERO](#) SQL mode is enabled. For example:

```
INSERT INTO animals (id,name) VALUES(0,'groundhog');
```

If the column is declared [NOT NULL](#), it is also possible to assign [NULL](#) to the column to generate sequence numbers. For example:

```
INSERT INTO animals (id,name) VALUES(NULL,'squirrel');
```

When you insert any other value into an [AUTO_INCREMENT](#) column, the column is set to that value and the sequence is reset so that the next automatically generated value follows sequentially from the largest column value. For example:

```
INSERT INTO animals (id,name) VALUES(100,'rabbit');
```

```
INSERT INTO animals (id,name) VALUES(NULL,'mouse');
SELECT * FROM animals;
```

id	name
1	dog
2	cat
3	penguin
4	lax
5	whale
6	ostrich
7	groundhog
8	squirrel
100	rabbit
101	mouse

Updating an existing `AUTO_INCREMENT` column value also resets the `AUTO_INCREMENT` sequence.

You can retrieve the most recent automatically generated `AUTO_INCREMENT` value with the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function. These functions are connection-specific, so their return values are not affected by another connection which is also performing inserts.

Use the smallest integer data type for the `AUTO_INCREMENT` column that is large enough to hold the maximum sequence value you require. When the column reaches the upper limit of the data type, the next attempt to generate a sequence number fails. Use the `UNSIGNED` attribute if possible to allow a greater range. For example, if you use `TINYINT`, the maximum permissible sequence number is 127. For `TINYINT UNSIGNED`, the maximum is 255. See [Section 13.1.2, “Integer Types \(Exact Value\) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT”](#) for the ranges of all the integer types.

Note

For a multiple-row insert, `LAST_INSERT_ID()` and `mysql_insert_id()` actually return the `AUTO_INCREMENT` key from the *first* of the inserted rows. This enables multiple-row inserts to be reproduced correctly on other servers in a replication setup.

To start with an `AUTO_INCREMENT` value other than 1, set that value with `CREATE TABLE` or `ALTER TABLE`, like this:

```
mysql> ALTER TABLE tbl AUTO_INCREMENT = 100;
```

InnoDB Notes

For information about `AUTO_INCREMENT` usage specific to `InnoDB`, see [Section 17.6.1.6, “AUTO_INCREMENT Handling in InnoDB”](#).

MyISAM Notes

- For `MyISAM` tables, you can specify `AUTO_INCREMENT` on a secondary column in a multiple-column index. In this case, the generated value for the `AUTO_INCREMENT` column is calculated as `MAX(auto_increment_column) + 1 WHERE prefix=given-prefix`. This is useful when you want to put data into ordered groups.

```
CREATE TABLE animals (
  grp ENUM('fish','mammal','bird') NOT NULL,
  id MEDIUMINT NOT NULL AUTO_INCREMENT,
  name CHAR(30) NOT NULL,
  PRIMARY KEY (grp,id)
) ENGINE=MyISAM;

INSERT INTO animals (grp,name) VALUES
  ('mammal','dog'),('mammal','cat'),
  ('bird','penguin'),('fish','lax'),('mammal','whale'),
```

```
('bird','ostrich');

SELECT * FROM animals ORDER BY grp,id;
```

Which returns:

grp	id	name
fish	1	lax
mammal	1	dog
mammal	2	cat
mammal	3	whale
bird	1	penguin
bird	2	ostrich

In this case (when the [AUTO_INCREMENT](#) column is part of a multiple-column index), [AUTO_INCREMENT](#) values are reused if you delete the row with the biggest [AUTO_INCREMENT](#) value in any group. This happens even for [MyISAM](#) tables, for which [AUTO_INCREMENT](#) values normally are not reused.

- If the [AUTO_INCREMENT](#) column is part of multiple indexes, MySQL generates sequence values using the index that begins with the [AUTO_INCREMENT](#) column, if there is one. For example, if the `animals` table contained indexes `PRIMARY KEY (grp, id)` and `INDEX (id)`, MySQL would ignore the `PRIMARY KEY` for generating sequence values. As a result, the table would contain a single sequence, not a sequence per `grp` value.

Further Reading

More information about [AUTO_INCREMENT](#) is available here:

- How to assign the [AUTO_INCREMENT](#) attribute to a column: [Section 15.1.20, “CREATE TABLE Statement”](#), and [Section 15.1.9, “ALTER TABLE Statement”](#).
- How [AUTO_INCREMENT](#) behaves depending on the [NO_AUTO_VALUE_ON_ZERO](#) SQL mode: [Section 7.1.11, “Server SQL Modes”](#).

5.7 Using MySQL with Apache

There are programs that let you authenticate your users from a MySQL database and also let you write your log files into a MySQL table.

You can change the Apache logging format to be easily readable by MySQL by putting the following into the Apache configuration file:

```
LogFormat "%h %Y%m%d%H%M%S"t,%>s,"%b", "%{Content-Type}o", \
          \"%U\", \"%{Referer}i\", \"%{User-Agent}i\""
```

To load a log file in that format into MySQL, you can use a statement something like this:

```
LOAD DATA INFILE '/local/access_log' INTO TABLE tbl_name
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"' ESCAPED BY '\\'
```

The named table should be created to have columns that correspond to those that the `LogFormat` line writes to the log file.

6.7.1 mysql_config — Display Options for Compiling Clients	590
6.7.2 my_print_defaults — Display Options from Option Files	591
6.8 Miscellaneous Programs	593
6.8.1 lz4_decompress — Decompress mysqlpump LZ4-Compressed Output	593
6.8.2 perror — Display MySQL Error Message Information	593
6.8.3 zlib_decompress — Decompress mysqlpump ZLIB-Compressed Output	594
6.9 Environment Variables	594
6.10 Unix Signal Handling in MySQL	597

This chapter provides a brief overview of the MySQL command-line programs provided by Oracle Corporation. It also discusses the general syntax for specifying options when you run these programs. Most programs have options that are specific to their own operation, but the option syntax is similar for all of them. Finally, the chapter provides more detailed descriptions of individual programs, including which options they recognize.

6.1 Overview of MySQL Programs

There are many different programs in a MySQL installation. This section provides a brief overview of them. Later sections provide a more detailed description of each one, with the exception of NDB Cluster programs. Each program's description indicates its invocation syntax and the options that it supports. [Section 25.5, “NDB Cluster Programs”](#), describes programs specific to NDB Cluster.

Most MySQL distributions include all of these programs, except for those programs that are platform-specific. (For example, the server startup scripts are not used on Windows.) The exception is that RPM distributions are more specialized. There is one RPM for the server, another for client programs, and so forth. If you appear to be missing one or more programs, see [Chapter 2, *Installing MySQL*](#), for information on types of distributions and what they contain. It may be that you have a distribution that does not include all programs and you need to install an additional package.

Each MySQL program takes many different options. Most programs provide a `--help` option that you can use to get a description of the program's different options. For example, try `mysql --help`.

You can override default option values for MySQL programs by specifying options on the command line or in an option file. See [Section 6.2, “Using MySQL Programs”](#), for general information on invoking programs and specifying program options.

The MySQL server, `mysqld`, is the main program that does most of the work in a MySQL installation. The server is accompanied by several related scripts that assist you in starting and stopping the server:

- `mysqld`

The SQL daemon (that is, the MySQL server). To use client programs, `mysqld` must be running, because clients gain access to databases by connecting to the server. See [Section 6.3.1, “mysqld — The MySQL Server”](#).

- `mysqld_safe`

A server startup script. `mysqld_safe` attempts to start `mysqld`. See [Section 6.3.2, “mysqld_safe — MySQL Server Startup Script”](#).

- `mysql.server`

A server startup script. This script is used on systems that use System V-style run directories containing scripts that start system services for particular run levels. It invokes `mysqld_safe` to start the MySQL server. See [Section 6.3.3, “mysql.server — MySQL Server Startup Script”](#).

- `mysqld_multi`

A server startup script that can start or stop multiple servers installed on the system. See [Section 6.3.4, “mysqld_multi — Manage Multiple MySQL Servers”](#).

Several programs perform setup operations during MySQL installation or upgrading:

- `comp_err`

This program is used during the MySQL build/installation process. It compiles error message files from the error source files. See [Section 6.4.1, “comp_err — Compile MySQL Error Message File”](#).

- `mysql_secure_installation`

This program enables you to improve the security of your MySQL installation. See [Section 6.4.2, “mysql_secure_installation — Improve MySQL Installation Security”](#).

- `mysql_ssl_rsa_setup`

**Note**

`mysql_ssl_rsa_setup` is deprecated.

This program creates the SSL certificate and key files and RSA key-pair files required to support secure connections, if those files are missing. Files created by `mysql_ssl_rsa_setup` can be used for secure connections using SSL or RSA. See [Section 6.4.3, “mysql_ssl_rsa_setup — Create SSL/RSA Files”](#).

- `mysql_tzinfo_to_sql`

This program loads the time zone tables in the `mysql` database using the contents of the host system `zoneinfo` database (the set of files describing time zones). See [Section 6.4.4, “mysql_tzinfo_to_sql — Load the Time Zone Tables”](#).

- `mysql_upgrade`

The MySQL server performs the upgrade tasks previously handled by `mysql_upgrade` (for details, see [Section 3.4, “What the MySQL Upgrade Process Upgrades”](#)).

MySQL client programs that connect to the MySQL server:

- `mysql`

The command-line tool for interactively entering SQL statements or executing them from a file in batch mode. See [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#).

- `mysqladmin`

A client that performs administrative operations, such as creating or dropping databases, reloading the grant tables, flushing tables to disk, and reopening log files. `mysqladmin` can also be used to retrieve version, process, and status information from the server. See [Section 6.5.2, “mysqladmin — A MySQL Server Administration Program”](#).

- `mysqlcheck`

A table-maintenance client that checks, repairs, analyzes, and optimizes tables. See [Section 6.5.3, “mysqlcheck — A Table Maintenance Program”](#).

- `mysqldump`

A client that dumps a MySQL database into a file as SQL, text, or XML. See [Section 6.5.4, “mysqldump — A Database Backup Program”](#).

- `mysqlimport`

A client that imports text files into their respective tables using `LOAD DATA`. See [Section 6.5.5, “mysqlimport — A Data Import Program”](#).

- `mysqlpump`

A client that dumps a MySQL database into a file as SQL. See [Section 6.5.6, “mysqlpump — A Database Backup Program”](#).

- `mysqlsh`

MySQL Shell is an advanced client and code editor for MySQL Server. See [MySQL Shell 8.2](#). In addition to the provided SQL functionality, similar to `mysql`, MySQL Shell provides scripting capabilities for JavaScript and Python and includes APIs for working with MySQL. X DevAPI enables you to work with both relational and document data, see [Chapter 22, Using MySQL as a Document Store](#). AdminAPI enables you to work with InnoDB Cluster, see [MySQL AdminAPI](#).

- `mysqlshow`

A client that displays information about databases, tables, columns, and indexes. See [Section 6.5.7, “mysqlshow — Display Database, Table, and Column Information”](#).

- `mysqlslap`

A client that is designed to emulate client load for a MySQL server and report the timing of each stage. It works as if multiple clients are accessing the server. See [Section 6.5.8, “mysqlslap — A Load Emulation Client”](#).

MySQL administrative and utility programs:

- `innochecksum`

An offline InnoDB offline file checksum utility. See [Section 6.6.2, “innochecksum — Offline InnoDB File Checksum Utility”](#).

- `myisam_ftdump`

A utility that displays information about full-text indexes in MyISAM tables. See [Section 6.6.3, “myisam_ftdump — Display Full-Text Index information”](#).

- `myisamchk`

A utility to describe, check, optimize, and repair MyISAM tables. See [Section 6.6.4, “myisamchk — MyISAM Table-Maintenance Utility”](#).

- `myisamlog`

A utility that processes the contents of a MyISAM log file. See [Section 6.6.5, “myisamlog — Display MyISAM Log File Contents”](#).

- `myisampack`

A utility that compresses MyISAM tables to produce smaller read-only tables. See [Section 6.6.6, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#).

- `mysql_config_editor`

A utility that enables you to store authentication credentials in a secure, encrypted login path file named `.mylogin.cnf`. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

- `mysql_migrate_keyring`

A utility for migrating keys between one keyring component and another. See [Section 6.6.8, “mysql_migrate_keyring — Keyring Key Migration Utility”](#).

- `mysqlbinlog`

A utility for reading statements from a binary log. The log of executed statements contained in the binary log files can be used to help recover from a crash. See [Section 6.6.9, “mysqlbinlog — Utility for Processing Binary Log Files”](#).

- `mysqldumpslow`

A utility to read and summarize the contents of a slow query log. See [Section 6.6.10](#), “[mysqldumpslow — Summarize Slow Query Log Files](#)”.

MySQL program-development utilities:

- `mysql_config`

A shell script that produces the option values needed when compiling MySQL programs. See [Section 6.7.1](#), “[mysql_config — Display Options for Compiling Clients](#)”.

- `my_print_defaults`

A utility that shows which options are present in option groups of option files. See [Section 6.7.2](#), “[my_print_defaults — Display Options from Option Files](#)”.

Miscellaneous utilities:

- `lz4_decompress`

A utility that decompresses `mysqlpump` output that was created using LZ4 compression. See [Section 6.8.1](#), “[lz4_decompress — Decompress mysqlpump LZ4-Compressed Output](#)”.

- `perror`

A utility that displays the meaning of system or MySQL error codes. See [Section 6.8.2](#), “[perror — Display MySQL Error Message Information](#)”.

- `zlib_decompress`

A utility that decompresses `mysqlpump` output that was created using ZLIB compression. See [Section 6.8.3](#), “[zlib_decompress — Decompress mysqlpump ZLIB-Compressed Output](#)”.

Oracle Corporation also provides the [MySQL Workbench](#) GUI tool, which is used to administer MySQL servers and databases, to create, execute, and evaluate queries, and to migrate schemas and data from other relational database management systems for use with MySQL.

MySQL client programs that communicate with the server using the MySQL client/server library use the following environment variables.

Environment Variable	Meaning
<code>MYSQL_UNIX_PORT</code>	The default Unix socket file; used for connections to <code>localhost</code>
<code>MYSQL_TCP_PORT</code>	The default port number; used for TCP/IP connections
<code>MYSQL_DEBUG</code>	Debug trace options when debugging
<code>TMPDIR</code>	The directory where temporary tables and files are created

For a full list of environment variables used by MySQL programs, see [Section 6.9](#), “[Environment Variables](#)”.

6.2 Using MySQL Programs

6.2.1 Invoking MySQL Programs

To invoke a MySQL program from the command line (that is, from your shell or command prompt), enter the program name followed by any options or other arguments needed to instruct the program what you want it to do. The following commands show some sample program invocations. `$>` represents the prompt for your command interpreter; it is not part of what you type. The particular

prompt you see depends on your command interpreter. Typical prompts are `$` for `sh`, `ksh`, or `bash`, `%` for `csh` or `tcsh`, and `C:\>` for the Windows `command.com` or `cmd.exe` command interpreters.

```
$> mysql --user=root test
$> mysqladmin extended-status variables
$> mysqlshow --help
$> mysqldump -u root personnel
```

Arguments that begin with a single or double dash (`-`, `--`) specify program options. Options typically indicate the type of connection a program should make to the server or affect its operational mode. Option syntax is described in [Section 6.2.2, “Specifying Program Options”](#).

Nonoption arguments (arguments with no leading dash) provide additional information to the program. For example, the `mysql` program interprets the first nonoption argument as a database name, so the command `mysql --user=root test` indicates that you want to use the `test` database.

Later sections that describe individual programs indicate which options a program supports and describe the meaning of any additional nonoption arguments.

Some options are common to a number of programs. The most frequently used of these are the `--host` (or `-h`), `--user` (or `-u`), and `--password` (or `-p`) options that specify connection parameters. They indicate the host where the MySQL server is running, and the user name and password of your MySQL account. All MySQL client programs understand these options; they enable you to specify which server to connect to and the account to use on that server. Other connection options are `--port` (or `-P`) to specify a TCP/IP port number and `--socket` (or `-S`) to specify a Unix socket file on Unix (or named-pipe name on Windows). For more information on options that specify connection options, see [Section 6.2.4, “Connecting to the MySQL Server Using Command Options”](#).

You may find it necessary to invoke MySQL programs using the path name to the `bin` directory in which they are installed. This is likely to be the case if you get a “program not found” error whenever you attempt to run a MySQL program from any directory other than the `bin` directory. To make it more convenient to use MySQL, you can add the path name of the `bin` directory to your `PATH` environment variable setting. That enables you to run a program by typing only its name, not its entire path name. For example, if `mysql` is installed in `/usr/local/mysql/bin`, you can run the program by invoking it as `mysql`, and it is not necessary to invoke it as `/usr/local/mysql/bin/mysql`.

Consult the documentation for your command interpreter for instructions on setting your `PATH` variable. The syntax for setting environment variables is interpreter-specific. (Some information is given in [Section 6.2.9, “Setting Environment Variables”](#).) After modifying your `PATH` setting, open a new console window on Windows or log in again on Unix so that the setting goes into effect.

6.2.2 Specifying Program Options

There are several ways to specify options for MySQL programs:

- List the options on the command line following the program name. This is common for options that apply to a specific invocation of the program.
- List the options in an option file that the program reads when it starts. This is common for options that you want the program to use each time it runs.
- List the options in environment variables (see [Section 6.2.9, “Setting Environment Variables”](#)). This method is useful for options that you want to apply each time the program runs. In practice, option files are used more commonly for this purpose, but [Section 7.8.3, “Running Multiple MySQL Instances on Unix”](#), discusses one situation in which environment variables can be very helpful. It describes a handy technique that uses such variables to specify the TCP/IP port number and Unix socket file for the server and for client programs.

Options are processed in order, so if an option is specified multiple times, the last occurrence takes precedence. The following command causes `mysql` to connect to the server running on `localhost`:

```
mysql -h example.com -h localhost
```

There is one exception: For `mysqld`, the *first* instance of the `--user` option is used as a security precaution, to prevent a user specified in an option file from being overridden on the command line.

If conflicting or related options are given, later options take precedence over earlier options. The following command runs `mysql` in “no column names” mode:

```
mysql --column-names --skip-column-names
```

MySQL programs determine which options are given first by examining environment variables, then by processing option files, and then by checking the command line. Because later options take precedence over earlier ones, the processing order means that environment variables have the lowest precedence and command-line options the highest.

For the server, one exception applies: The `mysqld-auto.cnf` option file in the data directory is processed last, so it takes precedence even over command-line options.

You can take advantage of the way that MySQL programs process options by specifying default option values for a program in an option file. That enables you to avoid typing them each time you run the program while enabling you to override the defaults if necessary by using command-line options.

6.2.2.1 Using Options on the Command Line

Program options specified on the command line follow these rules:

- Options are given after the command name.
- An option argument begins with one dash or two dashes, depending on whether it is a short form or long form of the option name. Many options have both short and long forms. For example, `-?` and `--help` are the short and long forms of the option that instructs a MySQL program to display its help message.
- Option names are case-sensitive. `-v` and `-V` are both legal and have different meanings. (They are the corresponding short forms of the `--verbose` and `--version` options.)
- Some options take a value following the option name. For example, `-h localhost` or `--host=localhost` indicate the MySQL server host to a client program. The option value tells the program the name of the host where the MySQL server is running.
- For a long option that takes a value, separate the option name and the value by an `=` sign. For a short option that takes a value, the option value can immediately follow the option letter, or there can be a space between: `-hlocalhost` and `-h localhost` are equivalent. An exception to this rule is the option for specifying your MySQL password. This option can be given in long form as `--password=pass_val` or as `--password`. In the latter case (with no password value given), the program interactively prompts you for the password. The password option also may be given in short form as `-ppass_val` or as `-p`. However, for the short form, if the password value is given, it must follow the option letter with *no intervening space*: If a space follows the option letter, the program has no way to tell whether a following argument is supposed to be the password value or some other kind of argument. Consequently, the following two commands have two completely different meanings:

```
mysql -ptest
mysql -p test
```

The first command instructs `mysql` to use a password value of `test`, but specifies no default database. The second instructs `mysql` to prompt for the password value and to use `test` as the default database.

- Within option names, dash (`-`) and underscore (`_`) may be used interchangeably in most cases, although the leading dashes *cannot* be given as underscores. For example, `--skip-grant-tables` and `--skip_grant_tables` are equivalent.

In this Manual, we use dashes in option names, except where underscores are significant. This is the case with, for example, `--log-bin` and `--log_bin`, which are different options. We encourage you to do so as well.

- The MySQL server has certain command options that may be specified only at startup, and a set of system variables, some of which may be set at startup, at runtime, or both. System variable names use underscores rather than dashes, and when referenced at runtime (for example, using `SET` or `SELECT` statements), must be written using underscores:

```
SET GLOBAL general_log = ON;
SELECT @@GLOBAL.general_log;
```

At server startup, the syntax for system variables is the same as for command options, so within variable names, dashes and underscores may be used interchangeably. For example, `--general_log=ON` and `--general-log=ON` are equivalent. (This is also true for system variables set within option files.)

- For options that take a numeric value, the value can be given with a suffix of `K`, `M`, or `G` to indicate a multiplier of 1024 , 1024^2 or 1024^3 . As of MySQL 8.0.14, a suffix can also be `T`, `P`, and `E` to indicate a multiplier of 1024^4 , 1024^5 or 1024^6 . Suffix letters can be uppercase or lowercase.

For example, the following command tells `mysqladmin` to ping the server 1024 times, sleeping 10 seconds between each ping:

```
mysqladmin --count=1K --sleep=10 ping
```

- When specifying file names as option values, avoid the use of the `~` shell metacharacter. It might not be interpreted as you expect.

Option values that contain spaces must be quoted when given on the command line. For example, the `--execute` (or `-e`) option can be used with `mysql` to pass one or more semicolon-separated SQL statements to the server. When this option is used, `mysql` executes the statements in the option value and exits. The statements must be enclosed by quotation marks. For example:

```
$> mysql -u root -p -e "SELECT VERSION();SELECT NOW()"
Enter password: *****
+-----+
| VERSION() |
+-----+
| 8.0.19    |
+-----+
+-----+
| NOW()     |
+-----+
| 2019-09-03 10:36:48 |
+-----+
$>
```

Note

The long form (`--execute`) is followed by an equal sign (=).

To use quoted values within a statement, you must either escape the inner quotation marks, or use a different type of quotation marks within the statement from those used to quote the statement itself. The capabilities of your command processor dictate your choices for whether you can use single or double quotation marks and the syntax for escaping quote characters. For example, if your command processor supports quoting with single or double quotation marks, you can use double quotation marks around the statement, and single quotation marks for any quoted values within the statement.

6.2.2.2 Using Option Files

Most MySQL programs can read startup options from option files (sometimes called configuration files). Option files provide a convenient way to specify commonly used options so that they need not be entered on the command line each time you run a program.

To determine whether a program reads option files, invoke it with the `--help` option. (For `mysqld`, use `--verbose` and `--help`.) If the program reads option files, the help message indicates which files it looks for and which option groups it recognizes.

Note

A MySQL program started with the `--no-defaults` option reads no option files other than `.mylogin.cnf`.

A server started with the `persisted_globals_load` system variable disabled does not read `mysqld-auto.cnf`.

Many option files are plain text files, created using any text editor. The exceptions are:

- The `.mylogin.cnf` file that contains login path options. This is an encrypted file created by the `mysql_config_editor` utility. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#). A “login path” is an option group that permits only certain options: `host`, `user`, `password`, `port` and `socket`. Client programs specify which login path to read from `.mylogin.cnf` using the `--login-path` option.

To specify an alternative login path file name, set the `MYSQLE_TEST_LOGIN_FILE` environment variable. This variable is used by the `mysql-test-run.pl` testing utility, but also is recognized by `mysql_config_editor` and by MySQL clients such as `mysql`, `mysqladmin`, and so forth.

- The `mysqld-auto.cnf` file in the data directory. This JSON-format file contains persisted system variable settings. It is created by the server upon execution of `SET PERSIST` or `SET PERSIST_ONLY` statements. See [Section 7.1.9.3, “Persisted System Variables”](#). Management of `mysqld-auto.cnf` should be left to the server and not performed manually.

- [Option File Processing Order](#)
- [Option File Syntax](#)
- [Option File Inclusions](#)

Option File Processing Order

MySQL looks for option files in the order described in the following discussion and reads any that exist. If an option file you want to use does not exist, create it using the appropriate method, as just discussed.

Note

For information about option files used with NDB Cluster programs, see [Section 25.4, “Configuration of NDB Cluster”](#).

On Windows, MySQL programs read startup options from the files shown in the following table, in the specified order (files listed first are read first, files read later take precedence).

Table 6.1 Option Files Read on Windows Systems

File Name	Purpose
<code>%WINDIR%\my.ini</code> , <code>%WINDIR%\my.cnf</code>	Global options
<code>C:\my.ini</code> , <code>C:\my.cnf</code>	Global options
<code>BASEDIR\my.ini</code> , <code>BASEDIR\my.cnf</code>	Global options

File Name	Purpose
<code>defaults-extra-file</code>	The file specified with <code>--defaults-extra-file</code> , if any
<code>%APPDATA%\MySQL\mylogin.cnf</code>	Login path options (clients only)
<code>DATADIR\mysqld-auto.cnf</code>	System variables persisted with <code>SET PERSIST</code> or <code>SET PERSIST_ONLY</code> (server only)

In the preceding table, `%WINDIR%` represents the location of your Windows directory. This is commonly `C:\WINDOWS`. Use the following command to determine its exact location from the value of the `WINDIR` environment variable:

```
C:\> echo %WINDIR%
```

`%APPDATA%` represents the value of the Windows application data directory. Use the following command to determine its exact location from the value of the `APPDATA` environment variable:

```
C:\> echo %APPDATA%
```

`BASEDIR` represents the MySQL base installation directory. When MySQL 8.3 has been installed using the MSI, this is typically `C:\PROGRAMDIR\MySQL\MySQL Server 8.3` in which `PROGRAMDIR` represents the programs directory (usually `Program Files` for English-language versions of Windows).

Important

Although MySQL Configurator places most files under `PROGRAMDIR`, it installs `my.ini` under the `C:\ProgramData\MySQL\MySQL Server 8.3\` directory by default.

`DATADIR` represents the MySQL data directory. As used to find `mysqld-auto.cnf`, its default value is the data directory location built in when MySQL was compiled, but can be changed by `--datadir` specified as an option-file or command-line option processed before `mysqld-auto.cnf` is processed.

On Unix and Unix-like systems, MySQL programs read startup options from the files shown in the following table, in the specified order (files listed first are read first, files read later take precedence).

Note

On Unix platforms, MySQL ignores configuration files that are world-writable. This is intentional as a security measure.

Table 6.2 Option Files Read on Unix and Unix-Like Systems

File Name	Purpose
<code>/etc/my.cnf</code>	Global options
<code>/etc/mysql/my.cnf</code>	Global options
<code>SYSCONFDIR/my.cnf</code>	Global options
<code>\$MYSQL_HOME/my.cnf</code>	Server-specific options (server only)
<code>defaults-extra-file</code>	The file specified with <code>--defaults-extra-file</code> , if any
<code>~/.my.cnf</code>	User-specific options
<code>~/.mylogin.cnf</code>	User-specific login path options (clients only)
<code>DATADIR/mysqld-auto.cnf</code>	System variables persisted with <code>SET PERSIST</code> or <code>SET PERSIST_ONLY</code> (server only)

In the preceding table, `~` represents the current user's home directory (the value of `$HOME`).

`SYSCONFDIR` represents the directory specified with the `SYSCONFDIR` option to `CMake` when MySQL was built. By default, this is the `etc` directory located under the compiled-in installation directory.

`MYSQL_HOME` is an environment variable containing the path to the directory in which the server-specific `my.cnf` file resides. If `MYSQL_HOME` is not set and you start the server using the `mysqld_safe` program, `mysqld_safe` sets it to `BASEDIR`, the MySQL base installation directory.

`DATADIR` represents the MySQL data directory. As used to find `mysqld-auto.cnf`, its default value is the data directory location built in when MySQL was compiled, but can be changed by `--datadir` specified as an option-file or command-line option processed before `mysqld-auto.cnf` is processed.

If multiple instances of a given option are found, the last instance takes precedence, with one exception: For `mysqld`, the *first* instance of the `--user` option is used as a security precaution, to prevent a user specified in an option file from being overridden on the command line.

Option File Syntax

The following description of option file syntax applies to files that you edit manually. This excludes `.mylogin.cnf`, which is created using `mysql_config_editor` and is encrypted, and `mysqld-auto.cnf`, which the server creates in JSON format.

Any long option that may be given on the command line when running a MySQL program can be given in an option file as well. To get the list of available options for a program, run it with the `--help` option. (For `mysqld`, use `--verbose` and `--help`.)

The syntax for specifying options in an option file is similar to command-line syntax (see [Section 6.2.2.1, “Using Options on the Command Line”](#)). However, in an option file, you omit the leading two dashes from the option name and you specify only one option per line. For example, `--quick` and `--host=localhost` on the command line should be specified as `quick` and `host=localhost` on separate lines in an option file. To specify an option of the form `--loose-opt_name` in an option file, write it as `loose-opt_name`.

Empty lines in option files are ignored. Nonempty lines can take any of the following forms:

- `#comment, ;comment`

Comment lines start with `#` or `;`. A `#` comment can start in the middle of a line as well.

- `[group]`

`group` is the name of the program or group for which you want to set options. After a group line, any option-setting lines apply to the named group until the end of the option file or another group line is given. Option group names are not case-sensitive.

- `opt_name`

This is equivalent to `--opt_name` on the command line.

- `opt_name=value`

This is equivalent to `--opt_name=value` on the command line. In an option file, you can have spaces around the `=` character, something that is not true on the command line. The value optionally can be enclosed within single quotation marks or double quotation marks, which is useful if the value contains a `#` comment character.

Leading and trailing spaces are automatically deleted from option names and values.

You can use the escape sequences `\b`, `\t`, `\n`, `\r`, `\\`, and `\s` in option values to represent the backspace, tab, newline, carriage return, backslash, and space characters. In option files, these escaping rules apply:

- A backslash followed by a valid escape sequence character is converted to the character represented by the sequence. For example, `\s` is converted to a space.

- A backslash not followed by a valid escape sequence character remains unchanged. For example, `\S` is retained as is.

The preceding rules mean that a literal backslash can be given as `\\`, or as `\` if it is not followed by a valid escape sequence character.

The rules for escape sequences in option files differ slightly from the rules for escape sequences in string literals in SQL statements. In the latter context, if “`x`” is not a valid escape sequence character, `\x` becomes “`x`” rather than `\x`. See [Section 11.1.1, “String Literals”](#).

The escaping rules for option file values are especially pertinent for Windows path names, which use `\` as a path name separator. A separator in a Windows path name must be written as `\\` if it is followed by an escape sequence character. It can be written as `\` or `\` if it is not. Alternatively, `/` may be used in Windows path names and is treated as `\`. Suppose that you want to specify a base directory of `C:\Program Files\MySQL\MySQL Server 8.3` in an option file. This can be done several ways. Some examples:

```
basedir="C:\Program Files\MySQL\MySQL Server 8.3"
basedir="C:\\Program Files\\MySQL\\MySQL Server 8.3"
basedir="C:/Program Files/MySQL/MySQL Server 8.3"
basedir=C:\\Program\\sFiles\\MySQL\\MySQL\\sServer\\s8.3
```

If an option group name is the same as a program name, options in the group apply specifically to that program. For example, the `[mysqld]` and `[mysql]` groups apply to the `mysqld` server and the `mysql` client program, respectively.

The `[client]` option group is read by all client programs provided in MySQL distributions (but *not* by `mysqld`). To understand how third-party client programs that use the C API can use option files, see the C API documentation at [mysql_options\(\)](#).

The `[client]` group enables you to specify options that apply to all clients. For example, `[client]` is the appropriate group to use to specify the password for connecting to the server. (But make sure that the option file is accessible only by yourself, so that other people cannot discover your password.) Be sure not to put an option in the `[client]` group unless it is recognized by *all* client programs that you use. Programs that do not understand the option quit after displaying an error message if you try to run them.

List more general option groups first and more specific groups later. For example, a `[client]` group is more general because it is read by all client programs, whereas a `[mysqldump]` group is read only by `mysqldump`. Options specified later override options specified earlier, so putting the option groups in the order `[client]`, `[mysqldump]` enables `mysqldump`-specific options to override `[client]` options.

Here is a typical global option file:

```
[client]
port=3306
socket=/tmp/mysql.sock

[mysqld]
port=3306
socket=/tmp/mysql.sock
key_buffer_size=16M
max_allowed_packet=128M

[mysqldump]
quick
```

Here is a typical user option file:

```
[client]
# The following password is sent to all standard MySQL clients
password="my password"

[mysql]
```

```
no-auto-rehash
connect_timeout=2
```

To create option groups to be read only by `mysqld` servers from specific MySQL release series, use groups with names of `[mysqld-8.2]`, `[mysqld-8.3]`, and so forth. The following group indicates that the `sql_mode` setting should be used only by MySQL servers with 8.3.x version numbers:

```
[mysqld-8.3]
sql_mode=TRADITIONAL
```

Option File Inclusions

It is possible to use `!include` directives in option files to include other option files and `!includedir` to search specific directories for option files. For example, to include the `/home/mydir/myopt.cnf` file, use the following directive:

```
!include /home/mydir/myopt.cnf
```

To search the `/home/mydir` directory and read option files found there, use this directive:

```
!includedir /home/mydir
```

MySQL makes no guarantee about the order in which option files in the directory are read.

Note

Any files to be found and included using the `!includedir` directive on Unix operating systems *must* have file names ending in `.cnf`. On Windows, this directive checks for files with the `.ini` or `.cnf` extension.

Write the contents of an included option file like any other option file. That is, it should contain groups of options, each preceded by a `[group]` line that indicates the program to which the options apply.

While an included file is being processed, only those options in groups that the current program is looking for are used. Other groups are ignored. Suppose that a `my.cnf` file contains this line:

```
!include /home/mydir/myopt.cnf
```

And suppose that `/home/mydir/myopt.cnf` looks like this:

```
[mysqladmin]
force

[mysqld]
key_buffer_size=16M
```

If `my.cnf` is processed by `mysqld`, only the `[mysqld]` group in `/home/mydir/myopt.cnf` is used. If the file is processed by `mysqladmin`, only the `[mysqladmin]` group is used. If the file is processed by any other program, no options in `/home/mydir/myopt.cnf` are used.

The `!includedir` directive is processed similarly except that all option files in the named directory are read.

If an option file contains `!include` or `!includedir` directives, files named by those directives are processed whenever the option file is processed, no matter where they appear in the file.

For inclusion directives to work, the file path should not be specified within quotes and should have no escape sequences. For example, the following statements provided in `my.ini` read the option file `myopts.ini`:

```
!include C:/ProgramData/MySQL/MySQL Server/myopts.ini
!include C:\ProgramData\MySQL\MySQL Server\myopts.ini
!include C:\\ProgramData\\MySQL\\MySQL Server\\myopts.ini
```

On Windows, if `!include /path/to/extra.ini` is the last line in the file, make sure that a newline is appended at the end; otherwise, the line is ignored.

6.2.2.3 Command-Line Options that Affect Option-File Handling

Most MySQL programs that support option files handle the following options. Because these options affect option-file handling, they must be given on the command line and not in an option file. To work properly, each of these options must be given before other options, with these exceptions:

- `--print-defaults` may be used immediately after `--defaults-file`, `--defaults-extra-file`, `--login-path`, or `--no-login-paths`.
- On Windows, if the server is started with the `--defaults-file` and `--install` options, `--install` must be first. See [Section 2.3.3.8, “Starting MySQL as a Windows Service”](#).

When specifying file names as option values, avoid the use of the `~` shell metacharacter because it might not be interpreted as you expect.

Table 6.3 Option File Option Summary

Option Name	Description
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files
<code>--defaults-file</code>	Read only named option file
<code>--defaults-group-suffix</code>	Option group suffix value
<code>--login-path</code>	Read login path options from <code>.mylogin.cnf</code>
<code>--no-defaults</code>	Read no option files
<code>--no-login-paths</code>	Do not read options from login path file

- `--defaults-extra-file=file_name`

Command-Line Format	<code>--defaults-extra-file=filename</code>
Type	File name
Default Value	<code>[none]</code>

Read this option file after the global option file but (on Unix) before the user option file and (on all platforms) before the login path file. (For information about the order in which option files are used, see [Section 6.2.2.2, “Using Option Files”](#).) If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

See the introduction to this section regarding constraints on the position in which this option may be specified.

- `--defaults-file=file_name`

Command-Line Format	<code>--defaults-file=filename</code>
Type	File name
Default Value	<code>[none]</code>

Read only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exceptions: Even with `--defaults-file`, `mysqld` reads `mysqld-auto.cnf` and client programs read `.mylogin.cnf`.

See the introduction to this section regarding constraints on the position in which this option may be specified.

- `--defaults-group-suffix=string`

Command-Line Format	<code>--defaults-group-suffix=string</code>
Type	String
Default Value	<code>[none]</code>

Read not only the usual option groups, but also groups with the usual names and a suffix of `string`. For example, the `mysql` client normally reads the `[client]` and `[mysql]` groups. If this option is given as `--defaults-group-suffix=_other`, `mysql` also reads the `[client_other]` and `[mysql_other]` groups.

- `--login-path=name`

Command-Line Format	<code>--login-path=name</code>
Type	String
Default Value	<code>[none]</code>

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

A client program reads the option group corresponding to the named login path, in addition to option groups that the program reads by default. Consider this command:

```
mysql --login-path=mypath
```

By default, the `mysql` client reads the `[client]` and `[mysql]` option groups. So for the command shown, `mysql` reads `[client]` and `[mysql]` from other option files, and `[client]`, `[mysql]`, and `[mypath]` from the login path file.

Client programs read the login path file even when the `--no-defaults` option is used, unless `--no-login-paths` is set.

To specify an alternate login path file name, set the `MYSQL_TEST_LOGIN_FILE` environment variable.

See the introduction to this section regarding constraints on the position in which this option may be specified.

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
Type	Boolean

Default Value	false
---------------	-------

Skips reading options from the login path file. Client programs always read the login path file without this option even when the `--no-defaults` option is used.

See `--login-path` for related information.

See the introduction to this section regarding constraints on the position in which this option may be specified.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
Type	Boolean
Default Value	false

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that client programs read the `.mylogin.cnf` login path file, if it exists, even when `--no-defaults` is used unless `--no-login-paths` is set. This permits passwords to be specified in a safer way than on the command line even if `--no-defaults` is present. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
Type	Boolean
Default Value	false

Print the program name and all options that it gets from option files. Password values are masked.

See the introduction to this section regarding constraints on the position in which this option may be specified.

6.2.2.4 Program Option Modifiers

Some options are “boolean” and control behavior that can be turned on or off. For example, the `mysql` client supports a `--column-names` option that determines whether or not to display a row of column names at the beginning of query results. By default, this option is enabled. However, you may want to disable it in some instances, such as when sending the output of `mysql` into another program that expects to see only data and not an initial header line.

To disable column names, you can specify the option using any of these forms:

```
--disable-column-names
--skip-column-names
--column-names=0
```

The `--disable` and `--skip` prefixes and the `=0` suffix all have the same effect: They turn the option off.

The “enabled” form of the option may be specified in any of these ways:

```
--column-names
--enable-column-names
```

```
--column-names=1
```

The values `ON`, `TRUE`, `OFF`, and `FALSE` are also recognized for boolean options (not case-sensitive).

If an option is prefixed by `--loose`, a program does not exit with an error if it does not recognize the option, but instead issues only a warning:

```
$> mysql --loose-no-such-option
mysql: WARNING: unknown option '--loose-no-such-option'
```

The `--loose` prefix can be useful when you run programs from multiple installations of MySQL on the same machine and list options in an option file. An option that may not be recognized by all versions of a program can be given using the `--loose` prefix (or `loose` in an option file). Versions of the program that recognize the option process it normally, and versions that do not recognize it issue a warning and ignore it.

The `--maximum` prefix is available for `mysqld` only and permits a limit to be placed on how large client programs can set session system variables. To do this, use a `--maximum` prefix with the variable name. For example, `--maximum-max_heap_table_size=32M` prevents any client from making the heap table size limit larger than 32M.

The `--maximum` prefix is intended for use with system variables that have a session value. If applied to a system variable that has only a global value, an error occurs. For example, with `--maximum-back_log=200`, the server produces this error:

```
Maximum value of 'back_log' cannot be set
```

6.2.2.5 Using Options to Set Program Variables

Many MySQL programs have internal variables that can be set at runtime using the `SET` statement. See [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#), and [Section 7.1.9, “Using System Variables”](#).

Most of these program variables also can be set at server startup by using the same syntax that applies to specifying program options. For example, `mysql` has a `max_allowed_packet` variable that controls the maximum size of its communication buffer. To set the `max_allowed_packet` variable for `mysql` to a value of 16MB, use either of the following commands:

```
mysql --max_allowed_packet=16777216
mysql --max_allowed_packet=16M
```

The first command specifies the value in bytes. The second specifies the value in megabytes. For variables that take a numeric value, the value can be given with a suffix of `K`, `M`, or `G` to indicate a multiplier of 1024^1 , 1024^2 or 1024^3 . (For example, when used to set `max_allowed_packet`, the suffixes indicate units of kilobytes, megabytes, or gigabytes.) As of MySQL 8.0.14, a suffix can also be `T`, `P`, and `E` to indicate a multiplier of 1024^4 , 1024^5 or 1024^6 . Suffix letters can be uppercase or lowercase.

In an option file, variable settings are given without the leading dashes:

```
[mysql]
max_allowed_packet=16777216
```

Or:

```
[mysql]
max_allowed_packet=16M
```

If you like, underscores in an option name can be specified as dashes. The following option groups are equivalent. Both set the size of the server's key buffer to 512MB:

```
[mysqld]
key_buffer_size=512M
```

```
[mysqld]
key-buffer-size=512M
```

Suffixes for specifying a value multiplier can be used when setting a variable at program invocation time, but not to set the value with `SET` at runtime. On the other hand, with `SET`, you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at program invocation time, but the second is not:

```
$> mysql --max_allowed_packet=16M
$> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

6.2.2.6 Option Defaults, Options Expecting Values, and the = Sign

By convention, long forms of options that assign a value are written with an equals (=) sign, like this:

```
mysql --host=tonfisk --user=jon
```

For options that require a value (that is, not having a default value), the equal sign is not required, and so the following is also valid:

```
mysql --host tonfisk --user jon
```

In both cases, the `mysql` client attempts to connect to a MySQL server running on the host named “tonfisk” using an account with the user name “jon”.

Due to this behavior, problems can occasionally arise when no value is provided for an option that expects one. Consider the following example, where a user connects to a MySQL server running on host `tonfisk` as user `jon`:

```
$> mysql --host 85.224.35.45 --user jon
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 3
Server version: 8.3.0 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT CURRENT_USER();
+-----+
| CURRENT_USER() |
+-----+
| jon@%          |
+-----+
1 row in set (0.00 sec)
```

Omitting the required value for one of these option yields an error, such as the one shown here:

```
$> mysql --host 85.224.35.45 --user
mysql: option '--user' requires an argument
```

In this case, `mysql` was unable to find a value following the `--user` option because nothing came after it on the command line. However, if you omit the value for an option that is *not* the last option to be used, you obtain a different error that you may not be expecting:

```
$> mysql --host --user jon
ERROR 2005 (HY000): Unknown MySQL server host '--user' (1)
```

Because `mysql` assumes that any string following `--host` on the command line is a host name, `--host --user` is interpreted as `--host=--user`, and the client attempts to connect to a MySQL server running on a host named “--user”.

Options having default values always require an equal sign when assigning a value; failing to do so causes an error. For example, the MySQL server `--log-error` option has the default value

`host_name.err`, where `host_name` is the name of the host on which MySQL is running. Assume that you are running MySQL on a computer whose host name is “tonfisk”, and consider the following invocation of `mysqld_safe`:

```
$> mysqld_safe &
[1] 11699
$> 080112 12:53:40 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080112 12:53:40 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
$>
```

After shutting down the server, restart it as follows:

```
$> mysqld_safe --log-error &
[1] 11699
$> 080112 12:53:40 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080112 12:53:40 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
$>
```

The result is the same, since `--log-error` is not followed by anything else on the command line, and it supplies its own default value. (The `&` character tells the operating system to run MySQL in the background; it is ignored by MySQL itself.) Now suppose that you wish to log errors to a file named `my-errors.err`. You might try starting the server with `--log-error my-errors`, but this does not have the intended effect, as shown here:

```
$> mysqld_safe --log-error my-errors &
[1] 31357
$> 080111 22:53:31 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080111 22:53:32 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
080111 22:53:34 mysqld_safe mysqld from pid file /usr/local/mysql/var/tonfisk.pid ended

[1]+  Done                  ./mysqld_safe --log-error my-errors
```

The server attempted to start using `/usr/local/mysql/var/tonfisk.err` as the error log, but then shut down. Examining the last few lines of this file shows the reason:

```
$> tail /usr/local/mysql/var/tonfisk.err
2013-09-24T15:36:22.278034Z 0 [ERROR] Too many arguments (first extra is 'my-errors').
2013-09-24T15:36:22.278059Z 0 [Note] Use --verbose --help to get a list of available options!
2013-09-24T15:36:22.278076Z 0 [ERROR] Aborting
2013-09-24T15:36:22.279704Z 0 [Note] InnoDB: Starting shutdown...
2013-09-24T15:36:23.777471Z 0 [Note] InnoDB: Shutdown completed; log sequence number 2319086
2013-09-24T15:36:23.780134Z 0 [Note] mysqld: Shutdown complete
```

Because the `--log-error` option supplies a default value, you must use an equal sign to assign a different value to it, as shown here:

```
$> mysqld_safe --log-error=my-errors &
[1] 31437
$> 080111 22:54:15 mysqld_safe Logging to '/usr/local/mysql/var/my-errors.err'.
080111 22:54:15 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
$>
```

Now the server has been started successfully, and is logging errors to the file `/usr/local/mysql/var/my-errors.err`.

Similar issues can arise when specifying option values in option files. For example, consider a `my.cnf` file that contains the following:

```
[mysql]

host
user
```

When the `mysql` client reads this file, these entries are parsed as `--host --user` or `--host=--user`, with the result shown here:

```
$> mysql
```

```
ERROR 2005 (HY000): Unknown MySQL server host '--user' (1)
```

However, in option files, an equal sign is not assumed. Suppose the `my.cnf` file is as shown here:

```
[mysql]
user jon
```

Trying to start `mysql` in this case causes a different error:

```
$> mysql
mysql: unknown option '--user jon'
```

A similar error would occur if you were to write `host tonfisk` in the option file rather than `host=tonfisk`. Instead, you must use the equal sign:

```
[mysql]
user=jon
```

Now the login attempt succeeds:

```
$> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 5
Server version: 8.3.0 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT USER();
+-----+
| USER() |
+-----+
| jon@localhost |
+-----+
1 row in set (0.00 sec)
```

This is not the same behavior as with the command line, where the equal sign is not required:

```
$> mysql --user jon --host tonfisk
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 6
Server version: 8.3.0 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT USER();
+-----+
| USER() |
+-----+
| jon@tonfisk |
+-----+
1 row in set (0.00 sec)
```

Specifying an option requiring a value without a value in an option file causes the server to abort with an error.

6.2.3 Command Options for Connecting to the Server

This section describes options supported by most MySQL client programs that control how client programs establish connections to the server, whether connections are encrypted, and whether connections are compressed. These options can be given on the command line or in an option file.

- [Command Options for Connection Establishment](#)
- [Command Options for Encrypted Connections](#)
- [Command Options for Connection Compression](#)

Command Options for Connection Establishment

This section describes options that control how client programs establish connections to the server. For additional information and examples showing how to use them, see [Section 6.2.4, “Connecting to the MySQL Server Using Command Options”](#).

Table 6.4 Connection-Establishment Option Summary

Option Name	Description
<code>--default-auth</code>	Authentication plugin to use
<code>--host</code>	Host on which MySQL server is located
<code>--password</code>	Password to use when connecting to server
<code>--password1</code>	First multifactor authentication password to use when connecting to server
<code>--password2</code>	Second multifactor authentication password to use when connecting to server
<code>--password3</code>	Third multifactor authentication password to use when connecting to server
<code>--pipe</code>	Connect to server using named pipe (Windows only)
<code>--plugin-dir</code>	Directory where plugins are installed
<code>--port</code>	TCP/IP port number for connection
<code>--protocol</code>	Transport protocol to use
<code>--shared-memory-base-name</code>	Shared-memory name for shared-memory connections (Windows only)
<code>--socket</code>	Unix socket file or Windows named pipe to use
<code>--user</code>	MySQL user name to use when connecting to server

- `--default-auth=plugin`

Command-Line Format	<code>--default-auth=plugin</code>
Type	String

A hint about which client-side authentication plugin to use. See [Section 8.2.17, “Pluggable Authentication”](#).

- `--host=host_name`, `-h host_name`

Command-Line Format	<code>--host=host_name</code>
Type	String
Default Value	<code>localhost</code>

The host on which the MySQL server is running. The value can be a host name, IPv4 address, or IPv6 address. The default value is `localhost`.

- `--password[=pass_val]`, `-p[pass_val]`

Command-Line Format	<code>--password[=password]</code>
Type	String
Default Value	<code>[none]</code>

The password of the MySQL account used for connecting to the server. The password value is optional. If not given, the client program prompts for one. If given, there must be *no space* between `--password=` or `-p` and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See [Section 8.1.2.1, “End-User Guidelines for Password Security”](#).

To explicitly specify that there is no password and that the client program should not prompt for one, use the `--skip-password` option.

- `--password1[=pass_val]`

Command-Line Format	<code>--password1[=password]</code>
Type	String

The password for multifactor authentication factor 1 of the MySQL account used for connecting to the server. The password value is optional. If not given, the client program prompts for one. If given, there must be *no space* between `--password1=` and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See [Section 8.1.2.1, “End-User Guidelines for Password Security”](#).

To explicitly specify that there is no password and that the client program should not prompt for one, use the `--skip-password1` option.

`--password1` and `--password` are synonymous, as are `--skip-password1` and `--skip-password`.

- `--password2[=pass_val]`

Command-Line Format	<code>--password2[=password]</code>
Type	String

The password for multifactor authentication factor 2 of the MySQL account used for connecting to the server. The semantics of this option are similar to the semantics for `--password1`; see the description of that option for details.

- `--password3[=pass_val]`

Command-Line Format	<code>--password3[=password]</code>
Type	String

The password for multifactor authentication factor 3 of the MySQL account used for connecting to the server. The semantics of this option are similar to the semantics for `--password1`; see the description of that option for details.

- `--pipe, -W`

Command-Line Format	<code>--pipe</code>
Type	String

On Windows, connect to the server using a named pipe. This option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--plugin-dir=dir_name`

Command-Line Format	<code>--plugin-dir=dir_name</code>
Type	Directory name

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but the client program does not find it. See [Section 8.2.17, “Pluggable Authentication”](#).

- `--port=port_num, -P port_num`

Command-Line Format	<code>--port=port_num</code>
Type	Numeric
Default Value	3306

For TCP/IP connections, the port number to use. The default port number is 3306.

- `--protocol={TCP | SOCKET | PIPE | MEMORY}`

Command-Line Format	<code>--protocol=type</code>
Type	String
Default Value	[see text]
Valid Values	TCP SOCKET PIPE MEMORY

This option explicitly specifies which transport protocol to use for connecting to the server. It is useful when other connection parameters normally result in use of a protocol other than the one you want. For example, connections on Unix to `localhost` are made using a Unix socket file by default:

```
mysql --host=localhost
```

To force TCP/IP transport to be used instead, specify a `--protocol` option:

```
mysql --host=localhost --protocol=TCP
```

The following table shows the permissible `--protocol` option values and indicates the applicable platforms for each value. The values are not case-sensitive.

<code>--protocol</code> Value	Transport Protocol Used	Applicable Platforms
TCP	TCP/IP transport to local or remote server	All
SOCKET	Unix socket-file transport to local server	Unix and Unix-like systems

<code>--protocol</code> Value	Transport Protocol Used	Applicable Platforms
PIPE	Named-pipe transport to local server	Windows
MEMORY	Shared-memory transport to local server	Windows

See also [Section 6.2.7, “Connection Transport Protocols”](#)

- `--shared-memory-base-name=name`

Command-Line Format	<code>--shared-memory-base-name=name</code>
Platform Specific	Windows

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

- `--socket=path, -S path`

Command-Line Format	<code>--socket={file_name pipe_name}</code>
Type	String

On Unix, the name of the Unix socket file to use for connections made using a named pipe to a local server. The default Unix socket file name is `/tmp/mysql.sock`.

On Windows, the name of the named pipe to use for connections to a local server. The default Windows pipe name is `MySQL`. The pipe name is not case-sensitive.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--user=user_name, -u user_name`

Command-Line Format	<code>--user=user_name</code>
Type	String

The user name of the MySQL account to use for connecting to the server. The default user name is `ODBC` on Windows or your Unix login name on Unix.

Command Options for Encrypted Connections

This section describes options for client programs that specify whether to use encrypted connections to the server, the names of certificate and key files, and other parameters related to encrypted-connection support. For examples of suggested use and how to check whether a connection is encrypted, see [Section 8.3.1, “Configuring MySQL to Use Encrypted Connections”](#).

Note

These options have an effect only for connections that use a transport protocol subject to encryption; that is, TCP/IP and Unix socket-file connections. See [Section 6.2.7, “Connection Transport Protocols”](#)

For information about using encrypted connections from the MySQL C API, see [Support for Encrypted Connections](#).

Table 6.5 Connection-Encryption Option Summary

Option Name	Description
--get-server-public-key	Request RSA public key from server
--server-public-key-path	Path name to file containing RSA public key
--ssl-ca	File that contains list of trusted SSL Certificate Authorities
--ssl-capath	Directory that contains trusted SSL Certificate Authority certificate files
--ssl-cert	File that contains X.509 certificate
--ssl-cipher	Permissible ciphers for connection encryption
--ssl-crl	File that contains certificate revocation lists
--ssl-crlpath	Directory that contains certificate revocation-list files
--ssl-fips-mode	Whether to enable FIPS mode on client side
--ssl-key	File that contains X.509 key
--ssl-mode	Desired security state of connection to server
--ssl-session-data	File that contains SSL session data
--ssl-session-data-continue-on-failed-reuse	Whether to establish connections if session reuse fails
--tls-ciphersuites	Permissible TLSv1.3 ciphersuites for encrypted connections
--tls-version	Permissible TLS protocols for encrypted connections

- [--get-server-public-key](#)

Command-Line Format	--get-server-public-key
Type	Boolean

Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the [caching_sha2_password](#) authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If [--server-public-key-path=file_name](#) is given and specifies a valid public key file, it takes precedence over [--get-server-public-key](#).

For information about the [caching_sha2_password](#) plugin, see [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

- [--server-public-key-path=file_name](#)

Command-Line Format	--server-public-key-path=file_name
Type	File name

The path name to a file in PEM format containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

This option is available only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see [Section 8.4.1.3, “SHA-256 Pluggable Authentication”](#), and [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

- `--ssl-ca=file_name`

Command-Line Format	<code>--ssl-ca=file_name</code>
Type	File name

The path name of the Certificate Authority (CA) certificate file in PEM format. The file contains a list of trusted SSL Certificate Authorities.

To tell the client not to authenticate the server certificate when establishing an encrypted connection to the server, specify neither `--ssl-ca` nor `--ssl-capath`. The server still verifies the client according to any applicable requirements established for the client account, and it still uses any `ssl_ca` or `ssl_capath` system variable values specified on the server side.

To specify the CA file for the server, set the `ssl_ca` system variable.

- `--ssl-capath=dir_name`

Command-Line Format	<code>--ssl-capath=dir_name</code>
Type	Directory name

The path name of the directory that contains trusted SSL certificate authority (CA) certificate files in PEM format.

To tell the client not to authenticate the server certificate when establishing an encrypted connection to the server, specify neither `--ssl-ca` nor `--ssl-capath`. The server still verifies the client according to any applicable requirements established for the client account, and it still uses any `ssl_ca` or `ssl_capath` system variable values specified on the server side.

To specify the CA directory for the server, set the `ssl_capath` system variable.

- `--ssl-cert=file_name`

Command-Line Format	<code>--ssl-cert=file_name</code>
Type	File name

- `--ssl-cipher=cipher_list`

Command-Line Format	<code>--ssl-cipher=name</code>
Type	String

The list of permissible encryption ciphers for connections that use TLS protocols up through TLSv1.2. If no cipher in the list is supported, encrypted connections that use these TLS protocols do not work.

For greatest portability, `cipher_list` should be a list of one or more cipher names, separated by colons. Examples:

```
--ssl-cipher=AES128-SHA
--ssl-cipher=DHE-RSA-AES128-GCM-SHA256:AES128-SHA
```

OpenSSL supports the syntax for specifying ciphers described in the OpenSSL documentation at <https://www.openssl.org/docs/manmaster/man1/ciphers.html>.

For information about which encryption ciphers MySQL supports, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

To specify the encryption ciphers for the server, set the `ssl_cipher` system variable.

- `--ssl-crl=file_name`

Command-Line Format	<code>--ssl-crl=file_name</code>
Type	File name

The path name of the file containing certificate revocation lists in PEM format.

If neither `--ssl-crl` nor `--ssl-crlpath` is given, no CRL checks are performed, even if the CA path contains certificate revocation lists.

To specify the revocation-list file for the server, set the `ssl_crl` system variable.

- `--ssl-crlpath=dir_name`

Command-Line Format	<code>--ssl-crlpath=dir_name</code>
Type	Directory name

The path name of the directory that contains certificate revocation-list files in PEM format.

If neither `--ssl-crl` nor `--ssl-crlpath` is given, no CRL checks are performed, even if the CA path contains certificate revocation lists.

To specify the revocation-list directory for the server, set the `ssl_crlpath` system variable.

- `--ssl-fips-mode={OFF|ON|STRICT}`

Command-Line Format	<code>--ssl-fips-mode={OFF ON STRICT}</code>
Deprecated	Yes
Type	Enumeration
Default Value	OFF
Valid Values	OFF

	ON
	STRICT

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations to permit. See [Section 8.8, “FIPS Support”](#).

These `--ssl-fips-mode` values are permissible:

- `OFF`: Disable FIPS mode.
- `ON`: Enable FIPS mode.
- `STRICT`: Enable “strict” FIPS mode.

Note

If the OpenSSL FIPS Object Module is not available, the only permissible value for `--ssl-fips-mode` is `OFF`. In this case, setting `--ssl-fips-mode` to `ON` or `STRICT` causes the client to produce a warning at startup and to operate in non-FIPS mode.

To specify the FIPS mode for the server, set the `ssl_fips_mode` system variable.

- `--ssl-key=file_name`

Command-Line Format	<code>--ssl-key=file_name</code>
Type	File name

The path name of the client SSL private key file in PEM format. For better security, use a certificate with an RSA key size of at least 2048 bits.

If the key file is protected by a passphrase, the client program prompts the user for the passphrase. The password must be given interactively; it cannot be stored in a file. If the passphrase is incorrect, the program continues as if it could not read the key.

To specify the server SSL private key file, set the `ssl_key` system variable.

- `--ssl-mode=mode`

Command-Line Format	<code>--ssl-mode=mode</code>
Type	Enumeration
Default Value	<code>PREFERRED</code>
Valid Values	<code>DISABLED</code> <code>PREFERRED</code> <code>REQUIRED</code> <code>VERIFY_CA</code> <code>VERIFY_IDENTITY</code>

This option specifies the desired security state of the connection to the server. These mode values are permissible, in order of increasing strictness:

- **DISABLED**: Establish an unencrypted connection.
- **PREFERRED**: Establish an encrypted connection if the server supports encrypted connections, falling back to an unencrypted connection if an encrypted connection cannot be established. This is the default if `--ssl-mode` is not specified.

Connections over Unix socket files are not encrypted with a mode of **PREFERRED**. To enforce encryption for Unix socket-file connections, use a mode of **REQUIRED** or stricter. (However, socket-file transport is secure by default, so encrypting a socket-file connection makes it no more secure and increases CPU load.)

- **REQUIRED**: Establish an encrypted connection if the server supports encrypted connections. The connection attempt fails if an encrypted connection cannot be established.
- **VERIFY_CA**: Like **REQUIRED**, but additionally verify the server Certificate Authority (CA) certificate against the configured CA certificates. The connection attempt fails if no valid matching CA certificates are found.
- **VERIFY_IDENTITY**: Like **VERIFY_CA**, but additionally perform host name identity verification by checking the host name the client uses for connecting to the server against the identity in the certificate that the server sends to the client:
 - If the client uses OpenSSL 1.0.2 or higher, the client checks whether the host name that it uses for connecting matches either the Subject Alternative Name value or the Common Name value in the server certificate. Host name identity verification also works with certificates that specify the Common Name using wildcards.
 - Otherwise, the client checks whether the host name that it uses for connecting matches the Common Name value in the server certificate.

The connection fails if there is a mismatch. For encrypted connections, this option helps prevent man-in-the-middle attacks.

Note

Host name identity verification with **VERIFY_IDENTITY** does not work with self-signed certificates that are created automatically by the server or manually using `mysql_ssl_rsa_setup` (see [Section 8.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#)). Such self-signed certificates do not contain the server name as the Common Name value.

Important

The default setting, `--ssl-mode=PREFERRED`, produces an encrypted connection if the other default settings are unchanged. However, to help prevent sophisticated man-in-the-middle attacks, it is important for the client to verify the server's identity. The settings `--ssl-mode=VERIFY_CA` and `--ssl-mode=VERIFY_IDENTITY` are a better choice than the default setting to help prevent this type of attack. To implement one of these settings, you must first ensure that the CA certificate for the server is reliably available to all the clients that use it in your environment, otherwise availability issues will result. For this reason, they are not the default setting.

The `--ssl-mode` option interacts with CA certificate options as follows:

- If `--ssl-mode` is not explicitly set otherwise, use of `--ssl-ca` or `--ssl-capath` implies `--ssl-mode=VERIFY_CA`.

- For `--ssl-mode` values of `VERIFY_CA` or `VERIFY_IDENTITY`, `--ssl-ca` or `--ssl-capath` is also required, to supply a CA certificate that matches the one used by the server.
- An explicit `--ssl-mode` option with a value other than `VERIFY_CA` or `VERIFY_IDENTITY`, together with an explicit `--ssl-ca` or `--ssl-capath` option, produces a warning that no verification of the server certificate is performed, despite a CA certificate option being specified.

To require use of encrypted connections by a MySQL account, use `CREATE USER` to create the account with a `REQUIRE SSL` clause, or use `ALTER USER` for an existing account to add a `REQUIRE SSL` clause. This causes connection attempts by clients that use the account to be rejected unless MySQL supports encrypted connections and an encrypted connection can be established.

The `REQUIRE` clause permits other encryption-related options, which can be used to enforce security requirements stricter than `REQUIRE SSL`. For additional details about which command options may or must be specified by clients that connect using accounts configured using the various `REQUIRE` options, see [CREATE USER SSL/TLS Options](#).

- `--ssl-session-data=file_name`

Command-Line Format	<code>--ssl-session-data=file_name</code>
Type	File name

The path name of the client SSL session data file in PEM format for session reuse.

When you invoke a MySQL client program with the `--ssl-session-data` option, the client attempts to deserialize session data from the file, if provided, and then use it to establish a new connection. If you supply a file, but the session is not reused, then the connection fails unless you also specified the `--ssl-session-data-continue-on-failed-reuse` option on the command line when you invoked the client program.

The `mysql` command, `ssl_session_data_print`, generates the session data file (see [Section 6.5.1.2, “mysql Client Commands”](#)).

- `ssl-session-data-continue-on-failed-reuse`

Command-Line Format	<code>--ssl-session-data-continue-on-failed-reuse</code>
Type	Boolean
Default Value	OFF

Controls whether a new connection is started to replace an attempted connection that tried but failed to reuse session data specified with the `--ssl-session-data` command-line option. By default, the `--ssl-session-data-continue-on-failed-reuse` command-line option is off, which causes a client program to return a connect failure when session data are supplied and not reused.

To ensure that a new, unrelated connection opens after session reuse fails silently, invoke MySQL client programs with both the `--ssl-session-data` and `--ssl-session-data-continue-on-failed-reuse` command-line options.

- `--tls-ciphersuites=ciphersuite_list`

Command-Line Format	<code>--tls-ciphersuites=ciphersuite_list</code>
Type	String

Default Value	empty string
---------------	--------------

This option specifies which ciphersuites the client permits for encrypted connections that use TLSv1.3. The value is a list of zero or more colon-separated ciphersuite names. For example:

```
mysql --tls-ciphersuites="suite1:suite2:suite3"
```

The ciphersuites that can be named for this option depend on the SSL library used to compile MySQL. If this option is not set, the client permits the default set of ciphersuites. If the option is set to the empty string, no ciphersuites are enabled and encrypted connections cannot be established. For more information, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

To specify which ciphersuites the server permits, set the `tls_ciphersuites` system variable.

- `--tls-version=protocol_list`

Command-Line Format	<code>--tls-version=protocol_list</code>
Type	String
Default Value	<code>TLSv1,TLSv1.1,TLSv1.2,TLSv1.3</code> (OpenSSL 1.1.1 or higher) <code>TLSv1,TLSv1.1,TLSv1.2</code> (otherwise)

This option specifies the TLS protocols the client permits for encrypted connections. The value is a list of one or more comma-separated protocol versions. For example:

```
mysql --tls-version="TLSv1.2,TLSv1.3"
```

The protocols that can be named for this option depend on the SSL library used to compile MySQL, and on the MySQL Server release.

Important

- Clients, including MySQL Shell, that support the `--tls-version` option cannot make a TLS/SSL connection with the protocol set to TLSv1 or TLSv1.1. If a client attempts to connect using these protocols, for TCP connections, the connection fails, and an error is returned to the client. For socket connections, if `--ssl-mode` is set to `REQUIRED`, the connection fails, otherwise the connection is made but with TLS/SSL disabled. See [Removal of Support for the TLSv1 and TLSv1.1 Protocols](#) for more information.
- Support for the TLSv1.3 protocol is available in MySQL Server, provided that MySQL Server was compiled using OpenSSL 1.1.1 or higher. The server checks the version of OpenSSL at startup, and if it is lower than 1.1.1, TLSv1.3 is removed from the default value for the server system variables relating to the TLS version (such as the `tls_version` system variable).

Permitted protocols should be chosen such as not to leave “holes” in the list. For example, these values do not have holes:

```
--tls-version="TLSv1.2,TLSv1.3"
--tls-version="TLSv1.3"
```

For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

To specify which TLS protocols the server permits, set the `tls_version` system variable.

Command Options for Connection Compression

This section describes options that enable client programs to control use of compression for connections to the server. For additional information and examples showing how to use them, see [Section 6.2.8, “Connection Compression Control”](#).

Table 6.6 Connection-Compression Option Summary

Option Name	Description
<code>--compress</code>	Compress all information sent between client and server
<code>--compression-algorithms</code>	Permitted compression algorithms for connections to server
<code>--zstd-compression-level</code>	Compression level for connections to server that use zstd compression

- `--compress, -C`

Command-Line Format	<code>--compress[={OFF ON}]</code>
Deprecated	Yes
Type	Boolean
Default Value	<code>OFF</code>

Compress all information sent between the client and the server if possible.

This option is deprecated. Expect it to be removed in a future version of MySQL. See [Configuring Legacy Connection Compression](#).

- `--compression-algorithms=value`

Command-Line Format	<code>--compression-algorithms=value</code>
Type	Set
Default Value	<code>uncompressed</code>
Valid Values	<code>zlib</code> <code>zstd</code> <code>uncompressed</code>

The permitted compression algorithms for connections to the server. The available algorithms are the same as for the `protocol_compression_algorithms` system variable. The default value is `uncompressed`.

- `--zstd-compression-level=level`

Command-Line Format	<code>--zstd-compression-level=#</code>
Type	Integer

The compression level to use for connections to the server that use the `zstd` compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression. The default `zstd` compression level is 3. The compression level setting has no effect on connections that do not use `zstd` compression.

6.2.4 Connecting to the MySQL Server Using Command Options

This section describes use of command-line options to specify how to establish connections to the MySQL server, for clients such as `mysql` or `mysqldump`. For information on establishing connections using URI-like connection strings or key-value pairs, for clients such as MySQL Shell, see [Section 6.2.5, “Connecting to the Server Using URI-Like Strings or Key-Value Pairs”](#). For additional information if you are unable to connect, see [Section 8.2.22, “Troubleshooting Problems Connecting to MySQL”](#).

For a client program to connect to the MySQL server, it must use the proper connection parameters, such as the name of the host where the server is running and the user name and password of your MySQL account. Each connection parameter has a default value, but you can override default values as necessary using program options specified either on the command line or in an option file.

The examples here use the `mysql` client program, but the principles apply to other clients such as `mysqldump`, `mysqladmin`, or `mysqlshow`.

This command invokes `mysql` without specifying any explicit connection parameters:

```
mysql
```

Because there are no parameter options, the default values apply:

- The default host name is `localhost`. On Unix, this has a special meaning, as described later.
- The default user name is `ODBC` on Windows or your Unix login name on Unix.
- No password is sent because neither `--password` nor `-p` is given.
- For `mysql`, the first nonoption argument is taken as the name of the default database. Because there is no such argument, `mysql` selects no default database.

To specify the host name and user name explicitly, as well as a password, supply appropriate options on the command line. To select a default database, add a database-name argument. Examples:

```
mysql --host=localhost --user=myname --password=password mydb
mysql -h localhost -u myname -ppassword mydb
```

For password options, the password value is optional:

- If you use a `--password` or `-p` option and specify a password value, there must be *no space* between `--password=` or `-p` and the password following it.
- If you use `--password` or `-p` but do not specify a password value, the client program prompts you to enter the password. The password is not displayed as you enter it. This is more secure than giving the password on the command line, which might enable other users on your system to see the password line by executing a command such as `ps`. See [Section 8.1.2.1, “End-User Guidelines for Password Security”](#).
- To explicitly specify that there is no password and that the client program should not prompt for one, use the `--skip-password` option.

As just mentioned, including the password value on the command line is a security risk. To avoid this risk, specify the `--password` or `-p` option without any following password value:

```
mysql --host=localhost --user=myname --password mydb
mysql -h localhost -u myname -p mydb
```

When the `--password` or `-p` option is given with no password value, the client program prints a prompt and waits for you to enter the password. (In these examples, `mydb` is *not* interpreted as a password because it is separated from the preceding password option by a space.)

On some systems, the library routine that MySQL uses to prompt for a password automatically limits the password to eight characters. That limitation is a property of the system library, not MySQL. Internally, MySQL does not have any limit for the length of the password. To work around the limitation

on systems affected by it, specify your password in an option file (see [Section 6.2.2.2, “Using Option Files”](#)). Another workaround is to change your MySQL password to a value that has eight or fewer characters, but that has the disadvantage that shorter passwords tend to be less secure.

Client programs determine what type of connection to make as follows:

- If the host is not specified or is `localhost`, a connection to the local host occurs:
 - On Windows, the client connects using shared memory, if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.
 - On Unix, MySQL programs treat the host name `localhost` specially, in a way that is likely different from what you expect compared to other network-based programs: the client connects using a Unix socket file. The `--socket` option or the `MYSQL_UNIX_PORT` environment variable may be used to specify the socket name.
- On Windows, if `host` is `.` (period), or TCP/IP is not enabled and `--socket` is not specified or the host is empty, the client connects using a named pipe, if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. If named-pipe connections are not supported or if the user making the connection is not a member of the Windows group specified by the `named_pipe_full_access_group` system variable, an error occurs.
- Otherwise, the connection uses TCP/IP.

The `--protocol` option enables you to use a particular transport protocol even when other options normally result in use of a different protocol. That is, `--protocol` specifies the transport protocol explicitly and overrides the preceding rules, even for `localhost`.

Only connection options that are relevant to the selected transport protocol are used or checked. Other connection options are ignored. For example, with `--host=localhost` on Unix, the client attempts to connect to the local server using a Unix socket file, even if a `--port` or `-P` option is given to specify a TCP/IP port number.

To ensure that the client makes a TCP/IP connection to the local server, use `--host` or `-h` to specify a host name value of `127.0.0.1` (instead of `localhost`), or the IP address or name of the local server. You can also specify the transport protocol explicitly, even for `localhost`, by using the `--protocol=TCP` option. Examples:

```
mysql --host=127.0.0.1
mysql --protocol=TCP
```

If the server is configured to accept IPv6 connections, clients can connect to the local server over IPv6 using `--host>:::1`. See [Section 7.1.13, “IPv6 Support”](#).

On Windows, to force a MySQL client to use a named-pipe connection, specify the `--pipe` or `--protocol=PIPE` option, or specify `.` (period) as the host name. If the server was not started with the `named_pipe` system variable enabled to support named-pipe connections or if the user making the connection is not a member of the Windows group specified by the `named_pipe_full_access_group` system variable, an error occurs. Use the `--socket` option to specify the name of the pipe if you do not want to use the default pipe name.

Connections to remote servers use TCP/IP. This command connects to the server running on `remote.example.com` using the default port number (3306):

```
mysql --host=remote.example.com
```

To specify a port number explicitly, use the `--port` or `-P` option:

```
mysql --host=remote.example.com --port=13306
```

You can specify a port number for connections to a local server, too. However, as indicated previously, connections to `localhost` on Unix use a socket file by default, so unless you force a TCP/IP connection as previously described, any option that specifies a port number is ignored.

For this command, the program uses a socket file on Unix and the `--port` option is ignored:

```
mysql --port=13306 --host=localhost
```

To cause the port number to be used, force a TCP/IP connection. For example, invoke the program in either of these ways:

```
mysql --port=13306 --host=127.0.0.1
mysql --port=13306 --protocol=TCP
```

For additional information about options that control how client programs establish connections to the server, see [Section 6.2.3, “Command Options for Connecting to the Server”](#).

It is possible to specify connection parameters without entering them on the command line each time you invoke a client program:

- Specify the connection parameters in the `[client]` section of an option file. The relevant section of the file might look like this:

```
[client]
host=host_name
user=user_name
password=password
```

For more information, see [Section 6.2.2.2, “Using Option Files”](#).

- Some connection parameters can be specified using environment variables. Examples:
 - To specify the host for `mysql`, use `MYSQL_HOST`.
 - On Windows, to specify the MySQL user name, use `USER`.

For a list of supported environment variables, see [Section 6.9, “Environment Variables”](#).

6.2.5 Connecting to the Server Using URI-Like Strings or Key-Value Pairs

This section describes use of URI-like connection strings or key-value pairs to specify how to establish connections to the MySQL server, for clients such as MySQL Shell. For information on establishing connections using command-line options, for clients such as `mysql` or `mysqldump`, see [Section 6.2.4, “Connecting to the MySQL Server Using Command Options”](#). For additional information if you are unable to connect, see [Section 8.2.22, “Troubleshooting Problems Connecting to MySQL”](#).

Note

The term “URI-like” signifies connection-string syntax that is similar to but not identical to the URI (uniform resource identifier) syntax defined by [RFC 3986](#).

The following MySQL clients support connecting to a MySQL server using a URI-like connection string or key-value pairs:

- MySQL Shell
- MySQL Connectors which implement X DevAPI

This section documents all valid URI-like string and key-value pair connection parameters, many of which are similar to those specified with command-line options:

- Parameters specified with a URI-like string use a syntax such as `myuser@example.com:3306/main-schema`. For the full syntax, see [Connecting Using URI-Like Connection Strings](#).
- Parameters specified with key-value pairs use a syntax such as `{user:'myuser', host:'example.com', port:3306, schema:'main-schema'}`. For the full syntax, see [Connecting Using Key-Value Pairs](#).

Connection parameters are not case-sensitive. Each parameter, if specified, can be given only once. If a parameter is specified more than once, an error occurs.

This section covers the following topics:

- [Base Connection Parameters](#)
- [Additional Connection parameters](#)
- [Connecting Using URI-Like Connection Strings](#)
- [Connecting Using Key-Value Pairs](#)

Base Connection Parameters

The following discussion describes the parameters available when specifying a connection to MySQL. These parameters can be provided using either a string that conforms to the base URI-like syntax (see [Connecting Using URI-Like Connection Strings](#)), or as key-value pairs (see [Connecting Using Key-Value Pairs](#)).

- *scheme*: The transport protocol to use. Use `mysqlx` for X Protocol connections and `mysql` for classic MySQL protocol connections. If no protocol is specified, the server attempts to guess the protocol. Connectors that support DNS SRV can use the `mysqlx+srv` scheme (see [Connections Using DNS SRV Records](#)).
- *user*: The MySQL user account to provide for the authentication process.
- *password*: The password to use for the authentication process.

Warning

Specifying an explicit password in the connection specification is insecure and not recommended. Later discussion shows how to cause an interactive prompt for the password to occur.

- *host*: The host on which the server instance is running. The value can be a host name, IPv4 address, or IPv6 address. If no host is specified, the default is `localhost`.
- *port*: The TCP/IP network port on which the target MySQL server is listening for connections. If no port is specified, the default is 33060 for X Protocol connections and 3306 for classic MySQL protocol connections.
- *socket*: The path to a Unix socket file or the name of a Windows named pipe. Values are local file paths. In URI-like strings, they must be encoded, using either percent encoding or by surrounding the path with parentheses. Parentheses eliminate the need to percent encode characters such as the `/` directory separator character. For example, to connect as `root@localhost` using the Unix socket `/tmp/mysql.sock`, specify the path using percent encoding as `root@localhost?socket=%2Ftmp%2Fmysql.sock`, or using parentheses as `root@localhost?socket=(/tmp/mysql.sock)`.
- *schema*: The default database for the connection. If no database is specified, the connection has no default database.

The handling of `localhost` on Unix depends on the type of transport protocol. Connections using classic MySQL protocol handle `localhost` the same way as other MySQL clients, which means that `localhost` is assumed to be for socket-based connections. For connections using X Protocol, the behavior of `localhost` differs in that it is assumed to represent the loopback address, for example, IPv4 address 127.0.0.1.

Additional Connection parameters

You can specify options for the connection, either as attributes in a URI-like string by appending `?attribute=value`, or as key-value pairs. The following options are available:

- `ssl-mode`: The desired security state for the connection. The following modes are permissible:
 - `DISABLED`
 - `PREFERRED`
 - `REQUIRED`
 - `VERIFY_CA`
 - `VERIFY_IDENTITY`

**Important**

`VERIFY_CA` and `VERIFY_IDENTITY` are better choices than the default `PREFERRED`, because they help prevent man-in-the-middle attacks.

For information about these modes, see the `--ssl-mode` option description in [Command Options for Encrypted Connections](#).

- `ssl-ca`: The path to the X.509 certificate authority file in PEM format.
- `ssl-capath`: The path to the directory that contains the X.509 certificates authority files in PEM format.
- `ssl-cert`: The path to the X.509 certificate file in PEM format.
- `ssl-cipher`: The encryption cipher to use for connections that use TLS protocols up through TLSv1.2.
- `ssl-crl`: The path to the file that contains certificate revocation lists in PEM format.
- `ssl-crlpath`: The path to the directory that contains certificate revocation-list files in PEM format.
- `ssl-key`: The path to the X.509 key file in PEM format.
- `tls-version`: The TLS protocols permitted for classic MySQL protocol encrypted connections. This option is supported by MySQL Shell only. The value of `tls-version` (singular) is a comma separated list, for example `TLSv1.2,TLSv1.3`. For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#). This option depends on the `ssl-mode` option not being set to `DISABLED`.
- `tls-versions`: The permissible TLS protocols for encrypted X Protocol connections. The value of `tls-versions` (plural) is an array such as `[TLSv1.2,TLSv1.3]`. For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#). This option depends on the `ssl-mode` option not being set to `DISABLED`.
- `tls-ciphersuites`: The permitted TLS cipher suites. The value of `tls-ciphersuites` is a list of IANA cipher suite names as listed at [TLS Ciphersuites](#). For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#). This option depends on the `ssl-mode` option not being set to `DISABLED`.
- `auth-method`: The authentication method to use for the connection. The default is `AUTO`, meaning that the server attempts to guess. The following methods are permissible:
 - `AUTO`
 - `MYSQL41`
 - `SHA256_MEMORY`
 - `FROM_CAPABILITIES`

- `FALLBACK`
- `PLAIN`

For X Protocol connections, any configured `auth-method` is overridden to this sequence of authentication methods: `MYSQL41`, `SHA256_MEMORY`, `PLAIN`.

- `get-server-public-key`: Request from the server the public key required for RSA key pair-based password exchange. Use when connecting to MySQL 8+ servers over classic MySQL protocol with SSL mode `DISABLED`. You must specify the protocol in this case. For example:

```
mysql://user@localhost:3306?get-server-public-key=true
```

This option applies to clients that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `get-server-public-key`.

For information about the `caching_sha2_password` plugin, see [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

- `server-public-key-path`: The path name to a file in PEM format containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. Use when connecting to MySQL 8+ servers over classic MySQL protocol with SSL mode `DISABLED`.

This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `get-server-public-key`.

For information about the `sha256_password` and `caching_sha2_password` plugins, see [Section 8.4.1.3, “SHA-256 Pluggable Authentication”](#), and [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

- `ssh`: The URI for connection to an SSH server to access a MySQL server instance using SSH tunneling. The URI format is `[user@]host[:port]`. Use the `uri` option to specify the URI of the target MySQL server instance. For information on SSH tunnel connections from MySQL Shell, see [Using an SSH Tunnel](#).
- `uri`: The URI for a MySQL server instance that is to be accessed through an SSH tunnel from the server specified by the `ssh` option. The URI format is `[scheme://][user@]host[:port]`. Do not use the base connection parameters (`scheme`, `user`, `host`, `port`) to specify the MySQL server connection for SSH tunneling, just use the `uri` option.
- `ssh-password`: The password for the connection to the SSH server.

Warning

Specifying an explicit password in the connection specification is insecure and not recommended. MySQL Shell prompts for a password interactively when one is required.

- `ssh-config-file`: The SSH configuration file for the connection to the SSH server. You can use the MySQL Shell configuration option `ssh.configFile` to set a custom file as the default if

this option is not specified. If `ssh.configFile` has not been set, the default is the standard SSH configuration file `~/.ssh/config`.

- `ssh-identity-file`: The identity file to use for the connection to the SSH server. The default if this option is not specified is any identity file configured in an SSH agent (if used), or in the SSH configuration file, or the standard private key file in the SSH configuration folder (`~/.ssh/id_rsa`).
- `ssh-identity-pass`: The passphrase for the identity file specified by the `ssh-identity-file` option.

Warning

Specifying an explicit password in the connection specification is insecure and not recommended. MySQL Shell prompts for a password interactively when one is required.

- `connect-timeout`: An integer value used to configure the number of seconds that clients, such as MySQL Shell, wait until they stop trying to connect to an unresponsive MySQL server.
- `compression`: This option requests or disables compression for the connection.

The values available for this option are: `required`, which requests compression and fails if the server does not support it; `preferred`, which requests compression and falls back to an uncompressed connection; and `disabled`, which requests an uncompressed connection and fails if the server does not permit those. `preferred` is the default for X Protocol connections, and `disabled` is the default for classic MySQL protocol connections. For information on X Plugin connection compression control, see [Section 22.5.5, “Connection Compression with X Plugin”](#).

Note

Different MySQL clients implement their support for connection compression differently. Consult your client's documentation for details.

- `compression-algorithms` and `compression-level`: These options are available in MySQL Shell for more control over connection compression. You can specify them to select the compression algorithm used for the connection, and the numeric compression level used with that algorithm. You can also use `compression-algorithms` in place of `compression` to request compression for the connection. For information on MySQL Shell's connection compression control, see [Using Compressed Connections](#).
- `connection-attributes`: Controls the key-value pairs that application programs pass to the server at connect time. For general information about connection attributes, see [Section 29.12.9, “Performance Schema Connection Attribute Tables”](#). Clients usually define a default set of attributes, which can be disabled or enabled. For example:

```
mysqlx://user@host?connection-attributes
mysqlx://user@host?connection-attributes=true
mysqlx://user@host?connection-attributes=false
```

The default behavior is to send the default attribute set. Applications can specify attributes to be passed in addition to the default attributes. You specify additional connection attributes as a `connection-attributes` parameter in a connection string. The `connection-attributes` parameter value must be empty (the same as specifying `true`), a Boolean value (`true` or `false` to enable or disable the default attribute set), or a list or zero or more `key=value` specifiers separated by commas (to be sent in addition to the default attribute set). Within a list, a missing key value evaluates as an empty string. Further examples:

```
mysqlx://user@host?connection-attributes=[attr1=val1,attr2,attr3=]
mysqlx://user@host?connection-attributes=[]
```

Application-defined attribute names cannot begin with `_` because such names are reserved for internal attributes.

Connecting Using URI-Like Connection Strings

You can specify a connection to MySQL Server using a URI-like string. Such strings can be used with the MySQL Shell with the `--uri` command option, the MySQL Shell `\connect` command, and MySQL Connectors which implement X DevAPI.

Note

The term “URI-like” signifies connection-string syntax that is similar to but not identical to the URI (uniform resource identifier) syntax defined by [RFC 3986](#).

A URI-like connection string has the following syntax:

```
[scheme://][user[:[password]]@]host[:port][/schema][?attribute1=value1&attribute2=value2...
```

Important

Percent encoding must be used for reserved characters in the elements of the URI-like string. For example, if you specify a string that includes the `@` character, the character must be replaced by `%40`. If you include a zone ID in an IPv6 address, the `%` character used as the separator must be replaced with `%25`.

The parameters you can use in a URI-like connection string are described at [Base Connection Parameters](#).

MySQL Shell's `shell.parseUri()` and `shell.unparseUri()` methods can be used to deconstruct and assemble a URI-like connection string. Given a URI-like connection string, `shell.parseUri()` returns a dictionary containing each element found in the string. `shell.unparseUri()` converts a dictionary of URI components and connection options into a valid URI-like connection string for connecting to MySQL, which can be used in MySQL Shell or by MySQL Connectors which implement X DevAPI.

If no password is specified in the URI-like string, which is recommended, interactive clients prompt for the password. The following examples show how to specify URI-like strings with the user name `user_name`. In each case, the password is prompted for.

- An X Protocol connection to a local server instance listening at port 33065.

```
mysqlx://user_name@localhost:33065
```

- A classic MySQL protocol connection to a local server instance listening at port 3333.

```
mysql://user_name@localhost:3333
```

- An X Protocol connection to a remote server instance, using a host name, an IPv4 address, and an IPv6 address.

```
mysqlx://user_name@server.example.com/
mysqlx://user_name@198.51.100.14:123
mysqlx://user_name@[2001:db8:85a3:8d3:1319:8a2e:370:7348]
```

- An X Protocol connection using a socket, with the path provided using either percent encoding or parentheses.

```
mysqlx://user_name@/path%2Fto%2Fsocket.sock
mysqlx://user_name@(/path/to/socket.sock)
```

- An optional path can be specified, which represents a database.

```
# use 'world' as the default database
mysqlx://user_name@198.51.100.1/world

# use 'world_x' as the default database, encoding _ as %5F
mysqlx://user_name@198.51.100.2:33060/world%5Fx
```

- An optional query can be specified, consisting of values each given as a *key=value* pair or as a single *key*. To specify multiple values, separate them by `,` characters. A mix of *key=value* and *key* values is permissible. Values can be of type list, with list values ordered by appearance. Strings must be either percent encoded or surrounded by parentheses. The following are equivalent.

```
ssluser@127.0.0.1?ssl-ca=%2Froot%2Fclientcert%2Fca-cert.pem\
&ssl-cert=%2Froot%2Fclientcert%2Fclient-cert.pem\
&ssl-key=%2Froot%2Fclientcert%2Fclient-key

ssluser@127.0.0.1?ssl-ca=(/root/clientcert/ca-cert.pem)\
&ssl-cert=(/root/clientcert/client-cert.pem)\
&ssl-key=(/root/clientcert/client-key)
```

- To specify a TLS version and ciphersuite to use for encrypted connections:

```
mysql://user_name@198.51.100.2:3306/world%5Fx?\
tls-versions=[TLSv1.2,TLSv1.3]&tls-ciphersuites=[TLS_DHE_PSK_WITH_AES_128_\
GCM_SHA256, TLS_CHACHA20_POLY1305_SHA256]
```

The previous examples assume that connections require a password. With interactive clients, the specified user's password is requested at the login prompt. If the user account has no password (which is insecure and not recommended), or if socket peer-credential authentication is in use (for example, with Unix socket connections), you must explicitly specify in the connection string that no password is being provided and the password prompt is not required. To do this, place a `:` after the *user_name* in the string but do not specify a password after it. For example:

```
mysqlx://user_name:@localhost
```

Connecting Using Key-Value Pairs

In MySQL Shell and some MySQL Connectors which implement X DevAPI, you can specify a connection to MySQL Server using key-value pairs, supplied in language-natural constructs for the implementation. For example, you can supply connection parameters using key-value pairs as a JSON object in JavaScript, or as a dictionary in Python. Regardless of the way the key-value pairs are supplied, the concept remains the same: the keys as described in this section can be assigned values that are used to specify a connection. You can specify connections using key-value pairs in MySQL Shell's `shell.connect()` method or InnoDB Cluster's `dba.createCluster()` method, and with some of the MySQL Connectors which implement X DevAPI.

Generally, key-value pairs are surrounded by `{` and `}` characters and the `,` character is used as a separator between key-value pairs. The `:` character is used between keys and values, and strings must be delimited (for example, using the `'` character). It is not necessary to percent encode strings, unlike URI-like connection strings.

A connection specified as key-value pairs has the following format:

```
{ key: value, key: value, ... }
```

The parameters you can use as keys for a connection are described at [Base Connection Parameters](#).

If no password is specified in the key-value pairs, which is recommended, interactive clients prompt for the password. The following examples show how to specify connections using key-value pairs with the user name '*user_name*'. In each case, the password is prompted for.

- An X Protocol connection to a local server instance listening at port 33065.

```
{user:'user_name', host:'localhost', port:33065}
```

- A classic MySQL protocol connection to a local server instance listening at port 3333.

```
{user:'user_name', host:'localhost', port:3333}
```

- An X Protocol connection to a remote server instance, using a host name, an IPv4 address, and an IPv6 address.

```
{user:'user_name', host:'server.example.com'}
{user:'user_name', host:198.51.100.14:123}
{user:'user_name', host:[2001:db8:85a3:8d3:1319:8a2e:370:7348]}
```

- An X Protocol connection using a socket.

```
{user:'user_name', socket:'/path/to/socket/file'}
```

- An optional schema can be specified, which represents a database.

