Produces a `TIME` value. If the optional `M` value is given, it specifies the fractional seconds precision.

• **UNSIGNED [INTEGER]**
Cast Function and Operator Descriptions

Produces an unsigned **BIGINT** value.

- **YEAR**

  Produces a **YEAR** value. These rules govern conversion to **YEAR** as follows:

  - For a four-digit number in the range 1901-2155 inclusive, or for a string which can be interpreted as a four-digit number in this range, return the corresponding **YEAR** value.

  - For a number consisting of one or two digits, or for a string which can be interpreted as such a number, return a **YEAR** value as follows:
    
    - If the number is in the range 1-69 inclusive, add 2000 and return the sum.
    
    - If the number is in the range 70-99 inclusive, add 1900 and return the sum.

  - For a string which evaluates to 0, return 2000.

  - For the number 0, return 0.

  - For a **DATE**, **DATETIME**, or **TIMESTAMP** value, return the **YEAR** portion of the value. For a **TIME** value, return the current year.

  If you do not specify the type of a **TIME** argument, you may get a different result from what you expect, as shown here:

  ```
  mysql> SELECT CAST("11:35:00" AS YEAR), CAST(TIME "11:35:00" AS YEAR);
  +--------------------------+-------------------------------+
  | CAST("11:35:00" AS YEAR) | CAST(TIME "11:35:00" AS YEAR) |
  +--------------------------+-------------------------------+
  |                     2011 |                          2021 |
  +--------------------------+-------------------------------+
  ```

  - If the argument is of type **DECIMAL**, **DOUBLE**, **DECIMAL**, or **REAL**, round the value to the nearest integer, then attempt to cast the value to **YEAR** using the rules for integer values, as shown here:

    ```
    mysql> SELECT CAST(1944.35 AS YEAR), CAST(1944.50 AS YEAR);
    +-----------------------+-----------------------+
    | CAST(1944.35 AS YEAR) | CAST(1944.50 AS YEAR) |
    +-----------------------+-----------------------+
    |                  1944 |                  1945 |
    +-----------------------+-----------------------+
    mysql> SELECT CAST(66.35 AS YEAR), CAST(66.50 AS YEAR);
    +---------------------+---------------------+
    | CAST(66.35 AS YEAR) | CAST(66.50 AS YEAR) |
    +---------------------+---------------------+
    |                2066 |                2067 |
    +---------------------+---------------------+
    ```

  - An argument of type **GEOMETRY** cannot be converted to **YEAR**.

  - For a value that cannot be successfully converted to **YEAR**, return **NULL**.

  A string value containing non-numeric characters which must be truncated prior to conversion raises a warning, as shown here:

  ```
  mysql> SELECT CAST("1979aaa" AS YEAR);
  +-------------------------+
  | CAST("1979aaa" AS YEAR) |
  +-------------------------+
  |                     1979 |
  +-------------------------+
  1 row in set, 1 warning (0.00 sec)
  ```
InnoDB allows the use of an additional `ARRAY` keyword for creating a multi-valued index on a `JSON` array as part of `CREATE INDEX`, `CREATE TABLE`, and `ALTER TABLE` statements. `ARRAY` is not supported except when used to create a multi-valued index in one of these statements, in which case it is required. The column being indexed must be a column of type `JSON`. With `ARRAY`, the `type` following the `AS` keyword may specify any of the types supported by `CAST()`, with the exceptions of `BINARY`, `JSON`, and `YEAR`. For syntax information and examples, as well as other relevant information, see Multi-Valued Indexes.

**Cast Function and Operator Descriptions**

**Note**

CONVERT(), unlike `CAST()`, does not support multi-valued index creation or the `ARRAY` keyword.

`CAST()` supports retrieval of a `TIMESTAMP` value as being in UTC, using the `AT TIME ZONE` operator. The only supported time zone is UTC; this can be specified as either of `'+00:00'` or `'UTC'`. The only return type supported by this syntax is `DATETIME`, with an optional precision specifier in the range of 0 to 6, inclusive.

`TIMESTAMP` values that use timezone offsets are also supported.
If you use 'UTC' as the time zone specifier with this form of \texttt{CAST()}, and the server raises an error such as \textit{Unknown or incorrect time zone: 'UTC'}, you may need to install the MySQL time zone tables (see \textit{Populating the Time Zone Tables}).

\textit{AT TIME ZONE} does not support the \texttt{ARRAY} keyword, and is not supported by the \texttt{CONVERT()} function.

- \texttt{CONVERT(expr USING transcoding\_name)}

\begin{verbatim}
CONVERT(expr, type)
\end{verbatim}

\texttt{CONVERT(expr USING transcoding\_name)} is standard SQL syntax. The non-\texttt{USING} form of \texttt{CONVERT()} is ODBC syntax. Regardless of the syntax used, the function returns \texttt{NULL} if \texttt{expr} is \texttt{NULL}.

\texttt{CONVERT(expr USING transcoding\_name)} converts data between different character sets. In MySQL, transcoding names are the same as the corresponding character set names. For example, this statement converts the string \textit{'abc'} in the default character set to the corresponding string in the \texttt{utf8mb4} character set:

\begin{verbatim}
SELECT CONVERT('abc' USING utf8mb4);
\end{verbatim}

\texttt{CONVERT(expr, type)} syntax (without \texttt{USING}) takes an expression and a \texttt{type} value specifying a result type, and produces a result value of the specified type. This operation may also be expressed as \texttt{CAST(expr AS type)}, which is equivalent. For more information, see the description of \texttt{CAST()}.

### Character Set Conversions

\texttt{CONVERT()} with a \texttt{USING} clause converts data between character sets:

\begin{verbatim}
CONVERT(expr USING transcoding\_name)
\end{verbatim}

In MySQL, transcoding names are the same as the corresponding character set names.

Examples:

\begin{verbatim}
SELECT CONVERT('test' USING utf8mb4);
SELECT CONVERT('latin1'Müller' USING utf8mb4);
INSERT INTO utf8mb4_table (utf8mb4_column) VALUES (CONVERT(latin1_column USING utf8mb4));
SELECT CONVERT('abc', CHAR CHARACTER SET utf8mb4) FROM latin1_table;
\end{verbatim}

To convert strings between character sets, you can also use \texttt{CONVERT(expr, type)} syntax (without \texttt{USING}), or \texttt{CAST(expr AS type)}, which is equivalent:

\begin{verbatim}
CONVERT(string, CHAR[(N)] CHARACTER SET charset\_name)
CAST(string AS CHAR[(N)] CHARACTER SET charset\_name)
\end{verbatim}

Examples:

\begin{verbatim}
SELECT CONVERT('test', CHAR CHARACTER SET utf8mb4);
SELECT CAST('test' AS CHAR CHARACTER SET utf8mb4);
\end{verbatim}

If you specify \texttt{CHARACTER SET charset\_name} as just shown, the character set and collation of the result are \texttt{charset\_name} and the default collation of \texttt{charset\_name}. If you omit \texttt{CHARACTER SET charset\_name}, the character set and collation of the result are defined by the \texttt{character_set_connection} and \texttt{collation_connection} system variables that determine the default connection character set and collation (see Section 12.4, “Connection Character Sets and Collations”).

A \texttt{COLLATE} clause is not permitted within a \texttt{CONVERT()} or \texttt{CAST()} call, but you can apply it to the function result. For example, these are legal:
Character Set Conversions for String Comparisons

SELECT CONVERT('test' USING utf8mb4) COLLATE utf8mb4_bin;
SELECT CONVERT('test', CHARSET utf8mb4) COLLATE utf8mb4_bin;
SELECT CAST('test' AS CHAR CHARACTER SET utf8mb4) COLLATE utf8mb4_bin;

But these are illegal:

SELECT CONVERT('test' USING utf8mb4 COLLATE utf8mb4_bin);
SELECT CONVERT('test', CHARSET utf8mb4 COLLATE utf8mb4_bin);
SELECT CAST('test' AS CHAR CHARACTER SET utf8mb4 COLLATE utf8mb4_bin);

For string literals, another way to specify the character set is to use a character set introducer. _latin1 and _latin2 in the preceding example are instances of introducers. Unlike conversion functions such as CAST(), or CONVERT(), which convert a string from one character set to another, an introducer designates a string literal as having a particular character set, with no conversion involved. For more information, see Section 12.3.8, “Character Set Introducers”.

Character Set Conversions for String Comparisons

Normally, you cannot compare a BLOB value or other binary string in case-insensitive fashion because binary strings use the binary character set, which has no collation with the concept of lettercase. To perform a case-insensitive comparison, first use the CONVERT() or CAST() function to convert the value to a nonbinary string. Comparisons of the resulting string use its collation. For example, if the conversion result collation is not case-sensitive, a LIKE operation is not case-sensitive. That is true for the following operation because the default utf8mb4 collation (utf8mb4_0900_ai_ci) is not case-sensitive:

SELECT 'A' LIKE CONVERT(blob_col USING utf8mb4)
FROM tbl_name;

To specify a particular collation for the converted string, use a COLLATE clause following the CONVERT() call:

SELECT 'A' LIKE CONVERT(blob_col USING utf8mb4) COLLATE utf8mb4_unicode_ci
FROM tbl_name;

To use a different character set, substitute its name for utf8mb4 in the preceding statements (and similarly to use a different collation).

CONVERT() and CAST() can be used more generally for comparing strings represented in different character sets. For example, a comparison of these strings results in an error because they have different character sets:

mysql> SET @s1 = _latin1 'abc', @s2 = _latin2 'abc';
mysql> SELECT @s1 = @s2;
ERROR 1267 (HY000): Illegal mix of collations (latin1_swedish_ci,IMPLICIT) and (latin2_general_ci,IMPLICIT) for operation '='

Converting one of the strings to a character set compatible with the other enables the comparison to occur without error:

mysql> SELECT @s1 = CONVERT(@s2 USING latin1);
| @s1 = CONVERT(@s2 USING latin1) | 1 |
+---------------------------------+--

Converting one of the strings to a character set compatible with the other enables the comparison to occur without error:

mysql> SELECT @s1 = CONVERT(@s2 USING latin1);
| @s1 = CONVERT(@s2 USING latin1) | 1 |
+---------------------------------+--

Character set conversion is also useful preceding lettercase conversion of binary strings. LOWER() and UPPER() are ineffective when applied directly to binary strings because the concept of lettercase does not apply. To perform lettercase conversion of a binary string, first convert it to a nonbinary string using a character set appropriate for the data stored in the string:

mysql> SET @str = BINARY 'New York';
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING utf8mb4));
| LOWER(@str) | LOWER(CONVERT(@str USING utf8mb4)) |
Be aware that if you apply `BINARY`, `CAST()`, or `CONVERT()` to an indexed column, MySQL may not be able to use the index efficiently.