```
{user:'user_name', host:'localhost', schema:'world'}
```

The previous examples assume that connections require a password. With interactive clients, the specified user's password is requested at the login prompt. If the user account has no password (which is insecure and not recommended), or if socket peer-credential authentication is in use (for example, with Unix socket connections), you must explicitly specify that no password is being provided and the password prompt is not required. To do this, provide an empty string using `' '` after the `password` key. For example:

```
{user:'user_name', password:'', host:'localhost'}
```

6.2.6 Connecting to the Server Using DNS SRV Records

In the Domain Name System (DNS), a SRV record (service location record) is a type of resource record that enables a client to specify a name that indicates a service, protocol, and domain. A DNS lookup on the name returns a reply containing the names of multiple available servers in the domain that provide the required service. For information about DNS SRV, including how a record defines the preference order of the listed servers, see [RFC 2782](#).

MySQL supports the use of DNS SRV records for connecting to servers. A client that receives a DNS SRV lookup result attempts to connect to the MySQL server on each of the listed hosts in order of preference, based on the priority and weighting assigned to each host by the DNS administrator. A failure to connect occurs only if the client cannot connect to any of the servers.

When multiple MySQL instances, such as a cluster of servers, provide the same service for your applications, DNS SRV records can be used to assist with failover, load balancing, and replication services. It is cumbersome for applications to directly manage the set of candidate servers for connection attempts, and DNS SRV records provide an alternative:

- DNS SRV records enable a DNS administrator to map a single DNS domain to multiple servers. DNS SRV records also can be updated centrally by administrators when servers are added or removed from the configuration or when their host names are changed.
- Central management of DNS SRV records eliminates the need for individual clients to identify each possible host in connection requests, or for connections to be handled by an additional software component. An application can use the DNS SRV record to obtain information about candidate MySQL servers, instead of managing the server information itself.
- DNS SRV records can be used in combination with connection pooling, in which case connections to hosts that are no longer in the current list of DNS SRV records are removed from the pool when they become idle.

MySQL supports use of DNS SRV records to connect to servers in these contexts:

- Several MySQL Connectors implement DNS SRV support; connector-specific options enable requesting DNS SRV record lookup both for X Protocol connections and for classic MySQL protocol connections. For general information, see [Connections Using DNS SRV Records](#). For details, see the documentation for individual MySQL Connectors.
- The C API provides a `mysql_real_connect_dns_srv()` function that is similar to `mysql_real_connect()`, except that the argument list does not specify the particular host of the

MySQL server to connect to. Instead, it names a DNS SRV record that specifies a group of servers. See [mysql_real_connect_dns_srv\(\)](#).

- The `mysql` client has a `--dns-srv-name` option to indicate a DNS SRV record that specifies a group of servers. See [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#).

A DNS SRV name consists of a service, protocol, and domain, with the service and protocol each prefixed by an underscore:

```
_service._protocol.domain
```

The following DNS SRV record identifies multiple candidate servers, such as might be used by clients for establishing X Protocol connections:

Name	TTL	Class	Priority	Weight	Port	Target
_mysqlx._tcp.example.com.	86400	IN	SRV 0	5	33060	server1.example.com.
_mysqlx._tcp.example.com.	86400	IN	SRV 0	10	33060	server2.example.com.
_mysqlx._tcp.example.com.	86400	IN	SRV 10	5	33060	server3.example.com.
_mysqlx._tcp.example.com.	86400	IN	SRV 20	5	33060	server4.example.com.

Here, `mysqlx` indicates the X Protocol service and `tcp` indicates the TCP protocol. A client can request this DNS SRV record using the name `_mysqlx._tcp.example.com`. The particular syntax for specifying the name in the connection request depends on the type of client. For example, a client might support specifying the name within a URI-like connection string or as a key-value pair.

A DNS SRV record for classic protocol connections might look like this:

Name	TTL	Class	Priority	Weight	Port	Target
_mysql._tcp.example.com.	86400	IN	SRV 0	5	3306	server1.example.com.
_mysql._tcp.example.com.	86400	IN	SRV 0	10	3306	server2.example.com.
_mysql._tcp.example.com.	86400	IN	SRV 10	5	3306	server3.example.com.
_mysql._tcp.example.com.	86400	IN	SRV 20	5	3306	server4.example.com.

Here, the name `mysql` designates the classic MySQL protocol service, and the port is 3306 (the default classic MySQL protocol port) rather than 33060 (the default X Protocol port).

When DNS SRV record lookup is used, clients generally must apply these rules for connection requests (there may be client- or connector-specific exceptions):

- The request must specify the full DNS SRV record name, with the service and protocol names prefixed by underscores.
- The request must not specify multiple host names.
- The request must not specify a port number.
- Only TCP connections are supported. Unix socket files, Windows named pipes, and shared memory cannot be used.

For more information on using DNS SRV based connections in X DevAPI, see [Connections Using DNS SRV Records](#).

6.2.7 Connection Transport Protocols

For programs that use the MySQL client library (for example, `mysql` and `mysqldump`), MySQL supports connections to the server based on several transport protocols: TCP/IP, Unix socket file, named pipe, and shared memory. This section describes how to select these protocols, and how they are similar and different.

- [Transport Protocol Selection](#)
- [Transport Support for Local and Remote Connections](#)
- [Interpretation of localhost](#)

- [Encryption and Security Characteristics](#)
- [Connection Compression](#)

Transport Protocol Selection

For a given connection, if the transport protocol is not specified explicitly, it is determined implicitly. For example, connections to `localhost` result in a socket file connection on Unix and Unix-like systems, and a TCP/IP connection to `127.0.0.1` otherwise. For additional information, see [Section 6.2.4](#), “Connecting to the MySQL Server Using Command Options”.

To specify the protocol explicitly, use the `--protocol` command option. The following table shows the permissible values for `--protocol` and indicates the applicable platforms for each value. The values are not case-sensitive.

<code>--protocol</code> Value	Transport Protocol Used	Applicable Platforms
<code>TCP</code>	TCP/IP	All
<code>SOCKET</code>	Unix socket file	Unix and Unix-like systems
<code>PIPE</code>	Named pipe	Windows
<code>MEMORY</code>	Shared memory	Windows

Transport Support for Local and Remote Connections

TCP/IP transport supports connections to local or remote MySQL servers.

Socket-file, named-pipe, and shared-memory transports support connections only to local MySQL servers. (Named-pipe transport does allow for remote connections, but this capability is not implemented in MySQL.)

Interpretation of `localhost`

If the transport protocol is not specified explicitly, `localhost` is interpreted as follows:

- On Unix and Unix-like systems, a connection to `localhost` results in a socket-file connection.
- Otherwise, a connection to `localhost` results in a TCP/IP connection to `127.0.0.1`.

If the transport protocol is specified explicitly, `localhost` is interpreted with respect to that protocol. For example, with `--protocol=TCP`, a connection to `localhost` results in a TCP/IP connection to `127.0.0.1` on all platforms.

Encryption and Security Characteristics

TCP/IP and socket-file transports are subject to TLS/SSL encryption, using the options described in [Command Options for Encrypted Connections](#). Named-pipe and shared-memory transports are not subject to TLS/SSL encryption.

A connection is secure by default if made over a transport protocol that is secure by default. Otherwise, for protocols that are subject to TLS/SSL encryption, a connection may be made secure using encryption:

- TCP/IP connections are not secure by default, but can be encrypted to make them secure.
- Socket-file connections are secure by default. They can also be encrypted, but encrypting a socket-file connection makes it no more secure and increases CPU load.
- Named-pipe connections are not secure by default, and are not subject to encryption to make them secure. However, the `named_pipe_full_access_group` system variable is available to control which MySQL users are permitted to use named-pipe connections.

- Shared-memory connections are secure by default.

If the `require_secure_transport` system variable is enabled, the server permits only connections that use some form of secure transport. Per the preceding remarks, connections that use TCP/IP encrypted using TLS/SSL, a socket file, or shared memory are secure connections. TCP/IP connections not encrypted using TLS/SSL and named-pipe connections are not secure.

See also [Configuring Encrypted Connections as Mandatory](#).

Connection Compression

All transport protocols are subject to use of compression on the traffic between the client and server. If both compression and encryption are used for a given connection, compression occurs before encryption. For more information, see [Section 6.2.8, “Connection Compression Control”](#).

6.2.8 Connection Compression Control

Connections to the server can use compression on the traffic between client and server to reduce the number of bytes sent over the connection. By default, connections are uncompressed, but can be compressed if the server and the client agree on a mutually permitted compression algorithm.

Compressed connections originate on the client side but affect CPU load on both the client and server sides because both sides perform compression and decompression operations. Because enabling compression decreases performance, its benefits occur primarily when there is low network bandwidth, network transfer time dominates the cost of compression and decompression operations, and result sets are large.

This section describes the available compression-control configuration parameters and the information sources available for monitoring use of compression. It applies to classic MySQL protocol connections.

Compression control applies to connections to the server by client programs and by servers participating in source/replica replication or Group Replication. Compression control does not apply to connections for `FEDERATED` tables. In the following discussion, “client connection” is shorthand for a connection to the server originating from any source for which compression is supported, unless context indicates a specific connection type.

Note

X Protocol connections to a MySQL Server instance support compression, but compression for X Protocol connections operates independently from the compression for classic MySQL protocol connections described here, and is controlled separately. See [Section 22.5.5, “Connection Compression with X Plugin”](#) for information on X Protocol connection compression.

- [Configuring Connection Compression](#)
- [Configuring Legacy Connection Compression](#)
- [Monitoring Connection Compression](#)

Configuring Connection Compression

These configuration parameters are available for controlling connection compression:

- The `protocol_compression_algorithms` system variable configures which compression algorithms the server permits for incoming connections.
- The `--compression-algorithms` and `--zstd-compression-level` command-line options configure permitted compression algorithms and `zstd` compression level for these client programs: `mysql`, `mysqladmin`, `mysqlbinlog`, `mysqlcheck`, `mysqldump`, `mysqlimport`, `mysqlpump`,

`mysqlshow`, `mysqlslap`, and `mysqltest`, and `mysql_upgrade`. MySQL Shell also offers these command-line options.

- The `MYSQL_OPT_COMPRESSION_ALGORITHMS` and `MYSQL_OPT_ZSTD_COMPRESSION_LEVEL` options for the `mysql_options()` function configure permitted compression algorithms and `zstd` compression level for client programs that use the MySQL C API.
- The `SOURCE_COMPRESSION_ALGORITHMS` and `SOURCE_ZSTD_COMPRESSION_LEVEL` options for the `CHANGE REPLICATION SOURCE TO` statement configure permitted compression algorithms and `zstd` compression level for replica servers participating in source/replica replication.
- The `group_replication_recovery_compression_algorithms` and `group_replication_recovery_zstd_compression_level` system variables configure permitted compression algorithms and `zstd` compression level for Group Replication recovery connections when a new member joins a group and connects to a donor.

Configuration parameters that enable specifying compression algorithms are string-valued and take a list of one or more comma-separated compression algorithm names, in any order, chosen from the following items (not case-sensitive):

- `zlib`: Permit connections that use the `zlib` compression algorithm.
- `zstd`: Permit connections that use the `zstd` compression algorithm.
- `uncompressed`: Permit uncompressed connections.

Note

Because `uncompressed` is an algorithm name that may or may not be configured, it is possible to configure MySQL *not* to permit uncompressed connections.

Examples:

- To configure which compression algorithms the server permits for incoming connections, set the `protocol_compression_algorithms` system variable. By default, the server permits all available algorithms. To configure that setting explicitly at startup, use these lines in the server `my.cnf` file:

```
[mysqld]
protocol_compression_algorithms=zlib,zstd,uncompressed
```

To set and persist the `protocol_compression_algorithms` system variable to that value at runtime, use this statement:

```
SET PERSIST protocol_compression_algorithms='zlib,zstd,uncompressed';
```

`SET PERSIST` sets a value for the running MySQL instance. It also saves the value, causing it to carry over to subsequent server restarts. To change the value for the running MySQL instance without having it carry over to subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`. See [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#).

- To permit only incoming connections that use `zstd` compression, configure the server at startup like this:

```
[mysqld]
protocol_compression_algorithms=zstd
```

Or, to make the change at runtime:

```
SET PERSIST protocol_compression_algorithms='zstd';
```

- To permit the `mysql` client to initiate `zlib` or `uncompressed` connections, invoke it like this:

```
mysql --compression-algorithms=zlib,uncompressed
```

- To configure replicas to connect to the source using `zlib` or `zstd` connections, with a compression level of 7 for `zstd` connections, use a `CHANGE REPLICATION SOURCE TO` statement:

```
CHANGE REPLICATION SOURCE TO
SOURCE_COMPRESSION_ALGORITHMS = 'zlib,zstd',
SOURCE_ZSTD_COMPRESSION_LEVEL = 7;
```

This assumes that the `replica_compressed_protocol` system variable is disabled, for reasons described in [Configuring Legacy Connection Compression](#).

For successful connection setup, both sides of the connection must agree on a mutually permitted compression algorithm. The algorithm-negotiation process attempts to use `zlib`, then `zstd`, then `uncompressed`. If the two sides can find no common algorithm, the connection attempt fails.

Because both sides must agree on the compression algorithm, and because `uncompressed` is an algorithm value that is not necessarily permitted, fallback to an uncompressed connection does not necessarily occur. For example, if the server is configured to permit `zstd` and a client is configured to permit `zlib,uncompressed`, the client cannot connect at all. In this case, no algorithm is common to both sides, so connection attempts fail.

Configuration parameters that enable specifying the `zstd` compression level take an integer value from 1 to 22, with larger values indicating increasing levels of compression. The default `zstd` compression level is 3. The compression level setting has no effect on connections that do not use `zstd` compression.

A configurable `zstd` compression level enables choosing between less network traffic and higher CPU load versus more network traffic and lower CPU load. Higher compression levels reduce network congestion but the additional CPU load may reduce server performance.

Configuring Legacy Connection Compression

Prior to MySQL 8.0.18, these configuration parameters are available for controlling connection compression:

- Client programs support a `--compress` command-line option to specify use of compression for the connection to the server.
- For programs that use the MySQL C API, enabling the `MYSQL_OPT_COMPRESS` option for the `mysql_options()` function specifies use of compression for the connection to the server.
- For source/replica replication, enabling the system variable `replica_compressed_protocol` specifies use of compression for replica connections to the source.

In each case, when use of compression is specified, the connection uses the `zlib` compression algorithm if both sides permit it, with fallback to an uncompressed connection otherwise.

As of MySQL 8.0.18, the compression parameters just described become legacy parameters, due to the additional compression parameters introduced for more control over connection compression that are described in [Configuring Connection Compression](#). An exception is MySQL Shell, where the `--compress` command-line option remains current, and can be used to request compression without selecting compression algorithms. For information on MySQL Shell's connection compression control, see [Using Compressed Connections](#).

The legacy compression parameters interact with the newer parameters and their semantics change as follows:

- The meaning of the legacy `--compress` option depends on whether `--compression-algorithms` is specified:

- When `--compression-algorithms` is not specified, `--compress` is equivalent to specifying a client-side algorithm set of `zlib,uncompressed`.
- When `--compression-algorithms` is specified, `--compress` is equivalent to specifying an algorithm set of `zlib` and the full client-side algorithm set is the union of `zlib` plus the algorithms specified by `--compression-algorithms`. For example, with both `--compress` and `--compression-algorithms=zlib,zstd`, the permitted-algorithm set is `zlib` plus `zlib,zstd`; that is, `zlib,zstd`. With both `--compress` and `--compression-algorithms=zstd,uncompressed`, the permitted-algorithm set is `zlib` plus `zstd,uncompressed`; that is, `zlib,zstd,uncompressed`.
- The same type of interaction occurs between the legacy `MYSQL_OPT_COMPRESS` option and the `MYSQL_OPT_COMPRESSION_ALGORITHMS` option for the `mysql_options()` C API function.
- If the `replica_compressed_protocol` system variable is enabled, it takes precedence over `SOURCE_COMPRESSION_ALGORITHMS` and connections to the source use `zlib` compression if both source and replica permit that algorithm. If `replica_compressed_protocol` is disabled, the value of `SOURCE_COMPRESSION_ALGORITHMS` applies.

Monitoring Connection Compression

The `Compression` status variable is `ON` or `OFF` to indicate whether the current connection uses compression.

The `mysql` client `\status` command displays a line that says `Protocol: Compressed` if compression is enabled for the current connection. If that line is not present, the connection is uncompressed.

The MySQL Shell `\status` command displays a `Compression:` line that says `Disabled` or `Enabled` to indicate whether the connection is compressed.

These additional sources of information are available for monitoring connection compression:

- To monitor compression in use for client connections, use the `Compression_algorithm` and `Compression_level` status variables. For the current connection, their values indicate the compression algorithm and compression level, respectively.
- To determine which compression algorithms the server is configured to permit for incoming connections, check the `protocol_compression_algorithms` system variable.
- For source/replica replication connections, the configured compression algorithms and compression level are available from multiple sources:
 - The Performance Schema `replication_connection_configuration` table has `COMPRESSION_ALGORITHMS` and `ZSTD_COMPRESSION_LEVEL` columns.
 - The `mysql.slave_master_info` system table has `Master_compression_algorithms` and `Master_zstd_compression_level` columns. If the `master.info` file exists, it contains lines for those values as well.

6.2.9 Setting Environment Variables

Environment variables can be set at the command prompt to affect the current invocation of your command processor, or set permanently to affect future invocations. To set a variable permanently, you can set it in a startup file or by using the interface provided by your system for this purpose. Consult the documentation for your command interpreter for specific details. [Section 6.9, “Environment Variables”](#), lists all environment variables that affect MySQL program operation.

To specify a value for an environment variable, use the syntax appropriate for your command processor. For example, on Windows, you can set the `USER` variable to specify your MySQL account name. To do so, use this syntax:

```
SET USER=your_name
```

The syntax on Unix depends on your shell. Suppose that you want to specify the TCP/IP port number using the `MYSQL_TCP_PORT` variable. Typical syntax (such as for `sh`, `ksh`, `bash`, `zsh`, and so on) is as follows:

```
MYSQL_TCP_PORT=3306
export MYSQL_TCP_PORT
```

The first command sets the variable, and the `export` command exports the variable to the shell environment so that its value becomes accessible to MySQL and other processes.

For `csh` and `tcsh`, use `setenv` to make the shell variable available to the environment:

```
setenv MYSQL_TCP_PORT 3306
```

The commands to set environment variables can be executed at your command prompt to take effect immediately, but the settings persist only until you log out. To have the settings take effect each time you log in, use the interface provided by your system or place the appropriate command or commands in a startup file that your command interpreter reads each time it starts.

On Windows, you can set environment variables using the System Control Panel (under Advanced).

On Unix, typical shell startup files are `.bashrc` or `.bash_profile` for `bash`, or `.tcshrc` for `tcsh`.

Suppose that your MySQL programs are installed in `/usr/local/mysql/bin` and that you want to make it easy to invoke these programs. To do this, set the value of the `PATH` environment variable to include that directory. For example, if your shell is `bash`, add the following line to your `.bashrc` file:

```
PATH=${PATH}:/usr/local/mysql/bin
```

`bash` uses different startup files for login and nonlogin shells, so you might want to add the setting to `.bashrc` for login shells and to `.bash_profile` for nonlogin shells to make sure that `PATH` is set regardless.

If your shell is `tcsh`, add the following line to your `.tcshrc` file:

```
setenv PATH ${PATH}:/usr/local/mysql/bin
```

If the appropriate startup file does not exist in your home directory, create it with a text editor.

After modifying your `PATH` setting, open a new console window on Windows or log in again on Unix so that the setting goes into effect.

6.3 Server and Server-Startup Programs

This section describes `mysqld`, the MySQL server, and several programs that are used to start the server.

6.3.1 `mysqld` — The MySQL Server

`mysqld`, also known as MySQL Server, is a single multithreaded program that does most of the work in a MySQL installation. It does not spawn additional processes. MySQL Server manages access to the MySQL data directory that contains databases and tables. The data directory is also the default location for other information such as log files and status files.

Note

Some installation packages contain a debugging version of the server named `mysqld-debug`. Invoke this version instead of `mysqld` for debugging support, memory allocation checking, and trace file support (see [Section 7.9.1.2, “Creating Trace Files”](#)).

When MySQL server starts, it listens for network connections from client programs and manages access to databases on behalf of those clients.

The `mysqld` program has many options that can be specified at startup. For a complete list of options, run this command:

```
mysqld --verbose --help
```

MySQL Server also has a set of system variables that affect its operation as it runs. System variables can be set at server startup, and many of them can be changed at runtime to effect dynamic server reconfiguration. MySQL Server also has a set of status variables that provide information about its operation. You can monitor these status variables to access runtime performance characteristics.

For a full description of MySQL Server command options, system variables, and status variables, see [Section 7.1, “The MySQL Server”](#). For information about installing MySQL and setting up the initial configuration, see [Chapter 2, *Installing MySQL*](#).

6.3.2 `mysqld_safe` — MySQL Server Startup Script

`mysqld_safe` is the recommended way to start a `mysqld` server on Unix. `mysqld_safe` adds some safety features such as restarting the server when an error occurs and logging runtime information to an error log. A description of error logging is given later in this section.

Note

For some Linux platforms, MySQL installation from RPM or Debian packages includes systemd support for managing MySQL server startup and shutdown. On these platforms, `mysqld_safe` is not installed because it is unnecessary. For more information, see [Section 2.5.9, “Managing MySQL Server with systemd”](#).

One implication of the non-use of `mysqld_safe` on platforms that use systemd for server management is that use of `[mysqld_safe]` or `[safe_mysqld]` sections in option files is not supported and might lead to unexpected behavior.

`mysqld_safe` tries to start an executable named `mysqld`. To override the default behavior and specify explicitly the name of the server you want to run, specify a `--mysqld` or `--mysqld-version` option to `mysqld_safe`. You can also use `--ledir` to indicate the directory where `mysqld_safe` should look for the server.

Many of the options to `mysqld_safe` are the same as the options to `mysqld`. See [Section 7.1.7, “Server Command Options”](#).

Options unknown to `mysqld_safe` are passed to `mysqld` if they are specified on the command line, but ignored if they are specified in the `[mysqld_safe]` group of an option file. See [Section 6.2.2.2, “Using Option Files”](#).

`mysqld_safe` reads all options from the `[mysqld]`, `[server]`, and `[mysqld_safe]` sections in option files. For example, if you specify a `[mysqld]` section like this, `mysqld_safe` finds and uses the `--log-error` option:

```
[mysqld]
log-error=error.log
```

For backward compatibility, `mysqld_safe` also reads `[safe_mysqld]` sections, but to be current you should rename such sections to `[mysqld_safe]`.

`mysqld_safe` accepts options on the command line and in option files, as described in the following table. For information about option files used by MySQL programs, see [Section 6.2.2.2, “Using Option Files”](#).

Table 6.7 mysql_safe Options

Option Name	Description
<code>--basedir</code>	Path to MySQL installation directory
<code>--core-file-size</code>	Size of core file that mysqld should be able to create
<code>--datadir</code>	Path to data directory
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files
<code>--defaults-file</code>	Read only named option file
<code>--help</code>	Display help message and exit
<code>--ledir</code>	Path to directory where server is located
<code>--log-error</code>	Write error log to named file
<code>--malloc-lib</code>	Alternative malloc library to use for mysqld
<code>--mysqld</code>	Name of server program to start (in ledir directory)
<code>--mysqld-safe-log-timestamps</code>	Timestamp format for logging
<code>--mysqld-version</code>	Suffix for server program name
<code>--nice</code>	Use nice program to set server scheduling priority
<code>--no-defaults</code>	Read no option files
<code>--open-files-limit</code>	Number of files that mysqld should be able to open
<code>--pid-file</code>	Path name of server process ID file
<code>--plugin-dir</code>	Directory where plugins are installed
<code>--port</code>	Port number on which to listen for TCP/IP connections
<code>--skip-kill-mysqld</code>	Do not try to kill stray mysqld processes
<code>--skip-syslog</code>	Do not write error messages to syslog; use error log file
<code>--socket</code>	Socket file on which to listen for Unix socket connections
<code>--syslog</code>	Write error messages to syslog
<code>--syslog-tag</code>	Tag suffix for messages written to syslog
<code>--timezone</code>	Set TZ time zone environment variable to named value
<code>--user</code>	Run mysqld as user having name user_name or numeric user ID user_id

- `--help`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display a help message and exit.

- `--basedir=dir_name`

Command-Line Format	<code>--basedir=dir_name</code>
Type	Directory name

The path to the MySQL installation directory.

- `--core-file-size=size`

Command-Line Format	<code>--core-file-size=size</code>
Type	String

The size of the core file that `mysqld` should be able to create. The option value is passed to `ulimit -c`.

Note

The `innodb_buffer_pool_in_core_file` variable can be used to reduce the size of core files on operating systems that support it. For more information, see [Section 17.8.3.7, “Excluding Buffer Pool Pages from Core Files”](#).

- `--datadir=dir_name`

Command-Line Format	<code>--datadir=dir_name</code>
Type	Directory name

The path to the data directory.

- `--defaults-extra-file=file_name`

Command-Line Format	<code>--defaults-extra-file=file_name</code>
Type	File name

Read this option file in addition to the usual option files. If the file does not exist or is otherwise inaccessible, the server exits with an error. If `file_name` is not an absolute path name, it is interpreted relative to the current directory. This must be the first option on the command line if it is used.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-file=file_name`

Command-Line Format	<code>--defaults-file=file_name</code>
Type	File name

Use only the given option file. If the file does not exist or is otherwise inaccessible, the server exits with an error. If `file_name` is not an absolute path name, it is interpreted relative to the current directory. This must be the first option on the command line if it is used.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--ledir=dir_name`

Command-Line Format	<code>--ledir=dir_name</code>
Type	Directory name

If `mysql_safe` cannot find the server, use this option to indicate the path name to the directory where the server is located.

This option is accepted only on the command line, not in option files. On platforms that use `systemd`, the value can be specified in the value of `MYSQLD_OPTS`. See [Section 2.5.9, “Managing MySQL Server with systemd”](#).

- `--log-error=file_name`

Command-Line Format	<code>--log-error=file_name</code>
Type	File name

Write the error log to the given file. See [Section 7.4.2, “The Error Log”](#).

- `--mysqld-safe-log-timestamps`

Command-Line Format	<code>--mysqld-safe-log-timestamps=type</code>
Type	Enumeration
Default Value	<code>utc</code>
Valid Values	<code>system</code> <code>hyphen</code> <code>legacy</code>

This option controls the format for timestamps in log output produced by `mysql_safe`. The following list describes the permitted values. For any other value, `mysql_safe` logs a warning and uses `UTC` format.

- `UTC`, `utc`

ISO 8601 UTC format (same as `--log_timestamps=UTC` for the server). This is the default.

- `SYSTEM`, `system`

ISO 8601 local time format (same as `--log_timestamps=SYSTEM` for the server).

- `HYPHEN`, `hyphen`

`YY-MM-DD h:mm:ss` format, as in `mysql_safe` for MySQL 5.6.

- `LEGACY`, `legacy`

`YYMMDD hh:mm:ss` format, as in `mysql_safe` prior to MySQL 5.6.

- `--malloc-lib=[lib_name]`

Command-Line Format	<code>--malloc-lib=[lib_name]</code>
---------------------	--------------------------------------

Type	String
------	--------

The name of the library to use for memory allocation instead of the system `malloc()` library. The option value must be one of the directories `/usr/lib`, `/usr/lib64`, `/usr/lib/i386-linux-gnu`, or `/usr/lib/x86_64-linux-gnu`.

The `--malloc-lib` option works by modifying the `LD_PRELOAD` environment value to affect dynamic linking to enable the loader to find the memory-allocation library when `mysqld` runs:

- If the option is not given, or is given without a value (`--malloc-lib=`), `LD_PRELOAD` is not modified and no attempt is made to use `tcmalloc`.
- Prior to MySQL 8.0.21, if the option is given as `--malloc-lib=tcmalloc`, `mysqld_safe` looks for a `tcmalloc` library in `/usr/lib`. If `tcmalloc` is found, its path name is added to the beginning of the `LD_PRELOAD` value for `mysqld`. If `tcmalloc` is not found, `mysqld_safe` aborts with an error.

As of MySQL 8.0.21, `tcmalloc` is not a permitted value for the `--malloc-lib` option.

- If the option is given as `--malloc-lib=/path/to/some/library`, that full path is added to the beginning of the `LD_PRELOAD` value. If the full path points to a nonexistent or unreadable file, `mysqld_safe` aborts with an error.
- For cases where `mysqld_safe` adds a path name to `LD_PRELOAD`, it adds the path to the beginning of any existing value the variable already has.

Note

On systems that manage the server using `systemd`, `mysqld_safe` is not available. Instead, specify the allocation library by setting `LD_PRELOAD` in `/etc/sysconfig/mysql`.

Linux users can use the `libtcmalloc_minimal.so` library on any platform for which a `tcmalloc` package is installed in `/usr/lib` by adding these lines to the `my.cnf` file:

```
[mysqld_safe]
malloc-lib=tcmalloc
```

To use a specific `tcmalloc` library, specify its full path name. Example:

```
[mysqld_safe]
malloc-lib=/opt/lib/libtcmalloc_minimal.so
```

- `--mysqld=prog_name`

Command-Line Format	<code>--mysqld=file_name</code>
Type	File name

The name of the server program (in the `ledir` directory) that you want to start. This option is needed if you use the MySQL binary distribution but have the data directory outside of the binary distribution. If `mysqld_safe` cannot find the server, use the `--ledir` option to indicate the path name to the directory where the server is located.

This option is accepted only on the command line, not in option files. On platforms that use `systemd`, the value can be specified in the value of `MYSQLD_OPTS`. See [Section 2.5.9, “Managing MySQL Server with systemd”](#).

- `--mysqld-version=suffix`

Command-Line Format	<code>--mysqld-version=suffix</code>
Type	String

This option is similar to the `--mysqld` option, but you specify only the suffix for the server program name. The base name is assumed to be `mysqld`. For example, if you use `--mysqld-version=debug`, `mysqld_safe` starts the `mysqld-debug` program in the `ledir` directory. If the argument to `--mysqld-version` is empty, `mysqld_safe` uses `mysqld` in the `ledir` directory.

This option is accepted only on the command line, not in option files. On platforms that use `systemd`, the value can be specified in the value of `MYSQLD_OPTS`. See [Section 2.5.9, “Managing MySQL Server with systemd”](#).

- `--nice=priority`

Command-Line Format	<code>--nice=priority</code>
Type	Numeric

Use the `nice` program to set the server's scheduling priority to the given value.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
Type	String

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read. This must be the first option on the command line if it is used.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--open-files-limit=count`

Command-Line Format	<code>--open-files-limit=count</code>
Type	String

The number of files that `mysqld` should be able to open. The option value is passed to `ulimit -n`.

Note

You must start `mysqld_safe` as `root` for this to function properly.

- `--pid-file=file_name`

Command-Line Format	<code>--pid-file=file_name</code>
Type	File name

- `--plugin-dir=dir_name`

Command-Line Format	<code>--plugin-dir=dir_name</code>
Type	Directory name

The path name of the plugin directory.

- `--port=port_num`

Command-Line Format	<code>--port=number</code>
Type	Numeric

The port number that the server should use when listening for TCP/IP connections. The port number must be 1024 or higher unless the server is started by the `root` operating system user.

- `--skip-kill-mysqld`

Command-Line Format	<code>--skip-kill-mysqld</code>
---------------------	---------------------------------

Do not try to kill stray `mysqld` processes at startup. This option works only on Linux.

- `--socket=path`

Command-Line Format	<code>--socket=file_name</code>
Type	File name

The Unix socket file that the server should use when listening for local connections.

- `--syslog`, `--skip-syslog`

Command-Line Format	<code>--syslog</code>
Deprecated	Yes

Command-Line Format	<code>--skip-syslog</code>
Deprecated	Yes

`--syslog` causes error messages to be sent to `syslog` on systems that support the `logger` program. `--skip-syslog` suppresses the use of `syslog`; messages are written to an error log file.

When `syslog` is used for error logging, the `daemon.err` facility/severity is used for all log messages.

Using these options to control `mysqld` logging is deprecated. To write error log output to the system log, use the instructions at [Section 7.4.2.8, “Error Logging to the System Log”](#). To control the facility, use the server `log_syslog_facility` system variable.

- `--syslog-tag=tag`

Deprecated	Yes
------------	-----

For logging to `syslog`, messages from `mysqld_safe` and `mysqld` are written with identifiers of `mysqld_safe` and `mysqld`, respectively. To specify a suffix for the identifiers, use `--syslog-tag=tag`, which modifies the identifiers to be `mysqld_safe-tag` and `mysqld-tag`.

Using this option to control `mysqld` logging is deprecated. Use the server `log_syslog_tag` system variable instead. See [Section 7.4.2.8, “Error Logging to the System Log”](#).

- `--timezone=timezone`

Command-Line Format	<code>--timezone=timezone</code>
Type	String

Set the `TZ` time zone environment variable to the given option value. Consult your operating system documentation for legal time zone specification formats.

- `--user={user_name|user_id}`

Command-Line Format	<code>--user={user_name user_id}</code>
Type	String
Type	Numeric

Run the `mysqld` server as the user having the name `user_name` or the numeric user ID `user_id`. (“User” in this context refers to a system login account, not a MySQL user listed in the grant tables.)

If you execute `mysqld_safe` with the `--defaults-file` or `--defaults-extra-file` option to name an option file, the option must be the first one given on the command line or the option file is not used. For example, this command does not use the named option file:

```
mysql> mysqld_safe --port=port_num --defaults-file=file_name
```

Instead, use the following command:

```
mysql> mysqld_safe --defaults-file=file_name --port=port_num
```

The `mysqld_safe` script is written so that it normally can start a server that was installed from either a source or a binary distribution of MySQL, even though these types of distributions typically install the server in slightly different locations. (See [Section 2.1.5, “Installation Layouts”](#).) `mysqld_safe` expects one of the following conditions to be true:

- The server and databases can be found relative to the working directory (the directory from which `mysqld_safe` is invoked). For binary distributions, `mysqld_safe` looks under its working directory for `bin` and `data` directories. For source distributions, it looks for `libexec` and `var` directories. This condition should be met if you execute `mysqld_safe` from your MySQL installation directory (for example, `/usr/local/mysql` for a binary distribution).
- If the server and databases cannot be found relative to the working directory, `mysqld_safe` attempts to locate them by absolute path names. Typical locations are `/usr/local/libexec` and `/usr/local/var`. The actual locations are determined from the values configured into the distribution at the time it was built. They should be correct if MySQL is installed in the location specified at configuration time.

Because `mysqld_safe` tries to find the server and databases relative to its own working directory, you can install a binary distribution of MySQL anywhere, as long as you run `mysqld_safe` from the MySQL installation directory:

```
cd mysql_installation_directory
bin/mysqld_safe &
```

If `mysqld_safe` fails, even when invoked from the MySQL installation directory, specify the `--ledir` and `--datadir` options to indicate the directories in which the server and databases are located on your system.

`mysqld_safe` tries to use the `sleep` and `date` system utilities to determine how many times per second it has attempted to start. If these utilities are present and the attempted starts per second is greater than 5, `mysqld_safe` waits 1 full second before starting again. This is intended to prevent excessive CPU usage in the event of repeated failures. (Bug #11761530, Bug #54035)

When you use `mysqld_safe` to start `mysqld`, `mysqld_safe` arranges for error (and notice) messages from itself and from `mysqld` to go to the same destination.

There are several `mysqld_safe` options for controlling the destination of these messages:

- `--log-error=file_name`: Write error messages to the named error file.
- `--syslog`: Write error messages to `syslog` on systems that support the `logger` program.
- `--skip-syslog`: Do not write error messages to `syslog`. Messages are written to the default error log file (`host_name.err` in the data directory), or to a named file if the `--log-error` option is given.

If none of these options is given, the default is `--skip-syslog`.

When `mysqld_safe` writes a message, notices go to the logging destination (`syslog` or the error log file) and `stdout`. Errors go to the logging destination and `stderr`.

Note

Controlling `mysqld` logging from `mysqld_safe` is deprecated. Use the server's native `syslog` support instead. For more information, see [Section 7.4.2.8, “Error Logging to the System Log”](#).

6.3.3 mysql.server — MySQL Server Startup Script

MySQL distributions on Unix and Unix-like system include a script named `mysql.server`, which starts the MySQL server using `mysqld_safe`. It can be used on systems such as Linux and Solaris that use System V-style run directories to start and stop system services. It is also used by the macOS Startup Item for MySQL.

`mysql.server` is the script name as used within the MySQL source tree. The installed name might be different (for example, `mysqld` or `mysql`). In the following discussion, adjust the name `mysql.server` as appropriate for your system.

Note

For some Linux platforms, MySQL installation from RPM or Debian packages includes `systemd` support for managing MySQL server startup and shutdown. On these platforms, `mysql.server` and `mysqld_safe` are not installed because they are unnecessary. For more information, see [Section 2.5.9, “Managing MySQL Server with systemd”](#).

To start or stop the server manually using the `mysql.server` script, invoke it from the command line with `start` or `stop` arguments:

```
mysql.server start
mysql.server stop
```

`mysql.server` changes location to the MySQL installation directory, then invokes `mysqld_safe`. To run the server as some specific user, add an appropriate `user` option to the `[mysqld]` group of

the global `/etc/my.cnf` option file, as shown later in this section. (It is possible that you must edit `mysql.server` if you've installed a binary distribution of MySQL in a nonstandard location. Modify it to change location into the proper directory before it runs `mysqld_safe`. If you do this, your modified version of `mysql.server` may be overwritten if you upgrade MySQL in the future; make a copy of your edited version that you can reinstall.)

`mysql.server stop` stops the server by sending a signal to it. You can also stop the server manually by executing `mysqladmin shutdown`.

To start and stop MySQL automatically on your server, you must add start and stop commands to the appropriate places in your `/etc/rc*` files:

- If you use the Linux server RPM package (`MySQL-server-VERSION.rpm`), or a native Linux package installation, the `mysql.server` script may be installed in the `/etc/init.d` directory with the name `mysqld` or `mysql`. See [Section 2.5.4, “Installing MySQL on Linux Using RPM Packages from Oracle”](#), for more information on the Linux RPM packages.
- If you install MySQL from a source distribution or using a binary distribution format that does not install `mysql.server` automatically, you can install the script manually. It can be found in the `support-files` directory under the MySQL installation directory or in a MySQL source tree. Copy the script to the `/etc/init.d` directory with the name `mysql` and make it executable:

```
cp mysql.server /etc/init.d/mysql
chmod +x /etc/init.d/mysql
```

After installing the script, the commands needed to activate it to run at system startup depend on your operating system. On Linux, you can use `chkconfig`:

```
chkconfig --add mysql
```

On some Linux systems, the following command also seems to be necessary to fully enable the `mysql` script:

```
chkconfig --level 345 mysql on
```

- On FreeBSD, startup scripts generally should go in `/usr/local/etc/rc.d/`. Install the `mysql.server` script as `/usr/local/etc/rc.d/mysql.server.sh` to enable automatic startup. The `rc(8)` manual page states that scripts in this directory are executed only if their base name matches the `*.sh` shell file name pattern. Any other files or directories present within the directory are silently ignored.
- As an alternative to the preceding setup, some operating systems also use `/etc/rc.local` or `/etc/init.d/boot.local` to start additional services on startup. To start up MySQL using this method, append a command like the one following to the appropriate startup file:

```
/bin/sh -c 'cd /usr/local/mysql; ./bin/mysqld_safe --user=mysql &'
```

- For other systems, consult your operating system documentation to see how to install startup scripts.

`mysql.server` reads options from the `[mysql.server]` and `[mysqld]` sections of option files. For backward compatibility, it also reads `[mysql_server]` sections, but to be current you should rename such sections to `[mysql.server]`.

You can add options for `mysql.server` in a global `/etc/my.cnf` file. A typical `my.cnf` file might look like this:

```
[mysqld]
datadir=/usr/local/mysql/var
socket=/var/tmp/mysql.sock
port=3306
user=mysql

[mysql.server]
basedir=/usr/local/mysql
```

The `mysql.server` script supports the options shown in the following table. If specified, they *must* be placed in an option file, not on the command line. `mysql.server` supports only `start` and `stop` as command-line arguments.

Table 6.8 mysql.server Option-File Options

Option Name	Description	Type
<code>basedir</code>	Path to MySQL installation directory	Directory name
<code>datadir</code>	Path to MySQL data directory	Directory name
<code>pid-file</code>	File in which server should write its process ID	File name
<code>service-startup-timeout</code>	How long to wait for server startup	Integer

- `basedir=dir_name`

The path to the MySQL installation directory.

- `datadir=dir_name`

The path to the MySQL data directory.

- `pid-file=file_name`

The path name of the file in which the server should write its process ID. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

If this option is not given, `mysql.server` uses a default value of `host_name.pid`. The PID file value passed to `mysqld_safe` overrides any value specified in the `[mysqld_safe]` option file group. Because `mysql.server` reads the `[mysqld]` option file group but not the `[mysqld_safe]` group, you can ensure that `mysqld_safe` gets the same value when invoked from `mysql.server` as when invoked manually by putting the same `pid-file` setting in both the `[mysqld_safe]` and `[mysqld]` groups.

- `service-startup-timeout=seconds`

How long in seconds to wait for confirmation of server startup. If the server does not start within this time, `mysql.server` exits with an error. The default value is 900. A value of 0 means not to wait at all for startup. Negative values mean to wait forever (no timeout).

6.3.4 mysqld_multi — Manage Multiple MySQL Servers

`mysqld_multi` is designed to manage several `mysqld` processes that listen for connections on different Unix socket files and TCP/IP ports. It can start or stop servers, or report their current status.

Note

For some Linux platforms, MySQL installation from RPM or Debian packages includes systemd support for managing MySQL server startup and shutdown. On these platforms, `mysqld_multi` is not installed because it is unnecessary. For information about using systemd to handle multiple MySQL instances, see [Section 2.5.9, “Managing MySQL Server with systemd”](#).

`mysqld_multi` searches for groups named `[mysqldN]` in `my.cnf` (or in the file named by the `--defaults-file` option). `N` can be any positive integer. This number is referred to in the following discussion as the option group number, or *GNR*. Group numbers distinguish option groups from one another and are used as arguments to `mysqld_multi` to specify which servers you want to start, stop, or obtain a status report for. Options listed in these groups are the same that you would use in the

[`mysqld`] group used for starting `mysqld`. (See, for example, [Section 2.9.5, “Starting and Stopping MySQL Automatically”](#).) However, when using multiple servers, it is necessary that each one use its own value for options such as the Unix socket file and TCP/IP port number. For more information on which options must be unique per server in a multiple-server environment, see [Section 7.8, “Running Multiple MySQL Instances on One Machine”](#).

To invoke `mysqld_multi`, use the following syntax:

```
mysqld_multi [options] {start|stop|reload|report} [GNR[,GNR] ...]
```

`start`, `stop`, `reload` (stop and restart), and `report` indicate which operation to perform. You can perform the designated operation for a single server or multiple servers, depending on the *GNR* list that follows the option name. If there is no list, `mysqld_multi` performs the operation for all servers in the option file.

Each *GNR* value represents an option group number or range of group numbers. The value should be the number at the end of the group name in the option file. For example, the *GNR* for a group named [`mysqld17`] is 17. To specify a range of numbers, separate the first and last numbers by a dash. The *GNR* value `10-13` represents groups [`mysqld10`] through [`mysqld13`]. Multiple groups or group ranges can be specified on the command line, separated by commas. There must be no whitespace characters (spaces or tabs) in the *GNR* list; anything after a whitespace character is ignored.

This command starts a single server using option group [`mysqld17`]:

```
mysqld_multi start 17
```

This command stops several servers, using option groups [`mysqld8`] and [`mysqld10`] through [`mysqld13`]:

```
mysqld_multi stop 8,10-13
```

For an example of how you might set up an option file, use this command:

```
mysqld_multi --example
```

`mysqld_multi` searches for option files as follows:

- With `--no-defaults`, no option files are read.

Command-Line Format	<code>--no-defaults</code>
Type	Boolean
Default Value	<code>false</code>

- With `--defaults-file=filename`, only the named file is read.

Command-Line Format	<code>--defaults-file=filename</code>
Type	File name
Default Value	<code>[none]</code>

- Otherwise, option files in the standard list of locations are read, including any file named by the `--defaults-extra-file=filename` option, if one is given. (If the option is given multiple times, the last value is used.)

Command-Line Format	<code>--defaults-extra-file=filename</code>
Type	File name
Default Value	<code>[none]</code>

For additional information about these and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

Option files read are searched for `[mysqld_multi]` and `[mysqldN]` option groups. The `[mysqld_multi]` group can be used for options to `mysqld_multi` itself. `[mysqldN]` groups can be used for options passed to specific `mysqld` instances.

The `[mysqld]` or `[mysqld_safe]` groups can be used for common options read by all instances of `mysqld` or `mysqld_safe`. You can specify a `--defaults-file=file_name` option to use a different configuration file for that instance, in which case the `[mysqld]` or `[mysqld_safe]` groups from that file are used for that instance.

`mysqld_multi` supports the following options.

- `--help`

Command-Line Format	<code>--help</code>
Type	Boolean
Default Value	<code>false</code>

Display a help message and exit.

- `--example`

Command-Line Format	<code>--example</code>
Type	Boolean
Default Value	<code>false</code>

Display a sample option file.

- `--log=file_name`

Command-Line Format	<code>--log=path</code>
Type	File name
Default Value	<code>/var/log/mysqld_multi.log</code>

Specify the name of the log file. If the file exists, log output is appended to it.

- `--mysqladmin=prog_name`

Command-Line Format	<code>--mysqladmin=file</code>
Type	File name
Default Value	<code>[none]</code>

The `mysqladmin` binary to be used to stop servers.

- `--mysqld=prog_name`

Command-Line Format	<code>--mysqld=file</code>
Type	File name
Default Value	<code>[none]</code>

The `mysqld` binary to be used. Note that you can specify `mysqld_safe` as the value for this option also. If you use `mysqld_safe` to start the server, you can include the `mysqld` or `ledir` options in the corresponding `[mysqldN]` option group. These options indicate the name of the server that `mysqld_safe` should start and the path name of the directory where the server is located. (See the descriptions for these options in [Section 6.3.2, “mysqld_safe — MySQL Server Startup Script”](#).) Example:

```
[mysqld38]
mysqld = mysqld-debug
ledir  = /opt/local/mysql/libexec
```

- `--no-log`

Command-Line Format	<code>--no-log</code>
Type	Boolean
Default Value	<code>false</code>

Print log information to `stdout` rather than to the log file. By default, output goes to the log file.

- `--password=password`

Command-Line Format	<code>--password=string</code>
Type	String
Default Value	<code>[none]</code>

The password of the MySQL account to use when invoking `mysqladmin`. Note that the password value is not optional for this option, unlike for other MySQL programs.

- `--silent`

Command-Line Format	<code>--silent</code>
Type	Boolean
Default Value	<code>false</code>

Silent mode; disable warnings.

- `--tcp-ip`

Command-Line Format	<code>--tcp-ip</code>
Type	Boolean
Default Value	<code>false</code>

Connect to each MySQL server through the TCP/IP port instead of the Unix socket file. (If a socket file is missing, the server might still be running, but accessible only through the TCP/IP port.) By default, connections are made using the Unix socket file. This option affects `stop` and `report` operations.

- `--user=user_name`

Command-Line Format	<code>--user=name</code>
Type	String
Default Value	<code>root</code>

The user name of the MySQL account to use when invoking `mysqladmin`.

- `--verbose`

Command-Line Format	<code>--verbose</code>
Type	Boolean
Default Value	<code>false</code>

Be more verbose.

- `--version`

Command-Line Format	<code>--version</code>
Type	Boolean
Default Value	<code>false</code>

Display version information and exit.

Some notes about `mysqld_multi`:

- **Most important:** Before using `mysqld_multi` be sure that you understand the meanings of the options that are passed to the `mysqld` servers and *why* you would want to have separate `mysqld` processes. Beware of the dangers of using multiple `mysqld` servers with the same data directory. Use separate data directories, unless you *know* what you are doing. Starting multiple servers with the same data directory does *not* give you extra performance in a threaded system. See [Section 7.8](#), “Running Multiple MySQL Instances on One Machine”.

Important

Make sure that the data directory for each server is fully accessible to the Unix account that the specific `mysqld` process is started as. *Do not* use the Unix `root` account for this, unless you *know* what you are doing. See [Section 8.1.5](#), “How to Run MySQL as a Normal User”.

- Make sure that the MySQL account used for stopping the `mysqld` servers (with the `mysqladmin` program) has the same user name and password for each server. Also, make sure that the account has the `SHUTDOWN` privilege. If the servers that you want to manage have different user names or passwords for the administrative accounts, you might want to create an account on each server that has the same user name and password. For example, you might set up a common `multi_admin` account by executing the following commands for each server:

```
$> mysql -u root -S /tmp/mysql.sock -p
Enter password:
mysql> CREATE USER 'multi_admin'@'localhost' IDENTIFIED BY 'multipass';
mysql> GRANT SHUTDOWN ON *.* TO 'multi_admin'@'localhost';
```

See [Section 8.2](#), “Access Control and Account Management”. You have to do this for each `mysqld` server. Change the connection parameters appropriately when connecting to each one. Note that the host name part of the account name must permit you to connect as `multi_admin` from the host where you want to run `mysqld_multi`.

- The Unix socket file and the TCP/IP port number must be different for every `mysqld`. (Alternatively, if the host has multiple network addresses, you can set the `bind_address` system variable to cause different servers to listen to different interfaces.)
- The `--pid-file` option is very important if you are using `mysqld_safe` to start `mysqld` (for example, `--mysqld=mysqld_safe`) Every `mysqld` should have its own process ID file. The

advantage of using `mysqld_safe` instead of `mysqld` is that `mysqld_safe` monitors its `mysqld` process and restarts it if the process terminates due to a signal sent using `kill -9` or for other reasons, such as a segmentation fault.

- You might want to use the `--user` option for `mysqld`, but to do this you need to run the `mysqld_multi` script as the Unix superuser (`root`). Having the option in the option file doesn't matter; you just get a warning if you are not the superuser and the `mysqld` processes are started under your own Unix account.

The following example shows how you might set up an option file for use with `mysqld_multi`. The order in which the `mysqld` programs are started or stopped depends on the order in which they appear in the option file. Group numbers need not form an unbroken sequence. The first and fifth `[mysqldN]` groups were intentionally omitted from the example to illustrate that you can have “gaps” in the option file. This gives you more flexibility.

```
# This is an example of a my.cnf file for mysqld_multi.
# Usually this file is located in home dir ~/.my.cnf or /etc/my.cnf

[mysqld_multi]
mysqld      = /usr/local/mysql/bin/mysqld_safe
mysqladmin  = /usr/local/mysql/bin/mysqladmin
user        = multi_admin
password    = my_password

[mysqld2]
socket      = /tmp/mysql.sock2
port        = 3307
pid-file    = /usr/local/mysql/data2/hostname.pid2
datadir     = /usr/local/mysql/data2
language    = /usr/local/mysql/share/mysql/english
user        = unix_user1

[mysqld3]
mysqld      = /path/to/mysqld_safe
ledir       = /path/to/mysqld-binary/
mysqladmin  = /path/to/mysqladmin
socket      = /tmp/mysql.sock3
port        = 3308
pid-file    = /usr/local/mysql/data3/hostname.pid3
datadir     = /usr/local/mysql/data3
language    = /usr/local/mysql/share/mysql/swedish
user        = unix_user2

[mysqld4]
socket      = /tmp/mysql.sock4
port        = 3309
pid-file    = /usr/local/mysql/data4/hostname.pid4
datadir     = /usr/local/mysql/data4
language    = /usr/local/mysql/share/mysql/estonia
user        = unix_user3

[mysqld6]
socket      = /tmp/mysql.sock6
port        = 3311
pid-file    = /usr/local/mysql/data6/hostname.pid6
datadir     = /usr/local/mysql/data6
language    = /usr/local/mysql/share/mysql/japanese
user        = unix_user4
```

See [Section 6.2.2.2, “Using Option Files”](#).

6.4 Installation-Related Programs

The programs in this section are used when installing or upgrading MySQL.

6.4.1 `comp_err` — Compile MySQL Error Message File

`comp_err` creates the `errmsg.sys` file that is used by `mysqld` to determine the error messages to display for different error codes. `comp_err` normally is run automatically when MySQL is built. It compiles the `errmsg.sys` file from text-format error information in MySQL source distributions:

The error information comes from the `messages_to_error_log.txt` and `messages_to_clients.txt` files in the `share` directory.

For more information about defining error messages, see the comments within those files, along with the `errmsg_readme.txt` file.

`comp_err` also generates the `mysqld_error.h`, `mysqld_ename.h`, and `mysqld_errmsg.h` header files.

Invoke `comp_err` like this:

```
comp_err [options]
```

`comp_err` supports the following options.

- `--help`, `-?`

Command-Line Format	<code>--help</code>
Type	Boolean
Default Value	<code>false</code>

Display a help message and exit.

- `--charset=dir_name`, `-C dir_name`

Command-Line Format	<code>--charset</code>
Type	String
Default Value	<code>../share/charsets</code>

The character set directory. The default is `../sql/share/charsets`.

- `--debug=debug_options`, `-# debug_options`

Command-Line Format	<code>--debug=options</code>
Type	String
Default Value	<code>d:t:0,/tmp/comp_err.trace</code>

Write a debugging log. A typical `debug_options` string is `d:t:0,file_name`. The default is `d:t:0,/tmp/comp_err.trace`.

- `--debug-info`, `-T`

Command-Line Format	<code>--debug-info</code>
Type	Boolean
Default Value	<code>false</code>

Print some debugging information when the program exits.

- `--errmsg-file=file_name`, `-H file_name`

Command-Line Format	<code>--errmsg-file=name</code>
Type	File name
Default Value	<code>mysqld_errmsg.h</code>

The name of the error message file. The default is `mysqld_errmsg.h`.

- `--header-file=file_name, -H file_name`

Command-Line Format	<code>--header-file=name</code>
Type	File name
Default Value	<code>mysqld_error.h</code>

The name of the error header file. The default is `mysqld_error.h`.

- `--in-file-errlog=file_name, -e file_name`

Command-Line Format	<code>--in-file-errlog</code>
Type	File name
Default Value	<code>../share/messages_to_error_log.txt</code>

The name of the input file that defines error messages intended to be written to the error log. The default is `../share/messages_to_error_log.txt`.

- `--in-file-toclient=file_name, -c file_name`

Command-Line Format	<code>--in-file-toclient=path</code>
Type	File name
Default Value	<code>../share/messages_to_clients.txt</code>

The name of the input file that defines error messages intended to be written to clients. The default is `../share/messages_to_clients.txt`.

- `--name-file=file_name, -N file_name`

Command-Line Format	<code>--name-file=name</code>
Type	File name
Default Value	<code>mysqld_ename.h</code>

The name of the error name file. The default is `mysqld_ename.h`.

- `--out-dir=dir_name, -D dir_name`

Command-Line Format	<code>--out-dir=path</code>
Type	String
Default Value	<code>../share/</code>

The name of the output base directory. The default is `../sql/share/`.

- `--out-file=file_name, -O file_name`

Command-Line Format	<code>--out-file=name</code>
Type	File name
Default Value	<code>errmsg.sys</code>

The name of the output file. The default is `errmsg.sys`.

- `--version, -V`

Command-Line Format	<code>--version</code>
Type	Boolean
Default Value	<code>false</code>

Display version information and exit.

6.4.2 mysql_secure_installation — Improve MySQL Installation Security

This program enables you to improve the security of your MySQL installation in the following ways:

- You can set a password for `root` accounts.
- You can remove `root` accounts that are accessible from outside the local host.
- You can remove anonymous-user accounts.
- You can remove the `test` database (which by default can be accessed by all users, even anonymous users), and privileges that permit anyone to access databases with names that start with `test_`.

`mysql_secure_installation` helps you implement security recommendations similar to those described at [Section 2.9.4, “Securing the Initial MySQL Account”](#).

Normal usage is to connect to the local MySQL server; invoke `mysql_secure_installation` without arguments:

```
mysql_secure_installation
```

When executed, `mysql_secure_installation` prompts you to determine which actions to perform.

The `validate_password` component can be used for password strength checking. If the plugin is not installed, `mysql_secure_installation` prompts the user whether to install it. Any passwords entered later are checked using the plugin if it is enabled.

Most of the usual MySQL client options such as `--host` and `--port` can be used on the command line and in option files. For example, to connect to the local server over IPv6 using port 3307, use this command:

```
mysql_secure_installation --host>:::1 --port=3307
```

`mysql_secure_installation` supports the following options, which can be specified on the command line or in the `[mysql_secure_installation]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 6.2.2.2, “Using Option Files”](#).

Table 6.9 mysql_secure_installation Options

Option Name	Description
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files

Option Name	Description
<code>--defaults-file</code>	Read only named option file
<code>--defaults-group-suffix</code>	Option group suffix value
<code>--help</code>	Display help message and exit
<code>--host</code>	Host on which MySQL server is located
<code>--no-defaults</code>	Read no option files
<code>--password</code>	Accepted but always ignored. Whenever <code>mysql_secure_installation</code> is invoked, the user is prompted for a password, regardless
<code>--port</code>	TCP/IP port number for connection
<code>--print-defaults</code>	Print default options
<code>--protocol</code>	Transport protocol to use
<code>--socket</code>	Unix socket file or Windows named pipe to use
<code>--ssl-ca</code>	File that contains list of trusted SSL Certificate Authorities
<code>--ssl-capath</code>	Directory that contains trusted SSL Certificate Authority certificate files
<code>--ssl-cert</code>	File that contains X.509 certificate
<code>--ssl-cipher</code>	Permissible ciphers for connection encryption
<code>--ssl-crl</code>	File that contains certificate revocation lists
<code>--ssl-crlpath</code>	Directory that contains certificate revocation-list files
<code>--ssl-fips-mode</code>	Whether to enable FIPS mode on client side
<code>--ssl-key</code>	File that contains X.509 key
<code>--ssl-mode</code>	Desired security state of connection to server
<code>--ssl-session-data</code>	File that contains SSL session data
<code>--ssl-session-data-continue-on-failed-reuse</code>	Whether to establish connections if session reuse fails
<code>--tls-ciphersuites</code>	Permissible TLSv1.3 ciphersuites for encrypted connections
<code>--tls-sni-servername</code>	Server name supplied by the client
<code>--tls-version</code>	Permissible TLS protocols for encrypted connections
<code>--use-default</code>	Execute with no user interactivity
<code>--user</code>	MySQL user name to use when connecting to server

- `--help, -?`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display a help message and exit.

- `--defaults-extra-file=file_name`

Command-Line Format	<code>--defaults-extra-file=file_name</code>
Type	File name

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-file=file_name`

Command-Line Format	<code>--defaults-file=file_name</code>
Type	File name

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-group-suffix=str`

Command-Line Format	<code>--defaults-group-suffix=str</code>
Type	String

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysql_secure_installation` normally reads the `[client]` and `[mysql_secure_installation]` groups. If this option is given as `--defaults-group-suffix=_other`, `mysql_secure_installation` also reads the `[client_other]` and `[mysql_secure_installation_other]` groups.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--host=host_name, -h host_name`

Command-Line Format	<code>--host</code>
---------------------	---------------------

Connect to the MySQL server on the given host.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--password=password, -p password`

Command-Line Format	<code>--password=password</code>
Type	String
Default Value	<code>[none]</code>

This option is accepted but ignored. Whether or not this option is used, `mysql_secure_installation` always prompts the user for a password.

- `--port=port_num, -P port_num`

Command-Line Format	<code>--port=port_num</code>
Type	Numeric
Default Value	<code>3306</code>

For TCP/IP connections, the port number to use.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

Command-Line Format	<code>--protocol=type</code>
Type	String
Default Value	<code>[see text]</code>
Valid Values	TCP SOCKET PIPE MEMORY

The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see [Section 6.2.7, “Connection Transport Protocols”](#).

- `--socket=path, -S path`

Command-Line Format	<code>--socket={file_name pipe_name}</code>
---------------------	---

Type	String
------	--------

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See [Command Options for Encrypted Connections](#).

- `--ssl-fips-mode={OFF|ON|STRICT}`

Command-Line Format	<code>--ssl-fips-mode={OFF ON STRICT}</code>
Deprecated	Yes
Type	Enumeration
Default Value	<code>OFF</code>
Valid Values	<code>OFF</code> <code>ON</code> <code>STRICT</code>

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations to permit. See [Section 8.8, “FIPS Support”](#).

These `--ssl-fips-mode` values are permitted:

- `OFF`: Disable FIPS mode.
- `ON`: Enable FIPS mode.
- `STRICT`: Enable “strict” FIPS mode.

Note

If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is `OFF`. In this case, setting `--ssl-fips-mode` to `ON` or `STRICT` causes the client to produce a warning at startup and to operate in non-FIPS mode.

This option is deprecated. Expect it to be removed in a future version of MySQL.

- `--tls-ciphersuites=ciphersuite_list`

Command-Line Format	<code>--tls-ciphersuites=ciphersuite_list</code>
Type	String

The permissible ciphersuites for encrypted connections that use TLSv1.3. The value is a list of one or more colon-separated ciphersuite names. The ciphersuites that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `--tls-sni-servername=server_name`

Command-Line Format	<code>--tls-sni-servername=server_name</code>
Type	String

When specified, the name is passed to the `libmysqlclient` C API library using the `MYSQL_OPT_TLS_SNI_SERVERNAME` option of `mysql_options()`. The server name is not case-sensitive. To show which server name the client specified for the current session, if any, check the `Tls_sni_server_name` status variable.

Server Name Indication (SNI) is an extension to the TLS protocol (OpenSSL must be compiled using TLS extensions for this option to function). The MySQL implementation of SNI represents the client-side only.

- `--tls-version=protocol_list`

Command-Line Format	<code>--tls-version=protocol_list</code>
Type	String
Default Value	<code>TLSv1, TLSv1.1, TLSv1.2, TLSv1.3</code> (OpenSSL 1.1.1 or higher) <code>TLSv1, TLSv1.1, TLSv1.2</code> (otherwise)

The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `--use-default`

Command-Line Format	<code>--use-default</code>
Type	Boolean

Execute noninteractively. This option can be used for unattended installation operations.

- `--user=user_name, -u user_name`

Command-Line Format	<code>--user=user_name</code>
Type	String

The user name of the MySQL account to use for connecting to the server.

6.4.3 mysql_ssl_rsa_setup — Create SSL/RSA Files

Note

`mysql_ssl_rsa_setup` is deprecated. Instead, consider using MySQL server to generate missing SSL and RSA files automatically at startup (see [Automatic SSL and RSA File Generation](#)).

This program creates the SSL certificate and key files and RSA key-pair files required to support secure connections using SSL and secure password exchange using RSA over unencrypted connections, if those files are missing. `mysql_ssl_rsa_setup` can also be used to create new SSL files if the existing ones have expired.

**Note**

`mysql_ssl_rsa_setup` uses the `openssl` command, so its use is contingent on having OpenSSL installed on your machine.

Another way to generate SSL and RSA files, for MySQL distributions compiled using OpenSSL, is to have the server generate them automatically. See [Section 8.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#).

**Important**

`mysql_ssl_rsa_setup` helps lower the barrier to using SSL by making it easier to generate the required files. However, certificates generated by `mysql_ssl_rsa_setup` are self-signed, which is not very secure. After you gain experience using the files created by `mysql_ssl_rsa_setup`, consider obtaining a CA certificate from a registered certificate authority.

Invoke `mysql_ssl_rsa_setup` like this:

```
mysql_ssl_rsa_setup [options]
```

Typical options are `--datadir` to specify where to create the files, and `--verbose` to see the `openssl` commands that `mysql_ssl_rsa_setup` executes.

`mysql_ssl_rsa_setup` attempts to create SSL and RSA files using a default set of file names. It works as follows:

1. `mysql_ssl_rsa_setup` checks for the `openssl` binary at the locations specified by the `PATH` environment variable. If `openssl` is not found, `mysql_ssl_rsa_setup` does nothing. If `openssl` is present, `mysql_ssl_rsa_setup` looks for default SSL and RSA files in the MySQL data directory specified by the `--datadir` option, or the compiled-in data directory if the `--datadir` option is not given.
2. `mysql_ssl_rsa_setup` checks the data directory for SSL files with the following names:

```
ca.pem
server-cert.pem
server-key.pem
```

3. If any of those files are present, `mysql_ssl_rsa_setup` creates no SSL files. Otherwise, it invokes `openssl` to create them, plus some additional files:

ca.pem	Self-signed CA certificate
ca-key.pem	CA private key
server-cert.pem	Server certificate
server-key.pem	Server private key
client-cert.pem	Client certificate
client-key.pem	Client private key

These files enable secure client connections using SSL; see [Section 8.3.1, “Configuring MySQL to Use Encrypted Connections”](#).

4. `mysql_ssl_rsa_setup` checks the data directory for RSA files with the following names:

private_key.pem	Private member of private/public key pair
public_key.pem	Public member of private/public key pair

5. If any of these files are present, `mysql_ssl_rsa_setup` creates no RSA files. Otherwise, it invokes `openssl` to create them. These files enable secure password exchange using RSA over unencrypted connections for accounts authenticated by the `sha256_password` or `caching_sha2_password` plugin; see [Section 8.4.1.3, “SHA-256 Pluggable Authentication”](#), and [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

For information about the characteristics of files created by `mysql_ssl_rsa_setup`, see [Section 8.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#).

At startup, the MySQL server automatically uses the SSL files created by `mysql_ssl_rsa_setup` to enable SSL if no explicit SSL options are given other than `--ssl` (possibly along with `ssl_cipher`). If you prefer to designate the files explicitly, invoke clients with the `--ssl-ca`, `--ssl-cert`, and `--ssl-key` options at startup to name the `ca.pem`, `server-cert.pem`, and `server-key.pem` files, respectively.

The server also automatically uses the RSA files created by `mysql_ssl_rsa_setup` to enable RSA if no explicit RSA options are given.

If the server is SSL-enabled, clients use SSL by default for the connection. To specify certificate and key files explicitly, use the `--ssl-ca`, `--ssl-cert`, and `--ssl-key` options to name the `ca.pem`, `client-cert.pem`, and `client-key.pem` files, respectively. However, some additional client setup may be required first because `mysql_ssl_rsa_setup` by default creates those files in the data directory. The permissions for the data directory normally enable access only to the system account that runs the MySQL server, so client programs cannot use files located there. To make the files available, copy them to a directory that is readable (but *not* writable) by clients:

- For local clients, the MySQL installation directory can be used. For example, if the data directory is a subdirectory of the installation directory and your current location is the data directory, you can copy the files like this:

```
cp ca.pem client-cert.pem client-key.pem ..
```

- For remote clients, distribute the files using a secure channel to ensure they are not tampered with during transit.

If the SSL files used for a MySQL installation have expired, you can use `mysql_ssl_rsa_setup` to create new ones:

1. Stop the server.
2. Rename or remove the existing SSL files. You may wish to make a backup of them first. (The RSA files do not expire, so you need not remove them. `mysql_ssl_rsa_setup` can see that they exist and does not overwrite them.)
3. Run `mysql_ssl_rsa_setup` with the `--datadir` option to specify where to create the new files.
4. Restart the server.

`mysql_ssl_rsa_setup` supports the following command-line options, which can be specified on the command line or in the `[mysql_ssl_rsa_setup]` and `[mysqld]` groups of an option file. For information about option files used by MySQL programs, see [Section 6.2.2.2, “Using Option Files”](#).

Table 6.10 mysql_ssl_rsa_setup Options

Option Name	Description
<code>--datadir</code>	Path to data directory
<code>--help</code>	Display help message and exit
<code>--suffix</code>	Suffix for X.509 certificate Common Name attribute
<code>--uid</code>	Name of effective user to use for file permissions
<code>--verbose</code>	Verbose mode
<code>--version</code>	Display version information and exit

- `--help, ?`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display a help message and exit.

- `--datadir=dir_name`

Command-Line Format	<code>--datadir=dir_name</code>
Type	Directory name

The path to the directory that `mysql_ssl_rsa_setup` should check for default SSL and RSA files and in which it should create files if they are missing. The default is the compiled-in data directory.

- `--suffix=str`

Command-Line Format	<code>--suffix=str</code>
Type	String

The suffix for the Common Name attribute in X.509 certificates. The suffix value is limited to 17 characters. The default is based on the MySQL version number.

- `--uid=name, -v`

Command-Line Format	<code>--uid=name</code>
---------------------	-------------------------

The name of the user who should be the owner of any created files. The value is a user name, not a numeric user ID. In the absence of this option, files created by `mysql_ssl_rsa_setup` are owned by the user who executes it. This option is valid only if you execute the program as `root` on a system that supports the `chown()` system call.

- `--verbose, -v`

Command-Line Format	<code>--verbose</code>
---------------------	------------------------

Verbose mode. Produce more output about what the program does. For example, the program shows the `openssl` commands it runs, and produces output to indicate whether it skips SSL or RSA file creation because some default file already exists.

- `--version, -V`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

6.4.4 mysql_tzinfo_to_sql — Load the Time Zone Tables

The `mysql_tzinfo_to_sql` program loads the time zone tables in the `mysql` database. It is used on systems that have a `zoneinfo` database (the set of files describing time zones). Examples of such systems are Linux, FreeBSD, Solaris, and macOS. One likely location for these files is the `/usr/share/zoneinfo` directory (`/usr/share/lib/zoneinfo` on Solaris). If your system does not have a `zoneinfo` database, you can use the downloadable package described in [Section 7.1.15, “MySQL Server Time Zone Support”](#).

`mysql_tzinfo_to_sql` can be invoked several ways:

```
mysql_tzinfo_to_sql tz_dir
mysql_tzinfo_to_sql tz_file tz_name
mysql_tzinfo_to_sql --leap tz_file
```

For the first invocation syntax, pass the `zoneinfo` directory path name to `mysql_tzinfo_to_sql` and send the output into the `mysql` program. For example:

```
mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root mysql
```

`mysql_tzinfo_to_sql` reads your system's time zone files and generates SQL statements from them. `mysql` processes those statements to load the time zone tables.

The second syntax causes `mysql_tzinfo_to_sql` to load a single time zone file `tz_file` that corresponds to a time zone name `tz_name`:

```
mysql_tzinfo_to_sql tz_file tz_name | mysql -u root mysql
```

If your time zone needs to account for leap seconds, invoke `mysql_tzinfo_to_sql` using the third syntax, which initializes the leap second information. `tz_file` is the name of your time zone file:

```
mysql_tzinfo_to_sql --leap tz_file | mysql -u root mysql
```

After running `mysql_tzinfo_to_sql`, it is best to restart the server so that it does not continue to use any previously cached time zone data.

6.4.5 mysql_upgrade — Deprecated; Performs No Tasks and Exits with Status 0

Note

The MySQL server performs the upgrade tasks previously handled by `mysql_upgrade` (for details, see [Section 3.4, “What the MySQL Upgrade Process Upgrades”](#)). Consequently, `mysql_upgrade` is unneeded and is deprecated; expect it to be removed in a future version of MySQL. Because `mysql_upgrade` no longer performs upgrade tasks, it exits with status 0 unconditionally.

6.5 Client Programs

This section describes client programs that connect to the MySQL server.

6.5.1 mysql — The MySQL Command-Line Client

`mysql` is a simple SQL shell with input line editing capabilities. It supports interactive and noninteractive use. When used interactively, query results are presented in an ASCII-table format. When used noninteractively (for example, as a filter), the result is presented in tab-separated format. The output format can be changed using command options.

If you have problems due to insufficient memory for large result sets, use the `--quick` option. This forces `mysql` to retrieve results from the server a row at a time rather than retrieving the entire result set and buffering it in memory before displaying it. This is done by returning the result set using the `mysql_use_result()` C API function in the client/server library rather than `mysql_store_result()`.

Note

Alternatively, MySQL Shell offers access to the X DevAPI. For details, see [MySQL Shell 8.2](#).

Using `mysql` is very easy. Invoke it from the prompt of your command interpreter as follows:

```
mysql db_name
```

Or:

```
mysql --user=user_name --password db_name
```

In this case, you'll need to enter your password in response to the prompt that `mysql` displays:

```
Enter password: your_password
```

Then type an SQL statement, end it with `;`, `\g`, or `\G` and press Enter.

Typing **Control+C** interrupts the current statement if there is one, or cancels any partial input line otherwise.

You can execute SQL statements in a script file (batch file) like this:

```
mysql db_name < script.sql > output.tab
```

On Unix, the `mysql` client logs statements executed interactively to a history file. See [Section 6.5.1.3](#), “`mysql` Client Logging”.

6.5.1.1 `mysql` Client Options

`mysql` supports the following options, which can be specified on the command line or in the `[mysql]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 6.2.2.2](#), “Using Option Files”.

Table 6.11 `mysql` Client Options

Option Name	Description
<code>--auto-rehash</code>	Enable automatic rehashing
<code>--auto-vertical-output</code>	Enable automatic vertical result set display
<code>--batch</code>	Do not use history file
<code>--binary-as-hex</code>	Display binary values in hexadecimal notation
<code>--binary-mode</code>	Disable <code>\r\n</code> - to - <code>\n</code> translation and treatment of <code>\0</code> as end-of-query
<code>--bind-address</code>	Use specified network interface to connect to MySQL Server
<code>--character-sets-dir</code>	Directory where character sets are installed
<code>--column-names</code>	Write column names in results
<code>--column-type-info</code>	Display result set metadata
<code>--comments</code>	Whether to retain or strip comments in statements sent to the server
<code>--compress</code>	Compress all information sent between client and server
<code>--compression-algorithms</code>	Permitted compression algorithms for connections to server
<code>--connect-expired-password</code>	Indicate to server that client can handle expired-password sandbox mode
<code>--connect-timeout</code>	Number of seconds before connection timeout
<code>--database</code>	The database to use
<code>--debug</code>	Write debugging log; supported only if MySQL was built with debugging support
<code>--debug-check</code>	Print debugging information when program exits
<code>--debug-info</code>	Print debugging information, memory, and CPU statistics when program exits
<code>--default-auth</code>	Authentication plugin to use
<code>--default-character-set</code>	Specify default character set
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files
<code>--defaults-file</code>	Read only named option file

Option Name	Description
<code>--defaults-group-suffix</code>	Option group suffix value
<code>--delimiter</code>	Set the statement delimiter
<code>--dns-srv-name</code>	Use DNS SRV lookup for host information
<code>--enable-cleartext-plugin</code>	Enable cleartext authentication plugin
<code>--execute</code>	Execute the statement and quit
<code>--fido-register-factor</code>	Multifactor authentication factors for which registration must be done
<code>--force</code>	Continue even if an SQL error occurs
<code>--get-server-public-key</code>	Request RSA public key from server
<code>--help</code>	Display help message and exit
<code>--histignore</code>	Patterns specifying which statements to ignore for logging
<code>--host</code>	Host on which MySQL server is located
<code>--html</code>	Produce HTML output
<code>--ignore-spaces</code>	Ignore spaces after function names
<code>--init-command</code>	SQL statement to execute after connecting
<code>--init-command-add</code>	Add an additional SQL statement to execute after connecting or re-connecting to MySQL server
<code>--line-numbers</code>	Write line numbers for errors
<code>--load-data-local-dir</code>	Directory for files named in LOAD DATA LOCAL statements
<code>--local-infile</code>	Enable or disable for LOCAL capability for LOAD DATA
<code>--login-path</code>	Read login path options from <code>.mylogin.cnf</code>
<code>--max-allowed-packet</code>	Maximum packet length to send to or receive from server
<code>--max-join-size</code>	The automatic limit for rows in a join when using <code>--safe-updates</code>
<code>--named-commands</code>	Enable named mysql commands
<code>--net-buffer-length</code>	Buffer size for TCP/IP and socket communication
<code>--network-namespace</code>	Specify network namespace
<code>--no-auto-rehash</code>	Disable automatic rehashing
<code>--no-beep</code>	Do not beep when errors occur
<code>--no-defaults</code>	Read no option files
<code>--no-login-paths</code>	Do not read login paths from the login path file
<code>--one-database</code>	Ignore statements except those for the default database named on the command line
<code>--pager</code>	Use the given command for paging query output
<code>--password</code>	Password to use when connecting to server
<code>--password1</code>	First multifactor authentication password to use when connecting to server
<code>--password2</code>	Second multifactor authentication password to use when connecting to server

Option Name	Description
<code>--password3</code>	Third multifactor authentication password to use when connecting to server
<code>--pipe</code>	Connect to server using named pipe (Windows only)
<code>--plugin-authentication-kerberos-client-mode</code>	Permit GSSAPI pluggable authentication through the MIT Kerberos library on Windows
<code>--plugin-authentication-webauthn-client-preserve-privacy</code>	Permit user to choose a key to be used for assertion
<code>--plugin-dir</code>	Directory where plugins are installed
<code>--port</code>	TCP/IP port number for connection
<code>--print-defaults</code>	Print default options
<code>--prompt</code>	Set the prompt to the specified format
<code>--protocol</code>	Transport protocol to use
<code>--quick</code>	Do not cache each query result
<code>--raw</code>	Write column values without escape conversion
<code>--reconnect</code>	If the connection to the server is lost, automatically try to reconnect
<code>--register-factor</code>	Multifactor authentication factors for which registration must be done
<code>--safe-updates, --i-am-a-dummy</code>	Allow only UPDATE and DELETE statements that specify key values
<code>--select-limit</code>	The automatic limit for SELECT statements when using <code>--safe-updates</code>
<code>--server-public-key-path</code>	Path name to file containing RSA public key
<code>--shared-memory-base-name</code>	Shared-memory name for shared-memory connections (Windows only)
<code>--show-warnings</code>	Show warnings after each statement if there are any
<code>--sigint-ignore</code>	Ignore SIGINT signals (typically the result of typing Control+C)
<code>--silent</code>	Silent mode
<code>--skip-auto-rehash</code>	Disable automatic rehashing
<code>--skip-column-names</code>	Do not write column names in results
<code>--skip-line-numbers</code>	Skip line numbers for errors
<code>--skip-named-commands</code>	Disable named mysql commands
<code>--skip-pager</code>	Disable paging
<code>--skip-reconnect</code>	Disable reconnecting
<code>--socket</code>	Unix socket file or Windows named pipe to use
<code>--ssl-ca</code>	File that contains list of trusted SSL Certificate Authorities
<code>--ssl-capath</code>	Directory that contains trusted SSL Certificate Authority certificate files
<code>--ssl-cert</code>	File that contains X.509 certificate
<code>--ssl-cipher</code>	Permissible ciphers for connection encryption

Option Name	Description
<code>--ssl-crl</code>	File that contains certificate revocation lists
<code>--ssl-crlpath</code>	Directory that contains certificate revocation-list files
<code>--ssl-fips-mode</code>	Whether to enable FIPS mode on client side
<code>--ssl-key</code>	File that contains X.509 key
<code>--ssl-mode</code>	Desired security state of connection to server
<code>--ssl-session-data</code>	File that contains SSL session data
<code>--ssl-session-data-continue-on-failed-reuse</code>	Whether to establish connections if session reuse fails
<code>--syslog</code>	Log interactive statements to syslog
<code>--table</code>	Display output in tabular format
<code>--tee</code>	Append a copy of output to named file
<code>--telemetry_client</code>	Enables the telemetry client.
<code>--otel_bsp_max_export_batch_size</code>	See variable <code>OTEL_BSP_MAX_EXPORT_BATCH_SIZE</code> .
<code>--otel_bsp_max_queue_size</code>	See variable <code>OTEL_BSP_MAX_QUEUE_SIZE</code> .
<code>--otel_bsp_schedule_delay</code>	See variable <code>OTEL_BSP_SCHEDULE_DELAY</code> .
<code>--otel_exporter_otlp_traces_certificates</code>	Not in use at this time. Reserved for future development.
<code>--otel_exporter_otlp_traces_client_certificates</code>	Not in use at this time. Reserved for future development.
<code>--otel_exporter_otlp_traces_client_key</code>	Not in use at this time. Reserved for future development.
<code>--otel_exporter_otlp_traces_compression</code>	Compression type
<code>--otel_exporter_otlp_traces_endpoint</code>	The trace export endpoint
<code>--otel_exporter_otlp_traces_headers</code>	Key-value pairs to be used as headers associated with HTTP requests
<code>--otel_exporter_otlp_traces_protocol</code>	The OTLP transport protocol
<code>--otel_exporter_otlp_traces_timeout</code>	Time OLTP exporter waits for each batch export
<code>--otel-help</code>	When enabled, prints help about <code>telemetry_client</code> options.
<code>--otel_log_level</code>	Controls which opentelemetry logs are printed in the server logs
<code>--otel_resource_attributes</code>	See corresponding OpenTelemetry variable <code>OTEL_RESOURCE_ATTRIBUTES</code> .
<code>--otel-trace</code>	This system variable controls whether telemetry traces are collected or not.
<code>--tls-ciphersuites</code>	Permissible TLSv1.3 ciphersuites for encrypted connections
<code>--tls-sni-servername</code>	Server name supplied by the client
<code>--tls-version</code>	Permissible TLS protocols for encrypted connections
<code>--unbuffered</code>	Flush the buffer after each query
<code>--user</code>	MySQL user name to use when connecting to server

Option Name	Description
<code>--verbose</code>	Verbose mode
<code>--version</code>	Display version information and exit
<code>--vertical</code>	Print query output rows vertically (one line per column value)
<code>--wait</code>	If the connection cannot be established, wait and retry instead of aborting
<code>--xml</code>	Produce XML output
<code>--zstd-compression-level</code>	Compression level for connections to server that use zstd compression

- `--help, -?`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display a help message and exit.

- `--auto-rehash`

Command-Line Format	<code>--auto-rehash</code>
Disabled by	<code>skip-auto-rehash</code>

Enable automatic rehashing. This option is on by default, which enables database, table, and column name completion. Use `--disable-auto-rehash` to disable rehashing. That causes `mysql` to start faster, but you must issue the `rehash` command or its `\#` shortcut if you want to use name completion.

To complete a name, enter the first part and press Tab. If the name is unambiguous, `mysql` completes it. Otherwise, you can press Tab again to see the possible names that begin with what you have typed so far. Completion does not occur if there is no default database.

Note

This feature requires a MySQL client that is compiled with the **readline** library. Typically, the **readline** library is not available on Windows.

- `--auto-vertical-output`

Command-Line Format	<code>--auto-vertical-output</code>
---------------------	-------------------------------------

Cause result sets to be displayed vertically if they are too wide for the current window, and using normal tabular format otherwise. (This applies to statements terminated by `;` or `\G`.)

- `--batch, -B`

Command-Line Format	<code>--batch</code>
---------------------	----------------------

- `--binary-as-hex`

Command-Line Format	<code>--binary-as-hex</code>
Type	Boolean
Default Value	<code>FALSE</code> in noninteractive mode

When this option is given, `mysql` displays binary data using hexadecimal notation (*0xvalue*). This occurs whether the overall output display format is tabular, vertical, HTML, or XML.

`--binary-as-hex` when enabled affects display of all binary strings, including those returned by functions such as `CHAR()` and `UNHEX()`. The following example demonstrates this using the ASCII code for `A` (65 decimal, 41 hexadecimal):

- `--binary-as-hex` disabled:

```
mysql> SELECT CHAR(0x41), UNHEX('41');
+-----+-----+
| CHAR(0x41) | UNHEX('41') |
+-----+-----+
| A          | A           |
+-----+-----+
```

- `--binary-as-hex` enabled:

```
mysql> SELECT CHAR(0x41), UNHEX('41');
+-----+-----+
| CHAR(0x41) | UNHEX('41') |
+-----+-----+
| 0x41       | 0x41        |
+-----+-----+
```

To write a binary string expression so that it displays as a character string regardless of whether `--binary-as-hex` is enabled, use these techniques:

- The `CHAR()` function has a `USING charset` clause:

```
mysql> SELECT CHAR(0x41 USING utf8mb4);
+-----+
| CHAR(0x41 USING utf8mb4) |
+-----+
| A                          |
+-----+
```

- More generally, use `CONVERT()` to convert an expression to a given character set:

```
mysql> SELECT CONVERT(UNHEX('41') USING utf8mb4);
+-----+
| CONVERT(UNHEX('41') USING utf8mb4) |
+-----+
| A                                  |
+-----+
```

When `mysql` operates in interactive mode, this option is enabled by default. In addition, output from the `status` (or `\s`) command includes this line when the option is enabled implicitly or explicitly:

```
Binary data as: Hexadecimal
```

To disable hexadecimal notation, use `--skip-binary-as-hex`

- `--binary-mode`

Command-Line Format	<code>--binary-mode</code>
---------------------	----------------------------

This option helps when processing `mysqlbinlog` output that may contain `BLOB` values. By default, `mysql` translates `\r\n` in statement strings to `\n` and interprets `\0` as the statement terminator. `--binary-mode` disables both features. It also disables all `mysql` commands except `charset` and `delimiter` in noninteractive mode (for input piped to `mysql` or loaded using the `source` command).

- `--bind-address=ip_address`

Command-Line Format	<code>--bind-address=ip_address</code>
---------------------	--

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- `--character-sets-dir=dir_name`

Command-Line Format	<code>--character-sets-dir=dir_name</code>
Type	Directory name

The directory where character sets are installed. See [Section 12.15, “Character Set Configuration”](#).

- `--column-names`

Command-Line Format	<code>--column-names</code>
---------------------	-----------------------------

Write column names in results.

- `--column-type-info`

Command-Line Format	<code>--column-type-info</code>
---------------------	---------------------------------

Display result set metadata. This information corresponds to the contents of C API `MYSQL_FIELD` data structures. See [C API Basic Data Structures](#).

- `--comments, -c`

Command-Line Format	<code>--comments</code>
Type	Boolean
Default Value	<code>TRUE</code>

Whether to preserve or strip comments in statements sent to the server. The default is to preserve them; to strip them, start `mysql` with `--skip-comments`.

- `--compress, -C`

Command-Line Format	<code>--compress[={OFF ON}]</code>
Deprecated	Yes
Type	Boolean
Default Value	OFF

Compress all information sent between the client and the server if possible. See [Section 6.2.8, “Connection Compression Control”](#).

This option is deprecated. Expect it to be removed in a future version of MySQL. See [Configuring Legacy Connection Compression](#).

- `--compression-algorithms=value`

Command-Line Format	<code>--compression-algorithms=value</code>
Type	Set
Default Value	uncompressed
Valid Values	zlib zstd uncompressed

The permitted compression algorithms for connections to the server. The available algorithms are the same as for the `protocol_compression_algorithms` system variable. The default value is `uncompressed`.

For more information, see [Section 6.2.8, “Connection Compression Control”](#).

- `--connect-expired-password`

Command-Line Format	<code>--connect-expired-password</code>
---------------------	---

Indicate to the server that the client can handle sandbox mode if the account used to connect has an expired password. This can be useful for noninteractive invocations of `mysql` because normally the server disconnects noninteractive clients that attempt to connect using an account with an expired password. (See [Section 8.2.16, “Server Handling of Expired Passwords”](#).)

- `--connect-timeout=value`

Command-Line Format	<code>--connect-timeout=value</code>
Type	Numeric
Default Value	0

The number of seconds before connection timeout. (Default value is 0.)

- `--database=db_name, -D db_name`

Command-Line Format	<code>--database=dbname</code>
---------------------	--------------------------------

Type	String
------	--------

The database to use. This is useful primarily in an option file.

- `--debug[=debug_options], -# [debug_options]`

Command-Line Format	<code>--debug[=debug_options]</code>
Type	String
Default Value	<code>d:t:o,/tmp/mysql.trace</code>

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysql.trace`.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-check`

Command-Line Format	<code>--debug-check</code>
Type	Boolean
Default Value	<code>FALSE</code>

Print some debugging information when the program exits.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-info, -T`

Command-Line Format	<code>--debug-info</code>
Type	Boolean
Default Value	<code>FALSE</code>

Print debugging information and memory and CPU usage statistics when the program exits.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--default-auth=plugin`

Command-Line Format	<code>--default-auth=plugin</code>
Type	String

A hint about which client-side authentication plugin to use. See [Section 8.2.17, “Pluggable Authentication”](#).

- `--default-character-set=charset_name`

Command-Line Format	<code>--default-character-set=charset_name</code>
---------------------	---

Type	String
------	--------

Use `charset_name` as the default character set for the client and connection.

This option can be useful if the operating system uses one character set and the `mysql` client by default uses another. In this case, output may be formatted incorrectly. You can usually fix such issues by using this option to force the client to use the system character set instead.

For more information, see [Section 12.4, “Connection Character Sets and Collations”](#), and [Section 12.15, “Character Set Configuration”](#).

- `--defaults-extra-file=file_name`

Command-Line Format	<code>--defaults-extra-file=file_name</code>
Type	File name

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-file=file_name`

Command-Line Format	<code>--defaults-file=file_name</code>
Type	File name

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-group-suffix=str`

Command-Line Format	<code>--defaults-group-suffix=str</code>
Type	String

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysql` normally reads the `[client]` and `[mysql]` groups. If this option is given as `--defaults-group-suffix=_other`, `mysql` also reads the `[client_other]` and `[mysql_other]` groups.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--delimiter=str`

Command-Line Format	<code>--delimiter=str</code>
Type	String

Default Value	<code>;</code>
---------------	----------------

Set the statement delimiter. The default is the semicolon character (`;`).

- `--disable-named-commands`

Disable named commands. Use the `*` form only, or use named commands only at the beginning of a line ending with a semicolon (`;`). `mysql` starts with this option *enabled* by default. However, even with this option, long-format commands still work from the first line. See [Section 6.5.1.2, “mysql Client Commands”](#).

- `--dns-srv-name=name`

Command-Line Format	<code>--dns-srv-name=name</code>
Type	String

Specifies the name of a DNS SRV record that determines the candidate hosts to use for establishing a connection to a MySQL server. For information about DNS SRV support in MySQL, see [Section 6.2.6, “Connecting to the Server Using DNS SRV Records”](#).

Suppose that DNS is configured with this SRV information for the `example.com` domain:

Name	TTL	Class	Priority	Weight	Port	Target
<code>_mysql._tcp.example.com.</code>	86400	IN	SRV	0	5	<code>host1.example.com</code>
<code>_mysql._tcp.example.com.</code>	86400	IN	SRV	0	10	<code>host2.example.com</code>
<code>_mysql._tcp.example.com.</code>	86400	IN	SRV	10	5	<code>host3.example.com</code>
<code>_mysql._tcp.example.com.</code>	86400	IN	SRV	20	5	<code>host4.example.com</code>

To use that DNS SRV record, invoke `mysql` like this:

```
mysql --dns-srv-name=_mysql._tcp.example.com
```

`mysql` then attempts a connection to each server in the group until a successful connection is established. A failure to connect occurs only if a connection cannot be established to any of the servers. The priority and weight values in the DNS SRV record determine the order in which servers should be tried.

When invoked with `--dns-srv-name`, `mysql` attempts to establish TCP connections only.

The `--dns-srv-name` option takes precedence over the `--host` option if both are given. `--dns-srv-name` causes connection establishment to use the `mysql_real_connect_dns_srv()` C API function rather than `mysql_real_connect()`. However, if the `connect` command is subsequently used at runtime and specifies a host name argument, that host name takes precedence over any `--dns-srv-name` option given at `mysql` startup to specify a DNS SRV record.

- `--enable-cleartext-plugin`

Command-Line Format	<code>--enable-cleartext-plugin</code>
Type	Boolean
Default Value	<code>FALSE</code>

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 8.4.1.4, “Client-Side Cleartext Pluggable Authentication”](#).)

- `--execute=statement, -e statement`

Command-Line Format	<code>--execute=statement</code>
---------------------	----------------------------------

Type	String
------	--------

Execute the statement and quit. The default output format is like that produced with `--batch`. See [Section 6.2.2.1, “Using Options on the Command Line”](#), for some examples. With this option, `mysql` does not use the history file.

- `--fido-register-factor=value`

Command-Line Format	<code>--fido-register-factor=value</code>
Deprecated	Yes
Type	String

Note

This option is deprecated and subject to removal in a future MySQL release. It is superseded by the `--register-factor` option, which supports FIDO/FIDO2 device-based authentication. For related information, see [Section 8.4.1.11, “WebAuthn Pluggable Authentication”](#).

The factor or factors for which FIDO device registration must be performed. This option value must be a single value, or two values separated by commas. Each value must be 2 or 3, so the permitted option values are `'2'`, `'3'`, `'2,3'` and `'3,2'`.

For example, an account that requires registration for a 3rd authentication factor invokes the `mysql` client as follows:

```
mysql --user=user_name --fido-register-factor=3
```

An account that requires registration for a 2nd and 3rd authentication factor invokes the `mysql` client as follows:

```
mysql --user=user_name --fido-register-factor=2,3
```

If registration is successful, a connection is established. If there is an authentication factor with a pending registration, a connection is placed into pending registration mode when attempting to connect to the server. In this case, disconnect and reconnect with the correct `--fido-register-factor` value to complete the registration.

Registration is a two step process comprising *initiate registration* and *finish registration* steps. The initiate registration step executes this statement:

```
ALTER USER user_factor INITIATE REGISTRATION
```

The statement returns a result set containing a 32 byte challenge, the user name, and the relying party ID (see [authentication_fido_rp_id](#)).

The finish registration step executes this statement:

```
ALTER USER user_factor FINISH REGISTRATION SET CHALLENGE_RESPONSE AS 'auth_string'
```

The statement completes the registration and sends the following information to the server as part of the `auth_string`: authenticator data, an optional attestation certificate in X.509 format, and a signature.

The initiate and registration steps must be performed in a single connection, as the challenge received by the client during the initiate step is saved to the client connection handler. Registration would fail if the registration step was performed by a different connection. The `--fido-register-factor` option executes both the initiate and registration steps, which avoids the failure scenario

described above and prevents having to execute the `ALTER USER` initiate and registration statements manually.

The `--fido-register-factor` option is only available for the `mysql` client and MySQL Shell. Other MySQL client programs do not support it.

For related information, see [Using FIDO Authentication](#).

- `--force, -f`

Command-Line Format	<code>--force</code>
---------------------	----------------------

Continue even if an SQL error occurs.

- `--get-server-public-key`

Command-Line Format	<code>--get-server-public-key</code>
Type	Boolean

Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For information about the `caching_sha2_password` plugin, see [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

- `--histignore`

Command-Line Format	<code>--histignore=pattern_list</code>
Type	String

A list of one or more colon-separated patterns specifying statements to ignore for logging purposes. These patterns are added to the default pattern list (`"*IDENTIFIED*: *PASSWORD*"`). The value specified for this option affects logging of statements written to the history file, and to `syslog` if the `--syslog` option is given. For more information, see [Section 6.5.1.3, “mysql Client Logging”](#).

- `--host=host_name, -h host_name`

Command-Line Format	<code>--host=host_name</code>
Type	String
Default Value	<code>localhost</code>

Connect to the MySQL server on the given host.

The `--dns-srv-name` option takes precedence over the `--host` option if both are given. `--dns-srv-name` causes connection establishment to use the `mysql_real_connect_dns_srv()` C API function rather than `mysql_real_connect()`. However, if the `connect` command is subsequently used at runtime and specifies a host name argument, that host name takes precedence over any `--dns-srv-name` option given at `mysql` startup to specify a DNS SRV record.

- `--html, -H`

Command-Line Format	<code>--html</code>
---------------------	---------------------

Produce HTML output.

- `--ignore-spaces, -i`

Command-Line Format	<code>--ignore-spaces</code>
---------------------	------------------------------

Ignore spaces after function names. The effect of this is described in the discussion for the `IGNORE_SPACE` SQL mode (see [Section 7.1.11, “Server SQL Modes”](#)).

- `--init-command=str`

Command-Line Format	<code>--init-command=str</code>
---------------------	---------------------------------

Single SQL statement to execute after connecting to the server. If auto-reconnect is enabled, the statement is executed again after reconnection occurs. The definition resets existing statements defined by it or `init-command-add`.

- `--init-command-add=str`

Command-Line Format	<code>--init-command-add=str</code>
---------------------	-------------------------------------

Add an additional SQL statement to execute after connecting or reconnecting to the MySQL server. It's usable without `--init-command` but has no effect if used before it because `init-command` resets the list of commands to call. Option added in MySQL 8.2.0.

- `--line-numbers`

Command-Line Format	<code>--line-numbers</code>
Disabled by	<code>skip-line-numbers</code>

Write line numbers for errors. Disable this with `--skip-line-numbers`.

- `--load-data-local-dir=dir_name`

Command-Line Format	<code>--load-data-local-dir=dir_name</code>
Type	Directory name

Default Value	empty string
---------------	--------------

This option affects the client-side [LOCAL](#) capability for [LOAD DATA](#) operations. It specifies the directory in which files named in [LOAD DATA LOCAL](#) statements must be located. The effect of [--load-data-local-dir](#) depends on whether [LOCAL](#) data loading is enabled or disabled:

- If [LOCAL](#) data loading is enabled, either by default in the MySQL client library or by specifying [--local-infile\[=1\]](#), the [--load-data-local-dir](#) option is ignored.
- If [LOCAL](#) data loading is disabled, either by default in the MySQL client library or by specifying [--local-infile=0](#), the [--load-data-local-dir](#) option applies.

When [--load-data-local-dir](#) applies, the option value designates the directory in which local data files must be located. Comparison of the directory path name and the path name of files to be loaded is case-sensitive regardless of the case sensitivity of the underlying file system. If the option value is the empty string, it names no directory, with the result that no files are permitted for local data loading.

For example, to explicitly disable local data loading except for files located in the `/my/local/data` directory, invoke `mysql` like this:

```
mysql --local-infile=0 --load-data-local-dir=/my/local/data
```

When both [--local-infile](#) and [--load-data-local-dir](#) are given, the order in which they are given does not matter.

Successful use of [LOCAL](#) load operations within `mysql` also requires that the server permits local loading; see [Section 8.1.6, “Security Considerations for LOAD DATA LOCAL”](#)

- [--local-infile\[={0|1}\]](#)

Command-Line Format	--local-infile[={0 1}]
Type	Boolean
Default Value	FALSE

By default, [LOCAL](#) capability for [LOAD DATA](#) is determined by the default compiled into the MySQL client library. To enable or disable [LOCAL](#) data loading explicitly, use the [--local-infile](#) option. When given with no value, the option enables [LOCAL](#) data loading. When given as [--local-infile=0](#) or [--local-infile=1](#), the option disables or enables [LOCAL](#) data loading.

If [LOCAL](#) capability is disabled, the [--load-data-local-dir](#) option can be used to permit restricted local loading of files located in a designated directory.

Successful use of [LOCAL](#) load operations within `mysql` also requires that the server permits local loading; see [Section 8.1.6, “Security Considerations for LOAD DATA LOCAL”](#)

- [--login-path=name](#)

Command-Line Format	--login-path=name
Type	String

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to

authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

See `--login-path` for related information.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--max-allowed-packet=value`

Command-Line Format	<code>--max-allowed-packet=value</code>
Type	Numeric
Default Value	16777216

The maximum size of the buffer for client/server communication. The default is 16MB, the maximum is 1GB.

- `--max-join-size=value`

Command-Line Format	<code>--max-join-size=value</code>
Type	Numeric
Default Value	1000000

The automatic limit for rows in a join when using `--safe-updates`. (Default value is 1,000,000.)

- `--named-commands, -G`

Command-Line Format	<code>--named-commands</code>
Disabled by	<code>skip-named-commands</code>

Enable named `mysql` commands. Long-format commands are permitted, not just short-format commands. For example, `quit` and `\q` both are recognized. Use `--skip-named-commands` to disable named commands. See [Section 6.5.1.2, “mysql Client Commands”](#).

- `--net-buffer-length=value`

Command-Line Format	<code>--net-buffer-length=value</code>
Type	Numeric
Default Value	16384

- `--network-namespace=name`

Command-Line Format	<code>--network-namespace=name</code>
Type	String

The network namespace to use for TCP/IP connections. If omitted, the connection uses the default (global) namespace. For information about network namespaces, see [Section 7.1.14, “Network Namespace Support”](#).

This option is available only on platforms that implement network namespace support.

- `--no-auto-rehash`, `-A`

Command-Line Format	<code>--no-auto-rehash</code>
Deprecated	Yes

This has the same effect as `--skip-auto-rehash`. See the description for `--auto-rehash`.

- `--no-beep`, `-b`

Command-Line Format	<code>--no-beep</code>
---------------------	------------------------

Do not beep when errors occur.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--oci-config-file=PATH`

Command-Line Format	<code>--oci-config-file</code>
Type	String
Default Value	

Alternate path to the Oracle Cloud Infrastructure CLI configuration file. Specify the location of the configuration file. If your existing default profile is the correct one, you do not need to specify this option. However, if you have an existing configuration file, with multiple profiles or a different default from the tenancy of the user you want to connect with, specify this option.

- `--one-database`, `-o`

Command-Line Format	<code>--one-database</code>
---------------------	-----------------------------

Ignore statements except those that occur while the default database is the one named on the command line. This option is rudimentary and should be used with care. Statement filtering is based only on [USE](#) statements.

Initially, `mysql` executes statements in the input because specifying a database `db_name` on the command line is equivalent to inserting `USE db_name` at the beginning of the input. Then, for each `USE` statement encountered, `mysql` accepts or rejects following statements depending on whether the database named is the one on the command line. The content of the statements is immaterial.

Suppose that `mysql` is invoked to process this set of statements:

```
DELETE FROM db2.t2;
USE db2;
DROP TABLE db1.t1;
CREATE TABLE db1.t1 (i INT);
USE db1;
INSERT INTO t1 (i) VALUES(1);
CREATE TABLE db2.t1 (j INT);
```

If the command line is `mysql --force --one-database db1`, `mysql` handles the input as follows:

- The `DELETE` statement is executed because the default database is `db1`, even though the statement names a table in a different database.
- The `DROP TABLE` and `CREATE TABLE` statements are not executed because the default database is not `db1`, even though the statements name a table in `db1`.
- The `INSERT` and `CREATE TABLE` statements are executed because the default database is `db1`, even though the `CREATE TABLE` statement names a table in a different database.
- `--pager[=command]`

Command-Line Format	<code>--pager[=command]</code>
Disabled by	<code>skip-pager</code>
Type	String

Use the given command for paging query output. If the command is omitted, the default pager is the value of your `PAGER` environment variable. Valid pagers are `less`, `more`, `cat [> filename]`, and so forth. This option works only on Unix and only in interactive mode. To disable paging, use `--skip-pager`. [Section 6.5.1.2, “mysql Client Commands”](#), discusses output paging further.

- `--password[=password], -p[password]`

Command-Line Format	<code>--password[=password]</code>
Type	String

The password of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysql` prompts for one. If given, there must be *no space* between `--password=` or `-p` and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See [Section 8.1.2.1, “End-User Guidelines for Password Security”](#).

To explicitly specify that there is no password and that `mysql` should not prompt for one, use the `--skip-password` option.

- `--password1[=pass_val]`

The password for multifactor authentication factor 1 of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysql` prompts for one. If given, there must be *no space* between `--password1=` and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See [Section 8.1.2.1, “End-User Guidelines for Password Security”](#).

To explicitly specify that there is no password and that `mysql` should not prompt for one, use the `--skip-password1` option.

`--password1` and `--password` are synonymous, as are `--skip-password1` and `--skip-password`.

- `--password2[=pass_val]`

The password for multifactor authentication factor 2 of the MySQL account used for connecting to the server. The semantics of this option are similar to the semantics for `--password1`; see the description of that option for details.

- `--password3[=pass_val]`

The password for multifactor authentication factor 3 of the MySQL account used for connecting to the server. The semantics of this option are similar to the semantics for `--password1`; see the description of that option for details.

- `--pipe, -W`

Command-Line Format	<code>--pipe</code>
Type	String

On Windows, connect to the server using a named pipe. This option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--plugin-authentication-kerberos-client-mode=value`

Command-Line Format	<code>--plugin-authentication-kerberos-client-mode</code>
Type	String
Default Value	SSPI
Valid Values	GSSAPI SSPI

On Windows, the `authentication_kerberos_client` authentication plugin supports this plugin option. It provides two possible values that the client user can set at runtime: `SSPI` and `GSSAPI`.

The default value for the client-side plugin option uses Security Support Provider Interface (SSPI), which is capable of acquiring credentials from the Windows in-memory cache. Alternatively, the client user can select a mode that supports Generic Security Service Application Program Interface (GSSAPI) through the MIT Kerberos library on Windows. GSSAPI is capable of acquiring cached credentials previously generated by using the `kinit` command.

For more information, see [Commands for Windows Clients in GSSAPI Mode](#).

- `--plugin-authentication-webauthn-client-preserve-privacy={OFF|ON}`

Command-Line Format	<code>--plugin-authentication-webauthn-client-preserve-privacy</code>
Type	Boolean
Default Value	<code>OFF</code>

Determines how assertions are sent to server in case there are more than one discoverable credentials stored for a given RP ID (a unique name given to the relying-party server, which is the MySQL server). If the FIDO2 device contains multiple resident keys for a given RP ID, this option allows the user to choose a key to be used for assertion. It provides two possible values that the client user can set. The default value is `OFF`. If set to `OFF`, the challenge is signed by all credentials available for a given RP ID and all signatures are sent to server. If set to `ON`, the user is prompted to choose the credential to be used for signature.

Note

This option has no effect if the device does not support the resident-key feature.

For more information, see [Section 8.4.1.11, “WebAuthn Pluggable Authentication”](#).

- `--plugin-dir=dir_name`

Command-Line Format	<code>--plugin-dir=dir_name</code>
Type	Directory name

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysql` does not find it. See [Section 8.2.17, “Pluggable Authentication”](#).

- `--port=port_num, -P port_num`

Command-Line Format	<code>--port=port_num</code>
Type	Numeric
Default Value	<code>3306</code>

For TCP/IP connections, the port number to use.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--prompt=format_str`

Type	String
Default Value	<code>mysql></code>

Set the prompt to the specified format. The default is `mysql>`. The special sequences that the prompt can contain are described in [Section 6.5.1.2, “mysql Client Commands”](#).

- `--protocol={TCP | SOCKET | PIPE | MEMORY}`

Command-Line Format	<code>--protocol=type</code>
Type	String
Default Value	[see text]
Valid Values	TCP SOCKET PIPE MEMORY

The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see [Section 6.2.7, “Connection Transport Protocols”](#).

- `--quick, -q`

Command-Line Format	<code>--quick</code>
---------------------	----------------------

Do not cache each query result, print each row as it is received. This may slow down the server if the output is suspended. With this option, `mysql` does not use the history file.

By default, `mysql` fetches all result rows before producing any output; while storing these, it calculates a running maximum column length from the actual value of each column in succession. When printing the output, it uses this maximum to format it. When `--quick` is specified, `mysql` does not have the rows for which to calculate the length before starting, and so uses the maximum length. In the following example, table `t1` has a single column of type `BIGINT` and containing 4 rows. The default output is 9 characters wide; this width is equal the maximum number of characters in any of the column values in the rows returned (5), plus 2 characters each for the spaces used as padding and the `|` characters used as column delimiters). The output when using the `--quick` option is 25 characters wide; this is equal to the number of characters needed to represent `-9223372036854775808`, which is the longest possible value that can be stored in a (signed) `BIGINT` column, or 19 characters, plus the 4 characters used for padding and column delimiters. The difference can be seen here:

```
$> mysql -t test -e "SELECT * FROM t1"
+-----+
| c1    |
+-----+
| 100   |
| 1000  |
| 10000 |
| 10    |
+-----+

$> mysql --quick -t test -e "SELECT * FROM t1"
+-----+
| c1    |
+-----+
| 100   |
```

```
|          1000 |
|         10000 |
|           10  |
+-----+

```

- `--raw, -r`

Command-Line Format	<code>--raw</code>
---------------------	--------------------

For tabular output, the “boxing” around columns enables one column value to be distinguished from another. For nontabular output (such as is produced in batch mode or when the `--batch` or `--silent` option is given), special characters are escaped in the output so they can be identified easily. Newline, tab, `NUL`, and backslash are written as `\n`, `\t`, `\0`, and `\\`. The `--raw` option disables this character escaping.

The following example demonstrates tabular versus nontabular output and the use of raw mode to disable escaping:

```
% mysql
mysql> SELECT CHAR(92);
+-----+
| CHAR(92) |
+-----+
| \        |
+-----+

% mysql -s
mysql> SELECT CHAR(92);
CHAR(92)
\\

% mysql -s -r
mysql> SELECT CHAR(92);
CHAR(92)
\

```

- `--reconnect`

Command-Line Format	<code>--reconnect</code>
Disabled by	<code>skip-reconnect</code>

If the connection to the server is lost, automatically try to reconnect. A single reconnect attempt is made each time the connection is lost. To suppress reconnection behavior, use `--skip-reconnect`.

- `--register-factor=value`

Command-Line Format	<code>--register-factor=value</code>
Type	String

The factor or factors for which FIDO/FIDO2 device registration must be performed before WebAuthn device-based authentication can be used. This option value must be a single value, or two values

separated by commas. Each value must be 2 or 3, so the permitted option values are '2', '3', '2,3' and '3,2'.

For example, an account that requires registration for a 3rd authentication factor invokes the `mysql` client as follows:

```
mysql --user=user_name --register-factor=3
```

An account that requires registration for a 2nd and 3rd authentication factor invokes the `mysql` client as follows:

```
mysql --user=user_name --register-factor=2,3
```

If registration is successful, a connection is established. If there is an authentication factor with a pending registration, a connection is placed into pending registration mode when attempting to connect to the server. In this case, disconnect and reconnect with the correct `--register-factor` value to complete the registration.

Registration is a two step process comprising *initiate registration* and *finish registration* steps. The initiate registration step executes this statement:

```
ALTER USER user_factor INITIATE REGISTRATION
```

The statement returns a result set containing a 32 byte challenge, the user name, and the relying party ID (see `authentication_webauthn_rp_id`).

The finish registration step executes this statement:

```
ALTER USER user_factor FINISH REGISTRATION SET CHALLENGE_RESPONSE AS 'auth_string'
```

The statement completes the registration and sends the following information to the server as part of the `auth_string`: authenticator data, an optional attestation certificate in X.509 format, and a signature.

The initiate and registration steps must be performed in a single connection, as the challenge received by the client during the initiate step is saved to the client connection handler. Registration would fail if the registration step was performed by a different connection. The `--register-factor` option executes both the initiate and registration steps, which avoids the failure scenario described above and prevents having to execute the `ALTER USER` initiate and registration statements manually.

The `--register-factor` option is only available for the `mysql` and MySQL Shell clients. Other MySQL client programs do not support it.

For related information, see [Using WebAuthn Authentication](#).

- `--safe-updates`, `--i-am-a-dummy`, `-U`

Command-Line Format	<code>--safe-updates</code> <code>--i-am-a-dummy</code>
Type	Boolean
Default Value	<code>FALSE</code>

If this option is enabled, `UPDATE` and `DELETE` statements that do not use a key in the `WHERE` clause or a `LIMIT` clause produce an error. In addition, restrictions are placed on `SELECT` statements that produce (or are estimated to produce) very large result sets. If you have set this option in an option file, you can use `--skip-safe-updates` on the command line to override it. For more information about this option, see [Using Safe-Updates Mode \(--safe-updates\)](#).

- `--select-limit=value`

Command-Line Format	<code>--select-limit=value</code>
Type	Numeric
Default Value	1000

The automatic limit for `SELECT` statements when using `--safe-updates`. (Default value is 1,000.)

- `--server-public-key-path=file_name`

Command-Line Format	<code>--server-public-key-path=file_name</code>
Type	File name

The path name to a file in PEM format containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For `sha256_password`, this option applies only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see [Section 8.4.1.3, “SHA-256 Pluggable Authentication”](#), and [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

- `--shared-memory-base-name=name`

Command-Line Format	<code>--shared-memory-base-name=name</code>
Platform Specific	Windows

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

- `--show-warnings`

Command-Line Format	<code>--show-warnings</code>
---------------------	------------------------------

Cause warnings to be shown after each statement if there are any. This option applies to interactive and batch mode.

- `--sigint-ignore`

Command-Line Format	<code>--sigint-ignore</code>
---------------------	------------------------------

Ignore `SIGINT` signals (typically the result of typing **Control+C**).

Without this option, typing **Control+C** interrupts the current statement if there is one, or cancels any partial input line otherwise.

- `--silent, -s`

Command-Line Format	<code>--silent</code>
---------------------	-----------------------

Silent mode. Produce less output. This option can be given multiple times to produce less and less output.

This option results in nontabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the `--raw` option.

- `--skip-column-names, -N`

Command-Line Format	<code>--skip-column-names</code>
---------------------	----------------------------------

Do not write column names in results. Use of this option causes the output to be right-aligned, as shown here:

```
$> echo "SELECT * FROM t1" | mysql -t test
+-----+
| c1      |
+-----+
| a,c,d   |
| c       |
+-----+
$> echo "SELECT * FROM t1" | ./mysql -uroot -Nt test
+-----+
| a,c,d   |
|         c |
+-----+
```

- `--skip-line-numbers, -L`

Command-Line Format	<code>--skip-line-numbers</code>
---------------------	----------------------------------

Do not write line numbers for errors. Useful when you want to compare result files that include error messages.

- `--socket=path, -S path`

Command-Line Format	<code>--socket={file_name pipe_name}</code>
Type	String

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See [Command Options for Encrypted Connections](#).

- `--ssl-fips-mode={OFF|ON|STRICT}`

Command-Line Format	<code>--ssl-fips-mode={OFF ON STRICT}</code>
Deprecated	Yes
Type	Enumeration
Default Value	<code>OFF</code>
Valid Values	<code>OFF</code> <code>ON</code> <code>STRICT</code>

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations to permit. See [Section 8.8, “FIPS Support”](#).

These `--ssl-fips-mode` values are permitted:

- `OFF`: Disable FIPS mode.
- `ON`: Enable FIPS mode.
- `STRICT`: Enable “strict” FIPS mode.

Note

If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is `OFF`. In this case, setting `--ssl-fips-mode` to `ON` or `STRICT` causes the client to produce a warning at startup and to operate in non-FIPS mode.

This option is deprecated. Expect it to be removed in a future version of MySQL.

- `--syslog, -j`

Command-Line Format	<code>--syslog</code>
---------------------	-----------------------

This option causes `mysql` to send interactive statements to the system logging facility. On Unix, this is `syslog`; on Windows, it is the Windows Event Log. The destination where logged messages appear is system dependent. On Linux, the destination is often the `/var/log/messages` file.

Here is a sample of output generated on Linux by using `--syslog`. This output is formatted for readability; each logged message actually takes a single line.

```
Mar  7 12:39:25 myhost MysqlClient[20824]:
  SYSTEM_USER:'oscar', MYSQL_USER:'my_oscar', CONNECTION_ID:23,
  DB_SERVER:'127.0.0.1', DB:'--', QUERY:'USE test;'
Mar  7 12:39:28 myhost MysqlClient[20824]:
  SYSTEM_USER:'oscar', MYSQL_USER:'my_oscar', CONNECTION_ID:23,
```

```
DB_SERVER: '127.0.0.1', DB: 'test', QUERY: 'SHOW TABLES;'
```

For more information, see [Section 6.5.1.3, “mysql Client Logging”](#).

- `--table, -t`

Command-Line Format	<code>--table</code>
---------------------	----------------------

Display output in table format. This is the default for interactive use, but can be used to produce table output in batch mode.

- `--tee=file_name`

Command-Line Format	<code>--tee=file_name</code>
Type	File name

Append a copy of output to the given file. This option works only in interactive mode. [Section 6.5.1.2, “mysql Client Commands”](#), discusses tee files further.

- `--tls-ciphersuites=ciphersuite_list`

Command-Line Format	<code>--tls-ciphersuites=ciphersuite_list</code>
Type	String

The permissible ciphersuites for encrypted connections that use TLSv1.3. The value is a list of one or more colon-separated ciphersuite names. The ciphersuites that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `--tls-sni-servername=server_name`

Command-Line Format	<code>--tls-sni-servername=server_name</code>
Type	String

When specified, the name is passed to the `libmysqlclient` C API library using the `MYSQL_OPT_TLS_SNI_SERVERNAME` option of `mysql_options()`. The server name is not case-sensitive. To show which server name the client specified for the current session, if any, check the `Tls_sni_server_name` status variable.

Server Name Indication (SNI) is an extension to the TLS protocol (OpenSSL must be compiled using TLS extensions for this option to function). The MySQL implementation of SNI represents the client-side only.

- `--tls-version=protocol_list`

Command-Line Format	<code>--tls-version=protocol_list</code>
Type	String
Default Value	<code>TLSv1, TLSv1.1, TLSv1.2, TLSv1.3</code> (OpenSSL 1.1.1 or higher) <code>TLSv1, TLSv1.1, TLSv1.2</code> (otherwise)

The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL

library used to compile MySQL. For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `--unbuffered, -n`

Command-Line Format	<code>--unbuffered</code>
---------------------	---------------------------

Flush the buffer after each query.

- `--user=user_name, -u user_name`

Command-Line Format	<code>--user=user_name</code>
Type	String

The user name of the MySQL account to use for connecting to the server.

- `--verbose, -v`

Command-Line Format	<code>--verbose</code>
---------------------	------------------------

Verbose mode. Produce more output about what the program does. This option can be given multiple times to produce more and more output. (For example, `-v -v -v` produces table output format even in batch mode.)

- `--version, -V`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

- `--vertical, -E`

Command-Line Format	<code>--vertical</code>
---------------------	-------------------------

Print query output rows vertically (one line per column value). Without this option, you can specify vertical output for individual statements by terminating them with `\G`.

- `--wait, -w`

Command-Line Format	<code>--wait</code>
---------------------	---------------------

If the connection cannot be established, wait and retry instead of aborting.

- `--xml, -X`

Command-Line Format	<code>--xml</code>
---------------------	--------------------

Produce XML output.