### Cast Operations on Spatial Types

`CAST()` and `CONVERT()` support casting geometry values from one spatial type to another, for certain combinations of spatial types. The following list shows the permitted type combinations, where “MySQL extension” designates casts implemented in MySQL beyond those defined in the SQL/MM standard:

- **From Point to:**
  - `MultiPoint`
  - `GeometryCollection`

- **From LineString to:**
  - `Polygon` (MySQL extension)
  - `MultiPoint` (MySQL extension)
  - `MultiLineString`
  - `GeometryCollection`

- **From Polygon to:**
  - `LineString` (MySQL extension)
  - `MultiLineString` (MySQL extension)
  - `MultiPolygon`
  - `GeometryCollection`

- **From MultiPoint to:**
  - `Point`
  - `LineString` (MySQL extension)
  - `GeometryCollection`

- **From MultiLineString to:**
  - `LineString`
  - `Polygon` (MySQL extension)
  - `MultiPolygon` (MySQL extension)
  - `GeometryCollection`

- **From MultiPolygon to:**
  - `Polygon`
  - `MultiLineString` (MySQL extension)
  - `GeometryCollection`
Cast Operations on Spatial Types

- From `GeometryCollection` to:
  - `Point`
  - `LineString`
  - `Polygon`
  - `MultiPoint`
  - `MultiLineString`
  - `MultiPolygon`

In spatial casts, `GeometryCollection` and `GeomCollection` are synonyms for the same result type.

Some conditions apply to all spatial type casts, and some conditions apply only when the cast result is to have a particular spatial type. For information about terms such as “well-formed geometry,” see Section 13.4.4, “Geometry Well-Formedness and Validity”.

- **General Conditions for Spatial Casts**
- **Conditions for Casts to Point**
- **Conditions for Casts to LineString**
- **Conditions for Casts to Polygon**
- **Conditions for Casts to MultiPoint**
- **Conditions for Casts to MultiLineString**
- **Conditions for Casts to MultiPolygon**
- **Conditions for Casts to GeometryCollection**

### General Conditions for Spatial Casts

These conditions apply to all spatial casts regardless of the result type:

- The result of a cast is in the same SRS as that of the expression to cast.
- Casting between spatial types does not change coordinate values or order.
- If the expression to cast is `NULL`, the function result is `NULL`.
- Casting to spatial types using the `JSON_VALUE()` function with a `RETURNING` clause specifying a spatial type is not permitted.
- Casting to an `ARRAY` of spatial types is not permitted.
- If the spatial type combination is permitted but the expression to cast is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If the spatial type combination is permitted but the expression to cast is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- If the expression to cast has a geographic SRS but has a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range (−180, 180], an `ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE` error occurs.
Cast Operations on Spatial Types

- If a latitude value is not in the range \([-90, 90]\), an `ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

Conditions for Casts to Point

When the cast result type is `Point`, these conditions apply:

- If the expression to cast is a well-formed geometry of type `Point`, the function result is that `Point`.

- If the expression to cast is a well-formed geometry of type `MultiPoint` containing a single `Point`, the function result is that `Point`. If the expression contains more than one `Point`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

- If the expression to cast is a well-formed geometry of type `GeometryCollection` containing only a single `Point`, the function result is that `Point`. If the expression is empty, contains more than one `Point`, or contains other geometry types, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

- If the expression to cast is a well-formed geometry of type other than `Point`, `MultiPoint`, `GeometryCollection`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

Conditions for Casts to LineString

When the cast result type is `LineString`, these conditions apply:

- If the expression to cast is a well-formed geometry of type `LineString`, the function result is that `LineString`.

- If the expression to cast is a well-formed geometry of type `Polygon` that has no inner rings, the function result is a `LineString` containing the points of the outer ring in the same order. If the expression has inner rings, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

- If the expression to cast is a well-formed geometry of type `MultiPoint` containing at least two points, the function result is a `LineString` containing the points of the `MultiPoint` in the order they appear in the expression. If the expression contains only one `Point`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

- If the expression to cast is a well-formed geometry of type `MultiLineString` containing a single `LineString`, the function result is that `LineString`. If the expression contains more than one `LineString`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

- If the expression to cast is a well-formed geometry of type `GeometryCollection`, containing only a single `LineString`, the function result is that `LineString`. If the expression is empty, contains more than one `LineString`, or contains other geometry types, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

- If the expression to cast is a well-formed geometry of type other than `LineString`, `Polygon`, `MultiPoint`, `MultiLineString`, or `GeometryCollection`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

Conditions for Casts to Polygon

When the cast result type is `Polygon`, these conditions apply:

- If the expression to cast is a well-formed geometry of type `LineString` that is a ring (that is, the start and end points are the same), the function result is a `Polygon` with an outer ring consisting of the points of the `LineString` in the same order. If the expression is not a ring, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs. If the ring is not in the correct order (the exterior ring must be counter-clockwise), an `ERINVALID CAST POLYGON_RING_DIRECTION` error occurs.
Cast Operations on Spatial Types

• If the expression to cast is a well-formed geometry of type `Polygon`, the function result is that `Polygon`.

• If the expression to cast is a well-formed geometry of type `MultiLineString` where all elements are rings, the function result is a `Polygon` with the first `LineString` as outer ring and any additional `LineString` values as inner rings. If any element of the expression is not a ring, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs. If any ring is not in the correct order (the exterior ring must be counter-clockwise, interior rings must be clockwise), an `ER_INVALID_CAST_POLYGON_RING_DIRECTION` error occurs.

• If the expression to cast is a well-formed geometry of type `MultiPolygon` containing a single `Polygon`, the function result is that `Polygon`. If the expression contains more than one `Polygon`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

• If the expression to cast is a well-formed geometry of type `GeometryCollection` containing only points, the function result is a `MultiPoint` containing those points. If the `GeometryCollection` is empty or contains other geometry types, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

• If the expression to cast is a well-formed geometry of type other than `Point`, `LineString`, `MultiPoint`, or `GeometryCollection`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

Conditions for Casts to MultiPoint

When the cast result type is `MultiPoint`, these conditions apply:

• If the expression to cast is a well-formed geometry of type `Point`, the function result is a `MultiPoint` containing that `Point` as its sole element.

• If the expression to cast is a well-formed geometry of type `LineString`, the function result is a `MultiPoint` containing the points of the `LineString` in the same order.

• If the expression to cast is a well-formed geometry of type `MultiPoint`, the function result is that `MultiPoint`.

• If the expression to cast is a well-formed geometry of type `GeometryCollection` containing only points, the function result is a `MultiPoint` containing those points. If the `GeometryCollection` is empty or contains other geometry types, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

• If the expression to cast is a well-formed geometry of type other than `Point`, `LineString`, `MultiPoint`, or `GeometryCollection`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

Conditions for Casts to MultiLineString

When the cast result type is `MultiLineString`, these conditions apply:

• If the expression to cast is a well-formed geometry of type `LineString`, the function result is a `MultiLineString` containing that `LineString` as its sole element.

• If the expression to cast is a well-formed geometry of type `Polygon`, the function result is a `MultiLineString` containing the outer ring of the `Polygon` as its first element and any inner rings as additional elements in the order they appear in the expression.

• If the expression to cast is a well-formed geometry of type `MultiLineString`, the function result is that `MultiLineString`.

• If the expression to cast is a well-formed geometry of type `MultiPolygon` containing only polygons without inner rings, the function result is a `MultiLineString` containing the polygon rings in the order they appear in the expression. If the expression contains any polygons with inner rings, an `ER_WRONG_PARAMETERS_TO_STORED_FCT` error occurs.
• If the expression to cast is a well-formed geometry of type `GeometryCollection` containing only linestrings, the function result is a `MultiLineString` containing those linestrings. If the expression is empty or contains other geometry types, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

• If the expression to cast is a well-formed geometry of type other than `LineString`, `Polygon`, `MultiLineString`, `MultiPolygon`, or `GeometryCollection`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

Conditions for Casts to `MultiPolygon`

When the cast result type is `MultiPolygon`, these conditions apply:

• If the expression to cast is a well-formed geometry of type `Polygon`, the function result is a `MultiPolygon` containing the `Polygon` as its sole element.

• If the expression to cast is a well-formed geometry of type `MultiLineString` where all elements are rings, the function result is a `MultiPolygon` containing a `Polygon` with only an outer ring for each element of the expression. If any element is not a ring, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs. If any ring is not in the correct order (exterior ring must be counter-clockwise), an `ER_INVALID_CAST_POLYGON_RING_DIRECTION` error occurs.

• If the expression to cast is a well-formed geometry of type `MultiPolygon`, the function result is that `MultiPolygon`.

• If the expression to cast is a well-formed geometry of type `GeometryCollection` containing only polygons, the function result is a `MultiPolygon` containing those polygons. If the expression is empty or contains other geometry types, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

• If the expression to cast is a well-formed geometry of type other than `Polygon`, `MultiLineString`, `MultiPolygon`, or `GeometryCollection`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

Conditions for Casts to `GeometryCollection`

When the cast result type is `GeometryCollection`, these conditions apply:

• `GeometryCollection` and `GeomCollection` are synonyms for the same result type.

• If the expression to cast is a well-formed geometry of type `Point`, the function result is a `GeometryCollection` containing that `Point` as its sole element.

• If the expression to cast is a well-formed geometry of type `LineString`, the function result is a `GeometryCollection` containing that `LineString` as its sole element.

• If the expression to cast is a well-formed geometry of type `Polygon`, the function result is a `GeometryCollection` containing that `Polygon` as its sole element.

• If the expression to cast is a well-formed geometry of type `MultiPoint`, the function result is a `GeometryCollection` containing the points in the order they appear in the expression.

• If the expression to cast is a well-formed geometry of type `MultiLineString`, the function result is a `GeometryCollection` containing the linestrings in the order they appear in the expression.

• If the expression to cast is a well-formed geometry of type `MultiPolygon`, the function result is a `GeometryCollection` containing the elements of the `MultiPolygon` in the order they appear in the expression.

• If the expression to cast is a well-formed geometry of type `GeometryCollection`, the function result is that `GeometryCollection`.

Other Uses for Cast Operations

The cast functions are useful for creating a column with a specific type in a `CREATE TABLE ... SELECT` statement:
Other Uses for Cast Operations

```sql
mysql> CREATE TABLE new_table SELECT CAST('2000-01-01' AS DATE) AS c1;
mysql> SHOW CREATE TABLE new_table
+-----------------------+
<table>
<thead>
<tr>
<th>Table</th>
</tr>
</thead>
<tbody>
<tr>
<td>new_table</td>
</tr>
</tbody>
</table>
+-----------------------+
| Create Table: CREATE TABLE `new_table` (|
| `c1` date DEFAULT NULL |
| ) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci |
```

The cast functions are useful for sorting ENUM columns in lexical order. Normally, sorting of ENUM columns occurs using the internal numeric values. Casting the values to CHAR results in a lexical sort:

```sql
SELECT enum_col FROM tbl_name
ORDER BY CAST(enum_col AS CHAR);
```

CAST() also changes the result if you use it as part of a more complex expression such as CONCAT('Date: ',CAST(NOW() AS DATE)).

For temporal values, there is little need to use CAST() to extract data in different formats. Instead, use a function such as EXTRACT(), DATE_FORMAT(), or TIME_FORMAT(). See Section 14.7, “Date and Time Functions”.

To cast a string to a number, it normally suffices to use the string value in numeric context:

```sql
mysql> SELECT 1+'1';
  
-> 2
```

That is also true for hexadecimal and bit literals, which are binary strings by default:

```sql
mysql> SELECT X'41', X'41'+0;
  
-> 'A', 65
mysql> SELECT b'1100001', b'1100001'+0;
  
-> 'a', 97
```

A string used in an arithmetic operation is converted to a floating-point number during expression evaluation.

A number used in string context is converted to a string:

```sql
mysql> SELECT CONCAT('hello you ',2);
  
-> 'hello you 2'
```

For information about implicit conversion of numbers to strings, see Section 14.3, “Type Conversion in Expression Evaluation”.

MySQL supports arithmetic with both signed and unsigned 64-bit values. For numeric operators (such as + or −) where one of the operands is an unsigned integer, the result is unsigned by default (see Section 14.6.1, “Arithmetic Operators”). To override this, use the SIGNED or UNSIGNED cast operator to cast a value to a signed or unsigned 64-bit integer, respectively.

```sql
mysql> SELECT 1 - 2;
  
-> -1
mysql> SELECT CAST(1 - 2 AS UNSIGNED);
  
-> 18446744073709551615
mysql> SELECT CAST(CAST(1 - 2 AS UNSIGNED) AS SIGNED);
  
-> -1
```

If either operand is a floating-point value, the result is a floating-point value and is not affected by the preceding rule. (In this context, DECIMAL column values are regarded as floating-point values.)

```sql
mysql> SELECT CAST(1 AS UNSIGNED) - 2.0;
  
-> -1.0
```

The SQL mode affects the result of conversion operations (see Section 7.1.11, “Server SQL Modes”).
XML Functions

- For conversion of a “zero” date string to a date, `CONVERT()` and `CAST()` return `NULL` and produce a warning when the `NO_ZERO_DATE` SQL mode is enabled.
- For integer subtraction, if the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the subtraction result is signed even if any operand is unsigned.

### 14.11 XML Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ExtractValue()</code></td>
<td>Extract a value from an XML string using XPath notation</td>
</tr>
<tr>
<td><code>UpdateXML()</code></td>
<td>Return replaced XML fragment</td>
</tr>
</tbody>
</table>

This section discusses XML and related functionality in MySQL.

**Note**

It is possible to obtain XML-formatted output from MySQL in the `mysql` and `mysqldump` clients by invoking them with the `--xml` option. See Section 6.5.1, “mysql — The MySQL Command-Line Client”, and Section 6.5.4, “mysqldump — A Database Backup Program”.

Two functions providing basic XPath 1.0 (XML Path Language, version 1.0) capabilities are available. Some basic information about XPath syntax and usage is provided later in this section; however, an in-depth discussion of these topics is beyond the scope of this manual, and you should refer to the XML Path Language (XPath) 1.0 standard for definitive information. A useful resource for those new to XPath or who desire a refresher in the basics is the Zvon.org XPath Tutorial, which is available in several languages.

**Note**

These functions remain under development. We continue to improve these and other aspects of XML and XPath functionality in MySQL 8.4 and onwards. You may discuss these, ask questions about them, and obtain help from other users with them in the MySQL XML User Forum.

XPath expressions used with these functions support user variables and local stored program variables. User variables are weakly checked; variables local to stored programs are strongly checked (see also Bug #26518):

- **User variables (weak checking).** Variables using the syntax `$@variable_name` (that is, user variables) are not checked. No warnings or errors are issued by the server if a variable has the wrong type or has previously not been assigned a value. This also means the user is fully responsible for any typographical errors, since no warnings are given if (for example) `$@myvariable` is used where `$@myvariable` was intended.

Example:

```sql
mysql> SET @xml = '<a><b>X</b><b>Y</b></a>';
Query OK, 0 rows affected (0.00 sec)

mysql> SET @i =1, @j = 2;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @i, ExtractValue(@xml, '//b[@j]');
+------+--------------------------------+
| @i   | ExtractValue(@xml, '//b[@j]') |
+------+--------------------------------+
|    1  | X                             |
+------+--------------------------------+```
• **Variables in stored programs (strong checking).** Variables using the syntax `$_variable_name` can be declared and used with these functions when they are called inside stored programs. Such variables are local to the stored program in which they are defined, and are strongly checked for type and value.

Example:

```sql
mysql> SELECT @j, ExtractValue(@xml, '//b[$@j]');
+------+--------------------------------+
| @j   | ExtractValue(@xml, '//b[$@j]') |
+------+--------------------------------+
| 2    | Y                              |
+------+--------------------------------+
1 row in set (0.00 sec)

mysql> SELECT @k, ExtractValue(@xml, '//b[$@k]');
+------+--------------------------------+
| @k   | ExtractValue(@xml, '//b[$@k]') |
+------+--------------------------------+
| NULL |                                |
+------+--------------------------------+
1 row in set (0.00 sec)
```

**Parameters.** Variables used in XPath expressions inside stored routines that are passed in as parameters are also subject to strong checking.

Expressions containing user variables or variables local to stored programs must otherwise (except for notation) conform to the rules for XPath expressions containing variables as given in the XPath 1.0 specification.
A user variable used to store an XPath expression is treated as an empty string. Because of this, it is not possible to store an XPath expression as a user variable. (Bug #32911)

- `ExtractValue(xml_frag, xpath_expr)`

`ExtractValue()` takes two string arguments, a fragment of XML markup `xml_frag` and an XPath expression `xpath_expr` (also known as a locator); it returns the text (CDATA) of the first text node which is a child of the element or elements matched by the XPath expression.

Using this function is the equivalent of performing a match using the `xpath_expr` after appending `/text()`. In other words, `ExtractValue('<a><b>Sakila</b></a>', '/a/b')` and `ExtractValue('<a><b>Sakila</b></a>/a>', '/a/b/text()')` produce the same result. If `xml_frag` or `xpath_expr` is NULL, the function returns NULL.

If multiple matches are found, the content of the first child text node of each matching element is returned (in the order matched) as a single, space-delimited string.

If no matching text node is found for the expression (including the implicit `/text()`)—for whatever reason, as long as `xpath_expr` is valid, and `xml_frag` consists of elements which are properly nested and closed—an empty string is returned. No distinction is made between a match on an empty element and no match at all. This is by design.

If you need to determine whether no matching element was found in `xml_frag` or such an element was found but contained no child text nodes, you should test the result of an expression that uses the XPath `count()` function. For example, both of these statements return an empty string, as shown here:

```
mysql> SELECT ExtractValue('<a><b/></a>', '/a/b');
+-------------------------------------+
| ExtractValue('<a><b/></a>', '/a/b') |
| +-------------------------------------+
1 row in set (0.00 sec)
mysql> SELECT ExtractValue('<a><c/></a>', '/a/b');
+-------------------------------------+
| ExtractValue('<a><c/></a>', '/a/b') |
| +-------------------------------------+
1 row in set (0.00 sec)
```

However, you can determine whether there was actually a matching element using the following:

```
mysql> SELECT ExtractValue('<a><b/></a>', 'count(/a/b)');
+-------------------------------------+
| ExtractValue('<a><b/></a>', 'count(/a/b)') |
| +-------------------------------------+
| 1                                    |
| +-------------------------------------+
1 row in set (0.00 sec)
mysql> SELECT ExtractValue('<a><c/></a>', 'count(/a/b)');
+-------------------------------------+
| ExtractValue('<a><c/></a>', 'count(/a/b)') |
| +-------------------------------------+
| 0                                    |
| +-------------------------------------+
| 0                                    |
+-------------------------------------+
```

2193
Important

ExtractValue() returns only CDATA, and does not return any tags that might be contained within a matching tag, nor any of their content (see the result returned as val1 in the following example).

```sql
mysql> SELECT
    -> ExtractValue('<a>ccc<b>ddd</b></a>', '/a') AS val1,
    -> ExtractValue('<a>ccc<b>ddd</b></a>', '/a/b') AS val2,
    -> ExtractValue('<a>ccc<b>ddd</b></a>', '//b') AS val3,
    -> ExtractValue('<a>ccc<b>ddd</b><b>eee</b></a>', '/b') AS val4,
    -> ExtractValue('<a>ccc<b>ddd</b><b>eee</b></a>', '//b') AS val5;
```

```
+------+------+------+------+---------+
| val1 | val2 | val3 | val4 | val5    |
+------+------+------+------+---------+
| ccc  | ddd  | ddd  |      | ddd eee |
+------+------+------+------+---------+
```

This function uses the current SQL collation for making comparisons with contains(), performing the same collation aggregation as other string functions (such as CONCAT()), in taking into account the collation coercibility of their arguments; see Section 12.8.4, “Collation Coercibility in Expressions”, for an explanation of the rules governing this behavior.

(Previously, binary—that is, case-sensitive—comparison was always used.)

NULL is returned if xml_frag contains elements which are not properly nested or closed, and a warning is generated, as shown in this example:

```sql
mysql> SELECT ExtractValue('<a>c</a><b>', '//a');
```

```
+-----------------------------------+
| ExtractValue('<a>c</a><b>', '//a') |  
+-----------------------------------+
| NULL                              |  
+-----------------------------------+
```

mysql> SHOW WARNINGS\G

```
*************************** 1. row ***************************
Level: Warning
Code: 1525
Message: Incorrect XML value: 'parse error at line 1 pos 11: END-OF-INPUT unexpected ('>' wanted)'
```

mysql> SELECT ExtractValue('<a>c</a><b/>', '//a');
```
```
+-------------------------------------+
| ExtractValue('<a>c</a><b/>', '//a') |  
+-------------------------------------+
| c                                  |  
+-------------------------------------+
```

UpdateXML(xml_target, xpath_expr, new_xml)

This function replaces a single portion of a given fragment of XML markup xml_target with a new XML fragment new_xml, and then returns the changed XML. The portion of xml_target that is replaced matches an XPath expression xpath_expr supplied by the user.