```
<field name="column_name">NULL</field>
```

The output when `--xml` is used with `mysql` matches that of `mysqldump --xml`. See [Section 6.5.4, “mysqldump — A Database Backup Program”](#), for details.

The XML output also uses an XML namespace, as shown here:

```
$> mysql --xml -uroot -e "SHOW VARIABLES LIKE 'version%'"
<?xml version="1.0"?>

<resultset statement="SHOW VARIABLES LIKE 'version%'" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <row>
    <field name="Variable_name">version</field>
    <field name="Value">5.0.40-debug</field>
  </row>

  <row>
    <field name="Variable_name">version_comment</field>
    <field name="Value">Source distribution</field>
  </row>

  <row>
    <field name="Variable_name">version_compile_machine</field>
    <field name="Value">i686</field>
  </row>

  <row>
    <field name="Variable_name">version_compile_os</field>
    <field name="Value">suse-linux-gnu</field>
  </row>
</resultset>
```

- `--zstd-compression-level=level`

Command-Line Format	<code>--zstd-compression-level=#</code>
Type	Integer

The compression level to use for connections to the server that use the `zstd` compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression. The default `zstd` compression level is 3. The compression level setting has no effect on connections that do not use `zstd` compression.

For more information, see [Section 6.2.8, “Connection Compression Control”](#).

- `telemetry_client`

Command-Line Format	<code>--telemetry_client</code>
Type	Boolean
Default Value	<code>OFF</code>

Enables the telemetry client plugin (Linux only).

6.5.1.2 mysql Client Commands

`mysql` sends each SQL statement that you issue to the server to be executed. There is also a set of commands that `mysql` itself interprets. For a list of these commands, type `help` or `\h` at the `mysql>` prompt:

```
mysql> help

List of all MySQL commands:
Note that all text commands must be first on line and end with ';'
?          (\?) Synonym for 'help'.
clear      (\c) Clear the current input statement.
connect    (\r) Reconnect to the server. Optional arguments are db and host.
delimiter  (\d) Set statement delimiter.
edit       (\e) Edit command with $EDITOR.
ego        (\G) Send command to mysql server, display result vertically.
exit       (\q) Exit mysql. Same as quit.
go         (\g) Send command to mysql server.
help       (\h) Display this help.
nopager    (\n) Disable pager, print to stdout.
notee      (\t) Don't write into outfile.
pager      (\P) Set PAGER [to_pager]. Print the query results via PAGER.
print      (\p) Print current command.
prompt     (\R) Change your mysql prompt.
quit       (\q) Quit mysql.
rehash     (\#) Rebuild completion hash.
source     (\.) Execute an SQL script file. Takes a file name as an argument.
status     (\s) Get status information from the server.
system     (\!) Execute a system shell command.
tee        (\T) Set outfile [to_outfile]. Append everything into given
           outfile.
use        (\u) Use another database. Takes database name as argument.
charset    (\C) Switch to another charset. Might be needed for processing
           binlog with multi-byte charsets.
warnings   (\W) Show warnings after every statement.
nowarning  (\w) Don't show warnings after every statement.
resetconnection(\x) Clean session context.
query_attributes Sets string parameters (name1 value1 name2 value2 ...)
for the next query to pick up.
ssl_session_data_print Serializes the current SSL session data to stdout
or file.

For server side help, type 'help contents'
```

If `mysql` is invoked with the `--binary-mode` option, all `mysql` commands are disabled except `charset` and `delimiter` in noninteractive mode (for input piped to `mysql` or loaded using the `source` command).

Each command has both a long and short form. The long form is not case-sensitive; the short form is. The long form can be followed by an optional semicolon terminator, but the short form should not.

The use of short-form commands within multiple-line `/* ... */` comments is not supported. Short-form commands do work within single-line `/*! ... */` version comments, as do `/*+ ... */` optimizer-hint comments, which are stored in object definitions. If there is a concern that optimizer-hint comments may be stored in object definitions so that dump files when reloaded with `mysql` would result in execution of such commands, either invoke `mysql` with the `--binary-mode` option or use a reload client other than `mysql`.

- `help [arg], \h [arg], \? [arg], ? [arg]`

Display a help message listing the available `mysql` commands.

If you provide an argument to the `help` command, `mysql` uses it as a search string to access server-side help from the contents of the MySQL Reference Manual. For more information, see [Section 6.5.1.4, “mysql Client Server-Side Help”](#).

- `charset charset_name, \C charset_name`

Change the default character set and issue a `SET NAMES` statement. This enables the character set to remain synchronized on the client and server if `mysql` is run with auto-reconnect enabled (which is not recommended), because the specified character set is used for reconnects.

- `clear, \c`

Clear the current input. Use this if you change your mind about executing the statement that you are entering.

- `connect [db_name [host_name]], \r [db_name [host_name]]`

Reconnect to the server. The optional database name and host name arguments may be given to specify the default database or the host where the server is running. If omitted, the current values are used.

If the `connect` command specifies a host name argument, that host takes precedence over any `--dns-srv-name` option given at `mysql` startup to specify a DNS SRV record.

- `delimiter str, \d str`

Change the string that `mysql` interprets as the separator between SQL statements. The default is the semicolon character (`;`).

The delimiter string can be specified as an unquoted or quoted argument on the `delimiter` command line. Quoting can be done with either single quote (`'`), double quote (`"`), or backtick (```) characters. To include a quote within a quoted string, either quote the string with a different quote character or escape the quote with a backslash (`\`) character. Backslash should be avoided outside of quoted strings because it is the escape character for MySQL. For an unquoted argument, the delimiter is read up to the first space or end of line. For a quoted argument, the delimiter is read up to the matching quote on the line.

`mysql` interprets instances of the delimiter string as a statement delimiter anywhere it occurs, except within quoted strings. Be careful about defining a delimiter that might occur within other words. For example, if you define the delimiter as `x`, it is not possible to use the word `INDEX` in statements. `mysql` interprets this as `INDE` followed by the delimiter `x`.

When the delimiter recognized by `mysql` is set to something other than the default of `;`, instances of that character are sent to the server without interpretation. However, the server itself still interprets `;` as a statement delimiter and processes statements accordingly. This behavior on the server side comes into play for multiple-statement execution (see [Multiple Statement Execution Support](#)), and for parsing the body of stored procedures and functions, triggers, and events (see [Section 27.1, “Defining Stored Programs”](#)).

- `edit, \e`

Edit the current input statement. `mysql` checks the values of the `EDITOR` and `VISUAL` environment variables to determine which editor to use. The default editor is `vi` if neither variable is set.

The `edit` command works only in Unix.

- `ego, \G`

Send the current statement to the server to be executed and display the result using vertical format.

- `exit, \q`

Exit `mysql`.

- `go, \g`

Send the current statement to the server to be executed.

- `nopager, \n`

Disable output paging. See the description for `pager`.

The `nopager` command works only in Unix.

- `notee, \t`

Disable output copying to the tee file. See the description for `tee`.

- `nowarning, \w`

Disable display of warnings after each statement.

- `pager [command], \P [command]`

Enable output paging. By using the `--pager` option when you invoke `mysql`, it is possible to browse or search query results in interactive mode with Unix programs such as `less`, `more`, or any other similar program. If you specify no value for the option, `mysql` checks the value of the `PAGER` environment variable and sets the pager to that. Pager functionality works only in interactive mode.

Output paging can be enabled interactively with the `pager` command and disabled with `nopager`. The command takes an optional argument; if given, the paging program is set to that. With no argument, the pager is set to the pager that was set on the command line, or `stdout` if no pager was specified.

Output paging works only in Unix because it uses the `popen()` function, which does not exist on Windows. For Windows, the `tee` option can be used instead to save query output, although it is not as convenient as `pager` for browsing output in some situations.

- `print, \p`

Print the current input statement without executing it.

- `prompt [str], \R [str]`

Reconfigure the `mysql` prompt to the given string. The special character sequences that can be used in the prompt are described later in this section.

If you specify the `prompt` command with no argument, `mysql` resets the prompt to the default of `mysql>`.

- `query_attributes name value [name value ...]`

Define query attributes that apply to the next query sent to the server. For discussion of the purpose and use of query attributes, see [Section 11.6, “Query Attributes”](#).

The `query_attributes` command follows these rules:

- The format and quoting rules for attribute names and values are the same as for the `delimiter` command.
- The command permits up to 32 attribute name/value pairs. Names and values may be up to 1024 characters long. If a name is given without a value, an error occurs.
- If multiple `query_attributes` commands are issued prior to query execution, only the last command applies. After sending the query, `mysql` clears the attribute set.
- If multiple attributes are defined with the same name, attempts to retrieve the attribute value have an undefined result.
- An attribute defined with an empty name cannot be retrieved by name.

- If a reconnect occurs while `mysql` executes the query, `mysql` restores the attributes after reconnecting so the query can be executed again with the same attributes.

- `quit, \q`

Exit `mysql`.

- `rehash, \#`

Rebuild the completion hash that enables database, table, and column name completion while you are entering statements. (See the description for the `--auto-rehash` option.)

- `resetconnection, \x`

Reset the connection to clear the session state. This includes clearing any current query attributes defined using the `query_attributes` command.

Resetting a connection has effects similar to `mysql_change_user()` or an auto-reconnect except that the connection is not closed and reopened, and re-authentication is not done. See `mysql_change_user()`, and [Automatic Reconnection Control](#).

This example shows how `resetconnection` clears a value maintained in the session state:

```
mysql> SELECT LAST_INSERT_ID(3);
+-----+
| LAST_INSERT_ID(3) |
+-----+
|                  3 |
+-----+

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
|                  3 |
+-----+

mysql> resetconnection;

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
|                  0 |
+-----+
```

- `source file_name, \. file_name`

Read the named file and executes the statements contained therein. On Windows, specify path name separators as `/` or `\\`.

Quote characters are taken as part of the file name itself. For best results, the name should not include space characters.

- `ssl_session_data_print [file_name]`

Fetches, serializes, and optionally stores the session data of a successful connection. The optional file name and arguments may be given to specify the file to store serialized session data. If omitted, the session data is printed to `stdout`.

If the MySQL session is configured for reuse, session data from the file is deserialized and supplied to the `connect` command to reconnect. When the session is reused successfully, the `status` command contains a row showing `SSL session reused: true` while the client remains reconnected to the server.

- `status, \s`

Provide status information about the connection and the server you are using. If you are running with `--safe-updates` enabled, `status` also prints the values for the `mysql` variables that affect your queries.

- `system command, \! command`

Execute the given command using your default command interpreter.

- `tee [file_name], \T [file_name]`

By using the `--tee` option when you invoke `mysql`, you can log statements and their output. All the data displayed on the screen is appended into a given file. This can be very useful for debugging purposes also. `mysql` flushes results to the file after each statement, just before it prints its next prompt. Tee functionality works only in interactive mode.

You can enable this feature interactively with the `tee` command. Without a parameter, the previous file is used. The `tee` file can be disabled with the `notee` command. Executing `tee` again re-enables logging.

- `use db_name, \u db_name`

Use `db_name` as the default database.

- `warnings, \W`

Enable display of warnings after each statement (if there are any).

Here are a few tips about the `pager` command:

- You can use it to write to a file and the results go only to the file:

```
mysql> pager cat > /tmp/log.txt
```

You can also pass any options for the program that you want to use as your pager:

```
mysql> pager less -n -i -S
```

- In the preceding example, note the `-S` option. You may find it very useful for browsing wide query results. Sometimes a very wide result set is difficult to read on the screen. The `-S` option to `less` can make the result set much more readable because you can scroll it horizontally using the left-arrow and right-arrow keys. You can also use `-S` interactively within `less` to switch the horizontal-browse mode on and off. For more information, read the `less` manual page:

```
man less
```

- The `-F` and `-X` options may be used with `less` to cause it to exit if output fits on one screen, which is convenient when no scrolling is necessary:

```
mysql> pager less -n -i -S -F -X
```

- You can specify very complex pager commands for handling query output:

```
mysql> pager cat | tee /dr1/tmp/res.txt \
      | tee /dr2/tmp/res2.txt | less -n -i -S
```

In this example, the command would send query results to two files in two different directories on two different file systems mounted on `/dr1` and `/dr2`, yet still display the results onscreen using `less`.

You can also combine the `tee` and `pager` functions. Have a `tee` file enabled and `pager` set to `less`, and you are able to browse the results using the `less` program and still have everything appended into a file the same time. The difference between the Unix `tee` used with the `pager` command and the `mysql` built-in `tee` command is that the built-in `tee` works even if you do not have the Unix `tee`

available. The built-in `tee` also logs everything that is printed on the screen, whereas the Unix `tee` used with `pager` does not log quite that much. Additionally, `tee` file logging can be turned on and off interactively from within `mysql`. This is useful when you want to log some queries to a file, but not others.

The `prompt` command reconfigures the default `mysql>` prompt. The string for defining the prompt can contain the following special sequences.

Option	Description
<code>\C</code>	The current connection identifier
<code>\c</code>	A counter that increments for each statement you issue
<code>\D</code>	The full current date
<code>\d</code>	The default database
<code>\h</code>	The server host
<code>\l</code>	The current delimiter
<code>\m</code>	Minutes of the current time
<code>\n</code>	A newline character
<code>\O</code>	The current month in three-letter format (Jan, Feb, ...)
<code>\o</code>	The current month in numeric format
<code>\P</code>	am/pm
<code>\p</code>	The current TCP/IP port or socket file
<code>\R</code>	The current time, in 24-hour military time (0–23)
<code>\r</code>	The current time, standard 12-hour time (1–12)
<code>\S</code>	Semicolon
<code>\s</code>	Seconds of the current time
<code>\T</code>	Print an asterisk (*) if the current session is inside a transaction block
<code>\t</code>	A tab character
<code>\U</code>	Your full <code>user_name@host_name</code> account name
<code>\u</code>	Your user name
<code>\v</code>	The server version
<code>\w</code>	The current day of the week in three-letter format (Mon, Tue, ...)
<code>\Y</code>	The current year, four digits
<code>\y</code>	The current year, two digits
<code>_</code>	A space
<code>\</code>	A space (a space follows the backslash)
<code>\'</code>	Single quote
<code>\"</code>	Double quote
<code>\\</code>	A literal <code>\</code> backslash character
<code>\x</code>	<code>x</code> , for any “ <code>x</code> ” not listed above

You can set the prompt in several ways:

- *Use an environment variable.* You can set the `MYSQL_PS1` environment variable to a prompt string. For example:

```
export MYSQL_PS1="(\u@\h) [\d]> "
```

- *Use a command-line option.* You can set the `--prompt` option on the command line to `mysql`. For example:

```
$> mysql --prompt="(\u@\h) [\d]> "
(user@host) [database]>
```

- *Use an option file.* You can set the `prompt` option in the `[mysql]` group of any MySQL option file, such as `/etc/my.cnf` or the `.my.cnf` file in your home directory. For example:

```
[mysql]
prompt=(\u@\h) [\d]>\_
```

In this example, note that the backslashes are doubled. If you set the prompt using the `prompt` option in an option file, it is advisable to double the backslashes when using the special prompt options. There is some overlap in the set of permissible prompt options and the set of special escape sequences that are recognized in option files. (The rules for escape sequences in option files are listed in [Section 6.2.2.2, “Using Option Files”](#).) The overlap may cause you problems if you use single backslashes. For example, `\s` is interpreted as a space rather than as the current seconds value. The following example shows how to define a prompt within an option file to include the current time in `hh:mm:ss>` format:

```
[mysql]
prompt="\r:\m:\s> "
```

- *Set the prompt interactively.* You can change your prompt interactively by using the `prompt` (or `\R`) command. For example:

```
mysql> prompt (\u@\h) [\d]>\_
PROMPT set to '(\u@\h) [\d]>\_'
(user@host) [database]>
(user@host) [database]> prompt
Returning to default PROMPT of mysql>
mysql>
```

6.5.1.3 mysql Client Logging

The `mysql` client can do these types of logging for statements executed interactively:

- On Unix, `mysql` writes the statements to a history file. By default, this file is named `.mysql_history` in your home directory. To specify a different file, set the value of the `MYSQL_HISTFILE` environment variable.
- On all platforms, if the `--syslog` option is given, `mysql` writes the statements to the system logging facility. On Unix, this is `syslog`; on Windows, it is the Windows Event Log. The destination where logged messages appear is system dependent. On Linux, the destination is often the `/var/log/messages` file.

The following discussion describes characteristics that apply to all logging types and provides information specific to each logging type.

- [How Logging Occurs](#)
- [Controlling the History File](#)
- [syslog Logging Characteristics](#)

How Logging Occurs

For each enabled logging destination, statement logging occurs as follows:

- Statements are logged only when executed interactively. Statements are noninteractive, for example, when read from a file or a pipe. It is also possible to suppress statement logging by using the `--batch` or `--execute` option.

- Statements are ignored and not logged if they match any pattern in the “ignore” list. This list is described later.
- `mysql` logs each nonignored, nonempty statement line individually.
- If a nonignored statement spans multiple lines (not including the terminating delimiter), `mysql` concatenates the lines to form the complete statement, maps newlines to spaces, and logs the result, plus a delimiter.

Consequently, an input statement that spans multiple lines can be logged twice. Consider this input:

```
mysql> SELECT
-> 'Today is'
-> ,
-> CURDATE()
-> ;
```

In this case, `mysql` logs the “SELECT”, “Today is”, “,”, “CURDATE()”, and “;” lines as it reads them. It also logs the complete statement, after mapping `SELECT\n'Today is'\n,\nCURDATE()` to `SELECT 'Today is' , CURDATE()`, plus a delimiter. Thus, these lines appear in logged output:

```
SELECT
'Today is'
,
CURDATE()
;
SELECT 'Today is' , CURDATE();
```

`mysql` ignores for logging purposes statements that match any pattern in the “ignore” list. By default, the pattern list is “`*IDENTIFIED*: *PASSWORD*`”, to ignore statements that refer to passwords. Pattern matching is not case-sensitive. Within patterns, two characters are special:

- `?` matches any single character.
- `*` matches any sequence of zero or more characters.

To specify additional patterns, use the `--histignore` option or set the `MYSQL_HISTIGNORE` environment variable. (If both are specified, the option value takes precedence.) The value should be a list of one or more colon-separated patterns, which are appended to the default pattern list.

Patterns specified on the command line might need to be quoted or escaped to prevent your command interpreter from treating them specially. For example, to suppress logging for `UPDATE` and `DELETE` statements in addition to statements that refer to passwords, invoke `mysql` like this:

```
mysql --histignore="*UPDATE*: *DELETE*"
```

Controlling the History File

The `.mysql_history` file should be protected with a restrictive access mode because sensitive information might be written to it, such as the text of SQL statements that contain passwords. See [Section 8.1.2.1, “End-User Guidelines for Password Security”](#). Statements in the file are accessible from the `mysql` client when the **up-arrow** key is used to recall the history. See [Disabling Interactive History](#).

If you do not want to maintain a history file, first remove `.mysql_history` if it exists. Then use either of the following techniques to prevent it from being created again:

- Set the `MYSQL_HISTFILE` environment variable to `/dev/null`. To cause this setting to take effect each time you log in, put it in one of your shell's startup files.
- Create `.mysql_history` as a symbolic link to `/dev/null`; this need be done only once:

```
ln -s /dev/null $HOME/.mysql_history
```

syslog Logging Characteristics

If the `--syslog` option is given, `mysql` writes interactive statements to the system logging facility. Message logging has the following characteristics.

Logging occurs at the “information” level. This corresponds to the `LOG_INFO` priority for `syslog` on Unix/Linux `syslog` capability and to `EVENTLOG_INFORMATION_TYPE` for the Windows Event Log. Consult your system documentation for configuration of your logging capability.

Message size is limited to 1024 bytes.

Messages consist of the identifier `MysqlClient` followed by these values:

- `SYSTEM_USER`

The operating system user name (login name) or `--` if the user is unknown.

- `MYSQL_USER`

The MySQL user name (specified with the `--user` option) or `--` if the user is unknown.

- `CONNECTION_ID`:

The client connection identifier. This is the same as the `CONNECTION_ID()` function value within the session.

- `DB_SERVER`

The server host or `--` if the host is unknown.

- `DB`

The default database or `--` if no database has been selected.

- `QUERY`

The text of the logged statement.

Here is a sample of output generated on Linux by using `--syslog`. This output is formatted for readability; each logged message actually takes a single line.

```
Mar  7 12:39:25 myhost MysqlClient[20824]:
  SYSTEM_USER:'oscar', MYSQL_USER:'my_oscar', CONNECTION_ID:23,
  DB_SERVER:'127.0.0.1', DB:'--', QUERY:'USE test;'
Mar  7 12:39:28 myhost MysqlClient[20824]:
  SYSTEM_USER:'oscar', MYSQL_USER:'my_oscar', CONNECTION_ID:23,
  DB_SERVER:'127.0.0.1', DB:'test', QUERY:'SHOW TABLES;'
```

6.5.1.4 mysql Client Server-Side Help

```
mysql> help search_string
```

If you provide an argument to the `help` command, `mysql` uses it as a search string to access server-side help from the contents of the MySQL Reference Manual. The proper operation of this command requires that the help tables in the `mysql` database be initialized with help topic information (see [Section 7.1.17, “Server-Side Help Support”](#)).

If there is no match for the search string, the search fails:

```
mysql> help me

Nothing found
Please try to run 'help contents' for a list of all accessible topics
```

Use `help contents` to see a list of the help categories:

```
mysql> help contents
You asked for help about help category: "Contents"
For more information, type 'help <item>', where <item> is one of the
following categories:
  Account Management
  Administration
  Data Definition
  Data Manipulation
  Data Types
  Functions
  Functions and Modifiers for Use with GROUP BY
  Geographic Features
  Language Structure
  Plugins
  Storage Engines
  Stored Routines
  Table Maintenance
  Transactions
  Triggers
```

If the search string matches multiple items, `mysql` shows a list of matching topics:

```
mysql> help logs
Many help items for your request exist.
To make a more specific request, please type 'help <item>',
where <item> is one of the following topics:
  SHOW
  SHOW BINARY LOGS
  SHOW ENGINE
  SHOW LOGS
```

Use a topic as the search string to see the help entry for that topic:

```
mysql> help show binary logs
Name: 'SHOW BINARY LOGS'
Description:
Syntax:
SHOW BINARY LOGS
SHOW MASTER LOGS

Lists the binary log files on the server. This statement is used as
part of the procedure described in [purge-binary-logs], that shows how
to determine which logs can be purged.
```

```
mysql> SHOW BINARY LOGS;
+-----+-----+-----+
| Log_name          | File_size | Encrypted |
+-----+-----+-----+
| binlog.000015     | 724935   | Yes       |
| binlog.000016     | 733481   | Yes       |
+-----+-----+-----+
```

The search string can contain the wildcard characters `%` and `_`. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. For example, `HELP rep%` returns a list of topics that begin with `rep`:

```
mysql> HELP rep%
Many help items for your request exist.
To make a more specific request, please type 'help <item>',
where <item> is one of the following
topics:
  REPAIR TABLE
  REPEAT FUNCTION
  REPEAT LOOP
  REPLACE
  REPLACE FUNCTION
```

6.5.1.5 Executing SQL Statements from a Text File

The `mysql` client typically is used interactively, like this:

```
mysql db_name
```

However, it is also possible to put your SQL statements in a file and then tell `mysql` to read its input from that file. To do so, create a text file `text_file` that contains the statements you wish to execute. Then invoke `mysql` as shown here:

```
mysql db_name < text_file
```

If you place a `USE db_name` statement as the first statement in the file, it is unnecessary to specify the database name on the command line:

```
mysql < text_file
```

If you are already running `mysql`, you can execute an SQL script file using the `source` command or `\.` command:

```
mysql> source file_name
mysql> \. file_name
```

Sometimes you may want your script to display progress information to the user. For this you can insert statements like this:

```
SELECT '<info_to_display>' AS ' ';
```

The statement shown outputs `<info_to_display>`.

You can also invoke `mysql` with the `--verbose` option, which causes each statement to be displayed before the result that it produces.

`mysql` ignores Unicode byte order mark (BOM) characters at the beginning of input files. Previously, it read them and sent them to the server, resulting in a syntax error. Presence of a BOM does not cause `mysql` to change its default character set. To do that, invoke `mysql` with an option such as `--default-character-set=utf8mb4`.

For more information about batch mode, see [Section 5.5, “Using mysql in Batch Mode”](#).

6.5.1.6 mysql Client Tips

This section provides information about techniques for more effective use of `mysql` and about `mysql` operational behavior.

- [Input-Line Editing](#)
- [Disabling Interactive History](#)
- [Unicode Support on Windows](#)
- [Displaying Query Results Vertically](#)
- [Using Safe-Updates Mode \(--safe-updates\)](#)
- [Disabling mysql Auto-Reconnect](#)
- [mysql Client Parser Versus Server Parser](#)

Input-Line Editing

`mysql` supports input-line editing, which enables you to modify the current input line in place or recall previous input lines. For example, the **left-arrow** and **right-arrow** keys move horizontally within the current input line, and the **up-arrow** and **down-arrow** keys move up and down through the set of previously entered lines. **Backspace** deletes the character before the cursor and typing new characters enters them at the cursor position. To enter the line, press **Enter**.

On Windows, the editing key sequences are the same as supported for command editing in console windows. On Unix, the key sequences depend on the input library used to build `mysql` (for example, the `libedit` or `readline` library).

Documentation for the `libedit` and `readline` libraries is available online. To change the set of key sequences permitted by a given input library, define key bindings in the library startup file. This is a file in your home directory: `.editrc` for `libedit` and `.inputrc` for `readline`.

For example, in `libedit`, **Control+W** deletes everything before the current cursor position and **Control+U** deletes the entire line. In `readline`, **Control+W** deletes the word before the cursor and **Control+U** deletes everything before the current cursor position. If `mysql` was built using `libedit`, a user who prefers the `readline` behavior for these two keys can put the following lines in the `.editrc` file (creating the file if necessary):

```
bind "^W" ed-delete-prev-word
bind "^U" vi-kill-line-prev
```

To see the current set of key bindings, temporarily put a line that says only `bind` at the end of `.editrc`. `mysql` shows the bindings when it starts.

Disabling Interactive History

The **up-arrow** key enables you to recall input lines from current and previous sessions. In cases where a console is shared, this behavior may be unsuitable. `mysql` supports disabling the interactive history partially or fully, depending on the host platform.

On Windows, the history is stored in memory. **Alt+F7** deletes all input lines stored in memory for the current history buffer. It also deletes the list of sequential numbers in front of the input lines displayed with **F7** and recalled (by number) with **F9**. New input lines entered after you press **Alt+F7** repopulate the current history buffer. Clearing the buffer does not prevent logging to the Windows Event Viewer, if the `--syslog` option was used to start `mysql`. Closing the console window also clears the current history buffer.

To disable interactive history on Unix, first delete the `.mysql_history` file, if it exists (previous entries are recalled otherwise). Then start `mysql` with the `--histignore="*"` option to ignore all new input lines. To re-enable the recall (and logging) behavior, restart `mysql` without the option.

If you prevent the `.mysql_history` file from being created (see [Controlling the History File](#)) and use `--histignore="*"` to start the `mysql` client, the interactive history recall facility is disabled fully. Alternatively, if you omit the `--histignore` option, you can recall the input lines entered during the current session.

Unicode Support on Windows

Windows provides APIs based on UTF-16LE for reading from and writing to the console; the `mysql` client for Windows is able to use these APIs. The Windows installer creates an item in the MySQL menu named `MySQL command line client - Unicode`. This item invokes the `mysql` client with properties set to communicate through the console to the MySQL server using Unicode.

To take advantage of this support manually, run `mysql` within a console that uses a compatible Unicode font and set the default character set to a Unicode character set that is supported for communication with the server:

1. Open a console window.
2. Go to the console window properties, select the font tab, and choose Lucida Console or some other compatible Unicode font. This is necessary because console windows start by default using a DOS raster font that is inadequate for Unicode.
3. Execute `mysql.exe` with the `--default-character-set=utf8mb4` (or `utf8mb3`) option. This option is necessary because `utf16le` is one of the character sets that cannot be used as the client character set. See [Impermissible Client Character Sets](#).

With those changes, `mysql` uses the Windows APIs to communicate with the console using UTF-16LE, and communicate with the server using UTF-8. (The menu item mentioned previously sets the font and character set as just described.)

To avoid those steps each time you run `mysql`, you can create a shortcut that invokes `mysql.exe`. The shortcut should set the console font to Lucida Console or some other compatible Unicode font, and pass the `--default-character-set=utf8mb4` (or `utf8mb3`) option to `mysql.exe`.

Alternatively, create a shortcut that only sets the console font, and set the character set in the `[mysql]` group of your `my.ini` file:

```
[mysql]
default-character-set=utf8mb4 # or utf8mb3
```

Displaying Query Results Vertically

Some query results are much more readable when displayed vertically, instead of in the usual horizontal table format. Queries can be displayed vertically by terminating the query with `\G` instead of a semicolon. For example, longer text values that include newlines often are much easier to read with vertical output:

```
mysql> SELECT * FROM mails WHERE LENGTH(txt) < 300 LIMIT 300,1\G
***** 1. row *****
  msg_nro: 3068
    date: 2000-03-01 23:29:50
time_zone: +0200
mail_from: Jones
  reply: jones@example.com
mail_to: "John Smith" <smith@example.com>
   sbj: UTF-8
   txt: >>>> "John" == John Smith writes:

John> Hi. I think this is a good idea. Is anyone familiar
John> with UTF-8 or Unicode? Otherwise, I'll put this on my
John> TODO list and see what happens.

Yes, please do that.

Regards,
Jones

1 row in set (0.09 sec)
```

Using Safe-Updates Mode (--safe-updates)

For beginners, a useful startup option is `--safe-updates` (or `--i-am-a-dummy`, which has the same effect). Safe-updates mode is helpful for cases when you might have issued an `UPDATE` or `DELETE` statement but forgotten the `WHERE` clause indicating which rows to modify. Normally, such statements update or delete all rows in the table. With `--safe-updates`, you can modify rows only by specifying the key values that identify them, or a `LIMIT` clause, or both. This helps prevent accidents. Safe-updates mode also restricts `SELECT` statements that produce (or are estimated to produce) very large result sets.

The `--safe-updates` option causes `mysql` to execute the following statement when it connects to the MySQL server, to set the session values of the `sql_safe_updates`, `sql_select_limit`, and `max_join_size` system variables:

```
SET sql_safe_updates=1, sql_select_limit=1000, max_join_size=1000000;
```

The `SET` statement affects statement processing as follows:

- Enabling `sql_safe_updates` causes `UPDATE` and `DELETE` statements to produce an error if they do not specify a key constraint in the `WHERE` clause, or provide a `LIMIT` clause, or both. For example:

```
UPDATE tbl_name SET not_key_column=val WHERE key_column=val;

UPDATE tbl_name SET not_key_column=val LIMIT 1;
```

- Setting `sql_select_limit` to 1,000 causes the server to limit all `SELECT` result sets to 1,000 rows unless the statement includes a `LIMIT` clause.
- Setting `max_join_size` to 1,000,000 causes multiple-table `SELECT` statements to produce an error if the server estimates it must examine more than 1,000,000 row combinations.

To specify result set limits different from 1,000 and 1,000,000, you can override the defaults by using the `--select-limit` and `--max-join-size` options when you invoke `mysql`:

```
mysql --safe-updates --select-limit=500 --max-join-size=10000
```

It is possible for `UPDATE` and `DELETE` statements to produce an error in safe-updates mode even with a key specified in the `WHERE` clause, if the optimizer decides not to use the index on the key column:

- Range access on the index cannot be used if memory usage exceeds that permitted by the `range_optimizer_max_mem_size` system variable. The optimizer then falls back to a table scan. See [Limiting Memory Use for Range Optimization](#).
- If key comparisons require type conversion, the index may not be used (see [Section 10.3.1, “How MySQL Uses Indexes”](#)). Suppose that an indexed string column `c1` is compared to a numeric value using `WHERE c1 = 2222`. For such comparisons, the string value is converted to a number and the operands are compared numerically (see [Section 14.3, “Type Conversion in Expression Evaluation”](#)), preventing use of the index. If safe-updates mode is enabled, an error occurs.

These behaviors are included in safe-updates mode:

- `EXPLAIN` with `UPDATE` and `DELETE` statements does not produce safe-updates errors. This enables use of `EXPLAIN` plus `SHOW WARNINGS` to see why an index is not used, which can be helpful in cases such as when a `range_optimizer_max_mem_size` violation or type conversion occurs and the optimizer does not use an index even though a key column was specified in the `WHERE` clause.
- When a safe-updates error occurs, the error message includes the first diagnostic that was produced, to provide information about the reason for failure. For example, the message may indicate that the `range_optimizer_max_mem_size` value was exceeded or type conversion occurred, either of which can preclude use of an index.
- For multiple-table deletes and updates, an error is produced with safe updates enabled only if any target table uses a table scan.

Disabling mysql Auto-Reconnect

If the `mysql` client loses its connection to the server while sending a statement, it immediately and automatically tries to reconnect once to the server and send the statement again. However, even if `mysql` succeeds in reconnecting, your first connection has ended and all your previous session objects and settings are lost: temporary tables, the autocommit mode, and user-defined and session variables. Also, any current transaction rolls back. This behavior may be dangerous for you, as in the following example where the server was shut down and restarted between the first and second statements without you knowing it:

```
mysql> SET @a=1;
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t VALUES(@a);
ERROR 2006: MySQL server has gone away
No connection. Trying to reconnect...
Connection id: 1
Current database: test

Query OK, 1 row affected (1.30 sec)

mysql> SELECT * FROM t;
+-----+
| a     |
+-----+
| NULL  |
+-----+
```

```
1 row in set (0.05 sec)
```

The `@a` user variable has been lost with the connection, and after the reconnection it is undefined. If it is important to have `mysql` terminate with an error if the connection has been lost, you can start the `mysql` client with the `--skip-reconnect` option.

For more information about auto-reconnect and its effect on state information when a reconnection occurs, see [Automatic Reconnection Control](#).

mysql Client Parser Versus Server Parser

The `mysql` client uses a parser on the client side that is not a duplicate of the complete parser used by the `mysqld` server on the server side. This can lead to differences in treatment of certain constructs. Examples:

- The server parser treats strings delimited by " characters as identifiers rather than as plain strings if the `ANSI_QUOTES` SQL mode is enabled.

The `mysql` client parser does not take the `ANSI_QUOTES` SQL mode into account. It treats strings delimited by ", ', and ` characters the same, regardless of whether `ANSI_QUOTES` is enabled.

- Within `/*! ... */` and `/*+ ... */` comments, the `mysql` client parser interprets short-form `mysql` commands. The server parser does not interpret them because these commands have no meaning on the server side.

If it is desirable for `mysql` not to interpret short-form commands within comments, a partial workaround is to use the `--binary-mode` option, which causes all `mysql` commands to be disabled except `\C` and `\d` in noninteractive mode (for input piped to `mysql` or loaded using the `source` command).

6.5.2 mysqladmin — A MySQL Server Administration Program

`mysqladmin` is a client for performing administrative operations. You can use it to check the server's configuration and current status, to create and drop databases, and more.

Invoke `mysqladmin` like this:

```
mysqladmin [options] command [command-arg] [command [command-arg]] ...
```

`mysqladmin` supports the following commands. Some of the commands take an argument following the command name.

- `create db_name`

Create a new database named `db_name`.

- `debug`

Prior to MySQL 8.0.20, tell the server to write debug information to the error log. The connected user must have the `SUPER` privilege. Format and content of this information is subject to change.

This includes information about the Event Scheduler. See [Section 27.4.5, “Event Scheduler Status”](#).

- `drop db_name`

Delete the database named `db_name` and all its tables.

- `extended-status`

Display the server status variables and their values.

- `flush-hosts`

Flush all information in the host cache. See [Section 7.1.12.3, “DNS Lookups and the Host Cache”](#).

- `flush-logs [log_type ...]`

Flush all logs.

The `mysqladmin flush-logs` command permits optional log types to be given, to specify which logs to flush. Following the `flush-logs` command, you can provide a space-separated list of one or more of the following log types: `binary`, `engine`, `error`, `general`, `relay`, `slow`. These correspond to the log types that can be specified for the `FLUSH LOGS` SQL statement.

- `flush-privileges`

Reload the grant tables (same as `reload`).

- `flush-status`

Clear status variables.

- `flush-tables`

Flush all tables.

- `kill id,id,...`

Kill server threads. If multiple thread ID values are given, there must be no spaces in the list.

To kill threads belonging to other users, the connected user must have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege).

- `password new_password`

Set a new password. This changes the password to `new_password` for the account that you use with `mysqladmin` for connecting to the server. Thus, the next time you invoke `mysqladmin` (or any other client program) using the same account, you must specify the new password.

Warning

Setting a password using `mysqladmin` should be considered *insecure*. On some systems, your password becomes visible to system status programs such as `ps` that may be invoked by other users to display command lines. MySQL clients typically overwrite the command-line password argument with zeros during their initialization sequence. However, there is still a brief interval during which the value is visible. Also, on some systems this overwriting strategy is ineffective and the password remains visible to `ps`. (SystemV Unix systems and perhaps others are subject to this problem.)

If the `new_password` value contains spaces or other characters that are special to your command interpreter, you need to enclose it within quotation marks. On Windows, be sure to use double quotation marks rather than single quotation marks; single quotation marks are not stripped from the password, but rather are interpreted as part of the password. For example:

```
mysqladmin password "my new password"
```

The new password can be omitted following the `password` command. In this case, `mysqladmin` prompts for the password value, which enables you to avoid specifying the password on the command line. Omitting the password value should be done only if `password` is the final command on the `mysqladmin` command line. Otherwise, the next argument is taken as the password.

Caution

Do not use this command used if the server was started with the `--skip-grant-tables` option. No password change is applied. This is true even if you precede the `password` command with `flush-privileges` on

the same command line to re-enable the grant tables because the flush operation occurs after you connect. However, you can use `mysqladmin flush-privileges` to re-enable the grant table and then use a separate `mysqladmin password` command to change the password.

- `ping`

Check whether the server is available. The return status from `mysqladmin` is 0 if the server is running, 1 if it is not. This is 0 even in case of an error such as `Access denied`, because this means that the server is running but refused the connection, which is different from the server not running.

- `processlist`

Show a list of active server threads. This is like the output of the `SHOW PROCESSLIST` statement. If the `--verbose` option is given, the output is like that of `SHOW FULL PROCESSLIST`. (See [Section 15.7.7.31, “SHOW PROCESSLIST Statement”](#).)

- `reload`

Reload the grant tables.

- `refresh`

Flush all tables and close and open log files.

- `shutdown`

Stop the server.

- `start-replica`

Start replication on a replica server.

- `start-slave`

This is a deprecated alias for `start-replica`.

- `status`

Display a short server status message.

- `stop-replica`

Stop replication on a replica server.

- `stop-slave`

This is a deprecated alias for `stop-replica`.

- `variables`

Display the server system variables and their values.

- `version`

Display version information from the server.

All commands can be shortened to any unique prefix. For example:

```
$> mysqladmin proc stat
+-----+-----+-----+-----+-----+-----+-----+-----+
| Id | User | Host | db | Command | Time | State | Info |
+-----+-----+-----+-----+-----+-----+-----+-----+
| 51 | jones | localhost | | Query | 0 | | show processlist |
+-----+-----+-----+-----+-----+-----+-----+-----+
```

```
Uptime: 1473624  Threads: 1  Questions: 39487
Slow queries: 0  Opens: 541  Flush tables: 1
Open tables: 19  Queries per second avg: 0.0268
```

The `mysqladmin status` command result displays the following values:

- `Uptime`

The number of seconds the MySQL server has been running.

- `Threads`

The number of active threads (clients).

- `Questions`

The number of questions (queries) from clients since the server was started.

- `Slow queries`

The number of queries that have taken more than `long_query_time` seconds. See [Section 7.4.5, “The Slow Query Log”](#).

- `Opens`

The number of tables the server has opened.

- `Flush tables`

The number of `flush-*`, `refresh`, and `reload` commands the server has executed.

- `Open tables`

The number of tables that currently are open.

If you execute `mysqladmin shutdown` when connecting to a local server using a Unix socket file, `mysqladmin` waits until the server's process ID file has been removed, to ensure that the server has stopped properly.

`mysqladmin` supports the following options, which can be specified on the command line or in the `[mysqladmin]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 6.2.2.2, “Using Option Files”](#).

Table 6.12 mysqladmin Options

Option Name	Description
<code>--bind-address</code>	Use specified network interface to connect to MySQL Server
<code>--character-sets-dir</code>	Directory where character sets can be found
<code>--compress</code>	Compress all information sent between client and server
<code>--compression-algorithms</code>	Permitted compression algorithms for connections to server
<code>--connect-timeout</code>	Number of seconds before connection timeout
<code>--count</code>	Number of iterations to make for repeated command execution
<code>--debug</code>	Write debugging log
<code>--debug-check</code>	Print debugging information when program exits
<code>--debug-info</code>	Print debugging information, memory, and CPU statistics when program exits

Option Name	Description
<code>--default-auth</code>	Authentication plugin to use
<code>--default-character-set</code>	Specify default character set
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files
<code>--defaults-file</code>	Read only named option file
<code>--defaults-group-suffix</code>	Option group suffix value
<code>--enable-cleartext-plugin</code>	Enable cleartext authentication plugin
<code>--force</code>	Continue even if an SQL error occurs
<code>--get-server-public-key</code>	Request RSA public key from server
<code>--help</code>	Display help message and exit
<code>--host</code>	Host on which MySQL server is located
<code>--login-path</code>	Read login path options from <code>.mylogin.cnf</code>
<code>--no-beep</code>	Do not beep when errors occur
<code>--no-defaults</code>	Read no option files
<code>--no-login-paths</code>	Do not read login paths from the login path file
<code>--password</code>	Password to use when connecting to server
<code>--password1</code>	First multifactor authentication password to use when connecting to server
<code>--password2</code>	Second multifactor authentication password to use when connecting to server
<code>--password3</code>	Third multifactor authentication password to use when connecting to server
<code>--pipe</code>	Connect to server using named pipe (Windows only)
<code>--plugin-dir</code>	Directory where plugins are installed
<code>--port</code>	TCP/IP port number for connection
<code>--print-defaults</code>	Print default options
<code>--protocol</code>	Transport protocol to use
<code>--relative</code>	Show the difference between the current and previous values when used with the <code>--sleep</code> option
<code>--server-public-key-path</code>	Path name to file containing RSA public key
<code>--shared-memory-base-name</code>	Shared-memory name for shared-memory connections (Windows only)
<code>--show-warnings</code>	Show warnings after statement execution
<code>--shutdown-timeout</code>	The maximum number of seconds to wait for server shutdown
<code>--silent</code>	Silent mode
<code>--sleep</code>	Execute commands repeatedly, sleeping for delay seconds in between
<code>--socket</code>	Unix socket file or Windows named pipe to use
<code>--ssl-ca</code>	File that contains list of trusted SSL Certificate Authorities
<code>--ssl-capath</code>	Directory that contains trusted SSL Certificate Authority certificate files

Option Name	Description
<code>--ssl-cert</code>	File that contains X.509 certificate
<code>--ssl-cipher</code>	Permissible ciphers for connection encryption
<code>--ssl-crl</code>	File that contains certificate revocation lists
<code>--ssl-crlpath</code>	Directory that contains certificate revocation-list files
<code>--ssl-fips-mode</code>	Whether to enable FIPS mode on client side
<code>--ssl-key</code>	File that contains X.509 key
<code>--ssl-mode</code>	Desired security state of connection to server
<code>--ssl-session-data</code>	File that contains SSL session data
<code>--ssl-session-data-continue-on-failed-reuse</code>	Whether to establish connections if session reuse fails
<code>--tls-ciphersuites</code>	Permissible TLSv1.3 ciphersuites for encrypted connections
<code>--tls-sni-servername</code>	Server name supplied by the client
<code>--tls-version</code>	Permissible TLS protocols for encrypted connections
<code>--user</code>	MySQL user name to use when connecting to server
<code>--verbose</code>	Verbose mode
<code>--version</code>	Display version information and exit
<code>--vertical</code>	Print query output rows vertically (one line per column value)
<code>--wait</code>	If the connection cannot be established, wait and retry instead of aborting
<code>--zstd-compression-level</code>	Compression level for connections to server that use zstd compression

- `--help, -?`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display a help message and exit.

- `--bind-address=ip_address`

Command-Line Format	<code>--bind-address=ip_address</code>
---------------------	--

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- `--character-sets-dir=dir_name`

Command-Line Format	<code>--character-sets-dir=path</code>
Type	String
Default Value	<code>[none]</code>

- `--compress, -C`

Command-Line Format	<code>--compress[={OFF ON}]</code>
Deprecated	Yes
Type	Boolean
Default Value	OFF

Compress all information sent between the client and the server if possible. See [Section 6.2.8, “Connection Compression Control”](#).

This option is deprecated. Expect it to be removed in a future version of MySQL. See [Configuring Legacy Connection Compression](#).

- `--compression-algorithms=value`

Command-Line Format	<code>--compression-algorithms=value</code>
Type	Set
Default Value	uncompressed
Valid Values	zlib zstd uncompressed

The permitted compression algorithms for connections to the server. The available algorithms are the same as for the `protocol_compression_algorithms` system variable. The default value is `uncompressed`.

For more information, see [Section 6.2.8, “Connection Compression Control”](#).

- `--connect-timeout=value`

Command-Line Format	<code>--connect-timeout=value</code>
Type	Numeric
Default Value	43200

The maximum number of seconds before connection timeout. The default value is 43200 (12 hours).

- `--count=N, -c N`

Command-Line Format	<code>--count=#</code>
---------------------	------------------------

The number of iterations to make for repeated command execution if the `--sleep` option is given.

- `--debug[=debug_options], -# [debug_options]`

Command-Line Format	<code>--debug[=debug_options]</code>
Type	String
Default Value	<code>d:t:o,/tmp/mysqladmin.trace</code>

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysqladmin.trace`.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-check`

Command-Line Format	<code>--debug-check</code>
Type	Boolean
Default Value	<code>FALSE</code>

Print some debugging information when the program exits.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-info`

Command-Line Format	<code>--debug-info</code>
Type	Boolean
Default Value	<code>FALSE</code>

Print debugging information and memory and CPU usage statistics when the program exits.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--default-auth=plugin`

Command-Line Format	<code>--default-auth=plugin</code>
Type	String

A hint about which client-side authentication plugin to use. See [Section 8.2.17, “Pluggable Authentication”](#).

- `--default-character-set=charset_name`

Command-Line Format	<code>--default-character-set=charset_name</code>
Type	String

Use `charset_name` as the default character set. See [Section 12.15, “Character Set Configuration”](#).

- `--defaults-extra-file=file_name`

Command-Line Format	<code>--defaults-extra-file=file_name</code>
Type	File name

- `--defaults-file=file_name`

Command-Line Format	<code>--defaults-file=file_name</code>
Type	File name

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-group-suffix=str`

Command-Line Format	<code>--defaults-group-suffix=str</code>
Type	String

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqladmin` normally reads the `[client]` and `[mysqladmin]` groups. If this option is given as `--defaults-group-suffix=_other`, `mysqladmin` also reads the `[client_other]` and `[mysqladmin_other]` groups.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--enable-cleartext-plugin`

Command-Line Format	<code>--enable-cleartext-plugin</code>
Type	Boolean
Default Value	<code>FALSE</code>

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 8.4.1.4, “Client-Side Cleartext Pluggable Authentication”](#).)

- `--force, -f`

Command-Line Format	<code>--force</code>
---------------------	----------------------

Do not ask for confirmation for the `drop db_name` command. With multiple commands, continue even if an error occurs.

- `--get-server-public-key`

Command-Line Format	<code>--get-server-public-key</code>
Type	Boolean

Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the server does not send the public key unless requested. This option

password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For information about the `caching_sha2_password` plugin, see [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

- `--host=host_name, -h host_name`

Command-Line Format	<code>--host=host_name</code>
Type	String
Default Value	<code>localhost</code>

Connect to the MySQL server on the given host.

- `--login-path=name`

Command-Line Format	<code>--login-path=name</code>
Type	String

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

See `--login-path` for related information.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--no-beep, -b`

Command-Line Format	<code>--no-beep</code>
---------------------	------------------------

Suppress the warning beep that is emitted by default for errors such as a failure to connect to the server.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--password[=password]`, `-p[password]`

Command-Line Format	<code>--password[=password]</code>
Type	String

The password of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysqladmin` prompts for one. If given, there must be *no space* between `--password=` or `-p` and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See [Section 8.1.2.1, “End-User Guidelines for Password Security”](#).

To explicitly specify that there is no password and that `mysqladmin` should not prompt for one, use the `--skip-password` option.

- `--password1[=pass_val]`

The password for multifactor authentication factor 1 of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysql` prompts for one. If given, there must be *no space* between `--password1=` and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See [Section 8.1.2.1, “End-User Guidelines for Password Security”](#).

To explicitly specify that there is no password and that `mysqladmin` should not prompt for one, use the `--skip-password1` option.

`--password1` and `--password` are synonymous, as are `--skip-password1` and `--skip-password`.

- `--password2[=pass_val]`

The password for multifactor authentication factor 2 of the MySQL account used for connecting to the server. The semantics of this option are similar to the semantics for `--password1`; see the description of that option for details.

- `--password3[=pass_val]`

The password for multifactor authentication factor 3 of the MySQL account used for connecting to the server. The semantics of this option are similar to the semantics for `--password1`; see the description of that option for details.

- `--pipe, -W`

Command-Line Format	<code>--pipe</code>
Type	String

On Windows, connect to the server using a named pipe. This option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--plugin-dir=dir_name`

Command-Line Format	<code>--plugin-dir=dir_name</code>
Type	Directory name

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqladmin` does not find it. See [Section 8.2.17, “Pluggable Authentication”](#).

- `--port=port_num, -P port_num`

Command-Line Format	<code>--port=port_num</code>
Type	Numeric
Default Value	3306

For TCP/IP connections, the port number to use.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--protocol={TCP | SOCKET | PIPE | MEMORY}`

Command-Line Format	<code>--protocol=type</code>
Type	String
Default Value	[see text]
Valid Values	TCP SOCKET PIPE MEMORY

The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see [Section 6.2.7, “Connection Transport Protocols”](#).

- `--relative, -r`

Command-Line Format	<code>--relative</code>
---------------------	-------------------------

Show the difference between the current and previous values when used with the `--sleep` option. This option works only with the `extended-status` command.

- `--server-public-key-path=file_name`

Command-Line Format	<code>--server-public-key-path=file_name</code>
Type	File name

The path name to a file in PEM format containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For `sha256_password`, this option applies only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see [Section 8.4.1.3, “SHA-256 Pluggable Authentication”](#), and [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

- `--shared-memory-base-name=name`

Command-Line Format	<code>--shared-memory-base-name=name</code>
Platform Specific	Windows

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

- `--show-warnings`

Command-Line Format	<code>--show-warnings</code>
---------------------	------------------------------

Show warnings resulting from execution of statements sent to the server.

- `--shutdown-timeout=value`

Command-Line Format	<code>--shutdown-timeout=seconds</code>
---------------------	---

Default Value	3600
---------------	------

The maximum number of seconds to wait for server shutdown. The default value is 3600 (1 hour).

- `--silent, -s`

Command-Line Format	<code>--silent</code>
---------------------	-----------------------

Exit silently if a connection to the server cannot be established.

- `--sleep=delay, -i delay`

Command-Line Format	<code>--sleep=delay</code>
---------------------	----------------------------

Execute commands repeatedly, sleeping for *delay* seconds in between. The `--count` option determines the number of iterations. If `--count` is not given, `mysqladmin` executes commands indefinitely until interrupted.

- `--socket=path, -S path`

Command-Line Format	<code>--socket={file_name pipe_name}</code>
Type	String

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See [Command Options for Encrypted Connections](#).

- `--ssl-fips-mode={OFF|ON|STRICT}`

Command-Line Format	<code>--ssl-fips-mode={OFF ON STRICT}</code>
Deprecated	Yes
Type	Enumeration
Default Value	OFF
Valid Values	OFF ON

STRICT

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations to permit. See [Section 8.8, “FIPS Support”](#).

These `--ssl-fips-mode` values are permitted:

- `OFF`: Disable FIPS mode.
- `ON`: Enable FIPS mode.
- `STRICT`: Enable “strict” FIPS mode.

Note

If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is `OFF`. In this case, setting `--ssl-fips-mode` to `ON` or `STRICT` causes the client to produce a warning at startup and to operate in non-FIPS mode.

This option is deprecated. Expect it to be removed in a future version of MySQL.

- `--tls-ciphersuites=ciphersuite_list`

Command-Line Format	<code>--tls-ciphersuites=ciphersuite_list</code>
Type	String

The permissible ciphersuites for encrypted connections that use TLSv1.3. The value is a list of one or more colon-separated ciphersuite names. The ciphersuites that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `--tls-sni-servername=server_name`

Command-Line Format	<code>--tls-sni-servername=server_name</code>
Type	String

When specified, the name is passed to the `libmysqlclient` C API library using the `MYSQL_OPT_TLS_SNI_SERVERNAME` option of `mysql_options()`. The server name is not case-sensitive. To show which server name the client specified for the current session, if any, check the `Tls_sni_server_name` status variable.

Server Name Indication (SNI) is an extension to the TLS protocol (OpenSSL must be compiled using TLS extensions for this option to function). The MySQL implementation of SNI represents the client-side only.

- `--tls-version=protocol_list`

Command-Line Format	<code>--tls-version=protocol_list</code>
Type	String
Default Value	<code>TLSv1,TLSv1.1,TLSv1.2,TLSv1.3</code> (OpenSSL 1.1.1 or higher)

	TLsv1, TLsv1.1, TLsv1.2 (otherwise)
--	-------------------------------------

The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `--user=user_name, -u user_name`

Command-Line Format	<code>--user=user_name,</code>
Type	String

The user name of the MySQL account to use for connecting to the server.

If you are using the [Rewriter](#) plugin, grant this user the `SKIP_QUERY_REWRITE` privilege.

- `--verbose, -v`

Command-Line Format	<code>--verbose</code>
---------------------	------------------------

Verbose mode. Print more information about what the program does.

- `--version, -V`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

- `--vertical, -E`

Command-Line Format	<code>--vertical</code>
---------------------	-------------------------

Print output vertically. This is similar to `--relative`, but prints output vertically.

- `--wait[=count], -w[count]`

Command-Line Format	<code>--wait</code>
---------------------	---------------------

If the connection cannot be established, wait and retry instead of aborting. If a `count` value is given, it indicates the number of times to retry. The default is one time.

- `--zstd-compression-level=level`

Command-Line Format	<code>--zstd-compression-level=#</code>
Type	Integer

The compression level to use for connections to the server that use the `zstd` compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression. The default `zstd` compression level is 3. The compression level setting has no effect on connections that do not use `zstd` compression.

For more information, see [Section 6.2.8, “Connection Compression Control”](#).

6.5.3 mysqlcheck — A Table Maintenance Program

The `mysqlcheck` client performs table maintenance: It checks, repairs, optimizes, or analyzes tables.

Each table is locked and therefore unavailable to other sessions while it is being processed, although for check operations, the table is locked with a `READ` lock only (see [Section 15.3.6, “LOCK TABLES and UNLOCK TABLES Statements”](#), for more information about `READ` and `WRITE` locks). Table maintenance operations can be time-consuming, particularly for large tables. If you use the `--databases` or `--all-databases` option to process all tables in one or more databases, an invocation of `mysqlcheck` might take a long time. (This is also true for the MySQL upgrade procedure if it determines that table checking is needed because it processes tables the same way.)

`mysqlcheck` must be used when the `mysqld` server is running, which means that you do not have to stop the server to perform table maintenance.

`mysqlcheck` uses the SQL statements `CHECK TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, and `OPTIMIZE TABLE` in a convenient way for the user. It determines which statements to use for the operation you want to perform, and then sends the statements to the server to be executed. For details about which storage engines each statement works with, see the descriptions for those statements in [Section 15.7.3, “Table Maintenance Statements”](#).

All storage engines do not necessarily support all four maintenance operations. In such cases, an error message is displayed. For example, if `test.t` is an `MEMORY` table, an attempt to check it produces this result:

```
$> mysqlcheck test t
test.t
note      : The storage engine for the table doesn't support check
```

If `mysqlcheck` is unable to repair a table, see [Section 3.14, “Rebuilding or Repairing Tables or Indexes”](#) for manual table repair strategies. This is the case, for example, for `InnoDB` tables, which can be checked with `CHECK TABLE`, but not repaired with `REPAIR TABLE`.

Caution

It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors.

There are three general ways to invoke `mysqlcheck`:

```
mysqlcheck [options] db_name [tbl_name ...]
mysqlcheck [options] --databases db_name ...
mysqlcheck [options] --all-databases
```

If you do not name any tables following `db_name` or if you use the `--databases` or `--all-databases` option, entire databases are checked.

`mysqlcheck` has a special feature compared to other client programs. The default behavior of checking tables (`--check`) can be changed by renaming the binary. If you want to have a tool that repairs tables by default, you should just make a copy of `mysqlcheck` named `mysqlrepair`, or make a symbolic link to `mysqlcheck` named `mysqlrepair`. If you invoke `mysqlrepair`, it repairs tables.

The names shown in the following table can be used to change `mysqlcheck` default behavior.

Command	Meaning
<code>mysqlrepair</code>	The default option is <code>--repair</code>
<code>mysqlanalyze</code>	The default option is <code>--analyze</code>
<code>mysqloptimize</code>	The default option is <code>--optimize</code>

`mysqlcheck` supports the following options, which can be specified on the command line or in the `[mysqlcheck]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 6.2.2.2, “Using Option Files”](#).

Table 6.13 mysqlcheck Options

Option Name	Description
<code>--all-databases</code>	Check all tables in all databases
<code>--all-in-1</code>	Execute a single statement for each database that names all the tables from that database
<code>--analyze</code>	Analyze the tables
<code>--auto-repair</code>	If a checked table is corrupted, automatically fix it
<code>--bind-address</code>	Use specified network interface to connect to MySQL Server
<code>--character-sets-dir</code>	Directory where character sets are installed
<code>--check</code>	Check the tables for errors
<code>--check-only-changed</code>	Check only tables that have changed since the last check
<code>--check-upgrade</code>	Invoke CHECK TABLE with the FOR UPGRADE option
<code>--compress</code>	Compress all information sent between client and server
<code>--compression-algorithms</code>	Permitted compression algorithms for connections to server
<code>--databases</code>	Interpret all arguments as database names
<code>--debug</code>	Write debugging log
<code>--debug-check</code>	Print debugging information when program exits
<code>--debug-info</code>	Print debugging information, memory, and CPU statistics when program exits
<code>--default-auth</code>	Authentication plugin to use
<code>--default-character-set</code>	Specify default character set
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files
<code>--defaults-file</code>	Read only named option file
<code>--defaults-group-suffix</code>	Option group suffix value
<code>--enable-cleartext-plugin</code>	Enable cleartext authentication plugin
<code>--extended</code>	Check and repair tables
<code>--fast</code>	Check only tables that have not been closed properly
<code>--force</code>	Continue even if an SQL error occurs
<code>--get-server-public-key</code>	Request RSA public key from server
<code>--help</code>	Display help message and exit
<code>--host</code>	Host on which MySQL server is located
<code>--login-path</code>	Read login path options from <code>.mylogin.cnf</code>
<code>--medium-check</code>	Do a check that is faster than an <code>--extended</code> operation
<code>--no-defaults</code>	Read no option files

Option Name	Description
<code>--no-login-paths</code>	Do not read login paths from the login path file
<code>--optimize</code>	Optimize the tables
<code>--password</code>	Password to use when connecting to server
<code>--password1</code>	First multifactor authentication password to use when connecting to server
<code>--password2</code>	Second multifactor authentication password to use when connecting to server
<code>--password3</code>	Third multifactor authentication password to use when connecting to server
<code>--pipe</code>	Connect to server using named pipe (Windows only)
<code>--plugin-dir</code>	Directory where plugins are installed
<code>--port</code>	TCP/IP port number for connection
<code>--print-defaults</code>	Print default options
<code>--protocol</code>	Transport protocol to use
<code>--quick</code>	The fastest method of checking
<code>--repair</code>	Perform a repair that can fix almost anything except unique keys that are not unique
<code>--server-public-key-path</code>	Path name to file containing RSA public key
<code>--shared-memory-base-name</code>	Shared-memory name for shared-memory connections (Windows only)
<code>--silent</code>	Silent mode
<code>--skip-database</code>	Omit this database from performed operations
<code>--socket</code>	Unix socket file or Windows named pipe to use
<code>--ssl-ca</code>	File that contains list of trusted SSL Certificate Authorities
<code>--ssl-capath</code>	Directory that contains trusted SSL Certificate Authority certificate files
<code>--ssl-cert</code>	File that contains X.509 certificate
<code>--ssl-cipher</code>	Permissible ciphers for connection encryption
<code>--ssl-crl</code>	File that contains certificate revocation lists
<code>--ssl-crlpath</code>	Directory that contains certificate revocation-list files
<code>--ssl-fips-mode</code>	Whether to enable FIPS mode on client side
<code>--ssl-key</code>	File that contains X.509 key
<code>--ssl-mode</code>	Desired security state of connection to server
<code>--ssl-session-data</code>	File that contains SSL session data
<code>--ssl-session-data-continue-on-failed-reuse</code>	Whether to establish connections if session reuse fails
<code>--tables</code>	Overrides the <code>--databases</code> or <code>-B</code> option
<code>--tls-ciphersuites</code>	Permissible TLSv1.3 ciphersuites for encrypted connections
<code>--tls-sni-servername</code>	Server name supplied by the client

Option Name	Description
<code>--tls-version</code>	Permissible TLS protocols for encrypted connections
<code>--use-frm</code>	For repair operations on MyISAM tables
<code>--user</code>	MySQL user name to use when connecting to server
<code>--verbose</code>	Verbose mode
<code>--version</code>	Display version information and exit
<code>--write-binlog</code>	Log ANALYZE, OPTIMIZE, REPAIR statements to binary log. <code>--skip-write-binlog</code> adds <code>NO_WRITE_TO_BINLOG</code> to these statements
<code>--zstd-compression-level</code>	Compression level for connections to server that use zstd compression

- `--help, -?`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display a help message and exit.

- `--all-databases, -A`

Command-Line Format	<code>--all-databases</code>
---------------------	------------------------------

Check all tables in all databases. This is the same as using the `--databases` option and naming all the databases on the command line, except that the `INFORMATION_SCHEMA` and `performance_schema` databases are not checked. They can be checked by explicitly naming them with the `--databases` option.

- `--all-in-1, -1`

Command-Line Format	<code>--all-in-1</code>
---------------------	-------------------------

Instead of issuing a statement for each table, execute a single statement for each database that names all the tables from that database to be processed.

- `--analyze, -a`

Command-Line Format	<code>--analyze</code>
---------------------	------------------------

Analyze the tables.

- `--auto-repair`

Command-Line Format	<code>--auto-repair</code>
---------------------	----------------------------

If a checked table is corrupted, automatically fix it. Any necessary repairs are done after all tables have been checked.

- `--bind-address=ip_address`

Command-Line Format	<code>--bind-address=ip_address</code>
---------------------	--

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- `--character-sets-dir=dir_name`

Command-Line Format	<code>--character-sets-dir=dir_name</code>
Type	Directory name

The directory where character sets are installed. See [Section 12.15, “Character Set Configuration”](#).

- `--check, -c`

Command-Line Format	<code>--check</code>
---------------------	----------------------

Check the tables for errors. This is the default operation.

- `--check-only-changed, -C`

Command-Line Format	<code>--check-only-changed</code>
---------------------	-----------------------------------

Check only tables that have changed since the last check or that have not been closed properly.

- `--check-upgrade, -g`

Command-Line Format	<code>--check-upgrade</code>
---------------------	------------------------------

Invoke `CHECK TABLE` with the `FOR UPGRADE` option to check tables for incompatibilities with the current version of the server.

- `--compress`

Command-Line Format	<code>--compress[={OFF ON}]</code>
Deprecated	Yes
Type	Boolean
Default Value	OFF

Compress all information sent between the client and the server if possible. See [Section 6.2.8, “Connection Compression Control”](#).

This option is deprecated. Expect it to be removed in a future version of MySQL. See [Configuring Legacy Connection Compression](#).

- `--compression-algorithms=value`

Command-Line Format	<code>--compression-algorithms=value</code>	387
Type	Set	
Default Value	uncompressed	

uncompressed

The permitted compression algorithms for connections to the server. The available algorithms are the same as for the `protocol_compression_algorithms` system variable. The default value is `uncompressed`.

For more information, see [Section 6.2.8, “Connection Compression Control”](#).

- `--databases, -B`

Command-Line Format	<code>--databases</code>
---------------------	--------------------------

Process all tables in the named databases. Normally, `mysqlcheck` treats the first name argument on the command line as a database name and any following names as table names. With this option, it treats all name arguments as database names.

- `--debug[=debug_options], -# [debug_options]`

Command-Line Format	<code>--debug[=debug_options]</code>
Type	String
Default Value	<code>d:t:o</code>

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o`.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-check`

Command-Line Format	<code>--debug-check</code>
Type	Boolean
Default Value	<code>FALSE</code>

Print some debugging information when the program exits.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-info`

Command-Line Format	<code>--debug-info</code>
Type	Boolean
Default Value	<code>FALSE</code>

Print debugging information and memory and CPU usage statistics when the program exits.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--default-character-set=charset_name`

Command-Line Format	<code>--default-character-set=charset_name</code>
Type	String

Use `charset_name` as the default character set. See [Section 12.15, “Character Set Configuration”](#).

- `--defaults-extra-file=file_name`

Command-Line Format	<code>--defaults-extra-file=file_name</code>
Type	File name

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-file=file_name`

Command-Line Format	<code>--defaults-file=file_name</code>
Type	File name

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-group-suffix=str`

Command-Line Format	<code>--defaults-group-suffix=str</code>
Type	String

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlcheck` normally reads the `[client]` and `[mysqlcheck]` groups. If this option is given as `--defaults-group-suffix=_other`, `mysqlcheck` also reads the `[client_other]` and `[mysqlcheck_other]` groups.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--extended, -e`

Command-Line Format	<code>--extended</code>
---------------------	-------------------------

If you are using this option to check tables, it ensures that they are 100% consistent but takes a long time.

If you are using this option to repair tables, it runs an extended repair that may not only take a long time to execute, but may produce a lot of garbage rows also!

- `--default-auth=plugin`

Command-Line Format	<code>--default-auth=plugin</code>
Type	String

A hint about which client-side authentication plugin to use. See [Section 8.2.17, “Pluggable Authentication”](#).

- `--enable-cleartext-plugin`

Command-Line Format	<code>--enable-cleartext-plugin</code>
Type	Boolean
Default Value	<code>FALSE</code>

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 8.4.1.4, “Client-Side Cleartext Pluggable Authentication”](#).)

- `--fast, -F`

Command-Line Format	<code>--fast</code>
---------------------	---------------------

Check only tables that have not been closed properly.

- `--force, -f`

Command-Line Format	<code>--force</code>
---------------------	----------------------

Continue even if an SQL error occurs.

- `--get-server-public-key`

Command-Line Format	<code>--get-server-public-key</code>
Type	Boolean

Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For information about the `caching_sha2_password` plugin, see [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

- `--host=host_name, -h host_name`

Command-Line Format	<code>--host=host_name</code>
Type	String
Default Value	<code>localhost</code>

Connect to the MySQL server on the given host.

- `--login-path=name`

Command-Line Format	<code>--login-path=name</code>
Type	String

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

See `--login-path` for related information.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--medium-check, -m`

Command-Line Format	<code>--medium-check</code>
---------------------	-----------------------------

Do a check that is faster than an `--extended` operation. This finds only 99.99% of all errors, which should be good enough in most cases.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--optimize, -o`

Command-Line Format	<code>--optimize</code>
---------------------	-------------------------

Optimize the tables.

- `--password[=password], -p[password]`

Command-Line Format	<code>--password[=password]</code>
Type	String

The password of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysqlcheck` prompts for one. If given, there must be *no space* between `--password=` or `-p` and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See [Section 8.1.2.1, “End-User Guidelines for Password Security”](#).

To explicitly specify that there is no password and that `mysqlcheck` should not prompt for one, use the `--skip-password` option.

- `--password1[=pass_val]`

The password for multifactor authentication factor 1 of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysqlcheck` prompts for one. If given, there must be *no space* between `--password1=` and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See [Section 8.1.2.1, “End-User Guidelines for Password Security”](#).

To explicitly specify that there is no password and that `mysqlcheck` should not prompt for one, use the `--skip-password1` option.

`--password1` and `--password` are synonymous, as are `--skip-password1` and `--skip-password`.

- `--password2[=pass_val]`

The password for multifactor authentication factor 2 of the MySQL account used for connecting to the server. The semantics of this option are similar to the semantics for `--password1`; see the description of that option for details.

- `--password3[=pass_val]`

The password for multifactor authentication factor 3 of the MySQL account used for connecting to the server. The semantics of this option are similar to the semantics for `--password1`; see the description of that option for details.

- `--pipe, -W`

Command-Line Format	<code>--pipe</code>
Type	String

On Windows, connect to the server using a named pipe. This option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--plugin-dir=dir_name`

Command-Line Format	<code>--plugin-dir=dir_name</code>
---------------------	------------------------------------

Type	Directory name
------	----------------

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlcheck` does not find it. See [Section 8.2.17](#), “Pluggable Authentication”.

- `--port=port_num, -P port_num`

Command-Line Format	<code>--port=port_num</code>
Type	Numeric
Default Value	3306

For TCP/IP connections, the port number to use.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see [Section 6.2.2.3](#), “Command-Line Options that Affect Option-File Handling”.

- `--protocol={TCP | SOCKET | PIPE | MEMORY}`

Command-Line Format	<code>--protocol=type</code>
Type	String
Default Value	[see text]
Valid Values	TCP SOCKET PIPE MEMORY

The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see [Section 6.2.7](#), “Connection Transport Protocols”.

- `--quick, -q`

Command-Line Format	<code>--quick</code>
---------------------	----------------------

If you are using this option to check tables, it prevents the check from scanning the rows to check for incorrect links. This is the fastest check method.

If you are using this option to repair tables, it tries to repair only the index tree. This is the fastest repair method.

- `--repair, -r`

Command-Line Format	<code>--repair</code>
---------------------	-----------------------

Perform a repair that can fix almost anything except unique keys that are not unique.

- `--server-public-key-path=file_name`

Command-Line Format	<code>--server-public-key-path=file_name</code>
Type	File name

The path name to a file in PEM format containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For `sha256_password`, this option applies only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see [Section 8.4.1.3, “SHA-256 Pluggable Authentication”](#), and [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

- `--shared-memory-base-name=name`

Command-Line Format	<code>--shared-memory-base-name=name</code>
Platform Specific	Windows

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

- `--silent, -s`

Command-Line Format	<code>--silent</code>
---------------------	-----------------------

Silent mode. Print only error messages.

- `--skip-database=db_name`

Command-Line Format	<code>--skip-database=db_name</code>
---------------------	--------------------------------------

Do not include the named database (case-sensitive) in the operations performed by `mysqlcheck`.

- `--socket=path, -S path`

Command-Line Format	<code>--socket={file_name pipe_name}</code>
---------------------	---

Type	String
------	--------

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See [Command Options for Encrypted Connections](#).

- `--ssl-fips-mode={OFF|ON|STRICT}`

Command-Line Format	<code>--ssl-fips-mode={OFF ON STRICT}</code>
Deprecated	Yes
Type	Enumeration
Default Value	<code>OFF</code>
Valid Values	<code>OFF</code> <code>ON</code> <code>STRICT</code>

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations to permit. See [Section 8.8, “FIPS Support”](#).

These `--ssl-fips-mode` values are permitted:

- `OFF`: Disable FIPS mode.
- `ON`: Enable FIPS mode.
- `STRICT`: Enable “strict” FIPS mode.

Note

If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is `OFF`. In this case, setting `--ssl-fips-mode` to `ON` or `STRICT` causes the client to produce a warning at startup and to operate in non-FIPS mode.

This option is deprecated. Expect it to be removed in a future version of MySQL.

- `--tables`

Command-Line Format	<code>--tables</code>
---------------------	-----------------------

- `--tls-ciphersuites=ciphersuite_list`

Command-Line Format	<code>--tls-ciphersuites=ciphersuite_list</code>
Type	String

The permissible ciphersuites for encrypted connections that use TLSv1.3. The value is a list of one or more colon-separated ciphersuite names. The ciphersuites that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `--tls-sni-servername=server_name`

Command-Line Format	<code>--tls-sni-servername=server_name</code>
Type	String

When specified, the name is passed to the `libmysqlclient` C API library using the `MYSQL_OPT_TLS_SNI_SERVERNAME` option of `mysql_options()`. The server name is not case-sensitive. To show which server name the client specified for the current session, if any, check the `Tls_sni_server_name` status variable.

Server Name Indication (SNI) is an extension to the TLS protocol (OpenSSL must be compiled using TLS extensions for this option to function). The MySQL implementation of SNI represents the client-side only.

- `--tls-version=protocol_list`

Command-Line Format	<code>--tls-version=protocol_list</code>
Type	String
Default Value	<code>TLSv1,TLSv1.1,TLSv1.2,TLSv1.3</code> (OpenSSL 1.1.1 or higher) <code>TLSv1,TLSv1.1,TLSv1.2</code> (otherwise)

The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `--use-frm`

Command-Line Format	<code>--use-frm</code>
---------------------	------------------------

For repair operations on `MyISAM` tables, get the table structure from the data dictionary so that the table can be repaired even if the `.MYI` header is corrupted.

- `--user=user_name, -u user_name`

Command-Line Format	<code>--user=user_name,</code>
Type	String

- `--verbose, -v`

Command-Line Format	<code>--verbose</code>
---------------------	------------------------

Verbose mode. Print information about the various stages of program operation.

- `--version, -V`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

- `--write-binlog`

Command-Line Format	<code>--write-binlog</code>
---------------------	-----------------------------

This option is enabled by default, so that `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements generated by `mysqlcheck` are written to the binary log. Use `--skip-write-binlog` to cause `NO_WRITE_TO_BINLOG` to be added to the statements so that they are not logged. Use the `--skip-write-binlog` when these statements should not be sent to replicas or run when using the binary logs for recovery from backup.

- `--zstd-compression-level=level`

Command-Line Format	<code>--zstd-compression-level=#</code>
Type	Integer

The compression level to use for connections to the server that use the `zstd` compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression. The default `zstd` compression level is 3. The compression level setting has no effect on connections that do not use `zstd` compression.

For more information, see [Section 6.2.8, “Connection Compression Control”](#).

6.5.4 mysqldump — A Database Backup Program

The `mysqldump` client utility performs [logical backups](#), producing a set of SQL statements that can be executed to reproduce the original database object definitions and table data. It dumps one or more MySQL databases for backup or transfer to another SQL server. The `mysqldump` command can also generate output in CSV, other delimited text, or XML format.

Tip

Consider using the [MySQL Shell dump utilities](#), which provide parallel dumping with multiple threads, file compression, and progress information display, as well as cloud features such as Oracle Cloud Infrastructure Object Storage streaming, and MySQL HeatWave Service compatibility checks and modifications. Dumps can be easily imported into a MySQL Server instance or a MySQL HeatWave Service DB System using the [MySQL Shell load dump utilities](#). Installation instructions for MySQL Shell can be found [here](#).

- [Performance and Scalability Considerations](#)
- [Invocation Syntax](#)
- [Option Syntax - Alphabetical Summary](#)

- [Connection Options](#)
- [Option-File Options](#)
- [DDL Options](#)
- [Debug Options](#)
- [Help Options](#)
- [Internationalization Options](#)
- [Replication Options](#)
- [Format Options](#)
- [Filtering Options](#)
- [Performance Options](#)
- [Transactional Options](#)
- [Option Groups](#)
- [Examples](#)
- [Restrictions](#)

`mysqldump` requires at least the `SELECT` privilege for dumped tables, `SHOW VIEW` for dumped views, `TRIGGER` for dumped triggers, `LOCK TABLES` if the `--single-transaction` option is not used, `PROCESS` if the `--no-tablespaces` option is not used, and the `RELOAD` or `FLUSH TABLES` privilege with `--single-transaction` if both `gtid_mode=ON` and `--set-gtid=purged=ON|AUTO`. Certain options might require other privileges as noted in the option descriptions.

To reload a dump file, you must have the privileges required to execute the statements that it contains, such as the appropriate `CREATE` privileges for objects created by those statements.

`mysqldump` output can include `ALTER DATABASE` statements that change the database collation. These may be used when dumping stored programs to preserve their character encodings. To reload a dump file containing such statements, the `ALTER` privilege for the affected database is required.

Note

A dump made using PowerShell on Windows with output redirection creates a file that has UTF-16 encoding:

```
mysqldump [options] > dump.sql
```

However, UTF-16 is not permitted as a connection character set (see [Impermissible Client Character Sets](#)), so the dump file cannot be loaded correctly. To work around this issue, use the `--result-file` option, which creates the output in ASCII format:

```
mysqldump [options] --result-file=dump.sql
```

It is not recommended to load a dump file when GTIDs are enabled on the server (`gtid_mode=ON`), if your dump file includes system tables. `mysqldump` issues DML instructions for the system tables which use the non-transactional MyISAM storage engine, and this combination is not permitted when GTIDs are enabled.

Performance and Scalability Considerations

`mysqldump` advantages include the convenience and flexibility of viewing or even editing the output before restoring. You can clone databases for development and DBA work, or produce slight variations

of an existing database for testing. It is not intended as a fast or scalable solution for backing up substantial amounts of data. With large data sizes, even if the backup step takes a reasonable time, restoring the data can be very slow because replaying the SQL statements involves disk I/O for insertion, index creation, and so on.

For large-scale backup and restore, a [physical](#) backup is more appropriate, to copy the data files in their original format so that they can be restored quickly.

If your tables are primarily [InnoDB](#) tables, or if you have a mix of [InnoDB](#) and [MyISAM](#) tables, consider using [mysqlbackup](#), which is available as part of MySQL Enterprise. This tool provides high performance for [InnoDB](#) backups with minimal disruption; it can also back up tables from [MyISAM](#) and other storage engines; it also provides a number of convenient options to accommodate different backup scenarios. See [Section 32.1, “MySQL Enterprise Backup Overview”](#).

[mysqldump](#) can retrieve and dump table contents row by row, or it can retrieve the entire content from a table and buffer it in memory before dumping it. Buffering in memory can be a problem if you are dumping large tables. To dump tables row by row, use the `--quick` option (or `--opt`, which enables `--quick`). The `--opt` option (and hence `--quick`) is enabled by default, so to enable memory buffering, use `--skip-quick`.

If you are using a recent version of [mysqldump](#) to generate a dump to be reloaded into a very old MySQL server, use the `--skip-opt` option instead of the `--opt` or `--extended-insert` option.

For additional information about [mysqldump](#), see [Section 9.4, “Using mysqldump for Backups”](#).

Invocation Syntax

There are in general three ways to use [mysqldump](#)—in order to dump a set of one or more tables, a set of one or more complete databases, or an entire MySQL server—as shown here:

```
mysqldump [options] db_name [tbl_name ...]
mysqldump [options] --databases db_name ...
mysqldump [options] --all-databases
```

To dump entire databases, do not name any tables following `db_name`, or use the `--databases` or `--all-databases` option.

To see a list of the options your version of [mysqldump](#) supports, issue the command `mysqldump --help`.

Option Syntax - Alphabetical Summary

[mysqldump](#) supports the following options, which can be specified on the command line or in the `[mysqldump]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 6.2.2.2, “Using Option Files”](#).

Table 6.14 mysqldump Options

Option Name	Description
<code>--add-drop-database</code>	Add DROP DATABASE statement before each CREATE DATABASE statement
<code>--add-drop-table</code>	Add DROP TABLE statement before each CREATE TABLE statement
<code>--add-drop-trigger</code>	Add DROP TRIGGER statement before each CREATE TRIGGER statement
<code>--add-locks</code>	Surround each table dump with LOCK TABLES and UNLOCK TABLES statements
<code>--all-databases</code>	Dump all tables in all databases
<code>--allow-keywords</code>	Allow creation of column names that are keywords

Option Name	Description
<code>--apply-replica-statements</code>	Include STOP REPLICATION prior to CHANGE REPLICATION SOURCE TO statement and START REPLICATION at end of output
<code>--apply-slave-statements</code>	Include STOP SLAVE prior to CHANGE MASTER statement and START SLAVE at end of output
<code>--bind-address</code>	Use specified network interface to connect to MySQL Server
<code>--character-sets-dir</code>	Directory where character sets are installed
<code>--column-statistics</code>	Write ANALYZE TABLE statements to generate statistics histograms
<code>--comments</code>	Add comments to dump file
<code>--compact</code>	Produce more compact output
<code>--compatible</code>	Produce output that is more compatible with other database systems or with older MySQL servers
<code>--complete-insert</code>	Use complete INSERT statements that include column names
<code>--compress</code>	Compress all information sent between client and server
<code>--compression-algorithms</code>	Permitted compression algorithms for connections to server
<code>--create-options</code>	Include all MySQL-specific table options in CREATE TABLE statements
<code>--databases</code>	Interpret all name arguments as database names
<code>--debug</code>	Write debugging log
<code>--debug-check</code>	Print debugging information when program exits
<code>--debug-info</code>	Print debugging information, memory, and CPU statistics when program exits
<code>--default-auth</code>	Authentication plugin to use
<code>--default-character-set</code>	Specify default character set
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files
<code>--defaults-file</code>	Read only named option file
<code>--defaults-group-suffix</code>	Option group suffix value
<code>--delete-master-logs</code>	On a replication source server, delete the binary logs after performing the dump operation
<code>--delete-source-logs</code>	On a replication source server, delete the binary logs after performing the dump operation
<code>--disable-keys</code>	For each table, surround INSERT statements with statements to disable and enable keys
<code>--dump-date</code>	Include dump date as "Dump completed on" comment if --comments is given
<code>--dump-replica</code>	Include CHANGE REPLICATION SOURCE TO statement that lists binary log coordinates of replica's source
<code>--dump-slave</code>	Include CHANGE MASTER statement that lists binary log coordinates of replica's source

Option Name	Description
<code>--enable-cleartext-plugin</code>	Enable cleartext authentication plugin
<code>--events</code>	Dump events from dumped databases
<code>--extended-insert</code>	Use multiple-row INSERT syntax
<code>--fields-enclosed-by</code>	This option is used with the <code>--tab</code> option and has the same meaning as the corresponding clause for LOAD DATA
<code>--fields-escaped-by</code>	This option is used with the <code>--tab</code> option and has the same meaning as the corresponding clause for LOAD DATA
<code>--fields-optionally-enclosed-by</code>	This option is used with the <code>--tab</code> option and has the same meaning as the corresponding clause for LOAD DATA
<code>--fields-terminated-by</code>	This option is used with the <code>--tab</code> option and has the same meaning as the corresponding clause for LOAD DATA
<code>--flush-logs</code>	Flush MySQL server log files before starting dump
<code>--flush-privileges</code>	Emit a FLUSH PRIVILEGES statement after dumping mysql database
<code>--force</code>	Continue even if an SQL error occurs during a table dump
<code>--get-server-public-key</code>	Request RSA public key from server
<code>--help</code>	Display help message and exit
<code>--hex-blob</code>	Dump binary columns using hexadecimal notation
<code>--host</code>	Host on which MySQL server is located
<code>--ignore-error</code>	Ignore specified errors
<code>--ignore-table</code>	Do not dump given table
<code>--ignore-views</code>	Skip dumping table views
<code>--include-master-host-port</code>	Include MASTER_HOST/MASTER_PORT options in CHANGE MASTER statement produced with <code>--dump-slave</code>
<code>--include-source-host-port</code>	Include SOURCE_HOST and SOURCE_PORT options in CHANGE REPLICATION SOURCE TO statement produced with <code>--dump-replica</code>
<code>--init-command</code>	Single SQL statement to execute after connecting or re-connecting to MySQL server; resets existing defined commands
<code>--init-command-add</code>	Add an additional SQL statement to execute after connecting or re-connecting to MySQL server
<code>--insert-ignore</code>	Write INSERT IGNORE rather than INSERT statements
<code>--lines-terminated-by</code>	This option is used with the <code>--tab</code> option and has the same meaning as the corresponding clause for LOAD DATA
<code>--lock-all-tables</code>	Lock all tables across all databases
<code>--lock-tables</code>	Lock all tables before dumping them
<code>--log-error</code>	Append warnings and errors to named file

Option Name	Description
<code>--login-path</code>	Read login path options from <code>.mylogin.cnf</code>
<code>--master-data</code>	Write the binary log file name and position to the output
<code>--max-allowed-packet</code>	Maximum packet length to send to or receive from server
<code>--mysqld-long-query-time</code>	Session value for slow query threshold
<code>--net-buffer-length</code>	Buffer size for TCP/IP and socket communication
<code>--network-timeout</code>	Increase network timeouts to permit larger table dumps
<code>--no-autocommit</code>	Enclose the INSERT statements for each dumped table within SET autocommit = 0 and COMMIT statements
<code>--no-create-db</code>	Do not write CREATE DATABASE statements
<code>--no-create-info</code>	Do not write CREATE TABLE statements that re-create each dumped table
<code>--no-data</code>	Do not dump table contents
<code>--no-defaults</code>	Read no option files
<code>--no-login-paths</code>	Do not read login paths from the login path file
<code>--no-set-names</code>	Same as <code>--skip-set-charset</code>
<code>--no-tablespaces</code>	Do not write any CREATE LOGFILE GROUP or CREATE TABLESPACE statements in output
<code>--opt</code>	Shorthand for <code>--add-drop-table --add-locks --create-options --disable-keys --extended-insert --lock-tables --quick --set-charset</code>
<code>--order-by-primary</code>	Dump each table's rows sorted by its primary key, or by its first unique index
<code>--output-as-version</code>	Determines replica and event terminology used in dumps; for compatibility with older versions
<code>--password</code>	Password to use when connecting to server
<code>--password1</code>	First multifactor authentication password to use when connecting to server
<code>--password2</code>	Second multifactor authentication password to use when connecting to server
<code>--password3</code>	Third multifactor authentication password to use when connecting to server
<code>--pipe</code>	Connect to server using named pipe (Windows only)
<code>--plugin-authentication-kerberos-client-mode</code>	Permit GSSAPI pluggable authentication through the MIT Kerberos library on Windows
<code>--plugin-dir</code>	Directory where plugins are installed
<code>--port</code>	TCP/IP port number for connection
<code>--print-defaults</code>	Print default options
<code>--protocol</code>	Transport protocol to use
<code>--quick</code>	Retrieve rows for a table from the server a row at a time

Option Name	Description
<code>--quote-names</code>	Quote identifiers within backtick characters
<code>--replace</code>	Write REPLACE statements rather than INSERT statements
<code>--result-file</code>	Direct output to a given file
<code>--routines</code>	Dump stored routines (procedures and functions) from dumped databases
<code>--server-public-key-path</code>	Path name to file containing RSA public key
<code>--set-charset</code>	Add SET NAMES default_character_set to output
<code>--set-gtid-purged</code>	Whether to add SET @@GLOBAL.GTID_PURGED to output
<code>--shared-memory-base-name</code>	Shared-memory name for shared-memory connections (Windows only)
<code>--show-create-skip-secondary-engine</code>	Exclude SECONDARY ENGINE clause from CREATE TABLE statements
<code>--single-transaction</code>	Issue a BEGIN SQL statement before dumping data from server
<code>--skip-add-drop-table</code>	Do not add a DROP TABLE statement before each CREATE TABLE statement
<code>--skip-add-locks</code>	Do not add locks
<code>--skip-comments</code>	Do not add comments to dump file
<code>--skip-compact</code>	Do not produce more compact output
<code>--skip-disable-keys</code>	Do not disable keys
<code>--skip-extended-insert</code>	Turn off extended-insert
<code>--skip-generated-invisible-primary-key</code>	Do not include generated invisible primary keys in dump file
<code>--skip-opt</code>	Turn off options set by --opt
<code>--skip-quick</code>	Do not retrieve rows for a table from the server a row at a time
<code>--skip-quote-names</code>	Do not quote identifiers
<code>--skip-set-charset</code>	Do not write SET NAMES statement
<code>--skip-triggers</code>	Do not dump triggers
<code>--skip-tz-utc</code>	Turn off tz-utc
<code>--socket</code>	Unix socket file or Windows named pipe to use
<code>--source-data</code>	Write the binary log file name and position to the output
<code>--ssl-ca</code>	File that contains list of trusted SSL Certificate Authorities
<code>--ssl-capath</code>	Directory that contains trusted SSL Certificate Authority certificate files
<code>--ssl-cert</code>	File that contains X.509 certificate
<code>--ssl-cipher</code>	Permissible ciphers for connection encryption
<code>--ssl-crl</code>	File that contains certificate revocation lists
<code>--ssl-crlpath</code>	Directory that contains certificate revocation-list files

Option Name	Description
<code>--ssl-fips-mode</code>	Whether to enable FIPS mode on client side
<code>--ssl-key</code>	File that contains X.509 key
<code>--ssl-mode</code>	Desired security state of connection to server
<code>--ssl-session-data</code>	File that contains SSL session data
<code>--ssl-session-data-continue-on-failed-reuse</code>	Whether to establish connections if session reuse fails
<code>--tab</code>	Produce tab-separated data files
<code>--tables</code>	Override <code>--databases</code> or <code>-B</code> option
<code>--tls-ciphersuites</code>	Permissible TLSv1.3 ciphersuites for encrypted connections
<code>--tls-sni-servername</code>	Server name supplied by the client
<code>--tls-version</code>	Permissible TLS protocols for encrypted connections
<code>--triggers</code>	Dump triggers for each dumped table
<code>--tz-utc</code>	Add SET TIME_ZONE='+00:00' to dump file
<code>--user</code>	MySQL user name to use when connecting to server
<code>--verbose</code>	Verbose mode
<code>--version</code>	Display version information and exit
<code>--where</code>	Dump only rows selected by given WHERE condition
<code>--xml</code>	Produce XML output
<code>--zstd-compression-level</code>	Compression level for connections to server that use zstd compression

Connection Options

The `mysqldump` command logs into a MySQL server to extract information. The following options specify how to connect to the MySQL server, either on the same machine or a remote system.

- `--bind-address=ip_address`

Command-Line Format	<code>--bind-address=ip_address</code>
---------------------	--

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- `--compress, -C`

Command-Line Format	<code>--compress[={OFF ON}]</code>
Deprecated	Yes
Type	Boolean
Default Value	<code>OFF</code>

Compress all information sent between the client and the server if possible. See [Section 6.2.8, “Connection Compression Control”](#).

This option is deprecated. Expect it to be removed in a future version of MySQL. See [Configuring Legacy Connection Compression](#).

- `--compression-algorithms=value`

Command-Line Format	<code>--compression-algorithms=value</code>
Type	Set
Default Value	<code>uncompressed</code>
Valid Values	<code>zlib</code> <code>zstd</code> <code>uncompressed</code>

The permitted compression algorithms for connections to the server. The available algorithms are the same as for the `protocol_compression_algorithms` system variable. The default value is `uncompressed`.

For more information, see [Section 6.2.8, “Connection Compression Control”](#).

- `--default-auth=plugin`

Command-Line Format	<code>--default-auth=plugin</code>
Type	String

A hint about which client-side authentication plugin to use. See [Section 8.2.17, “Pluggable Authentication”](#).

- `--enable-cleartext-plugin`

Command-Line Format	<code>--enable-cleartext-plugin</code>
Type	Boolean
Default Value	<code>FALSE</code>

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 8.4.1.4, “Client-Side Cleartext Pluggable Authentication”](#).)

- `--get-server-public-key`

Command-Line Format	<code>--get-server-public-key</code>
Type	Boolean

Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based

password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For information about the `caching_sha2_password` plugin, see [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

- `--host=host_name, -h host_name`

Command-Line Format	<code>--host</code>
---------------------	---------------------

Dump data from the MySQL server on the given host. The default host is `localhost`.

- `--login-path=name`

Command-Line Format	<code>--login-path=name</code>
Type	String

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

See `--login-path` for related information.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--password[=password], -p[password]`

Command-Line Format	<code>--password[=password]</code>
Type	String

The password of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysqldump` prompts for one. If given, there must be *no space* between `--password=` or `-p` and the password following it. If no password option is specified, the default is to send no password.

- `--password1[=pass_val]`

The password for multifactor authentication factor 1 of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysqldump` prompts for one. If given, there must be *no space* between `--password1=` and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See [Section 8.1.2.1, “End-User Guidelines for Password Security”](#).

To explicitly specify that there is no password and that `mysqldump` should not prompt for one, use the `--skip-password1` option.

`--password1` and `--password` are synonymous, as are `--skip-password1` and `--skip-password`.

- `--password2[=pass_val]`

The password for multifactor authentication factor 2 of the MySQL account used for connecting to the server. The semantics of this option are similar to the semantics for `--password1`; see the description of that option for details.

- `--password3[=pass_val]`

The password for multifactor authentication factor 3 of the MySQL account used for connecting to the server. The semantics of this option are similar to the semantics for `--password1`; see the description of that option for details.

- `--pipe, -W`

Command-Line Format	<code>--pipe</code>
Type	String

On Windows, connect to the server using a named pipe. This option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--plugin-authentication-kerberos-client-mode=value`

Command-Line Format	<code>--plugin-authentication-kerberos-client-mode</code>
Type	String
Default Value	SSPI
Valid Values	GSSAPI

On Windows, the `authentication_kerberos_client` authentication plugin supports this plugin option. It provides two possible values that the client user can set at runtime: `SSPI` and `GSSAPI`.

The default value for the client-side plugin option uses Security Support Provider Interface (SSPI), which is capable of acquiring credentials from the Windows in-memory cache. Alternatively, the client user can select a mode that supports Generic Security Service Application Program Interface (GSSAPI) through the MIT Kerberos library on Windows. GSSAPI is capable of acquiring cached credentials previously generated by using the `kinit` command.

For more information, see [Commands for Windows Clients in GSSAPI Mode](#).

- `--plugin-dir=dir_name`

Command-Line Format	<code>--plugin-dir=dir_name</code>
Type	Directory name

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqldump` does not find it. See [Section 8.2.17, “Pluggable Authentication”](#).

- `--port=port_num, -P port_num`

Command-Line Format	<code>--port=port_num</code>
Type	Numeric
Default Value	3306

For TCP/IP connections, the port number to use.

- `--protocol={TCP | SOCKET | PIPE | MEMORY}`

Command-Line Format	<code>--protocol=type</code>
Type	String
Default Value	[see text]
Valid Values	TCP SOCKET PIPE MEMORY

The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see [Section 6.2.7, “Connection Transport Protocols”](#).

- `--server-public-key-path=file_name`

Command-Line Format	<code>--server-public-key-path=file_name</code>
Type	File name

The path name to a file in PEM format containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For `sha256_password`, this option applies only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see [Section 8.4.1.3, “SHA-256 Pluggable Authentication”](#), and [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

- `--socket=path, -S path`

Command-Line Format	<code>--socket={file_name pipe_name}</code>
Type	String

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See [Command Options for Encrypted Connections](#).

- `--ssl-fips-mode={OFF|ON|STRICT}`

Command-Line Format	<code>--ssl-fips-mode={OFF ON STRICT}</code>
Deprecated	Yes
Type	Enumeration
Default Value	<code>OFF</code>
Valid Values	<code>OFF</code> <code>ON</code> <code>STRICT</code>

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations to permit. See [Section 8.8, “FIPS Support”](#).

These `--ssl-fips-mode` values are permitted:

- `OFF`: Disable FIPS mode.
- `ON`: Enable FIPS mode.
- `STRICT`: Enable “strict” FIPS mode.

Note

If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is `OFF`. In this case, setting `--ssl-fips-mode` to `ON` or `STRICT` causes the client to produce a warning at startup and to operate in non-FIPS mode.

This option is deprecated. Expect it to be removed in a future version of MySQL.

- `--tls-ciphersuites=ciphersuite_list`

Command-Line Format	<code>--tls-ciphersuites=ciphersuite_list</code>
---------------------	--

Type	String
------	--------

The permissible ciphersuites for encrypted connections that use TLSv1.3. The value is a list of one or more colon-separated ciphersuite names. The ciphersuites that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `--tls-sni-servername=server_name`

Command-Line Format	<code>--tls-sni-servername=server_name</code>
Type	String

When specified, the name is passed to the `libmysqlclient` C API library using the `MYSQL_OPT_TLS_SNI_SERVERNAME` option of `mysql_options()`. The server name is not case-sensitive. To show which server name the client specified for the current session, if any, check the `Tls_sni_server_name` status variable.

Server Name Indication (SNI) is an extension to the TLS protocol (OpenSSL must be compiled using TLS extensions for this option to function). The MySQL implementation of SNI represents the client-side only.

- `--tls-version=protocol_list`

Command-Line Format	<code>--tls-version=protocol_list</code>
Type	String
Default Value	<code>TLSv1, TLSv1.1, TLSv1.2, TLSv1.3</code> (OpenSSL 1.1.1 or higher) <code>TLSv1, TLSv1.1, TLSv1.2</code> (otherwise)

The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `--user=user_name, -u user_name`

Command-Line Format	<code>--user=user_name</code>
Type	String

The user name of the MySQL account to use for connecting to the server.

If you are using the `Rewriter` plugin, you should grant this user the `SKIP_QUERY_REWRITE` privilege.

- `--zstd-compression-level=level`

Command-Line Format	<code>--zstd-compression-level=#</code>
Type	Integer

The default `zstd` compression level is 3. The compression level setting has no effect on connections that do not use `zstd` compression.

For more information, see [Section 6.2.8, “Connection Compression Control”](#).

Option-File Options

These options are used to control which option files to read.

- `--defaults-extra-file=file_name`

Command-Line Format	<code>--defaults-extra-file=file_name</code>
Type	File name

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-file=file_name`

Command-Line Format	<code>--defaults-file=file_name</code>
Type	File name

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-group-suffix=str`

Command-Line Format	<code>--defaults-group-suffix=str</code>
Type	String

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqldump` normally reads the `[client]` and `[mysqldump]` groups. If this option is given as `--defaults-group-suffix=_other`, `mysqldump` also reads the `[client_other]` and `[mysqldump_other]` groups.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults`

is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

DDL Options

Usage scenarios for `mysqldump` include setting up an entire new MySQL instance (including database tables), and replacing data inside an existing instance with existing databases and tables. The following options let you specify which things to tear down and set up when restoring a dump, by encoding various DDL statements within the dump file.

- `--add-drop-database`

Command-Line Format	<code>--add-drop-database</code>
---------------------	----------------------------------

Write a `DROP DATABASE` statement before each `CREATE DATABASE` statement. This option is typically used in conjunction with the `--all-databases` or `--databases` option because no `CREATE DATABASE` statements are written unless one of those options is specified.

Note

In MySQL 8.3, the `mysql` schema is considered a system schema that cannot be dropped by end users. If `--add-drop-database` is used with `--all-databases` or with `--databases` where the list of schemas to be dumped includes `mysql`, the dump file contains a `DROP DATABASE `mysql`` statement that causes an error when the dump file is reloaded.

Instead, to use `--add-drop-database`, use `--databases` with a list of schemas to be dumped, where the list does not include `mysql`.

- `--add-drop-table`

Command-Line Format	<code>--add-drop-table</code>
---------------------	-------------------------------

Write a `DROP TABLE` statement before each `CREATE TABLE` statement.

- `--add-drop-trigger`

Command-Line Format	<code>--add-drop-trigger</code>
---------------------	---------------------------------

Write a `DROP TRIGGER` statement before each `CREATE TRIGGER` statement.

- `--all-tablespaces, -Y`

Command-Line Format	<code>--all-tablespaces</code>
---------------------	--------------------------------

Adds to a table dump all SQL statements needed to create any tablespaces used by an [NDB](#) table. This information is not otherwise included in the output from [mysqldump](#). This option is currently relevant only to NDB Cluster tables.

- [--no-create-db, -n](#)

Command-Line Format	--no-create-db
---------------------	--------------------------------

Suppress the [CREATE DATABASE](#) statements that are otherwise included in the output if the [--databases](#) or [--all-databases](#) option is given.

- [--no-create-info, -t](#)

Command-Line Format	--no-create-info
---------------------	----------------------------------

Do not write [CREATE TABLE](#) statements that create each dumped table.

Note

This option does *not* exclude statements creating log file groups or tablespaces from [mysqldump](#) output; however, you can use the [--no-tablespaces](#) option for this purpose.

- [--no-tablespaces, -y](#)

Command-Line Format	--no-tablespaces
---------------------	----------------------------------

This option suppresses all [CREATE LOGFILE GROUP](#) and [CREATE TABLESPACE](#) statements in the output of [mysqldump](#).

- [--replace](#)

Command-Line Format	--replace
---------------------	---------------------------

Write [REPLACE](#) statements rather than [INSERT](#) statements.

Debug Options

The following options print debugging information, encode debugging information in the dump file, or let the dump operation proceed regardless of potential problems.

- [--allow-keywords](#)

Command-Line Format	--allow-keywords
---------------------	----------------------------------

Permit creation of column names that are keywords. This works by prefixing each column name with the table name.

- [--comments, -i](#)

Command-Line Format	--comments
---------------------	----------------------------

Write additional information in the dump file such as program version, server version, and host. This option is enabled by default. To suppress this additional information, use [--skip-comments](#).

- `--debug[=debug_options], -# [debug_options]`

Command-Line Format	<code>--debug[=debug_options]</code>
Type	String
Default Value	<code>d:t:o,/tmp/mysqldump.trace</code>

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default value is `d:t:o,/tmp/mysqldump.trace`.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-check`

Command-Line Format	<code>--debug-check</code>
Type	Boolean
Default Value	<code>FALSE</code>

Print some debugging information when the program exits.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-info`

Command-Line Format	<code>--debug-info</code>
Type	Boolean
Default Value	<code>FALSE</code>

Print debugging information and memory and CPU usage statistics when the program exits.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--dump-date`

Command-Line Format	<code>--dump-date</code>
Type	Boolean
Default Value	<code>TRUE</code>

If the `--comments` option is given, `mysqldump` produces a comment at the end of the dump of the following form:

```
-- Dump completed on DATE
```

However, the date causes dump files taken at different times to appear to be different, even if the data are otherwise identical. `--dump-date` and `--skip-dump-date` control whether the date is added to the comment. The default is `--dump-date` (include the date in the comment). `--skip-dump-date` suppresses date printing.

- `--force, -f`

Command-Line Format	<code>--force</code>
---------------------	----------------------

Ignore all errors; continue even if an SQL error occurs during a table dump.

One use for this option is to cause `mysqldump` to continue executing even when it encounters a view that has become invalid because the definition refers to a table that has been dropped. Without `--force`, `mysqldump` exits with an error message. With `--force`, `mysqldump` prints the error message, but it also writes an SQL comment containing the view definition to the dump output and continues executing.

If the `--ignore-error` option is also given to ignore specific errors, `--force` takes precedence.

- `--log-error=file_name`

Command-Line Format	<code>--log-error=file_name</code>
Type	File name

Log warnings and errors by appending them to the named file. The default is to do no logging.

- `--skip-comments`

Command-Line Format	<code>--skip-comments</code>
---------------------	------------------------------

See the description for the `--comments` option.

- `--verbose, -v`

Command-Line Format	<code>--verbose</code>
---------------------	------------------------

Verbose mode. Print more information about what the program does.

Help Options

The following options display information about the `mysqldump` command itself.

- `--help, -?`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display a help message and exit.

- `--version, -V`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

Internationalization Options

The following options change how the `mysqldump` command represents character data with national language settings.

- `--character-sets-dir=dir_name`

Command-Line Format	<code>--character-sets-dir=dir_name</code>
Type	Directory name

The directory where character sets are installed. See [Section 12.15, “Character Set Configuration”](#).

- `--default-character-set=charset_name`

Command-Line Format	<code>--default-character-set=charset_name</code>
Type	String
Default Value	<code>utf8</code>

Use `charset_name` as the default character set. See [Section 12.15, “Character Set Configuration”](#). If no character set is specified, `mysqldump` uses `utf8mb4`.

- `--no-set-names, -N`

Command-Line Format	<code>--no-set-names</code>
Deprecated	Yes

Turns off the `--set-charset` setting, the same as specifying `--skip-set-charset`.

- `--set-charset`

Command-Line Format	<code>--set-charset</code>
Disabled by	<code>skip-set-charset</code>

Write `SET NAMES default_character_set` to the output. This option is enabled by default. To suppress the `SET NAMES` statement, use `--skip-set-charset`.

Replication Options

The `mysqldump` command is frequently used to create an empty instance, or an instance including data, on a replica server in a replication configuration. The following options apply to dumping and restoring data on replication source servers and replicas.

- `--apply-replica-statements`

Command-Line Format	<code>--apply-replica-statements</code>
Type	Boolean
Default Value	<code>FALSE</code>

For a replica dump produced with the `--dump-replica` option, this option adds a `STOP REPLICATION` statement before the statement with the binary log coordinates, and a `START REPLICATION` statement at the end of the output.

- `--apply-slave-statements`

Command-Line Format	<code>--apply-slave-statements</code>
Deprecated	Yes
Type	Boolean

Default Value	FALSE
---------------	-------

This is a deprecated alias for `--apply-replica-statements`.

- `--delete-source-logs`

Command-Line Format	<code>--delete-source-logs</code>
---------------------	-----------------------------------

On a replication source server, delete the binary logs by sending a `PURGE BINARY LOGS` statement to the server after performing the dump operation. The options require the `RELOAD` privilege as well as privileges sufficient to execute that statement. This option automatically enables `--source-data`.

- `--delete-master-logs`

Command-Line Format	<code>--delete-master-logs</code>
Deprecated	Yes

This is a deprecated alias for `--delete-source-logs`.

- `--dump-replica[=value]`

Command-Line Format	<code>--dump-replica[=value]</code>
Type	Numeric
Default Value	1
Valid Values	1 2

This option is similar to `--source-data`, except that it's used to dump a replica server to produce a dump file that can be used to set up another server as a replica that has the same source as the dumped server. The option causes the dump output to include a `CHANGE REPLICATION SOURCE TO` statement that indicates the binary log coordinates (file name and position) of the dumped replica's source. The `CHANGE REPLICATION SOURCE TO` statement reads the values of `Relay_Master_Log_File` and `Exec_Master_Log_Pos` from the `SHOW REPLICA STATUS` output and uses them for `SOURCE_LOG_FILE` and `SOURCE_LOG_POS` respectively. These are the replication source server coordinates from which the replica starts replicating.

Note

Inconsistencies in the sequence of transactions from the relay log which have been executed can cause the wrong position to be used. See

Section 19.5.1.34, “Replication and Transaction Inconsistencies” for more information.

`--dump-replica` causes the coordinates from the source to be used rather than those of the dumped server, as is done by the `--source-data` option. In addition, specifying this option overrides the `--source-data` option.

Warning

`--dump-replica` should not be used if the server where the dump is going to be applied uses `gtid_mode=ON` and `SOURCE_AUTO_POSITION=1`.

The option value is handled the same way as for `--source-data`. Setting no value or 1 causes a `CHANGE REPLICATION SOURCE TO` statement to be written to the dump. Setting 2 causes the statement to be written but encased in SQL comments. It has the same effect as `--source-data` in terms of enabling or disabling other options and in how locking is handled.

`--dump-replica` causes `mysqldump` to stop the replication SQL thread before the dump and restart it again after.

`--dump-replica` sends a `SHOW REPLICATION STATUS` statement to the server to obtain information, so they require privileges sufficient to execute that statement.

`--apply-replica-statements` and `--include-source-host-port` options can be used in conjunction with `--dump-replica`.

- `--dump-slave[=value]`

Command-Line Format	<code>--dump-slave[=value]</code>
Deprecated	Yes
Type	Numeric
Default Value	1
Valid Values	1 2

This is a deprecated alias for `--dump-replica`.

- `--include-source-host-port`

Command-Line Format	<code>--include-source-host-port</code>
Type	Boolean
Default Value	<code>FALSE</code>

Adds the `SOURCE_HOST` and `SOURCE_PORT` options for the host name and TCP/IP port number of the replica's source, to the `CHANGE REPLICATION SOURCE TO` statement in a replica dump produced with the `--dump-replica` option.

- `--include-master-host-port`

Command-Line Format	<code>--include-master-host-port</code>
Deprecated	Yes
Type	Boolean
Default Value	<code>FALSE</code>

This is a deprecated alias for `--include-source-host-port`.

- `--master-data[=value]`

Command-Line Format	<code>--master-data[=value]</code>
Deprecated	Yes
Type	Numeric
Default Value	1
Valid Values	1 2

This is a deprecated alias for `--source-data`.

- `--output-as-version=value`

Command-Line Format	<code>--output-as-version=value</code>
Type	Enumeration
Default Value	<code>SERVER</code>
Valid Values	<code>BEFORE_8_0_23</code> <code>BEFORE_8_2_0</code>

Determines the level of terminology used for statements relating to replicas and events, making it possible to create dumps compatible with older versions of MySQL that do not accept the newer terminology. This option can take any one of the following values, with effects described as listed here:

- `SERVER`: Reads the server version and uses the latest versions of statements compatible with that version. This is the default value.
- `BEFORE_8_0_23`: Replication SQL statements using deprecated terms such as “slave” and “master” are written to the output in place of those using “replica” and “source”, as in MySQL versions prior to 8.0.23.

This option also duplicates the effects of `BEFORE_8_2_0` on the output of `SHOW CREATE EVENT`.

- `BEFORE_8_2_0`: This option causes `SHOW CREATE EVENT` to reflect how the event would have been created in a MySQL server prior to version 8.2.0, displaying `DISABLE ON SLAVE` rather than `DISABLE ON REPLICA`.

This option affects the output from `--events`, `--dump-replica`, `--source-data`, `--apply-replica-statements`, and `--include-source-host-port`.

Added in MySQL 8.2.0.

- `--source-data[=value]`

Command-Line Format	<code>--source-data[=value]</code>
Type	Numeric
Default Value	1
Valid Values	1 2

Used to dump a replication source server to produce a dump file that can be used to set up another server as a replica of the source. The options cause the dump output to include a `CHANGE REPLICATION SOURCE TO` statement that indicates the binary log coordinates (file name and position) of the dumped server. These are the replication source server coordinates from which the replica should start replicating after you load the dump file into the replica.

If the option value is 2, the `CHANGE REPLICATION SOURCE TO` statement is written as an SQL comment, and thus is informative only; it has no effect when the dump file is reloaded. If the option value is 1, the statement is not written as a comment and takes effect when the dump file is reloaded. If no option value is specified, the default value is 1.

`--source-data` sends a `SHOW BINARY LOG STATUS` statement to the server to obtain information, so they require privileges sufficient to execute that statement. This option also requires the `RELOAD` privilege and the binary log must be enabled.

`--source-data` automatically turns off `--lock-tables`. They also turn on `--lock-all-tables`, unless `--single-transaction` also is specified, in which case, a global read lock is acquired only for a short time at the beginning of the dump (see the description for `--single-transaction`). In all cases, any action on logs happens at the exact moment of the dump.

It is also possible to set up a replica by dumping an existing replica of the source, using the `--dump-replica` option, which overrides `--source-data` causing it to be ignored.

- `--set-gtid-purged=value`

Command-Line Format	<code>--set-gtid-purged=value</code>
Type	Enumeration
Default Value	<code>AUTO</code>
Valid Values	<code>OFF</code> <code>ON</code> <code>AUTO</code>

This option is for servers that use GTID-based replication (`gtid_mode=ON`). It controls the inclusion of a `SET @@GLOBAL.gtid_purged` statement in the dump output, which updates the value of `gtid_purged` on a server where the dump file is reloaded, to add the GTID set from the source server's `gtid_executed` system variable. `gtid_purged` holds the GTIDs of all transactions that have been applied on the server, but do not exist on any binary log file on the server. `mysqldump` therefore adds the GTIDs for the transactions that were executed on the source server, so that the target server records these transactions as applied, although it does not have them in its binary logs. `--set-gtid-purged` also controls the inclusion of a `SET @@SESSION.sql_log_bin=0` statement, which disables binary logging while the dump file is being reloaded. This statement prevents new GTIDs from being generated and assigned to the transactions in the dump file as they are executed, so that the original GTIDs for the transactions are used.

If you do not set the `--set-gtid-purged` option, the default is that a `SET @@GLOBAL.gtid_purged` statement is included in the dump output if GTIDs are enabled on the server you are backing up, and the set of GTIDs in the global value of the `gtid_executed` system variable is not empty. A `SET @@SESSION.sql_log_bin=0` statement is also included if GTIDs are enabled on the server.

You can either replace the value of `gtid_purged` with a specified GTID set, or add a plus sign (+) to the statement to append a specified GTID set to the GTID set that is already held by `gtid_purged`. The `SET @@GLOBAL.gtid_purged` statement recorded by `mysqldump` includes a

plus sign (+) in a version-specific comment, such that MySQL adds the GTID set from the dump file to the existing `gtid_purged` value.

It is important to note that the value that is included by `mysqldump` for the `SET @@GLOBAL.gtid_purged` statement includes the GTIDs of all transactions in the `gtid_executed` set on the server, even those that changed suppressed parts of the database, or other databases on the server that were not included in a partial dump. This can mean that after the `gtid_purged` value has been updated on the server where the dump file is replayed, GTIDs are present that do not relate to any data on the target server. If you do not replay any further dump files on the target server, the extraneous GTIDs do not cause any problems with the future operation of the server, but they make it harder to compare or reconcile GTID sets on different servers in the replication topology. If you do replay a further dump file on the target server that contains the same GTIDs (for example, another partial dump from the same origin server), any `SET @@GLOBAL.gtid_purged` statement in the second dump file fails. In this case, either remove the statement manually before replaying the dump file, or output the dump file without the statement.

If the `SET @@GLOBAL.gtid_purged` statement would not have the desired result on your target server, you can exclude the statement from the output, or include it but comment it out so that it is not actioned automatically. You can also include the statement but manually edit it in the dump file to achieve the desired result.

The possible values for the `--set-gtid-purged` option are as follows:

<code>AUTO</code>	The default value. If GTIDs are enabled on the server you are backing up and <code>gtid_executed</code> is not empty, <code>SET @@GLOBAL.gtid_purged</code> is added to the output, containing the GTID set from <code>gtid_executed</code> . If GTIDs are enabled, <code>SET @@SESSION.sql_log_bin=0</code> is added to the output. If GTIDs are not enabled on the server, the statements are not added to the output.
<code>OFF</code>	<code>SET @@GLOBAL.gtid_purged</code> is not added to the output, and <code>SET @@SESSION.sql_log_bin=0</code> is not added to the output. For a server where GTIDs are not in use, use this option or <code>AUTO</code> . Only use this option for a server where GTIDs are in use if you are sure that the required GTID set is already present in <code>gtid_purged</code> on the target server and should not be changed, or if you plan to identify and add any missing GTIDs manually.
<code>ON</code>	If GTIDs are enabled on the server you are backing up, <code>SET @@GLOBAL.gtid_purged</code> is added to the output (unless <code>gtid_executed</code> is empty), and <code>SET @@SESSION.sql_log_bin=0</code> is added to the output. An error occurs if you set this option but GTIDs are not enabled on the server. For a server where GTIDs are in use, use this option or <code>AUTO</code> , unless you are sure that the GTIDs in <code>gtid_executed</code> are not needed on the target server.
<code>COMMENTED</code>	If GTIDs are enabled on the server you are backing up, <code>SET @@GLOBAL.gtid_purged</code> is added to the output (unless <code>gtid_executed</code> is empty), but it is commented out. This means that the value of <code>gtid_executed</code> is available in the output, but no action is taken automatically when the dump file is reloaded. <code>SET @@SESSION.sql_log_bin=0</code> is added to the output, and it is not commented out. With <code>COMMENTED</code> , you can control the use of the <code>gtid_executed</code> set manually or through automation. For example, you might prefer to do this if you are migrating data to another server that already has different active databases.

Format Options

The following options specify how to represent the entire dump file or certain kinds of data in the dump file. They also control whether certain optional information is written to the dump file.

- `--compact`

Command-Line Format	<code>--compact</code>
---------------------	------------------------

Produce more compact output. This option enables the `--skip-add-drop-table`, `--skip-add-locks`, `--skip-comments`, `--skip-disable-keys`, and `--skip-set-charset` options.

- `--compatible=name`

Command-Line Format	<code>--compatible=name[,name,...]</code>
Type	String
Default Value	<code>''</code>
Valid Values	<code>ansi</code> <code>mysql323</code> <code>mysql40</code> <code>postgresql</code> <code>oracle</code> <code>mssql</code> <code>db2</code> <code>maxdb</code> <code>no_key_options</code> <code>no_table_options</code> <code>no_key_options</code>

Produce output that is more compatible with other database systems or with older MySQL servers. The only permitted value for this option is `ansi`, which has the same meaning as the corresponding option for setting the server SQL mode. See [Section 7.1.11, “Server SQL Modes”](#).

- `--complete-insert, -c`

Command-Line Format	<code>--complete-insert</code>
---------------------	--------------------------------

Use complete `INSERT` statements that include column names.

- `--create-options`

Command-Line Format	<code>--create-options</code>
---------------------	-------------------------------

Include all MySQL-specific table options in the `CREATE TABLE` statements.

- `--fields-terminated-by=...`, `--fields-enclosed-by=...`, `--fields-optionally-enclosed-by=...`, `--fields-escaped-by=...`

Command-Line Format	<code>--fields-terminated-by=string</code>
Type	String

Command-Line Format	<code>--fields-enclosed-by=string</code>
Type	String

Command-Line Format	<code>--fields-optionally-enclosed-by=string</code>
Type	String

Command-Line Format	<code>--fields-escaped-by</code>
Type	String

These options are used with the `--tab` option and have the same meaning as the corresponding `FIELDS` clauses for `LOAD DATA`. See [Section 15.2.9, “LOAD DATA Statement”](#).

- `--hex-blob`

Command-Line Format	<code>--hex-blob</code>
---------------------	-------------------------

Dump binary columns using hexadecimal notation (for example, `'abc'` becomes `0x616263`). The affected data types are `BINARY`, `VARBINARY`, `BLOB` types, `BIT`, all spatial data types, and other non-binary data types when used with the [binary character set](#).

The `--hex-blob` option is ignored when the `--tab` is used.

- `--lines-terminated-by=...`

Command-Line Format	<code>--lines-terminated-by=string</code>
Type	String

This option is used with the `--tab` option and has the same meaning as the corresponding `LINES` clause for `LOAD DATA`. See [Section 15.2.9, “LOAD DATA Statement”](#).

- `--quote-names`, `-Q`

Command-Line Format	<code>--quote-names</code>
Disabled by	<code>skip-quote-names</code>

Quote identifiers (such as database, table, and column names) within ``` characters. If the `ANSI_QUOTES` SQL mode is enabled, identifiers are quoted within `"` characters. This option is enabled by default. It can be disabled with `--skip-quote-names`, but this option should be given after any option such as `--compatible` that may enable `--quote-names`.

- `--result-file=file_name`, `-r file_name`

Command-Line Format	<code>--result-file=file_name</code>
---------------------	--------------------------------------

Type	File name
------	-----------

Direct output to the named file. The result file is created and its previous contents overwritten, even if an error occurs while generating the dump.

This option should be used on Windows to prevent newline `\n` characters from being converted to `\r\n` carriage return/newline sequences.

- `--show-create-skip-secondary-engine=value`

Command-Line Format	<code>--show-create-skip-secondary-engine</code>
---------------------	--

Excludes the `SECONDARY ENGINE` clause from `CREATE TABLE` statements. It does so by enabling the `show_create_table_skip_secondary_engine` system variable for the duration of the dump operation. Alternatively, you can enable the `show_create_table_skip_secondary_engine` system variable prior to using `mysqldump`.

- `--tab=dir_name, -T dir_name`

Command-Line Format	<code>--tab=dir_name</code>
Type	Directory name

Produce tab-separated text-format data files. For each dumped table, `mysqldump` creates a `tbl_name.sql` file that contains the `CREATE TABLE` statement that creates the table, and the server writes a `tbl_name.txt` file that contains its data. The option value is the directory in which to write the files.

Note

This option should be used only when `mysqldump` is run on the same machine as the `mysqld` server. Because the server creates `*.txt` files in the directory that you specify, the directory must be writable by the server and the MySQL account that you use must have the `FILE` privilege. Because `mysqldump` creates `*.sql` in the same directory, it must be writable by your system login account.

By default, the `.txt` data files are formatted using tab characters between column values and a newline at the end of each line. The format can be specified explicitly using the `--fields-xxx` and `--lines-terminated-by` options.

Column values are converted to the character set specified by the `--default-character-set` option.

- `--tz-utc`

Command-Line Format	<code>--tz-utc</code>
Disabled by	<code>skip-tz-utc</code>

This option enables `TIMESTAMP` columns to be dumped and reloaded between servers in different time zones. `mysqldump` sets its connection time zone to UTC and adds `SET TIME_ZONE=' +00:00 '` to the dump file. Without this option, `TIMESTAMP` columns are dumped and reloaded in the time zones local to the source and destination servers, which can cause the values to change if the servers are in different time zones. `--tz-utc` also protects against changes due to daylight saving time. `--tz-utc` is enabled by default. To disable it, use `--skip-tz-utc`.

- `--xml, -X`

Command-Line Format	<code>--xml</code>
---------------------	--------------------

Write dump output as well-formed XML.

NULL, 'NULL', and Empty Values: For a column named `column_name`, the `NULL` value, an empty string, and the string value `'NULL'` are distinguished from one another in the output generated by this option as follows.

Value:	XML Representation:
<code>NULL</code> (<i>unknown value</i>)	<code><field name="column_name" xsi:nil="true" /></code>
<code>' '</code> (<i>empty string</i>)	<code><field name="column_name"></field></code>
<code>'NULL'</code> (<i>string value</i>)	<code><field name="column_name">NULL</field></code>

The output from the `mysql` client when run using the `--xml` option also follows the preceding rules. (See [Section 6.5.1.1, “mysql Client Options”](#).)

XML output from `mysqldump` includes the XML namespace, as shown here:

```
$> mysqldump --xml -u root world City
<?xml version="1.0"?>
<mysqldump xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<database name="world">
<table_structure name="City">
<field Field="ID" Type="int(11)" Null="NO" Key="PRI" Extra="auto_increment" />
<field Field="Name" Type="char(35)" Null="NO" Key="" Default="" Extra="" />
<field Field="CountryCode" Type="char(3)" Null="NO" Key="" Default="" Extra="" />
<field Field="District" Type="char(20)" Null="NO" Key="" Default="" Extra="" />
<field Field="Population" Type="int(11)" Null="NO" Key="" Default="0" Extra="" />
<key Table="City" Non_unique="0" Key_name="PRIMARY" Seq_in_index="1" Column_name="ID"

</row>
...
<row>
<field name="ID">4079</field>
<field name="Name">Rafah</field>
<field name="CountryCode">PSE</field>
<field name="District">Rafah</field>
<field name="Population">92020</field>
</row>
</table_data>
</database>
</mysqldump>
```

Filtering Options

The following options control which kinds of schema objects are written to the dump file: by category, such as triggers or events; by name, for example, choosing which databases and tables to dump; or even filtering rows from the table data using a [WHERE](#) clause.

- [--all-databases](#), [-A](#)

Command-Line Format	--all-databases
---------------------	---------------------------------

Dump all tables in all databases. This is the same as using the [--databases](#) option and naming all the databases on the command line.

Note

See the [--add-drop-database](#) description for information about an incompatibility of that option with [--all-databases](#).

Prior to MySQL 8.3, the [--routines](#) and [--events](#) options for [mysqldump](#) and [mysqlpump](#) were not required to include stored routines and events when using the [--all-databases](#) option: The dump included the [mysql](#) system database, and therefore also the [mysql.proc](#) and [mysql.event](#) tables containing stored routine and event definitions. As of MySQL 8.3, the [mysql.event](#) and [mysql.proc](#) tables are not used. Definitions for the corresponding objects are stored in data dictionary tables, but those tables are not dumped. To include stored routines and events in a dump made using [--all-databases](#), use the [--routines](#) and [--events](#) options explicitly.

- [--databases](#), [-B](#)

Command-Line Format	--databases
---------------------	-----------------------------

Dump several databases. Normally, [mysqldump](#) treats the first name argument on the command line as a database name and following names as table names. With this option, it treats all name arguments as database names. [CREATE DATABASE](#) and [USE](#) statements are included in the output before each new database.

This option may be used to dump the [performance_schema](#) database, which normally is not dumped even with the [--all-databases](#) option. (Also use the [--skip-lock-tables](#) option.)

Note

See the [--add-drop-database](#) description for information about an incompatibility of that option with [--databases](#).

- [--events](#), [-E](#)

Command-Line Format	--events
---------------------	--------------------------

Include Event Scheduler events for the dumped databases in the output. This option requires the [EVENT](#) privileges for those databases.

The output generated by using [--events](#) contains [CREATE EVENT](#) statements to create the events.

- [--ignore-error=error\[,error\]...](#)

Command-Line Format	--ignore-error=error[,error]...
Type	String

Ignore the specified errors. The option value is a list of comma-separated error numbers specifying the errors to ignore during `mysqldump` execution. If the `--force` option is also given to ignore all errors, `--force` takes precedence.

- `--ignore-table=db_name.tbl_name`

Command-Line Format	<code>--ignore-table=db_name.tbl_name</code>
Type	String

Do not dump the given table, which must be specified using both the database and table names. To ignore multiple tables, use this option multiple times. This option also can be used to ignore views.

- `--ignore-views=boolean`

Command-Line Format	<code>--ignore-views</code>
Type	Boolean
Default Value	<code>FALSE</code>

Skips table views in the dump file. Option added in MySQL 8.2.0.

- `--init-command=str`

Command-Line Format	<code>--init-command=str</code>
Type	String

Single SQL statement to execute after connecting to the MySQL server. The definition resets existing statements defined by it or `init-command-add`. Option added in MySQL 8.2.0.

- `--init-command-add=str`

Command-Line Format	<code>--init-command-add=str</code>
Type	String

Add an additional SQL statement to execute after connecting or reconnecting to the MySQL server. It's usable without `--init-command` but has no effect if used before it because `init-command` resets the list of commands to call. Option added in MySQL 8.2.0.

- `--no-data, -d`

Command-Line Format	<code>--no-data</code>
---------------------	------------------------

Do not write any table row information (that is, do not dump table contents). This is useful if you want to dump only the `CREATE TABLE` statement for the table (for example, to create an empty copy of the table by loading the dump file).

- `--routines, -R`

Command-Line Format	<code>--routines</code>
---------------------	-------------------------

Include stored routines (procedures and functions) for the dumped databases in the output. This option requires the global `SELECT` privilege.

The output generated by using `--routines` contains `CREATE PROCEDURE` and `CREATE FUNCTION` statements to create the routines.

- `--skip-generated-invisible-primary-key`

Command-Line Format	<code>--skip-generated-invisible-primary-key</code>
Type	Boolean
Default Value	<code>FALSE</code>

This option causes generated invisible primary keys to be excluded from the output. For more information, see [Section 15.1.20.11, “Generated Invisible Primary Keys”](#).

- `--tables`

Command-Line Format	<code>--tables</code>
---------------------	-----------------------

Override the `--databases` or `-B` option. `mysqldump` regards all name arguments following the option as table names.

- `--triggers`

Command-Line Format	<code>--triggers</code>
Disabled by	<code>skip-triggers</code>

Include triggers for each dumped table in the output. This option is enabled by default; disable it with `--skip-triggers`.

To be able to dump a table's triggers, you must have the `TRIGGER` privilege for the table.

Multiple triggers are permitted. `mysqldump` dumps triggers in activation order so that when the dump file is reloaded, triggers are created in the same activation order. However, if a `mysqldump` dump file contains multiple triggers for a table that have the same trigger event and action time, an error occurs for attempts to load the dump file into an older server that does not support multiple triggers. (For a workaround, see [Downgrade Notes](#); you can convert triggers to be compatible with older servers.)

- `--where='where_condition', -w 'where_condition'`

Command-Line Format	<code>--where='where_condition'</code>
---------------------	--

Dump only rows selected by the given `WHERE` condition. Quotes around the condition are mandatory if it contains spaces or other characters that are special to your command interpreter.

Examples:

```
--where="user='jimf' "
-w"userid>1"
```

```
-w"userid<1"
```

Performance Options

The following options are the most relevant for the performance particularly of the restore operations. For large data sets, restore operation (processing the `INSERT` statements in the dump file) is the most time-consuming part. When it is urgent to restore data quickly, plan and test the performance of this stage in advance. For restore times measured in hours, you might prefer an alternative backup and restore solution, such as [MySQL Enterprise Backup](#) for `InnoDB`-only and mixed-use databases.

Performance is also affected by the [transactional options](#), primarily for the dump operation.

- `--column-statistics`

Command-Line Format	<code>--column-statistics</code>
Type	Boolean
Default Value	<code>OFF</code>

Add `ANALYZE TABLE` statements to the output to generate histogram statistics for dumped tables when the dump file is reloaded. This option is disabled by default because histogram generation for large tables can take a long time.

- `--disable-keys, -K`

Command-Line Format	<code>--disable-keys</code>
---------------------	-----------------------------

For each table, surround the `INSERT` statements with `/*!40000 ALTER TABLE tbl_name DISABLE KEYS */;` and `/*!40000 ALTER TABLE tbl_name ENABLE KEYS */;` statements. This makes loading the dump file faster because the indexes are created after all rows are inserted. This option is effective only for nonunique indexes of `MyISAM` tables.

- `--extended-insert, -e`

Command-Line Format	<code>--extended-insert</code>
Disabled by	<code>skip-extended-insert</code>

Write `INSERT` statements using multiple-row syntax that includes several `VALUES` lists. This results in a smaller dump file and speeds up inserts when the file is reloaded.

- `--insert-ignore`

Command-Line Format	<code>--insert-ignore</code>
---------------------	------------------------------

Write `INSERT IGNORE` statements rather than `INSERT` statements.

- `--max-allowed-packet=value`

Command-Line Format	<code>--max-allowed-packet=value</code>
Type	Numeric
Default Value	<code>25165824</code>

The maximum size of the buffer for client/server communication. The default is 24MB, the maximum is 1GB.

**Note**

The value of this option is specific to `mysqldump` and should not be confused with the MySQL server's `max_allowed_packet` system variable; the server value cannot be exceeded by a single packet from `mysqldump`, regardless of any setting for the `mysqldump` option, even if the latter is larger.

- `--mysqld-long-query-time=value`

Command-Line Format	<code>--mysqld-long-query-time=value</code>
Type	Numeric
Default Value	Server global setting

Set the session value of the `long_query_time` system variable. Use this option if you want to increase the time allowed for `mysqldump`'s queries before they are logged to the slow query log file. `mysqldump` performs a full table scan, which means its queries can often exceed a global `long_query_time` setting that is useful for regular queries. The default global setting is 10 seconds.

You can use `--mysqld-long-query-time` to specify a session value from 0 (meaning that every query from `mysqldump` is logged to the slow query log) to 31536000, which is 365 days in seconds. For `mysqldump`'s option, you can only specify whole seconds. When you do not specify this option, the server's global setting applies to `mysqldump`'s queries.

- `--net-buffer-length=value`

Command-Line Format	<code>--net-buffer-length=value</code>
Type	Numeric
Default Value	16384

The initial size of the buffer for client/server communication. When creating multiple-row `INSERT` statements (as with the `--extended-insert` or `--opt` option), `mysqldump` creates rows up to `--net-buffer-length` bytes long. If you increase this variable, ensure that the MySQL server `net_buffer_length` system variable has a value at least this large.

- `--network-timeout, -M`

Command-Line Format	<code>--network-timeout[={0 1}]</code>
Type	Boolean
Default Value	TRUE

Enable large tables to be dumped by setting `--max-allowed-packet` to its maximum value and network read and write timeouts to a large value. This option is enabled by default. To disable it, use `--skip-network-timeout`.

- `--opt`

Command-Line Format	<code>--opt</code>
Disabled by	<code>skip-opt</code>

This option, enabled by default, is shorthand for the combination of `--add-drop-table` `--add-locks` `--create-options` `--disable-keys` `--extended-insert` `--lock-tables` `--quick`

`--set-charset`. It gives a fast dump operation and produces a dump file that can be reloaded into a MySQL server quickly.

Because the `--opt` option is enabled by default, you only specify its converse, the `--skip-opt` to turn off several default settings. See the discussion of [mysqldump option groups](#) for information about selectively enabling or disabling a subset of the options affected by `--opt`.

- `--quick, -q`

Command-Line Format	<code>--quick</code>
Disabled by	<code>skip-quick</code>

This option is useful for dumping large tables. It forces `mysqldump` to retrieve rows for a table from the server a row at a time rather than retrieving the entire row set and buffering it in memory before writing it out.

- `--skip-opt`

Command-Line Format	<code>--skip-opt</code>
---------------------	-------------------------

See the description for the `--opt` option.

Transactional Options

The following options trade off the performance of the dump operation, against the reliability and consistency of the exported data.

- `--add-locks`

Command-Line Format	<code>--add-locks</code>
---------------------	--------------------------

Surround each table dump with `LOCK TABLES` and `UNLOCK TABLES` statements. This results in faster inserts when the dump file is reloaded. See [Section 10.2.5.1, “Optimizing INSERT Statements”](#).

- `--flush-logs, -F`

Command-Line Format	<code>--flush-logs</code>
---------------------	---------------------------

Flush the MySQL server log files before starting the dump. This option requires the `RELOAD` privilege. If you use this option in combination with the `--all-databases` option, the logs are flushed *for each database dumped*. The exception is when using `--lock-all-tables`, `--source-data`, or `--single-transaction`. In these cases, the logs are flushed only once, corresponding to the moment that all tables are locked by `FLUSH TABLES WITH READ LOCK`. If you want your dump and the log flush to happen at exactly the same moment, you should use `--flush-logs` together with `--lock-all-tables`, `--source-data`, or `--single-transaction`.

- `--flush-privileges`

Command-Line Format	<code>--flush-privileges</code>
---------------------	---------------------------------

Add a `FLUSH PRIVILEGES` statement to the dump output after dumping the `mysql` database. This option should be used any time the dump contains the `mysql` database and any other database that depends on the data in the `mysql` database for proper restoration.

Because the dump file contains a `FLUSH PRIVILEGES` statement, reloading the file requires privileges sufficient to execute that statement.

Note

For upgrades to MySQL 5.7 or higher from older versions, do not use `--flush-privileges`. For upgrade instructions in this case, see [Section 3.5, “Changes in MySQL 8.3”](#).

- `--lock-all-tables, -x`

Command-Line Format	<code>--lock-all-tables</code>
---------------------	--------------------------------

Lock all tables across all databases. This is achieved by acquiring a global read lock for the duration of the whole dump. This option automatically turns off `--single-transaction` and `--lock-tables`.

- `--lock-tables, -l`

Command-Line Format	<code>--lock-tables</code>
---------------------	----------------------------

For each dumped database, lock all tables to be dumped before dumping them. The tables are locked with `READ LOCAL` to permit concurrent inserts in the case of `MyISAM` tables. For transactional tables such as `InnoDB`, `--single-transaction` is a much better option than `--lock-tables` because it does not need to lock the tables at all.

Because `--lock-tables` locks tables for each database separately, this option does not guarantee that the tables in the dump file are logically consistent between databases. Tables in different databases may be dumped in completely different states.

Some options, such as `--opt`, automatically enable `--lock-tables`. If you want to override this, use `--skip-lock-tables` at the end of the option list.

- `--no-autocommit`

Command-Line Format	<code>--no-autocommit</code>
---------------------	------------------------------

Enclose the `INSERT` statements for each dumped table within `SET autocommit = 0` and `COMMIT` statements.

- `--order-by-primary`

Command-Line Format	<code>--order-by-primary</code>
---------------------	---------------------------------

Dump each table's rows sorted by its primary key, or by its first unique index, if such an index exists. This is useful when dumping a `MyISAM` table to be loaded into an `InnoDB` table, but makes the dump operation take considerably longer.

- `--shared-memory-base-name=name`

Command-Line Format	<code>--shared-memory-base-name=name</code>
---------------------	---

Platform Specific	Windows
-------------------	---------

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

- `--single-transaction`

Command-Line Format	<code>--single-transaction</code>
---------------------	-----------------------------------

This option sets the transaction isolation mode to `REPEATABLE READ` and sends a `START TRANSACTION` SQL statement to the server before dumping data. It is useful only with transactional tables such as `InnoDB`, because then it dumps the consistent state of the database at the time when `START TRANSACTION` was issued without blocking any applications.

The `RELOAD` or `FLUSH TABLES` privilege is required with `--single-transaction` if both `gtid_mode=ON` and `--set-gtid=purged=ON|AUTO`.

When using this option, you should keep in mind that only `InnoDB` tables are dumped in a consistent state. For example, any `MyISAM` or `MEMORY` tables dumped while using this option may still change state.

While a `--single-transaction` dump is in process, to ensure a valid dump file (correct table contents and binary log coordinates), no other connection should use the following statements: `ALTER TABLE`, `CREATE TABLE`, `DROP TABLE`, `RENAME TABLE`, `TRUNCATE TABLE`. A consistent read is not isolated from those statements, so use of them on a table to be dumped can cause the `SELECT` that is performed by `mysqldump` to retrieve the table contents to obtain incorrect contents or fail.

The `--single-transaction` option and the `--lock-tables` option are mutually exclusive because `LOCK TABLES` causes any pending transactions to be committed implicitly.

To dump large tables, combine the `--single-transaction` option with the `--quick` option.

Option Groups

- The `--opt` option turns on several settings that work together to perform a fast dump operation. All of these settings are on by default, because `--opt` is on by default. Thus you rarely if ever specify `--opt`. Instead, you can turn these settings off as a group by specifying `--skip-opt`, then optionally re-enable certain settings by specifying the associated options later on the command line.
- The `--compact` option turns off several settings that control whether optional statements and comments appear in the output. Again, you can follow this option with other options that re-enable certain settings, or turn all the settings on by using the `--skip-compact` form.

When you selectively enable or disable the effect of a group option, order is important because options are processed first to last. For example, `--disable-keys --lock-tables --skip-opt` would not have the intended effect; it is the same as `--skip-opt` by itself.

Examples

To make a backup of an entire database:

```
mysqldump db_name > backup-file.sql
```

To load the dump file back into the server:

```
mysql db_name < backup-file.sql
```

Another way to reload the dump file:

```
mysql -e "source /path-to-backup/backup-file.sql" db_name
```

`mysqldump` is also very useful for populating databases by copying data from one MySQL server to another:

```
mysqldump --opt db_name | mysql --host=remote_host -C db_name
```

You can dump several databases with one command:

```
mysqldump --databases db_name1 [db_name2 ...] > my_databases.sql
```

To dump all databases, use the `--all-databases` option:

```
mysqldump --all-databases > all_databases.sql
```

For `InnoDB` tables, `mysqldump` provides a way of making an online backup:

```
mysqldump --all-databases --source-data --single-transaction > all_databases.sql
```

This backup acquires a global read lock on all tables (using `FLUSH TABLES WITH READ LOCK`) at the beginning of the dump. As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If long updating statements are running when the `FLUSH` statement is issued, the MySQL server may get stalled until those statements finish. After that, the dump becomes lock free and does not disturb reads and writes on the tables. If the update statements that the MySQL server receives are short (in terms of execution time), the initial lock period should not be noticeable, even with many updates.

For point-in-time recovery (also known as “roll-forward,” when you need to restore an old backup and replay the changes that happened since that backup), it is often useful to rotate the binary log (see [Section 7.4.4, “The Binary Log”](#)) or at least know the binary log coordinates to which the dump corresponds:

```
mysqldump --all-databases --source-data=2 > all_databases.sql
```

Or:

```
mysqldump --all-databases --flush-logs --source-data=2 > all_databases.sql
```

The `--source-data` option can be used simultaneously with the `--single-transaction` option, which provides a convenient way to make an online backup suitable for use prior to point-in-time recovery if tables are stored using the `InnoDB` storage engine.

For more information on making backups, see [Section 9.2, “Database Backup Methods”](#), and [Section 9.3, “Example Backup and Recovery Strategy”](#).

- To select the effect of `--opt` except for some features, use the `--skip` option for each feature. To disable extended inserts and memory buffering, use `--opt --skip-extended-insert --skip-quick`. (Actually, `--skip-extended-insert --skip-quick` is sufficient because `--opt` is on by default.)
- To reverse `--opt` for all features except disabling of indexes and table locking, use `--skip-opt --disable-keys --lock-tables`.

Restrictions

`mysqldump` does not dump the `performance_schema` or `sys` schema by default. To dump any of these, name them explicitly on the command line. You can also name them with the `--databases` option. For `performance_schema`, also use the `--skip-lock-tables` option.

`mysqldump` does not dump the `INFORMATION_SCHEMA` schema.

`mysqldump` does not dump `InnoDB CREATE TABLESPACE` statements.

`mysqldump` does not dump the NDB Cluster `ndbinfo` information database.

`mysqldump` includes statements to recreate the `general_log` and `slow_query_log` tables for dumps of the `mysql` database. Log table contents are not dumped.

If you encounter problems backing up views due to insufficient privileges, see [Section 27.9, “Restrictions on Views”](#) for a workaround.

6.5.5 mysqlimport — A Data Import Program

The `mysqlimport` client provides a command-line interface to the `LOAD DATA` SQL statement. Most options to `mysqlimport` correspond directly to clauses of `LOAD DATA` syntax. See [Section 15.2.9, “LOAD DATA Statement”](#).

Invoke `mysqlimport` like this:

```
mysqlimport [options] db_name textfile1 [textfile2 ...]
```

For each text file named on the command line, `mysqlimport` strips any extension from the file name and uses the result to determine the name of the table into which to import the file's contents. For example, files named `patient.txt`, `patient.text`, and `patient` all would be imported into a table named `patient`.

`mysqlimport` supports the following options, which can be specified on the command line or in the `[mysqlimport]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 6.2.2.2, “Using Option Files”](#).

Table 6.15 mysqlimport Options

Option Name	Description
<code>--bind-address</code>	Use specified network interface to connect to MySQL Server
<code>--character-sets-dir</code>	Directory where character sets can be found
<code>--columns</code>	This option takes a comma-separated list of column names as its value
<code>--compress</code>	Compress all information sent between client and server
<code>--compression-algorithms</code>	Permitted compression algorithms for connections to server
<code>--debug</code>	Write debugging log
<code>--debug-check</code>	Print debugging information when program exits
<code>--debug-info</code>	Print debugging information, memory, and CPU statistics when program exits
<code>--default-auth</code>	Authentication plugin to use
<code>--default-character-set</code>	Specify default character set
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files
<code>--defaults-file</code>	Read only named option file
<code>--defaults-group-suffix</code>	Option group suffix value
<code>--delete</code>	Empty the table before importing the text file
<code>--enable-cleartext-plugin</code>	Enable cleartext authentication plugin
<code>--fields-enclosed-by</code>	This option has the same meaning as the corresponding clause for <code>LOAD DATA</code>
<code>--fields-escaped-by</code>	This option has the same meaning as the corresponding clause for <code>LOAD DATA</code>

Option Name	Description
<code>--fields-optionally-enclosed-by</code>	This option has the same meaning as the corresponding clause for LOAD DATA
<code>--fields-terminated-by</code>	This option has the same meaning as the corresponding clause for LOAD DATA
<code>--force</code>	Continue even if an SQL error occurs
<code>--get-server-public-key</code>	Request RSA public key from server
<code>--help</code>	Display help message and exit
<code>--host</code>	Host on which MySQL server is located
<code>--ignore</code>	See the description for the <code>--replace</code> option
<code>--ignore-lines</code>	Ignore the first N lines of the data file
<code>--lines-terminated-by</code>	This option has the same meaning as the corresponding clause for LOAD DATA
<code>--local</code>	Read input files locally from the client host
<code>--lock-tables</code>	Lock all tables for writing before processing any text files
<code>--login-path</code>	Read login path options from <code>.mylogin.cnf</code>
<code>--low-priority</code>	Use <code>LOW_PRIORITY</code> when loading the table
<code>--no-defaults</code>	Read no option files
<code>--no-login-paths</code>	Do not read login paths from the login path file
<code>--password</code>	Password to use when connecting to server
<code>--password1</code>	First multifactor authentication password to use when connecting to server
<code>--password2</code>	Second multifactor authentication password to use when connecting to server
<code>--password3</code>	Third multifactor authentication password to use when connecting to server
<code>--pipe</code>	Connect to server using named pipe (Windows only)
<code>--plugin-dir</code>	Directory where plugins are installed
<code>--port</code>	TCP/IP port number for connection
<code>--print-defaults</code>	Print default options
<code>--protocol</code>	Transport protocol to use
<code>--replace</code>	The <code>--replace</code> and <code>--ignore</code> options control handling of input rows that duplicate existing rows on unique key values
<code>--server-public-key-path</code>	Path name to file containing RSA public key
<code>--shared-memory-base-name</code>	Shared-memory name for shared-memory connections (Windows only)
<code>--silent</code>	Produce output only when errors occur
<code>--socket</code>	Unix socket file or Windows named pipe to use
<code>--ssl-ca</code>	File that contains list of trusted SSL Certificate Authorities
<code>--ssl-capath</code>	Directory that contains trusted SSL Certificate Authority certificate files

Option Name	Description
<code>--ssl-cert</code>	File that contains X.509 certificate
<code>--ssl-cipher</code>	Permissible ciphers for connection encryption
<code>--ssl-crl</code>	File that contains certificate revocation lists
<code>--ssl-crlpath</code>	Directory that contains certificate revocation-list files
<code>--ssl-fips-mode</code>	Whether to enable FIPS mode on client side
<code>--ssl-key</code>	File that contains X.509 key
<code>--ssl-mode</code>	Desired security state of connection to server
<code>--ssl-session-data</code>	File that contains SSL session data
<code>--ssl-session-data-continue-on-failed-reuse</code>	Whether to establish connections if session reuse fails
<code>--tls-ciphersuites</code>	Permissible TLSv1.3 ciphersuites for encrypted connections
<code>--tls-sni-servername</code>	Server name supplied by the client
<code>--tls-version</code>	Permissible TLS protocols for encrypted connections
<code>--use-threads</code>	Number of threads for parallel file-loading
<code>--user</code>	MySQL user name to use when connecting to server
<code>--verbose</code>	Verbose mode
<code>--version</code>	Display version information and exit
<code>--zstd-compression-level</code>	Compression level for connections to server that use zstd compression

- `--help, -?`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display a help message and exit.

- `--bind-address=ip_address`

Command-Line Format	<code>--bind-address=ip_address</code>
---------------------	--

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- `--character-sets-dir=dir_name`

Command-Line Format	<code>--character-sets-dir=path</code>
Type	String
Default Value	<code>[none]</code>

The directory where character sets are installed. See [Section 12.15, “Character Set Configuration”](#).

- `--columns=column_list, -c column_list`

Command-Line Format	<code>--columns=column_list</code>
---------------------	------------------------------------

This option takes a list of comma-separated column names as its value. The order of the column names indicates how to match data file columns with table columns.

- `--compress, -C`

Command-Line Format	<code>--compress[={OFF ON}]</code>
Deprecated	Yes
Type	Boolean
Default Value	OFF

Compress all information sent between the client and the server if possible. See [Section 6.2.8, “Connection Compression Control”](#).

This option is deprecated. Expect it to be removed in a future version of MySQL. See [Configuring Legacy Connection Compression](#).

- `--compression-algorithms=value`

Command-Line Format	<code>--compression-algorithms=value</code>
Type	Set
Default Value	uncompressed
Valid Values	zlib zstd uncompressed

The permitted compression algorithms for connections to the server. The available algorithms are the same as for the `protocol_compression_algorithms` system variable. The default value is `uncompressed`.

For more information, see [Section 6.2.8, “Connection Compression Control”](#).

- `--debug[=debug_options], -# [debug_options]`

Command-Line Format	<code>--debug[=debug_options]</code>
Type	String
Default Value	d:t:o

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o`.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-check`

Command-Line Format	<code>--debug-check</code>
Type	Boolean

Default Value	FALSE
---------------	-------

Print some debugging information when the program exits.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-info`

Command-Line Format	<code>--debug-info</code>
Type	Boolean
Default Value	FALSE

Print debugging information and memory and CPU usage statistics when the program exits.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--default-character-set=charset_name`

Command-Line Format	<code>--default-character-set=charset_name</code>
Type	String

Use `charset_name` as the default character set. See [Section 12.15, “Character Set Configuration”](#).

- `--default-auth=plugin`

Command-Line Format	<code>--default-auth=plugin</code>
Type	String

A hint about which client-side authentication plugin to use. See [Section 8.2.17, “Pluggable Authentication”](#).

- `--defaults-extra-file=file_name`

Command-Line Format	<code>--defaults-extra-file=file_name</code>
Type	File name

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-file=file_name`

Command-Line Format	<code>--defaults-file=file_name</code>
Type	File name

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-group-suffix=str`

Command-Line Format	<code>--defaults-group-suffix=str</code>
Type	String

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlimport` normally reads the `[client]` and `[mysqlimport]` groups. If this option is given as `--defaults-group-suffix=_other`, `mysqlimport` also reads the `[client_other]` and `[mysqlimport_other]` groups.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--delete, -D`

Command-Line Format	<code>--delete</code>
---------------------	-----------------------

Empty the table before importing the text file.

- `--enable-cleartext-plugin`

Command-Line Format	<code>--enable-cleartext-plugin</code>
Type	Boolean
Default Value	<code>FALSE</code>

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 8.4.1.4, “Client-Side Cleartext Pluggable Authentication”](#).)

- `--fields-terminated-by=...`, `--fields-enclosed-by=...`, `--fields-optionally-enclosed-by=...`, `--fields-escaped-by=...`

Command-Line Format	<code>--fields-terminated-by=string</code>
Type	String

Command-Line Format	<code>--fields-enclosed-by=string</code>
Type	String

Command-Line Format	<code>--fields-optionally-enclosed-by=string</code>
Type	String

Type	String
------	--------

These options have the same meaning as the corresponding clauses for `LOAD DATA`. See [Section 15.2.9, “LOAD DATA Statement”](#).

- `--force, -f`

Command-Line Format	<code>--force</code>
---------------------	----------------------

Ignore errors. For example, if a table for a text file does not exist, continue processing any remaining files. Without `--force`, `mysqlimport` exits if a table does not exist.

- `--get-server-public-key`

Command-Line Format	<code>--get-server-public-key</code>
Type	Boolean

Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For information about the `caching_sha2_password` plugin, see [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

- `--host=host_name, -h host_name`

Command-Line Format	<code>--host=host_name</code>
Type	String
Default Value	<code>localhost</code>

Import data to the MySQL server on the given host. The default host is `localhost`.

- `--ignore, -i`

Command-Line Format	<code>--ignore</code>
---------------------	-----------------------

See the description for the `--replace` option.

- `--ignore-lines=N`

Command-Line Format	<code>--ignore-lines=#</code>	441
Type	Numeric	

- `--lines-terminated-by=...`

Command-Line Format	<code>--lines-terminated-by=string</code>
Type	String

This option has the same meaning as the corresponding clause for `LOAD DATA`. For example, to import Windows files that have lines terminated with carriage return/linefeed pairs, use `--lines-terminated-by="\r\n"`. (You might have to double the backslashes, depending on the escaping conventions of your command interpreter.) See [Section 15.2.9, “LOAD DATA Statement”](#).

- `--local, -L`

Command-Line Format	<code>--local</code>
Type	Boolean
Default Value	<code>FALSE</code>

By default, files are read by the server on the server host. With this option, `mysqlimport` reads input files locally on the client host.

Successful use of `LOCAL` load operations within `mysqlimport` also requires that the server permits local loading; see [Section 8.1.6, “Security Considerations for LOAD DATA LOCAL”](#)

- `--lock-tables, -l`

Command-Line Format	<code>--lock-tables</code>
---------------------	----------------------------

Lock *all* tables for writing before processing any text files. This ensures that all tables are synchronized on the server.

- `--login-path=name`

Command-Line Format	<code>--login-path=name</code>
Type	String

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

See `--login-path` for related information.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--low-priority`

Command-Line Format	<code>--low-priority</code>
---------------------	-----------------------------

Use `LOW_PRIORITY` when loading the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--password[=password], -p[password]`

Command-Line Format	<code>--password[=password]</code>
Type	String

The password of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysqlimport` prompts for one. If given, there must be *no space* between `--password=` or `-p` and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See [Section 8.1.2.1, “End-User Guidelines for Password Security”](#).

To explicitly specify that there is no password and that `mysqlimport` should not prompt for one, use the `--skip-password` option.

- `--password1[=pass_val]`

The password for multifactor authentication factor 1 of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysqlimport` prompts for one. If given, there must be *no space* between `--password1=` and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See [Section 8.1.2.1, “End-User Guidelines for Password Security”](#).

To explicitly specify that there is no password and that `mysqlimport` should not prompt for one, use the `--skip-password1` option.

`--password1` and `--password` are synonymous, as are `--skip-password1` and `--skip-password`.

- `--password2[=pass_val]`

The password for multifactor authentication factor 2 of the MySQL account used for connecting to the server. The semantics of this option are similar to the semantics for `--password1`; see the description of that option for details.

- `--password3[=pass_val]`

The password for multifactor authentication factor 3 of the MySQL account used for connecting to the server. The semantics of this option are similar to the semantics for `--password1`; see the description of that option for details.

- `--pipe, -W`

Command-Line Format	<code>--pipe</code>
Type	String

On Windows, connect to the server using a named pipe. This option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--plugin-dir=dir_name`

Command-Line Format	<code>--plugin-dir=dir_name</code>
Type	Directory name

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlimport` does not find it. See [Section 8.2.17, “Pluggable Authentication”](#).

- `--port=port_num, -P port_num`

Command-Line Format	<code>--port=port_num</code>
Type	Numeric
Default Value	3306

For TCP/IP connections, the port number to use.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--protocol={TCP | SOCKET | PIPE | MEMORY}`

Command-Line Format	<code>--protocol=type</code>
Type	String
Default Value	[see text]
Valid Values	TCP

	SOCKET
	PIPE
	MEMORY

The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see [Section 6.2.7, “Connection Transport Protocols”](#).

- `--replace, -r`

Command-Line Format	<code>--replace</code>
---------------------	------------------------

The `--replace` and `--ignore` options control handling of input rows that duplicate existing rows on unique key values. If you specify `--replace`, new rows replace existing rows that have the same unique key value. If you specify `--ignore`, input rows that duplicate an existing row on a unique key value are skipped. If you do not specify either option, an error occurs when a duplicate key value is found, and the rest of the text file is ignored.

- `--server-public-key-path=file_name`

Command-Line Format	<code>--server-public-key-path=file_name</code>
Type	File name

The path name to a file in PEM format containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For `sha256_password`, this option applies only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see [Section 8.4.1.3, “SHA-256 Pluggable Authentication”](#), and [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

- `--shared-memory-base-name=name`

Command-Line Format	<code>--shared-memory-base-name=name</code>
Platform Specific	Windows

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

- `--silent, -s`

Command-Line Format	<code>--silent</code>
---------------------	-----------------------

Silent mode. Produce output only when errors occur.

- `--socket=path, -S path`

Command-Line Format	<code>--socket={file_name pipe_name}</code>
Type	String

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See [Command Options for Encrypted Connections](#).

- `--ssl-fips-mode={OFF|ON|STRICT}`

Command-Line Format	<code>--ssl-fips-mode={OFF ON STRICT}</code>
Deprecated	Yes
Type	Enumeration
Default Value	<code>OFF</code>
Valid Values	<code>OFF</code> <code>ON</code> <code>STRICT</code>

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations to permit. See [Section 8.8, “FIPS Support”](#).

These `--ssl-fips-mode` values are permitted:

- `OFF`: Disable FIPS mode.
- `ON`: Enable FIPS mode.
- `STRICT`: Enable “strict” FIPS mode.

Note

If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is `OFF`. In this case, setting `--ssl-fips-mode` to `ON` or `STRICT` causes the client to produce a warning at startup and to operate in non-FIPS mode.

This option is deprecated. Expect it to be removed in a future version of MySQL.

- `--tls-ciphersuites=ciphersuite_list`

Command-Line Format	<code>--tls-ciphersuites=ciphersuite_list</code>
Type	String

The permissible ciphersuites for encrypted connections that use TLSv1.3. The value is a list of one or more colon-separated ciphersuite names. The ciphersuites that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `--tls-sni-servername=server_name`

Command-Line Format	<code>--tls-sni-servername=server_name</code>
Type	String

When specified, the name is passed to the `libmysqlclient` C API library using the `MYSQL_OPT_TLS_SNI_SERVERNAME` option of `mysql_options()`. The server name is not case-sensitive. To show which server name the client specified for the current session, if any, check the `Tls_sni_server_name` status variable.

Server Name Indication (SNI) is an extension to the TLS protocol (OpenSSL must be compiled using TLS extensions for this option to function). The MySQL implementation of SNI represents the client-side only.

- `--tls-version=protocol_list`

Command-Line Format	<code>--tls-version=protocol_list</code>
Type	String
Default Value	<code>TLSv1, TLSv1.1, TLSv1.2, TLSv1.3</code> (OpenSSL 1.1.1 or higher) <code>TLSv1, TLSv1.1, TLSv1.2</code> (otherwise)

The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `--user=user_name, -u user_name`

Command-Line Format	<code>--user=user_name,</code>
Type	String

The user name of the MySQL account to use for connecting to the server.

- `--use-threads=N`

Command-Line Format	<code>--use-threads=#</code>
Type	Numeric

Load files in parallel using *N* threads.

- `--verbose, -v`

Command-Line Format	<code>--verbose</code>
---------------------	------------------------

Verbose mode. Print more information about what the program does.

- `--version, -V`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

- `--zstd-compression-level=level`

Command-Line Format	<code>--zstd-compression-level=#</code>
Type	Integer

The compression level to use for connections to the server that use the `zstd` compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression. The default `zstd` compression level is 3. The compression level setting has no effect on connections that do not use `zstd` compression.

For more information, see [Section 6.2.8, “Connection Compression Control”](#).

Here is a sample session that demonstrates use of `mysqlimport`:

```
$> mysql -e 'CREATE TABLE impptest(id INT, n VARCHAR(30))' test
$> ed
a
100      Max Sydow
101      Count Dracula
.
w impptest.txt
32
q
$> od -c impptest.txt
0000000  1  0  0  \t  M  a  x           S  y  d  o  w  \n  1  0
0000020  1  \t  C  o  u  n  t           D  r  a  c  u  l  a  \n
0000040
$> mysqlimport --local test impptest.txt
test.impptest: Records: 2 Deleted: 0 Skipped: 0 Warnings: 0
$> mysql -e 'SELECT * FROM impptest' test
+-----+-----+
| id  | n                |
+-----+-----+
| 100 | Max Sydow       |
| 101 | Count Dracula   |
+-----+-----+
```

6.5.6 mysqlpump — A Database Backup Program

- [mysqlpump Invocation Syntax](#)
- [mysqlpump Option Summary](#)
- [mysqlpump Option Descriptions](#)
- [mysqlpump Object Selection](#)
- [mysqlpump Parallel Processing](#)
- [mysqlpump Restrictions](#)

The `mysqlpump` client utility performs [logical backups](#), producing a set of SQL statements that can be executed to reproduce the original database object definitions and table data. It dumps one or more MySQL databases for backup or transfer to another SQL server.

Note

`mysqlpump` is deprecated as of MySQL 8.0.34 / 8.1.0; expect it to be removed in a future version of MySQL. You can use such MySQL programs as `mysqldump` and MySQL Shell to perform logical backups, dump databases, and similar tasks instead.

Tip

Consider using the [MySQL Shell dump utilities](#), which provide parallel dumping with multiple threads, file compression, and progress information display, as well as cloud features such as Oracle Cloud Infrastructure Object Storage streaming, and MySQL HeatWave Service compatibility checks and modifications. Dumps can be easily imported into a MySQL Server instance or a MySQL HeatWave Service DB System using the [MySQL Shell load dump utilities](#). Installation instructions for MySQL Shell can be found [here](#).

`mysqlpump` features include:

- Parallel processing of databases, and of objects within databases, to speed up the dump process
- Better control over which databases and database objects (tables, stored programs, user accounts) to dump
- Dumping of user accounts as account-management statements (`CREATE USER`, `GRANT`) rather than as inserts into the `mysql` system database
- Capability of creating compressed output
- Progress indicator (the values are estimates)
- For dump file reloading, faster secondary index creation for `InnoDB` tables by adding indexes after rows are inserted

Note

`mysqlpump` uses MySQL features introduced in MySQL 5.7, and thus assumes use with MySQL 5.7 or higher.

`mysqlpump` requires at least the `SELECT` privilege for dumped tables, `SHOW VIEW` for dumped views, `TRIGGER` for dumped triggers, and `LOCK TABLES` if the `--single-transaction` option is not used. The `SELECT` privilege on the `mysql` system database is required to dump user definitions. Certain options might require other privileges as noted in the option descriptions.

To reload a dump file, you must have the privileges required to execute the statements that it contains, such as the appropriate `CREATE` privileges for objects created by those statements.

Note

A dump made using PowerShell on Windows with output redirection creates a file that has UTF-16 encoding:

```
mysqlpump [options] > dump.sql
```

However, UTF-16 is not permitted as a connection character set (see [Section 12.4, “Connection Character Sets and Collations”](#)), so the dump file cannot be loaded correctly. To work around this issue, use the `--result-file` option, which creates the output in ASCII format:

```
mysqlpump [options] --result-file=dump.sql
```

mysqlpump Invocation Syntax

By default, `mysqlpump` dumps all databases (with certain exceptions noted in [mysqlpump Restrictions](#)). To specify this behavior explicitly, use the `--all-databases` option:

```
mysqlpump --all-databases
```

To dump a single database, or certain tables within that database, name the database on the command line, optionally followed by table names:

```
mysqlpump db_name
mysqlpump db_name tbl_name1 tbl_name2 ...
```

To treat all name arguments as database names, use the `--databases` option:

```
mysqlpump --databases db_name1 db_name2 ...
```

By default, `mysqlpump` does not dump user account definitions, even if you dump the `mysql` system database that contains the grant tables. To dump grant table contents as logical definitions in the form of `CREATE USER` and `GRANT` statements, use the `--users` option and suppress all database dumping:

```
mysqlpump --exclude-databases=% --users
```

In the preceding command, `%` is a wildcard that matches all database names for the `--exclude-databases` option.

`mysqlpump` supports several options for including or excluding databases, tables, stored programs, and user definitions. See [mysqlpump Object Selection](#).

To reload a dump file, execute the statements that it contains. For example, use the `mysql` client:

```
mysqlpump [options] > dump.sql
mysql < dump.sql
```

The following discussion provides additional `mysqlpump` usage examples.

To see a list of the options `mysqlpump` supports, issue the command `mysqlpump --help`.

mysqlpump Option Summary

`mysqlpump` supports the following options, which can be specified on the command line or in the `[mysqlpump]` and `[client]` groups of an option file. `mysqlpump` also reads the `[mysql_dump]` group but this behavior is deprecated. For information about option files used by MySQL programs, see [Section 6.2.2.2, “Using Option Files”](#).

Table 6.16 mysqlpump Options

Option Name	Description
<code>--add-drop-database</code>	Add DROP DATABASE statement before each CREATE DATABASE statement
<code>--add-drop-table</code>	Add DROP TABLE statement before each CREATE TABLE statement
<code>--add-drop-user</code>	Add DROP USER statement before each CREATE USER statement
<code>--add-locks</code>	Surround each table dump with LOCK TABLES and UNLOCK TABLES statements
<code>--all-databases</code>	Dump all databases
<code>--bind-address</code>	Use specified network interface to connect to MySQL Server
<code>--character-sets-dir</code>	Directory where character sets are installed

Option Name	Description
<code>--column-statistics</code>	Write ANALYZE TABLE statements to generate statistics histograms
<code>--complete-insert</code>	Use complete INSERT statements that include column names
<code>--compress</code>	Compress all information sent between client and server
<code>--compress-output</code>	Output compression algorithm
<code>--compression-algorithms</code>	Permitted compression algorithms for connections to server
<code>--databases</code>	Interpret all name arguments as database names
<code>--debug</code>	Write debugging log
<code>--debug-check</code>	Print debugging information when program exits
<code>--debug-info</code>	Print debugging information, memory, and CPU statistics when program exits
<code>--default-auth</code>	Authentication plugin to use
<code>--default-character-set</code>	Specify default character set
<code>--default-parallelism</code>	Default number of threads for parallel processing
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files
<code>--defaults-file</code>	Read only named option file
<code>--defaults-group-suffix</code>	Option group suffix value
<code>--defer-table-indexes</code>	For reloading, defer index creation until after loading table rows
<code>--events</code>	Dump events from dumped databases
<code>--exclude-databases</code>	Databases to exclude from dump
<code>--exclude-events</code>	Events to exclude from dump
<code>--exclude-routines</code>	Routines to exclude from dump
<code>--exclude-tables</code>	Tables to exclude from dump
<code>--exclude-triggers</code>	Triggers to exclude from dump
<code>--exclude-users</code>	Users to exclude from dump
<code>--extended-insert</code>	Use multiple-row INSERT syntax
<code>--get-server-public-key</code>	Request RSA public key from server
<code>--help</code>	Display help message and exit
<code>--hex-blob</code>	Dump binary columns using hexadecimal notation
<code>--host</code>	Host on which MySQL server is located
<code>--include-databases</code>	Databases to include in dump
<code>--include-events</code>	Events to include in dump
<code>--include-routines</code>	Routines to include in dump
<code>--include-tables</code>	Tables to include in dump
<code>--include-triggers</code>	Triggers to include in dump
<code>--include-users</code>	Users to include in dump
<code>--insert-ignore</code>	Write INSERT IGNORE rather than INSERT statements

Option Name	Description
<code>--log-error-file</code>	Append warnings and errors to named file
<code>--login-path</code>	Read login path options from <code>.mylogin.cnf</code>
<code>--max-allowed-packet</code>	Maximum packet length to send to or receive from server
<code>--net-buffer-length</code>	Buffer size for TCP/IP and socket communication
<code>--no-create-db</code>	Do not write CREATE DATABASE statements
<code>--no-create-info</code>	Do not write CREATE TABLE statements that re-create each dumped table
<code>--no-defaults</code>	Read no option files
<code>--no-login-paths</code>	Do not read login paths from the login path file
<code>--parallel-schemas</code>	Specify schema-processing parallelism
<code>--password</code>	Password to use when connecting to server
<code>--password1</code>	First multifactor authentication password to use when connecting to server
<code>--password2</code>	Second multifactor authentication password to use when connecting to server
<code>--password3</code>	Third multifactor authentication password to use when connecting to server
<code>--plugin-dir</code>	Directory where plugins are installed
<code>--port</code>	TCP/IP port number for connection
<code>--print-defaults</code>	Print default options
<code>--protocol</code>	Transport protocol to use
<code>--replace</code>	Write REPLACE statements rather than INSERT statements
<code>--result-file</code>	Direct output to a given file
<code>--routines</code>	Dump stored routines (procedures and functions) from dumped databases
<code>--server-public-key-path</code>	Path name to file containing RSA public key
<code>--set-charset</code>	Add SET NAMES default_character_set to output
<code>--set-gtid-purged</code>	Whether to add SET @@GLOBAL.GTID_PURGED to output
<code>--single-transaction</code>	Dump tables within single transaction
<code>--skip-definer</code>	Omit DEFINER and SQL SECURITY clauses from view and stored program CREATE statements
<code>--skip-dump-rows</code>	Do not dump table rows
<code>--skip-generated-invisible-primary-key</code>	Do not dump information about generated invisible primary keys
<code>--socket</code>	Unix socket file or Windows named pipe to use
<code>--ssl-ca</code>	File that contains list of trusted SSL Certificate Authorities
<code>--ssl-capath</code>	Directory that contains trusted SSL Certificate Authority certificate files
<code>--ssl-cert</code>	File that contains X.509 certificate
<code>--ssl-cipher</code>	Permissible ciphers for connection encryption

Option Name	Description
<code>--ssl-crl</code>	File that contains certificate revocation lists
<code>--ssl-crlpath</code>	Directory that contains certificate revocation-list files
<code>--ssl-fips-mode</code>	Whether to enable FIPS mode on client side
<code>--ssl-key</code>	File that contains X.509 key
<code>--ssl-mode</code>	Desired security state of connection to server
<code>--ssl-session-data</code>	File that contains SSL session data
<code>--ssl-session-data-continue-on-failed-reuse</code>	Whether to establish connections if session reuse fails
<code>--tls-ciphersuites</code>	Permissible TLSv1.3 ciphersuites for encrypted connections
<code>--tls-sni-servername</code>	Server name supplied by the client
<code>--tls-version</code>	Permissible TLS protocols for encrypted connections
<code>--triggers</code>	Dump triggers for each dumped table
<code>--tz-utc</code>	Add SET TIME_ZONE='+00:00' to dump file
<code>--user</code>	MySQL user name to use when connecting to server
<code>--users</code>	Dump user accounts
<code>--version</code>	Display version information and exit
<code>--watch-progress</code>	Display progress indicator
<code>--zstd-compression-level</code>	Compression level for connections to server that use zstd compression

mysqlpump Option Descriptions

- `--help, -?`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display a help message and exit.

- `--add-drop-database`

Command-Line Format	<code>--add-drop-database</code>
---------------------	----------------------------------

Write a `DROP DATABASE` statement before each `CREATE DATABASE` statement.

Note

In MySQL 8.3, the `mysql` schema is considered a system schema that cannot be dropped by end users. If `--add-drop-database` is used with `--all-databases` or with `--databases` where the list of schemas to be dumped includes `mysql`, the dump file contains a `DROP DATABASE `mysql`` statement that causes an error when the dump file is reloaded.

Instead, to use `--add-drop-database`, use `--databases` with a list of schemas to be dumped, where the list does not include `mysql`.

- `--add-drop-table`

Command-Line Format	<code>--add-drop-table</code>
---------------------	-------------------------------

Write a `DROP TABLE` statement before each `CREATE TABLE` statement.

- `--add-drop-user`

Command-Line Format	<code>--add-drop-user</code>
---------------------	------------------------------

Write a `DROP USER` statement before each `CREATE USER` statement.

- `--add-locks`

Command-Line Format	<code>--add-locks</code>
---------------------	--------------------------

Surround each table dump with `LOCK TABLES` and `UNLOCK TABLES` statements. This results in faster inserts when the dump file is reloaded. See [Section 10.2.5.1, “Optimizing INSERT Statements”](#).

This option does not work with parallelism because `INSERT` statements from different tables can be interleaved and `UNLOCK TABLES` following the end of the inserts for one table could release locks on tables for which inserts remain.

`--add-locks` and `--single-transaction` are mutually exclusive.

- `--all-databases, -A`

Command-Line Format	<code>--all-databases</code>
---------------------	------------------------------

Dump all databases (with certain exceptions noted in [mysqlpump Restrictions](#)). This is the default behavior if no other is specified explicitly.

`--all-databases` and `--databases` are mutually exclusive.

Note

See the `--add-drop-database` description for information about an incompatibility of that option with `--all-databases`.

Prior to MySQL 8.3, the `--routines` and `--events` options for `mysqldump` and `mysqlpump` were not required to include stored routines and events when using the `--all-databases` option: The dump included the `mysql` system database, and therefore also the `mysql.proc` and `mysql.event` tables containing stored routine and event definitions. As of MySQL 8.3, the `mysql.event` and `mysql.proc` tables are not used. Definitions for the corresponding objects are stored in data dictionary tables, but those tables are not dumped. To include stored routines and events in a dump made using `--all-databases`, use the `--routines` and `--events` options explicitly.

- `--bind-address=ip_address`

Command-Line Format	<code>--bind-address=ip_address</code>
---------------------	--

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- `--character-sets-dir=path`

Command-Line Format	<code>--character-sets-dir=dir_name</code>
Type	Directory name

The directory where character sets are installed. See [Section 12.15, “Character Set Configuration”](#).

- `--column-statistics`

Command-Line Format	<code>--column-statistics</code>
Type	Boolean
Default Value	OFF

Add `ANALYZE TABLE` statements to the output to generate histogram statistics for dumped tables when the dump file is reloaded. This option is disabled by default because histogram generation for large tables can take a long time.

- `--complete-insert`

Command-Line Format	<code>--complete-insert</code>
---------------------	--------------------------------

Write complete `INSERT` statements that include column names.

- `--compress, -C`

Command-Line Format	<code>--compress[={OFF ON}]</code>
Deprecated	Yes
Type	Boolean
Default Value	OFF

Compress all information sent between the client and the server if possible. See [Section 6.2.8, “Connection Compression Control”](#).

This option is deprecated. Expect it to be removed in a future version of MySQL. See [Configuring Legacy Connection Compression](#).

- `--compress-output=algorithm`

Command-Line Format	<code>--compress-output=algorithm</code>
Type	Enumeration
Valid Values	LZ4 ZLIB

By default, `mysqlpump` does not compress output. This option specifies output compression using the specified algorithm. Permitted algorithms are `LZ4` and `ZLIB`.

To uncompress compressed output, you must have an appropriate utility. If the system commands `lz4` and `openssl zlib` are not available, MySQL distributions include `lz4_decompress` and `zlib_decompress` utilities that can be used to decompress `mysqlpump` output that was compressed using the `--compress-output=LZ4` and `--compress-output=ZLIB` options. For more information, see [Section 6.8.1, “lz4_decompress — Decompress mysqlpump LZ4-Compressed](#)

Output”, and [Section 6.8.3, “zlib_decompress — Decompress mysqlpump ZLIB-Compressed Output”](#).

- `--compression-algorithms=value`

Command-Line Format	<code>--compression-algorithms=value</code>
Type	Set
Default Value	<code>uncompressed</code>
Valid Values	<code>zlib</code> <code>zstd</code> <code>uncompressed</code>

The permitted compression algorithms for connections to the server. The available algorithms are the same as for the `protocol_compression_algorithms` system variable. The default value is `uncompressed`.

For more information, see [Section 6.2.8, “Connection Compression Control”](#).

- `--databases, -B`

Command-Line Format	<code>--databases</code>
---------------------	--------------------------

Normally, `mysqlpump` treats the first name argument on the command line as a database name and any following names as table names. With this option, it treats all name arguments as database names. `CREATE DATABASE` statements are included in the output before each new database.

`--all-databases` and `--databases` are mutually exclusive.

Note

See the `--add-drop-database` description for information about an incompatibility of that option with `--databases`.

- `--debug[=debug_options], -# [debug_options]`

Command-Line Format	<code>--debug[=debug_options]</code>
Type	String
Default Value	<code>d:t:o,/tmp/mysqlpump.trace</code>

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysqlpump.trace`.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-check`

Command-Line Format	<code>--debug-check</code>
Type	Boolean
Default Value	<code>FALSE</code>

Print some debugging information when the program exits.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-info, -T`

Command-Line Format	<code>--debug-info</code>
Type	Boolean
Default Value	<code>FALSE</code>

Print debugging information and memory and CPU usage statistics when the program exits.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--default-auth=plugin`

Command-Line Format	<code>--default-auth=plugin</code>
Type	String

A hint about which client-side authentication plugin to use. See [Section 8.2.17, “Pluggable Authentication”](#).

- `--default-character-set=charset_name`

Command-Line Format	<code>--default-character-set=charset_name</code>
Type	String
Default Value	<code>utf8</code>

Use `charset_name` as the default character set. See [Section 12.15, “Character Set Configuration”](#). If no character set is specified, `mysqlpump` uses `utf8mb4`.

- `--default-parallelism=N`

Command-Line Format	<code>--default-parallelism=N</code>
Type	Integer
Default Value	<code>2</code>

The default number of threads for each parallel processing queue. The default is 2.

The `--parallel-schemas` option also affects parallelism and can be used to override the default number of threads. For more information, see [mysqlpump Parallel Processing](#).

With `--default-parallelism=0` and no `--parallel-schemas` options, `mysqlpump` runs as a single-threaded process and creates no queues.

With parallelism enabled, it is possible for output from different databases to be interleaved.

- `--defaults-extra-file=file_name`

Command-Line Format	<code>--defaults-extra-file=file_name</code>
---------------------	--

Type	File name
------	-----------

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-file=file_name`

Command-Line Format	<code>--defaults-file=file_name</code>
Type	File name

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-group-suffix=str`

Command-Line Format	<code>--defaults-group-suffix=str</code>
Type	String

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlpump` normally reads the `[client]` and `[mysqlpump]` groups. If this option is given as `--defaults-group-suffix=_other`, `mysqlpump` also reads the `[client_other]` and `[mysqlpump_other]` groups.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defer-table-indexes`

Command-Line Format	<code>--defer-table-indexes</code>
Type	Boolean
Default Value	<code>TRUE</code>

In the dump output, defer index creation for each table until after its rows have been loaded. This works for all storage engines, but for `InnoDB` applies only for secondary indexes.

This option is enabled by default; use `--skip-defer-table-indexes` to disable it.

- `--events`

Command-Line Format	<code>--events</code>
Type	Boolean

Default Value	TRUE
---------------	------

Include Event Scheduler events for the dumped databases in the output. Event dumping requires the [EVENT](#) privileges for those databases.

The output generated by using `--events` contains `CREATE EVENT` statements to create the events.

This option is enabled by default; use `--skip-events` to disable it.

- `--exclude-databases=db_list`

Command-Line Format	<code>--exclude-databases=db_list</code>
Type	String

Do not dump the databases in `db_list`, which is a list of one or more comma-separated database names. Multiple instances of this option are additive. For more information, see [mysqlpump Object Selection](#).

- `--exclude-events=event_list`

Command-Line Format	<code>--exclude-events=event_list</code>
Type	String

Do not dump the databases in `event_list`, which is a list of one or more comma-separated event names. Multiple instances of this option are additive. For more information, see [mysqlpump Object Selection](#).

- `--exclude-routines=routine_list`

Command-Line Format	<code>--exclude-routines=routine_list</code>
Type	String

Do not dump the events in `routine_list`, which is a list of one or more comma-separated routine (stored procedure or function) names. Multiple instances of this option are additive. For more information, see [mysqlpump Object Selection](#).

- `--exclude-tables=table_list`

Command-Line Format	<code>--exclude-tables=table_list</code>
Type	String

Do not dump the tables in `table_list`, which is a list of one or more comma-separated table names. Multiple instances of this option are additive. For more information, see [mysqlpump Object Selection](#).

- `--exclude-triggers=trigger_list`

Command-Line Format	<code>--exclude-triggers=trigger_list</code>
---------------------	--

Type	String
------	--------

Do not dump the triggers in `trigger_list`, which is a list of one or more comma-separated trigger names. Multiple instances of this option are additive. For more information, see [mysqlpump Object Selection](#).

- `--exclude-users=user_list`

Command-Line Format	<code>--exclude-users=user_list</code>
Type	String

Do not dump the user accounts in `user_list`, which is a list of one or more comma-separated account names. Multiple instances of this option are additive. For more information, see [mysqlpump Object Selection](#).

- `--extended-insert=N`

Command-Line Format	<code>--extended-insert=N</code>
---------------------	----------------------------------

Write `INSERT` statements using multiple-row syntax that includes several `VALUES` lists. This results in a smaller dump file and speeds up inserts when the file is reloaded.

The option value indicates the number of rows to include in each `INSERT` statement. The default is 250. A value of 1 produces one `INSERT` statement per table row.

- `--get-server-public-key`

Command-Line Format	<code>--get-server-public-key</code>
Type	Boolean

Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For information about the `caching_sha2_password` plugin, see [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

- `--hex-blob`

Command-Line Format	<code>--hex-blob</code>
---------------------	-------------------------

Dump binary columns using hexadecimal notation (for example, `'abc'` becomes `0x616263`). The affected data types are `BINARY`, `VARBINARY`, `BLOB` types, `BIT`, all spatial data types, and other non-binary data types when used with the [binary character set](#).

- `--host=host_name, -h host_name`

Command-Line Format	<code>--host</code>
---------------------	---------------------

Dump data from the MySQL server on the given host.

- `--include-databases=db_list`

Command-Line Format	<code>--include-databases=db_list</code>
Type	String

Dump the databases in `db_list`, which is a list of one or more comma-separated database names. The dump includes all objects in the named databases. Multiple instances of this option are additive. For more information, see [mysqlpump Object Selection](#).

- `--include-events=event_list`

Command-Line Format	<code>--include-events=event_list</code>
Type	String

Dump the events in `event_list`, which is a list of one or more comma-separated event names. Multiple instances of this option are additive. For more information, see [mysqlpump Object Selection](#).

- `--include-routines=routine_list`

Command-Line Format	<code>--include-routines=routine_list</code>
Type	String

Dump the routines in `routine_list`, which is a list of one or more comma-separated routine (stored procedure or function) names. Multiple instances of this option are additive. For more information, see [mysqlpump Object Selection](#).

- `--include-tables=table_list`

Command-Line Format	<code>--include-tables=table_list</code>
Type	String

Dump the tables in `table_list`, which is a list of one or more comma-separated table names. Multiple instances of this option are additive. For more information, see [mysqlpump Object Selection](#).

- `--include-triggers=trigger_list`

Command-Line Format	<code>--include-triggers=trigger_list</code>
Type	String

Dump the triggers in `trigger_list`, which is a list of one or more comma-separated trigger names. Multiple instances of this option are additive. For more information, see [mysqlpump Object Selection](#).

- `--include-users=user_list`

Command-Line Format	<code>--include-users=user_list</code>
---------------------	--

Type	String
------	--------

Dump the user accounts in *user_list*, which is a list of one or more comma-separated user names. Multiple instances of this option are additive. For more information, see [mysqlpump Object Selection](#).

- `--insert-ignore`

Command-Line Format	<code>--insert-ignore</code>
---------------------	------------------------------

Write `INSERT IGNORE` statements rather than `INSERT` statements.

- `--log-error-file=file_name`

Command-Line Format	<code>--log-error-file=file_name</code>
Type	File name

Log warnings and errors by appending them to the named file. If this option is not given, `mysqlpump` writes warnings and errors to the standard error output.

- `--login-path=name`

Command-Line Format	<code>--login-path=name</code>
Type	String

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

See `--login-path` for related information.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--max-allowed-packet=N`

Command-Line Format	<code>--max-allowed-packet=N</code>
Type	Numeric
Default Value	25165824

- `--net-buffer-length=N`

Command-Line Format	<code>--net-buffer-length=N</code>
Type	Numeric
Default Value	1047552

The initial size of the buffer for client/server communication. When creating multiple-row `INSERT` statements (as with the `--extended-insert` option), `mysqlpump` creates rows up to *N* bytes long. If you use this option to increase the value, ensure that the MySQL server `net_buffer_length` system variable has a value at least this large.

- `--no-create-db`

Command-Line Format	<code>--no-create-db</code>
---------------------	-----------------------------

Suppress any `CREATE DATABASE` statements that might otherwise be included in the output.

- `--no-create-info, -t`

Command-Line Format	<code>--no-create-info</code>
---------------------	-------------------------------

Do not write `CREATE TABLE` statements that create each dumped table.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--parallel-schemas=[N:]db_list`

Command-Line Format	<code>--parallel-schemas=[N:]schema_list</code>
Type	String

Create a queue for processing the databases in `db_list`, which is a list of one or more comma-separated database names. If *N* is given, the queue uses *N* threads. If *N* is not given, the `--default-parallelism` option determines the number of queue threads.

Multiple instances of this option create multiple queues. `mysqlpump` also creates a default queue to use for databases not named in any `--parallel-schemas` option, and for dumping user definitions if command options select them. For more information, see [mysqlpump Parallel](#)

- `--password[=password], -p[password]`

Command-Line Format	<code>--password[=password]</code>
Type	String

The password of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysqlpump` prompts for one. If given, there must be *no space* between `--password=` or `-p` and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See [Section 8.1.2.1, “End-User Guidelines for Password Security”](#).

To explicitly specify that there is no password and that `mysqlpump` should not prompt for one, use the `--skip-password` option.

- `--password1[=pass_val]`

The password for multifactor authentication factor 1 of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysqlpump` prompts for one. If given, there must be *no space* between `--password1=` and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See [Section 8.1.2.1, “End-User Guidelines for Password Security”](#).

To explicitly specify that there is no password and that `mysqlpump` should not prompt for one, use the `--skip-password1` option.

`--password1` and `--password` are synonymous, as are `--skip-password1` and `--skip-password`.

- `--password2[=pass_val]`

The password for multifactor authentication factor 2 of the MySQL account used for connecting to the server. The semantics of this option are similar to the semantics for `--password1`; see the description of that option for details.

- `--password3[=pass_val]`

The password for multifactor authentication factor 3 of the MySQL account used for connecting to the server. The semantics of this option are similar to the semantics for `--password1`; see the description of that option for details.

- `--plugin-dir=dir_name`

Command-Line Format	<code>--plugin-dir=dir_name</code>
Type	Directory name

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlpump` does not find it. See [Section 8.2.17, “Pluggable Authentication”](#).

- `--port=port_num, -P port_num`

Command-Line Format	<code>--port=port_num</code>
---------------------	------------------------------

Type	Numeric
Default Value	3306

For TCP/IP connections, the port number to use.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

Command-Line Format	<code>--protocol=type</code>
Type	String
Default Value	[see text]
Valid Values	TCP SOCKET PIPE MEMORY

The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see [Section 6.2.7, “Connection Transport Protocols”](#).

- `--replace`

Command-Line Format	<code>--replace</code>
---------------------	------------------------

Write `REPLACE` statements rather than `INSERT` statements.

- `--result-file=file_name`

Command-Line Format	<code>--result-file=file_name</code>
Type	File name

Direct output to the named file. The result file is created and its previous contents overwritten, even if an error occurs while generating the dump.

This option should be used on Windows to prevent newline `\n` characters from being converted to `\r\n` carriage return/newline sequences.

- `--routines`

Command-Line Format	<code>--routines</code>
Type	Boolean
Default Value	TRUE

Include stored routines (procedures and functions) for the dumped databases in the output. This option requires the global `SELECT` privilege.

The output generated by using `--routines` contains `CREATE PROCEDURE` and `CREATE FUNCTION` statements to create the routines.

This option is enabled by default; use `--skip-routines` to disable it.

- `--server-public-key-path=file_name`

Command-Line Format	<code>--server-public-key-path=file_name</code>
Type	File name

The path name to a file in PEM format containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For `sha256_password`, this option applies only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see [Section 8.4.1.3, “SHA-256 Pluggable Authentication”](#), and [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

- `--set-charset`

Command-Line Format	<code>--set-charset</code>
---------------------	----------------------------

Write `SET NAMES default_character_set` to the output.

This option is enabled by default. To disable it and suppress the `SET NAMES` statement, use `--skip-set-charset`.

- `--set-gtid-purged=value`

Command-Line Format	<code>--set-gtid-purged=value</code>
Type	Enumeration
Default Value	<code>AUTO</code>
Valid Values	<code>OFF</code> <code>ON</code> <code>AUTO</code>

This option enables control over global transaction ID (GTID) information written to the dump file, by indicating whether to add a `SET @@GLOBAL.gtid_purged` statement to the output. This option

may also cause a statement to be written to the output that disables binary logging while the dump file is being reloaded.

The following table shows the permitted option values. The default value is `AUTO`.

Value	Meaning
<code>OFF</code>	Add no <code>SET</code> statement to the output.
<code>ON</code>	Add a <code>SET</code> statement to the output. An error occurs if GTIDs are not enabled on the server.
<code>AUTO</code>	Add a <code>SET</code> statement to the output if GTIDs are enabled on the server.

The `--set-gtid-purged` option has the following effect on binary logging when the dump file is reloaded:

- `--set-gtid-purged=OFF`: `SET @@SESSION.SQL_LOG_BIN=0;` is not added to the output.
- `--set-gtid-purged=ON`: `SET @@SESSION.SQL_LOG_BIN=0;` is added to the output.
- `--set-gtid-purged=AUTO`: `SET @@SESSION.SQL_LOG_BIN=0;` is added to the output if GTIDs are enabled on the server you are backing up (that is, if `AUTO` evaluates to `ON`).
- `--single-transaction`

Command-Line Format	<code>--single-transaction</code>
---------------------	-----------------------------------

This option sets the transaction isolation mode to `REPEATABLE READ` and sends a `START TRANSACTION` SQL statement to the server before dumping data. It is useful only with transactional tables such as `InnoDB`, because then it dumps the consistent state of the database at the time when `START TRANSACTION` was issued without blocking any applications.

When using this option, you should keep in mind that only `InnoDB` tables are dumped in a consistent state. For example, any `MyISAM` or `MEMORY` tables dumped while using this option may still change state.

While a `--single-transaction` dump is in process, to ensure a valid dump file (correct table contents and binary log coordinates), no other connection should use the following statements: `ALTER TABLE`, `CREATE TABLE`, `DROP TABLE`, `RENAME TABLE`, `TRUNCATE TABLE`. A consistent read is not isolated from those statements, so use of them on a table to be dumped can cause the `SELECT` that is performed by `mysqlpump` to retrieve the table contents to obtain incorrect contents or fail.

`--add-locks` and `--single-transaction` are mutually exclusive.

- `--skip-definer`

Command-Line Format	<code>--skip-definer</code>
Type	Boolean
Default Value	<code>FALSE</code>

Omit `DEFINER` and `SQL SECURITY` clauses from the `CREATE` statements for views and stored programs. The dump file, when reloaded, creates objects that use the default `DEFINER` and `SQL SECURITY` values. See [Section 27.6, “Stored Object Access Control”](#).

- `--skip-dump-rows, -d`

Command-Line Format	<code>--skip-dump-rows</code>
Type	Boolean
Default Value	<code>FALSE</code>

Do not dump table rows.

- `--skip-generated-invisible-primary-key`

Command-Line Format	<code>--skip-generated-invisible-primary-key</code>
Type	Boolean
Default Value	<code>FALSE</code>

This option causes generated invisible primary keys (GIPKs) to be excluded from the dump. See [Section 15.1.20.11, “Generated Invisible Primary Keys”](#), for more information about GIPKs and GIPK mode.

- `--socket=path, -S path`

Command-Line Format	<code>--socket={file_name pipe_name}</code>
Type	String

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See [Command Options for Encrypted Connections](#).

- `--ssl-fips-mode={OFF|ON|STRICT}`

Command-Line Format	<code>--ssl-fips-mode={OFF ON STRICT}</code>
Deprecated	Yes
Type	Enumeration
Default Value	<code>OFF</code>
Valid Values	<code>OFF</code> <code>ON</code>

STRICT

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations to permit. See [Section 8.8, “FIPS Support”](#).

These `--ssl-fips-mode` values are permitted:

- `OFF`: Disable FIPS mode.
- `ON`: Enable FIPS mode.
- `STRICT`: Enable “strict” FIPS mode.

Note

If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is `OFF`. In this case, setting `--ssl-fips-mode` to `ON` or `STRICT` causes the client to produce a warning at startup and to operate in non-FIPS mode.

This option is deprecated. Expect it to be removed in a future version of MySQL.

- `--tls-ciphersuites=ciphersuite_list`

Command-Line Format	<code>--tls-ciphersuites=ciphersuite_list</code>
Type	String

The permissible ciphersuites for encrypted connections that use TLSv1.3. The value is a list of one or more colon-separated ciphersuite names. The ciphersuites that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `--tls-sni-servername=server_name`

Command-Line Format	<code>--tls-sni-servername=server_name</code>
Type	String

When specified, the name is passed to the `libmysqlclient` C API library using the `MYSQL_OPT_TLS_SNI_SERVERNAME` option of `mysql_options()`. The server name is not case-sensitive. To show which server name the client specified for the current session, if any, check the `Tls_sni_server_name` status variable.

Server Name Indication (SNI) is an extension to the TLS protocol (OpenSSL must be compiled using TLS extensions for this option to function). The MySQL implementation of SNI represents the client-side only.

- `--tls-version=protocol_list`

Command-Line Format	<code>--tls-version=protocol_list</code>
Type	String
Default Value	<code>TLSv1,TLSv1.1,TLSv1.2,TLSv1.3</code> (OpenSSL 1.1.1 or higher)

	TLsv1, TLsv1.1, TLsv1.2 (otherwise)
--	-------------------------------------

The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `--triggers`

Command-Line Format	<code>--triggers</code>
Type	Boolean
Default Value	TRUE

Include triggers for each dumped table in the output.

This option is enabled by default; use `--skip-triggers` to disable it.

- `--tz-utc`

Command-Line Format	<code>--tz-utc</code>
---------------------	-----------------------

This option enables `TIMESTAMP` columns to be dumped and reloaded between servers in different time zones. `mysqlpump` sets its connection time zone to UTC and adds `SET TIME_ZONE= '+00:00'` to the dump file. Without this option, `TIMESTAMP` columns are dumped and reloaded in the time zones local to the source and destination servers, which can cause the values to change if the servers are in different time zones. `--tz-utc` also protects against changes due to daylight saving time.

This option is enabled by default; use `--skip-tz-utc` to disable it.

- `--user=user_name, -u user_name`

Command-Line Format	<code>--user=user_name</code>
Type	String

The user name of the MySQL account to use for connecting to the server.

If you are using the `Rewriter` plugin, you should grant this user the `SKIP_QUERY_REWRITE` privilege.

- `--users`

Command-Line Format	<code>--users</code>
Type	Boolean
Default Value	FALSE

Dump user accounts as logical definitions in the form of `CREATE USER` and `GRANT` statements.

User definitions are stored in the grant tables in the `mysql` system database. By default, `mysqlpump` does not include the grant tables in `mysql` database dumps. To dump the contents of the grant tables as logical definitions, use the `--users` option and suppress all database dumping:

```
mysqlpump --exclude-databases=% --users
```

- `--version, -V`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

- `--watch-progress`

Command-Line Format	<code>--watch-progress</code>
Type	Boolean
Default Value	TRUE

Periodically display a progress indicator that provides information about the completed and total number of tables, rows, and other objects.

This option is enabled by default; use `--skip-watch-progress` to disable it.

- `--zstd-compression-level=level`

Command-Line Format	<code>--zstd-compression-level=#</code>
Type	Integer

The compression level to use for connections to the server that use the `zstd` compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression. The default `zstd` compression level is 3. The compression level setting has no effect on connections that do not use `zstd` compression.

For more information, see [Section 6.2.8, “Connection Compression Control”](#).

mysqlpump Object Selection

`mysqlpump` has a set of inclusion and exclusion options that enable filtering of several object types and provide flexible control over which objects to dump:

- `--include-databases` and `--exclude-databases` apply to databases and all objects within them.
- `--include-tables` and `--exclude-tables` apply to tables. These options also affect triggers associated with tables unless the trigger-specific options are given.
- `--include-triggers` and `--exclude-triggers` apply to triggers.
- `--include-routines` and `--exclude-routines` apply to stored procedures and functions. If a routine option matches a stored procedure name, it also matches a stored function of the same name.
- `--include-events` and `--exclude-events` apply to Event Scheduler events.
- `--include-users` and `--exclude-users` apply to user accounts.

Any inclusion or exclusion option may be given multiple times. The effect is additive. Order of these options does not matter.

The value of each inclusion and exclusion option is a list of comma-separated names of the appropriate object type. For example:

```
--exclude-databases=test,world
--include-tables=customer,invoice
```

Wildcard characters are permitted in the object names:

- `%` matches any sequence of zero or more characters.
- `_` matches any single character.

For example, `--include-tables=t%,__tmp` matches all table names that begin with `t` and all five-character table names that end with `tmp`.

For users, a name specified without a host part is interpreted with an implied host of `%`. For example, `u1` and `u1@%` are equivalent. This is the same equivalence that applies in MySQL generally (see [Section 8.2.4, “Specifying Account Names”](#)).

Inclusion and exclusion options interact as follows:

- By default, with no inclusion or exclusion options, `mysqlpump` dumps all databases (with certain exceptions noted in [mysqlpump Restrictions](#)).
- If inclusion options are given in the absence of exclusion options, only the objects named as included are dumped.
- If exclusion options are given in the absence of inclusion options, all objects are dumped except those named as excluded.
- If inclusion and exclusion options are given, all objects named as excluded and not named as included are not dumped. All other objects are dumped.

If multiple databases are being dumped, it is possible to name tables, triggers, and routines in a specific database by qualifying the object names with the database name. The following command dumps databases `db1` and `db2`, but excludes tables `db1.t1` and `db2.t2`:

```
mysqlpump --include-databases=db1,db2 --exclude-tables=db1.t1,db2.t2
```

The following options provide alternative ways to specify which databases to dump:

- The `--all-databases` option dumps all databases (with certain exceptions noted in [mysqlpump Restrictions](#)). It is equivalent to specifying no object options at all (the default `mysqlpump` action is to dump everything).
- `--include-databases=%` is similar to `--all-databases`, but selects all databases for dumping, even those that are exceptions for `--all-databases`.
- The `--databases` option causes `mysqlpump` to treat all name arguments as names of databases to dump. It is equivalent to an `--include-databases` option that names the same databases.

mysqlpump Parallel Processing

`mysqlpump` can use parallelism to achieve concurrent processing. You can select concurrency between databases (to dump multiple databases simultaneously) and within databases (to dump multiple objects from a given database simultaneously).

By default, `mysqlpump` sets up one queue with two threads. You can create additional queues and control the number of threads assigned to each one, including the default queue:

- `--default-parallelism=N` specifies the default number of threads used for each queue. In the absence of this option, `N` is 2.

The default queue always uses the default number of threads. Additional queues use the default number of threads unless you specify otherwise.

- `--parallel-schemas=[N:]db_list` sets up a processing queue for dumping the databases named in `db_list` and optionally specifies how many threads the queue uses. `db_list` is a list of comma-separated database names. If the option argument begins with `N:`, the queue uses

N threads. Otherwise, the `--default-parallelism` option determines the number of queue threads.

Multiple instances of the `--parallel-schemas` option create multiple queues.

Names in the database list are permitted to contain the same `%` and `_` wildcard characters supported for filtering options (see [mysqlpump Object Selection](#)).

`mysqlpump` uses the default queue for processing any databases not named explicitly with a `--parallel-schemas` option, and for dumping user definitions if command options select them.

In general, with multiple queues, `mysqlpump` uses parallelism between the sets of databases processed by the queues, to dump multiple databases simultaneously. For a queue that uses multiple threads, `mysqlpump` uses parallelism within databases, to dump multiple objects from a given database simultaneously. Exceptions can occur; for example, `mysqlpump` may block queues while it obtains from the server lists of objects in databases.

With parallelism enabled, it is possible for output from different databases to be interleaved. For example, `INSERT` statements from multiple tables dumped in parallel can be interleaved; the statements are not written in any particular order. This does not affect reloading because output statements qualify object names with database names or are preceded by `USE` statements as required.

The granularity for parallelism is a single database object. For example, a single table cannot be dumped in parallel using multiple threads.

Examples:

```
mysqlpump --parallel-schemas=db1,db2 --parallel-schemas=db3
```

`mysqlpump` sets up a queue to process `db1` and `db2`, another queue to process `db3`, and a default queue to process all other databases. All queues use two threads.

```
mysqlpump --parallel-schemas=db1,db2 --parallel-schemas=db3
          --default-parallelism=4
```

This is the same as the previous example except that all queues use four threads.