If no expression matching xpath_expr is found, or if multiple matches are found, the function returns the original xml_target XML fragment. All three arguments should be strings. If any of the arguments to UpdateXML() are NULL, the function returns NULL.

```sql
mysql> SELECT
    -> UpdateXML('<a><b>ccc</b><d></d></a>', '/a', '<e>fff</e>') AS val1,
```

```
 2194
```
XML Functions

- UpdateXML('<a><b>ccc</b><d></d></a>', '/b', '<e>fff</e>') AS val2,
- UpdateXML('<a><b>ccc</b><d></d></a>', '//b', '<e>fff</e>') AS val3,
- UpdateXML('<a><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val4,
- UpdateXML('<a><d></d><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val5

*************************** 1. row ***************************
val1: <e>fff</e>
val2: <a><b>ccc</b><d></d></a>
val3: <a><e>fff</e><d></d></a>
val4: <a><b>ccc</b><e>fff</e></a>
val5: <a><d></d><b>ccc</b><d></d></a>

Note
A discussion in depth of XPath syntax and usage are beyond the scope of this manual. Please see the XML Path Language (XPath) 1.0 specification for definitive information. A useful resource for those new to XPath or who are wishing a refresher in the basics is the Zvon.org XPath Tutorial, which is available in several languages.

Descriptions and examples of some basic XPath expressions follow:

- **/tag**
  Matches <tag/> if and only if <tag/> is the root element.
  Example: /a has a match in <a><b/></a> because it matches the outermost (root) tag. It does not match the inner a element in <b><a/></b> because in this instance it is the child of another element.

- **/tag1/tag2**
  Matches <tag2/> if and only if it is a child of <tag1/>, and <tag1/> is the root element.
  Example: /a/b matches the b element in the XML fragment <a><b/></a> because it is a child of the root element a. It does not have a match in <b><a/></b> because in this case, b is the root element (and hence the child of no other element). Nor does the XPath expression have a match in <a><c><b/></c></a>; here, b is a descendant of a, but not actually a child of a.

  This construct is extendable to three or more elements. For example, the XPath expression /a/b/c matches the c element in the fragment <a><b><c/></b></a>.

- **//@tag**
  Matches any instance of <tag>.
  Example: //a matches the a element in any of the following: <a><b><c/></b></a>; <c><a><b/></b></c>; <b><a/></b>.

  // can be combined with /. For example, //a/b matches the b element in either of the fragments <a><b/></a> or <a><b/></a>.

Note
//@tag is the equivalent of /descendant-or-self::*/@tag. A common error is to confuse this with /descendant-or-self::*:tag, although the latter expression can actually lead to very different results, as can be seen here:

mysql> SET @xml = '<a><b><c>w</c><b>x</b><d>y</d>z</b></a>);
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @xml;
2195
• The * operator acts as a “wildcard” that matches any element. For example, the expression */b matches the b element in either of the XML fragments <a><b/></a> or <c><b/></c>. However, the expression does not produce a match in the fragment <b><a/></b> because b must be a child of some other element. The wildcard may be used in any position: The expression */b/* matches any child of a b element that is itself not the root element.

• You can match any of several locators using the | (UNION) operator. For example, the expression //b|//c matches all b and c elements in the XML target.

• It is also possible to match an element based on the value of one or more of its attributes. This done using the syntax tag[@attribute="value"]; For example, the expression //b[@id="idB"] matches the second b element in the fragment <a><b id="idA"/></c><b id="idB"/></a>. To match against any element having attribute="value", use the XPath expression // *[attribute="value"].
To filter multiple attribute values, simply use multiple attribute-comparison clauses in succession. For example, the expression 

```
//b[@c="x"][@d="y"]
```

matches the element `<b c="x" d="y"/>` occurring anywhere in a given XML fragment.

To find elements for which the same attribute matches any of several values, you can use multiple locators joined by the `|` operator. For example, to match all `b` elements whose `c` attributes have either of the values 23 or 17, use the expression 

```
//b[@c="23"]|//b[@c="17"]
```

You can also use the logical `or` operator for this purpose: 

```
//b[@c="23" or @c="17"]
```

Note

The difference between `or` and `|` is that `or` joins conditions, while `|` joins result sets.

XPath Limitations. The XPath syntax supported by these functions is currently subject to the following limitations:

- Nodeset-to-nodeset comparison (such as `'/a/b[@c=0d]'`) is not supported.

- All of the standard XPath comparison operators are supported. (Bug #22823)

- Relative locator expressions are resolved in the context of the root node. For example, consider the following query and result:

```sql
mysql> SELECT ExtractValue(
                      -> '<a><b c="1">X</b><b c="2">Y</b></a>',
                      -> 'a/b',
                      -> ) AS result;
```

```
+--------+
<table>
<thead>
<tr>
<th>result</th>
</tr>
</thead>
<tbody>
<tr>
<td>X Y</td>
</tr>
<tr>
<td>---------</td>
</tr>
</tbody>
</table>
1 row in set (0.03 sec)
```

In this case, the locator `a/b` resolves to `/a/b`.

Relative locators are also supported within predicates. In the following example, `d[../@c="1"]` is resolved as `/a/b[@c="1"]/d`:

```sql
mysql> SELECT ExtractValue(
                      -> '<a>
                      -> <b c="1"><d>X</d></b>
                      -> <b c="2"><d>X</d></b>
                      -> </a>',
                      -> 'a/b/d[../@c="1"]')
                      -> ) AS result;
```

```
+--------+
<table>
<thead>
<tr>
<th>result</th>
</tr>
</thead>
<tbody>
<tr>
<td>X</td>
</tr>
<tr>
<td>---------</td>
</tr>
</tbody>
</table>
1 row in set (0.00 sec)
```

- Locators prefixed with expressions that evaluate as scalar values—including variable references, literals, numbers, and scalar function calls—are not permitted, and their use results in an error.

- The `::` operator is not supported in combination with node types such as the following:

  - `axis::comment()`
  - `axis::text()`
  - `axis::processing-instructions()`
XML Functions

- `axis::node()`

However, name tests (such as `axis::name` and `axis::*`) are supported, as shown in these examples:

```sql
mysql> SELECT ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::b');
+-------------------------------------------------------------------+
| ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::b')            |
+-------------------------------------------------------------------+
| x                                                                  |
+-------------------------------------------------------------------+
1 row in set (0.02 sec)

mysql> SELECT ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::*');
+-------------------------------------------------------------------+
| ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::*')            |
| x y                                                                |
+-------------------------------------------------------------------+
1 row in set (0.01 sec)
```

- “Up-and-down” navigation is not supported in cases where the path would lead “above” the root element. That is, you cannot use expressions which match on descendants of ancestors of a given element, where one or more of the ancestors of the current element is also an ancestor of the root element (see Bug #16321).

- The following XPath functions are not supported, or have known issues as indicated:
  - `id()`
  - `lang()`
  - `local-name()`
  - `name()`
  - `namespace-uri()`
  - `normalize-space()`
  - `starts-with()`
  - `string()`
  - `substring-after()`
  - `substring-before()`
  - `translate()`

- The following axes are not supported:
  - `following-sibling`
  - `following`
  - `preceding-sibling`
  - `preceding`

XPath expressions passed as arguments to `ExtractValue()` and `UpdateXML()` may contain the colon character (:) in element selectors, which enables their use with markup employing XML namespaces notation. For example:

```sql
mysql> SET @xml = '<a>111<b:c>222<d>333</d><e:f>444</e:f></b:c></a>';
```
XML Functions

Query OK, 0 rows affected (0.00 sec)

```sql
mysql> SELECT ExtractValue(xml, '//e:f');
+-----------------------------+
| ExtractValue(xml, '//e:f')  |
+-----------------------------+
| 444                         |
+-----------------------------+
1 row in set (0.00 sec)

mysql> SELECT UpdateXML(xml, '//b:c', '<g:h>555</g:h>');
+---------------------------------------------------------------+
| UpdateXML(xml, '//b:c', '<g:h>555</g:h>')                    |
| <a>111<g:h>555</g:h></a>                                    |
+---------------------------------------------------------------+
1 row in set (0.00 sec)
```

This is similar in some respects to what is permitted by Apache Xalan and some other parsers, and is much simpler than requiring namespace declarations or the use of the `namespace-uri()` and `local-name()` functions.

**Error handling.** For both `ExtractValue()` and `UpdateXML()`, the XPath locator used must be valid and the XML to be searched must consist of elements which are properly nested and closed. If the locator is invalid, an error is generated:

```sql
mysql> SELECT ExtractValue('<a>c</a><b/>', '/&a');
ERROR 1105 (HY000): XPATH syntax error: '&a'
```

If `xml_frag` does not consist of elements which are properly nested and closed, NULL is returned and a warning is generated, as shown in this example:

```sql
mysql> SELECT ExtractValue('<a>c</a><b>', '//a');
+-----------------------------------+
| ExtractValue('<a>c</a><b>', '//a') |
| NULL                              |
+-----------------------------------+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS
*************************** 1. row ***************************
Level: Warning
Code: 1525
Message: Incorrect XML value: 'parse error at line 1 pos 11: 
END-OF-INPUT unexpected ('>' wanted)'
1 row in set (0.00 sec)
```

Important

The replacement XML used as the third argument to `UpdateXML()` is not checked to determine whether it consists solely of elements which are properly nested and closed.

**XPath Injection.** Code injection occurs when malicious code is introduced into the system to gain unauthorized access to privileges and data. It is based on exploiting assumptions made by developers about the type and content of data input from users. XPath is no exception in this regard.

A common scenario in which this can happen is the case of application which handles authorization by matching the combination of a login name and password with those found in an XML file, using an XPath expression like this one:
This is the XPath equivalent of an SQL statement like this one:

```sql
SELECT id FROM users WHERE login='neapolitan' AND password='1c3cr34m';
```

A PHP application employing XPath might handle the login process like this:

```php
<?php
    $file     =   "users.xml";
    $login    =   $POST["login"];  
    $password =   $POST["password"]; 

    $xpath = "/user[login/text()="$login" and password/text()="$password"]/attribute::id";
    if( file_exists($file) )
    {
        $xml = simplexml_load_file($file);
        if($result = $xml->xpath($xpath))
            echo "You are now logged in as user $result[0].";
        else
            echo "Invalid login name or password."
    }
    else
        exit("Failed to open $file.");
?>
```

No checks are performed on the input. This means that a malevolent user can “short-circuit” the test by entering `" or 1=1` for both the login name and password, resulting in `$xpath` being evaluated as shown here:

```
//user[login/text()='" or 1=1 and password/text()='" or 1=1']/attribute::id
```

Since the expression inside the square brackets always evaluates as `true`, it is effectively the same as this one, which matches the `id` attribute of every `user` element in the XML document:

```
//user/attribute::id
```

One way in which this particular attack can be circumvented is simply by quoting the variable names to be interpolated in the definition of `$xpath`, forcing the values passed from a Web form to be converted to strings:

```
$xpath = "/user[login/text()='$login' and password/text()='$password']/attribute::id";
```

This is the same strategy that is often recommended for preventing SQL injection attacks. In general, the practices you should follow for preventing XPath injection attacks are the same as for preventing SQL injection:

- Never accepted untested data from users in your application.
- Check all user-submitted data for type; reject or convert data that is of the wrong type
- Test numeric data for out of range values; truncate, round, or reject values that are out of range. Test strings for illegal characters and either strip them out or reject input containing them.
- Do not output explicit error messages that might provide an unauthorized user with clues that could be used to compromise the system; log these to a file or database table instead.

Just as SQL injection attacks can be used to obtain information about database schemas, so can XPath injection be used to traverse XML files to uncover their structure, as discussed in Amit Klein’s paper *Blind XPath Injection* (PDF file, 46KB).

It is also important to check the output being sent back to the client. Consider what can happen when we use the MySQL `ExtractValue()` function:
Because `ExtractValue()` returns multiple matches as a single space-delimited string, this injection attack provides every valid ID contained within `users.xml` to the user as a single row of output. As an extra safeguard, you should also test output before returning it to the user. Here is a simple example:

```sql
mysq1> SELECT @id = ExtractValue(
  -> LOAD_FILE('users.xml'),
  -> '//user[login/text()="" or 1=1 and password/text()="" or 1=1]/attribute::id'
  -> } AS id;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT IF(
  -> INSTR(@id, ' ') = 0,
  -> @id,
  -> 'Unable to retrieve user ID'
  -> ) AS singleID;
+---------------+
<table>
<thead>
<tr>
<th>singleID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unable to retrieve user ID</td>
</tr>
</tbody>
</table>
+---------------+
1 row in set (0.00 sec)
```

In general, the guidelines for returning data to users securely are the same as for accepting user input. These can be summed up as:

- Always test outgoing data for type and permissible values.
- Never permit unauthorized users to view error messages that might provide information about the application that could be used to exploit it.

## 14.12 Bit Functions and Operators

Table 14.17 Bit Functions and Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&amp;</td>
<td>Bitwise AND</td>

</tr>
<tr>
<td>BIT_COUNT()</td>
<td>Return the number of bits that are set</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>~</td>
<td>Bitwise inversion</td>
</tr>
</tbody>
</table>

The following list describes available bit functions and operators:

- | Bitwise OR.

The result type depends on whether the arguments are evaluated as binary strings or numbers:
### Bit Functions and Operators

- **Binary-string evaluation** occurs when the arguments have a binary string type, and at least one of them is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument conversion to unsigned 64-bit integers as necessary.

- **Binary-string evaluation** produces a binary string of the same length as the arguments. If the arguments have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

For more information, see the introductory discussion in this section.

```sql
mysql> SELECT 29 | 15;
-> 31
mysql> SELECT _binary X'40404040' | X'01020304';
-> 'ABCD'
```

If bitwise OR is invoked from within the `mysql` client, binary string results display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 6.5.1, “mysql — The MySQL Command-Line Client”.

- **Bitwise AND**.

  The result type depends on whether the arguments are evaluated as binary strings or numbers:

  - **Binary-string evaluation** occurs when the arguments have a binary string type, and at least one of them is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument conversion to unsigned 64-bit integers as necessary.

  - **Binary-string evaluation** produces a binary string of the same length as the arguments. If the arguments have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

  For more information, see the introductory discussion in this section.

  ```sql
  mysql> SELECT 29 & 15;
  -> 13
  mysql> SELECT HEX(_binary X'FF' & b'11110000');
  -> 'F0'
  ```

  If bitwise AND is invoked from within the `mysql` client, binary string results display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 6.5.1, “mysql — The MySQL Command-Line Client”.

- **Bitwise XOR**.

  The result type depends on whether the arguments are evaluated as binary strings or numbers:

  - **Binary-string evaluation** occurs when the arguments have a binary string type, and at least one of them is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument conversion to unsigned 64-bit integers as necessary.

  - **Binary-string evaluation** produces a binary string of the same length as the arguments. If the arguments have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

  For more information, see the introductory discussion in this section.

  ```sql
  mysql> SELECT 1 ^ 1;
  -> 0
  mysql> SELECT 1 ^ 0;
  ```
Bit Functions and Operators

mysql> SELECT 11 ^ 3;
-> 8
mysql> SELECT HEX(_binary X'FEDC' ^ X'1111');
-> 'EFCD'

If bitwise XOR is invoked from within the mysql client, binary string results display using hexadecimal notation, depending on the value of the --binary-as-hex. For more information about that option, see Section 6.5.1, "mysql — The MySQL Command-Line Client".

• <<

Shifts a longlong (BIGINT) number or binary string to the left.

The result type depends on whether the bit argument is evaluated as a binary string or number:

• Binary-string evaluation occurs when the bit argument has a binary string type, and is not a hexadecimal literal, bit literal, or NULL literal. Numeric evaluation occurs otherwise, with argument conversion to an unsigned 64-bit integer as necessary.

• Binary-string evaluation produces a binary string of the same length as the bit argument. Numeric evaluation produces an unsigned 64-bit integer.

Bits shifted off the end of the value are lost without warning, regardless of the argument type. In particular, if the shift count is greater or equal to the number of bits in the bit argument, all bits in the result are 0.

For more information, see the introductory discussion in this section.

mysql> SELECT 1 << 2;
-> 4
mysql> SELECT HEX(_binary X'00FF00FF00FF' << 8);
-> 'FF00FF00FF00'

If a bit shift is invoked from within the mysql client, binary string results display using hexadecimal notation, depending on the value of the --binary-as-hex. For more information about that option, see Section 6.5.1, "mysql — The MySQL Command-Line Client".

• >>

Shifts a longlong (BIGINT) number or binary string to the right.

The result type depends on whether the bit argument is evaluated as a binary string or number:

• Binary-string evaluation occurs when the bit argument has a binary string type, and is not a hexadecimal literal, bit literal, or NULL literal. Numeric evaluation occurs otherwise, with argument conversion to an unsigned 64-bit integer as necessary.

• Binary-string evaluation produces a binary string of the same length as the bit argument. Numeric evaluation produces an unsigned 64-bit integer.

Bits shifted off the end of the value are lost without warning, regardless of the argument type. In particular, if the shift count is greater or equal to the number of bits in the bit argument, all bits in the result are 0.

For more information, see the introductory discussion in this section.

mysql> SELECT 4 >> 2;
-> 1
mysql> SELECT HEX(_binary X'00FF00FF00FF' >> 8);
If a bit shift is invoked from within the `mysql` client, binary string results display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 6.5.1, “mysql — The MySQL Command-Line Client”.

- `~`

Invert all bits.

The result type depends on whether the bit argument is evaluated as a binary string or number:

- Binary-string evaluation occurs when the bit argument has a binary string type, and is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument conversion to an unsigned 64-bit integer as necessary.

- Binary-string evaluation produces a binary string of the same length as the bit argument. Numeric evaluation produces an unsigned 64-bit integer.

For more information, see the introductory discussion in this section.

```sql
mysql> SELECT 5 & ~1;
-> 4
mysql> SELECT HEX(~X'0000FFFF1111EEEE');
-> 'FFFF0000EEEE1111'
```

If bitwise inversion is invoked from within the `mysql` client, binary string results display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 6.5.1, “mysql — The MySQL Command-Line Client”.

- `BIT_COUNT(N)`

Returns the number of bits that are set in the argument `N` as an unsigned 64-bit integer, or `NULL` if the argument is `NULL`.

```sql
mysql> SELECT BIT_COUNT(64), BIT_COUNT(BINARY 64);
-> 1, 7
mysql> SELECT BIT_COUNT('64'), BIT_COUNT(_binary '64');
-> 1, 7
mysql> SELECT BIT_COUNT(X'40'), BIT_COUNT(_binary X'40');
-> 1, 1
```

Bit functions and operators comprise `BIT_COUNT()`, `BIT_AND()`, `BIT_OR()`, `BIT_XOR()`, `&`, `|`, `^`, `~`, `<<`, and `>>`. (The `BIT_AND()`, `BIT_OR()`, and `BIT_XOR()` aggregate functions are described in Section 14.19.1, “Aggregate Function Descriptions”.)

Bit functions and operators permit binary string type arguments (`BINARY`, `VARBINARY`, and the `BLOB` types) and return a value of like type. Nonbinary string arguments are converted to `BIGINT`.

Bit Operations

MySQL 8.4 handles binary string arguments directly (without conversion) and produces binary string results. Arguments that are not integers or binary strings are converted to integers.

Arguments that count as binary strings include column values, routine parameters, local variables, and user-defined variables that have a binary string type: BINARY, VARBINARY, or one of the BLOB types.

You can specify arguments to bit operations using hexadecimal literals or bit literals with the intent that they represent numbers; MySQL evaluates bit operations in numeric context when all bit arguments are hexadecimal or bit literals. For evaluation as binary strings instead, use the _binary introducer for at least one of the literal values.

- These bit operations evaluate the hexadecimal literals and bit literals as integers:

  ```
  mysql> SELECT X'40' | X'01', b'11110001' & b'01001111';
  +---------------+---------------------------+
  | X'40' | X'01' | b'11110001' & b'01001111' |
  +---------------+---------------------------+
  |            65 |                        65 |
  +---------------+---------------------------+
  ```

- These bit operations evaluate the hexadecimal literals and bit literals as binary strings, due to the _binary introducer:

  ```
  mysql> SELECT _binary X'40' | X'01', b'11110001' & _binary b'01001111';
  +-----------------------+-----------------------------------+
  | _binary X'40' | X'01' | b'11110001' & _binary b'01001111' |
  +-----------------------+-----------------------------------+
  | A                     | A                                 |
  +-----------------------+-----------------------------------+
  ```

Although the bit operations in both statements produce a result with a numeric value of 65, the second statement operates in binary-string context, for which 65 is ASCII A.