```
mysqlpump --parallel-schemas=5:db1,db2 --parallel-schemas=3:db3
```

The queue for `db1` and `db2` uses five threads, the queue for `db3` uses three threads, and the default queue uses the default of two threads.

As a special case, with `--default-parallelism=0` and no `--parallel-schemas` options, `mysqlpump` runs as a single-threaded process and creates no queues.

mysqlpump Restrictions

`mysqlpump` does not dump the `performance_schema`, `ndbinfo`, or `sys` schema by default. To dump any of these, name them explicitly on the command line. You can also name them with the `--databases` or `--include-databases` option.

`mysqlpump` does not dump the `INFORMATION_SCHEMA` schema.

`mysqlpump` does not dump `InnoDB CREATE TABLESPACE` statements.

`mysqlpump` dumps user accounts in logical form using `CREATE USER` and `GRANT` statements (for example, when you use the `--include-users` or `--users` option). For this reason, dumps of the `mysql` system database do not by default include the grant tables that contain user definitions: `user`, `db`, `tables_priv`, `columns_priv`, `procs_priv`, or `proxies_priv`. To dump any of the grant tables, name the `mysql` database followed by the table names:

```
mysqlpump mysql user db ...
```

6.5.7 mysqlshow — Display Database, Table, and Column Information

The `mysqlshow` client can be used to quickly see which databases exist, their tables, or a table's columns or indexes.

`mysqlshow` provides a command-line interface to several SQL `SHOW` statements. See [Section 15.7.7, “SHOW Statements”](#). The same information can be obtained by using those statements directly. For example, you can issue them from the `mysql` client program.

Invoke `mysqlshow` like this:

```
mysqlshow [options] [db_name [tbl_name [col_name]]]
```

- If no database is given, a list of database names is shown.
- If no table is given, all matching tables in the database are shown.
- If no column is given, all matching columns and column types in the table are shown.

The output displays only the names of those databases, tables, or columns for which you have some privileges.

If the last argument contains shell or SQL wildcard characters (`*`, `?`, `%`, or `_`), only those names that are matched by the wildcard are shown. If a database name contains any underscores, those should be escaped with a backslash (some Unix shells require two) to get a list of the proper tables or columns. `*` and `?` characters are converted into SQL `%` and `_` wildcard characters. This might cause some confusion when you try to display the columns for a table with a `_` in the name, because in this case, `mysqlshow` shows you only the table names that match the pattern. This is easily fixed by adding an extra `%` last on the command line as a separate argument.

`mysqlshow` supports the following options, which can be specified on the command line or in the `[mysqlshow]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 6.2.2.2, “Using Option Files”](#).

Table 6.17 mysqlshow Options

Option Name	Description
<code>--bind-address</code>	Use specified network interface to connect to MySQL Server
<code>--character-sets-dir</code>	Directory where character sets can be found
<code>--compress</code>	Compress all information sent between client and server
<code>--compression-algorithms</code>	Permitted compression algorithms for connections to server
<code>--count</code>	Show the number of rows per table
<code>--debug</code>	Write debugging log
<code>--debug-check</code>	Print debugging information when program exits
<code>--debug-info</code>	Print debugging information, memory, and CPU statistics when program exits
<code>--default-auth</code>	Authentication plugin to use
<code>--default-character-set</code>	Specify default character set
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files
<code>--defaults-file</code>	Read only named option file
<code>--defaults-group-suffix</code>	Option group suffix value
<code>--enable-cleartext-plugin</code>	Enable cleartext authentication plugin
<code>--get-server-public-key</code>	Request RSA public key from server
<code>--help</code>	Display help message and exit

Option Name	Description
<code>--host</code>	Host on which MySQL server is located
<code>--keys</code>	Show table indexes
<code>--login-path</code>	Read login path options from <code>.mylogin.cnf</code>
<code>--no-defaults</code>	Read no option files
<code>--no-login-paths</code>	Do not read login paths from the login path file
<code>--password</code>	Password to use when connecting to server
<code>--password1</code>	First multifactor authentication password to use when connecting to server
<code>--password2</code>	Second multifactor authentication password to use when connecting to server
<code>--password3</code>	Third multifactor authentication password to use when connecting to server
<code>--pipe</code>	Connect to server using named pipe (Windows only)
<code>--plugin-dir</code>	Directory where plugins are installed
<code>--port</code>	TCP/IP port number for connection
<code>--print-defaults</code>	Print default options
<code>--protocol</code>	Transport protocol to use
<code>--server-public-key-path</code>	Path name to file containing RSA public key
<code>--shared-memory-base-name</code>	Shared-memory name for shared-memory connections (Windows only)
<code>--show-table-type</code>	Show a column indicating the table type
<code>--socket</code>	Unix socket file or Windows named pipe to use
<code>--ssl-ca</code>	File that contains list of trusted SSL Certificate Authorities
<code>--ssl-capath</code>	Directory that contains trusted SSL Certificate Authority certificate files
<code>--ssl-cert</code>	File that contains X.509 certificate
<code>--ssl-cipher</code>	Permissible ciphers for connection encryption
<code>--ssl-crl</code>	File that contains certificate revocation lists
<code>--ssl-crlpath</code>	Directory that contains certificate revocation-list files
<code>--ssl-fips-mode</code>	Whether to enable FIPS mode on client side
<code>--ssl-key</code>	File that contains X.509 key
<code>--ssl-mode</code>	Desired security state of connection to server
<code>--ssl-session-data</code>	File that contains SSL session data
<code>--ssl-session-data-continue-on-failed-reuse</code>	Whether to establish connections if session reuse fails
<code>--status</code>	Display extra information about each table
<code>--tls-ciphersuites</code>	Permissible TLSv1.3 ciphersuites for encrypted connections
<code>--tls-sni-servername</code>	Server name supplied by the client
<code>--tls-version</code>	Permissible TLS protocols for encrypted connections

Option Name	Description
<code>--user</code>	MySQL user name to use when connecting to server
<code>--verbose</code>	Verbose mode
<code>--version</code>	Display version information and exit
<code>--zstd-compression-level</code>	Compression level for connections to server that use zstd compression

- `--help`, `-?`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display a help message and exit.

- `--bind-address=ip_address`

Command-Line Format	<code>--bind-address=ip_address</code>
---------------------	--

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- `--character-sets-dir=dir_name`

Command-Line Format	<code>--character-sets-dir=path</code>
Type	String
Default Value	<code>[none]</code>

The directory where character sets are installed. See [Section 12.15, “Character Set Configuration”](#).

- `--compress`, `-C`

Command-Line Format	<code>--compress[={OFF ON}]</code>
Deprecated	Yes
Type	Boolean
Default Value	<code>OFF</code>

Compress all information sent between the client and the server if possible. See [Section 6.2.8, “Connection Compression Control”](#).

This option is deprecated. Expect it to be removed in a future version of MySQL. See [Configuring Legacy Connection Compression](#).

- `--compression-algorithms=value`

Command-Line Format	<code>--compression-algorithms=value</code>
Type	Set
Default Value	<code>uncompressed</code>
Valid Values	<code>zlib</code>

	<code>uncompressed</code>
--	---------------------------

The permitted compression algorithms for connections to the server. The available algorithms are the same as for the `protocol_compression_algorithms` system variable. The default value is `uncompressed`.

For more information, see [Section 6.2.8, “Connection Compression Control”](#).

- `--count`

Command-Line Format	<code>--count</code>
---------------------	----------------------

Show the number of rows per table. This can be slow for non-MyISAM tables.

- `--debug[=debug_options], -# [debug_options]`

Command-Line Format	<code>--debug[=debug_options]</code>
Type	String
Default Value	<code>d:t:o</code>

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o`.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-check`

Command-Line Format	<code>--debug-check</code>
Type	Boolean
Default Value	<code>FALSE</code>

Print some debugging information when the program exits.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-info`

Command-Line Format	<code>--debug-info</code>
Type	Boolean
Default Value	<code>FALSE</code>

Print debugging information and memory and CPU usage statistics when the program exits.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--default-character-set=charset_name`

Command-Line Format	<code>--default-character-set=charset_name</code>
Type	String

Use `charset_name` as the default character set. See [Section 12.15, “Character Set Configuration”](#).

- `--default-auth=plugin`

Command-Line Format	<code>--default-auth=plugin</code>
Type	String

A hint about which client-side authentication plugin to use. See [Section 8.2.17, “Pluggable Authentication”](#).

- `--defaults-extra-file=file_name`

Command-Line Format	<code>--defaults-extra-file=file_name</code>
Type	File name

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-file=file_name`

Command-Line Format	<code>--defaults-file=file_name</code>
Type	File name

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-group-suffix=str`

Command-Line Format	<code>--defaults-group-suffix=str</code>
Type	String

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlshow` normally reads the `[client]` and `[mysqlshow]` groups. If this option is given as `--defaults-group-suffix=_other`, `mysqlshow` also reads the `[client_other]` and `[mysqlshow_other]` groups.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--enable-cleartext-plugin`

Command-Line Format	<code>--enable-cleartext-plugin</code>
---------------------	--

Default Value	FALSE
---------------	-------

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 8.4.1.4, “Client-Side Cleartext Pluggable Authentication”](#).)

- `--get-server-public-key`

Command-Line Format	<code>--get-server-public-key</code>
Type	Boolean

Request from the server the RSA public key that it uses for key pair-based password exchange. This option applies to clients that connect to the server using an account that authenticates with the `caching_sha2_password` authentication plugin. For connections by such accounts, the server does not send the public key to the client unless requested. The option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not needed, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For information about the `caching_sha2_password` plugin, see [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

- `--host=host_name, -h host_name`

Command-Line Format	<code>--host=host_name</code>
Type	String
Default Value	<code>localhost</code>

Connect to the MySQL server on the given host.

- `--keys, -k`

Command-Line Format	<code>--keys</code>
---------------------	---------------------

Show table indexes.

- `--login-path=name`

Command-Line Format	<code>--login-path=name</code>
Type	String

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

See `--login-path` for related information.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--password[=password], -p[password]`

Command-Line Format	<code>--password[=password]</code>
Type	String

The password of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysqlshow` prompts for one. If given, there must be *no space* between `--password=` or `-p` and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See [Section 8.1.2.1, “End-User Guidelines for Password Security”](#).

To explicitly specify that there is no password and that `mysqlshow` should not prompt for one, use the `--skip-password` option.

- `--password1[=pass_val]`

The password for multifactor authentication factor 1 of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysqlshow` prompts for one. If given, there must be *no space* between `--password1=` and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See [Section 8.1.2.1, “End-User Guidelines for Password Security”](#).

To explicitly specify that there is no password and that `mysqlshow` should not prompt for one, use the `--skip-password1` option.

`--password1` and `--password` are synonymous, as are `--skip-password1` and `--skip-password`.

- `--password2[=pass_val]`

The password for multifactor authentication factor 2 of the MySQL account used for connecting to the server. The semantics of this option are similar to the semantics for `--password1`; see the description of that option for details.

- `--password3[=pass_val]`

The password for multifactor authentication factor 3 of the MySQL account used for connecting to the server. The semantics of this option are similar to the semantics for `--password1`; see the description of that option for details.

- `--pipe, -W`

Command-Line Format	<code>--pipe</code>
Type	String

On Windows, connect to the server using a named pipe. This option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--plugin-dir=dir_name`

Command-Line Format	<code>--plugin-dir=dir_name</code>
Type	Directory name

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlshow` does not find it. See [Section 8.2.17, “Pluggable Authentication”](#).

- `--port=port_num, -P port_num`

Command-Line Format	<code>--port=port_num</code>
Type	Numeric
Default Value	3306

For TCP/IP connections, the port number to use.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--protocol={TCP | SOCKET | PIPE | MEMORY}`

Command-Line Format	<code>--protocol=type</code>
Type	String
Default Value	[see text]
Valid Values	TCP

	SOCKET
	PIPE
	MEMORY

The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see [Section 6.2.7, “Connection Transport Protocols”](#).

- `--server-public-key-path=file_name`

Command-Line Format	<code>--server-public-key-path=file_name</code>
Type	File name

The path name to a file in PEM format containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For `sha256_password`, this option applies only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see [Section 8.4.1.3, “SHA-256 Pluggable Authentication”](#), and [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

- `--shared-memory-base-name=name`

Command-Line Format	<code>--shared-memory-base-name=name</code>
Platform Specific	Windows

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

- `--show-table-type, -t`

Command-Line Format	<code>--show-table-type</code>
---------------------	--------------------------------

Show a column indicating the table type, as in `SHOW FULL TABLES`. The type is `BASE TABLE` or `VIEW`.

- `--socket=path, -S path`

Command-Line Format	<code>--socket={file_name pipe_name}</code>
---------------------	---

Type	String
------	--------

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See [Command Options for Encrypted Connections](#).

- `--ssl-fips-mode={OFF|ON|STRICT}`

Command-Line Format	<code>--ssl-fips-mode={OFF ON STRICT}</code>
Deprecated	Yes
Type	Enumeration
Default Value	<code>OFF</code>
Valid Values	<code>OFF</code> <code>ON</code> <code>STRICT</code>

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations to permit. See [Section 8.8, “FIPS Support”](#).

These `--ssl-fips-mode` values are permitted:

- `OFF`: Disable FIPS mode.
- `ON`: Enable FIPS mode.
- `STRICT`: Enable “strict” FIPS mode.

Note

If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is `OFF`. In this case, setting `--ssl-fips-mode` to `ON` or `STRICT` causes the client to produce a warning at startup and to operate in non-FIPS mode.

This option is deprecated. Expect it to be removed in a future version of MySQL.

- `--status, -i`

Command-Line Format	<code>--status</code>
---------------------	-----------------------

- `--tls-ciphersuites=ciphersuite_list`

Command-Line Format	<code>--tls-ciphersuites=ciphersuite_list</code>
Type	String

The permissible ciphersuites for encrypted connections that use TLSv1.3. The value is a list of one or more colon-separated ciphersuite names. The ciphersuites that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `--tls-sni-servername=server_name`

Command-Line Format	<code>--tls-sni-servername=server_name</code>
Type	String

When specified, the name is passed to the `libmysqlclient` C API library using the `MYSQL_OPT_TLS_SNI_SERVERNAME` option of `mysql_options()`. The server name is not case-sensitive. To show which server name the client specified for the current session, if any, check the `Tls_sni_server_name` status variable.

Server Name Indication (SNI) is an extension to the TLS protocol (OpenSSL must be compiled using TLS extensions for this option to function). The MySQL implementation of SNI represents the client-side only.

- `--tls-version=protocol_list`

Command-Line Format	<code>--tls-version=protocol_list</code>
Type	String
Default Value	<code>TLSv1,TLSv1.1,TLSv1.2,TLSv1.3</code> (OpenSSL 1.1.1 or higher) <code>TLSv1,TLSv1.1,TLSv1.2</code> (otherwise)

The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `--user=user_name, -u user_name`

Command-Line Format	<code>--user=user_name,</code>
Type	String

The user name of the MySQL account to use for connecting to the server.

- `--verbose, -v`

Command-Line Format	<code>--verbose</code>
---------------------	------------------------

Verbose mode. Print more information about what the program does. This option can be used

- `--version, -V`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

- `--zstd-compression-level=level`

Command-Line Format	<code>--zstd-compression-level=#</code>
Type	Integer

The compression level to use for connections to the server that use the `zstd` compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression. The default `zstd` compression level is 3. The compression level setting has no effect on connections that do not use `zstd` compression.

For more information, see [Section 6.2.8, “Connection Compression Control”](#).

6.5.8 mysqlslap — A Load Emulation Client

`mysqlslap` is a diagnostic program designed to emulate client load for a MySQL server and to report the timing of each stage. It works as if multiple clients are accessing the server.

Invoke `mysqlslap` like this:

```
mysqlslap [options]
```

Some options such as `--create` or `--query` enable you to specify a string containing an SQL statement or a file containing statements. If you specify a file, by default it must contain one statement per line. (That is, the implicit statement delimiter is the newline character.) Use the `--delimiter` option to specify a different delimiter, which enables you to specify statements that span multiple lines or place multiple statements on a single line. You cannot include comments in a file; `mysqlslap` does not understand them.

`mysqlslap` runs in three stages:

1. Create schema, table, and optionally any stored programs or data to use for the test. This stage uses a single client connection.
2. Run the load test. This stage can use many client connections.
3. Clean up (disconnect, drop table if specified). This stage uses a single client connection.

Examples:

Supply your own create and query SQL statements, with 50 clients querying and 200 selects for each (enter the command on a single line):

```
mysqlslap --delimiter=";"
--create="CREATE TABLE a (b int);INSERT INTO a VALUES (23)"
--query="SELECT * FROM a" --concurrency=50 --iterations=200
```

Let `mysqlslap` build the query SQL statement with a table of two `INT` columns and three `VARCHAR` columns. Use five clients querying 20 times each. Do not create the table or insert the data (that is, use the previous test's schema and data):

```
mysqlslap --concurrency=5 --iterations=20
--number-int-cols=2 --number-char-cols=3
--auto-generate-sql
```

Tell the program to load the create, insert, and query SQL statements from the specified files, where the `create.sql` file has multiple table creation statements delimited by `;` and multiple insert

statements delimited by `;`. The `--query` file should contain multiple queries delimited by `;`. Run all the load statements, then run all the queries in the query file with five clients (five times each):

```
mysqlslap --concurrency=5
--iterations=5 --query=query.sql --create=create.sql
--delimiter=";"
```

`mysqlslap` supports the following options, which can be specified on the command line or in the `[mysqlslap]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 6.2.2.2, “Using Option Files”](#).

Table 6.18 mysqlslap Options

Option Name	Description
<code>--auto-generate-sql</code>	Generate SQL statements automatically when they are not supplied in files or using command options
<code>--auto-generate-sql-add-autoincrement</code>	Add <code>AUTO_INCREMENT</code> column to automatically generated tables
<code>--auto-generate-sql-execute-number</code>	Specify how many queries to generate automatically
<code>--auto-generate-sql-guid-primary</code>	Add a GUID-based primary key to automatically generated tables
<code>--auto-generate-sql-load-type</code>	Specify the test load type
<code>--auto-generate-sql-secondary-indexes</code>	Specify how many secondary indexes to add to automatically generated tables
<code>--auto-generate-sql-unique-query-number</code>	How many different queries to generate for automatic tests
<code>--auto-generate-sql-unique-write-number</code>	How many different queries to generate for <code>--auto-generate-sql-write-number</code>
<code>--auto-generate-sql-write-number</code>	How many row inserts to perform on each thread
<code>--commit</code>	How many statements to execute before committing
<code>--compress</code>	Compress all information sent between client and server
<code>--compression-algorithms</code>	Permitted compression algorithms for connections to server
<code>--concurrency</code>	Number of clients to simulate when issuing the <code>SELECT</code> statement
<code>--create</code>	File or string containing the statement to use for creating the table
<code>--create-schema</code>	Schema in which to run the tests
<code>--csv</code>	Generate output in comma-separated values format
<code>--debug</code>	Write debugging log
<code>--debug-check</code>	Print debugging information when program exits
<code>--debug-info</code>	Print debugging information, memory, and CPU statistics when program exits
<code>--default-auth</code>	Authentication plugin to use
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files
<code>--defaults-file</code>	Read only named option file

Option Name	Description
<code>--defaults-group-suffix</code>	Option group suffix value
<code>--delimiter</code>	Delimiter to use in SQL statements
<code>--detach</code>	Detach (close and reopen) each connection after each N statements
<code>--enable-cleartext-plugin</code>	Enable cleartext authentication plugin
<code>--engine</code>	Storage engine to use for creating the table
<code>--get-server-public-key</code>	Request RSA public key from server
<code>--help</code>	Display help message and exit
<code>--host</code>	Host on which MySQL server is located
<code>--iterations</code>	Number of times to run the tests
<code>--login-path</code>	Read login path options from <code>.mylogin.cnf</code>
<code>--no-defaults</code>	Read no option files
<code>--no-drop</code>	Do not drop any schema created during the test run
<code>--no-login-paths</code>	Do not read login paths from the login path file
<code>--number-char-cols</code>	Number of VARCHAR columns to use if <code>--auto-generate-sql</code> is specified
<code>--number-int-cols</code>	Number of INT columns to use if <code>--auto-generate-sql</code> is specified
<code>--number-of-queries</code>	Limit each client to approximately this number of queries
<code>--only-print</code>	Do not connect to databases. mysqlslap only prints what it would have done
<code>--password</code>	Password to use when connecting to server
<code>--password1</code>	First multifactor authentication password to use when connecting to server
<code>--password2</code>	Second multifactor authentication password to use when connecting to server
<code>--password3</code>	Third multifactor authentication password to use when connecting to server
<code>--pipe</code>	Connect to server using named pipe (Windows only)
<code>--plugin-dir</code>	Directory where plugins are installed
<code>--port</code>	TCP/IP port number for connection
<code>--post-query</code>	File or string containing the statement to execute after the tests have completed
<code>--post-system</code>	String to execute using <code>system()</code> after the tests have completed
<code>--pre-query</code>	File or string containing the statement to execute before running the tests
<code>--pre-system</code>	String to execute using <code>system()</code> before running the tests
<code>--print-defaults</code>	Print default options
<code>--protocol</code>	Transport protocol to use

Option Name	Description
<code>--query</code>	File or string containing the SELECT statement to use for retrieving data
<code>--server-public-key-path</code>	Path name to file containing RSA public key
<code>--shared-memory-base-name</code>	Shared-memory name for shared-memory connections (Windows only)
<code>--silent</code>	Silent mode
<code>--socket</code>	Unix socket file or Windows named pipe to use
<code>--sql-mode</code>	Set SQL mode for client session
<code>--ssl-ca</code>	File that contains list of trusted SSL Certificate Authorities
<code>--ssl-capath</code>	Directory that contains trusted SSL Certificate Authority certificate files
<code>--ssl-cert</code>	File that contains X.509 certificate
<code>--ssl-cipher</code>	Permissible ciphers for connection encryption
<code>--ssl-crl</code>	File that contains certificate revocation lists
<code>--ssl-crlpath</code>	Directory that contains certificate revocation-list files
<code>--ssl-fips-mode</code>	Whether to enable FIPS mode on client side
<code>--ssl-key</code>	File that contains X.509 key
<code>--ssl-mode</code>	Desired security state of connection to server
<code>--ssl-session-data</code>	File that contains SSL session data
<code>--ssl-session-data-continue-on-failed-reuse</code>	Whether to establish connections if session reuse fails
<code>--tls-ciphersuites</code>	Permissible TLSv1.3 ciphersuites for encrypted connections
<code>--tls-sni-servername</code>	Server name supplied by the client
<code>--tls-version</code>	Permissible TLS protocols for encrypted connections
<code>--user</code>	MySQL user name to use when connecting to server
<code>--verbose</code>	Verbose mode
<code>--version</code>	Display version information and exit
<code>--zstd-compression-level</code>	Compression level for connections to server that use zstd compression

- `--help, -?`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display a help message and exit.

- `--auto-generate-sql, -a`

Command-Line Format	<code>--auto-generate-sql</code>
Type	Boolean

Default Value	FALSE
---------------	-------

Generate SQL statements automatically when they are not supplied in files or using command options.

- `--auto-generate-sql-add-autoincrement`

Command-Line Format	<code>--auto-generate-sql-add-autoincrement</code>
Type	Boolean
Default Value	FALSE

Add an `AUTO_INCREMENT` column to automatically generated tables.

- `--auto-generate-sql-execute-number=N`

Command-Line Format	<code>--auto-generate-sql-execute-number=#</code>
Type	Numeric

Specify how many queries to generate automatically.

- `--auto-generate-sql-guid-primary`

Command-Line Format	<code>--auto-generate-sql-guid-primary</code>
Type	Boolean
Default Value	FALSE

Add a GUID-based primary key to automatically generated tables.

- `--auto-generate-sql-load-type=type`

Command-Line Format	<code>--auto-generate-sql-load-type=type</code>
Type	Enumeration
Default Value	<code>mixed</code>
Valid Values	<code>read</code> <code>write</code> <code>key</code> <code>update</code> <code>mixed</code>

Specify the test load type. The permissible values are `read` (scan tables), `write` (insert into tables), `key` (read primary keys), `update` (update primary keys), or `mixed` (half inserts, half scanning selects). The default is `mixed`.

- `--auto-generate-sql-secondary-indexes=N`

Command-Line Format	<code>--auto-generate-sql-secondary-indexes=#</code>
---------------------	--

Type	Numeric
Default Value	0

Specify how many secondary indexes to add to automatically generated tables. By default, none are added.

- `--auto-generate-sql-unique-query-number=N`

Command-Line Format	<code>--auto-generate-sql-unique-query-number=#</code>
Type	Numeric
Default Value	10

How many different queries to generate for automatic tests. For example, if you run a `key` test that performs 1000 selects, you can use this option with a value of 1000 to run 1000 unique queries, or with a value of 50 to perform 50 different selects. The default is 10.

- `--auto-generate-sql-unique-write-number=N`

Command-Line Format	<code>--auto-generate-sql-unique-write-number=#</code>
Type	Numeric
Default Value	10

How many different queries to generate for `--auto-generate-sql-write-number`. The default is 10.

- `--auto-generate-sql-write-number=N`

Command-Line Format	<code>--auto-generate-sql-write-number=#</code>
Type	Numeric
Default Value	100

How many row inserts to perform. The default is 100.

- `--commit=N`

Command-Line Format	<code>--commit=#</code>
Type	Numeric
Default Value	0

How many statements to execute before committing. The default is 0 (no commits are done).

- `--compress, -C`

Command-Line Format	<code>--compress[={OFF ON}]</code>
Deprecated	Yes
Type	Boolean
Default Value	OFF

Compress all information sent between the client and the server if possible. See [Section 6.2.8, “Connection Compression Control”](#).

This option is deprecated. Expect it to be removed in a future version of MySQL. See [Configuring Legacy Connection Compression](#).

- `--compression-algorithms=value`

Command-Line Format	<code>--compression-algorithms=value</code>
Type	Set
Default Value	<code>uncompressed</code>
Valid Values	<code>zlib</code> <code>zstd</code> <code>uncompressed</code>

The permitted compression algorithms for connections to the server. The available algorithms are the same as for the `protocol_compression_algorithms` system variable. The default value is `uncompressed`.

For more information, see [Section 6.2.8, “Connection Compression Control”](#).

- `--concurrency=N, -c N`

Command-Line Format	<code>--concurrency=#</code>
Type	Numeric

The number of parallel clients to simulate.

- `--create=value`

Command-Line Format	<code>--create=value</code>
Type	String

The file or string containing the statement to use for creating the table.

- `--create-schema=value`

Command-Line Format	<code>--create-schema=value</code>
Type	String

The schema in which to run the tests.

Note

If the `--auto-generate-sql` option is also given, `mysqlslap` drops the schema at the end of the test run. To avoid this, use the `--no-drop` option as well.

- `--csv[=file_name]`

Type	File name
------	-----------

Generate output in comma-separated values format. The output goes to the named file, or to the standard output if no file is given.

- `--debug[=debug_options], -# [debug_options]`

Command-Line Format	<code>--debug[=debug_options]</code>
Type	String
Default Value	<code>d:t:o,/tmp/mysqlslap.trace</code>

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysqlslap.trace`.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-check`

Command-Line Format	<code>--debug-check</code>
Type	Boolean
Default Value	<code>FALSE</code>

Print some debugging information when the program exits.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-info, -T`

Command-Line Format	<code>--debug-info</code>
Type	Boolean
Default Value	<code>FALSE</code>

Print debugging information and memory and CPU usage statistics when the program exits.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--default-auth=plugin`

Command-Line Format	<code>--default-auth=plugin</code>
Type	String

A hint about which client-side authentication plugin to use. See [Section 8.2.17, “Pluggable Authentication”](#).

- `--defaults-extra-file=file_name`

Command-Line Format	<code>--defaults-extra-file=file_name</code>
Type	File name

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-file=file_name`

Command-Line Format	<code>--defaults-file=file_name</code>
Type	File name

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-group-suffix=str`

Command-Line Format	<code>--defaults-group-suffix=str</code>
Type	String

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlslap` normally reads the `[client]` and `[mysqlslap]` groups. If this option is given as `--defaults-group-suffix=_other`, `mysqlslap` also reads the `[client_other]` and `[mysqlslap_other]` groups.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--delimiter=str, -F str`

Command-Line Format	<code>--delimiter=str</code>
Type	String

The delimiter to use in SQL statements supplied in files or using command options.

- `--detach=N`

Command-Line Format	<code>--detach=#</code>
Type	Numeric
Default Value	0

Detach (close and reopen) each connection after each `N` statements. The default is 0 (connections are not detached).

- `--enable-cleartext-plugin`

Command-Line Format	<code>--enable-cleartext-plugin</code>
Type	Boolean

Default Value	FALSE
---------------	-------

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 8.4.1.4, “Client-Side Cleartext Pluggable Authentication”](#).)

- `--engine=engine_name, -e engine_name`

Command-Line Format	<code>--engine=engine_name</code>
Type	String

The storage engine to use for creating tables.

- `--get-server-public-key`

Command-Line Format	<code>--get-server-public-key</code>
Type	Boolean

Request from the server the RSA public key that it uses for key pair-based password exchange. This option applies to clients that connect to the server using an account that authenticates with the `caching_sha2_password` authentication plugin. For connections by such accounts, the server does not send the public key to the client unless requested. The option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not needed, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For information about the `caching_sha2_password` plugin, see [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

- `--host=host_name, -h host_name`

Command-Line Format	<code>--host=host_name</code>
Type	String
Default Value	<code>localhost</code>

Connect to the MySQL server on the given host.

- `--iterations=N, -i N`

Command-Line Format	<code>--iterations=#</code>
Type	Numeric

The number of times to run the tests.

- `--login-path=name`

Command-Line Format	<code>--login-path=name</code>
Type	String

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to

authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

See `--login-path` for related information.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--no-drop`

Command-Line Format	<code>--no-drop</code>
Type	Boolean
Default Value	FALSE

Prevent `mysqlslap` from dropping any schema it creates during the test run.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--number-char-cols=N, -x N`

Command-Line Format	<code>--number-char-cols=#</code>
Type	Numeric

The number of `VARCHAR` columns to use if `--auto-generate-sql` is specified.

- `--number-int-cols=N, -y N`

Command-Line Format	<code>--number-int-cols=#</code>
Type	Numeric

The number of `INT` columns to use if `--auto-generate-sql` is specified.

- `--number-of-queries=N`

Command-Line Format	<code>--number-of-queries=#</code>
Type	Numeric

Limit each client to approximately this many queries. Query counting takes into account the statement delimiter. For example, if you invoke `mysqlslap` as follows, the `;` delimiter is recognized so that each instance of the query string counts as two queries. As a result, 5 rows (not 10) are inserted.

```
mysqlslap --delimiter=";" --number-of-queries=10
          --query="use test;insert into t values(null)"
```

- `--only-print`

Command-Line Format	<code>--only-print</code>
Type	Boolean
Default Value	<code>FALSE</code>

Do not connect to databases. `mysqlslap` only prints what it would have done.

- `--password[=password], -p[password]`

Command-Line Format	<code>--password[=password]</code>
Type	String

The password of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysqlslap` prompts for one. If given, there must be *no space* between `--password=` or `-p` and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See [Section 8.1.2.1, “End-User Guidelines for Password Security”](#).

To explicitly specify that there is no password and that `mysqlslap` should not prompt for one, use the `--skip-password` option.

- `--password1[=pass_val]`

The password for multifactor authentication factor 1 of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysqlslap` prompts for one. If given, there must be *no space* between `--password1=` and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See [Section 8.1.2.1, “End-User Guidelines for Password Security”](#).

To explicitly specify that there is no password and that `mysqlslap` should not prompt for one, use the `--skip-password1` option.

`--password1` and `--password` are synonymous, as are `--skip-password1` and `--skip-password`.

- `--password2[=pass_val]`

The password for multifactor authentication factor 2 of the MySQL account used for connecting to the server. The semantics of this option are similar to the semantics for `--password1`; see the description of that option for details.

- `--password3[=pass_val]`

The password for multifactor authentication factor 3 of the MySQL account used for connecting to the server. The semantics of this option are similar to the semantics for `--password1`; see the description of that option for details.

- `--pipe, -W`

Command-Line Format	<code>--pipe</code>
Type	String

On Windows, connect to the server using a named pipe. This option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--plugin-dir=dir_name`

Command-Line Format	<code>--plugin-dir=dir_name</code>
Type	Directory name

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlslap` does not find it. See [Section 8.2.17, “Pluggable Authentication”](#).

- `--port=port_num, -P port_num`

Command-Line Format	<code>--port=port_num</code>
Type	Numeric
Default Value	3306

For TCP/IP connections, the port number to use.

- `--post-query=value`

Command-Line Format	<code>--post-query=value</code>
Type	String

The file or string containing the statement to execute after the tests have completed. This execution is not counted for timing purposes.

- `--post-system=str`

Command-Line Format	<code>--post-system=str</code>
---------------------	--------------------------------

Type	String
------	--------

The string to execute using `system()` after the tests have completed. This execution is not counted for timing purposes.

- `--pre-query=value`

Command-Line Format	<code>--pre-query=value</code>
Type	String

The file or string containing the statement to execute before running the tests. This execution is not counted for timing purposes.

- `--pre-system=str`

Command-Line Format	<code>--pre-system=str</code>
Type	String

The string to execute using `system()` before running the tests. This execution is not counted for timing purposes.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--protocol={TCP | SOCKET | PIPE | MEMORY}`

Command-Line Format	<code>--protocol=type</code>
Type	String
Default Value	[see text]
Valid Values	TCP SOCKET PIPE MEMORY

The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see [Section 6.2.7, “Connection Transport Protocols”](#).

- `--query=value, -q value`

Command-Line Format	<code>--query=value</code>
---------------------	----------------------------

Type	String
------	--------

The file or string containing the `SELECT` statement to use for retrieving data.

- `--server-public-key-path=file_name`

Command-Line Format	<code>--server-public-key-path=file_name</code>
Type	File name

The path name to a file in PEM format containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For `sha256_password`, this option applies only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see [Section 8.4.1.3, “SHA-256 Pluggable Authentication”](#), and [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

- `--shared-memory-base-name=name`

Command-Line Format	<code>--shared-memory-base-name=name</code>
Platform Specific	Windows

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

- `--silent, -s`

Command-Line Format	<code>--silent</code>
---------------------	-----------------------

Silent mode. No output.

- `--socket=path, -S path`

Command-Line Format	<code>--socket={file_name pipe_name}</code>
Type	String

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--sql-mode=mode`

Command-Line Format	<code>--sql-mode=mode</code>
Type	String

Set the SQL mode for the client session.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See [Command Options for Encrypted Connections](#).

- `--ssl-fips-mode={OFF|ON|STRICT}`

Command-Line Format	<code>--ssl-fips-mode={OFF ON STRICT}</code>
Deprecated	Yes
Type	Enumeration
Default Value	OFF
Valid Values	OFF ON STRICT

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations to permit. See [Section 8.8, “FIPS Support”](#).

These `--ssl-fips-mode` values are permitted:

- `OFF`: Disable FIPS mode.
- `ON`: Enable FIPS mode.
- `STRICT`: Enable “strict” FIPS mode.

Note

If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is `OFF`. In this case, setting `--ssl-fips-mode` to `ON` or `STRICT` causes the client to produce a warning at startup and to operate in non-FIPS mode.

This option is deprecated. Expect it to be removed in a future version of MySQL.

- `--tls-ciphersuites=ciphersuite_list`

Command-Line Format	<code>--tls-ciphersuites=ciphersuite_list</code>
Type	String

The permissible ciphersuites for encrypted connections that use TLSv1.3. The value is a list of one or more colon-separated ciphersuite names. The ciphersuites that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `--tls-sni-servername=server_name`

Command-Line Format	<code>--tls-sni-servername=server_name</code>
Type	String

When specified, the name is passed to the `libmysqlclient` C API library using the `MYSQL_OPT_TLS_SNI_SERVERNAME` option of `mysql_options()`. The server name is not case-sensitive. To show which server name the client specified for the current session, if any, check the `Tls_sni_server_name` status variable.

Server Name Indication (SNI) is an extension to the TLS protocol (OpenSSL must be compiled using TLS extensions for this option to function). The MySQL implementation of SNI represents the client-side only.

- `--tls-version=protocol_list`

Command-Line Format	<code>--tls-version=protocol_list</code>
Type	String
Default Value	<code>TLsv1, TLsv1.1, TLsv1.2, TLsv1.3</code> (OpenSSL 1.1.1 or higher) <code>TLsv1, TLsv1.1, TLsv1.2</code> (otherwise)

The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `--user=user_name, -u user_name`

Command-Line Format	<code>--user=user_name,</code>
Type	String

The user name of the MySQL account to use for connecting to the server.

- `--verbose, -v`

Command-Line Format	<code>--verbose</code>
---------------------	------------------------

Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

- `--version, -V`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

- `--zstd-compression-level=level`

Command-Line Format	<code>--zstd-compression-level=#</code>
---------------------	---

Type	Integer
------	---------

The compression level to use for connections to the server that use the `zstd` compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression. The default `zstd` compression level is 3. The compression level setting has no effect on connections that do not use `zstd` compression.

For more information, see [Section 6.2.8, “Connection Compression Control”](#).

6.6 Administrative and Utility Programs

This section describes administrative programs and programs that perform miscellaneous utility operations.

6.6.1 ibd2sdi — InnoDB Tablespace SDI Extraction Utility

`ibd2sdi` is a utility for extracting [serialized dictionary information](#) (SDI) from [InnoDB](#) tablespace files. SDI data is present in all persistent [InnoDB](#) tablespace files.

`ibd2sdi` can be run on [file-per-table](#) tablespace files (`*.ibd` files), [general tablespace](#) files (`*.ibd` files), [system tablespace](#) files (`ibdata*` files), and the data dictionary tablespace (`mysql.ibd`). It is not supported for use with temporary tablespaces or undo tablespaces.

`ibd2sdi` can be used at runtime or while the server is offline. During [DDL](#) operations, [ROLLBACK](#) operations, and undo log purge operations related to SDI, there may be a short interval of time when `ibd2sdi` fails to read SDI data stored in the tablespace.

`ibd2sdi` performs an uncommitted read of SDI from the specified tablespace. Redo logs and undo logs are not accessed.

Invoke the `ibd2sdi` utility like this:

```
ibd2sdi [options] file_name1 [file_name2 file_name3 ...]
```

`ibd2sdi` supports multi-file tablespaces like the [InnoDB](#) system tablespace, but it cannot be run on more than one tablespace at a time. For multi-file tablespaces, specify each file:

```
ibd2sdi ibdata1 ibdata2
```

The files of a multi-file tablespace must be specified in order of the ascending page number. If two successive files have the same space ID, the later file must start with the last page number of the previous file + 1.

`ibd2sdi` outputs SDI (containing id, type, and data fields) in [JSON](#) format.

ibd2sdi Options

`ibd2sdi` supports the following options:

- `--help`, `-h`

Command-Line Format	<code>--help</code>
Type	Boolean
Default Value	<code>false</code>

Display a help message and exit. For example:

```
Usage: ./ibd2sdi [-v] [-c <strict-check>] [-d <dump file name>] [-n] filename1 [filenames]
```

See <http://dev.mysql.com/doc/refman/8.0/en/ibd2sdi.html> for usage hints.

```
-h, --help          Display this help and exit.
-v, --version       Display version information and exit.
-#, --debug[=name]  Output debug log. See
                    http://dev.mysql.com/doc/refman/8.0/en/bug-package.html
-d, --dump-file=name
                    Dump the tablespace SDI into the file passed by user.
                    Without the filename, it will default to stdout
-s, --skip-data      Skip retrieving data from SDI records. Retrieve only id
                    and type.
-i, --id=#          Retrieve the SDI record matching the id passed by user.
-t, --type=#        Retrieve the SDI records matching the type passed by
                    user.
-c, --strict-check=name
                    Specify the strict checksum algorithm by the user.
                    Allowed values are innodb, crc32, none.
-n, --no-check       Ignore the checksum verification.
-p, --pretty         Pretty format the SDI output. If false, SDI would be not
                    human readable but it will be of less size
                    (Defaults to on; use --skip-pretty to disable.)
```

Variables (--variable-name=value)

and boolean options {FALSE|TRUE} Value (after reading options)

debug	(No default value)
dump-file	(No default value)
skip-data	FALSE
id	0
type	0
strict-check	crc32
no-check	FALSE
pretty	TRUE

- `--version, -v`

Command-Line Format	<code>--version</code>
Type	Boolean
Default Value	<code>false</code>

Display version information and exit. For example:

```
ibd2sdi Ver 8.0.3-dmr for Linux on x86_64 (Source distribution)
```

- `--debug[=debug_options], -# [debug_options]`

Command-Line Format	<code>--debug=options</code>
Type	String
Default Value	<code>[none]</code>

Prints a debug log. For debug options, refer to [Section 7.9.4, “The DEBUG Package”](#).

```
ibd2sdi --debug=d:t /tmp/ibd2sdi.trace
```

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--dump-file=, -d`

Command-Line Format	<code>--dump-file=file</code>
Type	File name
Default Value	<code>[none]</code>

Dumps serialized dictionary information (SDI) into the specified dump file. If a dump file is not specified, the tablespace SDI is dumped to `stdout`.

```
ibd2sdi --dump-file=file_name ../data/test/t1.ibd
```

- `--skip-data, -s`

Command-Line Format	<code>--skip-data</code>
Type	Boolean
Default Value	<code>false</code>

Skips retrieval of `data` field values from the serialized dictionary information (SDI) and only retrieves the `id` and `type` field values, which are primary keys for SDI records.

```
$> ibd2sdi --skip-data ../data/test/t1.ibd
["ibd2sdi"
,
{
  "type": 1,
  "id": 330
}
,
{
  "type": 2,
  "id": 7
}
]
```

- `--id=#, -i #`

Command-Line Format	<code>--id=#</code>
Type	Integer
Default Value	0

Retrieves serialized dictionary information (SDI) matching the specified table or tablespace object id. An object id is unique to the object type. Table and tablespace object IDs are also found in the `id` column of the `mysql.tables` and `mysql.tablespace` data dictionary tables. For information about data dictionary tables, see [Section 16.1, “Data Dictionary Schema”](#).

```
$> ibd2sdi --id=7 ../data/test/t1.ibd
["ibd2sdi"
,
{
  "type": 2,
  "id": 7,
  "object": {
    {
      "mysql_d_version_id": 80003,
      "dd_version": 80003,
      "sdi_version": 1,
      "dd_object_type": "Tablespace",
      "dd_object": {
        "name": "test/t1",
        "comment": "",
        "options": "",
        "se_private_data": "flags=16417;id=2;server_version=80003;space_version=1;",
        "engine": "InnoDB",
        "files": [
          {
            "ordinal_position": 1,
            "filename": "../test/t1.ibd",
            "se_private_data": "id=2;"
          }
        ]
      }
    }
  }
}
```

```

    }
  ]
}
}
]

```

- `--type=#, -t #`

Command-Line Format	<code>--type=#</code>
Type	Enumeration
Default Value	0
Valid Values	1 2

Retrieves serialized dictionary information (SDI) matching the specified object type. SDI is provided for table (`type=1`) and tablespace (`type=2`) objects.

This example shows output for a tablespace `ts1` in the `test` database:

```

$> ibd2sdi --type=2 ../data/test/ts1.ibd
["ibd2sdi"
,
{
  "type": 2,
  "id": 7,
  "object":
  {
    "mysql_d_version_id": 80003,
    "dd_version": 80003,
    "sdi_version": 1,
    "dd_object_type": "Tablespace",
    "dd_object": {
      "name": "test/ts1",
      "comment": "",
      "options": "",
      "se_private_data": "flags=16417;id=2;server_version=80003;space_version=1;",
      "engine": "InnoDB",
      "files": [
        {
          "ordinal_position": 1,
          "filename": "../test/ts1.ibd",
          "se_private_data": "id=2;"
        }
      ]
    }
  }
}
]

```

Due to the way in which InnoDB handles default value metadata, a default value may be present and non-empty in `ibd2sdi` output for a given table column even if it is not defined using `DEFAULT`. Consider the two tables created using the following statements, in the database named `i`:

```

CREATE TABLE t1 (c VARCHAR(16) NOT NULL);

CREATE TABLE t2 (c VARCHAR(16) NOT NULL DEFAULT "Sakila");

```

Using `ibd2sdi`, we can see that the `default_value` for column `c` is nonempty and is in fact padded to length in both tables, like this:

```

$> ibd2sdi ../data/i/t1.ibd | grep -m1 '"default_value"' | cut -b34- | sed -e s/,//
"AAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAA\nAAAAAAAAAAAA="

$> ibd2sdi ../data/i/t2.ibd | grep -m1 '"default_value"' | cut -b34- | sed -e s/,//

```

```
"B1Nha2lsYQAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAA\nAAAAAAAAAAAA="
```

Examination of `ibd2sdi` output may be easier using a JSON-aware utility like `jq`, as shown here:

```
$> ibd2sdi ../data/i/t1.ibd | jq '.[1]["object"]["dd_object"]["columns"][0]["default_value"]'
"AAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAA\nAAAAAAAAAAAA="

$> ibd2sdi ../data/i/t2.ibd | jq '.[1]["object"]["dd_object"]["columns"][0]["default_value"]'
"B1Nha2lsYQAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAA\nAAAAAAAAAAAA="
```

For more information, see the [MySQL Internals documentation](#).

- `--strict-check, -c`

Command-Line Format	<code>--strict-check=algorithm</code>
Type	Enumeration
Default Value	<code>crc32</code>
Valid Values	<code>crc32</code> <code>innodb</code> <code>none</code>

Specifies a strict checksum algorithm for validating the checksum of pages that are read. Options include `innodb`, `crc32`, and `none`.

In this example, the strict version of the `innodb` checksum algorithm is specified:

```
ibd2sdi --strict-check=innodb ../data/test/t1.ibd
```

In this example, the strict version of `crc32` checksum algorithm is specified:

```
ibd2sdi -c crc32 ../data/test/t1.ibd
```

If you do not specify the `--strict-check` option, validation is performed against non-strict `innodb`, `crc32` and `none` checksums.

- `--no-check, -n`

Command-Line Format	<code>--no-check</code>
Type	Boolean
Default Value	<code>false</code>

Skips checksum validation for pages that are read.

```
ibd2sdi --no-check ../data/test/t1.ibd
```

- `--pretty, -p`

Command-Line Format	<code>--pretty</code>
Type	Boolean
Default Value	<code>false</code>

Outputs SDI data in JSON pretty print format. Enabled by default. If disabled, SDI is not human readable but is smaller in size. Use `--skip-pretty` to disable.

```
ibd2sdi --skip-pretty ../data/test/t1.ibd
```

6.6.2 innochecksum — Offline InnoDB File Checksum Utility

`innochecksum` prints checksums for `InnoDB` files. This tool reads an `InnoDB` tablespace file, calculates the checksum for each page, compares the calculated checksum to the stored checksum, and reports mismatches, which indicate damaged pages. It was originally developed to speed up verifying the integrity of tablespace files after power outages but can also be used after file copies. Because checksum mismatches cause `InnoDB` to deliberately shut down a running server, it may be preferable to use this tool rather than waiting for an in-production server to encounter the damaged pages.

`innochecksum` cannot be used on tablespace files that the server already has open. For such files, you should use `CHECK TABLE` to check tables within the tablespace. Attempting to run `innochecksum` on a tablespace that the server already has open results in an `Unable to lock file` error.

If checksum mismatches are found, restore the tablespace from backup or start the server and attempt to use `mysqldump` to make a backup of the tables within the tablespace.

Invoke `innochecksum` like this:

```
innochecksum [options] file_name
```

innochecksum Options

`innochecksum` supports the following options. For options that refer to page numbers, the numbers are zero-based.

- `--help, -?`

Command-Line Format	<code>--help</code>
Type	Boolean
Default Value	<code>false</code>

Displays command line help. Example usage:

```
innochecksum --help
```

- `--info, -I`

Command-Line Format	<code>--info</code>
Type	Boolean
Default Value	<code>false</code>

Synonym for `--help`. Displays command line help. Example usage:

```
innochecksum --info
```

- `--version, -V`

Command-Line Format	<code>--version</code>
Type	Boolean
Default Value	<code>false</code>

Displays version information. Example usage:

```
innochecksum --version
```

- `--verbose, -v`

Command-Line Format	<code>--verbose</code>
Type	Boolean
Default Value	<code>false</code>

Verbose mode; prints a progress indicator to the log file every five seconds. In order for the progress indicator to be printed, the log file must be specified using the `--log option`. To turn on `verbose` mode, run:

```
innochecksum --verbose
```

To turn off verbose mode, run:

```
innochecksum --verbose=FALSE
```

The `--verbose` option and `--log` option can be specified at the same time. For example:

```
innochecksum --verbose --log=/var/lib/mysql/test/logtest.txt
```

To locate the progress indicator information in the log file, you can perform the following search:

```
cat ./logtest.txt | grep -i "okay"
```

The progress indicator information in the log file appears similar to the following:

```
page 1663 okay: 2.863% done
page 8447 okay: 14.537% done
page 13695 okay: 23.568% done
page 18815 okay: 32.379% done
page 23039 okay: 39.648% done
page 28351 okay: 48.789% done
page 33023 okay: 56.828% done
page 37951 okay: 65.308% done
page 44095 okay: 75.881% done
page 49407 okay: 85.022% done
page 54463 okay: 93.722% done
...
```

- `--count, -c`

Command-Line Format	<code>--count</code>
Type	Base name
Default Value	<code>true</code>

Print a count of the number of pages in the file and exit. Example usage:

```
innochecksum --count ../data/test/tab1.ibd
```

- `--start-page=num, -s num`

Command-Line Format	<code>--start-page=#</code>
Type	Numeric

Default Value	0
---------------	---

Start at this page number. Example usage:

```
innochecksum --start-page=600 ../data/test/tab1.ibd
```

or:

```
innochecksum -s 600 ../data/test/tab1.ibd
```

- `--end-page=num`, `-e num`

Command-Line Format	<code>--end-page=#</code>
Type	Numeric
Default Value	0
Minimum Value	0
Maximum Value	18446744073709551615

End at this page number. Example usage:

```
innochecksum --end-page=700 ../data/test/tab1.ibd
```

or:

```
innochecksum --p 700 ../data/test/tab1.ibd
```

- `--page=num`, `-p num`

Command-Line Format	<code>--page=#</code>
Type	Integer
Default Value	0

Check only this page number. Example usage:

```
innochecksum --page=701 ../data/test/tab1.ibd
```

- `--strict-check`, `-C`

Command-Line Format	<code>--strict-check=algorithm</code>
Type	Enumeration
Default Value	<code>crc32</code>
Valid Values	<code>innodb</code> <code>crc32</code>

none

Specify a strict checksum algorithm. Options include `innodb`, `crc32`, and `none`.

In this example, the `innodb` checksum algorithm is specified:

```
innochecksum --strict-check=innodb ../data/test/tab1.ibd
```

In this example, the `crc32` checksum algorithm is specified:

```
innochecksum -C crc32 ../data/test/tab1.ibd
```

The following conditions apply:

- If you do not specify the `--strict-check` option, `innochecksum` validates against `innodb`, `crc32` and `none`.
- If you specify the `none` option, only checksums generated by `none` are allowed.
- If you specify the `innodb` option, only checksums generated by `innodb` are allowed.
- If you specify the `crc32` option, only checksums generated by `crc32` are allowed.
- `--no-check`, `-n`

Command-Line Format	<code>--no-check</code>
Type	Boolean
Default Value	<code>false</code>

Ignore the checksum verification when rewriting a checksum. This option may only be used with the `innochecksum --write` option. If the `--write` option is not specified, `innochecksum` terminates.

In this example, an `innodb` checksum is rewritten to replace an invalid checksum:

```
innochecksum --no-check --write innodb ../data/test/tab1.ibd
```

- `--allow-mismatches`, `-a`

Command-Line Format	<code>--allow-mismatches=#</code>
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	18446744073709551615

The maximum number of checksum mismatches allowed before `innochecksum` terminates. The default setting is 0. If `--allow-mismatches=N`, where $N \geq 0$, N mismatches are permitted and `innochecksum` terminates at $N+1$. When `--allow-mismatches` is set to 0, `innochecksum` terminates on the first checksum mismatch.

In this example, an existing `innodb` checksum is rewritten to set `--allow-mismatches` to 1.

```
innochecksum --allow-mismatches=1 --write innodb ../data/test/tab1.ibd
```

With `--allow-mismatches` set to 1, if there is a mismatch at page 600 and another at page 700 on a file with 1000 pages, the checksum is updated for pages 0-599 and 601-699. Because `--`

`allow-mismatches` is set to 1, the checksum tolerates the first mismatch and terminates on the second mismatch, leaving page 600 and pages 700-999 unchanged.

- `--write=name, -w num`

Command-Line Format	<code>--write=algorithm</code>
Type	Enumeration
Default Value	<code>crc32</code>
Valid Values	<code>innodb</code> <code>crc32</code> <code>none</code>

Rewrite a checksum. When rewriting an invalid checksum, the `--no-check` option must be used together with the `--write` option. The `--no-check` option tells `innochecksum` to ignore verification of the invalid checksum. You do not have to specify the `--no-check` option if the current checksum is valid.

An algorithm must be specified when using the `--write` option. Possible values for the `--write` option are:

- `innodb`: A checksum calculated in software, using the original algorithm from InnoDB.
- `crc32`: A checksum calculated using the `crc32` algorithm, possibly done with a hardware assist.
- `none`: A constant number.

The `--write` option rewrites entire pages to disk. If the new checksum is identical to the existing checksum, the new checksum is not written to disk in order to minimize I/O.

`innochecksum` obtains an exclusive lock when the `--write` option is used.

In this example, a `crc32` checksum is written for `tab1.ibd`:

```
innochecksum -w crc32 ../data/test/tab1.ibd
```

In this example, a `crc32` checksum is rewritten to replace an invalid `crc32` checksum:

```
innochecksum --no-check --write crc32 ../data/test/tab1.ibd
```

- `--page-type-summary, -S`

Command-Line Format	<code>--page-type-summary</code>
Type	Boolean
Default Value	<code>false</code>

Display a count of each page type in a tablespace. Example usage:

```
innochecksum --page-type-summary ../data/test/tab1.ibd
```

Sample output for `--page-type-summary`:

```
File:../data/test/tab1.ibd
=====PAGE TYPE SUMMARY=====
#PAGE_COUNT PAGE_TYPE
=====
      2      Index page
      0      Undo log page
```

```

1      Inode page
0      Insert buffer free list page
2      Freshly allocated page
1      Insert buffer bitmap
0      System page
0      Transaction system page
1      File Space Header
0      Extent descriptor page
0      BLOB page
0      Compressed BLOB page
0      Other type of page
=====
Additional information:
Undo page type: 0 insert, 0 update, 0 other
Undo page state: 0 active, 0 cached, 0 to_free, 0 to_purge, 0 prepared, 0 other

```

- `--page-type-dump, -D`

Command-Line Format	<code>--page-type-dump=name</code>
Type	String
Default Value	[none]

Dump the page type information for each page in a tablespace to `stderr` or `stdout`. Example usage:

```
innochecksum --page-type-dump=/tmp/a.txt ../data/test/tab1.ibd
```

- `--log, -l`

Command-Line Format	<code>--log=path</code>
Type	File name
Default Value	[none]

Log output for the `innochecksum` tool. A log file name must be provided. Log output contains checksum values for each tablespace page. For uncompressed tables, LSN values are also provided. Example usage:

```
innochecksum --log=/tmp/log.txt ../data/test/tab1.ibd
```

or:

```
innochecksum -l /tmp/log.txt ../data/test/tab1.ibd
```

- `-` option.

Specify the `-` option to read from standard input. If the `-` option is missing when “read from standard in” is expected, `innochecksum` prints `innochecksum` usage information indicating that the “-” option was omitted. Example usages:

```
cat t1.ibd | innochecksum -
```

In this example, `innochecksum` writes the `crc32` checksum algorithm to `a.ibd` without changing the original `t1.ibd` file.

```
cat t1.ibd | innochecksum --write=crc32 - > a.ibd
```

Running innochecksum on Multiple User-defined Tablespace Files

Run `innochecksum` for all tablespace (`.ibd`) files in the “test” database:

```
innochecksum ./data/test/*.ibd
```

Run `innochecksum` for all tablespace files (`.ibd` files) that have a file name starting with “t”:

```
innochecksum ./data/test/t*.ibd
```

Run `innochecksum` for all tablespace files (`.ibd` files) in the `data` directory:

```
innochecksum ./data/*.ibd
```

Note

Running `innochecksum` on multiple user-defined tablespace files is not supported on Windows operating systems, as Windows shells such as `cmd.exe` do not support glob pattern expansion. On Windows systems, `innochecksum` must be run separately for each user-defined tablespace file. For example:

```
innochecksum.exe t1.ibd
innochecksum.exe t2.ibd
innochecksum.exe t3.ibd
```

Running innochecksum on Multiple System Tablespace Files

By default, there is only one `InnoDB` system tablespace file (`ibdata1`) but multiple files for the system tablespace can be defined using the `innodb_data_file_path` option. In the following example, three files for the system tablespace are defined using the `innodb_data_file_path` option: `ibdata1`, `ibdata2`, and `ibdata3`.

```
./bin/mysqld --no-defaults --innodb-data-file-path="ibdata1:10M;ibdata2:10M;ibdata3:10M:autoextend"
```

The three files (`ibdata1`, `ibdata2`, and `ibdata3`) form one logical system tablespace. To run `innochecksum` on multiple files that form one logical system tablespace, `innochecksum` requires the `-` option to read tablespace files from standard input, which is equivalent to concatenating multiple files to create one single file. For the example provided above, the following `innochecksum` command would be used:

```
cat ibdata* | innochecksum -
```

Refer to the `innochecksum` options information for more information about the “-” option.

Note

Running `innochecksum` on multiple files in the same tablespace is not supported on Windows operating systems, as Windows shells such as `cmd.exe` do not support glob pattern expansion. On Windows systems, `innochecksum` must be run separately for each system tablespace file. For example:

```
innochecksum.exe ibdata1
innochecksum.exe ibdata2
innochecksum.exe ibdata3
```

6.6.3 myisam_ftdump — Display Full-Text Index information

`myisam_ftdump` displays information about `FULLTEXT` indexes in `MyISAM` tables. It reads the `MyISAM` index file directly, so it must be run on the server host where the table is located. Before using `myisam_ftdump`, be sure to issue a `FLUSH TABLES` statement first if the server is running.

`myisam_ftdump` scans and dumps the entire index, which is not particularly fast. On the other hand, the distribution of words changes infrequently, so it need not be run often.

Invoke `myisam_ftdump` like this:

```
myisam_ftdump [options] tbl_name index_num
```

The `tbl_name` argument should be the name of a `MyISAM` table. You can also specify a table by naming its index file (the file with the `.MYI` suffix). If you do not invoke `myisam_ftdump` in the directory where the table files are located, the table or index file name must be preceded by the path name to the table's database directory. Index numbers begin with 0.

Example: Suppose that the `test` database contains a table named `mytexttable` that has the following definition:

```
CREATE TABLE mytexttable
(
  id    INT NOT NULL,
  txt   TEXT NOT NULL,
  PRIMARY KEY (id),
  FULLTEXT (txt)
) ENGINE=MyISAM;
```

The index on `id` is index 0 and the `FULLTEXT` index on `txt` is index 1. If your working directory is the `test` database directory, invoke `myisam_ftdump` as follows:

```
myisam_ftdump mytexttable 1
```

If the path name to the `test` database directory is `/usr/local/mysql/data/test`, you can also specify the table name argument using that path name. This is useful if you do not invoke `myisam_ftdump` in the database directory:

```
myisam_ftdump /usr/local/mysql/data/test/mytexttable 1
```

You can use `myisam_ftdump` to generate a list of index entries in order of frequency of occurrence like this on Unix-like systems:

```
myisam_ftdump -c mytexttable 1 | sort -r
```

On Windows, use:

```
myisam_ftdump -c mytexttable 1 | sort /R
```

`myisam_ftdump` supports the following options:

- `--help`, `-h`, `-?`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display a help message and exit.

- `--count`, `-c`

Command-Line Format	<code>--count</code>
---------------------	----------------------

Calculate per-word statistics (counts and global weights).

- `--dump`, `-d`

Command-Line Format	<code>--dump</code>
---------------------	---------------------

Dump the index, including data offsets and word weights.

- `--length`, `-l`

Command-Line Format	<code>--length</code>
---------------------	-----------------------

Report the length distribution.

- `--stats, -s`

Command-Line Format	<code>--stats</code>
---------------------	----------------------

Report global index statistics. This is the default operation if no other operation is specified.

- `--verbose, -v`

Command-Line Format	<code>--verbose</code>
---------------------	------------------------

Verbose mode. Print more output about what the program does.

6.6.4 myisamchk — MyISAM Table-Maintenance Utility

The `myisamchk` utility gets information about your database tables or checks, repairs, or optimizes them. `myisamchk` works with `MyISAM` tables (tables that have `.MYD` and `.MYI` files for storing data and indexes).

You can also use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair `MyISAM` tables. See [Section 15.7.3.2, “CHECK TABLE Statement”](#), and [Section 15.7.3.5, “REPAIR TABLE Statement”](#).

The use of `myisamchk` with partitioned tables is not supported.

Caution

It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors.

Invoke `myisamchk` like this:

```
myisamchk [options] tbl_name ...
```

The `options` specify what you want `myisamchk` to do. They are described in the following sections. You can also get a list of options by invoking `myisamchk --help`.

With no options, `myisamchk` simply checks your table as the default operation. To get more information or to tell `myisamchk` to take corrective action, specify options as described in the following discussion.

`tbl_name` is the database table you want to check or repair. If you run `myisamchk` somewhere other than in the database directory, you must specify the path to the database directory, because `myisamchk` has no idea where the database is located. In fact, `myisamchk` does not actually care whether the files you are working on are located in a database directory. You can copy the files that correspond to a database table into some other location and perform recovery operations on them there.

You can name several tables on the `myisamchk` command line if you wish. You can also specify a table by naming its index file (the file with the `.MYI` suffix). This enables you to specify all tables in a directory by using the pattern `*.MYI`. For example, if you are in a database directory, you can check all the `MyISAM` tables in that directory like this:

```
myisamchk *.MYI
```

If you are not in the database directory, you can check all the tables there by specifying the path to the directory:

```
myisamchk /path/to/database_dir/*.MYI
```

You can even check all tables in all databases by specifying a wildcard with the path to the MySQL data directory:

```
myisamchk /path/to/datadir/*/*.MYI
```

The recommended way to quickly check all [MyISAM](#) tables is:

```
myisamchk --silent --fast /path/to/datadir/*/*.MYI
```

If you want to check all [MyISAM](#) tables and repair any that are corrupted, you can use the following command:

```
myisamchk --silent --force --fast --update-state \
--key_buffer_size=64M --myisam_sort_buffer_size=64M \
--read_buffer_size=1M --write_buffer_size=1M \
/path/to/datadir/*/*.MYI
```

This command assumes that you have more than 64MB free. For more information about memory allocation with [myisamchk](#), see [Section 6.6.4.6, “myisamchk Memory Usage”](#).

For additional information about using [myisamchk](#), see [Section 9.6, “MyISAM Table Maintenance and Crash Recovery”](#).

Important

You must ensure that no other program is using the tables while you are running [myisamchk](#). The most effective means of doing so is to shut down the MySQL server while running [myisamchk](#), or to lock all tables that [myisamchk](#) is being used on.

Otherwise, when you run [myisamchk](#), it may display the following error message:

```
warning: clients are using or haven't closed the table properly
```

This means that you are trying to check a table that has been updated by another program (such as the [mysqld](#) server) that hasn't yet closed the file or that has died without closing the file properly, which can sometimes lead to the corruption of one or more [MyISAM](#) tables.

If [mysqld](#) is running, you must force it to flush any table modifications that are still buffered in memory by using [FLUSH TABLES](#). You should then ensure that no one is using the tables while you are running [myisamchk](#).

However, the easiest way to avoid this problem is to use [CHECK TABLE](#) instead of [myisamchk](#) to check tables. See [Section 15.7.3.2, “CHECK TABLE Statement”](#).

[myisamchk](#) supports the following options, which can be specified on the command line or in the [\[myisamchk\]](#) group of an option file. For information about option files used by MySQL programs, see [Section 6.2.2.2, “Using Option Files”](#).

Table 6.19 myisamchk Options

Option Name	Description
--analyze	Analyze the distribution of key values
--backup	Make a backup of the .MYD file as file_name-time.BAK
--block-search	Find the record that a block at the given offset belongs to
--character-sets-dir	Directory where character sets can be found
--check	Check the table for errors

Option Name	Description
<code>--check-only-changed</code>	Check only tables that have changed since the last check
<code>--correct-checksum</code>	Correct the checksum information for the table
<code>--data-file-length</code>	Maximum length of the data file (when re-creating data file when it is full)
<code>--debug</code>	Write debugging log
<code>--decode_bits</code>	Decode_bits
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files
<code>--defaults-file</code>	Read only named option file
<code>--defaults-group-suffix</code>	Option group suffix value
<code>--description</code>	Print some descriptive information about the table
<code>--extend-check</code>	Do very thorough table check or repair that tries to recover every possible row from the data file
<code>--fast</code>	Check only tables that haven't been closed properly
<code>--force</code>	Do a repair operation automatically if myisamchk finds any errors in the table
<code>--force</code>	Overwrite old temporary files. For use with the <code>-r</code> or <code>-o</code> option
<code>--ft_max_word_len</code>	Maximum word length for FULLTEXT indexes
<code>--ft_min_word_len</code>	Minimum word length for FULLTEXT indexes
<code>--ft_stopword_file</code>	Use stopwords from this file instead of built-in list
<code>--HELP</code>	Display help message and exit
<code>--help</code>	Display help message and exit
<code>--information</code>	Print informational statistics about the table that is checked
<code>--key_buffer_size</code>	Size of buffer used for index blocks for MyISAM tables
<code>--keys-used</code>	A bit-value that indicates which indexes to update
<code>--max-record-length</code>	Skip rows larger than the given length if myisamchk cannot allocate memory to hold them
<code>--medium-check</code>	Do a check that is faster than an <code>--extend-check</code> operation
<code>--myisam_block_size</code>	Block size to be used for MyISAM index pages
<code>--myisam_sort_buffer_size</code>	The buffer that is allocated when sorting the index when doing a REPAIR or when creating indexes with CREATE INDEX or ALTER TABLE
<code>--no-defaults</code>	Read no option files
<code>--parallel-recover</code>	Uses the same technique as <code>-r</code> and <code>-n</code> , but creates all the keys in parallel, using different threads (beta)
<code>--print-defaults</code>	Print default options
<code>--quick</code>	Achieve a faster repair by not modifying the data file

Option Name	Description
--read_buffer_size	Each thread that does a sequential scan allocates a buffer of this size for each table it scans
--read-only	Do not mark the table as checked
--recover	Do a repair that can fix almost any problem except unique keys that aren't unique
--safe-recover	Do a repair using an old recovery method that reads through all rows in order and updates all index trees based on the rows found
--set-auto-increment	Force AUTO_INCREMENT numbering for new records to start at the given value
--set-collation	Specify the collation to use for sorting table indexes
--silent	Silent mode
--sort_buffer_size	The buffer that is allocated when sorting the index when doing a REPAIR or when creating indexes with CREATE INDEX or ALTER TABLE
--sort-index	Sort the index tree blocks in high-low order
--sort_key_blocks	sort_key_blocks
--sort-records	Sort records according to a particular index
--sort-recover	Force myisamchk to use sorting to resolve the keys even if the temporary files would be very large
--stats_method	Specifies how MyISAM index statistics collection code should treat NULLs
--tmpdir	Directory to be used for storing temporary files
--unpack	Unpack a table that was packed with myisampack
--update-state	Store information in the .MYI file to indicate when the table was checked and whether the table crashed
--verbose	Verbose mode
--version	Display version information and exit
--wait	Wait for locked table to be unlocked, instead of terminating
--write_buffer_size	Write buffer size

6.6.4.1 myisamchk General Options

The options described in this section can be used for any type of table maintenance operation performed by `myisamchk`. The sections following this one describe options that pertain only to specific operations, such as table checking or repairing.

- `--help, -?`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display a help message and exit. Options are grouped by type of operation.

- `--HELP, -H`

Command-Line Format	<code>--HELP</code>
---------------------	---------------------

Display a help message and exit. Options are presented in a single list.

- `--debug=debug_options, -# debug_options`

Command-Line Format	<code>--debug[=debug_options]</code>
Type	String
Default Value	<code>d:t:o,/tmp/myisamchk.trace</code>

Write a debugging log. A typical *debug_options* string is `d:t:o,file_name`. The default is `d:t:o,/tmp/myisamchk.trace`.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--defaults-extra-file=file_name`

Command-Line Format	<code>--defaults-extra-file=file_name</code>
Type	File name

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If *file_name* is not an absolute path name, it is interpreted relative to the current directory.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-file=file_name`

Command-Line Format	<code>--defaults-file=file_name</code>
Type	File name

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If *file_name* is not an absolute path name, it is interpreted relative to the current directory.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-group-suffix=str`

Command-Line Format	<code>--defaults-group-suffix=str</code>
Type	String

Read not only the usual option groups, but also groups with the usual names and a suffix of *str*. For example, `myisamchk` normally reads the `[myisamchk]` group. If this option is given as `--defaults-group-suffix=_other`, `myisamchk` also reads the `[myisamchk_other]` group. 519

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--silent`, `-s`

Command-Line Format	<code>--silent</code>
---------------------	-----------------------

Silent mode. Write output only when errors occur. You can use `-s` twice (`-ss`) to make `myisamchk` very silent.

- `--verbose`, `-v`

Command-Line Format	<code>--verbose</code>
---------------------	------------------------

Verbose mode. Print more information about what the program does. This can be used with `-d` and `-e`. Use `-v` multiple times (`-vv`, `-vvv`) for even more output.

- `--version`, `-V`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

- `--wait`, `-w`

Command-Line Format	<code>--wait</code>
Type	Boolean
Default Value	<code>false</code>

You can also set the following variables by using `--var_name=value` syntax:

Variable	Default Value
<code>decode_bits</code>	9
<code>ft_max_word_len</code>	version-dependent
<code>ft_min_word_len</code>	4
<code>ft_stopword_file</code>	built-in list
<code>key_buffer_size</code>	523264
<code>myisam_block_size</code>	1024
<code>myisam_sort_key_blocks</code>	16
<code>read_buffer_size</code>	262136
<code>sort_buffer_size</code>	2097144
<code>sort_key_blocks</code>	16
<code>stats_method</code>	nulls_unequal
<code>write_buffer_size</code>	262136

The possible `myisamchk` variables and their default values can be examined with `myisamchk --help`:

`myisam_sort_buffer_size` is used when the keys are repaired by sorting keys, which is the normal case when you use `--recover`. `sort_buffer_size` is a deprecated synonym for `myisam_sort_buffer_size`.

`key_buffer_size` is used when you are checking the table with `--extend-check` or when the keys are repaired by inserting keys row by row into the table (like when doing normal inserts). Repairing through the key buffer is used in the following cases:

- You use `--safe-recover`.
- The temporary files needed to sort the keys would be more than twice as big as when creating the key file directly. This is often the case when you have large key values for `CHAR`, `VARCHAR`, or `TEXT` columns, because the sort operation needs to store the complete key values as it proceeds. If you have lots of temporary space and you can force `myisamchk` to repair by sorting, you can use the `--sort-recover` option.

Repairing through the key buffer takes much less disk space than using sorting, but is also much slower.

If you want a faster repair, set the `key_buffer_size` and `myisam_sort_buffer_size` variables to about 25% of your available memory. You can set both variables to large values, because only one of them is used at a time.

`myisam_block_size` is the size used for index blocks.

`stats_method` influences how `NULL` values are treated for index statistics collection when the `--analyze` option is given. It acts like the `myisam_stats_method` system variable. For more information, see the description of `myisam_stats_method` in [Section 7.1.8, “Server System Variables”](#), and [Section 10.3.8, “InnoDB and MyISAM Index Statistics Collection”](#).

`ft_min_word_len` and `ft_max_word_len` indicate the minimum and maximum word length for `FULLTEXT` indexes on `MyISAM` tables. `ft_stopword_file` names the stopwords file. These need to be set under the following circumstances.

If you use `myisamchk` to perform an operation that modifies table indexes (such as repair or analyze), the `FULLTEXT` indexes are rebuilt using the default full-text parameter values for minimum and

maximum word length and the stopword file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in [MyISAM](#) index files. To avoid the problem if you have modified the minimum or maximum word length or the stopword file in the server, specify the same [ft_min_word_len](#), [ft_max_word_len](#), and [ft_stopword_file](#) values to [myisamchk](#) that you use for [mysqld](#). For example, if you have set the minimum word length to 3, you can repair a table with [myisamchk](#) like this:

```
myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that [myisamchk](#) and the server use the same values for full-text parameters, you can place each one in both the [\[mysqld\]](#) and [\[myisamchk\]](#) sections of an option file:

```
[mysqld]
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using [myisamchk](#) is to use the [REPAIR TABLE](#), [ANALYZE TABLE](#), [OPTIMIZE TABLE](#), or [ALTER TABLE](#). These statements are performed by the server, which knows the proper full-text parameter values to use.

6.6.4.2 myisamchk Check Options

[myisamchk](#) supports the following options for table checking operations:

- [--check](#), [-c](#)

Command-Line Format	--check
---------------------	-------------------------

Check the table for errors. This is the default operation if you specify no option that selects an operation type explicitly.

- [--check-only-changed](#), [-C](#)

Command-Line Format	--check-only-changed
---------------------	--------------------------------------

Check only tables that have changed since the last check.

- [--extend-check](#), [-e](#)

Command-Line Format	--extend-check
---------------------	--------------------------------

Check the table very thoroughly. This is quite slow if the table has many indexes. This option should only be used in extreme cases. Normally, [myisamchk](#) or [myisamchk --medium-check](#) should be able to determine whether there are any errors in the table.

If you are using [--extend-check](#) and have plenty of memory, setting the [key_buffer_size](#) variable to a large value helps the repair operation run faster.

See also the description of this option under table repair options.

For a description of the output format, see [Section 6.6.4.5, “Obtaining Table Information with \[myisamchk\]\(#\)”](#).

- [--fast](#), [-F](#)

Command-Line Format	--fast
---------------------	------------------------

Check only tables that haven't been closed properly.

- `--force, -f`

Command-Line Format	<code>--force</code>
---------------------	----------------------

Do a repair operation automatically if `myisamchk` finds any errors in the table. The repair type is the same as that specified with the `--recover` or `-r` option.

- `--information, -i`

Command-Line Format	<code>--information</code>
---------------------	----------------------------

Print informational statistics about the table that is checked.

- `--medium-check, -m`

Command-Line Format	<code>--medium-check</code>
---------------------	-----------------------------

Do a check that is faster than an `--extend-check` operation. This finds only 99.99% of all errors, which should be good enough in most cases.

- `--read-only, -T`

Command-Line Format	<code>--read-only</code>
---------------------	--------------------------

Do not mark the table as checked. This is useful if you use `myisamchk` to check a table that is in use by some other application that does not use locking, such as `mysqld` when run with external locking disabled.

- `--update-state, -U`

Command-Line Format	<code>--update-state</code>
---------------------	-----------------------------

Store information in the `.MYI` file to indicate when the table was checked and whether the table crashed. This should be used to get full benefit of the `--check-only-changed` option, but you shouldn't use this option if the `mysqld` server is using the table and you are running it with external locking disabled.

6.6.4.3 myisamchk Repair Options

`myisamchk` supports the following options for table repair operations (operations performed when an option such as `--recover` or `--safe-recover` is given):

- `--backup, -B`

Command-Line Format	<code>--backup</code>
---------------------	-----------------------

Make a backup of the `.MYD` file as `file_name-time.BAK`

- `--character-sets-dir=dir_name`

Command-Line Format	<code>--character-sets-dir=path</code>
---------------------	--

Type	String
Default Value	[none]

The directory where character sets are installed. See [Section 12.15, “Character Set Configuration”](#).

- `--correct-checksum`

Command-Line Format	<code>--correct-checksum</code>
---------------------	---------------------------------

Correct the checksum information for the table.

- `--data-file-length=len, -D len`

Command-Line Format	<code>--data-file-length=len</code>
Type	Numeric

The maximum length of the data file (when re-creating data file when it is “full”).

- `--extend-check, -e`

Command-Line Format	<code>--extend-check</code>
---------------------	-----------------------------

Do a repair that tries to recover every possible row from the data file. Normally, this also finds a lot of garbage rows. Do not use this option unless you are desperate.

See also the description of this option under table checking options.

For a description of the output format, see [Section 6.6.4.5, “Obtaining Table Information with myisamchk”](#).

- `--force, -f`

Command-Line Format	<code>--force</code>
---------------------	----------------------

Overwrite old intermediate files (files with names like `tbl_name.TMD`) instead of aborting.

- `--keys-used=val, -k val`

Command-Line Format	<code>--keys-used=val</code>
Type	Numeric

For `myisamchk`, the option value is a bit value that indicates which indexes to update. Each binary bit of the option value corresponds to a table index, where the first index is bit 0. An option value of 0 disables updates to all indexes, which can be used to get faster inserts. Deactivated indexes can be reactivated by using `myisamchk -r`.

- `--max-record-length=len`

Command-Line Format	<code>--max-record-length=len</code>
Type	Numeric

Skip rows larger than the given length if `myisamchk` cannot allocate memory to hold them.

- `--parallel-recover, -p`

Command-Line Format	<code>--parallel-recover</code>
---------------------	---------------------------------

Note

This option is deprecated in MySQL 8.0.28 and removed in MySQL 8.0.30.

Use the same technique as `-r` and `-n`, but create all the keys in parallel, using different threads. *This is beta-quality code. Use at your own risk!*

- `--quick, -q`

Command-Line Format	<code>--quick</code>
---------------------	----------------------

Achieve a faster repair by modifying only the index file, not the data file. You can specify this option twice to force `myisamchk` to modify the original data file in case of duplicate keys.

- `--recover, -r`

Command-Line Format	<code>--recover</code>
---------------------	------------------------

Do a repair that can fix almost any problem except unique keys that are not unique (which is an extremely unlikely error with MyISAM tables). If you want to recover a table, this is the option to try first. You should try `--safe-recover` only if `myisamchk` reports that the table cannot be recovered using `--recover`. (In the unlikely case that `--recover` fails, the data file remains intact.)

If you have lots of memory, you should increase the value of `myisam_sort_buffer_size`.

- `--safe-recover, -o`

Command-Line Format	<code>--safe-recover</code>
---------------------	-----------------------------

Do a repair using an old recovery method that reads through all rows in order and updates all index trees based on the rows found. This is an order of magnitude slower than `--recover`, but can handle a couple of very unlikely cases that `--recover` cannot. This recovery method also uses much less disk space than `--recover`. Normally, you should repair first using `--recover`, and then with `--safe-recover` only if `--recover` fails.

If you have lots of memory, you should increase the value of `key_buffer_size`.

- `--set-collation=name`

Command-Line Format	<code>--set-collation=name</code>
Type	String

Specify the collation to use for sorting table indexes. The character set name is implied by the first part of the collation name.

- `--sort-recover, -n`

Command-Line Format	<code>--sort-recover</code>
---------------------	-----------------------------

Force `myisamchk` to use sorting to resolve the keys even if the temporary files would be very large.

- `--tmpdir=dir_name, -t dir_name`

Command-Line Format	<code>--tmpdir=dir_name</code>
Type	Directory name

The path of the directory to be used for storing temporary files. If this is not set, `myisamchk` uses the value of the `TMPDIR` environment variable. `--tmpdir` can be set to a list of directory paths that are used successively in round-robin fashion for creating temporary files. The separator character between directory names is the colon (:) on Unix and the semicolon (;) on Windows.

- `--unpack, -u`

Command-Line Format	<code>--unpack</code>
---------------------	-----------------------

Unpack a table that was packed with `myisampack`.

6.6.4.4 Other myisamchk Options

`myisamchk` supports the following options for actions other than table checks and repairs:

- `--analyze, -a`

Command-Line Format	<code>--analyze</code>
---------------------	------------------------

Analyze the distribution of key values. This improves join performance by enabling the join optimizer to better choose the order in which to join the tables and which indexes it should use. To obtain information about the key distribution, use a `myisamchk --description --verbose tbl_name` command or the `SHOW INDEX FROM tbl_name` statement.

- `--block-search=offset, -b offset`

Command-Line Format	<code>--block-search=offset</code>
Type	Numeric

Find the record that a block at the given offset belongs to.

- `--description, -d`

Command-Line Format	<code>--description</code>
---------------------	----------------------------

Print some descriptive information about the table. Specifying the `--verbose` option once or twice produces additional information. See [Section 6.6.4.5, “Obtaining Table Information with myisamchk”](#).

- `--set-auto-increment[=value], -A[value]`

Force `AUTO_INCREMENT` numbering for new records to start at the given value (or higher, if there are existing records with `AUTO_INCREMENT` values this large). If `value` is not specified, `AUTO_INCREMENT` numbers for new records begin with the largest value currently in the table, plus one.

- `--sort-index, -S`

Sort the index tree blocks in high-low order. This optimizes seeks and makes table scans that use indexes faster.

- `--sort-records=N, -R N`

Command-Line Format	<code>--sort-records=#</code>
Type	Numeric

Sort records according to a particular index. This makes your data much more localized and may speed up range-based `SELECT` and `ORDER BY` operations that use this index. (The first time you use this option to sort a table, it may be very slow.) To determine a table's index numbers, use `SHOW INDEX`, which displays a table's indexes in the same order that `myisamchk` sees them. Indexes are numbered beginning with 1.

If keys are not packed (`PACK_KEYS=0`), they have the same length, so when `myisamchk` sorts and moves records, it just overwrites record offsets in the index. If keys are packed (`PACK_KEYS=1`), `myisamchk` must unpack key blocks first, then re-create indexes and pack the key blocks again. (In this case, re-creating indexes is faster than updating offsets for each index.)

6.6.4.5 Obtaining Table Information with `myisamchk`

To obtain a description of a `MyISAM` table or statistics about it, use the commands shown here. The output from these commands is explained later in this section.

- `myisamchk -d tbl_name`

Runs `myisamchk` in “describe mode” to produce a description of your table. If you start the MySQL server with external locking disabled, `myisamchk` may report an error for a table that is updated while it runs. However, because `myisamchk` does not change the table in describe mode, there is no risk of destroying data.

- `myisamchk -dv tbl_name`

Adding `-v` runs `myisamchk` in verbose mode so that it produces more information about the table. Adding `-v` a second time produces even more information.

- `myisamchk -eis tbl_name`

Shows only the most important information from a table. This operation is slow because it must read the entire table.

- `myisamchk -eiv tbl_name`

This is like `-eis`, but tells you what is being done.

The `tbl_name` argument can be either the name of a `MyISAM` table or the name of its index file, as described in [Section 6.6.4, “myisamchk — MyISAM Table-Maintenance Utility”](#). Multiple `tbl_name` arguments can be given.

Suppose that a table named `person` has the following structure. (The `MAX_ROWS` table option is included so that in the example output from `myisamchk` shown later, some values are smaller and fit the output format more easily.)

```
CREATE TABLE person
(
  id          INT NOT NULL AUTO_INCREMENT,
  last_name   VARCHAR(20) NOT NULL,
  first_name  VARCHAR(20) NOT NULL,
  birth       DATE,
  death       DATE,
  PRIMARY KEY (id),
```

```
INDEX (last_name, first_name),
INDEX (birth)
) MAX_ROWS = 1000000 ENGINE=MYISAM;
```

Suppose also that the table has these data and index file sizes:

```
-rw-rw---- 1 mysql mysql 9347072 Aug 19 11:47 person.MYD
-rw-rw---- 1 mysql mysql 6066176 Aug 19 11:47 person.MYI
```

Example of `myisamchk -dvv` output:

```
MyISAM file:      person
Record format:    Packed
Character set:    utf8mb4_0900_ai_ci (255)
File-version:     1
Creation time:    2017-03-30 21:21:30
Status:           checked,analyzed,optimized keys,sorted index pages
Auto increment key: 1 Last value: 306688
Data records:      306688 Deleted blocks: 0
Datafile parts:     306688 Deleted data: 0
Datafile pointer (bytes): 4 Keyfile pointer (bytes): 3
Datafile length:    9347072 Keyfile length: 6066176
Max datafile length: 4294967294 Max keyfile length: 17179868159
Recordlength:      54

table description:
Key Start Len Index Type Rec/key Root Blocksize
1 2 4 unique long 1 1024
2 6 80 multip. varchar prefix 0 1024
87 80 varchar 0
3 168 3 multip. uint24 NULL 0 1024

Field Start Length Nullpos Nullbit Type
1 1 1
2 2 4 no zeros
3 6 81 varchar
4 87 81 varchar
5 168 3 1 1 no zeros
6 171 3 1 2 no zeros
```

Explanations for the types of information `myisamchk` produces are given here. “Keyfile” refers to the index file. “Record” and “row” are synonymous, as are “field” and “column.”

The initial part of the table description contains these values:

- `MyISAM file`

Name of the `MyISAM` (index) file.

- `Record format`

The format used to store table rows. The preceding examples use `Fixed length`. Other possible values are `Compressed` and `Packed`. (`Packed` corresponds to what `SHOW TABLE STATUS` reports as `Dynamic`.)

- `Character set`

The table default character set.

- `File-version`

Version of `MyISAM` format. Always 1.

- `Creation time`

When the data file was created.

- `Recover time`

When the index/data file was last reconstructed.

- `Status`

Table status flags. Possible values are `crashed`, `open`, `changed`, `analyzed`, `optimized keys`, and `sorted index pages`.

- `Auto increment key, Last value`

The key number associated the table's `AUTO_INCREMENT` column, and the most recently generated value for this column. These fields do not appear if there is no such column.

- `Data records`

The number of rows in the table.

- `Deleted blocks`

How many deleted blocks still have reserved space. You can optimize your table to minimize this space. See [Section 9.6.4, “MyISAM Table Optimization”](#).

- `Datafile parts`

For dynamic-row format, this indicates how many data blocks there are. For an optimized table without fragmented rows, this is the same as `Data records`.

- `Deleted data`

How many bytes of unreclaimed deleted data there are. You can optimize your table to minimize this space. See [Section 9.6.4, “MyISAM Table Optimization”](#).

- `Datafile pointer`

The size of the data file pointer, in bytes. It is usually 2, 3, 4, or 5 bytes. Most tables manage with 2 bytes, but this cannot be controlled from MySQL yet. For fixed tables, this is a row address. For dynamic tables, this is a byte address.

- `Keyfile pointer`

The size of the index file pointer, in bytes. It is usually 1, 2, or 3 bytes. Most tables manage with 2 bytes, but this is calculated automatically by MySQL. It is always a block address.

- `Max datafile length`

How long the table data file can become, in bytes.

- `Max keyfile length`

How long the table index file can become, in bytes.

- `Recordlength`

How much space each row takes, in bytes.

The `table description` part of the output includes a list of all keys in the table. For each key, `myisamchk` displays some low-level information:

- `Key`

This key's number. This value is shown only for the first column of the key. If this value is missing, the line corresponds to the second or later column of a multiple-column key. For the table shown in the example, there are two `table description` lines for the second index. This indicates that it is a multiple-part index with two parts.

- `Start`

Where in the row this portion of the index starts.

- `Len`

How long this portion of the index is. For packed numbers, this should always be the full length of the column. For strings, it may be shorter than the full length of the indexed column, because you can index a prefix of a string column. The total length of a multiple-part key is the sum of the `Len` values for all key parts.

- `Index`

Whether a key value can exist multiple times in the index. Possible values are `unique` or `multipl.` (multiple).

- `Type`

What data type this portion of the index has. This is a `MyISAM` data type with the possible values `packed`, `stripped`, or `empty`.

- `Root`

Address of the root index block.

- `Blocksize`

The size of each index block. By default this is 1024, but the value may be changed at compile time when MySQL is built from source.

- `Rec/key`

This is a statistical value used by the optimizer. It tells how many rows there are per value for this index. A unique index always has a value of 1. This may be updated after a table is loaded (or greatly changed) with `myisamchk -a`. If this is not updated at all, a default value of 30 is given.

The last part of the output provides information about each column:

- `Field`

The column number.

- `Start`

The byte position of the column within table rows.

- `Length`

The length of the column in bytes.

- `Nullpos, Nullbit`

For columns that can be `NULL`, `MyISAM` stores `NULL` values as a flag in a byte. Depending on how many nullable columns there are, there can be one or more bytes used for this purpose. The `Nullpos` and `Nullbit` values, if nonempty, indicate which byte and bit contains that flag indicating whether the column is `NULL`.

The position and number of bytes used to store `NULL` flags is shown in the line for field 1. This is why there are six `Field` lines for the `person` table even though it has only five columns.

- `Type`

The data type. The value may contain any of the following descriptors:

- `constant`
All rows have the same value.
- `no endspace`
Do not store endspace.
- `no endspace, not_always`
Do not store endspace and do not do endspace compression for all values.
- `no endspace, no empty`
Do not store endspace. Do not store empty values.
- `table-lookup`
The column was converted to an `ENUM`.
- `zerofill(N)`
The most significant `N` bytes in the value are always 0 and are not stored.
- `no zeros`
Do not store zeros.
- `always zero`
Zero values are stored using one bit.
- `Huff tree`
The number of the Huffman tree associated with the column.
- `Bits`
The number of bits used in the Huffman tree.

The `Huff tree` and `Bits` fields are displayed if the table has been compressed with `myisampack`. See [Section 6.6.6, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#), for an example of this information.

Example of `myisamchk -eiv` output:

```
Checking MyISAM file: person
Data records: 306688 Deleted blocks: 0
- check file-size
- check record delete-chain
No recordlinks
- check key delete-chain
block_size 1024:
- check index reference
- check data record references index: 1
Key: 1: Keyblocks used: 98% Packed: 0% Max levels: 3
- check data record references index: 2
Key: 2: Keyblocks used: 99% Packed: 97% Max levels: 3
- check data record references index: 3
Key: 3: Keyblocks used: 98% Packed: -14% Max levels: 3
Total: Keyblocks used: 98% Packed: 89%

- check records and index references
*** LOTS OF ROW NUMBERS DELETED ***
```

```

Records:          306688  M.recordlength:      25  Packed:          83%
Recordspace used:    97%  Empty space:         2%  Blocks/Record:   1.00
Record blocks:      306688  Delete blocks:      0
Record data:        7934464  Deleted data:       0
Lost space:         256512  Linkdata:          1156096

```

```

User time 43.08, System time 1.68
Maximum resident set size 0, Integral resident set size 0
Non-physical pagefaults 0, Physical pagefaults 0, Swaps 0
Blocks in 0 out 7, Messages in 0 out 0, Signals 0
Voluntary context switches 0, Involuntary context switches 0
Maximum memory usage: 1046926 bytes (1023k)

```

`myisamchk -eiv` output includes the following information:

- `Data records`

The number of rows in the table.

- `Deleted blocks`

How many deleted blocks still have reserved space. You can optimize your table to minimize this space. See [Section 9.6.4, “MyISAM Table Optimization”](#).

- `Key`

The key number.

- `Keyblocks used`

What percentage of the keyblocks are used. When a table has just been reorganized with `myisamchk`, the values are very high (very near theoretical maximum).

- `Packed`

MySQL tries to pack key values that have a common suffix. This can only be used for indexes on `CHAR` and `VARCHAR` columns. For long indexed strings that have similar leftmost parts, this can significantly reduce the space used. In the preceding example, the second key is 40 bytes long and a 97% reduction in space is achieved.

- `Max levels`

How deep the B-tree for this key is. Large tables with long key values get high values.

- `Records`

How many rows are in the table.

- `M.recordlength`

The average row length. This is the exact row length for tables with fixed-length rows, because all rows have the same length.

- `Packed`

MySQL strips spaces from the end of strings. The `Packed` value indicates the percentage of savings achieved by doing this.

- `Recordspace used`

What percentage of the data file is used.

- `Empty space`

What percentage of the data file is unused.

- [Blocks/Record](#)

Average number of blocks per row (that is, how many links a fragmented row is composed of). This is always 1.0 for fixed-format tables. This value should stay as close to 1.0 as possible. If it gets too large, you can reorganize the table. See [Section 9.6.4, “MyISAM Table Optimization”](#).

- [Recordblocks](#)

How many blocks (links) are used. For fixed-format tables, this is the same as the number of rows.

- [Deleteblocks](#)

How many blocks (links) are deleted.

- [Recorddata](#)

How many bytes in the data file are used.

- [Deleted data](#)

How many bytes in the data file are deleted (unused).

- [Lost space](#)

If a row is updated to a shorter length, some space is lost. This is the sum of all such losses, in bytes.

- [Linkdata](#)

When the dynamic table format is used, row fragments are linked with pointers (4 to 7 bytes each). [Linkdata](#) is the sum of the amount of storage used by all such pointers.

6.6.4.6 myisamchk Memory Usage

Memory allocation is important when you run [myisamchk](#). [myisamchk](#) uses no more memory than its memory-related variables are set to. If you are going to use [myisamchk](#) on very large tables, you should first decide how much memory you want it to use. The default is to use only about 3MB to perform repairs. By using larger values, you can get [myisamchk](#) to operate faster. For example, if you have more than 512MB RAM available, you could use options such as these (in addition to any other options you might specify):

```
myisamchk --myisam_sort_buffer_size=256M \  
--key_buffer_size=512M \  
--read_buffer_size=64M \  
--write_buffer_size=64M ...
```

Using [--myisam_sort_buffer_size=16M](#) is probably enough for most cases.

Be aware that [myisamchk](#) uses temporary files in [TMPDIR](#). If [TMPDIR](#) points to a memory file system, out of memory errors can easily occur. If this happens, run [myisamchk](#) with the [--tmpdir=dir_name](#) option to specify a directory located on a file system that has more space.

When performing repair operations, [myisamchk](#) also needs a lot of disk space:

- Twice the size of the data file (the original file and a copy). This space is not needed if you do a repair with [--quick](#); in this case, only the index file is re-created. *This space must be available on the same file system as the original data file*, as the copy is created in the same directory as the original.
- Space for the new index file that replaces the old one. The old index file is truncated at the start of the repair operation, so you usually ignore this space. This space must be available on the same file system as the original data file.

- When using `--recover` or `--sort-recover` (but not when using `--safe-recover`), you need space on disk for sorting. This space is allocated in the temporary directory (specified by `TMPDIR` or `--tmpdir=dir_name`). The following formula yields the amount of space required:

```
(largest_key + row_pointer_length) * number_of_rows * 2
```

You can check the length of the keys and the `row_pointer_length` with `myisamchk -dv tbl_name` (see [Section 6.6.4.5, “Obtaining Table Information with myisamchk”](#)). The `row_pointer_length` and `number_of_rows` values are the `Datafile pointer` and `Data records` values in the table description. To determine the `largest_key` value, check the `Key` lines in the table description. The `Len` column indicates the number of bytes for each key part. For a multiple-column index, the key size is the sum of the `Len` values for all key parts.

If you have a problem with disk space during repair, you can try `--safe-recover` instead of `--recover`.

6.6.5 myisamlog — Display MyISAM Log File Contents

`myisamlog` processes the contents of a `MyISAM` log file. To create such a file, start the server with a `--log-isam=log_file` option.

Invoke `myisamlog` like this:

```
myisamlog [options] [file_name [tbl_name] ...]
```

The default operation is update (`-u`). If a recovery is done (`-r`), all writes and possibly updates and deletes are done and errors are only counted. The default log file name is `myisam.log` if no `log_file` argument is given. If tables are named on the command line, only those tables are updated.

`myisamlog` supports the following options:

- `-?`, `-I`
Display a help message and exit.
- `-c N`
Execute only `N` commands.
- `-f N`
Specify the maximum number of open files.
- `-F filepath/`
Specify the file path with a trailing slash.
- `-i`
Display extra information before exiting.
- `-o offset`
Specify the starting offset.
- `-p N`
Remove `N` components from path.
- `-r`
Perform a recovery operation.
- `-R record_pos_file record_pos`

Specify record position file and record position.

- `-u`

Perform an update operation.

- `-v`

Verbose mode. Print more output about what the program does. This option can be given multiple times to produce more and more output.

- `-w write_file`

Specify the write file.

- `-V`

Display version information.

6.6.6 myisampack — Generate Compressed, Read-Only MyISAM Tables

The `myisampack` utility compresses `MyISAM` tables. `myisampack` works by compressing each column in the table separately. Usually, `myisampack` packs the data file 40% to 70%.

When the table is used later, the server reads into memory the information needed to decompress columns. This results in much better performance when accessing individual rows, because you only have to uncompress exactly one row.

MySQL uses `mmap()` when possible to perform memory mapping on compressed tables. If `mmap()` does not work, MySQL falls back to normal read/write file operations.

Please note the following:

- If the `mysqld` server was invoked with external locking disabled, it is not a good idea to invoke `myisampack` if the table might be updated by the server during the packing process. It is safest to compress tables with the server stopped.
- After packing a table, it becomes read only. This is generally intended (such as when accessing packed tables on a CD).
- `myisampack` does not support partitioned tables.

Invoke `myisampack` like this:

```
myisampack [options] file_name ...
```

Each file name argument should be the name of an index (`.MYI`) file. If you are not in the database directory, you should specify the path name to the file. It is permissible to omit the `.MYI` extension.

After you compress a table with `myisampack`, use `myisamchk -rq` to rebuild its indexes.

[Section 6.6.4, “myisamchk — MyISAM Table-Maintenance Utility”](#).

`myisampack` supports the following options. It also reads option files and supports the options for processing them described at [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--help, -?`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display a help message and exit.

- `--backup, -b`

Command-Line Format	<code>--backup</code>
---------------------	-----------------------

Make a backup of each table's data file using the name `tbl_name.OLD`.

- `--character-sets-dir=dir_name`

Command-Line Format	<code>--character-sets-dir=dir_name</code>
Type	Directory name

The directory where character sets are installed. See [Section 12.15, “Character Set Configuration”](#).

- `--debug[=debug_options], -# [debug_options]`

Command-Line Format	<code>--debug[=debug_options]</code>
Type	String
Default Value	<code>d:t:o</code>

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o`.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--force, -f`

Command-Line Format	<code>--force</code>
---------------------	----------------------

Produce a packed table even if it becomes larger than the original or if the intermediate file from an earlier invocation of `myisampack` exists. (`myisampack` creates an intermediate file named `tbl_name.TMD` in the database directory while it compresses the table. If you kill `myisampack`, the `.TMD` file might not be deleted.) Normally, `myisampack` exits with an error if it finds that `tbl_name.TMD` exists. With `--force`, `myisampack` packs the table anyway.

- `--join=big_tbl_name, -j big_tbl_name`

Command-Line Format	<code>--join=big_tbl_name</code>
Type	String

Join all tables named on the command line into a single packed table `big_tbl_name`. All tables that are to be combined *must* have identical structure (same column names and types, same indexes, and so forth).

`big_tbl_name` must not exist prior to the join operation. All source tables named on the command line to be merged into `big_tbl_name` must exist. The source tables are read for the join operation but not modified.

- `--silent, -s`

Command-Line Format	<code>--silent</code>
---------------------	-----------------------

Silent mode. Write output only when errors occur.

- `--test, -t`

Command-Line Format	<code>--test</code>
---------------------	---------------------

Do not actually pack the table, just test packing it.

- `--tmpdir=dir_name, -T dir_name`

Command-Line Format	<code>--tmpdir=dir_name</code>
Type	Directory name

Use the named directory as the location where `myisampack` creates temporary files.

- `--verbose, -v`

Command-Line Format	<code>--verbose</code>
---------------------	------------------------

Verbose mode. Write information about the progress of the packing operation and its result.

- `--version, -V`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

- `--wait, -w`

Command-Line Format	<code>--wait</code>
---------------------	---------------------

Wait and retry if the table is in use. If the `mysqld` server was invoked with external locking disabled, it is not a good idea to invoke `myisampack` if the table might be updated by the server during the packing process.

The following sequence of commands illustrates a typical table compression session:

```
$> ls -l station.*
-rw-rw-r-- 1 jones my 994128 Apr 17 19:00 station.MYD

`myisampack` displays the following kinds of information:

- `normal`

The number of columns for which no extra packing is used.

- `empty-space`

The number of columns containing values that are only spaces. These occupy one bit.

- `empty-zero`

The number of columns containing values that are only binary zeros. These occupy one bit.

- `empty-fill`

The number of integer columns that do not occupy the full byte range of their type. These are changed to a smaller type. For example, a `BIGINT` column (eight bytes) can be stored as a `TINYINT` column (one byte) if all its values are in the range from `-128` to `127`.

- `pre-space`

The number of decimal columns that are stored with leading spaces. In this case, each value contains a count for the number of leading spaces.

- `end-space`

The number of columns that have a lot of trailing spaces. In this case, each value contains a count for the number of trailing spaces.

- `table-lookup`

The column had only a small number of different values, which were converted to an `ENUM` before Huffman compression.

- `zero`

The number of columns for which all values are zero.

- `Original trees`

The initial number of Huffman trees.

- `After join`

The number of distinct Huffman trees left after joining trees to save some header space.

After a table has been compressed, the `Field` lines displayed by `myisamchk -dvv` include additional information about each column:

- `Type`

The data type. The value may contain any of the following descriptors:

- `constant`

All rows have the same value.

- `no endspace`

Do not store endspace.

- `no endspace, not_always`

Do not store endspace and do not do endspace compression for all values.

- `no endspace, no empty`

Do not store endspace. Do not store empty values.

- `table-lookup`

The column was converted to an `ENUM`.

- `zerofill(N)`

The most significant `N` bytes in the value are always 0 and are not stored.

- `no zeros`

Do not store zeros.

- `always zero`

Zero values are stored using one bit.

- `Huff tree`

The number of the Huffman tree associated with the column.

- `Bits`

The number of bits used in the Huffman tree.

After you run `myisampack`, use `myisamchk` to re-create any indexes. At this time, you can also sort the index blocks and create statistics needed for the MySQL optimizer to work more efficiently:

```
myisamchk -rq --sort-index --analyze tbl_name.MYI
```

After you have installed the packed table into the MySQL database directory, you should execute `mysqladmin flush-tables` to force `mysqld` to start using the new table.

To unpack a packed table, use the `--unpack` option to `myisamchk`.

6.6.7 mysql_config_editor — MySQL Configuration Utility

The `mysql_config_editor` utility enables you to store authentication credentials in an obfuscated login path file named `.mylogin.cnf`. The file location is the `%APPDATA%\MySQL` directory on Windows and the current user's home directory on non-Windows systems. The file can be read later by MySQL client programs to obtain authentication credentials for connecting to MySQL Server.

The unobfuscated format of the `.mylogin.cnf` login path file consists of option groups, similar to other option files. Each option group in `.mylogin.cnf` is called a "login path," which is a group that permits only certain options: `host`, `user`, `password`, `port` and `socket`. Think of a login path

option group as a set of options that specify which MySQL server to connect to and which account to authenticate as. Here is an unobfuscated example:

```
[client]
user = mydefaultname
password = mydefaultpass
host = 127.0.0.1
[mypath]
user = myothername
password = myotherpass
host = localhost
```

When you invoke a client program to connect to the server, the client uses `.mylogin.cnf` in conjunction with other option files. Its precedence is higher than other option files, but less than options specified explicitly on the client command line. For information about the order in which option files are used, see [Section 6.2.2.2, “Using Option Files”](#).

To specify an alternate login path file name, set the `MYSQL_TEST_LOGIN_FILE` environment variable. This variable is recognized by `mysql_config_editor`, by standard MySQL clients (`mysql`, `mysqladmin`, and so forth), and by the `mysql-test-run.pl` testing utility.

Programs use groups in the login path file as follows:

- `mysql_config_editor` operates on the `client` login path by default if you specify no `--login-path=name` option to indicate explicitly which login path to use.
- Without a `--login-path` option, client programs read the same option groups from the login path file that they read from other option files. Consider this command:

```
mysql
```

By default, the `mysql` client reads the `[client]` and `[mysql]` groups from other option files, so it reads them from the login path file as well.

- With a `--login-path` option, client programs additionally read the named login path from the login path file. The option groups read from other option files remain the same. Consider this command:

```
mysql --login-path=myspath
```

The `mysql` client reads `[client]` and `[mysql]` from other option files, and `[client]`, `[mysql]`, and `[myspath]` from the login path file.

- Client programs read the login path file even when the `--no-defaults` option is used, unless `--no-login-paths` is set. This permits passwords to be specified in a safer way than on the command line even if `--no-defaults` is present.

`mysql_config_editor` obfuscates the `.mylogin.cnf` file so it cannot be read as cleartext, and its contents when unobfuscated by client programs are used only in memory. In this way, passwords can be stored in a file in non-cleartext format and used later without ever needing to be exposed on the command line or in an environment variable. `mysql_config_editor` provides a `print` command for displaying the login path file contents, but even in this case, password values are masked so as never to appear in a way that other users can see them.

The obfuscation used by `mysql_config_editor` prevents passwords from appearing in `.mylogin.cnf` as cleartext and provides a measure of security by preventing inadvertent password exposure. For example, if you display a regular unobfuscated `my.cnf` option file on the screen, any passwords it contains are visible for anyone to see. With `.mylogin.cnf`, that is not true, but the obfuscation used is not likely to deter a determined attacker and you should not consider it unbreakable. A user who can gain system administration privileges on your machine to access your files could unobfuscate the `.mylogin.cnf` file with some effort.

The login path file must be readable and writable to the current user, and inaccessible to other users. Otherwise, `mysql_config_editor` ignores it, and client programs do not use it, either.

Invoke `mysql_config_editor` like this:

```
mysql_config_editor [program_options] command [command_options]
```

If the login path file does not exist, `mysql_config_editor` creates it.

Command arguments are given as follows:

- *program_options* consists of general `mysql_config_editor` options.
- *command* indicates what action to perform on the `.mylogin.cnf` login path file. For example, `set` writes a login path to the file, `remove` removes a login path, and `print` displays login path contents.
- *command_options* indicates any additional options specific to the command, such as the login path name and the values to use in the login path.

The position of the command name within the set of program arguments is significant. For example, these command lines have the same arguments, but produce different results:

```
mysql_config_editor --help set
mysql_config_editor set --help
```

The first command line displays a general `mysql_config_editor` help message, and ignores the `set` command. The second command line displays a help message specific to the `set` command.

Suppose that you want to establish a `client` login path that defines your default connection parameters, and an additional login path named `remote` for connecting to the MySQL server the host `remote.example.com`. You want to log in as follows:

- By default, to the local server with a user name and password of `localuser` and `localpass`
- To the remote server with a user name and password of `remoteuser` and `remotepass`

To set up the login paths in the `.mylogin.cnf` file, use the following `set` commands. Enter each command on a single line, and enter the appropriate passwords when prompted:

```
$> mysql_config_editor set --login-path=client
      --host=localhost --user=localuser --password
Enter password: enter password "localpass" here
$> mysql_config_editor set --login-path=remote
      --host=remote.example.com --user=remoteuser --password
Enter password: enter password "remotepass" here
```

`mysql_config_editor` uses the `client` login path by default, so the `--login-path=client` option can be omitted from the first command without changing its effect.

To see what `mysql_config_editor` writes to the `.mylogin.cnf` file, use the `print` command:

```
$> mysql_config_editor print --all
[client]
user = localuser
password = *****
host = localhost
[remote]
user = remoteuser
password = *****
host = remote.example.com
```

The `print` command displays each login path as a set of lines beginning with a group header indicating the login path name in square brackets, followed by the option values for the login path. Password values are masked and do not appear as cleartext.

If you do not specify `--all` to display all login paths or `--login-path=name` to display a named login path, the `print` command displays the `client` login path by default, if there is one.

As shown by the preceding example, the login path file can contain multiple login paths. In this way, `mysql_config_editor` makes it easy to set up multiple “personalities” for connecting to different MySQL servers, or for connecting to a given server using different accounts. Any of these can be

selected by name later using the `--login-path` option when you invoke a client program. For example, to connect to the remote server, use this command:

```
mysql --login-path=remote
```

Here, `mysql` reads the `[client]` and `[mysql]` option groups from other option files, and the `[client]`, `[mysql]`, and `[remote]` groups from the login path file.

To connect to the local server, use this command:

```
mysql --login-path=client
```

Because `mysql` reads the `client` and `mysql` login paths by default, the `--login-path` option does not add anything in this case. That command is equivalent to this one:

```
mysql
```

Options read from the login path file take precedence over options read from other option files. Options read from login path groups appearing later in the login path file take precedence over options read from groups appearing earlier in the file.

`mysql_config_editor` adds login paths to the login path file in the order you create them, so you should create more general login paths first and more specific paths later. If you need to move a login path within the file, you can remove it, then recreate it to add it to the end. For example, a `client` login path is more general because it is read by all client programs, whereas a `mysqldump` login path is read only by `mysqldump`. Options specified later override options specified earlier, so putting the login paths in the order `client`, `mysqldump` enables `mysqldump`-specific options to override `client` options.

When you use the `set` command with `mysql_config_editor` to create a login path, you need not specify all possible option values (host name, user name, password, port, socket). Only those values given are written to the path. Any missing values required later can be specified when you invoke a client path to connect to the MySQL server, either in other option files or on the command line. Any options specified on the command line override those specified in the login path file or other option files. For example, if the credentials in the `remote` login path also apply for the host `remote2.example.com`, connect to the server on that host like this:

```
mysql --login-path=remote --host=remote2.example.com
```

mysql_config_editor General Options

`mysql_config_editor` supports the following general options, which may be used preceding any command named on the command line. For descriptions of command-specific options, see [mysql_config_editor Commands and Command-Specific Options](#).

Table 6.20 mysql_config_editor General Options

Option Name	Description
<code>--debug</code>	Write debugging log
<code>--help</code>	Display help message and exit
<code>--verbose</code>	Verbose mode
<code>--version</code>	Display version information and exit

- `--help`, `-?`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display a general help message and exit.

To see a command-specific help message, invoke `mysql_config_editor` as follows, where `command` is a command other than `help`:

```
mysql_config_editor command --help
```

- `--debug[=debug_options], -# debug_options`

Command-Line Format	<code>--debug[=<i>debug_options</i>]</code>
Type	String
Default Value	<code>d:t:o</code>

Write a debugging log. A typical *debug_options* string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysql_config_editor.trace`.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--verbose, -v`

Command-Line Format	<code>--verbose</code>
---------------------	------------------------

Verbose mode. Print more information about what the program does. This option may be helpful in diagnosing problems if an operation does not have the effect you expect.

- `--version, -V`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

mysql_config_editor Commands and Command-Specific Options

This section describes the permitted `mysql_config_editor` commands, and, for each one, the command-specific options permitted following the command name on the command line.

In addition, `mysql_config_editor` supports general options that can be used preceding any command. For descriptions of these options, see [mysql_config_editor General Options](#).

`mysql_config_editor` supports these commands:

- `help`

Display a general help message and exit. This command takes no following options.

To see a command-specific help message, invoke `mysql_config_editor` as follows, where *command* is a command other than `help`:

```
mysql_config_editor command --help
```

- `print [options]`

Print the contents of the login path file in unobfuscated form, with the exception that passwords are displayed as `*****`.

The default login path name is `client` if no login path is named. If both `--all` and `--login-path` are given, `--all` takes precedence.

The `print` command permits these options following the command name:

- `--help, -?`

Display a help message for the `print` command and exit.

To see a general help message, use `mysql_config_editor --help`.

- `--all`

Print the contents of all login paths in the login path file.

- `--login-path=name, -G name`

Print the contents of the named login path.

- `remove [options]`

Remove a login path from the login path file, or modify a login path by removing options from it.

This command removes from the login path only such options as are specified with the `--host`, `--password`, `--port`, `--socket`, and `--user` options. If none of those options are given, `remove`

removes the entire login path. For example, this command removes only the `user` option from the `mypath` login path rather than the entire `mypath` login path:

```
mysql_config_editor remove --login-path=mypath --user
```

This command removes the entire `mypath` login path:

```
mysql_config_editor remove --login-path=mypath
```

The `remove` command permits these options following the command name:

- `--help, -?`

Display a help message for the `remove` command and exit.

To see a general help message, use `mysql_config_editor --help`.

- `--host, -h`

Remove the host name from the login path.

- `--login-path=name, -G name`

The login path to remove or modify. The default login path name is `client` if this option is not given.

- `--password, -p`

Remove the password from the login path.

- `--port, -P`

Remove the TCP/IP port number from the login path.

- `--socket, -S`

Remove the Unix socket file name from the login path.

- `--user, -u`

Remove the user name from the login path.

- `--warn, -w`

Warn and prompt the user for confirmation if the command attempts to remove the default login path (`client`) and `--login-path=client` was not specified. This option is enabled by default; use `--skip-warn` to disable it.

- `reset [options]`

Empty the contents of the login path file.

The `reset` command permits these options following the command name:

- `--help, -?`

Display a help message for the `reset` command and exit.

To see a general help message, use `mysql_config_editor --help`.

- `set [options]`

Write a login path to the login path file.

This command writes to the login path only such options as are specified with the `--host`, `--password`, `--port`, `--socket`, and `--user` options. If none of those options are given, `mysql_config_editor` writes the login path as an empty group.

The `set` command permits these options following the command name:

- `--help, -?`

Display a help message for the `set` command and exit.

To see a general help message, use `mysql_config_editor --help`.

- `--host=host_name, -h host_name`

The host name to write to the login path.

- `--login-path=name, -G name`

The login path to create. The default login path name is `client` if this option is not given.

- `--password, -p`

Prompt for a password to write to the login path. After `mysql_config_editor` displays the prompt, type the password and press Enter. To prevent other users from seeing the password, `mysql_config_editor` does not echo it.

To specify an empty password, press Enter at the password prompt. The resulting login path written to the login path file includes a line like this:

```
password =
```

- `--port=port_num, -P port_num`

The TCP/IP port number to write to the login path.

- `--socket=file_name, -S file_name`

The Unix socket file name to write to the login path.

- `--user=user_name, -u user_name`

The user name to write to the login path.

- `--warn, -w`

Warn and prompt the user for confirmation if the command attempts to overwrite an existing login path. This option is enabled by default; use `--skip-warn` to disable it.

6.6.8 mysql_migrate_keyring — Keyring Key Migration Utility

The `mysql_migrate_keyring` utility migrates keys between one keyring component and another. It supports offline and online migrations.

Invoke `mysql_migrate_keyring` like this (enter the command on a single line):

```
mysql_migrate_keyring
--component-dir=dir_name
--source-keyring=name
--destination-keyring=name
```

[other options]

For information about key migrations and instructions describing how to perform them using `mysql_migrate_keyring` and other methods, see [Section 8.4.4.14, “Migrating Keys Between Keyring Keystores”](#).

`mysql_migrate_keyring` supports the following options, which can be specified on the command line or in the `[mysql_migrate_keyring]` group of an option file. For information about option files used by MySQL programs, see [Section 6.2.2.2, “Using Option Files”](#).

Table 6.21 mysql_migrate_keyring Options

Option Name	Description
<code>--component-dir</code>	Directory for keyring components
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files
<code>--defaults-file</code>	Read only named option file
<code>--defaults-group-suffix</code>	Option group suffix value
<code>--destination-keyring</code>	Destination keyring component name
<code>--destination-keyring-configuration-dir</code>	Destination keyring component configuration directory
<code>--get-server-public-key</code>	Request RSA public key from server
<code>--help</code>	Display help message and exit
<code>--host</code>	Host on which MySQL server is located
<code>--login-path</code>	Read login path options from <code>.mylogin.cnf</code>
<code>--no-defaults</code>	Read no option files
<code>--no-login-paths</code>	Do not read login paths from the login path file
<code>--online-migration</code>	Migration source is an active server
<code>--password</code>	Password to use when connecting to server
<code>--port</code>	TCP/IP port number for connection
<code>--print-defaults</code>	Print default options
<code>--server-public-key-path</code>	Path name to file containing RSA public key
<code>--socket</code>	Unix socket file or Windows named pipe to use
<code>--source-keyring</code>	Source keyring component name
<code>--source-keyring-configuration-dir</code>	Source keyring component configuration directory
<code>--ssl-ca</code>	File that contains list of trusted SSL Certificate Authorities
<code>--ssl-capath</code>	Directory that contains trusted SSL Certificate Authority certificate files
<code>--ssl-cert</code>	File that contains X.509 certificate
<code>--ssl-cipher</code>	Permissible ciphers for connection encryption
<code>--ssl-crl</code>	File that contains certificate revocation lists
<code>--ssl-crlpath</code>	Directory that contains certificate revocation-list files
<code>--ssl-fips-mode</code>	Whether to enable FIPS mode on client side
<code>--ssl-key</code>	File that contains X.509 key
<code>--ssl-mode</code>	Desired security state of connection to server

Option Name	Description
<code>--ssl-session-data</code>	File that contains SSL session data
<code>--ssl-session-data-continue-on-failed-reuse</code>	Whether to establish connections if session reuse fails
<code>--tls-ciphersuites</code>	Permissible TLSv1.3 ciphersuites for encrypted connections
<code>--tls-sni-servername</code>	Server name supplied by the client
<code>--tls-version</code>	Permissible TLS protocols for encrypted connections
<code>--user</code>	MySQL user name to use when connecting to server
<code>--verbose</code>	Verbose mode
<code>--version</code>	Display version information and exit

- `--help, -h`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display a help message and exit.

- `--component-dir=dir_name`

Command-Line Format	<code>--component-dir=dir_name</code>
Type	Directory name

The directory where keyring components are located. This is typically the value of the `plugin_dir` system variable for the local MySQL server.

Note

`--component-dir`, `--source-keyring`, and `--destination-keyring` are mandatory for all keyring migration operations performed by `mysql_migrate_keyring`. In addition, the source and destination components must differ, and both components must be properly configured so that `mysql_migrate_keyring` can load and use them.

- `--defaults-extra-file=file_name`

Command-Line Format	<code>--defaults-extra-file=file_name</code>
Type	File name

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-file=file_name`

Command-Line Format	<code>--defaults-file=file_name</code>
Type	File name

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If *file_name* is not an absolute path name, it is interpreted relative to the current directory.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-group-suffix=str`

Command-Line Format	<code>--defaults-group-suffix=str</code>
Type	String

Read not only the usual option groups, but also groups with the usual names and a suffix of *str*. For example, `mysql_migrate_keyring` normally reads the `[mysql_migrate_keyring]` group. If this option is given as `--defaults-group-suffix=_other`, `mysql_migrate_keyring` also reads the `[mysql_migrate_keyring_other]` group.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--destination-keyring=name`

Command-Line Format	<code>--destination-keyring=name</code>
Type	String

The destination keyring component for key migration. The format and interpretation of the option value is the same as described for the `--source-keyring` option.

Note

`--component-dir`, `--source-keyring`, and `--destination-keyring` are mandatory for all keyring migration operations performed by `mysql_migrate_keyring`. In addition, the source and destination components must differ, and both components must be properly configured so that `mysql_migrate_keyring` can load and use them.

- `--destination-keyring-configuration-dir=dir_name`

Command-Line Format	<code>--destination-keyring-configuration-dir=dir_name</code>
Type	Directory name

This option applies only if the destination keyring component global configuration file contains `"read_local_config": true`, indicating that component configuration is contained in the local configuration file. The option value specifies the directory containing that local file.

- `--get-server-public-key`

Command-Line Format	<code>--get-server-public-key</code>
---------------------	--------------------------------------

Type	Boolean
------	---------

Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For information about the `caching_sha2_password` plugin, see [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

- `--host=host_name, -h host_name`

Command-Line Format	<code>--host=host_name</code>
Type	String
Default Value	<code>localhost</code>

The host location of the running server that is currently using one of the key migration keystores. Migration always occurs on the local host, so the option always specifies a value for connecting to a local server, such as `localhost`, `127.0.0.1`, `:::1`, or the local host IP address or host name.

- `--login-path=name`

Command-Line Format	<code>--login-path=name</code>
Type	String

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

See `--login-path` for related information.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See [Section 6.6.7](#), “`mysql_config_editor` — MySQL Configuration Utility”.

For additional information about this and other option-file options, see [Section 6.2.2.3](#), “Command-Line Options that Affect Option-File Handling”.

- `--online-migration`

Command-Line Format	<code>--online-migration</code>
Type	Boolean
Default Value	<code>FALSE</code>

This option is mandatory when a running server is using the keyring. It tells `mysql_migrate_keyring` to perform an online key migration. The option has these effects:

- `mysql_migrate_keyring` connects to the server using any connection options specified; these options are otherwise ignored.
- After `mysql_migrate_keyring` connects to the server, it tells the server to pause keyring operations. When key copying is complete, `mysql_migrate_keyring` tells the server it can resume keyring operations before disconnecting.
- `--password[=password]`, `-p[password]`

Command-Line Format	<code>--password[=password]</code>
Type	String

The password of the MySQL account used for connecting to the running server that is currently using one of the key migration keystores. The password value is optional. If not given, `mysql_migrate_keyring` prompts for one. If given, there must be *no space* between `--password=` or `-p` and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See [Section 8.1.2.1](#), “End-User Guidelines for Password Security”.

To explicitly specify that there is no password and that `mysql_migrate_keyring` should not prompt for one, use the `--skip-password` option.

- `--port=port_num`, `-P port_num`

Command-Line Format	<code>--port=port_num</code>	553
Type	Numeric	

Default Value	0
---------------	---

For TCP/IP connections, the port number for connecting to the running server that is currently using one of the key migration keystores.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--server-public-key-path=file_name`

Command-Line Format	<code>--server-public-key-path=file_name</code>
Type	File name

The path name to a file in PEM format containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For `sha256_password`, this option applies only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see [Section 8.4.1.3, “SHA-256 Pluggable Authentication”](#), and [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

- `--socket=path, -S path`

Command-Line Format	<code>--socket={file_name pipe_name}</code>
Type	String

For Unix socket file or Windows named pipe connections, the socket file or named pipe for connecting to the running server that is currently using one of the key migration keystores.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--source-keyring=name`

Command-Line Format	<code>--source-keyring=name</code>
---------------------	------------------------------------

Type	String
------	--------

The source keyring component for key migration. This is the component library file name specified without any platform-specific extension such as `.so` or `.dll`. For example, to use the component for which the library file is `component_keyring_file.so`, specify the option as `--source-keyring=component_keyring_file`.

Note

`--component-dir`, `--source-keyring`, and `--destination-keyring` are mandatory for all keyring migration operations performed by `mysql_migrate_keyring`. In addition, the source and destination components must differ, and both components must be properly configured so that `mysql_migrate_keyring` can load and use them.

- `--source-keyring-configuration-dir=dir_name`

Command-Line Format	<code>--source-keyring-configuration-dir=dir_name</code>
Type	Directory name

This option applies only if the source keyring component global configuration file contains `"read_local_config": true`, indicating that component configuration is contained in the local configuration file. The option value specifies the directory containing that local file.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See [Command Options for Encrypted Connections](#).

- `--ssl-fips-mode={OFF | ON | STRICT}`

Command-Line Format	<code>--ssl-fips-mode={OFF ON STRICT}</code>
Deprecated	Yes
Type	Enumeration
Default Value	<code>OFF</code>
Valid Values	<code>OFF</code> <code>ON</code> <code>STRICT</code>

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations to permit. See [Section 8.8, “FIPS Support”](#).

These `--ssl-fips-mode` values are permitted:

- `OFF`: Disable FIPS mode.
- `ON`: Enable FIPS mode.

- `STRICT`: Enable “strict” FIPS mode.

Note

If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is `OFF`. In this case, setting `--ssl-fips-mode` to `ON` or `STRICT` causes the client to produce a warning at startup and to operate in non-FIPS mode.

This option is deprecated. Expect it to be removed in a future version of MySQL.

- `--tls-ciphersuites=ciphersuite_list`

Command-Line Format	<code>--tls-ciphersuites=ciphersuite_list</code>
Type	String

The permissible ciphersuites for encrypted connections that use TLSv1.3. The value is a list of one or more colon-separated ciphersuite names. The ciphersuites that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `--tls-sni-servername=server_name`

Command-Line Format	<code>--tls-sni-servername=server_name</code>
Type	String

When specified, the name is passed to the `libmysqlclient` C API library using the `MYSQL_OPT_TLS_SNI_SERVERNAME` option of `mysql_options()`. The server name is not case-sensitive. To show which server name the client specified for the current session, if any, check the `Tls_sni_server_name` status variable.

Server Name Indication (SNI) is an extension to the TLS protocol (OpenSSL must be compiled using TLS extensions for this option to function). The MySQL implementation of SNI represents the client-side only.

- `--tls-version=protocol_list`

Command-Line Format	<code>--tls-version=protocol_list</code>
Type	String
Default Value	<code>TLSv1, TLSv1.1, TLSv1.2, TLSv1.3</code> (OpenSSL 1.1.1 or higher) <code>TLSv1, TLSv1.1, TLSv1.2</code> (otherwise)

The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `--user=user_name, -u user_name`

Command-Line Format	<code>--user=user_name</code>
---------------------	-------------------------------

Type	String
------	--------

The user name of the MySQL account used for connecting to the running server that is currently using one of the key migration keystores.

- `--verbose, -v`

Command-Line Format	<code>--verbose</code>
---------------------	------------------------

Verbose mode. Produce more output about what the program does.

- `--version, -V`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

6.6.9 mysqlbinlog — Utility for Processing Binary Log Files

The server's binary log consists of files containing “events” that describe modifications to database contents. The server writes these files in binary format. To display their contents in text format, use the `mysqlbinlog` utility. You can also use `mysqlbinlog` to display the contents of relay log files written by a replica server in a replication setup because relay logs have the same format as binary logs. The binary log and relay log are discussed further in [Section 7.4.4, “The Binary Log”](#), and [Section 19.2.4, “Relay Log and Replication Metadata Repositories”](#).

Invoke `mysqlbinlog` like this:

```
mysqlbinlog [options] log_file ...
```

For example, to display the contents of the binary log file named `binlog.000003`, use this command:

```
mysqlbinlog binlog.000003
```

The output includes events contained in `binlog.000003`. For statement-based logging, event information includes the SQL statement, the ID of the server on which it was executed, the timestamp when the statement was executed, how much time it took, and so forth. For row-based logging, the event indicates a row change rather than an SQL statement. See [Section 19.2.1, “Replication Formats”](#), for information about logging modes.

Events are preceded by header comments that provide additional information. For example:

```
# at 141
#100309 9:28:36 server id 123  end_log_pos 245
  Query thread_id=3350  exec_time=11  error_code=0
```

In the first line, the number following `at` indicates the file offset, or starting position, of the event in the binary log file.

The second line starts with a date and time indicating when the statement started on the server where the event originated. For replication, this timestamp is propagated to replica servers. `server id` is the `server_id` value of the server where the event originated. `end_log_pos` indicates where the next event starts (that is, it is the end position of the current event + 1). `thread_id` indicates which thread executed the event. `exec_time` is the time spent executing the event, on a replication source server. On a replica, it is the difference of the end execution time on the replica minus the beginning execution time on the source. The difference serves as an indicator of how much replication lags behind the source. `error_code` indicates the result from executing the event. Zero means that no error occurred.

**Note**

When using event groups, the file offsets of events may be grouped together and the comments of events may be grouped together. Do not mistake these grouped events for blank file offsets.

The output from `mysqlbinlog` can be re-executed (for example, by using it as input to `mysql`) to redo the statements in the log. This is useful for recovery operations after an unexpected server exit. For other usage examples, see the discussion later in this section and in [Section 9.5, “Point-in-Time \(Incremental\) Recovery”](#). To execute the internal-use `BINLOG` statements used by `mysqlbinlog`, the user requires the `BINLOG_ADMIN` privilege (or the deprecated `SUPER` privilege), or the `REPLICATION_APPLIER` privilege plus the appropriate privileges to execute each log event.

You can use `mysqlbinlog` to read binary log files directly and apply them to the local MySQL server. You can also read binary logs from a remote server by using the `--read-from-remote-server` option. To read remote binary logs, the connection parameter options can be given to indicate how to connect to the server. These options are `--host`, `--password`, `--port`, `--protocol`, `--socket`, and `--user`.

When binary log files have been encrypted, which can be done from MySQL 8.0.14 onwards, `mysqlbinlog` cannot read them directly, but can read them from the server using the `--read-from-remote-server` option. Binary log files are encrypted when the server's `binlog_encryption` system variable is set to `ON`. The `SHOW BINARY LOGS` statement shows whether a particular binary log file is encrypted or unencrypted. Encrypted and unencrypted binary log files can also be distinguished using the magic number at the start of the file header for encrypted log files (`0xFD62696E`), which differs from that used for unencrypted log files (`0xFE62696E`). Note that from MySQL 8.0.14, `mysqlbinlog` returns a suitable error if you attempt to read an encrypted binary log file directly, but older versions of `mysqlbinlog` do not recognise the file as a binary log file at all. For more information on binary log encryption, see [Section 19.3.2, “Encrypting Binary Log Files and Relay Log Files”](#).

When binary log transaction payloads have been compressed, which can be done from MySQL 8.0.20 onwards, `mysqlbinlog` versions from that release on automatically decompress and decode the transaction payloads, and print them as they would uncompressed events. Older versions of `mysqlbinlog` cannot read compressed transaction payloads. When the server's `binlog_transaction_compression` system variable is set to `ON`, transaction payloads are compressed and then written to the server's binary log file as a single event (a `Transaction_payload_event`). With the `--verbose` option, `mysqlbinlog` adds comments stating the compression algorithm used, the compressed payload size that was originally received, and the resulting payload size after decompression.

**Note**

The end position (`end_log_pos`) that `mysqlbinlog` states for an individual event that was part of a compressed transaction payload is the same as the end position of the original compressed payload. Multiple decompressed events can therefore have the same end position.

`mysqlbinlog`'s own connection compression does less if transaction payloads are already compressed, but still operates on uncompressed transactions and headers.

For more information on binary log transaction compression, see [Section 7.4.4.5, “Binary Log Transaction Compression”](#).

When running `mysqlbinlog` against a large binary log, be careful that the filesystem has enough space for the resulting files. To configure the directory that `mysqlbinlog` uses for temporary files, use the `TMPDIR` environment variable.

`mysqlbinlog` sets the value of `pseudo_replica_mode` to true before executing any SQL statements. This system variable affects the handling of XA transactions, the

`original_commit_timestamp` replication delay timestamp and the `original_server_version` system variable, and unsupported SQL modes.

`mysqlbinlog` supports the following options, which can be specified on the command line or in the `[mysqlbinlog]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 6.2.2.2, “Using Option Files”](#).

Table 6.22 mysqlbinlog Options

Option Name	Description
<code>--base64-output</code>	Print binary log entries using base-64 encoding
<code>--bind-address</code>	Use specified network interface to connect to MySQL Server
<code>--binlog-row-event-max-size</code>	Binary log max event size
<code>--character-sets-dir</code>	Directory where character sets are installed
<code>--compress</code>	Compress all information sent between client and server
<code>--compression-algorithms</code>	Permitted compression algorithms for connections to server
<code>--connection-server-id</code>	Used for testing and debugging. See text for applicable default values and other particulars
<code>--database</code>	List entries for just this database
<code>--debug</code>	Write debugging log
<code>--debug-check</code>	Print debugging information when program exits
<code>--debug-info</code>	Print debugging information, memory, and CPU statistics when program exits
<code>--default-auth</code>	Authentication plugin to use
<code>--defaults-extra-file</code>	Read named option file in addition to usual option files
<code>--defaults-file</code>	Read only named option file
<code>--defaults-group-suffix</code>	Option group suffix value
<code>--disable-log-bin</code>	Disable binary logging
<code>--exclude-gtids</code>	Do not show any of the groups in the GTID set provided
<code>--force-if-open</code>	Read binary log files even if open or not closed properly
<code>--force-read</code>	If mysqlbinlog reads a binary log event that it does not recognize, it prints a warning
<code>--get-server-public-key</code>	Request RSA public key from server
<code>--help</code>	Display help message and exit
<code>--hexdump</code>	Display a hex dump of the log in comments
<code>--host</code>	Host on which MySQL server is located
<code>--idempotent</code>	Cause the server to use idempotent mode while processing binary log updates from this session only
<code>--include-gtids</code>	Show only the groups in the GTID set provided
<code>--local-load</code>	Prepare local temporary files for LOAD DATA in the specified directory
<code>--login-path</code>	Read login path options from <code>.mylogin.cnf</code>

Option Name	Description
<code>--no-defaults</code>	Read no option files
<code>--no-login-paths</code>	Do not read login paths from the login path file
<code>--offset</code>	Skip the first N entries in the log
<code>--password</code>	Password to use when connecting to server
<code>--plugin-dir</code>	Directory where plugins are installed
<code>--port</code>	TCP/IP port number for connection
<code>--print-defaults</code>	Print default options
<code>--print-table-metadata</code>	Print table metadata
<code>--protocol</code>	Transport protocol to use
<code>--raw</code>	Write events in raw (binary) format to output files
<code>--read-from-remote-master</code>	Read the binary log from a MySQL replication source server rather than reading a local log file
<code>--read-from-remote-server</code>	Read binary log from MySQL server rather than local log file
<code>--read-from-remote-source</code>	Read the binary log from a MySQL replication source server rather than reading a local log file
<code>--require-row-format</code>	Require row-based binary logging format
<code>--result-file</code>	Direct output to named file
<code>--rewrite-db</code>	Create rewrite rules for databases when playing back from logs written in row-based format. Can be used multiple times
<code>--server-id</code>	Extract only those events created by the server having the given server ID
<code>--server-id-bits</code>	Tell mysqlbinlog how to interpret server IDs in binary log when log was written by a mysqld having its server-id-bits set to less than the maximum; supported only by MySQL Cluster version of mysqlbinlog
<code>--server-public-key-path</code>	Path name to file containing RSA public key
<code>--set-charset</code>	Add a SET NAMES charset_name statement to the output
<code>--shared-memory-base-name</code>	Shared-memory name for shared-memory connections (Windows only)
<code>--short-form</code>	Display only the statements contained in the log
<code>--skip-gtids</code>	Do not include the GTIDs from the binary log files in the output dump file
<code>--socket</code>	Unix socket file or Windows named pipe to use
<code>--ssl-ca</code>	File that contains list of trusted SSL Certificate Authorities
<code>--ssl-capath</code>	Directory that contains trusted SSL Certificate Authority certificate files
<code>--ssl-cert</code>	File that contains X.509 certificate
<code>--ssl-cipher</code>	Permissible ciphers for connection encryption
<code>--ssl-crl</code>	File that contains certificate revocation lists

Option Name	Description
<code>--ssl-crlpath</code>	Directory that contains certificate revocation-list files
<code>--ssl-fips-mode</code>	Whether to enable FIPS mode on client side
<code>--ssl-key</code>	File that contains X.509 key
<code>--ssl-mode</code>	Desired security state of connection to server
<code>--ssl-session-data</code>	File that contains SSL session data
<code>--ssl-session-data-continue-on-failed-reuse</code>	Whether to establish connections if session reuse fails
<code>--start-datetime</code>	Read binary log from first event with timestamp equal to or later than datetime argument
<code>--start-position</code>	Decode binary log from first event with position equal to or greater than argument
<code>--stop-datetime</code>	Stop reading binary log at first event with timestamp equal to or greater than datetime argument
<code>--stop-never</code>	Stay connected to server after reading last binary log file
<code>--stop-never-slave-server-id</code>	Slave server ID to report when connecting to server
<code>--stop-position</code>	Stop decoding binary log at first event with position equal to or greater than argument
<code>--tls-ciphersuites</code>	Permissible TLSv1.3 ciphersuites for encrypted connections
<code>--tls-sni-servername</code>	Server name supplied by the client
<code>--tls-version</code>	Permissible TLS protocols for encrypted connections
<code>--to-last-log</code>	Do not stop at the end of requested binary log from a MySQL server, but rather continue printing to end of last binary log
<code>--user</code>	MySQL user name to use when connecting to server
<code>--verbose</code>	Reconstruct row events as SQL statements
<code>--verify-binlog-checksum</code>	Verify checksums in binary log
<code>--version</code>	Display version information and exit
<code>--zstd-compression-level</code>	Compression level for connections to server that use zstd compression

- `--help, -?`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display a help message and exit.

- `--base64-output=value`

Command-Line Format	<code>--base64-output=value</code>
Type	String

Default Value	AUTO
Valid Values	AUTO NEVER DECODE-ROWS

This option determines when events should be displayed encoded as base-64 strings using `BINLOG` statements. The option has these permissible values (not case-sensitive):

- `AUTO` ("automatic") or `UNSPEC` ("unspecified") displays `BINLOG` statements automatically when necessary (that is, for format description events and row events). If no `--base64-output` option is given, the effect is the same as `--base64-output=AUTO`.

Note

Automatic `BINLOG` display is the only safe behavior if you intend to use the output of `mysqlbinlog` to re-execute binary log file contents. The other option values are intended only for debugging or testing purposes because they may produce output that does not include all events in executable form.

- `NEVER` causes `BINLOG` statements not to be displayed. `mysqlbinlog` exits with an error if a row event is found that must be displayed using `BINLOG`.
- `DECODE-ROWS` specifies to `mysqlbinlog` that you intend for row events to be decoded and displayed as commented SQL statements by also specifying the `--verbose` option. Like `NEVER`, `DECODE-ROWS` suppresses display of `BINLOG` statements, but unlike `NEVER`, it does not exit with an error if a row event is found.

For examples that show the effect of `--base64-output` and `--verbose` on row event output, see [Section 6.6.9.2, “mysqlbinlog Row Event Display”](#).

- `--bind-address=ip_address`

Command-Line Format	<code>--bind-address=ip_address</code>
---------------------	--

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- `--binlog-row-event-max-size=N`

Command-Line Format	<code>--binlog-row-event-max-size=#</code>
Type	Numeric
Default Value	4294967040
Minimum Value	256
Maximum Value	18446744073709547520

Specify the maximum size of a row-based binary log event, in bytes. Rows are grouped into events smaller than this size if possible. The value should be a multiple of 256. The default is 4GB.

- `--character-sets-dir=dir_name`

Command-Line Format	<code>--character-sets-dir=dir_name</code>
Type	Directory name

The directory where character sets are installed. See [Section 12.15, “Character Set Configuration”](#).

- `--compress`

Command-Line Format	<code>--compress[={OFF ON}]</code>
Deprecated	Yes
Type	Boolean
Default Value	OFF

Compress all information sent between the client and the server if possible. See [Section 6.2.8, “Connection Compression Control”](#).

This option was added in MySQL 8.0.17. As of MySQL 8.0.18 it is deprecated. Expect it to be removed in a future version of MySQL. See [Configuring Legacy Connection Compression](#).

- `--compression-algorithms=value`

Command-Line Format	<code>--compression-algorithms=value</code>
Type	Set
Default Value	uncompressed
Valid Values	zlib zstd uncompressed

The permitted compression algorithms for connections to the server. The available algorithms are the same as for the `protocol_compression_algorithms` system variable. The default value is `uncompressed`.

For more information, see [Section 6.2.8, “Connection Compression Control”](#).

- `--connection-server-id=server_id`

Command-Line Format	<code>--connection-server-id=#]</code>
Type	Integer
Default Value	0 (1)
Minimum Value	0 (1)
Maximum Value	4294967295

`--connection-server-id` specifies the server ID that `mysqlbinlog` reports when it connects to the server. It can be used to avoid a conflict with the ID of a replica server or another `mysqlbinlog` process.

If the `--read-from-remote-server` option is specified, `mysqlbinlog` reports a server ID of 0, which tells the server to disconnect after sending the last log file (nonblocking behavior). If the `--stop-never` option is also specified to maintain the connection to the server, `mysqlbinlog` reports a server ID of 1 by default instead of 0, and `--connection-server-id` can be used to replace that server ID if required. See [Section 6.6.9.4, “Specifying the mysqlbinlog Server ID”](#).

- `--database=db_name, -d db_name`

Command-Line Format	<code>--database=db_name</code>
Type	String

This option causes `mysqlbinlog` to output entries from the binary log (local log only) that occur while `db_name` is been selected as the default database by `USE`.

The `--database` option for `mysqlbinlog` is similar to the `--binlog-do-db` option for `mysqld`, but can be used to specify only one database. If `--database` is given multiple times, only the last instance is used.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--binlog-do-db` depend on whether statement-based or row-based logging is in use.

Statement-based logging. The `--database` option works as follows:

- While `db_name` is the default database, statements are output whether they modify tables in `db_name` or a different database.
- Unless `db_name` is selected as the default database, statements are not output, even if they modify tables in `db_name`.
- There is an exception for `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE`. The database being *created*, *altered*, or *dropped* is considered to be the default database when determining whether to output the statement.

Suppose that the binary log was created by executing these statements using statement-based-logging:

```
INSERT INTO test.t1 (i) VALUES(100);
INSERT INTO db2.t2 (j) VALUES(200);
USE test;
INSERT INTO test.t1 (i) VALUES(101);
INSERT INTO t1 (i) VALUES(102);
INSERT INTO db2.t2 (j) VALUES(201);
USE db2;
INSERT INTO test.t1 (i) VALUES(103);
INSERT INTO db2.t2 (j) VALUES(202);
INSERT INTO t2 (j) VALUES(203);
```

`mysqlbinlog --database=test` does not output the first two `INSERT` statements because there is no default database. It outputs the three `INSERT` statements following `USE test`, but not the three `INSERT` statements following `USE db2`.

`mysqlbinlog --database=db2` does not output the first two `INSERT` statements because there is no default database. It does not output the three `INSERT` statements following `USE test`, but does output the three `INSERT` statements following `USE db2`.

Row-based logging. `mysqlbinlog` outputs only entries that change tables belonging to `db_name`. The default database has no effect on this. Suppose that the binary log just described was created using row-based logging rather than statement-based logging. `mysqlbinlog --`

`database=test` outputs only those entries that modify `t1` in the test database, regardless of whether `USE` was issued or what the default database is.

If a server is running with `binlog_format` set to `MIXED` and you want it to be possible to use `mysqlbinlog` with the `--database` option, you must ensure that tables that are modified are in the database selected by `USE`. (In particular, no cross-database updates should be used.)

When used together with the `--rewrite-db` option, the `--rewrite-db` option is applied first; then the `--database` option is applied, using the rewritten database name. The order in which the options are provided makes no difference in this regard.

- `--debug[=debug_options], -# [debug_options]`

Command-Line Format	<code>--debug[=debug_options]</code>
Type	String
Default Value	<code>d:t:o,/tmp/mysqlbinlog.trace</code>

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysqlbinlog.trace`.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-check`

Command-Line Format	<code>--debug-check</code>
Type	Boolean
Default Value	<code>FALSE</code>

Print some debugging information when the program exits.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-info`

Command-Line Format	<code>--debug-info</code>
Type	Boolean
Default Value	<code>FALSE</code>

Print debugging information and memory and CPU usage statistics when the program exits.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--default-auth=plugin`

Command-Line Format	<code>--default-auth=plugin</code>
Type	String

A hint about which client-side authentication plugin to use. See [Section 8.2.17, “Pluggable Authentication”](#).

- `--defaults-extra-file=file_name`

Command-Line Format	<code>--defaults-extra-file=file_name</code>
Type	File name

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-file=file_name`

Command-Line Format	<code>--defaults-file=file_name</code>
Type	File name

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-group-suffix=str`

Command-Line Format	<code>--defaults-group-suffix=str</code>
Type	String

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlbinlog` normally reads the `[client]` and `[mysqlbinlog]` groups. If this option is given as `--defaults-group-suffix=_other`, `mysqlbinlog` also reads the `[client_other]` and `[mysqlbinlog_other]` groups.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--disable-log-bin, -D`

Command-Line Format	<code>--disable-log-bin</code>
---------------------	--------------------------------

Disable binary logging. This is useful for avoiding an endless loop if you use the `--to-last-log` option and are sending the output to the same MySQL server. This option also is useful when restoring after an unexpected exit to avoid duplication of the statements you have logged.

This option causes `mysqlbinlog` to include a `SET sql_log_bin = 0` statement in its output to disable binary logging of the remaining output. Manipulating the session value of the `sql_log_bin` system variable is a restricted operation, so this option requires that you have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

- `--exclude-gtids=gtid_set`

Command-Line Format	<code>--exclude-gtids=gtid_set</code>
Type	String

Default Value	
---------------	--

Do not display any of the groups listed in the [gtid_set](#).

- [--force-if-open](#), [-F](#)

Command-Line Format	--force-if-open
---------------------	---------------------------------

Read binary log files even if they are open or were not closed properly ([IN_USE](#) flag is set); do not fail if the file ends with a truncated event.

The [IN_USE](#) flag is set only for the binary log that is currently written by the server; if the server has crashed, the flag remains set until the server is started up again and recovers the binary log. Without this option, [mysqlbinlog](#) refuses to process a file with this flag set. Since the server may be in the process of writing the file, truncation of the last event is considered normal.

- [--force-read](#), [-f](#)

Command-Line Format	--force-read
---------------------	------------------------------

With this option, if [mysqlbinlog](#) reads a binary log event that it does not recognize, it prints a warning, ignores the event, and continues. Without this option, [mysqlbinlog](#) stops if it reads such an event.

- [--get-server-public-key](#)

Command-Line Format	--get-server-public-key
Type	Boolean

Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the [caching_sha2_password](#) authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If [--server-public-key-path=file_name](#) is given and specifies a valid public key file, it takes precedence over [--get-server-public-key](#).

For information about the [caching_sha2_password](#) plugin, see [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

- [--hexdump](#), [-H](#)

Command-Line Format	--hexdump
---------------------	---------------------------

Display a hex dump of the log in comments, as described in [Section 6.6.9.1, “mysqlbinlog Hex Dump Format”](#). The hex output can be helpful for replication debugging.

- [--host=host_name](#), [-h host_name](#)

Command-Line Format	--host=host_name
Type	String
Default Value	localhost

Get the binary log from the MySQL server on the given host.

- `--idempotent`

Command-Line Format	<code>--idempotent</code>
Type	Boolean
Default Value	<code>true</code>

Tell the MySQL Server to use idempotent mode while processing updates; this causes suppression of any duplicate-key or key-not-found errors that the server encounters in the current session while processing updates. This option may prove useful whenever it is desirable or necessary to replay one or more binary logs to a MySQL Server which may not contain all of the data to which the logs refer.

The scope of effect for this option includes the current `mysqlbinlog` client and session only.

- `--include-gtids=gtid_set`

Command-Line Format	<code>--include-gtids=gtid_set</code>
Type	String
Default Value	

Display only the groups listed in the `gtid_set`.

- `--local-load=dir_name, -l dir_name`

Command-Line Format	<code>--local-load=dir_name</code>
Type	Directory name

For data loading operations corresponding to `LOAD DATA` statements, `mysqlbinlog` extracts the files from the binary log events, writes them as temporary files to the local file system, and writes `LOAD DATA LOCAL` statements to cause the files to be loaded. By default, `mysqlbinlog` writes these temporary files to an operating system-specific directory. The `--local-load` option can be used to explicitly specify the directory where `mysqlbinlog` should prepare local temporary files.

Because other processes can write files to the default system-specific directory, it is advisable to specify the `--local-load` option to `mysqlbinlog` to designate a different directory for data files, and then designate that same directory by specifying the `--load-data-local-dir` option to `mysql` when processing the output from `mysqlbinlog`. For example:

```
mysqlbinlog --local-load=/my/local/data ...
| mysql --load-data-local-dir=/my/local/data ...
```

Important

These temporary files are not automatically removed by `mysqlbinlog` or any other MySQL program.

- `--login-path=name`

Command-Line Format	<code>--login-path=name</code>
---------------------	--------------------------------

Type	String
------	--------

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

See `--login-path` for related information.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--offset=N, -o N`

Command-Line Format	<code>--offset=#</code>
Type	Numeric

Skip the first `N` entries in the log.

- `--open-files-limit=N`

Command-Line Format	<code>--open-files-limit=#</code>
Type	Numeric
Default Value	8
Minimum Value	1
Maximum Value	[platform dependent]

Specify the number of open file descriptors to reserve.

- `--password[=password], -p[password]`

Command-Line Format	<code>--password[=password]</code>
Type	String

The password of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysqlbinlog` prompts for one. If given, there must be *no space* between `--password=` or `-p` and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See [Section 8.1.2.1, “End-User Guidelines for Password Security”](#).

To explicitly specify that there is no password and that `mysqlbinlog` should not prompt for one, use the `--skip-password` option.

- `--plugin-dir=dir_name`

Command-Line Format	<code>--plugin-dir=dir_name</code>
Type	Directory name

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlbinlog` does not find it. See [Section 8.2.17, “Pluggable Authentication”](#).

- `--port=port_num, -P port_num`

Command-Line Format	<code>--port=port_num</code>
Type	Numeric
Default Value	3306

The TCP/IP port number to use for connecting to a remote server.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--print-table-metadata`

Command-Line Format	<code>--print-table-metadata</code>
---------------------	-------------------------------------

Print table related metadata from the binary log. Configure the amount of table related metadata binary logged using `binlog-row-metadata`.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

Default Value	[see text]
Valid Values	TCP SOCKET PIPE MEMORY

The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see [Section 6.2.7, “Connection Transport Protocols”](#).

- `--raw`

Command-Line Format	<code>--raw</code>
Type	Boolean
Default Value	<code>FALSE</code>

By default, `mysqlbinlog` reads binary log files and writes events in text format. The `--raw` option tells `mysqlbinlog` to write them in their original binary format. Its use requires that `--read-from-remote-server` also be used because the files are requested from a server. `mysqlbinlog` writes one output file for each file read from the server. The `--raw` option can be used to make a backup of a server's binary log. With the `--stop-never` option, the backup is “live” because `mysqlbinlog` stays connected to the server. By default, output files are written in the current directory with the same names as the original log files. Output file names can be modified using the `--result-file` option. For more information, see [Section 6.6.9.3, “Using mysqlbinlog to Back Up Binary Log Files”](#).

- `--read-from-remote-source=type`

Command-Line Format	<code>--read-from-remote-source=type</code>
---------------------	---

This option reads binary logs from a MySQL server with the `COM_BINLOG_DUMP` or `COM_BINLOG_DUMP_GTID` commands by setting the option value to either `BINLOG-DUMP-NON-GTIDS` or `BINLOG-DUMP-GTIDS`, respectively. If `--read-from-remote-source=BINLOG-DUMP-GTIDS` is combined with `--exclude-gtids`, transactions can be filtered out on the source, avoiding unnecessary network traffic.

The connection parameter options are used with these options or the `--read-from-remote-server` option. These options are `--host`, `--password`, `--port`, `--protocol`, `--socket`, and `--user`. If none of the remote options is specified, the connection parameter options are ignored.

The `REPLICATION SLAVE` privilege is required to use these options.

- `--read-from-remote-master=type`

Command-Line Format	<code>--read-from-remote-master=type</code>
Deprecated	Yes

Deprecated synonym for `--read-from-remote-source`.

- `--read-from-remote-server=file_name, -R`

Command-Line Format	<code>--read-from-remote-server=file_name</code>
---------------------	--

Read the binary log from a MySQL server rather than reading a local log file. This option requires that the remote server be running. It works only for binary log files on the remote server and not relay log files. This accepts the binary log file name (including the numeric suffix) without the file path.

The connection parameter options are used with this option or the `--read-from-remote-source` option. These options are `--host`, `--password`, `--port`, `--protocol`, `--socket`, and `--user`. If neither of the remote options is specified, the connection parameter options are ignored.

The `REPLICATION SLAVE` privilege is required to use this option.

This option is like `--read-from-remote-source=BINLOG-DUMP-NON-GTIDS`.

- `--result-file=name, -r name`

Command-Line Format	<code>--result-file=name</code>
---------------------	---------------------------------

Without the `--raw` option, this option indicates the file to which `mysqlbinlog` writes text output. With `--raw`, `mysqlbinlog` writes one binary output file for each log file transferred from the server, writing them by default in the current directory using the same names as the original log file. In this case, the `--result-file` option value is treated as a prefix that modifies output file names.

- `--require-row-format`

Command-Line Format	<code>--require-row-format</code>
Type	Boolean
Default Value	false

Require row-based binary logging format for events. This option enforces row-based replication events for `mysqlbinlog` output. The stream of events produced with this option would be accepted by a replication channel that is secured using the `REQUIRE_ROW_FORMAT` option of the `CHANGE REPLICATION SOURCE TO` statement. `binlog_format=ROW` must be set on the server where the binary log was written. When you specify this option, `mysqlbinlog` stops with an error message if it encounters any events that are disallowed under the `REQUIRE_ROW_FORMAT` restrictions, including `LOAD DATA INFILE` instructions, creating or dropping temporary tables, `INTVAR`, `RAND`, or `USER_VAR` events, and non-row-based events within a DML transaction. `mysqlbinlog` also prints a `SET @@session.require_row_format` statement at the start of its output to apply the restrictions when the output is executed, and does not print the `SET @@session.pseudo_thread_id` statement.

- `--rewrite-db='from_name->to_name'`

Command-Line Format	<code>--rewrite-db='oldname->newname'</code>
Type	String

Default Value	[none]
---------------	--------

When reading from a row-based or statement-based log, rewrite all occurrences of *from_name* to *to_name*. Rewriting is done on the rows, for row-based logs, as well as on the `USE` clauses, for statement-based logs.

Warning

Statements in which table names are qualified with database names are not rewritten to use the new name when using this option.

The rewrite rule employed as a value for this option is a string having the form '*from_name*→*to_name*', as shown previously, and for this reason must be enclosed by quotation marks.

To employ multiple rewrite rules, specify the option multiple times, as shown here:

```
mysqlbinlog --rewrite-db='dbcurrent->dbold' --rewrite-db='dbtest->dbcurrent' \
  binlog.00001 > /tmp/statements.sql
```

When used together with the `--database` option, the `--rewrite-db` option is applied first; then `--database` option is applied, using the rewritten database name. The order in which the options are provided makes no difference in this regard.

This means that, for example, if `mysqlbinlog` is started with `--rewrite-db='mydb->yourdb'` `--database=yourdb`, then all updates to any tables in databases `mydb` and `yourdb` are included in the output. On the other hand, if it is started with `--rewrite-db='mydb->yourdb'` `--database=mydb`, then `mysqlbinlog` outputs no statements at all: since all updates to `mydb` are first rewritten as updates to `yourdb` before applying the `--database` option, there remain no updates that match `--database=mydb`.

- `--server-id=id`

Command-Line Format	<code>--server-id=id</code>
Type	Numeric

Display only those events created by the server having the given server ID.

- `--server-id-bits=N`

Command-Line Format	<code>--server-id-bits=#</code>
Type	Numeric
Default Value	32
Minimum Value	7
Maximum Value	32

Use only the first *N* bits of the `server_id` to identify the server. If the binary log was written by a `mysqld` with `server-id-bits` set to less than 32 and user data stored in the most significant bit, running `mysqlbinlog` with `--server-id-bits` set to 32 enables this data to be seen.

This option is supported only by the version of `mysqlbinlog` supplied with the NDB Cluster distribution, or built with NDB Cluster support.

- `--server-public-key-path=file_name`

Command-Line Format	<code>--server-public-key-path=file_name</code>
---------------------	---

Type	File name
------	-----------

The path name to a file in PEM format containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For `sha256_password`, this option applies only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see [Section 8.4.1.3, “SHA-256 Pluggable Authentication”](#), and [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

- `--set-charset=charset_name`

Command-Line Format	<code>--set-charset=charset_name</code>
Type	String

Add a `SET NAMES charset_name` statement to the output to specify the character set to be used for processing log files.

- `--shared-memory-base-name=name`

Command-Line Format	<code>--shared-memory-base-name=name</code>
Platform Specific	Windows

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

- `--short-form, -s`

Command-Line Format	<code>--short-form</code>
---------------------	---------------------------

Display only the statements contained in the log, without any extra information or row-based events. This is for testing only, and should not be used in production systems. It is deprecated, and you should expect it to be removed in a future release.

- `--skip-gtids[=(true|false)]`

Command-Line Format	<code>--skip-gtids[=(true false)]</code>
Type	Boolean
Default Value	<code>false</code>

Do not include the GTIDs from the binary log files in the output dump file. For example:

```
mysqlbinlog --skip-gtids binlog.000001 > /tmp/dump.sql
```

```
mysql -u root -p -e "source /tmp/dump.sql"
```

You should not normally use this option in production or in recovery, except in the specific, and rare, scenarios where the GTIDs are actively unwanted. For example, an administrator might want to duplicate selected transactions (such as table definitions) from a deployment to another, unrelated, deployment that will not replicate to or from the original. In that scenario, `--skip-gtids` can be used to enable the administrator to apply the transactions as if they were new, and ensure that the deployments remain unrelated. However, you should only use this option if the inclusion of the GTIDs causes a known issue for your use case.

- `--socket=path, -S path`

Command-Line Format	<code>--socket={file_name pipe_name}</code>
Type	String

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See [Command Options for Encrypted Connections](#).

- `--ssl-fips-mode={OFF|ON|STRICT}`

Command-Line Format	<code>--ssl-fips-mode={OFF ON STRICT}</code>
Deprecated	Yes
Type	Enumeration
Default Value	<code>OFF</code>
Valid Values	<code>OFF</code> <code>ON</code> <code>STRICT</code>

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations to permit. See [Section 8.8, “FIPS Support”](#).

These `--ssl-fips-mode` values are permitted:

- `OFF`: Disable FIPS mode.
- `ON`: Enable FIPS mode.
- `STRICT`: Enable “strict” FIPS mode.

Note

If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is `OFF`. In this case, setting `--ssl-fips-mode` to `ON`

or `STRICT` causes the client to produce a warning at startup and to operate in non-FIPS mode.

This option is deprecated. Expect it to be removed in a future version of MySQL.

- `--start-datetime=datetime`

Command-Line Format	<code>--start-datetime=datetime</code>
Type	Datetime

Start reading the binary log at the first event having a timestamp equal to or later than the `datetime` argument. The `datetime` value is relative to the local time zone on the machine where you run `mysqlbinlog`. The value should be in a format accepted for the `DATETIME` or `TIMESTAMP` data types. For example:

```
mysqlbinlog --start-datetime="2005-12-25 11:25:56" binlog.000003
```

This option is useful for point-in-time recovery. See [Section 9.5, “Point-in-Time \(Incremental\) Recovery”](#).

- `--start-position=N, -j N`

Command-Line Format	<code>--start-position=#</code>
Type	Numeric

Start decoding the binary log at the log position `N`, including in the output any events that begin at position `N` or after. The position is a byte point in the log file, not an event counter; it needs to point to the starting position of an event to generate useful output. This option applies to the first log file named on the command line.

Prior to MySQL 8.0.33, the maximum value supported for this option was 4294967295 ($2^{32}-1$). In MySQL 8.0.33 and later, it is 18446744073709551616 ($2^{64}-1$), unless `--read-from-remote-server` or `--read-from-remote-source` is also used, in which case the maximum is 4294967295.

This option is useful for point-in-time recovery. See [Section 9.5, “Point-in-Time \(Incremental\) Recovery”](#).

- `--stop-datetime=datetime`

Command-Line Format	<code>--stop-datetime=datetime</code>
---------------------	---------------------------------------

Stop reading the binary log at the first event having a timestamp equal to or later than the `datetime` argument. See the description of the `--start-datetime` option for information about the `datetime` value.

This option is useful for point-in-time recovery. See [Section 9.5, “Point-in-Time \(Incremental\) Recovery”](#).

- `--stop-never`

Command-Line Format	<code>--stop-never</code>
Type	Boolean

Default Value	FALSE
---------------	-------

This option is used with `--read-from-remote-server`. It tells `mysqlbinlog` to remain connected to the server. Otherwise `mysqlbinlog` exits when the last log file has been transferred from the server. `--stop-never` implies `--to-last-log`, so only the first log file to transfer need be named on the command line.

`--stop-never` is commonly used with `--raw` to make a live binary log backup, but also can be used without `--raw` to maintain a continuous text display of log events as the server generates them.

With `--stop-never`, by default, `mysqlbinlog` reports a server ID of 1 when it connects to the server. Use `--connection-server-id` to explicitly specify an alternative ID to report. It can be used to avoid a conflict with the ID of a replica server or another `mysqlbinlog` process. See [Section 6.6.9.4, “Specifying the mysqlbinlog Server ID”](#).

- `--stop-never-slave-server-id=id`

Command-Line Format	<code>--stop-never-slave-server-id=#</code>
Type	Numeric
Default Value	65535
Minimum Value	1

This option is deprecated; expect it to be removed in a future release. Use the `--connection-server-id` option instead to specify a server ID for `mysqlbinlog` to report.

- `--stop-position=N`

Command-Line Format	<code>--stop-position=#</code>
Type	Numeric

Stop decoding the binary log at the log position `N`, excluding from the output any events that begin at position `N` or after. The position is a byte point in the log file, not an event counter; it needs to point to a spot after the starting position of the last event you want to include in the output. The event starting before position `N` and finishing at or after the position is the last event to be processed. This option applies to the last log file named on the command line.

This option is useful for point-in-time recovery. See [Section 9.5, “Point-in-Time \(Incremental\) Recovery”](#).

- `--tls-ciphersuites=ciphersuite_list`

Command-Line Format	<code>--tls-ciphersuites=ciphersuite_list</code>
Type	String

The permissible ciphersuites for encrypted connections that use TLSv1.3. The value is a list of one or more colon-separated ciphersuite names. The ciphersuites that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `--tls-sni-servername=server_name`

Type	String
------	--------

When specified, the name is passed to the `libmysqlclient` C API library using the `MYSQL_OPT_TLS_SNI_SERVERNAME` option of `mysql_options()`. The server name is not case-sensitive. To show which server name the client specified for the current session, if any, check the `Tls_sni_server_name` status variable.

Server Name Indication (SNI) is an extension to the TLS protocol (OpenSSL must be compiled using TLS extensions for this option to function). The MySQL implementation of SNI represents the client-side only.

- `--tls-version=protocol_list`

Command-Line Format	<code>--tls-version=protocol_list</code>
Type	String
Default Value	<code>TLSv1,TLSv1.1,TLSv1.2,TLSv1.3</code> (OpenSSL 1.1.1 or higher) <code>TLSv1,TLSv1.1,TLSv1.2</code> (otherwise)

The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `--to-last-log, -t`

Command-Line Format	<code>--to-last-log</code>
---------------------	----------------------------

Do not stop at the end of the requested binary log from a MySQL server, but rather continue printing until the end of the last binary log. If you send the output to the same MySQL server, this may lead to an endless loop. This option requires `--read-from-remote-server`.

- `--user=user_name, -u user_name`

Command-Line Format	<code>--user=user_name,</code>
Type	String

The user name of the MySQL account to use when connecting to a remote server.

If you are using the `Rewriter` plugin with MySQL 8.0.31 or later, you should grant this user the `SKIP_QUERY_REWRITE` privilege.

- `--verbose, -v`

Command-Line Format	<code>--verbose</code>
---------------------	------------------------

informational log events such as row query log events if the `binlog_rows_query_log_events` system variable is set to `TRUE`.

For examples that show the effect of `--base64-output` and `--verbose` on row event output, see [Section 6.6.9.2, “mysqlbinlog Row Event Display”](#).

- `--verify-binlog-checksum, -c`

Command-Line Format	<code>--verify-binlog-checksum</code>
---------------------	---------------------------------------

Verify checksums in binary log files.

- `--version, -V`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

- `--zstd-compression-level=level`

Command-Line Format	<code>--zstd-compression-level=#</code>
Type	Integer

The compression level to use for connections to the server that use the `zstd` compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression. The default `zstd` compression level is 3. The compression level setting has no effect on connections that do not use `zstd` compression.

For more information, see [Section 6.2.8, “Connection Compression Control”](#).

You can pipe the output of `mysqlbinlog` into the `mysql` client to execute the events contained in the binary log. This technique is used to recover from an unexpected exit when you have an old backup (see [Section 9.5, “Point-in-Time \(Incremental\) Recovery”](#)). For example:

```
mysqlbinlog binlog.000001 | mysql -u root -p
```

Or:

```
mysqlbinlog binlog.[0-9]* | mysql -u root -p
```

If the statements produced by `mysqlbinlog` may contain `BLOB` values, these may cause problems when `mysql` processes them. In this case, invoke `mysql` with the `--binary-mode` option.

You can also redirect the output of `mysqlbinlog` to a text file instead, if you need to modify the statement log first (for example, to remove statements that you do not want to execute for some reason). After editing the file, execute the statements that it contains by using it as input to the `mysql` program:

```
mysqlbinlog binlog.000001 > tmpfile
... edit tmpfile ...
mysql -u root -p < tmpfile
```

When `mysqlbinlog` is invoked with the `--start-position` option, it displays only those events with an offset in the binary log greater than or equal to a given position (the given position must match the start of one event). It also has options to stop and start when it sees an event with a given date and time. This enables you to perform point-in-time recovery using the `--stop-datetime` option (to be able to say, for example, “roll forward my databases to how they were today at 10:30 a.m.”).

Processing multiple files. If you have more than one binary log to execute on the MySQL server, the safe method is to process them all using a single connection to the server. Here is an example that demonstrates what may be *unsafe*:

```
mysqlbinlog binlog.000001 | mysql -u root -p # DANGER!!
mysqlbinlog binlog.000002 | mysql -u root -p # DANGER!!
```

Processing binary logs this way using multiple connections to the server causes problems if the first log file contains a `CREATE TEMPORARY TABLE` statement and the second log contains a statement that uses the temporary table. When the first `mysql` process terminates, the server drops the temporary table. When the second `mysql` process attempts to use the table, the server reports “unknown table.”

To avoid problems like this, use a *single* `mysql` process to execute the contents of all binary logs that you want to process. Here is one way to do so:

```
mysqlbinlog binlog.000001 binlog.000002 | mysql -u root -p
```

Another approach is to write all the logs to a single file and then process the file:

```
mysqlbinlog binlog.000001 > /tmp/statements.sql
mysqlbinlog binlog.000002 >> /tmp/statements.sql
mysql -u root -p -e "source /tmp/statements.sql"
```

From MySQL 8.0.12, you can also supply multiple binary log files to `mysqlbinlog` as streamed input using a shell pipe. An archive of compressed binary log files can be decompressed and provided directly to `mysqlbinlog`. In this example, `binlog-files_1.gz` contains multiple binary log files for processing. The pipeline extracts the contents of `binlog-files_1.gz`, pipes the binary log files to `mysqlbinlog` as standard input, and pipes the output of `mysqlbinlog` into the `mysql` client for execution:

```
gzip -cd binlog-files_1.gz | ./mysqlbinlog - | ./mysql -uroot -p
```

You can specify more than one archive file, for example:

```
gzip -cd binlog-files_1.gz binlog-files_2.gz | ./mysqlbinlog - | ./mysql -uroot -p
```

For streamed input, do not use `--stop-position`, because `mysqlbinlog` cannot identify the last log file to apply this option.

LOAD DATA operations. `mysqlbinlog` can produce output that reproduces a `LOAD DATA` operation without the original data file. `mysqlbinlog` copies the data to a temporary file and writes a `LOAD DATA LOCAL` statement that refers to the file. The default location of the directory where these files are written is system-specific. To specify a directory explicitly, use the `--local-load` option.

Because `mysqlbinlog` converts `LOAD DATA` statements to `LOAD DATA LOCAL` statements (that is, it adds `LOCAL`), both the client and the server that you use to process the statements must be configured with the `LOCAL` capability enabled. See [Section 8.1.6, “Security Considerations for LOAD DATA LOCAL”](#).

Warning

The temporary files created for `LOAD DATA LOCAL` statements are *not* automatically deleted because they are needed until you actually execute those statements. You should delete the temporary files yourself after you no longer need the statement log. The files can be found in the temporary file directory and have names like `original_file_name-#-#`.

6.6.9.1 mysqlbinlog Hex Dump Format

The `--hexdump` option causes `mysqlbinlog` to produce a hex dump of the binary log contents:

```
mysqlbinlog --hexdump source-bin.000001
```

The hex output consists of comment lines beginning with `#`, so the output might look like this for the preceding command:

```
/*!40019 SET @@SESSION.max_insert_delayed_threads=0*/;
/*!50003 SET @OLD_COMPLETION_TYPE=@@COMPLETION_TYPE,COMPLETION_TYPE=0*/;
# at 4
#051024 17:24:13 server id 1  end_log_pos 98
# Position Timestamp Type Master ID Size Master Pos Flags
# 00000004 9d fc 5c 43 0f 01 00 00 00 5e 00 00 00 62 00 00 00 00 00
# 00000017 04 00 35 2e 30 2e 31 35 2d 64 65 62 75 67 2d 6c |..5.0.15.debug.1|

# Start: binlog v 4, server v 5.0.15-debug-log created 051024 17:24:13
# at startup
ROLLBACK;
```

Hex dump output currently contains the elements in the following list. This format is subject to change. For more information about binary log format, see [MySQL Internals: The Binary Log](#).

- **Position:** The byte position within the log file.
- **Timestamp:** The event timestamp. In the example shown, '9d fc 5c 43' is the representation of '051024 17:24:13' in hexadecimal.
- **Type:** The event type code.
- **Master ID:** The server ID of the replication source server that created the event.
- **Size:** The size in bytes of the event.
- **Master Pos:** The position of the next event in the original source's binary log file.
- **Flags:** Event flag values.

6.6.9.2 mysqlbinlog Row Event Display

The following examples illustrate how `mysqlbinlog` displays row events that specify data modifications. These correspond to events with the `WRITE_ROWS_EVENT`, `UPDATE_ROWS_EVENT`, and `DELETE_ROWS_EVENT` type codes. The `--base64-output=DECODE-ROWS` and `--verbose` options may be used to affect row event output.

Suppose that the server is using row-based binary logging and that you execute the following sequence of statements:

```
CREATE TABLE t
(
  id INT NOT NULL,
  name VARCHAR(20) NOT NULL,
  date DATE NULL
) ENGINE = InnoDB;

START TRANSACTION;
INSERT INTO t VALUES(1, 'apple', NULL);
UPDATE t SET name = 'pear', date = '2009-01-01' WHERE id = 1;
DELETE FROM t WHERE id = 1;
COMMIT;
```

By default, `mysqlbinlog` displays row events encoded as base-64 strings using `BINLOG` statements. Omitting extraneous lines, the output for the row events produced by the preceding statement sequence looks like this:

```
$> mysqlbinlog log_file
...
```

```
# at 218
#080828 15:03:08 server id 1  end_log_pos 258    Write_rows: table id 17 flags: STMT_END_F

BINLOG '

fAS3SBkBAAAAKgAAALoBAAQABEAAAAAAAAEAA//4AQAAAAWZWFyIbIP
'/*!*/;
```

To see the row events as comments in the form of “pseudo-SQL” statements, run `mysqlbinlog` with the `--verbose` or `-v` option. This output level also shows table partition information where applicable. The output contains lines beginning with `###`:

```
$> mysqlbinlog -v log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258    Write_rows: table id 17 flags: STMT_END_F

```

Specify `--verbose` or `-v` twice to also display data types and some metadata for each column, and informational log events such as row query log events if the `binlog_rows_query_log_events` system variable is set to `TRUE`. The output contains an additional comment following each column change:

```
$> mysqlbinlog -vv log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258    Write_rows: table id 17 flags: STMT_END_F

```

You can tell `mysqlbinlog` to suppress the `BINLOG` statements for row events by using the `--base64-output=DECODE-ROWS` option. This is similar to `--base64-output=NEVER` but does not exit with an error if a row event is found. The combination of `--base64-output=DECODE-ROWS` and `--verbose` provides a convenient way to see row events only as SQL statements:

```
$> mysqlbinlog -v --base64-output=DECODE-ROWS log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258    Write_rows: table id 17 flags: STMT_END_F
### INSERT INTO test.t
### SET
###   @1=1
###   @2='apple'
###   @3=NULL
...
# at 302
#080828 15:03:08 server id 1  end_log_pos 356    Update_rows: table id 17 flags: STMT_END_F
### UPDATE test.t
### WHERE
###   @1=1
###   @2='apple'
```

```

### @3=NULL
### SET
### @1=1
### @2='pear'
### @3='2009:01:01'
...
# at 400
#080828 15:03:08 server id 1 end_log_pos 442 Delete_rows: table id 17 flags: STMT_END_F
### DELETE FROM test.t
### WHERE
### @1=1
### @2='pear'
### @3='2009:01:01'

```

Note

You should not suppress `BINLOG` statements if you intend to re-execute `mysqlbinlog` output.

The SQL statements produced by `--verbose` for row events are much more readable than the corresponding `BINLOG` statements. However, they do not correspond exactly to the original SQL statements that generated the events. The following limitations apply:

- The original column names are lost and replaced by `@N`, where `N` is a column number.
- Character set information is not available in the binary log, which affects string column display:
 - There is no distinction made between corresponding binary and nonbinary string types (`BINARY` and `CHAR`, `VARBINARY` and `VARCHAR`, `BLOB` and `TEXT`). The output uses a data type of `STRING` for fixed-length strings and `VARSTRING` for variable-length strings.
 - For multibyte character sets, the maximum number of bytes per character is not present in the binary log, so the length for string types is displayed in bytes rather than in characters. For example, `STRING(4)` is used as the data type for values from either of these column types:

```

CHAR(4) CHARACTER SET latin1
CHAR(2) CHARACTER SET ucs2

```

- Due to the storage format for events of type `UPDATE_ROWS_EVENT`, `UPDATE` statements are displayed with the `WHERE` clause preceding the `SET` clause.

Proper interpretation of row events requires the information from the format description event at the beginning of the binary log. Because `mysqlbinlog` does not know in advance whether the rest of the log contains row events, by default it displays the format description event using a `BINLOG` statement in the initial part of the output.

If the binary log is known not to contain any events requiring a `BINLOG` statement (that is, no row events), the `--base64-output=NEVER` option can be used to prevent this header from being written.

6.6.9.3 Using mysqlbinlog to Back Up Binary Log Files

By default, `mysqlbinlog` reads binary log files and displays their contents in text format. This enables you to examine events within the files more easily and to re-execute them (for example, by using the output as input to `mysql`). `mysqlbinlog` can read log files directly from the local file system, or, with the `--read-from-remote-server` option, it can connect to a server and request binary log contents from that server. `mysqlbinlog` writes text output to its standard output, or to the file named as the value of the `--result-file=file_name` option if that option is given.

- [mysqlbinlog Backup Capabilities](#)
- [mysqlbinlog Backup Options](#)
- [Static and Live Backups](#)

- [Output File Naming](#)
- [Example: mysqldump + mysqlbinlog for Backup and Restore](#)
- [mysqlbinlog Backup Restrictions](#)

mysqlbinlog Backup Capabilities

`mysqlbinlog` can read binary log files and write new files containing the same content—that is, in binary format rather than text format. This capability enables you to easily back up a binary log in its original format. `mysqlbinlog` can make a static backup, backing up a set of log files and stopping when the end of the last file is reached. It can also make a continuous (“live”) backup, staying connected to the server when it reaches the end of the last log file and continuing to copy new events as they are generated. In continuous-backup operation, `mysqlbinlog` runs until the connection ends (for example, when the server exits) or `mysqlbinlog` is forcibly terminated. When the connection ends, `mysqlbinlog` does not wait and retry the connection, unlike a replica server. To continue a live backup after the server has been restarted, you must also restart `mysqlbinlog`.

Important

`mysqlbinlog` can back up both encrypted and unencrypted binary log files. However, copies of encrypted binary log files that are generated using `mysqlbinlog` are stored in an unencrypted format.

mysqlbinlog Backup Options

Binary log backup requires that you invoke `mysqlbinlog` with two options at minimum:

- The `--read-from-remote-server` (or `-R`) option tells `mysqlbinlog` to connect to a server and request its binary log. (This is similar to a replica server connecting to its replication source server.)
- The `--raw` option tells `mysqlbinlog` to write raw (binary) output, not text output.

Along with `--read-from-remote-server`, it is common to specify other options: `--host` indicates where the server is running, and you may also need to specify connection options such as `--user` and `--password`.

Several other options are useful in conjunction with `--raw`:

- `--stop-never`: Stay connected to the server after reaching the end of the last log file and continue to read new events.
- `--connection-server-id=id`: The server ID that `mysqlbinlog` reports when it connects to a server. When `--stop-never` is used, the default reported server ID is 1. If this causes a conflict with the ID of a replica server or another `mysqlbinlog` process, use `--connection-server-id` to specify an alternative server ID. See [Section 6.6.9.4, “Specifying the mysqlbinlog Server ID”](#).
- `--result-file`: A prefix for output file names, as described later.

Static and Live Backups

To back up a server's binary log files with `mysqlbinlog`, you must specify file names that actually exist on the server. If you do not know the names, connect to the server and use the `SHOW BINARY LOGS` statement to see the current names. Suppose that the statement produces this output:

```
mysql> SHOW BINARY LOGS;
+-----+-----+-----+
| Log_name      | File_size | Encrypted |
+-----+-----+-----+
| binlog.000130 | 27459     | No        |
| binlog.000131 | 13719     | No        |
| binlog.000132 | 43268     | No        |
```

With that information, you can use `mysqlbinlog` to back up the binary log to the current directory as follows (enter each command on a single line):

- To make a static backup of `binlog.000130` through `binlog.000132`, use either of these commands:

```
mysqlbinlog --read-from-remote-server --host=host_name --raw
binlog.000130 binlog.000131 binlog.000132

mysqlbinlog --read-from-remote-server --host=host_name --raw
--to-last-log binlog.000130
```

The first command specifies every file name explicitly. The second names only the first file and uses `--to-last-log` to read through the last. A difference between these commands is that if the server happens to open `binlog.000133` before `mysqlbinlog` reaches the end of `binlog.000132`, the first command does not read it, but the second command does.

- To make a live backup in which `mysqlbinlog` starts with `binlog.000130` to copy existing log files, then stays connected to copy new events as the server generates them:

```
mysqlbinlog --read-from-remote-server --host=host_name --raw
--stop-never binlog.000130
```

With `--stop-never`, it is not necessary to specify `--to-last-log` to read to the last log file because that option is implied.

Output File Naming

Without `--raw`, `mysqlbinlog` produces text output and the `--result-file` option, if given, specifies the name of the single file to which all output is written. With `--raw`, `mysqlbinlog` writes one binary output file for each log file transferred from the server. By default, `mysqlbinlog` writes the files in the current directory with the same names as the original log files. To modify the output file names, use the `--result-file` option. In conjunction with `--raw`, the `--result-file` option value is treated as a prefix that modifies the output file names.

Suppose that a server currently has binary log files named `binlog.000999` and up. If you use `mysqlbinlog --raw` to back up the files, the `--result-file` option produces output file names as shown in the following table. You can write the files to a specific directory by beginning the `--result-file` value with the directory path. If the `--result-file` value consists only of a directory name, the value must end with the pathname separator character. Output files are overwritten if they exist.

<code>--result-file</code> Option	Output File Names
<code>--result-file=x</code>	<code>xbinlog.000999</code> and up
<code>--result-file=/tmp/</code>	<code>/tmp/binlog.000999</code> and up
<code>--result-file=/tmp/x</code>	<code>/tmp/xbinlog.000999</code> and up

Example: mysqldump + mysqlbinlog for Backup and Restore

The following example describes a simple scenario that shows how to use `mysqldump` and `mysqlbinlog` together to back up a server's data and binary log, and how to use the backup to restore the server if data loss occurs. The example assumes that the server is running on host `host_name` and its first binary log file is named `binlog.000999`. Enter each command on a single line.

Use `mysqlbinlog` to make a continuous backup of the binary log:

```
mysqlbinlog --read-from-remote-server --host=host_name --raw
--stop-never binlog.000999
```

Use `mysqldump` to create a dump file as a snapshot of the server's data. Use `--all-databases`, `--events`, and `--routines` to back up all data, and `--source-data=2` to include the current binary log coordinates in the dump file.

```
mysqldump --host=host_name --all-databases --events --routines --source-data=2> dump_file
```

Execute the `mysqldump` command periodically to create newer snapshots as desired.

If data loss occurs (for example, if the server unexpectedly exits), use the most recent dump file to restore the data:

```
mysql --host=host_name -u root -p < dump_file
```

Then use the binary log backup to re-execute events that were written after the coordinates listed in the dump file. Suppose that the coordinates in the file look like this:

```
-- CHANGE REPLICATION SOURCE TO SOURCE_LOG_FILE='binlog.001002', SOURCE_LOG_POS=27284;
```

If the most recent backed-up log file is named `binlog.001004`, re-execute the log events like this:

```
mysqlbinlog --start-position=27284 binlog.001002 binlog.001003 binlog.001004  
| mysql --host=host_name -u root -p
```

You might find it easier to copy the backup files (dump file and binary log files) to the server host to make it easier to perform the restore operation, or if MySQL does not allow remote `root` access.

mysqlbinlog Backup Restrictions

Binary log backups with `mysqlbinlog` are subject to these restrictions:

- `mysqlbinlog` does not automatically reconnect to the MySQL server if the connection is lost (for example, if a server restart occurs or there is a network outage).
- The delay for a backup is similar to the delay for a replica server.

6.6.9.4 Specifying the mysqlbinlog Server ID

When invoked with the `--read-from-remote-server` option, `mysqlbinlog` connects to a MySQL server, specifies a server ID to identify itself, and requests binary log files from the server. You can use `mysqlbinlog` to request log files from a server in several ways:

- Specify an explicitly named set of files: For each file, `mysqlbinlog` connects and issues a `Binlog dump` command. The server sends the file and disconnects. There is one connection per file.
- Specify the beginning file and `--to-last-log`: `mysqlbinlog` connects and issues a `Binlog dump` command for all files. The server sends all files and disconnects.
- Specify the beginning file and `--stop-never` (which implies `--to-last-log`): `mysqlbinlog` connects and issues a `Binlog dump` command for all files. The server sends all files, but does not disconnect after sending the last one.

With `--read-from-remote-server` only, `mysqlbinlog` connects using a server ID of 0, which tells the server to disconnect after sending the last requested log file.

With `--read-from-remote-server` and `--stop-never`, `mysqlbinlog` connects using a nonzero server ID, so the server does not disconnect after sending the last log file. The server ID is 1 by default, but this can be changed with `--connection-server-id`.

Thus, for the first two ways of requesting files, the server disconnects because `mysqlbinlog` specifies a server ID of 0. It does not disconnect if `--stop-never` is given because `mysqlbinlog` specifies a nonzero server ID.

6.6.10 mysqldumpslow — Summarize Slow Query Log Files

The MySQL slow query log contains information about queries that take a long time to execute (see [Section 7.4.5, “The Slow Query Log”](#)). `mysqldumpslow` parses MySQL slow query log files and summarizes their contents.

Normally, `mysqldumpslow` groups queries that are similar except for the particular values of number and string data values. It “abstracts” these values to `N` and `'S'` when displaying summary output. To modify value abstracting behavior, use the `-a` and `-n` options.

Invoke `mysqldumpslow` like this:

```
mysqldumpslow [options] [log_file ...]
```

Example output with no options given:

```
Reading mysql slow query log from /usr/local/mysql/data/mysql83-slow.log
Count: 1  Time=4.32s (4s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
insert into t2 select * from t1

Count: 3  Time=2.53s (7s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
insert into t2 select * from t1 limit N

Count: 3  Time=2.13s (6s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
insert into t1 select * from t1
```

`mysqldumpslow` supports the following options.

Table 6.23 `mysqldumpslow` Options

Option Name	Description
<code>-a</code>	Do not abstract all numbers to <code>N</code> and strings to <code>'S'</code>
<code>-n</code>	Abstract numbers with at least the specified digits
<code>--debug</code>	Write debugging information
<code>-g</code>	Only consider statements that match the pattern
<code>--help</code>	Display help message and exit
<code>-h</code>	Host name of the server in the log file name
<code>-i</code>	Name of the server instance
<code>-l</code>	Do not subtract lock time from total time
<code>-r</code>	Reverse the sort order
<code>-s</code>	How to sort output
<code>-t</code>	Display only first num queries
<code>--verbose</code>	Verbose mode

- `--help`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display a help message and exit.

- `-a`

Do not abstract all numbers to `N` and strings to `'S'`.

- `--debug`, `-d`

Command-Line Format	<code>--debug</code>
---------------------	----------------------

Run in debug mode.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `-g pattern`

Type	String
------	--------

Consider only queries that match the (`grep`-style) pattern.

- `-h host_name`

Type	String
Default Value	*

Host name of MySQL server for `*-slow.log` file name. The value can contain a wildcard. The default is `*` (match all).

- `-i name`

Type	String
------	--------

Name of server instance (if using `mysql.server` startup script).

- `-l`

Do not subtract lock time from total time.

- `-n N`

Type	Numeric
------	---------

Abstract numbers with at least `N` digits within names.

- `-r`

Reverse the sort order.

- `-s sort_type`

Type	String
Default Value	<code>at</code>

How to sort the output. The value of `sort_type` should be chosen from the following list:

- `t, at`: Sort by query time or average query time
- `l, al`: Sort by lock time or average lock time
- `r, ar`: Sort by rows sent or average rows sent
- `c`: Sort by count

By default, `mysqldumpslow` sorts by average query time (equivalent to `-s at`).

- `-t N`

Type	Numeric
------	---------

Display only the first *N* queries in the output.

- `--verbose, -v`

Command-Line Format	<code>--verbose</code>
---------------------	------------------------

Verbose mode. Print more information about what the program does.

6.7 Program Development Utilities

This section describes some utilities that you may find useful when developing MySQL programs.

In shell scripts, you can use the `my_print_defaults` program to parse option files and see what options would be used by a given program. The following example shows the output that `my_print_defaults` might produce when asked to show the options found in the `[client]` and `[mysql]` groups:

```
$> my_print_defaults client mysql
--port=3306
--socket=/tmp/mysql.sock
--no-auto-rehash
```

Note for developers: Option file handling is implemented in the C client library simply by processing all options in the appropriate group or groups before any command-line arguments. This works well for programs that use the last instance of an option that is specified multiple times. If you have a C or C++ program that handles multiply specified options this way but that doesn't read option files, you need add only two lines to give it that capability. Check the source code of any of the standard MySQL clients to see how to do this.

Several other language interfaces to MySQL are based on the C client library, and some of them provide a way to access option file contents. These include Perl and Python. For details, see the documentation for your preferred interface.

6.7.1 mysql_config — Display Options for Compiling Clients

`mysql_config` provides you with useful information for compiling your MySQL client and connecting it to MySQL. It is a shell script, so it is available only on Unix and Unix-like systems.

Note

`pkg-config` can be used as an alternative to `mysql_config` for obtaining information such as compiler flags or link libraries required to compile MySQL applications. For more information, see [Building C API Client Programs Using pkg-config](#).

`mysql_config` supports the following options.

- `--cflags`

C Compiler flags to find include files and critical compiler flags and defines used when compiling the `libmysqlclient` library. The options returned are tied to the specific compiler that was used when the library was created and might clash with the settings for your own compiler. Use `--include` for more portable options that contain only include paths.

- `--cxxflags`

Like `--cflags`, but for C++ compiler flags.

- `--include`

Compiler options to find MySQL include files.

- `--libs`

Libraries and options required to link with the MySQL client library.

- `--libs_r`

Libraries and options required to link with the thread-safe MySQL client library. In MySQL 8.3, all client libraries are thread-safe, so this option need not be used. The `--libs` option can be used in all cases.

- `--plugindir`

The default plugin directory path name, defined when configuring MySQL.

- `--port`

The default TCP/IP port number, defined when configuring MySQL.

- `--socket`

The default Unix socket file, defined when configuring MySQL.

- `--variable=var_name`

Display the value of the named configuration variable. Permitted `var_name` values are `pkgincludedir` (the header file directory), `pkglibdir` (the library directory), and `plugindir` (the plugin directory).

- `--version`

Version number for the MySQL distribution.

If you invoke `mysql_config` with no options, it displays a list of all options that it supports, and their values:

```
$> mysql_config
Usage: /usr/local/mysql/bin/mysql_config [options]
Options:
  --cflags          [-I/usr/local/mysql/include/mysql -mcpu=pentiumpro]
  --cxxflags        [-I/usr/local/mysql/include/mysql -mcpu=pentiumpro]
  --include          [-I/usr/local/mysql/include/mysql]
  --libs            [-L/usr/local/mysql/lib/mysql -lmysqlclient
                    -lpthread -lm -lrt -lssl -lcrypto -ldl]
  --libs_r          [-L/usr/local/mysql/lib/mysql -lmysqlclient_r
                    -lpthread -lm -lrt -lssl -lcrypto -ldl]
  --plugindir       [/usr/local/mysql/lib/plugin]
  --socket          [/tmp/mysql.sock]
  --port            [3306]
  --version         [5.8.0-m17]
  --variable=VAR    VAR is one of:
                    pkgincludedir [/usr/local/mysql/include]
                    pkglibdir     [/usr/local/mysql/lib]
                    plugindir      [/usr/local/mysql/lib/plugin]
```

You can use `mysql_config` within a command line using backticks to include the output that it produces for particular options. For example, to compile and link a MySQL client program, use `mysql_config` as follows:

```
gcc -c `mysql_config --cflags` progname.c
gcc -o progname progname.o `mysql_config --libs`
```

6.7.2 my_print_defaults — Display Options from Option Files

`my_print_defaults` displays the options that are present in option groups of option files. The output indicates what options are used by programs that read the specified option groups. For example, the `mysqlcheck` program reads the `[mysqlcheck]` and `[client]` option groups. To see what options are present in those groups in the standard option files, invoke `my_print_defaults` like this:

```
$> my_print_defaults mysqlcheck client
--user=myusername
--password=password
--host=localhost
```

The output consists of options, one per line, in the form that they would be specified on the command line.

`my_print_defaults` supports the following options.

- `--help, -?`

Display a help message and exit.

- `--config-file=file_name, --defaults-file=file_name, -c file_name`

Read only the given option file.

- `--debug=debug_options, -# debug_options`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/my_print_defaults.trace`.

- `--defaults-extra-file=file_name, --extra-file=file_name, -e file_name`

Read this option file after the global option file but (on Unix) before the user option file.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-group-suffix=suffix, -g suffix`

In addition to the groups named on the command line, read groups that have the given suffix.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--login-path=name, -l name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--no-login-paths`

Skips reading options from the login path file.

See `--login-path` for related information.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--no-defaults, -n`

Return an empty string.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--show, -s`

`my_print_defaults` masks passwords by default. Use this option to display passwords as cleartext.

- `--verbose, -v`

Verbose mode. Print more information about what the program does.

- `--version, -V`

Display version information and exit.

6.8 Miscellaneous Programs

6.8.1 `lz4_decompress` — Decompress `mysqlpump` LZ4-Compressed Output

The `lz4_decompress` utility decompresses `mysqlpump` output that was created using LZ4 compression.

Note

If MySQL was configured with the `-DWITH_LZ4=system` option, `lz4_decompress` is not built. In this case, the system `lz4` command can be used instead.

Invoke `lz4_decompress` like this:

```
lz4_decompress input_file output_file
```

Example:

```
mysqlpump --compress-output=LZ4 > dump.lz4
lz4_decompress dump.lz4 dump.txt
```

To see a help message, invoke `lz4_decompress` with no arguments.

To decompress `mysqlpump` ZLIB-compressed output, use `zlib_decompress`. See [Section 6.8.3, “zlib_decompress — Decompress `mysqlpump` ZLIB-Compressed Output”](#).

6.8.2 `perror` — Display MySQL Error Message Information

`perror` displays the error message for MySQL or operating system error codes. Invoke `perror` like this:

```
perror [options] errorcode ...
```

`perror` attempts to be flexible in understanding its arguments. For example, for the `ER_WRONG_VALUE_FOR_VAR` error, `perror` understands any of these arguments: `1231`, `001231`, `MY-1231`, or `MY-001231`, or `ER_WRONG_VALUE_FOR_VAR`.

```
$> perror 1231
MySQL error code MY-001231 (ER_WRONG_VALUE_FOR_VAR): Variable '%-.64s'
can't be set to the value of '%-.200s'
```

If an error number is in the range where MySQL and operating system errors overlap, `perror` displays both error messages:

```
$> perror 1 13
OS error code 1: Operation not permitted
MySQL error code MY-000001: Can't create/write to file '%s' (OS errno %d - %s)
OS error code 13: Permission denied
MySQL error code MY-000013: Can't get stat of '%s' (OS errno %d - %s)
```

To obtain the error message for a MySQL Cluster error code, use the `ndb_perror` utility.

The meaning of system error messages may be dependent on your operating system. A given error code may mean different things on different operating systems.

`perror` supports the following options.

- `--help`, `--info`, `-I`, `-?`

Display a help message and exit.

- `--ndb`

Print the error message for a MySQL Cluster error code.

This option was removed in MySQL 8.0.13. Use the `ndb_perror` utility instead.

- `--silent`, `-s`

Silent mode. Print only the error message.

- `--verbose`, `-v`

Verbose mode. Print error code and message. This is the default behavior.

- `--version`, `-V`

Display version information and exit.

6.8.3 zlib_decompress — Decompress mysqlpump ZLIB-Compressed Output

The `zlib_decompress` utility decompresses `mysqlpump` output that was created using ZLIB compression.

Note

If MySQL was configured with the `-DWITH_ZLIB=system` option, `zlib_decompress` is not built. In this case, the system `openssl zlib` command can be used instead.

Invoke `zlib_decompress` like this:

```
zlib_decompress input_file output_file
```

Example:

```
mysqlpump --compress-output=ZLIB > dump.zlib
zlib_decompress dump.zlib dump.txt
```

To see a help message, invoke `zlib_decompress` with no arguments.

To decompress `mysqlpump` LZ4-compressed output, use `lz4_decompress`. See [Section 6.8.1, “lz4_decompress — Decompress mysqlpump LZ4-Compressed Output”](#).

6.9 Environment Variables

This section lists environment variables that are used directly or indirectly by MySQL. Most of these can also be found in other places in this manual.

Options on the command line take precedence over values specified in option files and environment variables, and values in option files take precedence over values in environment variables. In many cases, it is preferable to use an option file instead of environment variables to modify the behavior of MySQL. See [Section 6.2.2.2, “Using Option Files”](#).

Variable	Description
<code>AUTHENTICATION_KERBEROS_CLIENT_LOG</code>	Kerberos authentication logging level.
<code>AUTHENTICATION_LDAP_CLIENT_LOG</code>	Client-side LDAP authentication logging level.
<code>AUTHENTICATION_PAM_LOG</code>	PAM authentication plugin debug logging settings.
<code>CC</code>	The name of your C compiler (for running <code>CMake</code>).
<code>CXX</code>	The name of your C++ compiler (for running <code>CMake</code>).
<code>CC</code>	The name of your C compiler (for running <code>CMake</code>).
<code>DBI_USER</code>	The default user name for Perl DBI.
<code>DBI_TRACE</code>	Trace options for Perl DBI.
<code>HOME</code>	The default path for the <code>mysql</code> history file is <code>\$HOME/.mysql_history</code> .
<code>LD_RUN_PATH</code>	Used to specify the location of <code>libmysqlclient.so</code> .
<code>LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN</code>	Enable <code>mysql_clear_password</code> authentication plugin; see Section 8.4.1.4, “Client-Side Cleartext Pluggable Authentication” .
<code>LIBMYSQL_PLUGIN_DIR</code>	Directory in which to look for client plugins.
<code>LIBMYSQL_PLUGINS</code>	Client plugins to preload.
<code>MYSQL_DEBUG</code>	Debug trace options when debugging.
<code>MYSQL_GROUP_SUFFIX</code>	Option group suffix value (like specifying <code>--defaults-group-suffix</code>).
<code>MYSQL_HISTFILE</code>	The path to the <code>mysql</code> history file. If this variable is set, its value overrides the default for <code>\$HOME/.mysql_history</code> .
<code>MYSQL_HISTIGNORE</code>	Patterns specifying statements that <code>mysql</code> should not log to <code>\$HOME/.mysql_history</code> , or <code>syslog</code> if <code>--syslog</code> is given.
<code>MYSQL_HOME</code>	The path to the directory in which the server-specific <code>my.cnf</code> file resides.
<code>MYSQL_HOST</code>	The default host name used by the <code>mysql</code> command-line client.
<code>MYSQL_OPENSSL_UDF_DH_BITS_THRESHOLD</code>	Maximum key length for <code>create_dh_parameters()</code> . See Section 8.6.3, “MySQL Enterprise Encryption Usage and Examples” .
<code>MYSQL_OPENSSL_UDF_DSA_BITS_THRESHOLD</code>	Maximum DSA key length for <code>create_asymmetric_priv_key()</code> . See Section 8.6.3, “MySQL Enterprise Encryption Usage and Examples” .
<code>MYSQL_OPENSSL_UDF_RSA_BITS_THRESHOLD</code>	Maximum RSA key length for <code>create_asymmetric_priv_key()</code> . See

Variable	Description
	Section 8.6.3, “MySQL Enterprise Encryption Usage and Examples” .
<code>MYSQL_PS1</code>	The command prompt to use in the <code>mysql</code> command-line client.
<code>MYSQL_PWD</code>	The default password when connecting to <code>mysqld</code> . Using this is insecure. See note following table.
<code>MYSQL_TCP_PORT</code>	The default TCP/IP port number.
<code>MYSQL_TEST_LOGIN_FILE</code>	The name of the <code>.mylogin.cnf</code> login path file.
<code>MYSQL_TEST_TRACE_CRASH</code>	Whether the test protocol trace plugin crashes clients. See note following table.
<code>MYSQL_TEST_TRACE_DEBUG</code>	Whether the test protocol trace plugin produces output. See note following table.
<code>MYSQL_UNIX_PORT</code>	The default Unix socket file name; used for connections to <code>localhost</code> .
<code>MYSQLX_TCP_PORT</code>	The X Plugin default TCP/IP port number.
<code>MYSQLX_UNIX_PORT</code>	The X Plugin default Unix socket file name; used for connections to <code>localhost</code> .
<code>NOTIFY_SOCKET</code>	Socket used by <code>mysqld</code> to communicate with <code>systemd</code> .
<code>PATH</code>	Used by the shell to find MySQL programs.
<code>PKG_CONFIG_PATH</code>	Location of <code>mysqlclient.pc pkg-config</code> file. See note following table.
<code>TMPDIR</code>	The directory in which temporary files are created.
<code>TZ</code>	This should be set to your local time zone. See Section B.3.3.7, “Time Zone Problems” .
<code>UMASK</code>	The user-file creation mode when creating files. See note following table.
<code>UMASK_DIR</code>	The user-directory creation mode when creating directories. See note following table.
<code>USER</code>	The default user name on Windows when connecting to <code>mysqld</code> .

For information about the `mysql` history file, see [Section 6.5.1.3, “mysql Client Logging”](#).

Use of `MYSQL_PWD` to specify a MySQL password must be considered *extremely insecure* and should not be used. Some versions of `ps` include an option to display the environment of running processes. On some systems, if you set `MYSQL_PWD`, your password is exposed to any other user who runs `ps`. Even on systems without such a version of `ps`, it is unwise to assume that there are no other methods by which users can examine process environments.

`MYSQL_PWD` is deprecated as of MySQL 8.3; expect it to be removed in a future version of MySQL.

`MYSQL_TEST_LOGIN_FILE` is the path name of the login path file (the file created by `mysql_config_editor`). If not set, the default value is `%APPDATA%\MySQL\.mylogin.cnf` directory on Windows and `$HOME/.mylogin.cnf` on non-Windows systems. See [Section 6.6.7, “mysql_config_editor — MySQL Configuration Utility”](#).

The `MYSQL_TEST_TRACE_DEBUG` and `MYSQL_TEST_TRACE_CRASH` variables control the test protocol trace client plugin, if MySQL is built with that plugin enabled. For more information, see [Using the Test Protocol Trace Plugin](#).

The default `UMASK` and `UMASK_DIR` values are `0640` and `0750`, respectively. MySQL assumes that the value for `UMASK` or `UMASK_DIR` is in octal if it starts with a zero. For example, setting `UMASK=0600` is equivalent to `UMASK=384` because `0600` octal is `384` decimal.

The `UMASK` and `UMASK_DIR` variables, despite their names, are used as modes, not masks:

- If `UMASK` is set, `mysqld` uses `($UMASK | 0600)` as the mode for file creation, so that newly created files have a mode in the range from `0600` to `0666` (all values octal).
- If `UMASK_DIR` is set, `mysqld` uses `($UMASK_DIR | 0700)` as the base mode for directory creation, which then is AND-ed with `~(~$UMASK & 0666)`, so that newly created directories have a mode in the range from `0700` to `0777` (all values octal). The AND operation may remove read and write permissions from the directory mode, but not execute permissions.

See also [Section B.3.3.1, “Problems with File Permissions”](#).

It may be necessary to set `PKG_CONFIG_PATH` if you use `pkg-config` for building MySQL programs. See [Building C API Client Programs Using pkg-config](#).

6.10 Unix Signal Handling in MySQL

On Unix and Unix-like systems, a process can be the recipient of signals sent to it by the `root` system account or the system account that owns the process. Signals can be sent using the `kill` command. Some command interpreters associate certain key sequences with signals, such as **Control+C** to send a `SIGINT` signal. This section describes how the MySQL server and client programs respond to signals.

- [Server Response to Signals](#)
- [Client Response to Signals](#)

Server Response to Signals

`mysqld` responds to signals as follows:

- `SIGTERM` causes the server to shut down. This is like executing a `SHUTDOWN` statement without having to connect to the server (which for shutdown requires an account that has the `SHUTDOWN` privilege).
- `SIGHUP` causes the server to reload the grant tables and to flush tables, logs, the thread cache, and the host cache. These actions are like various forms of the `FLUSH` statement. Sending the signal enables the flush operations to be performed without having to connect to the server, which requires a MySQL account that has privileges sufficient for those operations.
- `SIGUSR1` causes the server to flush the error log, general query log, and slow query log. One use for `SIGUSR1` is to implement log rotation without having to connect to the server, which requires a MySQL account that has privileges sufficient for those operations. For information about log rotation, see [Section 7.4.6, “Server Log Maintenance”](#).

The server response to `SIGUSR1` is a subset of the response to `SIGHUP`, enabling `SIGUSR1` to be used as a more “lightweight” signal that flushes certain logs without the other `SIGHUP` effects such as flushing the thread and host caches and writing a status report to the error log.

- `SIGINT` normally is ignored by the server. Starting the server with the `--gdb` option installs an interrupt handler for `SIGINT` for debugging purposes. See [Section 7.9.1.4, “Debugging mysqld under gdb”](#).

Client Response to Signals

MySQL client programs respond to signals as follows:

- The `mysql` client interprets `SIGINT` (typically the result of typing **Control+C**) as instruction to interrupt the current statement if there is one, or to cancel any partial input line otherwise. This behavior can be disabled using the `--sigint-ignore` option to ignore `SIGINT` signals.
- Client programs that use the MySQL client library block `SIGPIPE` signals by default. These variations are possible:
 - Client can install their own `SIGPIPE` handler to override the default behavior. See [Writing C API Threaded Client Programs](#).
 - Clients can prevent installation of `SIGPIPE` handlers by specifying the `CLIENT_IGNORE_SIGPIPE` option to `mysql_real_connect()` at connect time. See [mysql_real_connect\(\)](#).

7.9.4 The DBUG Package	1121

MySQL Server ([mysqld](#)) is the main program that does most of the work in a MySQL installation. This chapter provides an overview of MySQL Server and covers general server administration:

- Server configuration
- The data directory, particularly the [mysql](#) system schema
- The server log files
- Management of multiple servers on a single machine

For additional information on administrative topics, see also:

- [Chapter 8, Security](#)
- [Chapter 9, Backup and Recovery](#)
- [Chapter 19, Replication](#)

7.1 The MySQL Server

[mysqld](#) is the MySQL server. The following discussion covers these MySQL server configuration topics:

- Startup options that the server supports. You can specify these options on the command line, through configuration files, or both.
- Server system variables. These variables reflect the current state and values of the startup options, some of which can be modified while the server is running.
- Server status variables. These variables contain counters and statistics about runtime operation.
- How to set the server SQL mode. This setting modifies certain aspects of SQL syntax and semantics, for example for compatibility with code from other database systems, or to control the error handling for particular situations.
- How the server manages client connections.
- Configuring and using IPv6 and network namespace support.
- Configuring and using time zone support.
- Using resource groups.
- Server-side help capabilities.
- Capabilities provided to enable client session state changes.
- The server shutdown process. There are performance and reliability considerations depending on the type of table (transactional or nontransactional) and whether you use replication.

For listings of MySQL server variables and options that have been added, deprecated, or removed in MySQL 8.3, see [Section 1.4, “Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 8.3”](#).

**Note**

Not all storage engines are supported by all MySQL server binaries and configurations. To find out how to determine which storage engines your MySQL server installation supports, see [Section 15.7.7.17, “SHOW ENGINES Statement”](#).

7.1.1 Configuring the Server

The MySQL server, `mysqld`, has many command options and system variables that can be set at startup to configure its operation. To determine the default command option and system variable values used by the server, execute this command:

```
$> mysqld --verbose --help
```

The command produces a list of all `mysqld` options and configurable system variables. Its output includes the default option and variable values and looks something like this:

```

abort-slave-event-count          0
activate-all-roles-on-login      FALSE
archive                          ON
allow-suspicious-udfs            FALSE
archive                          ON
authentication-policy            *,,
auto-generate-certs              TRUE
auto-increment-increment         1
auto-increment-offset            1
autocommit                       TRUE
...

transaction-read-only            FALSE
transaction-write-set-extraction XXHASH64
updatable-views-with-limit       YES
upgrade                          AUTO
validate-config                  FALSE
validate-user-plugins            TRUE
verbose                          TRUE
wait-timeout                     28800
windowing-use-high-precision     TRUE
xa-detach-on-prepare             TRUE

```

To see the current system variable values actually used by the server as it runs, connect to it and execute this statement:

```
mysql> SHOW VARIABLES;
```

To see some statistical and status indicators for a running server, execute this statement:

```
mysql> SHOW STATUS;
```

System variable and status information also is available using the `mysqladmin` command:

```
$> mysqladmin variables
$> mysqladmin extended-status
```

For a full description of all command options, system variables, and status variables, see these sections:

- [Section 7.1.7, “Server Command Options”](#)
- [Section 7.1.8, “Server System Variables”](#)
- [Section 7.1.10, “Server Status Variables”](#)

More detailed monitoring information is available from the Performance Schema; see [Chapter 29, MySQL Performance Schema](#). In addition, the MySQL `sys` schema is a set of objects that provides

convenient access to data collected by the Performance Schema; see [Chapter 30, MySQL sys Schema](#).

If you specify an option on the command line for `mysqld` or `mysqld_safe`, it remains in effect only for that invocation of the server. To use the option every time the server runs, put it in an option file. See [Section 6.2.2.2, “Using Option Files”](#).

Windows users may execute [Section 2.3.2, “Configuration: Using MySQL Configurator”](#) to help configure a MySQL server installation. This includes tasks such as configuring MySQL users, log files, the Windows service name, and sample databases.

7.1.2 Server Configuration Defaults

The MySQL server has many operating parameters, which you can change at server startup using command-line options or configuration files (option files). It is also possible to change many parameters at runtime. For general instructions on setting parameters at startup or runtime, see [Section 7.1.7, “Server Command Options”](#), and [Section 7.1.8, “Server System Variables”](#).

On Windows, MySQL Installer interacts with the user and creates a file named `my.ini` in the base installation directory as the default option file.

Note

On Windows, the `.ini` or `.cnf` option file extension might not be displayed.

After completing the installation process, you can edit the default option file at any time to modify the parameters used by the server. For example, to use a parameter setting in the file that is commented with a `#` character at the beginning of the line, remove the `#`, and modify the parameter value if necessary. To disable a setting, either add a `#` to the beginning of the line or remove it.

For non-Windows platforms, no default option file is created during either the server installation or the data directory initialization process. Create your option file by following the instructions given in [Section 6.2.2.2, “Using Option Files”](#). Without an option file, the server just starts with its default settings—see [Section 7.1.2, “Server Configuration Defaults”](#) on how to check those settings.

For additional information about option file format and syntax, see [Section 6.2.2.2, “Using Option Files”](#).

7.1.3 Server Configuration Validation

MySQL supports a `--validate-config` option that enables the startup configuration to be checked for problems without running the server in normal operational mode:

```
mysqld --validate-config
```

If no errors are found, the server terminates with an exit code of 0. If an error is found, the server displays a diagnostic message and terminates with an exit code of 1. For example:

```
$> mysqld --validate-config --no-such-option
2018-11-05T17:50:12.738919Z 0 [ERROR] [MY-000068] [Server] unknown
option '--no-such-option'.
2018-11-05T17:50:12.738962Z 0 [ERROR] [MY-010119] [Server] Aborting
```

The server terminates as soon as any error is found. For additional checks to occur, correct the initial problem and run the server with `--validate-config` again.

For the preceding example, where use of `--validate-config` results in display of an error message, the server exit code is 1. Warning and information messages may also be displayed, depending on the `log_error_verbosity` value, but do not produce immediate validation termination or an exit code of 1. For example, this command produces multiple warnings, both of which are displayed. But no error occurs, so the exit code is 0:

```
$> mysqld --validate-config --log_error_verbosity=2
```

```
--read-only=s --transaction_read_only=s
2018-11-05T15:43:18.445863Z 0 [Warning] [MY-000076] [Server] option
'read_only': boolean value 's' was not recognized. Set to OFF.
2018-11-05T15:43:18.445882Z 0 [Warning] [MY-000076] [Server] option
'transaction-read-only': boolean value 's' was not recognized. Set to OFF.
```

This command produces the same warnings, but also an error, so the error message is displayed along with the warnings and the exit code is 1:

```
$> mysql --validate-config --log_error_verbosity=2
--no-such-option --read-only=s --transaction_read_only=s
2018-11-05T15:43:53.152886Z 0 [Warning] [MY-000076] [Server] option
'read_only': boolean value 's' was not recognized. Set to OFF.
2018-11-05T15:43:53.152913Z 0 [Warning] [MY-000076] [Server] option
'transaction-read-only': boolean value 's' was not recognized. Set to OFF.
2018-11-05T15:43:53.164889Z 0 [ERROR] [MY-000068] [Server] unknown
option '--no-such-option'.
2018-11-05T15:43:53.165053Z 0 [ERROR] [MY-010119] [Server] Aborting
```

The scope of the `--validate-config` option is limited to configuration checking that the server can perform without undergoing its normal startup process. As such, the configuration check does not initialize storage engines and other plugins, components, and so forth, and does not validate options associated with those uninitialized subsystems.

`--validate-config` can be used any time, but is particularly useful after an upgrade, to check whether any options previously used with the older server are considered by the upgraded server to be deprecated or obsolete. For example, the `tx_read_only` system variable was deprecated in MySQL 5.7 and removed in 8.0. Suppose that a MySQL 5.7 server was run using that system variable in its `my.cnf` file and then upgraded to MySQL 8.3. Running the upgraded server with `--validate-config` to check the configuration produces this result:

```
$> mysql --validate-config
2018-11-05T10:40:02.712141Z 0 [ERROR] [MY-000067] [Server] unknown variable
'tx_read_only=ON'.
2018-11-05T10:40:02.712178Z 0 [ERROR] [MY-010119] [Server] Aborting
```

`--validate-config` can be used with the `--defaults-file` option to validate only the options in a specific file:

```
$> mysql --defaults-file=./my.cnf-test --validate-config
2018-11-05T10:40:02.712141Z 0 [ERROR] [MY-000067] [Server] unknown variable
'tx_read_only=ON'.
2018-11-05T10:40:02.712178Z 0 [ERROR] [MY-010119] [Server] Aborting
```

Remember that `--defaults-file`, if specified, must be the first option on the command line. (Executing the preceding example with the option order reversed produces a message that `--defaults-file` itself is unknown.)

7.1.4 Server Option, System Variable, and Status Variable Reference

The following table lists all command-line options, system variables, and status variables applicable within `mysql`.

The table lists command-line options (Cmd-line), options valid in configuration files (Option file), server system variables (System Var), and status variables (Status var) in one unified list, with an indication of where each option or variable is valid. If a server option set on the command line or in an option file differs from the name of the corresponding system variable, the variable name is noted immediately below the corresponding option. For system and status variables, the scope of the variable (Var Scope) is Global, Session, or both. Please see the corresponding item descriptions for details on setting and using the options and variables. Where appropriate, direct links to further information about the items are provided.

For a version of this table that is specific to NDB Cluster, see [Section 25.4.2.5, “NDB Cluster mysql Option and Variable Reference”](#).

Table 7.1 Command-Line Option, System Variable, and Status Variable Summary

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dynamic

Notes:

1. This option is dynamic, but should be set only by server. You should not set this variable manually.

7.1.5 Server System Variable Reference

The following table lists all system variables applicable within `mysqld`.

The table lists command-line options (Cmd-line), options valid in configuration files (Option file), server system variables (System Var), and status variables (Status var) in one unified list, with an indication of where each option or variable is valid. If a server option set on the command line or in an option file differs from the name of the corresponding system variable, the variable name is noted immediately below the corresponding option. The scope of the variable (Var Scope) is Global, Session, or both. Please see the corresponding item descriptions for details on setting and using the variables. Where appropriate, direct links to further information about the items are provided.

Table 7.2 System Variable Summary

Name	Cmd-Line	Option File	System Var	Var Scope	Dynamic
activate_all_roles	Yes_login	Yes	Yes	Global	Yes
admin_address	Yes	Yes	Yes	Global	No
admin_port	Yes	Yes	Yes	Global	No

Notes:

1. This option is dynamic, but should be set only by server. You should not set this variable manually.

7.1.6 Server Status Variable Reference

The following table lists all status variables applicable within `mysqld`.

The table lists each variable's data type and scope. The last column indicates whether the scope for each variable is Global, Session, or both. Please see the corresponding item descriptions for details on setting and using the variables. Where appropriate, direct links to further information about the items are provided.

Table 7.3 Status Variable Summary

Variable Name	Variable Type	Variable Scope
Aborted_clients	Integer	Global

7.1.7 Server Command Options

When you start the `mysqld` server, you can specify program options using any of the methods described in [Section 6.2.2, “Specifying Program Options”](#). The most common methods are to provide options in an option file or on the command line. However, in most cases it is desirable to make sure that the server uses the same options each time it runs. The best way to ensure this is to list them in an option file. See [Section 6.2.2.2, “Using Option Files”](#). That section also describes option file format and syntax.

`mysqld` reads options from the `[mysqld]` and `[server]` groups. `mysqld_safe` reads options from the `[mysqld]`, `[server]`, `[mysqld_safe]`, and `[safe_mysqld]` groups. `mysql.server` reads options from the `[mysqld]` and `[mysql.server]` groups.

`mysqld` accepts many command options. For a brief summary, execute this command:

```
mysqld --help
```

To see the full list, use this command:

```
mysqld --verbose --help
```

Some of the items in the list are actually system variables that can be set at server startup. These can be displayed at runtime using the `SHOW VARIABLES` statement. Some items displayed by the preceding `mysqld` command do not appear in `SHOW VARIABLES` output; this is because they are options only and not system variables.

The following list shows some of the most common server options. Additional options are described in other sections:

- Options that affect security: See [Section 8.1.4, “Security-Related mysqld Options and Variables”](#).

- SSL-related options: See [Command Options for Encrypted Connections](#).
- Binary log control options: See [Section 7.4.4, “The Binary Log”](#).
- Replication-related options: See [Section 19.1.6, “Replication and Binary Logging Options and Variables”](#).
- Options for loading plugins such as pluggable storage engines: See [Section 7.6.1, “Installing and Uninstalling Plugins”](#).
- Options specific to particular storage engines: See [Section 17.14, “InnoDB Startup Options and System Variables”](#) and [Section 18.2.1, “MyISAM Startup Options”](#).

Some options control the size of buffers or caches. For a given buffer, the server might need to allocate internal data structures. These structures typically are allocated from the total memory allocated to the buffer, and the amount of space required might be platform dependent. This means that when you assign a value to an option that controls a buffer size, the amount of space actually available might differ from the value assigned. In some cases, the amount might be less than the value assigned. It is also possible that the server adjusts a value upward. For example, if you assign a value of 0 to an option for which the minimal value is 1024, the server sets the value to 1024.

Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

Some options take file name values. Unless otherwise specified, the default file location is the data directory if the value is a relative path name. To specify the location explicitly, use an absolute path name. Suppose that the data directory is `/var/mysql/data`. If a file-valued option is given as a relative path name, it is located under `/var/mysql/data`. If the value is an absolute path name, its location is as given by the path name.

You can also set the values of server system variables at server startup by using variable names as options. To assign a value to a server system variable, use an option of the form `--var_name=value`. For example, `--sort_buffer_size=384M` sets the `sort_buffer_size` variable to a value of 384MB.

When you assign a value to a variable, MySQL might automatically correct the value to stay within a given range, or adjust the value to the closest permissible value if only certain values are permitted.

To restrict the maximum value to which a system variable can be set at runtime with the `SET` statement, specify this maximum by using an option of the form `--maximum-var_name=value` at server startup.

You can change the values of most system variables at runtime with the `SET` statement. See [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#).

[Section 7.1.8, “Server System Variables”](#), provides a full description for all variables, and additional information for setting them at server startup and runtime. For information on changing system variables, see [Section 7.1.1, “Configuring the Server”](#).

- `--help, -?`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display a short help message and exit. Use both the `--verbose` and `--help` options to see the full message.

- `--admin-ssl, --skip-admin-ssl`

Command-Line Format	<code>--admin-ssl[={OFF ON}]</code>
Deprecated	Yes
Type	Boolean
Default Value	<code>ON</code>

The `--admin-ssl` option is like the `--ssl` option, except that it applies to the administrative connection interface rather than the main connection interface. For information about these interfaces, see [Section 7.1.12.1, “Connection Interfaces”](#).

The `--admin-ssl` option specifies that the server permits but does not require encrypted connections on the administrative interface. This option is enabled by default.

`--admin-ssl` can be specified in negated form as `--skip-admin-ssl` or a synonym (`--admin-ssl=OFF`, `--disable-admin-ssl`). In this case, the option specifies that the server does *not* permit encrypted connections, regardless of the settings of the `admin_tsl_xxx` and `admin_ssl_xxx` system variables.

The `--admin-ssl` option has an effect only at server startup on whether the administrative interface supports encrypted connections. It is ignored and has no effect on the operation of `ALTER INSTANCE RELOAD TLS` at runtime. For example, you can use `--admin-ssl=OFF` to start the administrative interface with encrypted connections disabled, then reconfigure TLS and execute `ALTER INSTANCE RELOAD TLS FOR CHANNEL mysql_admin` to enable encrypted connections at runtime.

For general information about configuring connection-encryption support, see [Section 8.3.1, “Configuring MySQL to Use Encrypted Connections”](#). That discussion is written for the main connection interface, but the parameter names are similar for the administrative connection interface. Consider setting at least the `admin_ssl_cert` and `admin_ssl_key` system variables on the server side and the `--ssl-ca` (or `--ssl-capath`) option on the client side. For additional information specifically about the administrative interface, see [Administrative Interface Support for Encrypted Connections](#).

Because support for encrypted connections is enabled by default, it is normally unnecessary to specify `--admin-ssl`; this option is deprecated and subject to removal in a future MySQL version. If it is desired to disable encrypted connections, that can be done without specifying `--admin-ssl` in negated form. Set the `admin_tls_version` system variable to the empty value to indicate that no TLS versions are supported. For example, these lines in the server `my.cnf` file disable encrypted connections:

```
[mysqld]
admin_tls_version=''
```

- `--allow-suspicious-udfs`

Command-Line Format	<code>--allow-suspicious-udfs[={OFF ON}]</code>
Type	Boolean
Default Value	OFF

This option controls whether loadable functions that have only an `xxx` symbol for the main function can be loaded. By default, the option is off and only loadable functions that have at least one auxiliary symbol can be loaded; this prevents attempts at loading functions from shared object files other than those containing legitimate functions. See [Loadable Function Security Precautions](#).

- `--ansi`

Command-Line Format	<code>--ansi</code>
---------------------	---------------------

Use standard (ANSI) SQL syntax instead of MySQL syntax. For more precise control over the server SQL mode, use the `--sql-mode` option instead. See [Section 1.6, “MySQL Standards Compliance”](#), and [Section 7.1.11, “Server SQL Modes”](#).

- `--basedir=dir_name, -b dir_name`

Command-Line Format	<code>--basedir=dir_name</code>
System Variable	<code>basedir</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name
Default Value	parent of <code>mysqld</code> installation directory

The path to the MySQL installation directory. This option sets the `basedir` system variable.

The server executable determines its own full path name at startup and uses the parent of the directory in which it is located as the default `basedir` value. This in turn enables the server to use that `basedir` when searching for server-related information such as the `share` directory containing error messages.

- `--chroot=dir_name, -r dir_name`

Command-Line Format	<code>--chroot=dir_name</code>
Type	Directory name

Put the `mysqld` server in a closed environment during startup by using the `chroot()` system call. This is a recommended security measure. Use of this option somewhat limits `LOAD DATA` and `SELECT ... INTO OUTFILE`.

- `--console`

Command-Line Format	<code>--console</code>
Platform Specific	Windows

(Windows only.) Cause the default error log destination to be the console. This affects log sinks that base their own output destination on the default destination. See [Section 7.4.2, “The Error Log”](#). `mysqld` does not close the console window if this option is used.

`--console` takes precedence over `--log-error` if both are given.

- `--core-file`

Command-Line Format	<code>--core-file</code>
---------------------	--------------------------

When this option is used, write a core file if `mysqld` dies; no arguments are needed (or accepted). The name and location of the core file is system dependent. On Linux, a core file named `core.pid` is written to the current working directory of the process, which for `mysqld` is the data directory. `pid` represents the process ID of the server process. On macOS, a core file named `core.pid` is written to the `/cores` directory. On Solaris, use the `coreadm` command to specify where to write the core file and how to name it.

For some systems, to get a core file you must also specify the `--core-file-size` option to `mysqld_safe`. See [Section 6.3.2, “mysqld_safe — MySQL Server Startup Script”](#). On some systems, such as Solaris, you do not get a core file if you are also using the `--user` option. There

might be additional restrictions or limitations. For example, it might be necessary to execute `ulimit -c unlimited` before starting the server. Consult your system documentation.

The `innodb_buffer_pool_in_core_file` variable can be used to reduce the size of core files on operating systems that support it. For more information, see [Section 17.8.3.7, “Excluding Buffer Pool Pages from Core Files”](#).

- `--daemonize, -D`

Command-Line Format	<code>--daemonize[={OFF ON}]</code>
Type	Boolean
Default Value	OFF

This option causes the server to run as a traditional, forking daemon, permitting it to work with operating systems that use `systemd` for process control. For more information, see [Section 2.5.9, “Managing MySQL Server with `systemd`”](#).

`--daemonize` is mutually exclusive with `--initialize` and `--initialize-insecure`.

If the server is started using the `--daemonize` option and is not connected to a tty device, a default error logging option of `--log-error=""` is used in the absence of an explicit logging option, to direct error output to the default log file.

`-D` is a synonym for `--daemonize`.

- `--datadir=dir_name, -h dir_name`

Command-Line Format	<code>--datadir=dir_name</code>
System Variable	<code>datadir</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name

The path to the MySQL server data directory. This option sets the `datadir` system variable. See the description of that variable.

- `--debug[=debug_options], -# [debug_options]`

Command-Line Format	<code>--debug[=debug_options]</code>
System Variable	<code>debug</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value (Unix)	<code>d:t:i:o,/tmp/mysql.trace</code>
Default Value (Windows)	<code>d:t:i:O,\mysql.trace</code>

If MySQL is configured with the `-DWITH_DEBUG=1` CMake option, you can use this option to get a trace file of what `mysqld` is doing. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:i:o,/tmp/mysql.trace` on Unix and `d:t:i:O,\mysql.trace` on Windows.

is used to process SQL statements to dump a parser trace to the server's standard error output. Typically, this output is written to the error log.

This option may be given multiple times. Values that begin with `+` or `-` are added to or subtracted from the previous value. For example, `--debug=T --debug=+P` sets the value to `P:T`.

For more information, see [Section 7.9.4, “The DBUG Package”](#).

- `--debug-sync-timeout[=N]`

Command-Line Format	<code>--debug-sync-timeout[=#]</code>
Type	Integer

Controls whether the Debug Sync facility for testing and debugging is enabled. Use of Debug Sync requires that MySQL be configured with the `-DWITH_DEBUG=ON` CMake option (see [Section 2.8.7, “MySQL Source-Configuration Options”](#)); otherwise, this option is not available. The option value is a timeout in seconds. The default value is 0, which disables Debug Sync. To enable it, specify a value greater than 0; this value also becomes the default timeout for individual synchronization points. If the option is given without a value, the timeout is set to 300 seconds.

For a description of the Debug Sync facility and how to use synchronization points, see [MySQL Internals: Test Synchronization](#).

- `--default-time-zone=timezone`

Command-Line Format	<code>--default-time-zone=name</code>
Type	String

Set the default server time zone. This option sets the global `time_zone` system variable. If this option is not given, the default time zone is the same as the system time zone (given by the value of the `system_time_zone` system variable).

The `system_time_zone` variable differs from `time_zone`. Although they might have the same value, the latter variable is used to initialize the time zone for each client that connects. See [Section 7.1.15, “MySQL Server Time Zone Support”](#).

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory. This must be the first option on the command line if it is used.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-file=file_name`

Read only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

Exception: Even with `--defaults-file`, `mysqld` reads `mysqld-auto.cnf`.

Note

This must be the first option on the command line if it is used, except that if the server is started with the `--defaults-file` and `--install` (or `--`

`install-manual`) options, `--install` (or `--install-manual`) must be first.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqld` normally reads the `[mysqld]` group. If this option is given as `--defaults-group-suffix=_other`, `mysqld` also reads the `[mysqld_other]` group.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--early-plugin-load=plugin_list`

Command-Line Format	<code>--early-plugin-load=plugin_list</code>
Type	String
Default Value	empty string

This option tells the server which plugins to load before loading mandatory built-in plugins and before storage engine initialization. Early loading is supported only for plugins compiled with `PLUGIN_OPT_ALLOW_EARLY`. If multiple `--early-plugin-load` options are given, only the last one applies.

The option value is a semicolon-separated list of `plugin_library` and `name=plugin_library` values. Each `plugin_library` is the name of a library file that contains plugin code, and each `name` is the name of a plugin to load. If a plugin library is named without any preceding plugin name, the server loads all plugins in the library. With a preceding plugin name, the server loads only the named plugin from the library. The server looks for plugin library files in the directory named by the `plugin_dir` system variable.

For example, if plugins named `myplug1` and `myplug2` are contained in the plugin library files `myplug1.so` and `myplug2.so`, use this option to perform an early plugin load:

```
mysqld --early-plugin-load="myplug1=myplug1.so;myplug2=myplug2.so"
```

Quotes surround the argument value because otherwise some command interpreters interpret semicolon (;) as a special character. (For example, Unix shells treat it as a command terminator.)

Each named plugin is loaded early for a single invocation of `mysqld` only. After a restart, the plugin is not loaded early unless `--early-plugin-load` is used again.

If the server is started using `--initialize` or `--initialize-insecure`, plugins specified by `--early-plugin-load` are not loaded.

If the server is run with `--help`, plugins specified by `--early-plugin-load` are loaded but not initialized. This behavior ensures that plugin options are displayed in the help message.

`InnoDB` tablespace encryption relies on the MySQL Keyring for encryption key management, and the keyring plugin to be used must be loaded prior to storage engine initialization to facilitate `InnoDB` recovery for encrypted tables. For example, administrators who want the `keyring_file` plugin

loaded at startup should use `--early-plugin-load` with the appropriate option value (such as `keyring_file.so` on Unix and Unix-like systems or `keyring_file.dll` on Windows).

For information about InnoDB tablespace encryption, see [Section 17.13, “InnoDB Data-at-Rest Encryption”](#). For general information about plugin loading, see [Section 7.6.1, “Installing and Uninstalling Plugins”](#).

Note

For MySQL Keyring, this option is used only when the keystore is managed with a keyring plugin. If keystore management uses a keyring component rather than a plugin, specify component loading using a manifest file; see [Section 8.4.4.2, “Keyring Component Installation”](#).

- `--exit-info[=flags], -T [flags]`

Command-Line Format	<code>--exit-info[=flags]</code>
Type	Integer

This is a bitmask of different flags that you can use for debugging the `mysqld` server. Do not use this option unless you know *exactly* what it does!

- `--external-locking`

Command-Line Format	<code>--external-locking[={OFF ON}]</code>
Type	Boolean
Default Value	OFF

Enable external locking (system locking), which is disabled by default. If you use this option on a system on which `lockd` does not fully work (such as Linux), it is easy for `mysqld` to deadlock.

To disable external locking explicitly, use `--skip-external-locking`.

External locking affects only `MyISAM` table access. For more information, including conditions under which it can and cannot be used, see [Section 10.11.5, “External Locking”](#).

- `--flush`

Command-Line Format	<code>--flush[={OFF ON}]</code>
System Variable	<code>flush</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	OFF

Flush (synchronize) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See [Section B.3.3.3, “What to Do If MySQL Keeps Crashing”](#).

Note

If `--flush` is specified, the value of `flush_time` does not matter and changes to `flush_time` have no effect on flush behavior.

- `--gdb`

Command-Line Format	<code>--gdb[={OFF ON}]</code>
Type	Boolean
Default Value	OFF

Install an interrupt handler for `SIGINT` (needed to stop `mysqld` with `^C` to set breakpoints) and disable stack tracing and core file handling. See [Section 7.9.1.4, “Debugging mysqld under gdb”](#).

On Windows, this option also suppresses the forking that is used to implement the `RESTART` statement: Forking enables one process to act as a monitor to the other, which acts as the server. However, forking makes determining the server process to attach to for debugging more difficult, so starting the server with `--gdb` suppresses forking. For a server started with this option, `RESTART` simply exits and does not restart.

In non-debug settings, `--no-monitor` may be used to suppress forking the monitor process.

- `--initialize, -I`

Command-Line Format	<code>--initialize[={OFF ON}]</code>
Type	Boolean
Default Value	OFF

This option is used to initialize a MySQL installation by creating the data directory and populating the tables in the `mysql` system schema. For more information, see [Section 2.9.1, “Initializing the Data Directory”](#).

This option limits the effects of, or is not compatible with, a number of other startup options for the MySQL server. Some of the most common issues of this sort are noted here:

- We strongly recommend, when initializing the data directory with `--initialize`, that you specify no additional options other than `--datadir`, other options used for setting directory locations such as `--basedir`, and possibly `--user`, if required. Options for the running MySQL server can be specified when starting it once initialization has been completed and `mysqld` has shut down. This also applies when using `--initialize-insecure` instead of `--initialize`.
- When the server is started with `--initialize`, some functionality is unavailable that limits the statements permitted in any file named by the `init_file` system variable. For more information, see the description of that variable. In addition, the `disabled_storage_engines` system variable has no effect.
- The `--ndbcluster` option is ignored when used together with `--initialize`.
- `--initialize` is mutually exclusive with `--bootstrap` and `--daemonize`.

The items in the preceding list also apply when initializing the server using the `--initialize-insecure` option.

- `--initialize-insecure`

Command-Line Format	<code>--initialize-insecure[={OFF ON}]</code>
Type	Boolean
Default Value	OFF

This option is used to initialize a MySQL installation by creating the data directory and populating the tables in the `mysql` system schema. This option implies `--initialize`, and the same restrictions

and limitations apply; for more information, see the description of that option, and [Section 2.9.1, “Initializing the Data Directory”](#).

Warning

This option creates a MySQL `root` user with an empty password, which is insecure. For this reason, do not use it in production without setting this password manually. See [Post-Initialization root Password Assignment](#), for information about how to do this.

- `--innodb-xxx`

Set an option for the `InnoDB` storage engine. The `InnoDB` options are listed in [Section 17.14, “InnoDB Startup Options and System Variables”](#).

- `--install [service_name]`

Command-Line Format	<code>--install [service_name]</code>
Platform Specific	Windows

(Windows only) Install the server as a Windows service that starts automatically during Windows startup. The default service name is `MySQL` if no `service_name` value is given. For more information, see [Section 2.3.3.8, “Starting MySQL as a Windows Service”](#).

Note

If the server is started with the `--defaults-file` and `--install` options, `--install` must be first.

- `--install-manual [service_name]`

Command-Line Format	<code>--install-manual [service_name]</code>
Platform Specific	Windows

(Windows only) Install the server as a Windows service that must be started manually. It does not start automatically during Windows startup. The default service name is `MySQL` if no `service_name` value is given. For more information, see [Section 2.3.3.8, “Starting MySQL as a Windows Service”](#).

Note

If the server is started with the `--defaults-file` and `--install-manual` options, `--install-manual` must be first.

- `--language=lang_name, -L lang_name`

Command-Line Format	<code>--language=name</code>
Deprecated	Yes; use <code>lc-messages-dir</code> instead
System Variable	<code>language</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Directory name

Default Value	<code>/usr/local/mysql/share/mysql/english/</code>
---------------	--

The language to use for error messages. *lang_name* can be given as the language name or as the full path name to the directory where the language files are installed. See [Section 12.12, “Setting the Error Message Language”](#).

`--lc-messages-dir` and `--lc-messages` should be used rather than `--language`, which is deprecated (and handled as a synonym for `--lc-messages-dir`). You should expect the `--language` option to be removed in a future MySQL release.

- `--large-pages`

Command-Line Format	<code>--large-pages[={OFF ON}]</code>
System Variable	<code>large_pages</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Platform Specific	Linux
Type	Boolean
Default Value	OFF

Some hardware/operating system architectures support memory pages greater than the default (usually 4KB). The actual implementation of this support depends on the underlying hardware and operating system. Applications that perform a lot of memory accesses may obtain performance improvements by using large pages due to reduced Translation Lookaside Buffer (TLB) misses.

MySQL supports the Linux implementation of large page support (which is called HugeTLB in Linux). See [Section 10.12.3.3, “Enabling Large Page Support”](#). For Solaris support of large pages, see the description of the `--super-large-pages` option.

`--large-pages` is disabled by default.

- `--lc-messages=locale_name`

Command-Line Format	<code>--lc-messages=name</code>
System Variable	<code>lc_messages</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>en_US</code>

The locale to use for error messages. The default is `en_US`. The server converts the argument to a language name and combines it with the value of `--lc-messages-dir` to produce the location for the error message file. See [Section 12.12, “Setting the Error Message Language”](#).

- `--lc-messages-dir=dir_name`

Command-Line Format	<code>--lc-messages-dir=dir_name</code>
System Variable	<code>lc_messages_dir</code>
Scope	Global
Dynamic	No

SET_VAR Hint Applies	No
Type	Directory name

The directory where error messages are located. The server uses the value together with the value of `--lc-messages` to produce the location for the error message file. See [Section 12.12, “Setting the Error Message Language”](#).

- `--local-service`

Command-Line Format	<code>--local-service</code>
---------------------	------------------------------

(Windows only) A `--local-service` option following the service name causes the server to run using the `LocalService` Windows account that has limited system privileges. If both `--defaults-file` and `--local-service` are given following the service name, they can be in any order. See [Section 2.3.3.8, “Starting MySQL as a Windows Service”](#).

- `--log-error[=file_name]`

Command-Line Format	<code>--log-error[=file_name]</code>
System Variable	<code>log_error</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name

Set the default error log destination to the named file. This affects log sinks that base their own output destination on the default destination. See [Section 7.4.2, “The Error Log”](#).

If the option names no file, the default error log destination on Unix and Unix-like systems is a file named `host_name.err` in the data directory. The default destination on Windows is the same, unless the `--pid-file` option is specified. In that case, the file name is the PID file base name with a suffix of `.err` in the data directory.

If the option names a file, the default destination is that file (with an `.err` suffix added if the name has no suffix), located under the data directory unless an absolute path name is given to specify a different location.

If error log output cannot be redirected to the error log file, an error occurs and startup fails.

On Windows, `--console` takes precedence over `--log-error` if both are given. In this case, the default error log destination is the console rather than a file.

- `--log-isam[=file_name]`

Command-Line Format	<code>--log-isam[=file_name]</code>
Type	File name

Log all `MyISAM` changes to this file (used only when debugging `MyISAM`).

- `--log-raw`

Command-Line Format	<code>--log-raw[={OFF ON}]</code>
System Variable	<code>log_raw</code>
Scope	Global
Dynamic	Yes

<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Passwords in certain statements written to the general query log, slow query log, and binary log are rewritten by the server not to occur literally in plain text. Password rewriting can be suppressed for the general query log by starting the server with the `--log-raw` option. This option may be useful for diagnostic purposes, to see the exact text of statements as received by the server, but for security reasons is not recommended for production use.

If a query rewrite plugin is installed, the `--log-raw` option affects statement logging as follows:

- Without `--log-raw`, the server logs the statement returned by the query rewrite plugin. This may differ from the statement as received.
- With `--log-raw`, the server logs the original statement as received.

For more information, see [Section 8.1.2.3, “Passwords and Logging”](#).

- `--log-short-format`

Command-Line Format	<code>--log-short-format[={OFF ON}]</code>
Type	Boolean
Default Value	<code>OFF</code>

Log less information to the slow query log, if it has been activated.

- `--log-tc=file_name`

Command-Line Format	<code>--log-tc=file_name</code>
Type	File name
Default Value	<code>tc.log</code>

The name of the memory-mapped transaction coordinator log file (for XA transactions that affect multiple storage engines when the binary log is disabled). The default name is `tc.log`. The file is created under the data directory if not given as a full path name. This option is unused.

- `--log-tc-size=size`

Command-Line Format	<code>--log-tc-size=#</code>
Type	Integer
Default Value	<code>6 * page size</code>
Minimum Value	<code>6 * page size</code>
Maximum Value (64-bit platforms)	<code>18446744073709551615</code>
Maximum Value (32-bit platforms)	<code>4294967295</code>

The size in bytes of the memory-mapped transaction coordinator log. The default and minimum values are 6 times the page size, and the value must be a multiple of the page size.

- `--memlock`

Command-Line Format	<code>--memlock[={OFF ON}]</code>
Type	Boolean

Default Value	OFF
---------------	-----

Lock the `mysqld` process in memory. This option might help if you have a problem where the operating system is causing `mysqld` to swap to disk.

`--memlock` works on systems that support the `mlockall()` system call; this includes Solaris, most Linux distributions that use a 2.4 or higher kernel, and perhaps other Unix systems. On Linux systems, you can tell whether or not `mlockall()` (and thus this option) is supported by checking to see whether or not it is defined in the system `mman.h` file, like this:

```
$> grep mlockall /usr/include/sys/mman.h
```

If `mlockall()` is supported, you should see in the output of the previous command something like the following:

```
extern int mlockall (int __flags) __THROW;
```

Important

Use of this option may require you to run the server as `root`, which, for reasons of security, is normally not a good idea. See [Section 8.1.5, “How to Run MySQL as a Normal User”](#).

On Linux and perhaps other systems, you can avoid the need to run the server as `root` by changing the `limits.conf` file. See the notes regarding the `memlock` limit in [Section 10.12.3.3, “Enabling Large Page Support”](#).

You must not use this option on a system that does not support the `mlockall()` system call; if you do so, `mysqld` is very likely to exit as soon as you try to start it.

- `--myisam-block-size=N`

Command-Line Format	<code>--myisam-block-size=#</code>
Type	Integer
Default Value	1024
Minimum Value	1024
Maximum Value	16384

The block size to be used for `MyISAM` index pages.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read. This must be the first option on the command line if it is used.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--no-dd-upgrade`

Command-Line Format	<code>--no-dd-upgrade[={OFF ON}]</code>
Deprecated	Yes
Type	Boolean

Default Value	OFF
---------------	-----

**Note**

This option is deprecated. Use `--upgrade` instead.

Prevent automatic upgrade of the data dictionary tables during the MySQL server startup process. This option is typically used when starting the MySQL server following an in-place upgrade of an existing installation to a newer MySQL version, which may include changes to data dictionary table definitions.

When `--no-dd-upgrade` is specified, and the server finds that its expected version of the data dictionary differs from the version stored in the data dictionary itself, startup fails with an error stating that data dictionary upgrade is prohibited;

```
[ERROR] [MY-011091] [Server] Data dictionary upgrade prohibited by the
command line option '--no_dd_upgrade'.
[ERROR] [MY-010020] [Server] Data Dictionary initialization failed.
```

During a normal startup, the data dictionary version of the server is compared to the version stored in the data dictionary to determine whether data dictionary table definitions should be upgraded. If an upgrade is necessary and supported, the server creates data dictionary tables with updated definitions, copies persisted metadata to the new tables, atomically replaces the old tables with the new ones, and reinitializes the data dictionary. If an upgrade is not necessary, startup continues without updating data dictionary tables.

- `--no-monitor`

Command-Line Format	<code>--no-monitor[={OFF ON}]</code>
Platform Specific	Windows
Type	Boolean
Default Value	OFF

(Windows only). This option suppresses the forking that is used to implement the `RESTART` statement: Forking enables one process to act as a monitor to the other, which acts as the server. For a server started with this option, `RESTART` simply exits and does not restart.

- `--performance-schema-xxx`

Configure a Performance Schema option. For details, see [Section 29.14, “Performance Schema Command Options”](#).

- `--plugin-load=plugin_list`

Command-Line Format	<code>--plugin-load=plugin_list</code>
Type	String

This option tells the server to load the named plugins at startup. If multiple `--plugin-load` options are given, only the last one applies. Additional plugins to load may be specified using `--plugin-load-add` options.

The option value is a semicolon-separated list of `plugin_library` and `name=plugin_library` values. Each `plugin_library` is the name of a library file that contains plugin code, and each `name` is the name of a plugin to load. If a plugin library is named without any preceding plugin name, the server loads all plugins in the library. With a preceding plugin name, the server loads only the

named plugin from the library. The server looks for plugin library files in the directory named by the `plugin_dir` system variable.

For example, if plugins named `myplug1` and `myplug2` are contained in the plugin library files `myplug1.so` and `myplug2.so`, use this option to perform an early plugin load:

```
mysqld --plugin-load="myplug1=myplug1.so;myplug2=myplug2.so"
```

Quotes surround the argument value because otherwise some command interpreters interpret semicolon (;) as a special character. (For example, Unix shells treat it as a command terminator.)

Each named plugin is loaded for a single invocation of `mysqld` only. After a restart, the plugin is not loaded unless `--plugin-load` is used again. This is in contrast to `INSTALL PLUGIN`, which adds an entry to the `mysql.plugins` table to cause the plugin to be loaded for every normal server startup.

During the normal startup sequence, the server determines which plugins to load by reading the `mysql.plugins` system table. If the server is started with the `--skip-grant-tables` option, plugins registered in the `mysql.plugins` table are not loaded and are unavailable. `--plugin-load` enables plugins to be loaded even when `--skip-grant-tables` is given. `--plugin-load` also enables plugins to be loaded at startup that cannot be loaded at runtime.

This option does not set a corresponding system variable. The output of `SHOW PLUGINS` provides information about loaded plugins. More detailed information can be found in the Information Schema `PLUGINS` table. See [Section 7.6.2, “Obtaining Server Plugin Information”](#).

For additional information about plugin loading, see [Section 7.6.1, “Installing and Uninstalling Plugins”](#).

- `--plugin-load-add=plugin_list`

Command-Line Format	<code>--plugin-load-add=plugin_list</code>
Type	String

This option complements the `--plugin-load` option. `--plugin-load-add` adds a plugin or plugins to the set of plugins to be loaded at startup. The argument format is the same as for `--`

`plugin-load`. `--plugin-load-add` can be used to avoid specifying a large set of plugins as a single long unwieldy `--plugin-load` argument.

`--plugin-load-add` can be given in the absence of `--plugin-load`, but any instance of `--plugin-load-add` that appears before `--plugin-load` has no effect because `--plugin-load` resets the set of plugins to load. In other words, these options:

```
--plugin-load=x --plugin-load-add=y
```

are equivalent to this option:

```
--plugin-load="x;y"
```

But these options:

```
--plugin-load-add=y --plugin-load=x
```

are equivalent to this option:

```
--plugin-load=x
```

This option does not set a corresponding system variable. The output of `SHOW PLUGINS` provides information about loaded plugins. More detailed information can be found in the Information Schema `PLUGINS` table. See [Section 7.6.2, “Obtaining Server Plugin Information”](#).

For additional information about plugin loading, see [Section 7.6.1, “Installing and Uninstalling Plugins”](#).

- `--plugin-xxx`

Specifies an option that pertains to a server plugin. For example, many storage engines can be built as plugins, and for such engines, options for them can be specified with a `--plugin` prefix. Thus, the `--innodb-file-per-table` option for InnoDB can be specified as `--plugin-innodb-file-per-table`.

For boolean options that can be enabled or disabled, the `--skip` prefix and other alternative formats are supported as well (see [Section 6.2.2.4, “Program Option Modifiers”](#)). For example, `--skip-plugin-innodb-file-per-table` disables `innodb-file-per-table`.

The rationale for the `--plugin` prefix is that it enables plugin options to be specified unambiguously if there is a name conflict with a built-in server option. For example, were a plugin writer to name a plugin “sql” and implement a “mode” option, the option name might be `--sql-mode`, which would conflict with the built-in option of the same name. In such cases, references to the conflicting name are resolved in favor of the built-in option. To avoid the ambiguity, users can specify the plugin option as `--plugin-sql-mode`. Use of the `--plugin` prefix for plugin options is recommended to avoid any question of ambiguity.

- `--port=port_num, -P port_num`

Command-Line Format	<code>--port=port_num</code>
System Variable	<code>port</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	3306
Minimum Value	0

Maximum Value	65535
---------------	-------

The port number to use when listening for TCP/IP connections. On Unix and Unix-like systems, the port number must be 1024 or higher unless the server is started by the `root` operating system user. Setting this option to 0 causes the default value to be used.

- `--port-open-timeout=num`

Command-Line Format	<code>--port-open-timeout=#</code>
Type	Integer
Default Value	0

On some systems, when the server is stopped, the TCP/IP port might not become available immediately. If the server is restarted quickly afterward, its attempt to reopen the port can fail. This option indicates how many seconds the server should wait for the TCP/IP port to become free if it cannot be opened. The default is not to wait.

- `--print-defaults`

Print the program name and all options that it gets from option files. Password values are masked. This must be the first option on the command line if it is used, except that it may be used immediately after `--defaults-file` or `--defaults-extra-file`.

For additional information about this and other option-file options, see [Section 6.2.2.3, “Command-Line Options that Affect Option-File Handling”](#).

- `--remove [service_name]`

Command-Line Format	<code>--remove [service_name]</code>
Platform Specific	Windows

(Windows only) Remove a MySQL Windows service. The default service name is `MySQL` if no `service_name` value is given. For more information, see [Section 2.3.3.8, “Starting MySQL as a Windows Service”](#).

- `--safe-user-create`

Command-Line Format	<code>--safe-user-create[={OFF ON}]</code>
Deprecated	Yes
Type	Boolean
Default Value	OFF

If this option is enabled, a user cannot create new MySQL users by using the `GRANT` statement unless the user has the `INSERT` privilege for the `mysql.user` system table or any column in the table. If you want a user to have the ability to create new users that have those privileges that the user has the right to grant, you should grant the user the following privilege:

```
GRANT INSERT(user) ON mysql.user TO 'user_name'@'host_name';
```

This ensures that the user cannot change any privilege columns directly, but has to use the `GRANT` statement to give privileges to other users.

- `--skip-grant-tables`

Command-Line Format	<code>--skip-grant-tables[={OFF ON}]</code>
Type	Boolean
Default Value	OFF

This option affects the server startup sequence:

- `--skip-grant-tables` causes the server not to read the grant tables in the `mysql` system schema, and thus to start without using the privilege system at all. This gives anyone with access to the server *unrestricted access to all databases*.

Because starting the server with `--skip-grant-tables` disables authentication checks, the server also disables remote connections in that case by enabling `skip_networking`.

To cause a server started with `--skip-grant-tables` to load the grant tables at runtime, perform a privilege-flushing operation, which can be done in these ways:

- Issue a MySQL `FLUSH PRIVILEGES` statement after connecting to the server.
- Execute a `mysqladmin flush-privileges` or `mysqladmin reload` command from the command line.

Privilege flushing might also occur implicitly as a result of other actions performed after startup, thus causing the server to start using the grant tables. For example, the server flushes the privileges if it performs an upgrade during the startup sequence.

- `--skip-grant-tables` disables failed-login tracking and temporary account locking because those capabilities depend on the grant tables. See [Section 8.2.15, “Password Management”](#).
- `--skip-grant-tables` causes the server not to load certain other objects registered in the data dictionary or the `mysql` system schema:
 - Scheduled events installed using `CREATE EVENT` and registered in the `events` data dictionary table.
 - Plugins installed using `INSTALL PLUGIN` and registered in the `mysql.plugin` system table.

To cause plugins to be loaded even when using `--skip-grant-tables`, use the `--plugin-load` or `--plugin-load-add` option.

- Loadable functions installed using `CREATE FUNCTION` and registered in the `mysql.func` system table.

`--skip-grant-tables` does *not* suppress loading during startup of components.

- `--skip-grant-tables` causes the `disabled_storage_engines` system variable to have no effect.
- `--skip-new`

Command-Line Format	<code>--skip-new</code>
Deprecated	Yes

This option disables (what used to be considered) new, possibly unsafe behaviors. It results in these settings: `delay_key_write=OFF`, `concurrent_insert=NEVER`, `automatic_sp_privileges=OFF`. It also causes `OPTIMIZE TABLE` to be mapped to `ALTER TABLE` for storage engines for which `OPTIMIZE TABLE` is not supported.

This option is deprecated as of MySQL 8.2.0, and is subject to removal in a future release.

- `--skip-show-database`

Command-Line Format	<code>--skip-show-database</code>
System Variable	<code>skip_show_database</code>

Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

This option sets the [skip_show_database](#) system variable that controls who is permitted to use the [SHOW DATABASES](#) statement. See [Section 7.1.8, “Server System Variables”](#).

- [--skip-stack-trace](#)

Command-Line Format	--skip-stack-trace
---------------------	------------------------------------

Do not write stack traces. This option is useful when you are running `mysqld` under a debugger. On some systems, you also must use this option to get a core file. See [Section 7.9, “Debugging MySQL”](#).

- [--slow-start-timeout=timeout](#)

Command-Line Format	--slow-start-timeout=#
Type	Integer
Default Value	15000

This option controls the Windows service control manager's service start timeout. The value is the maximum number of milliseconds that the service control manager waits before trying to kill the windows service during startup. The default value is 15000 (15 seconds). If the MySQL service takes too long to start, you may need to increase this value. A value of 0 means there is no timeout.

- [--socket=path](#)

Command-Line Format	--socket={file_name pipe_name}
System Variable	socket
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value (Windows)	MySQL
Default Value (Other)	/tmp/mysql.sock

On Unix, this option specifies the Unix socket file to use when listening for local connections. The default value is [/tmp/mysql.sock](#). If this option is given, the server creates the file in the data directory unless an absolute path name is given to specify a different directory. On Windows, the option specifies the pipe name to use when listening for local connections that use a named pipe. The default value is [MySQL](#) (not case-sensitive).

- [--sql-mode=value\[,value\[,value...\]\]](#)

Command-Line Format	--sql-mode=name
System Variable	sql_mode
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes

Type	Set
Default Value	ONLY_FULL_GROUP_BY STRICT_TRANS_TABLES NO_ZERO_IN_DATE NO_ZERO_DATE ERROR_FOR_DIVISION_BY_ZERO NO_ENGINE_SUBSTITUTION
Valid Values	ALLOW_INVALID_DATES ANSI_QUOTES ERROR_FOR_DIVISION_BY_ZERO HIGH_NOT_PRECEDENCE IGNORE_SPACE NO_AUTO_VALUE_ON_ZERO NO_BACKSLASH_ESCAPES NO_DIR_IN_CREATE NO_ENGINE_SUBSTITUTION NO_UNSIGNED_SUBTRACTION NO_ZERO_DATE NO_ZERO_IN_DATE ONLY_FULL_GROUP_BY PAD_CHAR_TO_FULL_LENGTH PIPES_AS_CONCAT REAL_AS_FLOAT STRICT_ALL_TABLES STRICT_TRANS_TABLES TIME_TRUNCATE_FRACTIONAL

Set the SQL mode. See [Section 7.1.11, “Server SQL Modes”](#).

Note

MySQL installation programs may configure the SQL mode during the installation process.

If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

- `--ssl, --skip-ssl`

Command-Line Format	<code>--ssl [= {OFF ON}]</code>
Deprecated	Yes
Disabled by	<code>skip-ssl</code>

Type	Boolean
Default Value	ON

The `--ssl` option specifies that the server permits but does not require encrypted connections on the main connection interface. This option is enabled by default.

A similar option, `--admin-ssl`, is like the `--ssl`, except that it applies to the administrative connection interface rather than the main connection interface. For information about these interfaces, see [Section 7.1.12.1, “Connection Interfaces”](#).

`--ssl` can be specified in negated form as `--skip-ssl` or a synonym (`--ssl=OFF`, `--disable-ssl`). In this case, the option specifies that the server does *not* permit encrypted connections, regardless of the settings of the `tls_xxx` and `ssl_xxx` system variables.

The `--ssl` option has an effect only at server startup on whether the server supports encrypted connections. It is ignored and has no effect on the operation of `ALTER INSTANCE RELOAD TLS` at runtime. For example, you can use `--ssl=OFF` to start the server with encrypted connections disabled, then reconfigure TLS and execute `ALTER INSTANCE RELOAD TLS` to enable encrypted connections at runtime.

For more information about configuring whether the server permits clients to connect using SSL and indicating where to find SSL keys and certificates, see [Section 8.3.1, “Configuring MySQL to Use Encrypted Connections”](#), which also describes server capabilities for certificate and key file autogeneration and autodiscovery. Consider setting at least the `ssl_cert` and `ssl_key` system variables on the server side and the `--ssl-ca` (or `--ssl-capath`) option on the client side.

Because support for encrypted connections is enabled by default, it is normally unnecessary to specify `--ssl`, which is deprecated and thus subject to removal in a future MySQL release. If it is desired to disable encrypted connections, that can be done without specifying `--ssl` in negated form. Set the `tls_version` system variable to the empty value to indicate that no TLS versions are supported. For example, these lines in the server `my.cnf` file disable encrypted connections:

```
[mysqld]
tls_version='
```

- `--standalone`

Command-Line Format	<code>--standalone</code>
Platform Specific	Windows

Available on Windows only; instructs the MySQL server not to run as a service.

- `--super-large-pages`

Command-Line Format	<code>--super-large-pages[={OFF ON}]</code>
Platform Specific	Solaris
Type	Boolean
Default Value	OFF

Standard use of large pages in MySQL attempts to use the largest size supported, up to 4MB. Under Solaris, a “super large pages” feature enables uses of pages up to 256MB. This feature is available for recent SPARC platforms. It can be enabled or disabled by using the `--super-large-pages` or `--skip-super-large-pages` option.

- `--symbolic-links`, `--skip-symbolic-links`

Command-Line Format	<code>--symbolic-links[={OFF ON}]</code>
---------------------	--

Deprecated	Yes
Type	Boolean
Default Value	OFF

Enable or disable symbolic link support. On Unix, enabling symbolic links means that you can link a [MyISAM](#) index file or data file to another directory with the [INDEX DIRECTORY](#) or [DATA DIRECTORY](#) option of the [CREATE TABLE](#) statement. If you delete or rename the table, the files that its symbolic links point to also are deleted or renamed. See [Section 10.12.2.2, “Using Symbolic Links for MyISAM Tables on Unix”](#).

Note

Symbolic link support, along with the [--symbolic-links](#) option that controls it, is deprecated; you should expect it to be removed in a future version of MySQL. In addition, the option is disabled by default. The related [have_symlink](#) system variable also is deprecated; expect it to be removed in a future version of MySQL.

This option has no meaning on Windows.

- [--sysdate-is-now](#)

Command-Line Format	--sysdate-is-now [={OFF ON}]
Type	Boolean
Default Value	OFF

[SYSDATE\(\)](#) by default returns the time at which it executes, not the time at which the statement in which it occurs begins executing. This differs from the behavior of [NOW\(\)](#). This option causes [SYSDATE\(\)](#) to be a synonym for [NOW\(\)](#). For information about the implications for binary logging and replication, see the description for [SYSDATE\(\)](#) in [Section 14.7, “Date and Time Functions”](#) and for [SET TIMESTAMP](#) in [Section 7.1.8, “Server System Variables”](#).

- [--tc-heuristic-recover](#)={COMMIT|ROLLBACK}

Command-Line Format	--tc-heuristic-recover =name
Type	Enumeration
Default Value	OFF
Valid Values	OFF COMMIT ROLLBACK

The decision to use in a manual heuristic recovery.

If a [--tc-heuristic-recover](#) option is specified, the server exits regardless of whether manual heuristic recovery is successful.

On systems with more than one storage engine capable of two-phase commit, the [ROLLBACK](#) option is not safe and causes recovery to halt with the following error:

```
[ERROR] --tc-heuristic-recover rollback
strategy is not safe on systems with more than one 2-phase-commit-capable
storage engine. Aborting crash recovery.
```

- `--transaction-isolation=level`

Command-Line Format	<code>--transaction-isolation=name</code>
System Variable	<code>transaction_isolation</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>REPEATABLE-READ</code>
Valid Values	<code>READ-UNCOMMITTED</code> <code>READ-COMMITTED</code> <code>REPEATABLE-READ</code> <code>SERIALIZABLE</code>

Sets the default transaction isolation level. The `level` value can be `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, or `SERIALIZABLE`. See [Section 15.3.7, “SET TRANSACTION Statement”](#).

The default transaction isolation level can also be set at runtime using the `SET TRANSACTION` statement or by setting the `transaction_isolation` system variable.

- `--transaction-read-only`

Command-Line Format	<code>--transaction-read-only[={OFF ON}]</code>
System Variable	<code>transaction_read_only</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Sets the default transaction access mode. By default, read-only mode is disabled, so the mode is read/write.

To set the default transaction access mode at runtime, use the `SET TRANSACTION` statement or set the `transaction_read_only` system variable. See [Section 15.3.7, “SET TRANSACTION Statement”](#).

- `--tmpdir=dir_name, -t dir_name`

Command-Line Format	<code>--tmpdir=dir_name</code>
System Variable	<code>tmpdir</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Directory name

The path of the directory to use for creating temporary files. It might be useful if your default `/tmp` directory resides on a partition that is too small to hold temporary tables. This option accepts several

paths that are used in round-robin fashion. Paths should be separated by colon characters (:) on Unix and semicolon characters (;) on Windows.

`--tmpdir` can be a non-permanent location, such as a directory on a memory-based file system or a directory that is cleared when the server host restarts. If the MySQL server is acting as a replica, and you are using a non-permanent location for `--tmpdir`, consider setting a different temporary directory for the replica using the `replica_load_tmpdir` system variable. For a replica, the temporary files used to replicate `LOAD DATA` statements are stored in this directory, so with a permanent location they can survive machine restarts, although replication can now continue after a restart if the temporary files have been removed.

For more information about the storage location of temporary files, see [Section B.3.3.5, “Where MySQL Stores Temporary Files”](#).

- `--upgrade=value`

Command-Line Format	<code>--upgrade=value</code>
Type	Enumeration
Default Value	<code>AUTO</code>
Valid Values	<code>AUTO</code> <code>NONE</code> <code>MINIMAL</code>

FORCE

This option controls whether and how the server performs an automatic upgrade at startup. Automatic upgrade involves two steps:

- Step 1: Data dictionary upgrade.

This step upgrades:

- The data dictionary tables in the `mysql` schema. If the actual data dictionary version is lower than the current expected version, the server upgrades the data dictionary. If it cannot, or is prevented from doing so, the server cannot run.
- The Performance Schema and `INFORMATION_SCHEMA`.
- Step 2: Server upgrade.

This step comprises all other upgrade tasks. If the existing installation data has a lower MySQL version than the server expects, it must be upgraded:

- The system tables in the `mysql` schema (the remaining non-data dictionary tables).
- The `sys` schema.
- User schemas.

For details about upgrade steps 1 and 2, see [Section 3.4, “What the MySQL Upgrade Process Upgrades”](#).

These `--upgrade` option values are permitted:

- `AUTO`

The server performs an automatic upgrade of anything it finds to be out of date (steps 1 and 2). This is the default action if `--upgrade` is not specified explicitly.

- `NONE`

The server performs no automatic upgrade steps during the startup process (skips steps 1 and 2). Because this option value prevents a data dictionary upgrade, the server exits with an error if the data dictionary is found to be out of date:

```
[ERROR] [MY-013381] [Server] Server shutting down because upgrade is
required, yet prohibited by the command line option '--upgrade=NONE'.
[ERROR] [MY-010334] [Server] Failed to initialize DD Storage Engine
[ERROR] [MY-010020] [Server] Data Dictionary initialization failed.
```

- `MINIMAL`

The server upgrades the data dictionary, the Performance Schema, and the `INFORMATION_SCHEMA`, if necessary (step 1). Note that following an upgrade with this option, Group Replication cannot be started, because system tables on which the replication internals depend are not updated, and reduced functionality might also be apparent in other areas.

- `FORCE`

The server upgrades the data dictionary, the Performance Schema, and the `INFORMATION_SCHEMA`, if necessary (step 1). In addition, the server forces an upgrade of

everything else (step 2). Expect server startup to take longer with this option because the server checks all objects in all schemas.

`FORCE` is useful to force step 2 actions to be performed if the server thinks they are not necessary. For example, you may believe that a system table is missing or has become damaged and want to force a repair.

The following table summarizes the actions taken by the server for each option value.

Option Value	Server Performs Step 1?	Server Performs Step 2?
<code>AUTO</code>	If necessary	If necessary
<code>NONE</code>	No	No
<code>MINIMAL</code>	If necessary	No
<code>FORCE</code>	If necessary	Yes

- `--user={user_name|user_id}, -u {user_name|user_id}`

Command-Line Format	<code>--user=name</code>
Type	String

Run the `mysqld` server as the user having the name `user_name` or the numeric user ID `user_id`. (“User” in this context refers to a system login account, not a MySQL user listed in the grant tables.)

This option is *mandatory* when starting `mysqld` as `root`. The server changes its user ID during its startup sequence, causing it to run as that particular user rather than as `root`. See [Section 8.1.1, “Security Guidelines”](#).

To avoid a possible security hole where a user adds a `--user=root` option to a `my.cnf` file (thus causing the server to run as `root`), `mysqld` uses only the first `--user` option specified and produces a warning if there are multiple `--user` options. Options in `/etc/my.cnf` and `$MYSQL_HOME/my.cnf` are processed before command-line options, so it is recommended that you put a `--user` option in `/etc/my.cnf` and specify a value other than `root`. The option in `/etc/my.cnf` is found before any other `--user` options, which ensures that the server runs as a user other than `root`, and that a warning results if any other `--user` option is found.

- `--validate-config`

Command-Line Format	<code>--validate-config[={OFF ON}]</code>
Type	Boolean
Default Value	<code>OFF</code>

Validate the server startup configuration. If no errors are found, the server terminates with an exit code of 0. If an error is found, the server displays a diagnostic message and terminates with an exit code of 1. Warning and information messages may also be displayed, depending on the `log_error_verbosity` value, but do not produce immediate validation termination or an exit code of 1. For more information, see [Section 7.1.3, “Server Configuration Validation”](#).

- `--validate-user-plugins[={OFF|ON}]`

Command-Line Format	<code>--validate-user-plugins[={OFF ON}]</code>
Type	Boolean

Default Value	ON
---------------	----

If this option is enabled (the default), the server checks each user account and produces a warning if conditions are found that would make the account unusable:

- The account requires an authentication plugin that is not loaded.
- The account requires the `sha256_password` or `caching_sha2_password` authentication plugin but the server was started with neither SSL nor RSA enabled as required by the plugin.

Enabling `--validate-user-plugins` slows down server initialization and `FLUSH PRIVILEGES`. If you do not require the additional checking, you can disable this option at startup to avoid the performance decrement.

- `--verbose, -v`

Use this option with the `--help` option for detailed help.

- `--version, -V`

Display version information and exit.

7.1.8 Server System Variables

The MySQL server maintains many system variables that affect its operation. Most system variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically at runtime using the `SET` statement, which enables you to modify operation of the server without having to stop and restart it. Some variables are read-only, and their values are determined by the system environment, by how MySQL is installed on the system, or possibly by the options used to compile MySQL. Most system variables have a default value, but there are exceptions, including read-only variables. You can also use system variable values in expressions.

Setting a global system variable runtime value normally requires the `SYSTEM_VARIABLES_ADMIN` privilege (or the deprecated `SUPER` privilege). Setting a session system runtime variable value normally requires no special privileges and can be done by any user, although there are exceptions. For more information, see [Section 7.1.9.1, “System Variable Privileges”](#)

There are several ways to see the names and values of system variables:

- To see the values that a server uses based on its compiled-in defaults and any option files that it reads, use this command:

```
mysqld --verbose --help
```

- To see the values that a server uses based only on its compiled-in defaults, ignoring the settings in any option files, use this command:

```
mysqld --no-defaults --verbose --help
```

- To see the current values used by a running server, use the `SHOW VARIABLES` statement or the Performance Schema system variable tables. See [Section 29.12.14, “Performance Schema System Variable Tables”](#).

This section provides a description of each system variable. For a system variable summary table, see [Section 7.1.5, “Server System Variable Reference”](#). For more information about manipulation of system variables, see [Section 7.1.9, “Using System Variables”](#).

For additional system variable information, see these sections:

- [Section 7.1.9, “Using System Variables”](#), discusses the syntax for setting and displaying system variable values.
- [Section 7.1.9.2, “Dynamic System Variables”](#), lists the variables that can be set at runtime.

- Information on tuning system variables can be found in [Section 7.1.1, “Configuring the Server”](#).
- [Section 17.14, “InnoDB Startup Options and System Variables”](#), lists [InnoDB](#) system variables.
- [NDB Cluster System Variables](#), lists system variables which are specific to NDB Cluster.
- For information on server system variables specific to replication, see [Section 19.1.6, “Replication and Binary Logging Options and Variables”](#).

**Note**

Some of the following variable descriptions refer to “enabling” or “disabling” a variable. These variables can be enabled with the [SET](#) statement by setting them to [ON](#) or [1](#), or disabled by setting them to [OFF](#) or [0](#). Boolean variables can be set at startup to the values [ON](#), [TRUE](#), [OFF](#), and [FALSE](#) (not case-sensitive), as well as [1](#) and [0](#). See [Section 6.2.2.4, “Program Option Modifiers”](#).

Some system variables control the size of buffers or caches. For a given buffer, the server might need to allocate internal data structures. These structures typically are allocated from the total memory allocated to the buffer, and the amount of space required might be platform dependent. This means that when you assign a value to a system variable that controls a buffer size, the amount of space actually available might differ from the value assigned. In some cases, the amount might be less than the value assigned. It is also possible that the server adjusts a value upward. For example, if you assign a value of 0 to a variable for which the minimal value is 1024, the server sets the value to 1024.

Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

**Note**

Some system variable descriptions include a block size, in which case a value that is not an integer multiple of the stated block size is rounded down to the next lower multiple of the block size before being stored by the server, that is to [FLOOR\(value\) * block_size](#).

Example: Suppose that the block size for a given variable is given as 4096, and you set the value of the variable to 100000 (we assume that the variable's maximum value is greater than this number). Since $100000 / 4096 = 24.4140625$, the server automatically lowers the value to 98304 ($24 * 4096$) before storing it.

In some cases, the stated maximum for a variable is the maximum allowed by the MySQL parser, but is not an exact multiple of the block size. In such cases, the effective maximum is the next lower multiple of the block size.

Example: A system variable's maximum value is shown as 4294967295 ($2^{32}-1$), and its block size is 1024. $4294967295 / 1024 = 4194303.9990234375$, so if you set this variable to its stated maximum, the value actually stored is $4194303 * 1024 = 4294966272$.

Some system variables take file name values. Unless otherwise specified, the default file location is the data directory if the value is a relative path name. To specify the location explicitly, use an absolute path name. Suppose that the data directory is [/var/mysql/data](#). If a file-valued variable is given as a relative path name, it is located under [/var/mysql/data](#). If the value is an absolute path name, its location is as given by the path name.

- [activate_all_roles_on_login](#)

Command-Line Format	--activate-all-roles-on-login [={OFF ON}]
System Variable	activate_all_roles_on_login
Scope	Global

Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Whether to enable automatic activation of all granted roles when users log in to the server:

- If [activate_all_roles_on_login](#) is enabled, the server activates all roles granted to each account at login time. This takes precedence over default roles specified with [SET DEFAULT ROLE](#).
- If [activate_all_roles_on_login](#) is disabled, the server activates the default roles specified with [SET DEFAULT ROLE](#), if any, at login time.

Granted roles include those granted explicitly to the user and those named in the [mandatory_roles](#) system variable value.

[activate_all_roles_on_login](#) applies only at login time, and at the beginning of execution for stored programs and views that execute in definer context. To change the active roles within a session, use [SET ROLE](#). To change the active roles for a stored program, the program body should execute [SET ROLE](#).

- [admin_address](#)

Command-Line Format	--admin-address=addr
System Variable	admin_address
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String

The IP address on which to listen for TCP/IP connections on the administrative network interface (see [Section 7.1.12.1, “Connection Interfaces”](#)). There is no default [admin_address](#) value. If this variable is not specified at startup, the server maintains no administrative interface. The server also has a [bind_address](#) system variable for configuring regular (nonadministrative) client TCP/IP connections. See [Section 7.1.12.1, “Connection Interfaces”](#).

If [admin_address](#) is specified, its value must satisfy these requirements:

- The value must be a single IPv4 address, IPv6 address, or host name.
- The value cannot specify a wildcard address format (*, [0.0.0.0](#), or [::](#)).
- The value may include a network namespace specifier.

An IP address can be specified as an IPv4 or IPv6 address. If the value is a host name, the server resolves the name to an IP address and binds to that address. If a host name resolves to multiple IP addresses, the server uses the first IPv4 address if there are any, or the first IPv6 address otherwise.

The server treats different types of addresses as follows:

- If the address is an IPv4-mapped address, the server accepts TCP/IP connections for that address, in either IPv4 or IPv6 format. For example, if the server is bound to [::ffff:127.0.0.1](#), clients can connect using [--host=127.0.0.1](#) or [--host=::ffff:127.0.0.1](#).

- If the address is a “regular” IPv4 or IPv6 address (such as `127.0.0.1` or `::1`), the server accepts TCP/IP connections only for that IPv4 or IPv6 address.

These rules apply to specifying a network namespace for an address:

- A network namespace can be specified for an IP address or a host name.
- A network namespace cannot be specified for a wildcard IP address.
- For a given address, the network namespace is optional. If given, it must be specified as a `/ns` suffix immediately following the address.
- An address with no `/ns` suffix uses the host system global namespace. The global namespace is therefore the default.
- An address with a `/ns` suffix uses the namespace named `ns`.
- The host system must support network namespaces and each named namespace must previously have been set up. Naming a nonexistent namespace produces an error.

For additional information about network namespaces, see [Section 7.1.14, “Network Namespace Support”](#).

If binding to the address fails, the server produces an error and does not start.

The `admin_address` system variable is similar to the `bind_address` system variable that binds the server to an address for ordinary client connections, but with these differences:

- `bind_address` permits multiple addresses. `admin_address` permits a single address.
- `bind_address` permits wildcard addresses. `admin_address` does not.
- `admin_port`

Command-Line Format	<code>--admin-port=port_num</code>
System Variable	<code>admin_port</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>33062</code>
Minimum Value	<code>0</code>
Maximum Value	<code>65535</code>

The TCP/IP port number to use for connections on the administrative network interface (see [Section 7.1.12.1, “Connection Interfaces”](#)). Setting this variable to 0 causes the default value to be used.

Setting `admin_port` has no effect if `admin_address` is not specified because in that case the server maintains no administrative network interface.

- `admin_ssl_ca`

Command-Line Format	<code>--admin-ssl-ca=file_name</code>
System Variable	<code>admin_ssl_ca</code>
Scope	Global

Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	File name
Default Value	<code>NULL</code>

The `admin_ssl_ca` system variable is like `ssl_ca`, except that it applies to the administrative connection interface rather than the main connection interface. For information about configuring encryption support for the administrative interface, see [Administrative Interface Support for Encrypted Connections](#).

- `admin_ssl_capath`

Command-Line Format	<code>--admin-ssl-capath=dir_name</code>
System Variable	<code>admin_ssl_capath</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Directory name
Default Value	<code>NULL</code>

The `admin_ssl_capath` system variable is like `ssl_capath`, except that it applies to the administrative connection interface rather than the main connection interface. For information about configuring encryption support for the administrative interface, see [Administrative Interface Support for Encrypted Connections](#).

- `admin_ssl_cert`

Command-Line Format	<code>--admin-ssl-cert=file_name</code>
System Variable	<code>admin_ssl_cert</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	File name
Default Value	<code>NULL</code>

The `admin_ssl_cert` system variable is like `ssl_cert`, except that it applies to the administrative connection interface rather than the main connection interface. For information about configuring encryption support for the administrative interface, see [Administrative Interface Support for Encrypted Connections](#).

- `admin_ssl_cipher`

Command-Line Format	<code>--admin-ssl-cipher=name</code>
System Variable	<code>admin_ssl_cipher</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String

Default Value	NULL
---------------	------

The `admin_ssl_cipher` system variable is like `ssl_cipher`, except that it applies to the administrative connection interface rather than the main connection interface. For information about configuring encryption support for the administrative interface, see [Administrative Interface Support for Encrypted Connections](#).

- `admin_ssl_crl`

Command-Line Format	<code>--admin-ssl-crl=file_name</code>
System Variable	<code>admin_ssl_crl</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	File name
Default Value	NULL

The `admin_ssl_crl` system variable is like `ssl_crl`, except that it applies to the administrative connection interface rather than the main connection interface. For information about configuring encryption support for the administrative interface, see [Administrative Interface Support for Encrypted Connections](#).

- `admin_ssl_crlpath`

Command-Line Format	<code>--admin-ssl-crlpath=dir_name</code>
System Variable	<code>admin_ssl_crlpath</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Directory name
Default Value	NULL

The `admin_ssl_crlpath` system variable is like `ssl_crlpath`, except that it applies to the administrative connection interface rather than the main connection interface. For information about configuring encryption support for the administrative interface, see [Administrative Interface Support for Encrypted Connections](#).

- `admin_ssl_key`

Command-Line Format	<code>--admin-ssl-key=file_name</code>
System Variable	<code>admin_ssl_key</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	File name
Default Value	NULL

The `admin_ssl_key` system variable is like `ssl_key`, except that it applies to the administrative connection interface rather than the main connection interface. For information about configuring encryption support for the administrative interface, see [Administrative Interface Support for Encrypted Connections](#).

- `admin_tls_ciphersuites`

Command-Line Format	<code>--admin-tls-ciphersuites=ciphersuite_list</code>
System Variable	<code>admin_tls_ciphersuites</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>NULL</code>

The `admin_tls_ciphersuites` system variable is like `tls_ciphersuites`, except that it applies to the administrative connection interface rather than the main connection interface. For information about configuring encryption support for the administrative interface, see [Administrative Interface Support for Encrypted Connections](#).

- `admin_tls_version`

Command-Line Format	<code>--admin-tls-version=protocol_list</code>
System Variable	<code>admin_tls_version</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>TLSv1.2, TLSv1.3</code>

The `admin_tls_version` system variable is like `tls_version`, except that it applies to the administrative connection interface rather than the main connection interface. For information about configuring encryption support for the administrative interface, see [Administrative Interface Support for Encrypted Connections](#).

Important

- Support for the TLSv1 and TLSv1.1 connection protocols was removed from MySQL in MySQL 8.0. See [Removal of Support for the TLSv1 and TLSv1.1 Protocols](#) for more information.
- MySQL 8.3 supports the TLSv1.3 protocol, provided that the MySQL server was compiled using OpenSSL 1.1.1 or newer. The server checks the version of OpenSSL at startup, and if it is older than 1.1.1, TLSv1.3 is removed from the default value for the system variable. In that case, the default is `TLSv1.2`.

- `authentication_policy`

Command-Line Format	<code>--authentication-policy=value</code>
System Variable	<code>authentication_policy</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>*</code>

This variable is used to administer multifactor authentication (MFA) capabilities. It applies to the authentication factor-related clauses of `CREATE USER` and `ALTER USER` statements used to manage MySQL account definitions, where “factor” corresponds to an authentication method or plugin associated with an account:

- `authentication_policy` controls the number of authentication factors that accounts may have. That is, it controls which factors are required or permitted.
- `authentication_policy` also controls, for each factor, which plugins (or methods) are permitted.
- `authentication_policy`, in conjunction with `default_authentication_plugin`, determines the default authentication plugin for authentication specifications that do not name a plugin explicitly.

Because `authentication_policy` applies only when accounts are created or altered, changes to its value have no effect on existing user accounts.

**Note**

Although the `authentication_policy` system variable places certain constraints on the authentication-related clauses of `CREATE USER` and `ALTER USER` statements, a user who has the `AUTHENTICATION_POLICY_ADMIN` privilege is not subject to the constraints. (A warning does occur for statements that otherwise would not be permitted.)

The value of `authentication_policy` is a list of 1, 2, or 3 comma-separated elements. Each element present can be an authentication plugin name, an asterisk (*), empty, or missing. (Exception: Element 1 cannot be empty or missing.) In all cases, an element may be surrounded by whitespace characters and the entire list is enclosed in single quotes.

The type of value specified for element *N* in the list has implications for whether factor *N* must be present in account definitions, and which authentication plugins can be used:

- If element *N* is an authentication plugin name, an authentication method for factor *N* is required and must use the named plugin.

In addition, the plugin becomes the default plugin for factor *N* authentication methods that do not name a plugin explicitly. For details, see [The Default Authentication Plugin](#).

Authentication plugins that use internal credentials storage can only be specified for the first element and cannot repeat. For example, the following settings are not permitted:

- `authentication_policy = 'caching_sha2_password, sha256_password'`
- `authentication_policy = 'caching_sha2_password, authentication_webauthn, sha256_password'`
- If element *N* is an asterisk (*), an authentication method for factor *N* is required. It may use any authentication plugin that is valid for element *N* (as described later).
- If element *N* is empty, an authentication method for factor *N* is optional. If given, it may use any authentication plugin that is valid for element *N* (as described later).
- If element *N* is missing from the list (that is, there are fewer than *N*–1 commas in the value), an authentication method for factor *N* is forbidden. For example, a value of `'*'` permits only a single factor and thus enforces single-factor authentication (1FA) for new accounts created with `CREATE`

authentication_policy Value	Effective Policy
' * '	Permit only creating or altering accounts with one factor.
' * , * '	Permit only creating or altering accounts with two factors.
' * , * , * '	Permit only creating or altering accounts with three factors.
' * , '	Permit creating or altering accounts with one or two factors.
' * , , '	Permit creating or altering accounts with one, two, or three factors.

authentication_policy Value	Effective Policy
'*,*,'	Permit creating or altering accounts with two or three factors.
'*,auth_plugin'	Permit creating or altering accounts with two factors, where the first factor can be any authentication method, and the second factor must be the named plugin.
'auth_plugin*,'	Permit creating or altering accounts with two or three factors, where the first factor must be the named plugin.
'auth_plugin,'	Permit creating or altering accounts with one or two factors, where the first factor must be the named plugin.
'auth_plugin,auth_plugin,auth_plugin'	Permits creating or altering accounts with three factors, where the factors must use the named plugins.

- `authentication_windows_log_level`

Command-Line Format	<code>--authentication-windows-log-level=#</code>
System Variable	<code>authentication_windows_log_level</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	2
Minimum Value	0
Maximum Value	4

This variable is available only if the `authentication_windows` Windows authentication plugin is enabled and debugging code is enabled. See [Section 8.4.1.6, “Windows Pluggable Authentication”](#).

This variable sets the logging level for the Windows authentication plugin. The following table shows the permitted values.

Value	Description
0	No logging
1	Log only error messages
2	Log level 1 messages and warning messages
3	Log level 2 messages and information notes
4	Log level 3 messages and debug messages

- `authentication_windows_use_principal_name`

Command-Line Format	<code>--authentication-windows-use-principal-name[={OFF ON}]</code>
System Variable	<code>authentication_windows_use_principal_name</code>
Scope	Global
Dynamic	No

<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	ON

This variable is available only if the `authentication_windows` Windows authentication plugin is enabled. See [Section 8.4.1.6, “Windows Pluggable Authentication”](#).

A client that authenticates using the `InitSecurityContext()` function should provide a string identifying the service to which it connects (`targetName`). MySQL uses the principal name (UPN) of the account under which the server is running. The UPN has the form `user_id@computer_name` and need not be registered anywhere to be used. This UPN is sent by the server at the beginning of authentication handshake.

This variable controls whether the server sends the UPN in the initial challenge. By default, the variable is enabled. For security reasons, it can be disabled to avoid sending the server's account name to a client as cleartext. If the variable is disabled, the server always sends a `0x00` byte in the first challenge, the client does not specify `targetName`, and as a result, NTLM authentication is used.

If the server fails to obtain its UPN (which happens primarily in environments that do not support Kerberos authentication), the UPN is not sent by the server and NTLM authentication is used.

- `autocommit`

Command-Line Format	<code>--autocommit[={OFF ON}]</code>
System Variable	<code>autocommit</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	ON

The autocommit mode. If set to 1, all changes to a table take effect immediately. If set to 0, you must use `COMMIT` to accept a transaction or `ROLLBACK` to cancel it. If `autocommit` is 0 and you change it to 1, MySQL performs an automatic `COMMIT` of any open transaction. Another way to begin a transaction is to use a `START TRANSACTION` or `BEGIN` statement. See [Section 15.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Statements”](#).

By default, client connections begin with `autocommit` set to 1. To cause clients to begin with a default of 0, set the global `autocommit` value by starting the server with the `--autocommit=0` option. To set the variable using an option file, include these lines:

```
[mysqld]
autocommit=0
```

- `automatic_sp_privileges`

Command-Line Format	<code>--automatic-sp-privileges[={OFF ON}]</code>
System Variable	<code>automatic_sp_privileges</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean

Default Value	ON
---------------	----

When this variable has a value of 1 (the default), the server automatically grants the [EXECUTE](#) and [ALTER ROUTINE](#) privileges to the creator of a stored routine, if the user cannot already execute and alter or drop the routine. (The [ALTER ROUTINE](#) privilege is required to drop the routine.) The server also automatically drops those privileges from the creator when the routine is dropped. If [automatic_sp_privileges](#) is 0, the server does not automatically add or drop these privileges.

The creator of a routine is the account used to execute the [CREATE](#) statement for it. This might not be the same as the account named as the [DEFINER](#) in the routine definition.

If you start `mysqld` with `--skip-new`, [automatic_sp_privileges](#) is set to `OFF`.

See also [Section 27.2.2, “Stored Routines and MySQL Privileges”](#).

- [auto_generate_certs](#)

Command-Line Format	<code>--auto-generate-certs[={OFF ON}]</code>
System Variable	auto_generate_certs
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

This variable controls whether the server autogenerates SSL key and certificate files in the data directory, if they do not already exist.

At startup, the server automatically generates server-side and client-side SSL certificate and key files in the data directory if the [auto_generate_certs](#) system variable is enabled, no SSL options other than `--ssl` are specified, and the server-side SSL files are missing from the data directory. These files enable secure client connections using SSL; see [Section 8.3.1, “Configuring MySQL to Use Encrypted Connections”](#).

For more information about SSL file autogeneration, including file names and characteristics, see [Section 8.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#)

The [sha256_password_auto_generate_rsa_keys](#) and [caching_sha2_password_auto_generate_rsa_keys](#) system variables are related but control autogeneration of RSA key-pair files needed for secure password exchange using RSA over unencrypted connections.

- [avoid_temporal_upgrade](#)

Command-Line Format	<code>--avoid-temporal-upgrade[={OFF ON}]</code>
Deprecated	Yes
System Variable	avoid_temporal_upgrade
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean

Default Value	OFF
---------------	-----

This variable controls whether [ALTER TABLE](#) implicitly upgrades temporal columns found to be in pre-5.6.4 format ([TIME](#), [DATETIME](#), and [TIMESTAMP](#) columns without support for fractional seconds precision). Upgrading such columns requires a table rebuild, which prevents any use of fast alterations that might otherwise apply to the operation to be performed.

This variable is disabled by default. Enabling it causes [ALTER TABLE](#) not to rebuild temporal columns and thereby be able to take advantage of possible fast alterations.

This variable is deprecated; expect it to be removed in a future MySQL release.

- [back_log](#)

Command-Line Format	<code>--back-log=#</code>
System Variable	back_log
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	-1 (signifies autosizing; do not assign this literal value)
Minimum Value	1
Maximum Value	65535

The number of outstanding connection requests MySQL can have. This comes into play when the main MySQL thread gets very many connection requests in a very short time. It then takes some time (although very little) for the main thread to check the connection and start a new thread. The [back_log](#) value indicates how many requests can be stacked during this short time before MySQL momentarily stops answering new requests. You need to increase this only if you expect a large number of connections in a short period of time.

In other words, this value is the size of the listen queue for incoming TCP/IP connections. Your operating system has its own limit on the size of this queue. The manual page for the Unix [listen\(\)](#) system call should have more details. Check your OS documentation for the maximum value for this variable. [back_log](#) cannot be set higher than your operating system limit.

The default value is the value of [max_connections](#), which enables the permitted backlog to adjust to the maximum permitted number of connections.

- [basedir](#)

Command-Line Format	<code>--basedir=dir_name</code>
System Variable	basedir
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name
Default Value	parent of mysqld installation directory

The path to the MySQL installation base directory.

- [big_tables](#)

Command-Line Format	<code>--big-tables[={OFF ON}]</code>
System Variable	<code>big_tables</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

If enabled, the server stores all temporary tables on disk rather than in memory. This prevents most `The table tbl_name is full` errors for `SELECT` operations that require a large temporary table, but also slows down queries for which in-memory tables would suffice.

The default value for new connections is `OFF` (use in-memory temporary tables). Normally, it should never be necessary to enable this variable. When in-memory *internal* temporary tables are managed by the `TempTable` storage engine (the default), and the maximum amount of memory that can be occupied by the `TempTable` storage engine is exceeded, the `TempTable` storage engine starts storing data to temporary files on disk. When in-memory temporary tables are managed by the `MEMORY` storage engine, in-memory tables are automatically converted to disk-based tables as required. For more information, see [Section 10.4.4, “Internal Temporary Table Use in MySQL”](#).

- `bind_address`

Command-Line Format	<code>--bind-address=addr</code>
System Variable	<code>bind_address</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>*</code>

The MySQL server listens on one or more network sockets for TCP/IP connections. Each socket is bound to one address, but it is possible for an address to map onto multiple network interfaces. To specify how the server should listen for TCP/IP connections, set the `bind_address` system variable at server startup. The server also has an `admin_address` system variable that enables administrative connections on a dedicated interface. See [Section 7.1.12.1, “Connection Interfaces”](#).

If `bind_address` is specified, it accepts a list of one or more address values, each of which may specify a single non-wildcard IP address or host name. Each address may include a network namespace specifier. If only one address is specified, it may make use of one of the wildcard address formats that permit listening on multiple network interfaces (`*`, `0.0.0.0`, or `::`). Multiple addresses are separated by commas. When multiple values are listed, each value must specify a single non-wildcard IP address (either IPv4 or IPv6) or a host name, and wildcard address formats (`*`, `0.0.0.0`, or `::`) are not allowed.

IP addresses can be specified as IPv4 or IPv6 addresses. For any value that is a host name, the server resolves the name to an IP address and binds to that address. If a host name resolves to

multiple IP addresses, the server uses the first IPv4 address if there are any, or the first IPv6 address otherwise.

The server treats different types of addresses as follows:

- If the address is `*`, the server accepts TCP/IP connections on all server host IPv4 interfaces, and, if the server host supports IPv6, on all IPv6 interfaces. Use this address to permit both IPv4 and IPv6 connections on all server interfaces. This value is the default. If the variable specifies a list of multiple values, this value is not permitted.
- If the address is `0.0.0.0`, the server accepts TCP/IP connections on all server host IPv4 interfaces. If the variable specifies a list of multiple values, this value is not permitted.
- If the address is `::`, the server accepts TCP/IP connections on all server host IPv4 and IPv6 interfaces. If the variable specifies a list of multiple values, this value is not permitted.
- If the address is an IPv4-mapped address, the server accepts TCP/IP connections for that address, in either IPv4 or IPv6 format. For example, if the server is bound to `::ffff:127.0.0.1`, clients can connect using `--host=127.0.0.1` or `--host>::ffff:127.0.0.1`.
- If the address is a “regular” IPv4 or IPv6 address (such as `127.0.0.1` or `:::1`), the server accepts TCP/IP connections only for that IPv4 or IPv6 address.

These rules apply to specifying a network namespace for an address:

- A network namespace can be specified for an IP address or a host name.
- A network namespace cannot be specified for a wildcard IP address.
- For a given address, the network namespace is optional. If given, it must be specified as a `/ns` suffix immediately following the address.
- An address with no `/ns` suffix uses the host system global namespace. The global namespace is therefore the default.
- An address with a `/ns` suffix uses the namespace named `ns`.
- The host system must support network namespaces and each named namespace must previously have been set up. Naming a nonexistent namespace produces an error.
- If the variable value specifies multiple addresses, it can include addresses in the global namespace, in named namespaces, or a mix.

For additional information about network namespaces, see [Section 7.1.14, “Network Namespace Support”](#).

If binding to any address fails, the server produces an error and does not start.

Examples:

- `bind_address=*`

The server listens on all IPv4 or IPv6 addresses, as specified by the `*` wildcard.

- `bind_address=198.51.100.20`

The server listens only on the `198.51.100.20` IPv4 address.

- `bind_address=198.51.100.20,2001:db8:0:f101::1`

The server listens on the `198.51.100.20` IPv4 address and the `2001:db8:0:f101::1` IPv6 address.

- `bind_address=198.51.100.20,*`

This produces an error because wildcard addresses are not permitted when `bind_address` names a list of multiple values.

- `bind_address=198.51.100.20/red,2001:db8:0:f101::1/blue,192.0.2.50`

The server listens on the `198.51.100.20` IPv4 address in the `red` namespace, the `2001:db8:0:f101::1` IPv6 address in the `blue` namespace, and the `192.0.2.50` IPv4 address in the global namespace.

When `bind_address` names a single value (wildcard or non-wildcard), the server listens on a single socket, which for a wildcard address may be bound to multiple network interfaces. When `bind_address` names a list of multiple values, the server listens on one socket per value, with each socket bound to a single network interface. The number of sockets is linear with the number of values specified. Depending on operating system connection-acceptance efficiency, long value lists might incur a performance penalty for accepting TCP/IP connections.

Because file descriptors are allocated for listening sockets and network namespace files, it may be necessary to increase the `open_files_limit` system variable.

If you intend to bind the server to a specific address, be sure that the `mysql.user` system table contains an account with administrative privileges that you can use to connect to that address. Otherwise, you cannot shut down the server. For example, if you bind the server to `*`, you can connect to it using all existing accounts. But if you bind the server to `::1`, it accepts connections only on that address. In that case, first make sure that the `'root'@'::1'` account is present in the `mysql.user` table so you can still connect to the server to shut it down.

- `block_encryption_mode`

Command-Line Format	<code>--block-encryption-mode=#</code>
System Variable	<code>block_encryption_mode</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>aes-128-ecb</code>

This variable controls the block encryption mode for block-based algorithms such as AES. It affects encryption for `AES_ENCRYPT()` and `AES_DECRYPT()`.

`block_encryption_mode` takes a value in `aes-keylen-mode` format, where `keylen` is the key length in bits and `mode` is the encryption mode. The value is not case-sensitive. Permitted `keylen` values are 128, 192, and 256. Permitted `mode` values are `ECB`, `CBC`, `CFB1`, `CFB8`, `CFB128`, and `OFB`.

For example, this statement causes the AES encryption functions to use a key length of 256 bits and the CBC mode:

```
SET block_encryption_mode = 'aes-256-cbc';
```

An error occurs for attempts to set `block_encryption_mode` to a value containing an unsupported key length or a mode that the SSL library does not support.

- `build_id`

System Variable	<code>build_id</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Platform Specific	Linux

This is a 160-bit [SHA1](#) signature which is generated by the linker when compiling the server on Linux systems with `-DWITH_BUILD_ID=ON` (enabled by default), and converted to a hexadecimal string. This read-only value serves as a unique build ID, and is written into the server log at startup.

`build_id` is not supported on platforms other than Linux.

- `bulk_insert_buffer_size`

Command-Line Format	<code>--bulk-insert-buffer-size=#</code>
System Variable	<code>bulk_insert_buffer_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	8388608
Minimum Value	0
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295
Unit	bytes/thread

[MyISAM](#) uses a special tree-like cache to make bulk inserts faster for `INSERT ... SELECT`, `INSERT ... VALUES (...), (...), ...`, and `LOAD DATA` when adding data to nonempty tables. This variable limits the size of the cache tree in bytes per thread. Setting it to 0 disables this optimization. The default value is 8MB.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

- `caching_sha2_password_digest_rounds`

Command-Line Format	<code>--caching-sha2-password-digest-rounds=#</code>
System Variable	<code>caching_sha2_password_digest_rounds</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	5000
Minimum Value	5000

Maximum Value	4095000
---------------	---------

The number of hash rounds used by the `caching_sha2_password` authentication plugin for password storage.

Increasing the number of hashing rounds above the default value incurs a performance penalty that correlates with the amount of increase:

- Creating an account that uses the `caching_sha2_password` plugin has no impact on the client session within which the account is created, but the server must perform the hashing rounds to complete the operation.
- For client connections that use the account, the server must perform the hashing rounds and save the result in the cache. The result is longer login time for the first client connection, but not for subsequent connections. This behavior occurs after each server restart.
- `caching_sha2_password_auto_generate_rsa_keys`

Command-Line Format	<code>--caching-sha2-password-auto-generate-rsa-keys[={OFF ON}]</code>
System Variable	<code>caching_sha2_password_auto_generate_rsa_key</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	ON

The server uses this variable to determine whether to autogenerate RSA private/public key-pair files in the data directory if they do not already exist.

At startup, the server automatically generates RSA private/public key-pair files in the data directory if all of these conditions are true: The `sha256_password_auto_generate_rsa_keys` or `caching_sha2_password_auto_generate_rsa_keys` system variable is enabled; no RSA options are specified; the RSA files are missing from the data directory. These key-pair files enable secure password exchange using RSA over unencrypted connections for accounts authenticated by the `sha256_password` or `caching_sha2_password` plugin; see [Section 8.4.1.3, “SHA-256 Pluggable Authentication”](#), and [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

For more information about RSA file autogeneration, including file names and characteristics, see [Section 8.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#)

The `auto_generate_certs` system variable is related but controls autogeneration of SSL certificate and key files needed for secure connections using SSL.

- `caching_sha2_password_private_key_path`

Command-Line Format	<code>--caching-sha2-password-private-key-path=file_name</code>
System Variable	<code>caching_sha2_password_private_key_path</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	File name

Default Value	<code>private_key.pem</code>
---------------	------------------------------

This variable specifies the path name of the RSA private key file for the `caching_sha2_password` authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format.

Important

Because this file stores a private key, its access mode should be restricted so that only the MySQL server can read it.

For information about `caching_sha2_password`, see [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

- `caching_sha2_password_public_key_path`

Command-Line Format	<code>--caching-sha2-password-public-key-path=file_name</code>
System Variable	<code>caching_sha2_password_public_key_path</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	File name
Default Value	<code>public_key.pem</code>

This variable specifies the path name of the RSA public key file for the `caching_sha2_password` authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format.

For information about `caching_sha2_password`, including information about how clients request the RSA public key, see [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

- `character_set_client`

System Variable	<code>character_set_client</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>utf8mb4</code>

The character set for statements that arrive from the client. The session value of this variable is set using the character set requested by the client when the client connects to the server. (Many clients support a `--default-character-set` option to enable this character set to be specified explicitly. See also [Section 12.4, “Connection Character Sets and Collations”](#).) The global value of the variable is used to set the session value in cases when the client-requested value is unknown or not available, or the server is configured to ignore client requests. This can happen when the client requests a character set not known to the server, such as when a Japanese-enabled client requests `sjis` when connecting to a server not configured with `sjis` support.

Some character sets cannot be used as the client character set. Attempting to use them as the `character_set_client` value produces an error. See [Impermissible Client Character Sets](#).

- `character_set_connection`

System Variable	<code>character_set_connection</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>utf8mb4</code>

The character set used for literals specified without a character set introducer and for number-to-string conversion. For information about introducers, see [Section 12.3.8, “Character Set Introducers”](#).

- `character_set_database`

System Variable	<code>character_set_database</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>utf8mb4</code>
Footnote	This option is dynamic, but should be set only by server. You should not set this variable manually.

The character set used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `character_set_server`.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

The global `character_set_database` and `collation_database` system variables are deprecated; expect them to be removed in a future version of MySQL.

Assigning a value to the session `character_set_database` and `collation_database` system variables is deprecated and assignments produce a warning. Expect the session variables to become read-only (and assignments to them to produce an error) in a future version of MySQL in which it remains possible to access the session variables to determine the database character set and collation for the default database.

- `character_set_filesystem`

Command-Line Format	<code>--character-set-filesystem=name</code>
System Variable	<code>character_set_filesystem</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>binary</code>

The file system character set. This variable is used to interpret string literals that refer to file names, such as in the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements and the

`LOAD_FILE()` function. Such file names are converted from `character_set_client` to `character_set_filesystem` before the file opening attempt occurs. The default value is `binary`, which means that no conversion occurs. For systems on which multibyte file names are permitted, a different value may be more appropriate. For example, if the system represents file names using UTF-8, set `character_set_filesystem` to `'utf8mb4'`.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

- `character_set_results`

System Variable	<code>character_set_results</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>utf8mb4</code>

The character set used for returning query results to the client. This includes result data such as column values, result metadata such as column names, and error messages.

- `character_set_server`

Command-Line Format	<code>--character-set-server=name</code>
System Variable	<code>character_set_server</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>utf8mb4</code>

The servers default character set. See [Section 12.15, “Character Set Configuration”](#). If you set this variable, you should also set `collation_server` to specify the collation for the character set.

- `character_set_system`

System Variable	<code>character_set_system</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>utf8mb3</code>

The character set used by the server for storing identifiers. The value is always `utf8mb3`.

- `character_sets_dir`

Command-Line Format	<code>--character-sets-dir=dir_name</code>
System Variable	<code>character_sets_dir</code>
Scope	Global
Dynamic	No

SET_VAR Hint Applies	No
Type	Directory name

The directory where character sets are installed. See [Section 12.15, “Character Set Configuration”](#).

- [check_proxy_users](#)

Command-Line Format	<code>--check-proxy-users[={OFF ON}]</code>
System Variable	check_proxy_users
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Some authentication plugins implement proxy user mapping for themselves (for example, the PAM and Windows authentication plugins). Other authentication plugins do not support proxy users by default. Of these, some can request that the MySQL server itself map proxy users according to granted proxy privileges: [mysql_native_password](#), [sha256_password](#).

If the [check_proxy_users](#) system variable is enabled, the server performs proxy user mapping for any authentication plugins that make such a request. However, it may also be necessary to enable plugin-specific system variables to take advantage of server proxy user mapping support:

- For the deprecated [mysql_native_password](#) plugin, enable [mysql_native_password_proxy_users](#).
- For the [sha256_password](#) plugin, enable [sha256_password_proxy_users](#).

For information about user proxying, see [Section 8.2.19, “Proxy Users”](#).

- [collation_connection](#)

System Variable	collation_connection
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

The collation of the connection character set. [collation_connection](#) is important for comparisons of literal strings. For comparisons of strings with column values, [collation_connection](#) does not matter because columns have their own collation, which has a higher collation precedence (see [Section 12.8.4, “Collation Coercibility in Expressions”](#)).

Using the name of a user-defined collation for this variable raises a warning.

- [collation_database](#)

System Variable	collation_database
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

Default Value	<code>utf8mb4_0900_ai_ci</code>
Footnote	This option is dynamic, but should be set only by server. You should not set this variable manually.

The collation used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `collation_server`.

The global `character_set_database` and `collation_database` system variables are deprecated; expect them to be removed in a future version of MySQL.

Assigning a value to the session `character_set_database` and `collation_database` system variables is deprecated and assignments produce a warning. Expect the session variables to become read-only (and assignments to produce an error) in a future version of MySQL in which it remains possible to access the session variables to determine the database character set and collation for the default database.

Using the name of a user-defined collation for `collation_database` raises a warning.

- `collation_server`

Command-Line Format	<code>--collation-server=name</code>
System Variable	<code>collation_server</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>utf8mb4_0900_ai_ci</code>

The server's default collation. See [Section 12.15, “Character Set Configuration”](#).

Setting this to the name of a user-defined collation raises a warning.

- `completion_type`

Command-Line Format	<code>--completion-type=#</code>
System Variable	<code>completion_type</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>NO_CHAIN</code>
Valid Values	<code>NO_CHAIN</code> <code>CHAIN</code> <code>RELEASE</code> <code>0</code> <code>1</code>

The transaction completion type. This variable can take the values shown in the following table. The variable can be assigned using either the name values or corresponding integer values.

Value	Description
<code>NO_CHAIN</code> (or 0)	<code>COMMIT</code> and <code>ROLLBACK</code> are unaffected. This is the default value.
<code>CHAIN</code> (or 1)	<code>COMMIT</code> and <code>ROLLBACK</code> are equivalent to <code>COMMIT AND CHAIN</code> and <code>ROLLBACK AND CHAIN</code> , respectively. (A new transaction starts immediately with the same isolation level as the just-terminated transaction.)
<code>RELEASE</code> (or 2)	<code>COMMIT</code> and <code>ROLLBACK</code> are equivalent to <code>COMMIT RELEASE</code> and <code>ROLLBACK RELEASE</code> , respectively. (The server disconnects after terminating the transaction.)

`completion_type` affects transactions that begin with `START TRANSACTION` or `BEGIN` and end with `COMMIT` or `ROLLBACK`. It does not apply to implicit commits resulting from execution of the statements listed in [Section 15.3.3, “Statements That Cause an Implicit Commit”](#). It also does not apply for `XA COMMIT`, `XA ROLLBACK`, or when `autocommit=1`.

- `component_scheduler.enabled`

Command-Line Format	<code>--component-scheduler.enabled[=value]</code>
System Variable	<code>component_scheduler.enabled</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

When set to `OFF` at startup, the background thread does not start. Tasks can still be scheduled, but they do not run until `component_scheduler` is enabled. When set to `ON` at startup, the component is fully operational.

It is also possible to set the value dynamically to get the following effects:

- `ON` starts the background thread that begins servicing the queue immediately.
- `OFF` signals a termination of the background thread, which waits for it to end. The background thread checks the termination flag before accessing the queue to check for tasks to execute.
- `concurrent_insert`

Command-Line Format	<code>--concurrent-insert[=value]</code>
System Variable	<code>concurrent_insert</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No

Type	Enumeration
Default Value	AUTO
Valid Values	NEVER AUTO ALWAYS 0 1 2

If [AUTO](#) (the default), MySQL permits [INSERT](#) and [SELECT](#) statements to run concurrently for [MyISAM](#) tables that have no free blocks in the middle of the data file.

This variable can take the values shown in the following table. The variable can be assigned using either the name values or corresponding integer values.

Value	Description
NEVER (or 0)	Disables concurrent inserts
AUTO (or 1)	(Default) Enables concurrent insert for MyISAM tables that do not have holes
ALWAYS (or 2)	Enables concurrent inserts for all MyISAM tables, even those that have holes. For a table with a hole, new rows are inserted at the end of the table if it is in use by another thread. Otherwise, MySQL acquires a normal write lock and inserts the row into the hole.

If you start `mysqld` with `--skip-new`, `concurrent_insert` is set to [NEVER](#).

See also [Section 10.11.3, “Concurrent Inserts”](#).

- [connect_timeout](#)

Command-Line Format	<code>--connect-timeout=#</code>
System Variable	connect_timeout
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	10
Minimum Value	2
Maximum Value	31536000
Unit	seconds

The number of seconds that the `mysqld` server waits for a connect packet before responding with [Bad handshake](#). The default value is 10 seconds.

Increasing the `connect_timeout` value might help if clients frequently encounter errors of the form [Lost connection to MySQL server at 'XXX', system error: errno](#).

- `connection_memory_chunk_size`

Command-Line Format	<code>--connection-memory-chunk-size=#</code>
System Variable	<code>connection_memory_chunk_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	8192
Minimum Value	0
Maximum Value	536870912
Unit	bytes

Set the chunking size for updates to the global memory usage counter `Global_connection_memory`. The status variable is updated only when total memory consumption by all user connections changes by more than this amount. Disable updates by setting `connection_memory_chunk_size = 0`.

The memory calculation is exclusive of any memory used by system users such as the MySQL root user. Memory used by the `InnoDB` buffer pool is also not included.

You must have the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege to set this variable.

- `connection_memory_limit`

Command-Line Format	<code>--connection-memory-limit=#</code>
System Variable	<code>connection_memory_limit</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	18446744073709551615
Minimum Value	2097152
Maximum Value	18446744073709551615
Unit	bytes

Set the maximum amount of memory that can be used by a single user connection. If any user connection uses more than this amount, all queries from this connection are rejected with `ER_CONN_LIMIT`, including any queries currently running.

The limit set by this variable does not apply to system users, or to the MySQL root account. Memory used by the `InnoDB` buffer pool is also not included.

You must have the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege to set this variable.

- `core_file`

System Variable	<code>core_file</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No

Type	Boolean
Default Value	<code>OFF</code>

Whether to write a core file if the server unexpectedly exits. This variable is set by the `--core-file` option.

- `create_admin_listener_thread`

Command-Line Format	<code>--create-admin-listener-thread[={OFF ON}]</code>
System Variable	<code>create_admin_listener_thread</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Whether to use a dedicated listening thread for client connections on the administrative network interface (see [Section 7.1.12.1, “Connection Interfaces”](#)). The default is `OFF`; that is, the manager thread for ordinary connections on the main interface also handles connections for the administrative interface.

Depending on factors such as platform type and workload, you may find one setting for this variable yields better performance than the other setting.

Setting `create_admin_listener_thread` has no effect if `admin_address` is not specified because in that case the server maintains no administrative network interface.

- `cte_max_recursion_depth`

Command-Line Format	<code>--cte-max-recursion-depth=#</code>
System Variable	<code>cte_max_recursion_depth</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>1000</code>
Minimum Value	<code>0</code>
Maximum Value	<code>4294967295</code>

The common table expression (CTE) maximum recursion depth. The server terminates execution of any CTE that recurses more levels than the value of this variable. For more information, see [Limiting Common Table Expression Recursion](#).

- `datadir`

Command-Line Format	<code>--datadir=dir_name</code>
System Variable	<code>datadir</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No

Type	Directory name
------	----------------

The path to the MySQL server data directory. Relative paths are resolved with respect to the current directory. If you expect the server to be started automatically (that is, in contexts for which you cannot know the current directory in advance), it is best to specify the `datadir` value as an absolute path.

- `debug`

Command-Line Format	<code>--debug[=debug_options]</code>
System Variable	<code>debug</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value (Unix)	<code>d:t:i:o,/tmp/mysqld.trace</code>
Default Value (Windows)	<code>d:t:i:0,\mysqld.trace</code>

This variable indicates the current debugging settings. It is available only for servers built with debugging support. The initial value comes from the value of instances of the `--debug` option given at server startup. The global and session values may be set at runtime.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

Assigning a value that begins with `+` or `-` cause the value to added to or subtracted from the current value:

```
mysql> SET debug = 'T';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| T       |
+-----+

mysql> SET debug = '+P';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| P:T     |
+-----+

mysql> SET debug = '-P';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| T       |
+-----+
```

For more information, see [Section 7.9.4, “The DEBUG Package”](#).

- `debug_sync`

System Variable	<code>debug_sync</code>
Scope	Session
Dynamic	Yes

<code>SET_VAR</code> Hint Applies	No
Type	String

This variable is the user interface to the Debug Sync facility. Use of Debug Sync requires that MySQL be configured with the `-DWITH_DEBUG=ON` CMake option (see [Section 2.8.7, “MySQL Source-Configuration Options”](#)); otherwise, this system variable is not available.

The global variable value is read only and indicates whether the facility is enabled. By default, Debug Sync is disabled and the value of `debug_sync` is `OFF`. If the server is started with `--debug-sync-timeout=N`, where *N* is a timeout value greater than 0, Debug Sync is enabled and the value of `debug_sync` is `ON - current signal` followed by the signal name. Also, *N* becomes the default timeout for individual synchronization points.

The session value can be read by any user and has the same value as the global variable. The session value can be set to control synchronization points.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

For a description of the Debug Sync facility and how to use synchronization points, see [MySQL Internals: Test Synchronization](#).

- `default_authentication_plugin`

Command-Line Format	<code>--default-authentication-plugin=plugin_name</code>
Deprecated	Yes
System Variable	<code>default_authentication_plugin</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>caching_sha2_password</code>
Valid Values	<code>mysql_native_password</code> <code>sha256_password</code> <code>caching_sha2_password</code>

The default authentication plugin. This must be a plugin that uses internal credentials storage, so these values are permitted:

- `mysql_native_password` (deprecated): Use MySQL native passwords; see [Section 8.4.1.1, “Native Pluggable Authentication”](#).
- `sha256_password`: Use SHA-256 passwords; see [Section 8.4.1.3, “SHA-256 Pluggable Authentication”](#).

- `caching_sha2_password`: Use SHA-256 passwords; see [Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”](#).

For information about which authentication plugins use internal credentials storage, see [Section 8.2.15, “Password Management”](#).

`default_authentication_plugin` is used in conjunction with but at a lower precedence than the `authentication_policy` system variable. For details, see [The Default Authentication Plugin](#). `default_authentication_plugin` is deprecated, and subject to removal in a future MySQL version.

- `default_collation_for_utf8mb4`

System Variable	<code>default_collation_for_utf8mb4</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Valid Values	<code>utf8mb4_0900_ai_ci</code> <code>utf8mb4_general_ci</code>

Important

The `default_collation_for_utf8mb4` system variable is for internal use by MySQL Replication only.

This variable is set by the server to the default collation for the `utf8mb4` character set. The value of the variable is replicated from a source to a replica so that the replica can correctly process data originating from a source with a different default collation for `utf8mb4`. This variable is primarily intended to support replication from a MySQL 5.7 or older replication source server to a later MySQL replica server, or group replication with a MySQL 5.7 primary node and one or more MySQL 8.0 or later secondaries. The default collation for `utf8mb4` in MySQL 5.7 is `utf8mb4_general_ci`, but `utf8mb4_0900_ai_ci` in later release series. The variable is not present in releases earlier than MySQL 8.0, so if the replica does not receive a value for the variable, it assumes the source is from an earlier release and sets the value to the previous default collation `utf8mb4_general_ci`.

The default `utf8mb4` collation is used in the following statements:

- `SHOW COLLATION` and `SHOW CHARACTER SET`.
- `CREATE TABLE` and `ALTER TABLE` having a `CHARACTER SET utf8mb4` clause without a `COLLATION` clause, either for the table character set or for a column character set.
- `CREATE DATABASE` and `ALTER DATABASE` having a `CHARACTER SET utf8mb4` clause without a `COLLATION` clause.
- Any statement containing a string literal of the form `_utf8mb4'some text'` without a `COLLATE` clause.

See also [Section 12.9, “Unicode Support”](#).

- `default_password_lifetime`

Command-Line Format	<code>--default-password-lifetime=#</code>
System Variable	<code>default_password_lifetime</code>

Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	65535
Unit	days

This variable defines the global automatic password expiration policy. The default [default_password_lifetime](#) value is 0, which disables automatic password expiration. If the value of [default_password_lifetime](#) is a positive integer *N*, it indicates the permitted password lifetime; passwords must be changed every *N* days.

The global password expiration policy can be overridden as desired for individual accounts using the password expiration option of the [CREATE USER](#) and [ALTER USER](#) statements. See [Section 8.2.15, “Password Management”](#).

- [default_storage_engine](#)

Command-Line Format	--default-storage-engine=name
System Variable	default_storage_engine
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	InnoDB

The default storage engine for tables. See [Chapter 18, Alternative Storage Engines](#). This variable sets the storage engine for permanent tables only. To set the storage engine for [TEMPORARY](#) tables, set the [default_tmp_storage_engine](#) system variable.

To see which storage engines are available and enabled, use the [SHOW ENGINES](#) statement or query the [INFORMATION_SCHEMA ENGINES](#) table.

If you disable the default storage engine at server startup, you must set the default engine for both permanent and [TEMPORARY](#) tables to a different engine, or else the server does not start.

- [default_table_encryption](#)

Command-Line Format	--default-table-encryption[={OFF ON}]
System Variable	default_table_encryption
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Boolean

Default Value	OFF
---------------	-----

Defines the default encryption setting applied to schemas and general tablespaces when they are created without specifying an `ENCRYPTION` clause.

The `default_table_encryption` variable is only applicable to user-created schemas and general tablespaces. It does not govern encryption of the `mysql` system tablespace.

Setting the runtime value of `default_table_encryption` requires the `SYSTEM_VARIABLES_ADMIN` and `TABLE_ENCRYPTION_ADMIN` privileges, or the deprecated `SUPER` privilege.

`default_table_encryption` supports `SET PERSIST` and `SET PERSIST_ONLY` syntax. See [Section 7.1.9.3, “Persisted System Variables”](#).

For more information, see [Defining an Encryption Default for Schemas and General Tablespaces](#).

- `default_tmp_storage_engine`

Command-Line Format	<code>--default-tmp-storage-engine=name</code>
System Variable	<code>default_tmp_storage_engine</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Enumeration
Default Value	InnoDB

The default storage engine for `TEMPORARY` tables (created with `CREATE TEMPORARY TABLE`). To set the storage engine for permanent tables, set the `default_storage_engine` system variable. Also see the discussion of that variable regarding possible values.

If you disable the default storage engine at server startup, you must set the default engine for both permanent and `TEMPORARY` tables to a different engine, or else the server does not start.

- `default_week_format`

Command-Line Format	<code>--default-week-format=#</code>
System Variable	<code>default_week_format</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	7

The default mode value to use for the `WEEK()` function. See [Section 14.7, “Date and Time Functions”](#).

- `delay_key_write`

Command-Line Format	<code>--delay-key-write[={OFF ON ALL}]</code>
System Variable	<code>delay_key_write</code>

Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	ON
Valid Values	OFF ON ALL

This variable specifies how to use delayed key writes. It applies only to [MyISAM](#) tables. Delayed key writing causes key buffers not to be flushed between writes. See also [Section 18.2.1, “MyISAM Startup Options”](#).

This variable can have one of the following values to affect handling of the [DELAY_KEY_WRITE](#) table option that can be used in [CREATE TABLE](#) statements.

Option	Description
OFF	DELAY_KEY_WRITE is ignored.
ON	MySQL honors any DELAY_KEY_WRITE option specified in CREATE TABLE statements. This is the default value.
ALL	All new opened tables are treated as if they were created with the DELAY_KEY_WRITE option enabled.

Note

If you set this variable to [ALL](#), you should not use [MyISAM](#) tables from within another program (such as another MySQL server or [myisamchk](#)) when the tables are in use. Doing so leads to index corruption.

If [DELAY_KEY_WRITE](#) is enabled for a table, the key buffer is not flushed for the table on every index update, but only when the table is closed. This speeds up writes on keys a lot, but if you use this feature, you should add automatic checking of all [MyISAM](#) tables by starting the server with the [myisam_recover_options](#) system variable set (for example, [myisam_recover_options='BACKUP,FORCE'](#)). See [Section 7.1.8, “Server System Variables”](#), and [Section 18.2.1, “MyISAM Startup Options”](#).

If you start [mysqld](#) with [--skip-new](#), [delay_key_write](#) is set to [OFF](#).

Warning

If you enable external locking with [--external-locking](#), there is no protection against index corruption for tables that use delayed key writes.

- [delayed_insert_limit](#)

Command-Line Format	--delayed-insert-limit=#
Deprecated	Yes
System Variable	delayed_insert_limit
Scope	Global
Dynamic	Yes

SET_VAR Hint Applies	No
Type	Integer
Default Value	100
Minimum Value	1
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

This system variable is deprecated (because [DELAYED](#) inserts are not supported), and you should expect it to be removed in a future release.

- [delayed_insert_timeout](#)

Command-Line Format	--delayed-insert-timeout=#
Deprecated	Yes
System Variable	delayed_insert_timeout
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	300
Minimum Value	1
Maximum Value	31536000
Unit	seconds

This system variable is deprecated (because [DELAYED](#) inserts are not supported), and you should expect it to be removed in a future release.

- [delayed_queue_size](#)

Command-Line Format	--delayed-queue-size=#
Deprecated	Yes
System Variable	delayed_queue_size
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1000
Minimum Value	1
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

This system variable is deprecated (because [DELAYED](#) inserts are not supported), and you should expect it to be removed in a future release.

- [disabled_storage_engines](#)

Command-Line Format	--disabled-storage-engines=engine[,engine]...
---------------------	---

System Variable	<code>disabled_storage_engines</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>empty string</code>

This variable indicates which storage engines cannot be used to create tables or tablespaces. For example, to prevent new `MyISAM` or `FEDERATED` tables from being created, start the server with these lines in the server option file:

```
[mysqld]
disabled_storage_engines="MyISAM,FEDERATED"
```

By default, `disabled_storage_engines` is empty (no engines disabled), but it can be set to a comma-separated list of one or more engines (not case-sensitive). Any engine named in the value cannot be used to create tables or tablespaces with `CREATE TABLE` or `CREATE TABLESPACE`, and cannot be used with `ALTER TABLE ... ENGINE` or `ALTER TABLESPACE ... ENGINE` to change the storage engine of existing tables or tablespaces. Attempts to do so result in an `ER_DISABLED_STORAGE_ENGINE` error.

`disabled_storage_engines` does not restrict other DDL statements for existing tables, such as `CREATE INDEX`, `TRUNCATE TABLE`, `ANALYZE TABLE`, `DROP TABLE`, or `DROP TABLESPACE`. This permits a smooth transition so that existing tables or tablespaces that use a disabled engine can be migrated to a permitted engine by means such as `ALTER TABLE ... ENGINE permitted_engine`.

It is permitted to set the `default_storage_engine` or `default_tmp_storage_engine` system variable to a storage engine that is disabled. This could cause applications to behave erratically or fail, although that might be a useful technique in a development environment for identifying applications that use disabled engines, so that they can be modified.

`disabled_storage_engines` is disabled and has no effect if the server is started with any of these options: `--initialize`, `--initialize-insecure`, `--skip-grant-tables`.

Note

Setting `disabled_storage_engines` might cause an issue with `mysql_upgrade`. For details, see [Section 6.4.5, “mysql_upgrade — Deprecated; Performs No Tasks and Exits with Status 0”](#).

- `disconnect_on_expired_password`

Command-Line Format	<code>--disconnect-on-expired-password[={OFF ON}]</code>
System Variable	<code>disconnect_on_expired_password</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean

Default Value	ON
---------------	----

This variable controls how the server handles clients with expired passwords:

- If the client indicates that it can handle expired passwords, the value of `disconnect_on_expired_password` is irrelevant. The server permits the client to connect but puts it in sandbox mode.
- If the client does not indicate that it can handle expired passwords, the server handles the client according to the value of `disconnect_on_expired_password`:
 - If `disconnect_on_expired_password` is enabled, the server disconnects the client.
 - If `disconnect_on_expired_password` is disabled, the server permits the client to connect but puts it in sandbox mode.

For more information about the interaction of client and server settings relating to expired-password handling, see [Section 8.2.16, “Server Handling of Expired Passwords”](#).

- `div_precision_increment`

Command-Line Format	<code>--div-precision-increment=#</code>
System Variable	<code>div_precision_increment</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	4
Minimum Value	0
Maximum Value	30

This variable indicates the number of digits by which to increase the scale of the result of division operations performed with the `/` operator. The default value is 4. The minimum and maximum values are 0 and 30, respectively. The following example illustrates the effect of increasing the default value.

```
mysql> SELECT 1/7;
+-----+
| 1/7    |
+-----+
| 0.1429 |
+-----+
mysql> SET div_precision_increment = 12;
mysql> SELECT 1/7;
+-----+
| 1/7    |
+-----+
| 0.142857142857 |
+-----+
```

- `dragnet.log_error_filter_rules`

Command-Line Format	<code>--dragnet.log-error-filter-rules=value</code>
System Variable	<code>dragnet.log_error_filter_rules</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No

Type	String
Default Value	<code>IF prio>=INFORMATION THEN drop. IF EXISTS source_line THEN unset source_line.</code>

The filter rules that control operation of the `log_filter_dragnet` error log filter component. If `log_filter_dragnet` is not installed, `dragnet.log_error_filter_rules` is unavailable. If `log_filter_dragnet` is installed but not enabled, changes to `dragnet.log_error_filter_rules` have no effect.

The effect of the default value is similar to the filtering performed by the `log_sink_internal` filter with a setting of `log_error_verbosity=2`.

`dragnet.Status` status variable can be consulted to determine the result of the most recent assignment to `dragnet.log_error_filter_rules`.

- `enterprise_encryption.maximum_rsa_key_size`

Command-Line Format	<code>--enterprise-encryption.maximum-rsa-key-size=#</code>
System Variable	<code>enterprise_encryption.maximum_rsa_key_size</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	4096
Minimum Value	2048
Maximum Value	16384

This variable limits the maximum size of RSA keys generated by MySQL Enterprise Encryption. The variable is available only if the MySQL Enterprise Encryption component `component_enterprise_encryption` is installed. The variable is not available if the `openssl_udf` shared library is used to provide MySQL Enterprise Encryption functions.

The lowest setting is 2048 bits, which is the minimum RSA key length that is acceptable by current best practice. The default setting is 4096 bits. The highest setting is 16384 bits. Generating longer keys can consume significant CPU resources, so you can use this setting to limit keys to a length that provides adequate security for your requirements while balancing this with resource usage. Note that the functions provided by the `openssl_udf` shared library allow key lengths starting at 1024 bits, and following an upgrade to the component, the minimum key length is greater than this. See [Section 8.6.2, “Configuring MySQL Enterprise Encryption”](#) for more information.

- `enterprise_encryption.rsa_support_legacy_padding`

Command-Line Format	<code>--enterprise-encryption.rsa_support_legacy_padding[={OFF ON}]</code>
System Variable	<code>enterprise_encryption.rsa_support_legacy_paddi</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	OFF

This variable controls whether encrypted data and signatures that MySQL Enterprise Encryption produced with the `openssl_udf` shared library functions used, can be decrypted or verified by the functions of the MySQL Enterprise Encryption component `component_enterprise_encryption`. The variable is available only if the MySQL Enterprise Encryption component is installed, and it is not available if the `openssl_udf` shared library is used to provide MySQL Enterprise Encryption functions.

For the component functions to support decryption and verification for content produced by the legacy `openssl_udf` shared library functions, you must set the system variable `padding` to `ON`. When `ON` is set, if the component functions cannot decrypt or verify content when assuming it has the RSAES-OAEP or RSASSA-PSS scheme (as used by the component), they make another attempt assuming it has the RSAES-PKCS1-v1_5 or RSASSA-PKCS1-v1_5 scheme (as used by the `openssl_udf` shared library functions). When `OFF` is set, if the component functions cannot decrypt or verify content using their normal schemes, they return null output. See [Section 8.6.2, “Configuring MySQL Enterprise Encryption”](#) for more information.

- `end_markers_in_json`

Command-Line Format	<code>--end-markers-in-json[={OFF ON}]</code>
System Variable	<code>end_markers_in_json</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Boolean
Default Value	<code>OFF</code>

Whether optimizer JSON output should add end markers. See [MySQL Internals: The `end_markers_in_json` System Variable](#).

- `eq_range_index_dive_limit`

Command-Line Format	<code>--eq-range-index-dive-limit=#</code>
System Variable	<code>eq_range_index_dive_limit</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	<code>200</code>
Minimum Value	<code>0</code>
Maximum Value	<code>4294967295</code>

This variable indicates the number of equality ranges in an equality comparison condition when the optimizer should switch from using index dives to index statistics in estimating the number of qualifying rows. It applies to evaluation of expressions that have either of these equivalent forms, where the optimizer uses a nonunique index to look up `col_name` values:

```
col_name IN(val1, ..., valN)
col_name = val1 OR ... OR col_name = valN
```

In both cases, the expression contains *N* equality ranges. The optimizer can make row estimates using index dives or index statistics. If `eq_range_index_dive_limit` is greater than 0, the optimizer uses existing index statistics instead of index dives if there are `eq_range_index_dive_limit` or more equality ranges. Thus, to permit use of index dives for up

to N equality ranges, set `eq_range_index_dive_limit` to $N + 1$. To disable use of index statistics and always use index dives regardless of N , set `eq_range_index_dive_limit` to 0.

For more information, see [Equality Range Optimization of Many-Valued Comparisons](#).

To update table index statistics for best estimates, use `ANALYZE TABLE`.

- `error_count`

The number of errors that resulted from the last statement that generated messages. This variable is read only. See [Section 15.7.7.18, “SHOW ERRORS Statement”](#).

- `event_scheduler`

Command-Line Format	<code>--event-scheduler[=value]</code>
System Variable	<code>event_scheduler</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	ON
Valid Values	ON OFF DISABLED

This variable enables or disables, and starts or stops, the Event Scheduler. The possible status values are `ON`, `OFF`, and `DISABLED`. Turning the Event Scheduler `OFF` is not the same as disabling the Event Scheduler, which requires setting the status to `DISABLED`. This variable and its effects on the Event Scheduler's operation are discussed in greater detail in [Section 27.4.2, “Event Scheduler Configuration”](#)

- `explain_format`

Command-Line Format	<code>--explain-format=format</code>
System Variable	<code>explain_format</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	TRADITIONAL
Valid Values	TRADITIONAL (DEFAULT) JSON

This variable determines the default output format used by `EXPLAIN` in the absence of a `FORMAT` option when displaying a query execution plan. Possible values and their effects are listed here:

- **TRADITIONAL**: Use MySQL's traditional table-based output, as if `FORMAT=TRADITIONAL` had been specified as part of the `EXPLAIN` statement. This is the variable's default value. `DEFAULT` is also supported as a synonym for `TRADITIONAL`, and has exactly the same effect.

Note

`DEFAULT` cannot be used as part of an `EXPLAIN` statement's `FORMAT` option.

- **JSON**: Use the JSON output format, as if `FORMAT=JSON` had been specified.
- **TREE**: Use the tree-based output format, as if `FORMAT=TREE` had been specified.

The setting for this variable also affects `EXPLAIN ANALYZE`. For this purpose, `DEFAULT` and `TRADITIONAL` are interpreted as `TREE`. If the value of `explain_format` is `JSON` and an `EXPLAIN ANALYZE` statement having no `FORMAT` option is issued, the statement raises an error (`ER_NOT_SUPPORTED_YET`).

Using a format specifier with `EXPLAIN` or `EXPLAIN ANALYZE` overrides any setting for `explain_format`.

The `explain_format` system variable has no effect on `EXPLAIN` output when this statement is used to display information about table columns.

Setting the session value of `explain_format` requires no special privileges; setting it on the global level requires `SYSTEM_VARIABLES_ADMIN` (or the deprecated `SUPER` privilege). See [Section 7.1.9.1, “System Variable Privileges”](#).

For more information and examples, see [Obtaining Execution Plan Information](#).

- `explain_json_format_version`

Command-Line Format	<code>--explain-json-format-version=#</code>
System Variable	<code>explain_json_format_version</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value	2

Determines the version of the JSON output format used by `EXPLAIN FORMAT=JSON` statements. Setting this variable to 1 causes the server to use Version 1, which is the linear format always used for output from such statements in MySQL 8.2 and earlier. This is the default in MySQL 8.3. Setting `explain_json_format_version` to 2 causes the Version 2 format to be used; this JSON output format is based on access paths, and is intended to provide better compatibility with future versions of the MySQL Optimizer.

For an example of use, see [Obtaining Execution Plan Information](#).

- `explicit_defaults_for_timestamp`

Command-Line Format	<code>--explicit-defaults-for-timestamp[={OFF ON}]</code>
Deprecated	Yes
System Variable	<code>explicit_defaults_for_timestamp</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

This system variable determines whether the server enables certain nonstandard behaviors for default values and `NULL`-value handling in `TIMESTAMP` columns. By default, `explicit_defaults_for_timestamp` is enabled, which disables the nonstandard behaviors. Disabling `explicit_defaults_for_timestamp` results in a warning.

If `explicit_defaults_for_timestamp` is disabled, the server enables the nonstandard behaviors and handles `TIMESTAMP` columns as follows:

- `TIMESTAMP` columns not explicitly declared with the `NULL` attribute are automatically declared with the `NOT NULL` attribute. Assigning such a column a value of `NULL` is permitted and sets the column to the current timestamp. *Exception:* Attempting to insert `NULL` into a generated column declared as `TIMESTAMP NOT NULL` is rejected with an error.
- The first `TIMESTAMP` column in a table, if not explicitly declared with the `NULL` attribute or an explicit `DEFAULT` or `ON UPDATE` attribute, is automatically declared with the `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` attributes.
- `TIMESTAMP` columns following the first one, if not explicitly declared with the `NULL` attribute or an explicit `DEFAULT` attribute, are automatically declared as `DEFAULT '0000-00-00 00:00:00'` (the “zero” timestamp). For inserted rows that specify no explicit value for such a column, the column is assigned `'0000-00-00 00:00:00'` and no warning occurs.

Depending on whether strict SQL mode or the `NO_ZERO_DATE` SQL mode is enabled, a default value of `'0000-00-00 00:00:00'` may be invalid. Be aware that the `TRADITIONAL` SQL mode includes strict mode and `NO_ZERO_DATE`. See [Section 7.1.11, “Server SQL Modes”](#).

The nonstandard behaviors just described are deprecated; expect them to be removed in a future MySQL release.

If `explicit_defaults_for_timestamp` is enabled, the server disables the nonstandard behaviors and handles `TIMESTAMP` columns as follows:

- It is not possible to assign a `TIMESTAMP` column a value of `NULL` to set it to the current timestamp. To assign the current timestamp, set the column to `CURRENT_TIMESTAMP` or a synonym such as `NOW()`.
- `TIMESTAMP` columns not explicitly declared with the `NOT NULL` attribute are automatically declared with the `NULL` attribute and permit `NULL` values. Assigning such a column a value of `NULL` sets it to `NULL`, not the current timestamp.
- `TIMESTAMP` columns declared with the `NOT NULL` attribute do not permit `NULL` values. For inserts that specify `NULL` for such a column, the result is either an error for a single-row insert if strict SQL mode is enabled, or `'0000-00-00 00:00:00'` is inserted for multiple-row inserts with strict SQL mode disabled. In no case does assigning the column a value of `NULL` set it to the current timestamp.

- `TIMESTAMP` columns explicitly declared with the `NOT NULL` attribute and without an explicit `DEFAULT` attribute are treated as having no default value. For inserted rows that specify no explicit value for such a column, the result depends on the SQL mode. If strict SQL mode is enabled, an error occurs. If strict SQL mode is not enabled, the column is declared with the implicit default of `'0000-00-00 00:00:00'` and a warning occurs. This is similar to how MySQL treats other temporal types such as `DATETIME`.
- No `TIMESTAMP` column is automatically declared with the `DEFAULT CURRENT_TIMESTAMP` or `ON UPDATE CURRENT_TIMESTAMP` attributes. Those attributes must be explicitly specified.
- The first `TIMESTAMP` column in a table is not handled differently from `TIMESTAMP` columns following the first one.

If `explicit_defaults_for_timestamp` is disabled at server startup, this warning appears in the error log:

```
[Warning] TIMESTAMP with implicit DEFAULT value is deprecated.
Please use --explicit_defaults_for_timestamp server option (see
documentation for more details).
```

As indicated by the warning, to disable the deprecated nonstandard behaviors, enable the `explicit_defaults_for_timestamp` system variable at server startup.

Note

`explicit_defaults_for_timestamp` is itself deprecated because its only purpose is to permit control over deprecated `TIMESTAMP` behaviors that are to be removed in a future MySQL release. When removal of those behaviors occurs, expect `explicit_defaults_for_timestamp` to be removed as well.

For additional information, see [Section 13.2.5, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”](#).

- `external_user`

System Variable	<code>external_user</code>
Scope	Session
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String

The external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this variable is `NULL`. See [Section 8.2.19, “Proxy Users”](#).

- `flush`

Command-Line Format	<code>--flush[={OFF ON}]</code>
System Variable	<code>flush</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean

Default Value	OFF
---------------	-----

If `ON`, the server flushes (synchronizes) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See [Section B.3.3.3, “What to Do If MySQL Keeps Crashing”](#). This variable is set to `ON` if you start `mysqld` with the `--flush` option.

Note

If `flush` is enabled, the value of `flush_time` does not matter and changes to `flush_time` have no effect on flush behavior.

- `flush_time`

Command-Line Format	<code>--flush-time=#</code>
System Variable	<code>flush_time</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	31536000
Unit	seconds

If this is set to a nonzero value, all tables are closed every `flush_time` seconds to free up resources and synchronize unflushed data to disk. This option is best used only on systems with minimal resources.

Note

If `flush` is enabled, the value of `flush_time` does not matter and changes to `flush_time` have no effect on flush behavior.

- `foreign_key_checks`

System Variable	<code>foreign_key_checks</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Boolean
Default Value	<code>ON</code>

If set to 1 (the default), foreign key constraints are checked. If set to 0, foreign key constraints are ignored, with a couple of exceptions. When re-creating a table that was dropped, an error is returned if the table definition does not conform to the foreign key constraints referencing the table. Likewise, an `ALTER TABLE` operation returns an error if a foreign key definition is incorrectly formed. For more information, see [Section 15.1.20.5, “FOREIGN KEY Constraints”](#).

Setting this variable has the same effect on `NDB` tables as it does for `InnoDB` tables. Typically you leave this setting enabled during normal operation, to enforce [referential integrity](#). Disabling foreign

key checking can be useful for reloading [InnoDB](#) tables in an order different from that required by their parent/child relationships. See [Section 15.1.20.5, “FOREIGN KEY Constraints”](#).

Setting `foreign_key_checks` to 0 also affects data definition statements: `DROP SCHEMA` drops a schema even if it contains tables that have foreign keys that are referred to by tables outside the schema, and `DROP TABLE` drops tables that have foreign keys that are referred to by other tables.

Note

Setting `foreign_key_checks` to 1 does not trigger a scan of the existing table data. Therefore, rows added to the table while `foreign_key_checks = 0` are not verified for consistency.

Dropping an index required by a foreign key constraint is not permitted, even with `foreign_key_checks=0`. The foreign key constraint must be removed before dropping the index.

- `ft_boolean_syntax`

Command-Line Format	<code>--ft-boolean-syntax=name</code>
System Variable	<code>ft_boolean_syntax</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>+ -><()~*: " "& </code>

The list of operators supported by boolean full-text searches performed using `IN BOOLEAN MODE`. See [Section 14.9.2, “Boolean Full-Text Searches”](#).

The default variable value is `'+ -><()~*: " "&|'`. The rules for changing the value are as follows:

- Operator function is determined by position within the string.
 - The replacement value must be 14 characters.
 - Each character must be an ASCII nonalphanumeric character.
 - Either the first or second character must be a space.
 - No duplicates are permitted except the phrase quoting operators in positions 11 and 12. These two characters are not required to be the same, but they are the only two that may be.
 - Positions 10, 13, and 14 (which by default are set to `:`, `&`, and `|`) are reserved for future extensions.
- `ft_max_word_len`

Command-Line Format	<code>--ft-max-word-len=#</code>
System Variable	<code>ft_max_word_len</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>84</code>

Minimum Value	10
Maximum Value	84

The maximum length of the word to be included in a `MyISAM FULLTEXT` index.

Note

`FULLTEXT` indexes on `MyISAM` tables must be rebuilt after changing this variable. Use `REPAIR TABLE tbl_name QUICK`.

- `ft_min_word_len`

Command-Line Format	<code>--ft-min-word-len=#</code>
System Variable	<code>ft_min_word_len</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	4
Minimum Value	1
Maximum Value	82

The minimum length of the word to be included in a `MyISAM FULLTEXT` index.

Note

`FULLTEXT` indexes on `MyISAM` tables must be rebuilt after changing this variable. Use `REPAIR TABLE tbl_name QUICK`.

- `ft_query_expansion_limit`

Command-Line Format	<code>--ft-query-expansion-limit=#</code>
System Variable	<code>ft_query_expansion_limit</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	20
Minimum Value	0
Maximum Value	1000

The number of top matches to use for full-text searches performed using `WITH QUERY EXPANSION`.

- `ft_stopword_file`

Command-Line Format	<code>--ft-stopword-file=file_name</code>
System Variable	<code>ft_stopword_file</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	File name

The file from which to read the list of stopwords for full-text searches on [MyISAM](#) tables. The server looks for the file in the data directory unless an absolute path name is given to specify a different directory. All the words from the file are used; comments are *not* honored. By default, a built-in list of stopwords is used (as defined in the [storage/myisam/ft_static.c](#) file). Setting this variable to the empty string (`' '`) disables stopwords filtering. See also [Section 14.9.4, “Full-Text Stopwords”](#).

Note

[FULLTEXT](#) indexes on [MyISAM](#) tables must be rebuilt after changing this variable or the contents of the stopwords file. Use `REPAIR TABLE tbl_name QUICK`.

- [general_log](#)

Command-Line Format	<code>--general-log[={OFF ON}]</code>
System Variable	general_log
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Whether the general query log is enabled. The value can be 0 (or `OFF`) to disable the log or 1 (or `ON`) to enable the log. The destination for log output is controlled by the [log_output](#) system variable; if that value is `NONE`, no log entries are written even if the log is enabled.

- [general_log_file](#)

Command-Line Format	<code>--general-log-file=file_name</code>
System Variable	general_log_file
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	File name
Default Value	<code>host_name.log</code>

The name of the general query log file. The default value is `host_name.log`, but the initial value can be changed with the `--general_log_file` option.

- [generated_random_password_length](#)

Command-Line Format	<code>--generated-random-password-length=#</code>
System Variable	generated_random_password_length
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	<code>20</code>
Minimum Value	<code>5</code>

Maximum Value	255
---------------	-----

The maximum number of characters permitted in random passwords generated for `CREATE USER`, `ALTER USER`, and `SET PASSWORD` statements. For more information, see [Random Password Generation](#).

- `global_connection_memory_limit`

Command-Line Format	<code>--global-connection-memory-limit=#</code>
System Variable	<code>global_connection_memory_limit</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	18446744073709551615
Minimum Value	16777216
Maximum Value	18446744073709551615
Unit	bytes

Set the total amount of memory that can be used by all user connections; that is, `Global_connection_memory` should not exceed this amount. Any time that it does, all queries (including any currently running) from regular users are rejected with `ER_GLOBAL_CONN_LIMIT`.

Memory used by the system users such as the MySQL root user is included in this total, but is not counted towards the disconnection limit; such users are never disconnected due to memory usage.

Memory used by the `InnoDB` buffer pool is excluded from the total.

You must have the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege to set this variable.

- `global_connection_memory_tracking`

Command-Line Format	<code>--global-connection-memory-tracking={TRUE FALSE}</code>
System Variable	<code>global_connection_memory_tracking</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>FALSE</code>

Determines whether the server calculates `Global_connection_memory`. This variable must be enabled explicitly; otherwise, the memory calculation is not performed, and `Global_connection_memory` is not set.

You must have the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege to set this variable.

- `group_concat_max_len`

Command-Line Format	<code>--group-concat-max-len=#</code>
System Variable	<code>group_concat_max_len</code>
Scope	Global, Session

Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer
Default Value	1024
Minimum Value	4
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

The maximum permitted result length in bytes for the [GROUP_CONCAT\(\)](#) function. The default is 1024.

- [have_compress](#)

[YES](#) if the [zlib](#) compression library is available to the server, [NO](#) if not. If not, the [COMPRESS\(\)](#) and [UNCOMPRESS\(\)](#) functions cannot be used.

- [have_dynamic_loading](#)

[YES](#) if [mysqld](#) supports dynamic loading of plugins, [NO](#) if not. If the value is [NO](#), you cannot use options such as [--plugin-load](#) to load plugins at server startup, or the [INSTALL PLUGIN](#) statement to load plugins at runtime.

- [have_geometry](#)

[YES](#) if the server supports spatial data types, [NO](#) if not.

- [have_openssl](#)

This variable is a synonym for [have_ssl](#).

[have_openssl](#) is deprecated and subject to removal in a future MySQL version. For information about TLS properties of MySQL connection interfaces, consult the [tls_channel_status](#) table instead.

- [have_profiling](#)

[YES](#) if statement profiling capability is present, [NO](#) if not. If present, the [profiling](#) system variable controls whether this capability is enabled or disabled. See [Section 15.7.7.33, “SHOW PROFILES Statement”](#).

This variable is deprecated and you should expect it to be removed in a future MySQL release.

- [have_query_cache](#)

[have_query_cache](#) is deprecated, always has a value of [NO](#), and you should expect it to be removed in a future MySQL release.

- [have_rtree_keys](#)

[YES](#) if [RTREE](#) indexes are available, [NO](#) if not. (These are used for spatial indexes in [MyISAM](#) tables.)

- [have_ssl](#)

Deprecated	Yes
System Variable	have_ssl
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No

Type	String
Valid Values	YES (SSL support available) DISABLED (SSL support was compiled into server, but server was not started with necessary options to enable it)

[YES](#) if `mysqld` supports SSL connections, [DISABLED](#) if the server was compiled with SSL support, but was not started with the appropriate connection-encryption options. For more information, see [Section 2.8.6, “Configuring SSL Library Support”](#).

`have_ssl` is deprecated and subject to removal in a future MySQL version. For information about TLS properties of MySQL connection interfaces, consult the `tls_channel_status` table instead.

- [have_statement_timeout](#)

System Variable	have_statement_timeout
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean

Whether the statement execution timeout feature is available (see [Statement Execution Time Optimizer Hints](#)). The value can be [NO](#) if the background thread used by this feature could not be initialized.

- [have_symlink](#)

[YES](#) if symbolic link support is enabled, [NO](#) if not. This is required on Unix for support of the [DATA DIRECTORY](#) and [INDEX DIRECTORY](#) table options. If the server is started with the `--skip-symbolic-links` option, the value is [DISABLED](#).

This variable has no meaning on Windows.

Note

Symbolic link support, along with the `--symbolic-links` option that controls it, is deprecated; expect these to be removed in a future version of MySQL. In addition, the option is disabled by default. The related [have_symlink](#) system variable also is deprecated and you should expect it to be removed in a future version of MySQL.

- [histogram_generation_max_mem_size](#)

Command-Line Format	<code>--histogram-generation-max-mem-size=#</code>
System Variable	histogram_generation_max_mem_size
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	20000000
Minimum Value	1000000
Maximum Value (64-bit platforms)	18446744073709551615

Maximum Value (32-bit platforms)	4294967295
Unit	bytes

The maximum amount of memory available for generating histogram statistics. See [Section 10.9.6, “Optimizer Statistics”](#), and [Section 15.7.3.1, “ANALYZE TABLE Statement”](#).

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

- `host_cache_size`

Command-Line Format	<code>--host-cache-size=#</code>
System Variable	<code>host_cache_size</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	-1 (signifies autosizing; do not assign this literal value)
Minimum Value	0
Maximum Value	65536

The MySQL server maintains an in-memory host cache that contains client host name and IP address information and is used to avoid Domain Name System (DNS) lookups; see [Section 7.1.12.3, “DNS Lookups and the Host Cache”](#).

The `host_cache_size` variable controls the size of the host cache, as well as the size of the Performance Schema `host_cache` table that exposes the cache contents. Setting `host_cache_size` has these effects:

- Setting the size to 0 disables the host cache. With the cache disabled, the server performs a DNS lookup every time a client connects.
- Changing the size at runtime causes an implicit host cache flushing operation that clears the host cache, truncates the `host_cache` table, and unblocks any blocked hosts.

The default value is autosized to 128, plus 1 for a value of `max_connections` up to 500, plus 1 for every increment of 20 over 500 in the `max_connections` value, capped to a limit of 2000.

- `hostname`

System Variable	<code>hostname</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String

The server sets this variable to the server host name at startup. The maximum length is 255 characters.

- `identity`

This variable is a synonym for the `last_insert_id` variable. It exists for compatibility with other database systems. You can read its value with `SELECT @@identity`, and set it using `SET identity`.

- `init_connect`

Command-Line Format	<code>--init-connect=name</code>
System Variable	<code>init_connect</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String

A string to be executed by the server for each client that connects. The string consists of one or more SQL statements, separated by semicolon characters.

For users that have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege), the content of `init_connect` is not executed. This is done so that an erroneous value for `init_connect` does not prevent all clients from connecting. For example, the value might contain a statement that has a syntax error, thus causing client connections to fail. Not executing `init_connect` for users that have the `CONNECTION_ADMIN` or `SUPER` privilege enables them to open a connection and fix the `init_connect` value.

`init_connect` execution is skipped for any client user with an expired password. This is done because such a user cannot execute arbitrary statements, and thus `init_connect` execution fails, leaving the client unable to connect. Skipping `init_connect` execution enables the user to connect and change password.

The server discards any result sets produced by statements in the value of `init_connect`.

- `information_schema_stats_expiry`

Command-Line Format	<code>--information-schema-stats-expiry=#</code>
System Variable	<code>information_schema_stats_expiry</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	86400
Minimum Value	0
Maximum Value	31536000
Unit	seconds

Some `INFORMATION_SCHEMA` tables contain columns that provide table statistics:

```
STATISTICS.CARDINALITY
TABLES.AUTO_INCREMENT
TABLES.AVG_ROW_LENGTH
TABLES.CHECKSUM
TABLES.CHECK_TIME
TABLES.CREATE_TIME
TABLES.DATA_FREE
TABLES.DATA_LENGTH
TABLES.INDEX_LENGTH
```

```
TABLES.MAX_DATA_LENGTH
TABLES.TABLE_ROWS
TABLES.UPDATE_TIME
```

Those columns represent dynamic table metadata; that is, information that changes as table contents change.

By default, MySQL retrieves cached values for those columns from the `mysql.index_stats` and `mysql.table_stats` dictionary tables when the columns are queried, which is more efficient than retrieving statistics directly from the storage engine. If cached statistics are not available or have expired, MySQL retrieves the latest statistics from the storage engine and caches them in the `mysql.index_stats` and `mysql.table_stats` dictionary tables. Subsequent queries retrieve the cached statistics until the cached statistics expire. A server restart or the first opening of the `mysql.index_stats` and `mysql.table_stats` tables do not update cached statistics automatically.

The `information_schema_stats_expiry` session variable defines the period of time before cached statistics expire. The default is 86400 seconds (24 hours), but the time period can be extended to as much as one year.

To update cached values at any time for a given table, use `ANALYZE TABLE`.

To always retrieve the latest statistics directly from the storage engine and bypass cached values, set `information_schema_stats_expiry` to 0.

Querying statistics columns does not store or update statistics in the `mysql.index_stats` and `mysql.table_stats` dictionary tables under these circumstances:

- When cached statistics have not expired.
- When `information_schema_stats_expiry` is set to 0.
- When the server is in `read_only`, `super_read_only`, `transaction_read_only`, or `innodb_read_only` mode.
- When the query also fetches Performance Schema data.

The statistics cache may be updated during a multiple-statement transaction before it is known whether the transaction commits. As a result, the cache may contain information that does not correspond to a known committed state. This can occur with `autocommit=0` or after `START TRANSACTION`.

`information_schema_stats_expiry` is a session variable, and each client session can define its own expiration value. Statistics that are retrieved from the storage engine and cached by one session are available to other sessions.

For related information, see [Section 10.2.3, “Optimizing INFORMATION_SCHEMA Queries”](#).

- `init_file`

Command-Line Format	<code>--init-file=file_name</code>
System Variable	<code>init_file</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No

Type	File name
------	-----------

If specified, this variable names a file containing SQL statements to be read and executed during the startup process. The acceptable format for statements in this file support the following constructs:

- `delimiter ;`, to set the statement delimiter to the `;` character.
- `delimiter $$`, to set the statement delimiter to the `$$` character sequence.
- Multiple statements on the same line, delimited by the current delimiter.
- Multiple-line statements.
- Comments from a `#` character to the end of the line.
- Comments from a `--` sequence to the end of the line.
- C-style comments from a `/*` sequence to the following `*/` sequence, including over multiple lines.
- Multiple-line string literals enclosed within either single quote (`'`) or double quote (`"`) characters.

If the server is started with the `--initialize` or `--initialize-insecure` option, it operates in bootstrap mode and some functionality is unavailable that limits the statements permitted in the file. These include statements that relate to account management (such as `CREATE USER` or `GRANT`), replication, and global transaction identifiers. See [Section 19.1.3, "Replication with Global Transaction Identifiers"](#).

Threads created during server startup are used for tasks such as creating the data dictionary, running upgrade procedures, and creating system tables. To ensure a stable and predictable environment, these threads are executed with the server built-in defaults for some system variables, such as `sql_mode`, `character_set_server`, `collation_server`, `completion_type`, `explicit_defaults_for_timestamp`, and `default_table_encryption`.

These threads are also used to execute the statements in any file specified with `init_file` when starting the server, so such statements execute with the server's built-in default values for those system variables.

- `innodb_xxx`

InnoDB system variables are listed in [Section 17.14, "InnoDB Startup Options and System Variables"](#). These variables control many aspects of storage, memory use, and I/O patterns for InnoDB tables, and are especially important now that InnoDB is the default storage engine.

- `insert_id`

The value to be used by the following `INSERT` or `ALTER TABLE` statement when inserting an `AUTO_INCREMENT` value. This is mainly used with the binary log.

- `interactive_timeout`

Command-Line Format	<code>--interactive-timeout=#</code>
System Variable	<code>interactive_timeout</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	28800
Minimum Value	1

Maximum Value	31536000
Unit	seconds

The number of seconds the server waits for activity on an interactive connection before closing it. An interactive client is defined as a client that uses the `CLIENT_INTERACTIVE` option to `mysql_real_connect()`. See also `wait_timeout`.

- `internal_tmp_mem_storage_engine`

Command-Line Format	<code>--internal-tmp-mem-storage-engine=#</code>
System Variable	<code>internal_tmp_mem_storage_engine</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Enumeration
Default Value	<code>TempTable</code>
Valid Values	<code>MEMORY</code> <code>TempTable</code>

The storage engine for in-memory internal temporary tables (see [Section 10.4.4, “Internal Temporary Table Use in MySQL”](#)). Permitted values are `TempTable` (the default) and `MEMORY`.

The [optimizer](#) uses the storage engine defined by `internal_tmp_mem_storage_engine` for in-memory internal temporary tables.

Configuring a session setting for `internal_tmp_mem_storage_engine` requires the `SESSION_VARIABLES_ADMIN` or `SYSTEM_VARIABLES_ADMIN` privilege.

- `join_buffer_size`

Command-Line Format	<code>--join-buffer-size=#</code>
System Variable	<code>join_buffer_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	262144
Minimum Value	128
Maximum Value (Windows)	4294967168
Maximum Value (Other, 64-bit platforms)	18446744073709551488
Maximum Value (Other, 32-bit platforms)	4294967168
Unit	bytes
Block Size	128

The minimum size of the buffer that is used for plain index scans, range index scans, and joins that do not use indexes and thus perform full table scans. This variable also controls the amount of memory used for hash joins. Normally, the best way to get fast joins is to add indexes. Increase the value of `join_buffer_size` to get a faster full join when adding indexes is not possible. One join

buffer is allocated for each full join between two tables. For a complex join between several tables for which indexes are not used, multiple join buffers might be necessary.

The default is 256KB. The maximum permissible setting for `join_buffer_size` is 4GB-1. Larger values are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB-1 with a warning). The block size is 128, and a value that is not an exact multiple of the block size is rounded down to the next lower multiple of the block size by MySQL Server before storing the value for the system variable. The parser allows values up to the maximum unsigned integer value for the platform (4294967295 or $2^{32}-1$ for a 32-bit system, 18446744073709551615 or $2^{64}-1$ for a 64-bit system) but the actual maximum is a block size lower.

Unless a Block Nested-Loop or Batched Key Access algorithm is used, there is no gain from setting the buffer larger than required to hold each matching row, and all joins allocate at least the minimum size, so use caution in setting this variable to a large value globally. It is better to keep the global setting small and change the session setting to a larger value only in sessions that are doing large joins, or change the setting on a per-query basis by using a `SET_VAR` optimizer hint (see [Section 10.9.3, “Optimizer Hints”](#)). Memory allocation time can cause substantial performance drops if the global size is larger than needed by most queries that use it.

When Block Nested-Loop is used, a larger join buffer can be beneficial up to the point where all required columns from all rows in the first table are stored in the join buffer. This depends on the query; the optimal size may be smaller than holding all rows from the first tables.

When Batched Key Access is used, the value of `join_buffer_size` defines how large the batch of keys is in each request to the storage engine. The larger the buffer, the more sequential access is made to the right hand table of a join operation, which can significantly improve performance.

For additional information about join buffering, see [Section 10.2.1.7, “Nested-Loop Join Algorithms”](#). For information about Batched Key Access, see [Section 10.2.1.12, “Block Nested-Loop and Batched Key Access Joins”](#). For information about hash joins, see [Section 10.2.1.4, “Hash Join Optimization”](#).

- `keep_files_on_create`

Command-Line Format	<code>--keep-files-on-create[={OFF ON}]</code>
System Variable	<code>keep_files_on_create</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

If a `MyISAM` table is created with no `DATA DIRECTORY` option, the `.MYD` file is created in the database directory. By default, if `MyISAM` finds an existing `.MYD` file in this case, it overwrites it. The same applies to `.MYI` files for tables created with no `INDEX DIRECTORY` option. To suppress this behavior, set the `keep_files_on_create` variable to `ON` (1), in which case `MyISAM` does not overwrite existing files and returns an error instead. The default value is `OFF` (0).

If a `MyISAM` table is created with a `DATA DIRECTORY` or `INDEX DIRECTORY` option and an existing `.MYD` or `.MYI` file is found, `MyISAM` always returns an error. It does not overwrite a file in the specified directory.

- `key_buffer_size`

Command-Line Format	<code>--key-buffer-size=#</code>
System Variable	<code>key_buffer_size</code>
Scope	Global

Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	8388608
Minimum Value	0
Maximum Value (64-bit platforms)	OS_PER_PROCESS_LIMIT
Maximum Value (32-bit platforms)	4294967295
Unit	bytes

Index blocks for [MyISAM](#) tables are buffered and are shared by all threads. [key_buffer_size](#) is the size of the buffer used for index blocks. The key buffer is also known as the key cache.

The minimum permissible setting is 0, but you cannot set [key_buffer_size](#) to 0 dynamically. A setting of 0 drops the key cache, which is not permitted at runtime. Setting [key_buffer_size](#) to 0 is permitted only at startup, in which case the key cache is not initialized. Changing the [key_buffer_size](#) setting at runtime from a value of 0 to a permitted non-zero value initializes the key cache.

[key_buffer_size](#) can be increased or decreased only in increments or multiples of 4096 bytes. Increasing or decreasing the setting by a nonconforming value produces a warning and truncates the setting to a conforming value.

The maximum permissible setting for [key_buffer_size](#) is 4GB–1 on 32-bit platforms. Larger values are permitted for 64-bit platforms. The effective maximum size might be less, depending on your available physical RAM and per-process RAM limits imposed by your operating system or hardware platform. The value of this variable indicates the amount of memory requested. Internally, the server allocates as much memory as possible up to this amount, but the actual allocation might be less.

You can increase the value to get better index handling for all reads and multiple writes; on a system whose primary function is to run MySQL using the [MyISAM](#) storage engine, 25% of the machine's total memory is an acceptable value for this variable. However, you should be aware that, if you make the value too large (for example, more than 50% of the machine's total memory), your system might start to page and become extremely slow. This is because MySQL relies on the operating system to perform file system caching for data reads, so you must leave some room for the file system cache. You should also consider the memory requirements of any other storage engines that you may be using in addition to [MyISAM](#).

For even more speed when writing many rows at the same time, use [LOCK TABLES](#). See [Section 10.2.5.1, “Optimizing INSERT Statements”](#).

You can check the performance of the key buffer by issuing a [SHOW STATUS](#) statement and examining the [Key_read_requests](#), [Key_reads](#), [Key_write_requests](#), and [Key_writes](#) status variables. (See [Section 15.7.7, “SHOW Statements”](#).) The [Key_reads/Key_read_requests](#) ratio should normally be less than 0.01. The [Key_writes/Key_write_requests](#) ratio is usually near 1 if you are using mostly updates and deletes, but might be much smaller if you tend to do updates that affect many rows at the same time or if you are using the [DELAY_KEY_WRITE](#) table option.

The fraction of the key buffer in use can be determined using [key_buffer_size](#) in conjunction with the [Key_blocks_unused](#) status variable and the buffer block size, which is available from the [key_cache_block_size](#) system variable:

```
1 - ((Key_blocks_unused * key_cache_block_size) / key_buffer_size)
```

This value is an approximation because some space in the key buffer is allocated internally for administrative structures. Factors that influence the amount of overhead for these structures

include block size and pointer size. As block size increases, the percentage of the key buffer lost to overhead tends to decrease. Larger blocks results in a smaller number of read operations (because more keys are obtained per read), but conversely an increase in reads of keys that are not examined (if not all keys in a block are relevant to a query).

It is possible to create multiple [MyISAM](#) key caches. The size limit of 4GB applies to each cache individually, not as a group. See [Section 10.10.2, “The MyISAM Key Cache”](#).

- [key_cache_age_threshold](#)

Command-Line Format	<code>--key-cache-age-threshold=#</code>
System Variable	key_cache_age_threshold
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	300
Minimum Value	100
Maximum Value (64-bit platforms)	18446744073709551516
Maximum Value (32-bit platforms)	4294967196
Block Size	100

This value controls the demotion of buffers from the hot sublist of a key cache to the warm sublist. Lower values cause demotion to happen more quickly. The minimum value is 100. The default value is 300. See [Section 10.10.2, “The MyISAM Key Cache”](#).

- [key_cache_block_size](#)

Command-Line Format	<code>--key-cache-block-size=#</code>
System Variable	key_cache_block_size
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1024
Minimum Value	512
Maximum Value	16384
Unit	bytes
Block Size	512

The size in bytes of blocks in the key cache. The default value is 1024. See [Section 10.10.2, “The MyISAM Key Cache”](#).

- [key_cache_division_limit](#)

Command-Line Format	<code>--key-cache-division-limit=#</code>
System Variable	key_cache_division_limit
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No

Type	Integer
Default Value	100
Minimum Value	1
Maximum Value	100

The division point between the hot and warm sublists of the key cache buffer list. The value is the percentage of the buffer list to use for the warm sublist. Permissible values range from 1 to 100. The default value is 100. See [Section 10.10.2, “The MyISAM Key Cache”](#).

- [large_files_support](#)

System Variable	large_files_support
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean

Whether `mysqld` was compiled with options for large file support.

- [large_pages](#)

Command-Line Format	<code>--large-pages[={OFF ON}]</code>
System Variable	large_pages
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Platform Specific	Linux
Type	Boolean
Default Value	OFF

Whether large page support is enabled (via the `--large-pages` option). See [Section 10.12.3.3, “Enabling Large Page Support”](#).

- [large_page_size](#)

System Variable	large_page_size
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	65535
Unit	bytes

If large page support is enabled, this shows the size of memory pages. Large memory pages are supported only on Linux; on other platforms, the value of this variable is always 0. See [Section 10.12.3.3, “Enabling Large Page Support”](#).

- `last_insert_id`

The value to be returned from `LAST_INSERT_ID()`. This is stored in the binary log when you use `LAST_INSERT_ID()` in a statement that updates a table. Setting this variable does not update the value returned by the `mysql_insert_id()` C API function.

- `lc_messages`

Command-Line Format	<code>--lc-messages=name</code>
System Variable	<code>lc_messages</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>en_US</code>

The locale to use for error messages. The default is `en_US`. The server converts the argument to a language name and combines it with the value of `lc_messages_dir` to produce the location for the error message file. See [Section 12.12, “Setting the Error Message Language”](#).

- `lc_messages_dir`

Command-Line Format	<code>--lc-messages-dir=dir_name</code>
System Variable	<code>lc_messages_dir</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name

The directory where error messages are located. The server uses the value together with the value of `lc_messages` to produce the location for the error message file. See [Section 12.12, “Setting the Error Message Language”](#).

- `lc_time_names`

Command-Line Format	<code>--lc-time-names=value</code>
System Variable	<code>lc_time_names</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

This variable specifies the locale that controls the language used to display day and month names and abbreviations. This variable affects the output from the `DATE_FORMAT()`, `DAYNAME()` and `MONTHNAME()` functions. Locale names are POSIX-style values such as `'ja_JP'` or `'pt_BR'`. The default value is `'en_US'` regardless of your system's locale setting. For further information, see [Section 12.16, “MySQL Server Locale Support”](#).

- `license`

System Variable	<code>license</code>
Scope	Global

Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value	GPL

The type of license the server has.

- [local_infile](#)

Command-Line Format	<code>--local-infile[={OFF ON}]</code>
System Variable	local_infile
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

This variable controls server-side [LOCAL](#) capability for [LOAD DATA](#) statements. Depending on the [local_infile](#) setting, the server refuses or permits local data loading by clients that have [LOCAL](#) enabled on the client side.

To explicitly cause the server to refuse or permit [LOAD DATA LOCAL](#) statements (regardless of how client programs and libraries are configured at build time or runtime), start [mysqld](#) with [local_infile](#) disabled or enabled, respectively. [local_infile](#) can also be set at runtime. For more information, see [Section 8.1.6, “Security Considerations for LOAD DATA LOCAL”](#).

- [lock_wait_timeout](#)

Command-Line Format	<code>--lock-wait-timeout=#</code>
System Variable	lock_wait_timeout
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer
Default Value	31536000
Minimum Value	1
Maximum Value	31536000
Unit	seconds

This variable specifies the timeout in seconds for attempts to acquire metadata locks. The permissible values range from 1 to 31536000 (1 year). The default is 31536000.

This timeout applies to all statements that use metadata locks. These include DML and DDL operations on tables, views, stored procedures, and stored functions, as well as [LOCK TABLES](#), [FLUSH TABLES WITH READ LOCK](#), and [HANDLER](#) statements.

This timeout does not apply to implicit accesses to system tables in the [mysql](#) database, such as grant tables modified by [GRANT](#) or [REVOKE](#) statements or table logging statements. The timeout does apply to system tables accessed directly, such as with [SELECT](#) or [UPDATE](#).

The timeout value applies separately for each metadata lock attempt. A given statement can require more than one lock, so it is possible for the statement to block for longer than the

`lock_wait_timeout` value before reporting a timeout error. When lock timeout occurs, `ER_LOCK_WAIT_TIMEOUT` is reported.

`lock_wait_timeout` also defines the amount of time that a `LOCK INSTANCE FOR BACKUP` statement waits for a lock before giving up.

- `locked_in_memory`

System Variable	<code>locked_in_memory</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Whether `mysqld` was locked in memory with `--memlock`.

- `log_error`

Command-Line Format	<code>--log-error[=file_name]</code>
System Variable	<code>log_error</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	File name

The default error log destination. If the destination is the console, the value is `stderr`. Otherwise, the destination is a file and the `log_error` value is the file name. See [Section 7.4.2, “The Error Log”](#).

- `log_error_services`

Command-Line Format	<code>--log-error-services=value</code>
System Variable	<code>log_error_services</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>log_filter_internal;</code> <code>log_sink_internal</code>

The components to enable for error logging. The variable may contain a list with 0, 1, or many elements. In the latter case, elements may be delimited by semicolons or commas, optionally followed by space. A given setting cannot use both semicolon and comma separators. Component order is significant because the server executes components in the order listed.

Any loadable (not built in) component named in `log_error_services` is implicitly loaded if it is not already loaded. For more information, see [Section 7.4.2.1, “Error Log Configuration”](#).

- `log_error_suppression_list`

Command-Line Format	<code>--log-error-suppression-list=value</code>
System Variable	<code>log_error_suppression_list</code>

Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>empty string</code>

The `log_error_suppression_list` system variable applies to events intended for the error log and specifies which events to suppress when they occur with a priority of `WARNING` or `INFORMATION`. For example, if a particular type of warning is considered undesirable “noise” in the error log because it occurs frequently but is not of interest, it can be suppressed. This variable affects filtering performed by the `log_filter_internal` error log filter component, which is enabled by default (see [Section 7.5.3, “Error Log Components”](#)). If `log_filter_internal` is disabled, `log_error_suppression_list` has no effect.

The `log_error_suppression_list` value may be the empty string for no suppression, or a list of one or more comma-separated values indicating the error codes to suppress. Error codes may be specified in symbolic or numeric form. A numeric code may be specified with or without the `MY-` prefix. Leading zeros in the numeric part are not significant. Examples of permitted code formats:

```
ER_SERVER_SHUTDOWN_COMPLETE
MY-000031
000031
MY-31
31
```

Symbolic values are preferable to numeric values for readability and portability. For information about the permitted error symbols and numbers, see [MySQL 8.3 Error Message Reference](#).

The effect of `log_error_suppression_list` combines with that of `log_error_verbosity`. For additional information, see [Section 7.4.2.5, “Priority-Based Error Log Filtering \(log_filter_internal\)”](#).

- `log_error_verbosity`

Command-Line Format	<code>--log-error-verbosity=#</code>
System Variable	<code>log_error_verbosity</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	<code>2</code>
Minimum Value	<code>1</code>
Maximum Value	<code>3</code>

The `log_error_verbosity` system variable specifies the verbosity for handling events intended for the error log. This variable affects filtering performed by the `log_filter_internal` error

log filter component, which is enabled by default (see [Section 7.5.3, “Error Log Components”](#)). If `log_filter_internal` is disabled, `log_error_verbosity` has no effect.

Events intended for the error log have a priority of `ERROR`, `WARNING`, or `INFORMATION`. `log_error_verbosity` controls verbosity based on which priorities to permit for messages written to the log, as shown in the following table.

log_error_verbosity Value	Permitted Message Priorities
1	<code>ERROR</code>
2	<code>ERROR</code> , <code>WARNING</code>
3	<code>ERROR</code> , <code>WARNING</code> , <code>INFORMATION</code>

There is also a priority of `SYSTEM`. System messages about non-error situations are printed to the error log regardless of the `log_error_verbosity` value. These messages include startup and shutdown messages, and some significant changes to settings.

The effect of `log_error_verbosity` combines with that of `log_error_suppression_list`. For additional information, see [Section 7.4.2.5, “Priority-Based Error Log Filtering \(log_filter_internal\)”](#).

- `log_output`

Command-Line Format	<code>--log-output=name</code>
System Variable	<code>log_output</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Set
Default Value	<code>FILE</code>
Valid Values	<code>TABLE</code> <code>FILE</code> <code>NONE</code>

The destination or destinations for general query log and slow query log output. The value is a list one or more comma-separated words chosen from `TABLE`, `FILE`, and `NONE`. `TABLE` selects logging to the `general_log` and `slow_log` tables in the `mysql` system schema. `FILE` selects logging to log files. `NONE` disables logging. If `NONE` is present in the value, it takes precedence over any other words that are present. `TABLE` and `FILE` can both be given to select both log output destinations.

This variable selects log output destinations, but does not enable log output. To do that, enable the `general_log` and `slow_query_log` system variables. For `FILE` logging, the `general_log_file` and `slow_query_log_file` system variables determine the log file locations. For more information, see [Section 7.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”](#).

- `log_queries_not_using_indexes`

Command-Line Format	<code>--log-queries-not-using-indexes[={OFF ON}]</code>
System Variable	<code>log_queries_not_using_indexes</code>
Scope	Global
Dynamic	Yes

SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

If you enable this variable with the slow query log enabled, queries that are expected to retrieve all rows are logged. See [Section 7.4.5, “The Slow Query Log”](#). This option does not necessarily mean that no index is used. For example, a query that uses a full index scan uses an index but would be logged because the index would not limit the number of rows.

- [log_raw](#)

Command-Line Format	<code>--log-raw[={OFF ON}]</code>
System Variable	log_raw
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

The [log_raw](#) system variable is initially set to the value of the `--log-raw` option. See the description of that option for more information. The system variable may also be set at runtime to change password masking behavior.

- [log_slow_admin_statements](#)

Command-Line Format	<code>--log-slow-admin-statements[={OFF ON}]</code>
System Variable	log_slow_admin_statements
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Include slow administrative statements in the statements written to the slow query log. Administrative statements include [ALTER TABLE](#), [ANALYZE TABLE](#), [CHECK TABLE](#), [CREATE INDEX](#), [DROP INDEX](#), [OPTIMIZE TABLE](#), and [REPAIR TABLE](#).

- [log_slow_extra](#)

Command-Line Format	<code>--log-slow-extra[={OFF ON}]</code>
System Variable	log_slow_extra
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

If the slow query log is enabled and the output destination includes [FILE](#), the server writes additional fields to log file lines that provide information about slow statements. See [Section 7.4.5, “The Slow Query Log”](#). [TABLE](#) output is unaffected.

- `log_timestamps`

Command-Line Format	<code>--log-timestamps=#</code>
System Variable	<code>log_timestamps</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	UTC
Valid Values	UTC SYSTEM

This variable controls the time zone of timestamps in messages written to the error log, and in general query log and slow query log messages written to files. It does not affect the time zone of general query log and slow query log messages written to tables (`mysql.general_log`, `mysql.slow_log`). Rows retrieved from those tables can be converted from the local system time zone to any desired time zone with `CONVERT_TZ()` or by setting the session `time_zone` system variable.

Permitted `log_timestamps` values are `UTC` (the default) and `SYSTEM` (the local system time zone).

Timestamps are written using ISO 8601 / RFC 3339 format: `YYYY-MM-DDThh:mm:ss.uuuuuu` plus a tail value of `Z` signifying Zulu time (UTC) or `±hh:mm` (an offset from UTC).

- `log_throttle_queries_not_using_indexes`

Command-Line Format	<code>--log-throttle-queries-not-using-indexes=#</code>
System Variable	<code>log_throttle_queries_not_using_indexes</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295

If `log_queries_not_using_indexes` is enabled, the `log_throttle_queries_not_using_indexes` variable limits the number of such queries per minute that can be written to the slow query log. A value of 0 (the default) means “no limit”. For more information, see [Section 7.4.5, “The Slow Query Log”](#).

- `long_query_time`

Command-Line Format	<code>--long-query-time=#</code>
System Variable	<code>long_query_time</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Numeric

Default Value	10
Minimum Value	0
Maximum Value	31536000
Unit	seconds

If a query takes longer than this many seconds, the server increments the `Slow_queries` status variable. If the slow query log is enabled, the query is logged to the slow query log file. This value is measured in real time, not CPU time, so a query that is under the threshold on a lightly loaded system might be above the threshold on a heavily loaded one. The minimum and default values of `long_query_time` are 0 and 10, respectively. The maximum is 31536000, which is 365 days in seconds. The value can be specified to a resolution of microseconds. See [Section 7.4.5, “The Slow Query Log”](#).

Smaller values of this variable result in more statements being considered long-running, with the result that more space is required for the slow query log. For very small values (less than one second), the log may grow quite large in a small time. Increasing the number of statements considered long-running may also result in false positives for the “excessive Number of Long Running Processes” alert in MySQL Enterprise Monitor, especially if Group Replication is enabled. For these reasons, very small values should be used in test environments only, or, in production environments, only for a short period.

`mysqldump` performs a full table scan, which means its queries can often exceed a `long_query_time` setting that is useful for regular queries. If you want to exclude most or all of the queries generated by `mysqldump` from the slow query log, you can use `--mysqld-long-query-time` to change the session value of the system variable to a higher value.

- `low_priority_updates`

Command-Line Format	<code>--low-priority-updates[={OFF ON}]</code>
System Variable	<code>low_priority_updates</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	OFF

If set to 1, all `INSERT`, `UPDATE`, `DELETE`, and `LOCK TABLE WRITE` statements wait until there is no pending `SELECT` or `LOCK TABLE READ` on the affected table. The same effect can be obtained using `{INSERT | REPLACE | DELETE | UPDATE} LOW_PRIORITY ...` to lower the priority of only one query. This variable affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`). See [Section 10.11.2, “Table Locking Issues”](#).

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

- `lower_case_file_system`

System Variable	<code>lower_case_file_system</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No

Type	Boolean
------	---------

This variable describes the case sensitivity of file names on the file system where the data directory is located. `OFF` means file names are case-sensitive, `ON` means they are not case-sensitive. This variable is read only because it reflects a file system attribute and setting it would have no effect on the file system.

- `lower_case_table_names`

Command-Line Format	<code>--lower-case-table-names[=#]</code>
System Variable	<code>lower_case_table_names</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value (macOS)	2
Default Value (Unix)	0
Default Value (Windows)	1
Minimum Value	0
Maximum Value	2

If set to 0, table names are stored as specified and comparisons are case-sensitive. If set to 1, table names are stored in lowercase on disk and comparisons are not case-sensitive. If set to 2, table names are stored as given but compared in lowercase. This option also applies to database names and table aliases. For additional details, see [Section 11.2.3, “Identifier Case Sensitivity”](#).

The default value of this variable is platform-dependent (see `lower_case_file_system`). On Linux and other Unix-like systems, the default is 0. On Windows the default value is 1. On macOS, the default value is 2. On Linux (and other Unix-like systems), setting the value to 2 is not supported; the server forces the value to 0 instead.

You should *not* set `lower_case_table_names` to 0 if you are running MySQL on a system where the data directory resides on a case-insensitive file system (such as on Windows or macOS). It is an unsupported combination that could result in a hang condition when running an `INSERT INTO ... SELECT ... FROM tbl_name` operation with the wrong `tbl_name` lettercase. With `MyISAM`, accessing table names using different lettercases could cause index corruption.

An error message is printed and the server exits if you attempt to start the server with `--lower_case_table_names=0` on a case-insensitive file system.

The setting of this variable affects the behavior of replication filtering options with regard to case sensitivity. For more information, see [Section 19.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

It is prohibited to start the server with a `lower_case_table_names` setting that is different from the setting used when the server was initialized. The restriction is necessary because collations used by various data dictionary table fields are determined by the setting defined when the server is initialized, and restarting the server with a different setting would introduce inconsistencies with respect to how identifiers are ordered and compared.

It is therefore necessary to configure `lower_case_table_names` to the desired setting before initializing the server. In most cases, this requires configuring `lower_case_table_names` in a MySQL option file before starting the MySQL server for the first time. For APT installations on Debian and Ubuntu, however, the server is initialized for you, and there is no opportunity to configure the setting in an option file beforehand. You must therefore use the `debconf-set-selection` utility

prior to installing MySQL using APT to enable `lower_case_table_names`. To do so, run this command before installing MySQL using APT:

```
$> sudo debconf-set-selections <<< "mysql-server mysql-server/lowercase-table-names select Enabled"
```

- `mandatory_roles`

Command-Line Format	<code>--mandatory-roles=value</code>
System Variable	<code>mandatory_roles</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>empty string</code>

Roles the server should treat as mandatory. In effect, these roles are automatically granted to every user, although setting `mandatory_roles` does not actually change any user accounts, and the granted roles are not visible in the `mysql.role_edges` system table.

The variable value is a comma-separated list of role names. Example:

```
SET PERSIST mandatory_roles = '`role1`@`%`,`role2`,role3,role4@localhost';
```

Setting the runtime value of `mandatory_roles` requires the `ROLE_ADMIN` privilege, in addition to the `SYSTEM_VARIABLES_ADMIN` privilege (or the deprecated `SUPER` privilege) normally required to set a global system variable runtime value.

Role names consist of a user part and host part in `user_name@host_name` format. The host part, if omitted, defaults to `%`. For additional information, see [Section 8.2.5, “Specifying Role Names”](#).

The `mandatory_roles` value is a string, so user names and host names, if quoted, must be written in a fashion permitted for quoting within quoted strings.

Roles named in the value of `mandatory_roles` cannot be revoked with `REVOKE` or dropped with `DROP ROLE` or `DROP USER`.

To prevent sessions from being made system sessions by default, a role that has the `SYSTEM_USER` privilege cannot be listed in the value of the `mandatory_roles` system variable:

- If `mandatory_roles` is assigned a role at startup that has the `SYSTEM_USER` privilege, the server writes a message to the error log and exits.
- If `mandatory_roles` is assigned a role at runtime that has the `SYSTEM_USER` privilege, an error occurs and the `mandatory_roles` value remains unchanged.

Mandatory roles, like explicitly granted roles, do not take effect until activated (see [Activating Roles](#)). At login time, role activation occurs for all granted roles if the `activate_all_roles_on_login` system variable is enabled; otherwise, or for roles that are set as default roles otherwise. At runtime, `SET ROLE` activates roles.

Roles that do not exist when assigned to `mandatory_roles` but are created later may require special treatment to be considered mandatory. For details, see [Defining Mandatory Roles](#).

`SHOW GRANTS` displays mandatory roles according to the rules described in [Section 15.7.7.22, “SHOW GRANTS Statement”](#).

- `max_allowed_packet`

Command-Line Format	<code>--max-allowed-packet=#</code>
System Variable	<code>max_allowed_packet</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	67108864
Minimum Value	1024
Maximum Value	1073741824
Unit	bytes
Block Size	1024

The maximum size of one packet or any generated/intermediate string, or any parameter sent by the `mysql_stmt_send_long_data()` C API function. The default is 64MB.

The packet message buffer is initialized to `net_buffer_length` bytes, but can grow up to `max_allowed_packet` bytes when needed. This value by default is small, to catch large (possibly incorrect) packets.

You must increase this value if you are using large `BLOB` columns or long strings. It should be as big as the largest `BLOB` you want to use. The protocol limit for `max_allowed_packet` is 1GB. The value should be a multiple of 1024; nonmultiples are rounded down to the nearest multiple.

When you change the message buffer size by changing the value of the `max_allowed_packet` variable, you should also change the buffer size on the client side if your client program permits it. The default `max_allowed_packet` value built in to the client library is 1GB, but individual client programs might override this. For example, `mysql` and `mysqldump` have defaults of 16MB and 24MB, respectively. They also enable you to change the client-side value by setting `max_allowed_packet` on the command line or in an option file.

The session value of this variable is read only. The client can receive up to as many bytes as the session value. However, the server does not send to the client more bytes than the current global `max_allowed_packet` value. (The global value could be less than the session value if the global value is changed after the client connects.)

- `max_connect_errors`

Command-Line Format	<code>--max-connect-errors=#</code>
System Variable	<code>max_connect_errors</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	100
Minimum Value	1
Maximum Value (64-bit platforms)	18446744073709551615

Maximum Value (32-bit platforms)	4294967295
----------------------------------	------------

After `max_connect_errors` successive connection requests from a host are interrupted without a successful connection, the server blocks that host from further connections. If a connection from a host is established successfully within fewer than `max_connect_errors` attempts after a previous connection was interrupted, the error count for the host is cleared to zero. To unblock blocked hosts, flush the host cache; see [Flushing the Host Cache](#).

- `max_connections`

Command-Line Format	<code>--max-connections=#</code>
System Variable	<code>max_connections</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	151
Minimum Value	1
Maximum Value	100000

The maximum permitted number of simultaneous client connections. The maximum effective value is the lesser of the effective value of `open_files_limit` - 810, and the value actually set for `max_connections`.

For more information, see [Section 7.1.12.1, “Connection Interfaces”](#).

- `max_delayed_threads`

Command-Line Format	<code>--max-delayed-threads=#</code>
Deprecated	Yes
System Variable	<code>max_delayed_threads</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	20
Minimum Value	0
Maximum Value	16384

This system variable is deprecated (because `DELAYED` inserts are not supported) and subject to removal in a future MySQL release.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

- `max_digest_length`

Command-Line Format	<code>--max-digest-length=#</code>
System Variable	<code>max_digest_length</code>
Scope	Global

Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	1024
Minimum Value	0
Maximum Value	1048576
Unit	bytes

The maximum number of bytes of memory reserved per session for computation of normalized statement digests. Once that amount of space is used during digest computation, truncation occurs: no further tokens from a parsed statement are collected or figure into its digest value. Statements that differ only after that many bytes of parsed tokens produce the same normalized statement digest and are considered identical if compared or if aggregated for digest statistics.

Warning

Setting [max_digest_length](#) to zero disables digest production, which also disables server functionality that requires digests, such as MySQL Enterprise Firewall.

Decreasing the [max_digest_length](#) value reduces memory use but causes the digest value of more statements to become indistinguishable if they differ only at the end. Increasing the value permits longer statements to be distinguished but increases memory use, particularly for workloads that involve large numbers of simultaneous sessions (the server allocates [max_digest_length](#) bytes per session).

The parser uses this system variable as a limit on the maximum length of normalized statement digests that it computes. The Performance Schema, if it tracks statement digests, makes a copy of the digest value, using the [performance_schema_max_digest_length](#) system variable as a limit on the maximum length of digests that it stores. Consequently, if [performance_schema_max_digest_length](#) is less than [max_digest_length](#), digest values stored in the Performance Schema are truncated relative to the original digest values.

For more information about statement digesting, see [Section 29.10, “Performance Schema Statement Digests and Sampling”](#).

- [max_error_count](#)

Command-Line Format	<code>--max-error-count=#</code>
System Variable	max_error_count
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer
Default Value	1024
Minimum Value	0
Maximum Value	65535

The maximum number of error, warning, and information messages to be stored for display by the [SHOW ERRORS](#) and [SHOW WARNINGS](#) statements. This is the same as the number of condition

areas in the diagnostics area, and thus the number of conditions that can be inspected by `GET DIAGNOSTICS`.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

- `max_execution_time`

Command-Line Format	<code>--max-execution-time=#</code>
System Variable	<code>max_execution_time</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295
Unit	milliseconds

The execution timeout for `SELECT` statements, in milliseconds. If the value is 0, timeouts are not enabled.

`max_execution_time` applies as follows:

- The global `max_execution_time` value provides the default for the session value for new connections. The session value applies to `SELECT` executions executed within the session that include no `MAX_EXECUTION_TIME(N)` optimizer hint or for which `N` is 0.
 - `max_execution_time` applies to read-only `SELECT` statements. Statements that are not read only are those that invoke a stored function that modifies data as a side effect.
 - `max_execution_time` is ignored for `SELECT` statements in stored programs.
- `max_heap_table_size`

Command-Line Format	<code>--max-heap-table-size=#</code>
System Variable	<code>max_heap_table_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	16777216
Minimum Value	16384
Maximum Value (64-bit platforms)	18446744073709550592
Maximum Value (32-bit platforms)	4294966272
Unit	bytes

Block Size	1024
------------	------

This variable sets the maximum size to which user-created `MEMORY` tables are permitted to grow. The value of the variable is used to calculate `MEMORY` table `MAX_ROWS` values.

Setting this variable has no effect on any existing `MEMORY` table, unless the table is re-created with a statement such as `CREATE TABLE` or altered with `ALTER TABLE` or `TRUNCATE TABLE`. A server restart also sets the maximum size of existing `MEMORY` tables to the global `max_heap_table_size` value.

This variable is also used in conjunction with `tmp_table_size` to limit the size of internal in-memory tables. See [Section 10.4.4, “Internal Temporary Table Use in MySQL”](#).

`max_heap_table_size` is not replicated. See [Section 19.5.1.21, “Replication and MEMORY Tables”](#), and [Section 19.5.1.39, “Replication and Variables”](#), for more information.

- `max_insert_delayed_threads`

Deprecated	Yes
System Variable	<code>max_insert_delayed_threads</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	20
Maximum Value	16384

This variable is a synonym for `max_delayed_threads`. Like `max_delayed_threads`, it is deprecated (because `DELAYED` inserts are not supported) and subject to removal in a future MySQL release.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

- `max_join_size`

Command-Line Format	<code>--max-join-size=#</code>
System Variable	<code>max_join_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	18446744073709551615
Minimum Value	1

Maximum Value	18446744073709551615
---------------	----------------------

This represents a limit on the maximum number of row accesses in base tables made by a join. If the server's estimate indicates that a greater number of rows than `max_join_size` must be read from the base tables, the statement is rejected with an error.

Setting this variable to a value other than `DEFAULT` resets the value of `sql_big_selects` to 0. If you set the `sql_big_selects` value again, the `max_join_size` variable is ignored.

- `max_length_for_sort_data`

Command-Line Format	<code>--max-length-for-sort-data=#</code>
Deprecated	Yes
System Variable	<code>max_length_for_sort_data</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	4096
Minimum Value	4
Maximum Value	8388608
Unit	bytes

This variable is deprecated, and has no effect in MySQL 8.3.

- `max_points_in_geometry`

Command-Line Format	<code>--max-points-in-geometry=#</code>
System Variable	<code>max_points_in_geometry</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	65536
Minimum Value	3
Maximum Value	1048576

The maximum value of the `points_per_circle` argument to the `ST_Buffer_Strategy()` function.

- `max_prepared_stmt_count`

Command-Line Format	<code>--max-prepared-stmt-count=#</code>
System Variable	<code>max_prepared_stmt_count</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	16382

Minimum Value	0
Maximum Value	4194304

This variable limits the total number of prepared statements in the server. It can be used in environments where there is the potential for denial-of-service attacks based on running the server out of memory by preparing huge numbers of statements. If the value is set lower than the current number of prepared statements, existing statements are not affected and can be used, but no new statements can be prepared until the current number drops below the limit. Setting the value to 0 disables prepared statements.

- `max_seeks_for_key`

Command-Line Format	<code>--max-seeks-for-key=#</code>
System Variable	<code>max_seeks_for_key</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value (Windows)	4294967295
Default Value (Other, 64-bit platforms)	18446744073709551615
Default Value (Other, 32-bit platforms)	4294967295
Minimum Value	1
Maximum Value (Windows)	4294967295
Maximum Value (Other, 64-bit platforms)	18446744073709551615
Maximum Value (Other, 32-bit platforms)	4294967295

Limit the assumed maximum number of seeks when looking up rows based on a key. The MySQL optimizer assumes that no more than this number of key seeks are required when searching for matching rows in a table by scanning an index, regardless of the actual cardinality of the index (see [Section 15.7.7.23, “SHOW INDEX Statement”](#)). By setting this to a low value (say, 100), you can force MySQL to prefer indexes instead of table scans.

- `max_sort_length`

Command-Line Format	<code>--max-sort-length=#</code>
System Variable	<code>max_sort_length</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	1024
Minimum Value	4
Maximum Value	8388608
Unit	bytes

The number of bytes to use when sorting string values which use `PAD SPACE` collations. The server uses only the first `max_sort_length` bytes of any such value and ignores the rest. Consequently, such values that differ only after the first `max_sort_length` bytes compare as equal for `GROUP BY`, `ORDER BY`, and `DISTINCT` operations. (This behavior differs from previous versions of MySQL, where this setting was applied to all values used in comparisons.)

Increasing the value of `max_sort_length` may require increasing the value of `sort_buffer_size` as well. For details, see [Section 10.2.1.16, “ORDER BY Optimization”](#)

- `max_sp_recursion_depth`

Command-Line Format	<code>--max-sp-recursion-depth[=#]</code>
System Variable	<code>max_sp_recursion_depth</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	255

The number of times that any given stored procedure may be called recursively. The default value for this option is 0, which completely disables recursion in stored procedures. The maximum value is 255.

Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup.

- `max_user_connections`

Command-Line Format	<code>--max-user-connections=#</code>
System Variable	<code>max_user_connections</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295

The maximum number of simultaneous connections permitted to any given MySQL user account. A value of 0 (the default) means “no limit.”

This variable has a global value that can be set at server startup or runtime. It also has a read-only session value that indicates the effective simultaneous-connection limit that applies to the account associated with the current session. The session value is initialized as follows:

- If the user account has a nonzero `MAX_USER_CONNECTIONS` resource limit, the session `max_user_connections` value is set to that limit.
- Otherwise, the session `max_user_connections` value is set to the global value.

Account resource limits are specified using the `CREATE USER` or `ALTER USER` statement. See [Section 8.2.21, “Setting Account Resource Limits”](#).

- `max_write_lock_count`

Command-Line Format	<code>--max-write-lock-count=#</code>
System Variable	<code>max_write_lock_count</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value (Windows)	4294967295
Default Value (Other, 64-bit platforms)	18446744073709551615
Default Value (Other, 32-bit platforms)	4294967295
Minimum Value	1
Maximum Value (Windows)	4294967295
Maximum Value (Other, 64-bit platforms)	18446744073709551615
Maximum Value (Other, 32-bit platforms)	4294967295

After this many write locks, permit some pending read lock requests to be processed in between. Write lock requests have higher priority than read lock requests. However, if `max_write_lock_count` is set to some low value (say, 10), read lock requests may be preferred over pending write lock requests if the read lock requests have already been passed over in favor of 10 write lock requests. Normally this behavior does not occur because `max_write_lock_count` by default has a very large value.

- `mecab_rc_file`

Command-Line Format	<code>--mecab-rc-file=file_name</code>
System Variable	<code>mecab_rc_file</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	File name

The `mecab_rc_file` option is used when setting up the MeCab full-text parser.

The `mecab_rc_file` option defines the path to the `mecabrc` configuration file, which is the configuration file for MeCab. The option is read-only and can only be set at startup. The `mecabrc` configuration file is required to initialize MeCab.

For information about the MeCab full-text parser, see [Section 14.9.9, “MeCab Full-Text Parser Plugin”](#).

For information about options that can be specified in the MeCab `mecabrc` configuration file, refer to the [MeCab Documentation](#) on the [Google Developers](#) site.

- `min_examined_row_limit`

Command-Line Format	<code>--min-examined-row-limit=#</code>
System Variable	<code>min_examined_row_limit</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No

Type	Integer
Default Value	0
Minimum Value	0
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

Queries that examine fewer than this number of rows are not logged to the slow query log.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

- `myisam_data_pointer_size`

Command-Line Format	<code>--myisam-data-pointer-size=#</code>
System Variable	<code>myisam_data_pointer_size</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	6
Minimum Value	2
Maximum Value	7
Unit	bytes

The default pointer size in bytes, to be used by `CREATE TABLE` for `MyISAM` tables when no `MAX_ROWS` option is specified. This variable cannot be less than 2 or larger than 7. The default value is 6. See [Section B.3.2.10, “The table is full”](#).

- `myisam_max_sort_file_size`

Command-Line Format	<code>--myisam-max-sort-file-size=#</code>
System Variable	<code>myisam_max_sort_file_size</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value (Windows)	2146435072
Default Value (Other, 64-bit platforms)	9223372036853727232
Default Value (Other, 32-bit platforms)	2147483648
Minimum Value	0
Maximum Value (Windows)	2146435072
Maximum Value (Other, 64-bit platforms)	9223372036853727232
Maximum Value (Other, 32-bit platforms)	2147483648
Unit	bytes

The maximum size of the temporary file that MySQL is permitted to use while re-creating a `MyISAM` index (during `REPAIR TABLE`, `ALTER TABLE`, or `LOAD DATA`). If the file size would be larger than

this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

If [MyISAM](#) index files exceed this size and disk space is available, increasing the value may help performance. The space must be available in the file system containing the directory where the original index file is located.

- [myisam_mmap_size](#)

Command-Line Format	<code>--myisam-mmap-size=#</code>
System Variable	myisam_mmap_size
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value (64-bit platforms)	18446744073709551615
Default Value (32-bit platforms)	4294967295
Minimum Value	7
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295
Unit	bytes

The maximum amount of memory to use for memory mapping compressed [MyISAM](#) files. If many compressed [MyISAM](#) tables are used, the value can be decreased to reduce the likelihood of memory-swapping problems.

- [myisam_recover_options](#)

Command-Line Format	<code>--myisam-recover-options[=list]</code>
System Variable	myisam_recover_options
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	OFF
Valid Values	OFF DEFAULT BACKUP FORCE QUICK

Set the [MyISAM](#) storage engine recovery mode. The variable value is any combination of the values of [OFF](#), [DEFAULT](#), [BACKUP](#), [FORCE](#), or [QUICK](#). If you specify multiple values, separate them by commas. Specifying the variable with no value at server startup is the same as specifying [DEFAULT](#), and specifying with an explicit value of "" disables recovery (same as a value of [OFF](#)). If recovery is enabled, each time `mysqld` opens a [MyISAM](#) table, it checks whether the table is marked as crashed or was not closed properly. (The last option works only if you are running with external

locking disabled.) If this is the case, `mysqld` runs a check on the table. If the table was corrupted, `mysqld` attempts to repair it.

The following options affect how the repair works.

Option	Description
<code>OFF</code>	No recovery.
<code>DEFAULT</code>	Recovery without backup, forcing, or quick checking.
<code>BACKUP</code>	If the data file was changed during recovery, save a backup of the <code>tbl_name.MYD</code> file as <code>tbl_name-datetime.BAK</code> .
<code>FORCE</code>	Run recovery even if we would lose more than one row from the <code>.MYD</code> file.
<code>QUICK</code>	Do not check the rows in the table if there are not any delete blocks.

Before the server automatically repairs a table, it writes a note about the repair to the error log. If you want to be able to recover from most problems without user intervention, you should use the options `BACKUP`, `FORCE`. This forces a repair of a table even if some rows would be deleted, but it keeps the old data file as a backup so that you can later examine what happened.

See [Section 18.2.1, “MyISAM Startup Options”](#).

- `myisam_sort_buffer_size`

Command-Line Format	<code>--myisam-sort-buffer-size=#</code>
System Variable	<code>myisam_sort_buffer_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	8388608
Minimum Value	4096
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295
Unit	bytes

The size of the buffer that is allocated when sorting `MyISAM` indexes during a `REPAIR TABLE` or when creating indexes with `CREATE INDEX` or `ALTER TABLE`.

- `myisam_stats_method`

Command-Line Format	<code>--myisam-stats-method=name</code>
System Variable	<code>myisam_stats_method</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>nulls_unequal</code>

Valid Values	<code>nulls_unequal</code> <code>nulls_equal</code> <code>nulls_ignored</code>
--------------	--

How the server treats `NULL` values when collecting statistics about the distribution of index values for `MyISAM` tables. This variable has three possible values, `nulls_equal`, `nulls_unequal`, and `nulls_ignored`. For `nulls_equal`, all `NULL` index values are considered equal and form a single value group that has a size equal to the number of `NULL` values. For `nulls_unequal`, `NULL` values are considered unequal, and each `NULL` forms a distinct value group of size 1. For `nulls_ignored`, `NULL` values are ignored.

The method that is used for generating table statistics influences how the optimizer chooses indexes for query execution, as described in [Section 10.3.8, “InnoDB and MyISAM Index Statistics Collection”](#).

- `myisam_use_mmap`

Command-Line Format	<code>--myisam-use-mmap[={OFF ON}]</code>
System Variable	<code>myisam_use_mmap</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Use memory mapping for reading and writing `MyISAM` tables.

- `mysql_native_password_proxy_users`

Command-Line Format	<code>--mysql-native-password-proxy-users[={OFF ON}]</code>
System Variable	<code>mysql_native_password_proxy_users</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

This variable controls whether the `mysql_native_password` built-in authentication plugin (deprecated) supports proxy users. It has no effect unless the `check_proxy_users` system variable and the `mysql_native_password` plugin are enabled. For information about user proxying, see [Section 8.2.19, “Proxy Users”](#).

- `named_pipe`

Command-Line Format	<code>--named-pipe[={OFF ON}]</code>
System Variable	<code>named_pipe</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No

Platform Specific	Windows
Type	Boolean
Default Value	OFF

(Windows only.) Indicates whether the server supports connections over named pipes.

- `named_pipe_full_access_group`

Command-Line Format	<code>--named-pipe-full-access-group=value</code>
System Variable	<code>named_pipe_full_access_group</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Platform Specific	Windows
Type	String
Default Value	<code>empty string</code>
Valid Values	<code>empty string</code> <code>valid Windows local group name</code> <code>*everyone*</code>

(Windows only.) The access control granted to clients on the named pipe created by the MySQL server is set to the minimum necessary for successful communication when the `named_pipe` system variable is enabled to support named-pipe connections. Some MySQL client software can open named pipe connections without any additional configuration; however, other client software may still require full access to open a named pipe connection.

This variable sets the name of a Windows local group whose members are granted sufficient access by the MySQL server to use named-pipe clients. The default value is an empty string, which means that no Windows user is granted full access to the named pipe.

A new Windows local group name (for example, `mysql_access_client_users`) can be created in Windows and then used to replace the default value when access is absolutely necessary. In this case, limit the membership of the group to as few users as possible, removing users from the group when their client software is upgraded. A non-member of the group who attempts to open a connection to MySQL with the affected named-pipe client is denied access until a Windows administrator adds the user to the group. Newly added users must log out and log in again to join the group (required by Windows).

Setting the value to `'*everyone*'` provides a language-independent way of referring to the Everyone group on Windows. The Everyone group is not secure by default.

- `net_buffer_length`

Command-Line Format	<code>--net-buffer-length=#</code>
System Variable	<code>net_buffer_length</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	<code>16384</code>

Minimum Value	1024
Maximum Value	1048576
Unit	bytes
Block Size	1024

Each client thread is associated with a connection buffer and result buffer. Both begin with a size given by `net_buffer_length` but are dynamically enlarged up to `max_allowed_packet` bytes as needed. The result buffer shrinks to `net_buffer_length` after each SQL statement.

This variable should not normally be changed, but if you have very little memory, you can set it to the expected length of statements sent by clients. If statements exceed this length, the connection buffer is automatically enlarged. The maximum value to which `net_buffer_length` can be set is 1MB.

The session value of this variable is read only.

- `net_read_timeout`

Command-Line Format	<code>--net-read-timeout=#</code>
System Variable	<code>net_read_timeout</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	30
Minimum Value	1
Maximum Value	31536000
Unit	seconds

The number of seconds to wait for more data from a connection before aborting the read. When the server is reading from the client, `net_read_timeout` is the timeout value controlling when to abort. When the server is writing to the client, `net_write_timeout` is the timeout value controlling when to abort. See also `replica_net_timeout`.

- `net_retry_count`

Command-Line Format	<code>--net-retry-count=#</code>
System Variable	<code>net_retry_count</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	10
Minimum Value	1
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

If a read or write on a communication port is interrupted, retry this many times before giving up. This value should be set quite high on FreeBSD because internal interrupts are sent to all threads.

- `net_write_timeout`

Command-Line Format	<code>--net-write-timeout=#</code>
System Variable	<code>net_write_timeout</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	60
Minimum Value	1
Maximum Value	31536000
Unit	seconds

The number of seconds to wait for a block to be written to a connection before aborting the write. See also `net_read_timeout`.

- `new`

Command-Line Format	<code>--new[={OFF ON}]</code>
Deprecated	Yes
System Variable	<code>new</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Disabled by	<code>skip-new</code>
Type	Boolean
Default Value	OFF

This variable was used in MySQL 4.0 to turn on some 4.1 behaviors, and is retained for backward compatibility. Its value is always `OFF`.

This variable is deprecated as of MySQL 8.2.0, and is subject to removal in a future release.

In NDB Cluster, setting this variable to `ON` makes it possible to employ partitioning types other than `KEY` or `LINEAR KEY` with `NDB` tables. This experimental feature is not supported in production, and is now deprecated and thus subject to removal in a future release. For additional information, see [User-defined partitioning and the NDB storage engine \(NDB Cluster\)](#).

- `ngram_token_size`

Command-Line Format	<code>--ngram-token-size=#</code>
System Variable	<code>ngram_token_size</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	2
Minimum Value	1

Maximum Value	10
---------------	----

Defines the n-gram token size for the n-gram full-text parser. The `ngram_token_size` option is read-only and can only be modified at startup. The default value is 2 (bigram). The maximum value is 10.

For more information about how to configure this variable, see [Section 14.9.8, “ngram Full-Text Parser”](#).

- `offline_mode`

Command-Line Format	<code>--offline-mode[={OFF ON}]</code>
System Variable	<code>offline_mode</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

In offline mode, the MySQL instance disconnects client users unless they have relevant privileges, and does not allow them to initiate new connections. Clients that are refused access receive an `ER_SERVER_OFFLINE_MODE` error.

To put a server in offline mode, change the value of the `offline_mode` system variable from `OFF` to `ON`. To resume normal operations, change `offline_mode` from `ON` to `OFF`. To control offline mode, an administrator account must have the `SYSTEM_VARIABLES_ADMIN` privilege and the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege, which covers both these privileges). `CONNECTION_ADMIN` is required, to prevent accidental lockout.

Offline mode has these characteristics:

- Connected client users who do not have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege) are disconnected on the next request, with an appropriate error. Disconnection includes terminating running statements and releasing locks. Such clients also cannot initiate new connections, and receive an appropriate error.
 - Connected client users who have the `CONNECTION_ADMIN` or `SUPER` privilege are not disconnected, and can initiate new connections to manage the server.
 - If the user that puts a server in offline mode does not have the `SYSTEM_USER` privilege, connected client users who have the `SYSTEM_USER` privilege are also not disconnected. However, these users cannot initiate new connections to the server while it is in offline mode, unless they have the `CONNECTION_ADMIN` or `SUPER` privilege as well. It is only their existing connection that cannot be terminated, because the `SYSTEM_USER` privilege is required to kill a session or statement that is executing with the `SYSTEM_USER` privilege.
 - Replication threads are permitted to keep applying data to the server.
- `old`

Command-Line Format	<code>--old[={OFF ON}]</code>
Deprecated	Yes
System Variable	<code>old</code>
Scope	Global
Dynamic	No

<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

`old` is a compatibility variable. It is disabled by default, but can be enabled at startup to revert the server to behaviors present in older versions.

When `old` is enabled, it changes the default scope of index hints to that used prior to MySQL 5.1.17. That is, index hints with no `FOR` clause apply only to how indexes are used for row retrieval and not to resolution of `ORDER BY` or `GROUP BY` clauses. (See [Section 10.9.4, “Index Hints”](#).) Take care about enabling this in a replication setup. With statement-based binary logging, having different modes for the source and replicas might lead to replication errors.

This variable is deprecated as of MySQL 8.2.0, and is subject to removal in a future release.

- `old_alter_table`

Command-Line Format	<code>--old-alter-table[={OFF ON}]</code>
System Variable	<code>old_alter_table</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

When this variable is enabled, the server does not use the optimized method of processing an `ALTER TABLE` operation. It reverts to using a temporary table, copying over the data, and then renaming the temporary table to the original, as used by MySQL 5.0 and earlier. For more information on the operation of `ALTER TABLE`, see [Section 15.1.9, “ALTER TABLE Statement”](#).

`ALTER TABLE ... DROP PARTITION` with `old_alter_table=ON` rebuilds the partitioned table and attempts to move data from the dropped partition to another partition with a compatible `PARTITION ... VALUES` definition. Data that cannot be moved to another partition is deleted. In earlier releases, `ALTER TABLE ... DROP PARTITION` with `old_alter_table=ON` deletes data stored in the partition and drops the partition.

- `open_files_limit`

Command-Line Format	<code>--open-files-limit=#</code>
System Variable	<code>open_files_limit</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	5000, with possible adjustment
Minimum Value	0
Maximum Value	platform dependent

The number of file descriptors available to `mysqld` from the operating system:

- At startup, `mysqld` reserves descriptors with `setrlimit()`, using the value requested at by setting this variable directly or by using the `--open-files-limit` option to `mysqld_safe`. If `mysqld` produces the error `Too many open files`, try increasing the `open_files_limit`

value. Internally, the maximum value for this variable is the maximum unsigned integer value, but the actual maximum is platform dependent.

- At runtime, the value of `open_files_limit` indicates the number of file descriptors actually permitted to `mysqld` by the operating system, which might differ from the value requested at startup. If the number of file descriptors requested during startup cannot be allocated, `mysqld` writes a warning to the error log.

The effective `open_files_limit` value is based on the value specified at system startup (if any) and the values of `max_connections` and `table_open_cache`, using these formulas:

- $10 + \text{max_connections} + (\text{table_open_cache} * 2)$. Using the defaults for these variables yields 8161.

On Windows only, 2048 (the value of the C Run-Time Library file descriptor maximum) is added to this number. This totals 10209, again using the default values for the indicated system variables.

- $\text{max_connections} * 5$
- The operating system limit.

The server attempts to obtain the number of file descriptors using the maximum of those values, capped to the maximum unsigned integer value. If that many descriptors cannot be obtained, the server attempts to obtain as many as the system permits.

The effective value is 0 on systems where MySQL cannot change the number of open files.

On Unix, the value cannot be set greater than the value displayed by the `ulimit -n` command. On Linux systems using `systemd`, the value cannot be set greater than `LimitNOFILE` (this is `DefaultLimitNOFILE`, if `LimitNOFILE` is not set); otherwise, on Linux, the value of `open_files_limit` cannot exceed `ulimit -n`.

- `optimizer_prune_level`

Command-Line Format	<code>--optimizer-prune-level=#</code>
System Variable	<code>optimizer_prune_level</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	1
Minimum Value	0
Maximum Value	1

Controls the heuristics applied during query optimization to prune less-promising partial plans from the optimizer search space. A value of 0 disables heuristics so that the optimizer performs an exhaustive search. A value of 1 causes the optimizer to prune plans based on the number of rows retrieved by intermediate plans.

- `optimizer_search_depth`

Command-Line Format	<code>--optimizer-search-depth=#</code>
System Variable	<code>optimizer_search_depth</code>
Scope	Global, Session
Dynamic	Yes

<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	62
Minimum Value	0
Maximum Value	62

The maximum depth of search performed by the query optimizer. Values larger than the number of relations in a query result in better query plans, but take longer to generate an execution plan for a query. Values smaller than the number of relations in a query return an execution plan quicker, but the resulting plan may be far from being optimal. If set to 0, the system automatically picks a reasonable value.

- `optimizer_switch`

Command-Line Format	<code>--optimizer-switch=value</code>
System Variable	<code>optimizer_switch</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Set
Valid Values	<code>batched_key_access={on off}</code> <code>block_nested_loop={on off}</code> <code>condition_fanout_filter={on off}</code> <code>derived_condition_pushdown={on off}</code> <code>derived_merge={on off}</code> <code>duplicateweedout={on off}</code> <code>engine_condition_pushdown={on off}</code> <code>firstmatch={on off}</code> <code>hash_join={on off}</code> <code>index_condition_pushdown={on off}</code> <code>index_merge={on off}</code> <code>index_merge_intersection={on off}</code> <code>index_merge_sort_union={on off}</code> <code>index_merge_union={on off}</code> <code>loosescan={on off}</code> <code>materialization={on off}</code> <code>mrr={on off}</code> <code>mrr_cost_based={on off}</code> <code>prefer_ordering_index={on off}</code>

	semi_join={on off} skip_scan={on off} subquery_materialization_cost_based={on off} subquery_to_derived={on off} use_index_extensions={on off} use_invisible_indexes={on off}
Valid Values	batched_key_access={on off} block_nested_loop={on off} condition_fanout_filter={on off} derived_merge={on off} duplicateweedout={on off} engine_condition_pushdown={on off} firstmatch={on off} hash_join={on off} index_condition_pushdown={on off} index_merge={on off} index_merge_intersection={on off} index_merge_sort_union={on off} index_merge_union={on off} loosescan={on off} materialization={on off} mrr={on off} mrr_cost_based={on off} prefer_ordering_index={on off} semi_join={on off} skip_scan={on off} subquery_materialization_cost_based={on off} subquery_to_derived={on off} use_index_extensions={on off} use_invisible_indexes={on off}
Valid Values	batched_key_access={on off}

	<code>block_nested_loop={on off}</code> <code>condition_fanout_filter={on off}</code> <code>derived_merge={on off}</code> <code>duplicateweedout={on off}</code> <code>engine_condition_pushdown={on off}</code> <code>firstmatch={on off}</code> <code>hash_join={on off}</code> <code>index_condition_pushdown={on off}</code> <code>index_merge={on off}</code> <code>index_merge_intersection={on off}</code> <code>index_merge_sort_union={on off}</code> <code>index_merge_union={on off}</code> <code>loosescan={on off}</code> <code>materialization={on off}</code> <code>mrr={on off}</code> <code>mrr_cost_based={on off}</code> <code>semijoin={on off}</code> <code>skip_scan={on off}</code> <code>subquery_materialization_cost_based={on off}</code> <code>use_index_extensions={on off}</code> <code>use_invisible_indexes={on off}</code>
Valid Values	<code>batched_key_access={on off}</code> <code>block_nested_loop={on off}</code> <code>condition_fanout_filter={on off}</code> <code>derived_merge={on off}</code> <code>duplicateweedout={on off}</code> <code>engine_condition_pushdown={on off}</code> <code>firstmatch={on off}</code> <code>index_condition_pushdown={on off}</code> <code>index_merge={on off}</code> <code>index_merge_intersection={on off}</code>

```

index_merge_sort_union={on|off}

index_merge_union={on|off}

loosescan={on|off}

materialization={on|off}

mrr={on|off}

mrr_cost_based={on|off}

semijoin={on|off}

skip_scan={on|off}

subquery_materialization_cost_based={on|off}

use_index_extensions={on|off}

use_invisible_indexes={on|off}

```

The `optimizer_switch` system variable enables control over optimizer behavior. The value of this variable is a set of flags, each of which has a value of `on` or `off` to indicate whether the corresponding optimizer behavior is enabled or disabled. This variable has global and session values and can be changed at runtime. The global default can be set at server startup.

To see the current set of optimizer flags, select the variable value:

```

mysql> SELECT @@optimizer_switch\G
***** 1. row *****
@@optimizer_switch: index_merge=on,index_merge_union=on,
                    index_merge_sort_union=on,index_merge_intersection=on,
                    engine_condition_pushdown=on,index_condition_pushdown=on,
                    mrr=on,mrr_cost_based=on,block_nested_loop=on,
                    batched_key_access=off,materialization=on,semijoin=on,
                    loosescan=on,firstmatch=on,duplicateweedout=on,
                    subquery_materialization_cost_based=on,
                    use_index_extensions=on,condition_fanout_filter=on,
                    derived_merge=on,use_invisible_indexes=off,skip_scan=on,
                    hash_join=on,subquery_to_derived=off,
                    prefer_ordering_index=on,hypergraph_optimizer=off,
                    derived_condition_pushdown=on

```

For more information about the syntax of this variable and the optimizer behaviors that it controls, see [Section 10.9.2, “Switchable Optimizations”](#).

- `optimizer_trace`

Command-Line Format	<code>--optimizer-trace=value</code>
System Variable	<code>optimizer_trace</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String

This variable controls optimizer tracing. For details, see [MySQL Internals: Tracing the Optimizer](#).

- `optimizer_trace_features`

Command-Line Format	<code>--optimizer-trace-features=value</code>
System Variable	<code>optimizer_trace_features</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String

This variable enables or disables selected optimizer tracing features. For details, see [MySQL Internals: Tracing the Optimizer](#).

- `optimizer_trace_limit`

Command-Line Format	<code>--optimizer-trace-limit=#</code>
System Variable	<code>optimizer_trace_limit</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	0
Maximum Value	2147483647

The maximum number of optimizer traces to display. For details, see [MySQL Internals: Tracing the Optimizer](#).

- `optimizer_trace_max_mem_size`

Command-Line Format	<code>--optimizer-trace-max-mem-size=#</code>
System Variable	<code>optimizer_trace_max_mem_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	1048576
Minimum Value	0
Maximum Value	4294967295
Unit	bytes

The maximum cumulative size of stored optimizer traces. For details, see [MySQL Internals: Tracing the Optimizer](#).

- `optimizer_trace_offset`

Command-Line Format	<code>--optimizer-trace-offset=#</code>
System Variable	<code>optimizer_trace_offset</code>
Scope	Global, Session
Dynamic	Yes

SET_VAR Hint Applies	No
Type	Integer
Default Value	-1
Minimum Value	-2147483647
Maximum Value	2147483647

The offset of optimizer traces to display. For details, see [MySQL Internals: Tracing the Optimizer](#).

- [performance_schema_xxx](#)

Performance Schema system variables are listed in [Section 29.15, “Performance Schema System Variables”](#). These variables may be used to configure Performance Schema operation.

- [parser_max_mem_size](#)

Command-Line Format	<code>--parser-max-mem-size=#</code>
System Variable	parser_max_mem_size
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value (64-bit platforms)	18446744073709551615
Default Value (32-bit platforms)	4294967295
Minimum Value	10000000
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295
Unit	bytes

The maximum amount of memory available to the parser. The default value places no limit on memory available. The value can be reduced to protect against out-of-memory situations caused by parsing long or complex SQL statements.

- [partial_revokes](#)

Command-Line Format	<code>--partial-revokes[={OFF ON}]</code>
System Variable	partial_revokes
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF (if partial revokes do not exist) ON (if partial revokes exist)

Enabling this variable makes it possible to revoke privileges partially. Specifically, for users who have privileges at the global level, [partial_revokes](#) enables privileges for specific schemas to be revoked while leaving the privileges in place for other schemas. For example, a user who has the global [UPDATE](#) privilege can be restricted from exercising this privilege on the [mysql](#) system schema. (Or, stated another way, the user is enabled to exercise the [UPDATE](#) privilege on all schemas except the [mysql](#) schema.) In this sense, the user's global [UPDATE](#) privilege is partially revoked.

Once enabled, `partial_revokes` cannot be disabled if any account has privilege restrictions. If any such account exists, disabling `partial_revokes` fails:

- For attempts to disable `partial_revokes` at startup, the server logs an error message and enables `partial_revokes`.
- For attempts to disable `partial_revokes` at runtime, an error occurs and the `partial_revokes` value remains unchanged.

To disable `partial_revokes` in this case, first modify each account that has partially revoked privileges, either by re-granting the privileges or by removing the account.

Note

In privilege assignments, enabling `partial_revokes` causes MySQL to interpret occurrences of unescaped `_` and `%` SQL wildcard characters in schema names as literal characters, just as if they had been escaped as `_` and `\%`. Because this changes how MySQL interprets privileges, it may be advisable to avoid unescaped wildcard characters in privilege assignments for installations where `partial_revokes` may be enabled.

In addition, use of `_` and `%` as wildcard characters in grants is deprecated as of MySQL 8.2.0, and you should expect support for them to be removed in a future version of MySQL.

For more information, including instructions for removing partial revokes, see [Section 8.2.12, “Privilege Restriction Using Partial Revokes”](#).

- `password_history`

Command-Line Format	<code>--password-history=#</code>
System Variable	<code>password_history</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295

This variable defines the global policy for controlling reuse of previous passwords based on required minimum number of password changes. For an account password used previously, this variable indicates the number of subsequent account password changes that must occur before the password can be reused. If the value is 0 (the default), there is no reuse restriction based on number of password changes.

Changes to this variable apply immediately to all accounts defined with the `PASSWORD HISTORY DEFAULT` option.

The global number-of-changes password reuse policy can be overridden as desired for individual accounts using the `PASSWORD HISTORY` option of the `CREATE USER` and `ALTER USER` statements. See [Section 8.2.15, “Password Management”](#).

- `password_require_current`

Command-Line Format	<code>--password-require-current[={OFF ON}]</code>
System Variable	<code>password_require_current</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

This variable defines the global policy for controlling whether attempts to change an account password must specify the current password to be replaced.

Changes to this variable apply immediately to all accounts defined with the `PASSWORD REQUIRE CURRENT DEFAULT` option.

The global verification-required policy can be overridden as desired for individual accounts using the `PASSWORD REQUIRE` option of the `CREATE USER` and `ALTER USER` statements. See [Section 8.2.15, “Password Management”](#).

- `password_reuse_interval`

Command-Line Format	<code>--password-reuse-interval=#</code>
System Variable	<code>password_reuse_interval</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295
Unit	days

This variable defines the global policy for controlling reuse of previous passwords based on time elapsed. For an account password used previously, this variable indicates the number of days that must pass before the password can be reused. If the value is 0 (the default), there is no reuse restriction based on time elapsed.

Changes to this variable apply immediately to all accounts defined with the `PASSWORD REUSE INTERVAL DEFAULT` option.

The global time-elapsed password reuse policy can be overridden as desired for individual accounts using the `PASSWORD REUSE INTERVAL` option of the `CREATE USER` and `ALTER USER` statements. See [Section 8.2.15, “Password Management”](#).

- `persisted_globals_load`

Command-Line Format	<code>--persisted-globals-load[={OFF ON}]</code>
System Variable	<code>persisted_globals_load</code>
Scope	Global
Dynamic	No

<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	ON

Whether to load persisted configuration settings from the `mysqld-auto.cnf` file in the data directory. The server normally processes this file at startup after all other option files (see [Section 6.2.2.2, “Using Option Files”](#)). Disabling `persisted_globals_load` causes the server startup sequence to skip `mysqld-auto.cnf`.

To modify the contents of `mysqld-auto.cnf`, use the `SET PERSIST`, `SET PERSIST_ONLY`, and `RESET PERSIST` statements. See [Section 7.1.9.3, “Persisted System Variables”](#).

- `persist_only_admin_x509_subject`

Command-Line Format	<code>--persist-only-admin-x509-subject=string</code>
System Variable	<code>persist_only_admin_x509_subject</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>empty string</code>

`SET PERSIST` and `SET PERSIST_ONLY` enable system variables to be persisted to the `mysqld-auto.cnf` option file in the data directory (see [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#)). Persisting system variables enables runtime configuration changes that affect subsequent server restarts, which is convenient for remote administration not requiring direct access to MySQL server host option files. However, some system variables are nonpersistible or can be persisted only under certain restrictive conditions.

The `persist_only_admin_x509_subject` system variable specifies the SSL certificate X.509 Subject value that users must have to be able to persist system variables that are persist-restricted. The default value is the empty string, which disables the Subject check so that persist-restricted system variables cannot be persisted by any user.

If `persist_only_admin_x509_subject` is nonempty, users who connect to the server using an encrypted connection and supply an SSL certificate with the designated Subject value then can use `SET PERSIST_ONLY` to persist persist-restricted system variables. For information about persist-restricted system variables and instructions for configuring MySQL to enable `persist_only_admin_x509_subject`, see [Section 7.1.9.4, “Nonpersistible and Persist-Restricted System Variables”](#).

- `persist_sensitive_variables_in_plaintext`

Command-Line Format	<code>--persist_sensitive_variables_in_plaintext[={ON}]</code>
System Variable	<code>persist_sensitive_variables_in_plaintext</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean

Default Value	ON
---------------	----

`persist_sensitive_variables_in_plaintext` controls whether the server is permitted to store the values of sensitive system variables in an unencrypted format, if keyring component support is not available at the time when `SET PERSIST` is used to set the value of the system variable. It also controls whether or not the server can start if the encrypted values cannot be decrypted. Note that keyring plugins do not support secure storage of sensitive system variables; a keyring component (see [Section 8.4.4, “The MySQL Keyring”](#)) must be enabled on the MySQL Server instance to support secure storage.

The default setting, `ON`, encrypts the values if keyring component support is available, and persists them unencrypted (with a warning) if it is not. The next time any persisted system variable is set, if keyring support is available at that time, the server encrypts the values of any unencrypted sensitive system variables. The `ON` setting also allows the server to start if encrypted system variable values cannot be decrypted, in which case a warning is issued and the default values for the system variables are used. In that situation, their values cannot be changed until they can be decrypted.

The most secure setting, `OFF`, means sensitive system variable values cannot be persisted if keyring component support is unavailable. The `OFF` setting also means the server does not start if encrypted system variable values cannot be decrypted.

For more information, see [Persisting Sensitive System Variables](#).

- `pid_file`

Command-Line Format	<code>--pid-file=file_name</code>
System Variable	<code>pid_file</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	File name

The path name of the file in which the server writes its process ID. The server creates the file in the data directory unless an absolute path name is given to specify a different directory. If you specify this variable, you must specify a value. If you do not specify this variable, MySQL uses a default value of `host_name.pid`, where `host_name` is the name of the host machine.

The process ID file is used by other programs such as `mysqld_safe` to determine the server's process ID. On Windows, this variable also affects the default error log file name. See [Section 7.4.2, “The Error Log”](#).

- `plugin_dir`

Command-Line Format	<code>--plugin-dir=dir_name</code>
System Variable	<code>plugin_dir</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Directory name
Default Value	<code>BASEDIR/lib/plugin</code>

The path name of the plugin directory.

If the plugin directory is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by

making `plugin_dir` read only to the server or by setting `secure_file_priv` to a directory where `SELECT` writes can be made safely.

- `port`

Command-Line Format	<code>--port=port_num</code>
System Variable	<code>port</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	3306
Minimum Value	0
Maximum Value	65535

The number of the port on which the server listens for TCP/IP connections. This variable can be set with the `--port` option.

- `preload_buffer_size`

Command-Line Format	<code>--preload-buffer-size=#</code>
System Variable	<code>preload_buffer_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	32768
Minimum Value	1024
Maximum Value	1073741824
Unit	bytes

The size of the buffer that is allocated when preloading indexes.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

- `print_identified_with_as_hex`

Command-Line Format	<code>--print-identified-with-as-hex[={OFF ON}]</code>
System Variable	<code>print_identified_with_as_hex</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	OFF

Password hash values displayed in the `IDENTIFIED WITH` clause of output from `SHOW CREATE USER` may contain unprintable characters that have adverse effects on terminal displays and in other

environments. Enabling `print_identified_with_as_hex` causes `SHOW CREATE USER` to display such hash values as hexadecimal strings rather than as regular string literals. Hash values that do not contain unprintable characters still display as regular string literals, even with this variable enabled.

- `profiling`

If set to 0 or `OFF` (the default), statement profiling is disabled. If set to 1 or `ON`, statement profiling is enabled and the `SHOW PROFILE` and `SHOW PROFILES` statements provide access to profiling information. See [Section 15.7.7.33, “SHOW PROFILES Statement”](#).

This variable is deprecated; expect it to be removed in a future MySQL release.

- `profiling_history_size`

The number of statements for which to maintain profiling information if `profiling` is enabled. The default value is 15. The maximum value is 100. Setting the value to 0 effectively disables profiling. See [Section 15.7.7.33, “SHOW PROFILES Statement”](#).

This variable is deprecated; expect it to be removed in a future MySQL release.

- `protocol_compression_algorithms`

Command-Line Format	<code>--protocol-compression-algorithms=value</code>
System Variable	<code>protocol_compression_algorithms</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Set
Default Value	<code>zlib,zstd,uncompressed</code>
Valid Values	<code>zlib</code> <code>zstd</code> <code>uncompressed</code>

The compression algorithms that the server permits for incoming connections. These include connections by client programs and by servers participating in source/replica replication or Group Replication. Compression does not apply to connections for `FEDERATED` tables.

`protocol_compression_algorithms` does not control connection compression for X Protocol. See [Section 22.5.5, “Connection Compression with X Plugin”](#) for information on how this operates.

The variable value is a list of one or more comma-separated compression algorithm names, in any order, chosen from the following items (not case-sensitive):

- `zlib`: Permit connections that use the `zlib` compression algorithm.
- `zstd`: Permit connections that use the `zstd` compression algorithm.
- `uncompressed`: Permit uncompressed connections. If this algorithm name is not included in the `protocol_compression_algorithms` value, the server does not permit uncompressed connections. It permits only compressed connections that use whichever other algorithms are specified in the value, and there is no fallback to uncompressed connections.

The default value of `zlib,zstd,uncompressed` indicates that the server permits all compression algorithms.

For more information, see [Section 6.2.8, “Connection Compression Control”](#).

- `protocol_version`

System Variable	<code>protocol_version</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	10
Minimum Value	0
Maximum Value	4294967295

The version of the client/server protocol used by the MySQL server.

- `proxy_user`

System Variable	<code>proxy_user</code>
Scope	Session
Dynamic	No
SET_VAR Hint Applies	No
Type	String

If the current client is a proxy for another user, this variable is the proxy user account name. Otherwise, this variable is `NULL`. See [Section 8.2.19, “Proxy Users”](#).

- `pseudo_replica_mode`

System Variable	<code>pseudo_replica_mode</code>
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean

`pseudo_replica_mode` is for internal server use. It assists with the correct handling of transactions that originated on older or newer servers than the server currently processing them. `mysqlbinlog` sets the value of `pseudo_replica_mode` to true before executing any SQL statements.

Setting the session value of `pseudo_replica_mode` is a restricted operation. The session user must have either the `REPLICATION_APPLIER` privilege (see [Section 19.3.3, “Replication Privilege Checks”](#)), or privileges sufficient to set restricted session variables (see [Section 7.1.9.1, “System Variable Privileges”](#)). However, note that the variable is not intended for users to set; it is set automatically by the replication infrastructure.

`pseudo_replica_mode` has the following effects on the handling of prepared XA transactions, which can be attached to or detached from the handling session (by default, the session that issues `XA START`):

- If true, and the handling session has executed an internal-use `BINLOG` statement, XA transactions are automatically detached from the session as soon as the first part of the transaction up to `XA PREPARE` finishes, so they can be committed or rolled back by any session that has the `XA_RECOVER_ADMIN` privilege.

- If false, XA transactions remain attached to the handling session as long as that session is alive, during which time no other session can commit the transaction. The prepared transaction is only detached if the session disconnects or the server restarts.

`pseudo_replica_mode` has the following effects on the `original_commit_timestamp` replication delay timestamp and the `original_server_version` system variable:

- If true, transactions that do not explicitly set `original_commit_timestamp` or `original_server_version` are assumed to originate on another, unknown server, so the value 0, meaning unknown, is assigned to both the timestamp and the system variable.
- If false, transactions that do not explicitly set `original_commit_timestamp` or `original_server_version` are assumed to originate on the current server, so the current timestamp and the current server's version are assigned to the timestamp and the system variable.

`pseudo_replica_mode` has the following effects on the handling of a statement that sets one or more unsupported (removed or unknown) SQL modes:

- If true, the server ignores the unsupported mode and raises a warning.
- If false, the server rejects the statement with `ER_UNSUPPORTED_SQL_MODE`.

- `pseudo_slave_mode`

Deprecated	Yes
System Variable	<code>pseudo_slave_mode</code>
Scope	Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean

Deprecated alias for `pseudo_replica_mode`.

- `pseudo_thread_id`

System Variable	<code>pseudo_thread_id</code>
Scope	Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	2147483647
Minimum Value	0
Maximum Value	2147483647

This variable is for internal server use.

Warning

Changing the session value of the `pseudo_thread_id` system variable changes the value returned by the `CONNECTION_ID()` function.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

- `query_alloc_block_size`

Command-Line Format	<code>--query-alloc-block-size=#</code>
System Variable	<code>query_alloc_block_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	8192
Minimum Value	1024
Maximum Value	4294966272
Unit	bytes
Block Size	1024

The allocation size in bytes of memory blocks that are allocated for objects created during statement parsing and execution. If you have problems with memory fragmentation, it might help to increase this parameter.

The block size for the byte number is 1024. A value that is not an exact multiple of the block size is rounded down to the next lower multiple of the block size by MySQL Server before storing the value for the system variable. The parser allows values up to the maximum unsigned integer value for the platform (4294967295 or $2^{32}-1$ for a 32-bit system, 18446744073709551615 or $2^{64}-1$ for a 64-bit system) but the actual maximum is a block size lower.

- `query_prealloc_size`

Command-Line Format	<code>--query-prealloc-size=#</code>
Deprecated	Yes
System Variable	<code>query_prealloc_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	8192
Minimum Value	8192
Maximum Value (64-bit platforms)	18446744073709550592
Maximum Value (32-bit platforms)	4294966272
Unit	bytes
Block Size	1024

`query_prealloc_size` is deprecated, and setting it has no effect; you should expect its removal in a future release of MySQL.

- `rand_seed1`

System Variable	<code>rand_seed1</code>
Scope	Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No

Type	Integer
Default Value	N/A
Minimum Value	0