In numeric evaluation context, permitted values of hexadecimal literal and bit literal arguments have a maximum of 64 bits, as do results. By contrast, in binary-string evaluation context, permitted arguments (and results) can exceed 64 bits:

```
mysql> SELECT _binary X'4040404040404040' | X'0102030405060708';
+---------------------------------------------------+
| _binary X'4040404040404040' | X'0102030405060708' |
+---------------------------------------------------+
| ABCDEFGH                                          |
+---------------------------------------------------+
```  

There are several ways to refer to a hexadecimal literal or bit literal in a bit operation to cause binary-string evaluation:

- `_binary literal`
- `BINARY literal`
- `CAST(literal AS BINARY)`

Another way to produce binary-string evaluation of hexadecimal literals or bit literals is to assign them to user-defined variables, which results in variables that have a binary string type:

```
mysql> SET @v1 = X'40', @v2 = X'01', @v3 = b'11110001', @v4 = b'01001111';
mysql> SELECT @v1 | @v2, @v3 & @v4;
+-----------+-----------+
| @v1 | @v2 | @v3 & @v4 |
+-----------+-----------+
| A         | A         |
+-----------+-----------+
```  

In binary-string context, bitwise operation arguments must have the same length or an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs:

```
mysql> SELECT _binary X'40' | X'0001';
```
**Binary String Bit-Operation Examples**

To satisfy the equal-length requirement, pad the shorter value with leading zero digits or, if the longer value begins with leading zero digits and a shorter result value is acceptable, strip them:

```sql
mysql> SELECT _binary X'0040' | X'0001';
+---------------------------+
| _binary X'0040' | X'0001' |
| A                        |
+---------------------------+
mysql> SELECT _binary X'40' | X'01';
+-----------------------+
| _binary X'40' | X'01' |
| A                     |
+-----------------------+
```

Padding or stripping can also be accomplished using functions such as `LPAD()`, `RPAD()`, `SUBSTR()`, or `CAST()`. In such cases, the expression arguments are no longer all literals and `_binary` becomes unnecessary. Examples:

```sql
mysql> SELECT LPAD(X'40', 2, X'00') | X'0001';
+---------------------------------+
| LPAD(X'40', 2, X'00') | X'0001' |
| A                              |
+---------------------------------+
mysql> SELECT X'40' | SUBSTR(X'0001', 2, 1);
+-------------------------------+
| X'40' | SUBSTR(X'0001', 2, 1) |
| A                             |
+-------------------------------+
```

See also Special Handling of Hexadecimal Literals, Bit Literals, and NULL Literals.

**Binary String Bit-Operation Examples**

The following example illustrates use of bit operations to extract parts of a UUID value, in this case, the timestamp and IEEE 802 node number. This technique requires bitmasks for each extracted part.

Convert the text UUID to the corresponding 16-byte binary value so that it can be manipulated using bit operations in binary-string context:

```sql
mysql> SET @uuid = UUID_TO_BIN('6ccd780c-baba-1026-9564-5b8c656024db');
mysql> SELECT HEX(@uuid);
+----------------------------------+
| HEX(@uuid)                       |
| 6CCD780CBABA102695645B8C656024DB |
+----------------------------------+
```

Construct bitmasks for the timestamp and node number parts of the value. The timestamp comprises the first three parts (64 bits, bits 0 to 63) and the node number is the last part (48 bits, bits 80 to 127):

```sql
mysql> SET @ts_mask = CAST(X'FFFFFFFFFFFFFFFF' AS BINARY(16));
mysql> SELECT HEX(@ts_mask);
+----------------------------------+
| HEX(@ts_mask)                    |
| FFFFFFFFFFFFFFFFFF0000000000000000 |
+----------------------------------+
mysql> SET @node_mask = CAST(X'FFFFFFFFFFFF' AS BINARY(16)) >> 80;
mysql> SELECT HEX(@node_mask);
+----------------------------------+
| HEX(@node_mask)                  |
| 00000000000000000000FFFFFFFFFFFFF |
+----------------------------------+
```
The `CAST(...) AS BINARY(16)` function is used here because the masks must be the same length as the UUID value against which they are applied. The same result can be produced using other functions to pad the masks to the required length:

```
SET @ts_mask = RPAD(X'FFFFFFFFFFFFFFFF' , 16, X'00');
SET @node_mask = LPAD(X'FFFFFFFFFFFF', 16, X'00');
```

Use the masks to extract the timestamp and node number parts:

```
mysql> SELECT HEX(@uuid & @ts_mask) AS 'timestamp part';
+----------------------------------+
| timestamp part                   |
+----------------------------------+
| 6CCD780CBABA10260000000000000000 |
+----------------------------------+

mysql> SELECT HEX(@uuid & @node_mask) AS 'node part';
+----------------------------------+
| node part                        |
+----------------------------------+
| 000000000000000000005B8C656024DB |
+----------------------------------+
```

The preceding example uses these bit operations: right shift (`>>`) and bitwise AND (`&`).

Note

`UUID_TO_BIN()` takes a flag that causes some bit rearrangement in the resulting binary UUID value. If you use that flag, modify the extraction masks accordingly.

The next example uses bit operations to extract the network and host parts of an IPv6 address. Suppose that the network part has a length of 80 bits. Then the host part has a length of 128 – 80 = 48 bits. To extract the network and host parts of the address, convert it to a binary string, then use bit operations in binary-string context.

Convert the text IPv6 address to the corresponding binary string:

```
mysql> SET @ip = INET6_ATON('fe80::219:d1ff:fe91:1a72');
```

Define the network length in bits:

```
mysql> SET @net_len = 80;
```

Construct network and host masks by shifting the all-ones address left or right. To do this, begin with the address `::`, which is shorthand for all zeros, as you can see by converting it to a binary string like this:

```
mysql> SELECT HEX(INET6_ATON('::')) AS 'all zeros';
+----------------------------------+
| all zeros                        |
+----------------------------------+
| 00000000000000000000000000000000 |
+----------------------------------+
```

To produce the complementary value (all ones), use the `~` operator to invert the bits:

```
mysql> SELECT HEX(~INET6_ATON('::')) AS 'all ones';
+----------------------------------+
| all ones                         |
+----------------------------------+
| FFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFF |
+----------------------------------+
```

Shift the all-ones value left or right to produce the network and host masks:

```
mysql> SET @net_mask = ~INET6_ATON('::') << (128 - @net_len);
mysql> SET @host_mask = ~INET6_ATON('::') >> @net_len;
```
Display the masks to verify that they cover the correct parts of the address:

```
mysql> SELECT INET6_NTOA(@net_mask) AS 'network mask';
+----------------------------+
| network mask               |
+----------------------------+
| ffff:ffff:ffff:ffff:ffff:: |
+----------------------------+
mysql> SELECT INET6_NTOA(@host_mask) AS 'host mask';
+------------------------+
| host mask              |
+------------------------+
| ::ffff:255.255.255.255  |
+------------------------+
```

Extract and display the network and host parts of the address:

```
mysql> SET @net_part = @ip & @net_mask;
mysql> SET @host_part = @ip & @host_mask;
mysql> SELECT INET6_NTOA(@net_part) AS 'network part';
+-----------------+
| network part    |
+-----------------+
| fe80::219:0:0:0 |
+-----------------+
mysql> SELECT INET6_NTOA(@host_part) AS 'host part';
+------------------+
| host part        |
+------------------+
| ::d1ff:fe91:1a72 |
+------------------+
```

The preceding example uses these bit operations: Complement (~), left shift (<<), and bitwise AND (&).

The remaining discussion provides details on argument handling for each group of bit operations, and more information about literal-value handling in bit operations.

**Bitwise AND, OR, and XOR Operations**

For & | and ^ bit operations, the result type depends on whether the arguments are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the arguments have a binary string type, and at least one of them is not a hexadecimal literal, bit literal, or NULL literal. Numeric evaluation occurs otherwise, with argument conversion to unsigned 64-bit integers as necessary.

- Binary-string evaluation produces a binary string of the same length as the arguments. If the arguments have unequal lengths, an ER_INVALID_BITWISE_OPERANDS_SIZE error occurs. Numeric evaluation produces an unsigned 64-bit integer.

Examples of numeric evaluation:

```
mysql> SELECT 64 | 1, X'40' | X'01';
+--------+---------------+
| 64 | 1 | X'40' | X'01' |
+--------+---------------+
|     65 |            65 |
+--------+---------------+
```

Examples of binary-string evaluation:

```
mysql> SELECT _binary X'40' | X'01';
+-----------------------+
| _binary X'40' | X'01' |
+-----------------------+
| A                     |
```

mysql> SET @var1 = X'40', @var2 = X'01';
mysql> SELECT @var1 | @var2;
+--------+--------+
| @var1 | @var2 |
+--------+--------+
Bitwise Complement and Shift Operations

For ~, <<, and >> bit operations, the result type depends on whether the bit argument is evaluated as a binary string or number:

- Binary-string evaluation occurs when the bit argument has a binary string type, and is not a hexadecimal literal, bit literal, or NULL literal. Numeric evaluation occurs otherwise, with argument conversion to an unsigned 64-bit integer as necessary.

- Binary-string evaluation produces a binary string of the same length as the bit argument. Numeric evaluation produces an unsigned 64-bit integer.

For shift operations, bits shifted off the end of the value are lost without warning, regardless of the argument type. In particular, if the shift count is greater or equal to the number of bits in the bit argument, all bits in the result are 0.

Examples of numeric evaluation:

```
mysql> SELECT ~0, 64 << 2, X'40' << 2;
+----------------------+---------+------------+
| ~0                   | 64 << 2 | X'40' << 2 |
+----------------------+---------+------------+
| 18446744073709551615 |     256 |        256 |
+----------------------+---------+------------+
```

Examples of binary-string evaluation:

```
mysql> SELECT HEX(_binary X'1111000022220000' >> 16);
+----------------------------------------+
| HEX(_binary X'1111000022220000' >> 16) |
+----------------------------------------+
| 0000111100002222                       |
+----------------------------------------+
mysql> SELECT HEX(_binary X'1111000022220000' << 16);
+----------------------------------------+
| HEX(_binary X'1111000022220000' << 16) |
+----------------------------------------+
| 0000222200000000                       |
+----------------------------------------+
```

```
BIT_COUNT() Operations

The BIT_COUNT() function always returns an unsigned 64-bit integer, or NULL if the argument is NULL.

mysql> SELECT BIT_COUNT(127);
+------------------+
| BIT_COUNT(127)   |
|                  |
|                  |
+------------------+
|                  |
| 7                |
+------------------+
mysql> SELECT BIT_COUNT(b'010101'), BIT_COUNT(_binary b'010101');
+------------------+-------------------+
| BIT_COUNT(b'010101') | BIT_COUNT(_binary b'010101') |
|                    |                       |
+------------------+-------------------+
**BIT_AND(), BIT_OR(), and BIT_XOR() Operations**

For the `BIT_AND()`, `BIT_OR()`, and `BIT_XOR()` bit functions, the result type depends on whether the function argument values are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the argument values have a binary string type, and the argument is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument value conversion to unsigned 64-bit integers as necessary.

- Binary-string evaluation produces a binary string of the same length as the argument values. If argument values have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. If the argument size exceeds 511 bytes, an `ER_INVALID_BITWISE_AGGREGATE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

`NULL` values do not affect the result unless all values are `NULL`. In that case, the result is a neutral value having the same length as the length of the argument values (all bits 1 for `BIT_AND()`), all bits 0 for `BIT_OR()`, and `BIT_XOR()`).

Example:

```
CREATE TABLE t (group_id INT, a VARBINARY(6));
INSERT INTO t VALUES (1, NULL);
INSERT INTO t VALUES (1, NULL);
INSERT INTO t VALUES (2, NULL);
INSERT INTO t VALUES (2, X'1234');
INSERT INTO t VALUES (2, X'FF34');
SELECT HEX(BIT_AND(a)), HEX(BIT_OR(a)), HEX(BIT_XOR(a))
FROM t GROUP BY group_id;
```

<table>
<thead>
<tr>
<th>HEX(BIT_AND(a))</th>
<th>HEX(BIT_OR(a))</th>
<th>HEX(BIT_XOR(a))</th>
</tr>
</thead>
<tbody>
<tr>
<td>FFFFFFFFFF</td>
<td>000000000000</td>
<td>000000000000</td>
</tr>
<tr>
<td>1234</td>
<td>FF34</td>
<td>ED00</td>
</tr>
</tbody>
</table>

**Special Handling of Hexadecimal Literals, Bit Literals, and NULL Literals**

MySQL 8.4 evaluates bit operations in numeric context when all bit arguments are hexadecimal literals, bit literals, or `NULL` literals. That is, bit operations on binary-string bit arguments do not use binary-string evaluation if all bit arguments are unadorned hexadecimal literals, bit literals, or `NULL` literals. (This does not apply to such literals if they are written with a `_binary` introducer, `BINARY` operator, or other way of specifying them explicitly as binary strings.)

Examples:

- These bit operations evaluate the literals in numeric context and produce a `BIGINT` result:

  ```
  b'0001' | b'0010'
  X'0008' << 8
  ```

- These bit operations evaluate `NULL` in numeric context and produce a `BIGINT` result that has a `NULL` value:

  ```
  NULL & NULL
  NULL >> 4
  ```

You can cause those operations to evaluate the arguments in binary-string context by indicating explicitly that at least one argument is a binary string:

```
_binary b'0001' | b'0010'
_binary X'0008' << 8
BINARY NULL & NULL
```
The result of the last two expressions is NULL, just as without the BINARY operator, but the data type of the result is a binary string type rather than an integer type.

### 14.13 Encryption and Compression Functions

#### Table 14.18 Encryption Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AES_DECRYPT()</td>
<td>Decrypt using AES</td>
</tr>
<tr>
<td>AES_ENCRYPT()</td>
<td>Encrypt using AES</td>
</tr>
<tr>
<td>COMPRESS()</td>
<td>Return result as a binary string</td>
</tr>
<tr>
<td>MD5()</td>
<td>Calculate MD5 checksum</td>
</tr>
<tr>
<td>RANDOM_BYTES()</td>
<td>Return a random byte vector</td>
</tr>
<tr>
<td>SHA1(), SHA()</td>
<td>Calculate an SHA-1 160-bit checksum</td>
</tr>
<tr>
<td>SHA2()</td>
<td>Calculate an SHA-2 checksum</td>
</tr>
<tr>
<td>STATEMENT_DIGEST()</td>
<td>Compute statement digest hash value</td>
</tr>
<tr>
<td>STATEMENT_DIGEST_TEXT()</td>
<td>Compute normalized statement digest</td>
</tr>
<tr>
<td>UNCOMPRESS()</td>
<td>Uncompress a string compressed</td>
</tr>
<tr>
<td>UNCOMPRESSED_LENGTH()</td>
<td>Return the length of a string before compression</td>
</tr>
<tr>
<td>VALIDATE_PASSWORD_STRENGTH()</td>
<td>Determine strength of password</td>
</tr>
</tbody>
</table>

Many encryption and compression functions return strings for which the result might contain arbitrary byte values. If you want to store these results, use a column with a VARBINARY or BLOB binary string data type. This avoids potential problems with trailing space removal or character set conversion that would change data values, such as may occur if you use a nonbinary string data type (CHAR, VARCHAR, TEXT).

Some encryption functions return strings of ASCII characters: MD5(), SHA(), SHA1(), SHA2(), STATEMENT_DIGEST(), STATEMENT_DIGEST_TEXT(). Their return value is a string that has a character set and collation determined by the character_set_connection and collation_connection system variables. This is a nonbinary string unless the character set is binary.

If an application stores values from a function such as MD5() or SHA1() that returns a string of hex digits, more efficient storage and comparisons can be obtained by converting the hex representation to binary using UNHEX() and storing the result in a BINARY(N) column. Each pair of hexadecimal digits requires one byte in binary form, so the value of N depends on the length of the hex string. N is 16 for an MD5() value and 20 for a SHA1() value. For SHA2(), N ranges from 28 to 32 depending on the argument specifying the desired bit length of the result.

The size penalty for storing the hex string in a CHAR column is at least two times, up to eight times if the value is stored in a column that uses the utf8mb4 character set where each character uses 4 bytes. Storing the string also results in slower comparisons because of the larger values and the need to take character set collation rules into account.

Suppose that an application stores MD5() string values in a CHAR(32) column:

```sql
CREATE TABLE md5_tbl (md5_val CHAR(32), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(MD5('abcdef'), ...);
```

To convert hex strings to more compact form, modify the application to use UNHEX() and BINARY(16) instead as follows:

```sql
CREATE TABLE md5_tbl (md5_val BINARY(16), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(UNHEX(MD5('abcdef')), ...);
```
Applications should be prepared to handle the very rare case that a hashing function produces the same value for two different input values. One way to make collisions detectable is to make the hash column a primary key.

**Note**

Exploits for the MD5 and SHA-1 algorithms have become known. You may wish to consider using another one-way encryption function described in this section instead, such as `SHA2()`.

**Caution**

Passwords or other sensitive values supplied as arguments to encryption functions are sent as cleartext to the MySQL server unless an SSL connection is used. Also, such values appear in any MySQL logs to which they are written. To avoid these types of exposure, applications can encrypt sensitive values on the client side before sending them to the server. The same considerations apply to encryption keys. To avoid exposing these, applications can use stored procedures to encrypt and decrypt values on the server side.

- **AES_DECRYPT**(crypt_str, key_str[, init_vector][, kdf_name][, salt][, info | iterations])

This function decrypts data using the official AES (Advanced Encryption Standard) algorithm. For more information, see the description of **AES_ENCRYPT()**.

Statements that use **AES_DECRYPT()** are unsafe for statement-based replication.

- **AES_ENCRYPT**(str, key_str[, init_vector][, kdf_name][, salt][, info | iterations])

**AES_ENCRYPT()** and **AES_DECRYPT()** implement encryption and decryption of data using the official AES (Advanced Encryption Standard) algorithm, previously known as “Rijndael.” The AES standard permits various key lengths. By default these functions implement AES with a 128-bit key length. Key lengths of 196 or 256 bits can be used, as described later. The key length is a trade off between performance and security.

**AES_ENCRYPT()** encrypts the string `str` using the key string `key_str`, and returns a binary string containing the encrypted output. **AES_DECRYPT()** decrypts the encrypted string `crypt_str` using the key string `key_str`, and returns the original (binary) string in hexadecimal format. (To obtain the string as plaintext, cast the result to `CHAR`. Alternatively, start the mysql client with `--skip-binary-as-hex` to cause all binary values to be displayed as text.) If either function argument is `NULL`, the function returns `NULL`. If **AES_DECRYPT()** detects invalid data or incorrect padding, it returns `NULL`. However, it is possible for **AES_DECRYPT()** to return a non-`NULL` value (possibly garbage) if the input data or the key is invalid.

These functions support the use of a key derivation function (KDF) to create a cryptographically strong secret key from the information passed in `key_str`. The derived key is used to encrypt and decrypt the data, and it remains in the MySQL Server instance and is not accessible to users. Using a KDF is highly recommended, as it provides better security than specifying your own premade key or deriving it by a simpler method as you use the function. The functions support HKDF (available from OpenSSL 1.1.0), for which you can specify an optional salt and context-specific information to include in the keying material, and PBKDF2 (available from OpenSSL 1.0.2), for which you can specify an optional salt and set the number of iterations used to produce the key.

**AES_ENCRYPT()** and **AES_DECRYPT()** permit control of the block encryption mode. The **block_encryption_mode** system variable controls the mode for block-based encryption algorithms. Its default value is `aes-128-ecb`, which signifies encryption using a key length of 128 bits and ECB mode. For a description of the permitted values of this variable, see Section 7.1.8.
“Server System Variables”. The optional init_vector argument is used to provide an initialization vector for block encryption modes that require it.

Statements that use AES_ENCRYPT() or AES_DECRYPT() are unsafe for statement-based replication.

If AES_ENCRYPT() is invoked from within the mysql client, binary strings display using hexadecimal notation, depending on the value of the --binary-as-hex. For more information about that option, see Section 6.5.1, "mysql — The MySQL Command-Line Client".

The arguments for the AES_ENCRYPT() and AES_DECRYPT() functions are as follows:

- **str**: The string for AES_ENCRYPT() to encrypt using the key string key_str, or the key derived from it by the specified KDF. The string can be any length. Padding is automatically added to str so it is a multiple of a block as required by block-based algorithms such as AES. This padding is automatically removed by the AES_DECRYPT() function.

- **crypt_str**: The encrypted string for AES_DECRYPT() to decrypt using the key string key_str, or the key derived from it by the specified KDF. The string can be any length. The length of crypt_str can be calculated from the length of the original string using this formula:

  \[ 16 \times (\text{trunc}(\text{string\_length} / 16) + 1) \]

- **key_str**: The encryption key, or the input keying material that is used as the basis for deriving a key using a key derivation function (KDF). For the same instance of data, use the same value of key_str for encryption with AES_ENCRYPT() and decryption with AES_DECRYPT().

If you are using a KDF, key_str can be any arbitrary information such as a password or passphrase. In the further arguments for the function, you specify the KDF name, then add further options to increase the security as appropriate for the KDF.

When you use a KDF, the function creates a cryptographically strong secret key from the information passed in key_str and any salt or additional information that you provide in the other arguments. The derived key is used to encrypt and decrypt the data, and it remains in the MySQL Server instance and is not accessible to users. Using a KDF is highly recommended, as it provides better security than specifying your own premade key or deriving it by a simpler method as you use the function.

If you are not using a KDF, for a key length of 128 bits, the most secure way to pass a key to the key_str argument is to create a truly random 128-bit value and pass it as a binary value. For example:

```
INSERT INTO t
VALUES (1,AES_ENCRYPT('text',UNHEX('F3229A0B371ED2D9441B830D21A390C3')));
```

A passphrase can be used to generate an AES key by hashing the passphrase. For example:

```
INSERT INTO t
```
VALUES (1,AES_ENCRYPT('text', UNHEX(SHA2('My secret passphrase',512))));

If you exceed the maximum key length of 128 bits, a warning is returned. If you are not using a KDF, do not pass a password or passphrase directly to `key_str`, hash it first. Previous versions of this documentation suggested the former approach, but it is no longer recommended as the examples shown here are more secure.

An initialization vector, for block encryption modes that require it. The `block_encryption_mode` system variable controls the mode. For the same instance of data, use the same value of `init_vector` for encryption with `AES_ENCRYPT()` and decryption with `AES_DECRYPT()`.

**Note**

If you are using a KDF, you must specify an initialization vector or a null string for this argument, in order to access the later arguments to define the KDF.

For modes that require an initialization vector, it must be 16 bytes or longer (bytes in excess of 16 are ignored). An error occurs if `init_vector` is missing. For modes that do not require an initialization vector, it is ignored and a warning is generated if `init_vector` is specified, unless you are using a KDF.

The default value for the `block_encryption_mode` system variable is `aes-128-ecb`, or ECB mode, which does not require an initialization vector. The alternative permitted block encryption modes CBC, CFB1, CFB8, CFB128, and OFB all require an initialization vector.

A random string of bytes to use for the initialization vector can be produced by calling `RANDOM_BYTES(16)`.

The name of the key derivation function (KDF) to create a key from the input keying material passed in `key_str`, and other arguments as appropriate for the KDF. Optional.

For the same instance of data, use the same value of `kdf_name` for encryption with `AES_ENCRYPT()` and decryption with `AES_DECRYPT()`. When you specify `kdf_name`, you must specify `init_vector`, using either a valid initialization vector, or a null string if the encryption mode does not require an initialization vector.

The following values are supported:

**hkdf**

HKDF, which is available from OpenSSL 1.1.0. HKDF extracts a pseudorandom key from the keying material then expands it into additional keys. With HKDF, you can specify an optional salt (`salt`) and context-specific information such as application details.
Encryption and Compression Functions

### pbkdf2_hmac

PBKDF2, which is available from OpenSSL 1.0.2. PBKDF2 applies a pseudorandom function to the keying material, and repeats this process a large number of times to produce the key. With PBKDF2, you can specify an optional salt (\textit{salt}) to include in the keying material, and set the number of iterations used to produce the key (\textit{iterations}).

In this example, PBKDF2 is specified as the key derivation function, a salt is provided, and the number of iterations is doubled from the recommended minimum:

```sql
SELECT AES_ENCRYPT('mytext','mykeystring', '', 'pbkdf2_hmac','salt','2000');
```

### salt

A salt to be passed to the key derivation function (KDF). Optional. Both HKDF and PBKDF2 can use salts, and their use is recommended to help prevent attacks based on dictionaries of common passwords or rainbow tables.

A salt consists of random data, which for security must be different for each encryption operation. A random string of bytes to use for the salt can be produced by calling \texttt{RANDOM_BYTES()}. This example produces a 64-bit salt:

```sql
SET @salt = RANDOM_BYTES(8);
```

For the same instance of data, use the same value of \textit{salt} for encryption with \texttt{AES_ENCRYPT()} and decryption with \texttt{AES_DECRYPT()}. The salt can safely be stored along with the encrypted data.

### info

Context-specific information for HKDF to include in the keying material, such as information about the application. Optional; available when you specify \texttt{hkdf} as the KDF name. HKDF adds this information to the keying material specified in \texttt{key_str} and the salt specified in \texttt{salt} to produce the key.

For the same instance of data, use the same value of \textit{info} for encryption with \texttt{AES_ENCRYPT()} and decryption with \texttt{AES_DECRYPT()}. The iteration count for PBKDF2 to use when producing the key. Optional; available when you specify \texttt{pbkdf2_hmac} as the KDF name. A higher count gives greater resistance to brute-force attacks because it has a greater computational cost for the
attacker, but the same is necessarily true for the key derivation process. The default if you do not specify this argument is 1000, which is the minimum recommended by the OpenSSL standard.

For the same instance of data, use the same value of *iterations* for encryption with `AES_ENCRYPT()` and decryption with `AES_DECRYPT()`.

```sql
mysql> SET block_encryption_mode = 'aes-256-cbc';
mysql> SET @key_str = SHA2('My secret passphrase',512);
mysql> SET @init_vector = RANDOM_BYTES(16);
mysql> SET @crypt_str = AES_ENCRYPT('text',@key_str,@init_vector);
mysql> SELECT CAST(AES_DECRYPT(@crypt_str,@key_str,@init_vector) AS CHAR);
+-------------------------------------------------------------+
| CAST(AES_DECRYPT(@crypt_str,@key_str,@init_vector) AS CHAR) |
| text                                                        |
+-------------------------------------------------------------+
```

- **COMPRESS(string_to_compress)**

Compresses a string and returns the result as a binary string. This function requires MySQL to have been compiled with a compression library such as zlib. Otherwise, the return value is always NULL. The return value is also NULL if `string_to_compress` is NULL. The compressed string can be uncompressed with `UNCOMPRESS()`.

```sql
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',1000)));  
  -> 21
mysql> SELECT LENGTH(COMPRESS(''));  
  -> 0
mysql> SELECT LENGTH(COMPRESS('a'));  
  -> 13
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',16)));  
  -> 15
```

The compressed string contents are stored the following way:

- Empty strings are stored as empty strings.

- Nonempty strings are stored as a 4-byte length of the uncompressed string (low byte first), followed by the compressed string. If the string ends with space, an extra .character is added to avoid problems with endspace trimming should the result be stored in a CHAR or VARCHAR column. (However, use of nonbinary string data types such as CHAR or VARCHAR to store compressed strings is not recommended anyway because character set conversion may occur. Use a VARBINARY or BLOB binary string column instead.)

If `COMPRESS()` is invoked from within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 6.5.1, “mysql — The MySQL Command-Line Client”.

- **MD5(str)**

Calculates an MD5 128-bit checksum for the string. The value is returned as a string of 32 hexadecimal digits, or NULL if the argument was NULL. The return value can, for example, be used as a hash key. See the notes at the beginning of this section about storing hash values efficiently.

The return value is a string in the connection character set.

If FIPS mode is enabled, `MD5()` returns NULL. See Section 8.8, “FIPS Support”.

```sql
mysql> SELECT MD5('testing');  
  -> 'ae2b1fca515949e5d54fb22b8ed95575'
```

This is the “RSA Data Security, Inc. MD5 Message-Digest Algorithm.”
See the note regarding the MD5 algorithm at the beginning this section.

- **RANDOM_BYTES(len)**

This function returns a binary string of `len` random bytes generated using the random number generator of the SSL library. Permitted values of `len` range from 1 to 1024. For values outside that range, an error occurs. Returns NULL if `len` is NULL.

`RANDOM_BYTES()` can be used to provide the initialization vector for the `AES_DECRYPT()` and `AES_ENCRYPT()` functions. For use in that context, `len` must be at least 16. Larger values are permitted, but bytes in excess of 16 are ignored.

`RANDOM_BYTES()` generates a random value, which makes its result nondeterministic. Consequently, statements that use this function are unsafe for statement-based replication.

If `RANDOM_BYTES()` is invoked from within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 6.5.1, “`mysql` — The MySQL Command-Line Client”.

- **SHA1(str)**, **SHA(str)**

Calculates an SHA-1 160-bit checksum for the string, as described in RFC 3174 (Secure Hash Algorithm). The value is returned as a string of 40 hexadecimal digits, or NULL if the argument is NULL. One of the possible uses for this function is as a hash key. See the notes at the beginning of this section about storing hash values efficiently. **SHA()** is synonymous with **SHA1()**.

The return value is a string in the connection character set.

```sql
mysql> SELECT SHA1('abc');
-> 'a9993e364706816aba3e25717850c26c9cd0d89d'
```

**SHA1()** can be considered a cryptographically more secure equivalent of **MD5()**. However, see the note regarding the MD5 and SHA-1 algorithms at the beginning this section.

- **SHA2(str, hash_length)**

Calculates the SHA-2 family of hash functions (SHA-224, SHA-256, SHA-384, and SHA-512). The first argument is the plaintext string to be hashed. The second argument indicates the desired bit length of the result, which must have a value of 224, 256, 384, 512, or 0 (which is equivalent to 256). If either argument is NULL or the hash length is not one of the permitted values, the return value is NULL. Otherwise, the function result is a hash value containing the desired number of bits. See the notes at the beginning of this section about storing hash values efficiently.

The return value is a string in the connection character set.

```sql
mysql> SELECT SHA2('abc', 224);
-> '23097d2d234d5d223224a477bda255b32adbec4bda0b3f7e36c9da7'
```

This function works only if MySQL has been configured with SSL support. See Section 8.3, “Using Encrypted Connections”.

**SHA2()** can be considered cryptographically more secure than **MD5()** or **SHA1()**.

- **STATEMENT_DIGEST(statement)**

Given an SQL statement as a string, returns the statement digest hash value as a string in the connection character set, or NULL if the argument is NULL. The related **STATEMENT_DIGEST_TEXT()** function returns the normalized statement digest. For information
Both functions use the MySQL parser to parse the statement. If parsing fails, an error occurs. The error message includes the parse error only if the statement is provided as a literal string.

The `max_digest_length` system variable determines the maximum number of bytes available to these functions for computing normalized statement digests.

```
mysql> SET @stmt = 'SELECT * FROM mytable WHERE cola = 10 AND colb = 20';
mysql> SELECT STATEMENT_DIGEST(@stmt);
+------------------------------------------------------------------+
| STATEMENT_DIGEST(@stmt)                                          |
+------------------------------------------------------------------+
| 3bb95eeade896657c4526e74ff2a2862039d0a0fe8a9e7155b5fe492c978387 |
```

```
mysql> SELECT STATEMENT_DIGEST_TEXT(@stmt);
+----------------------------------------------------------+
| STATEMENT_DIGEST_TEXT(@stmt)                             |
+----------------------------------------------------------+
| SELECT * FROM `mytable` WHERE `cola` = ? AND `colb` = ?   |
```

- **STATEMENT_DIGEST_TEXT(statement)**

Given an SQL statement as a string, returns the normalized statement digest as a string in the connection character set, or NULL if the argument is NULL. For additional discussion and examples, see the description of the related `STATEMENT_DIGEST()` function.

- **UNCOMPRESS(string_to_uncompress)**

Uncompresses a string compressed by the `COMPRESS()` function. If the argument is not a compressed value, the result is NULL; if `string_to_uncompress` is NULL, the result is also NULL. This function requires MySQL to have been compiled with a compression library such as zlib. Otherwise, the return value is always NULL.

```
mysql> SELECT UNCOMPRESS(COMPRESS('any string'));
-> 'any string'
mysql> SELECT UNCOMPRESS('any string');
-> NULL
```

- **UNCOMPRESSED_LENGTH(compressed_string)**

Returns the length that the compressed string had before being compressed. Returns NULL if `compressed_string` is NULL.

```
mysql> SELECT UNCOMPRESSED_LENGTH(COMPRESS(REPEAT('a',30)));
-> 30
```

- **VALIDATE_PASSWORD_STRENGTH(str)**

Given an argument representing a plaintext password, this function returns an integer to indicate how strong the password is, or NULL if the argument is NULL. The return value ranges from 0 (weak) to 100 (strong).

Password assessment by `VALIDATE_PASSWORD_STRENGTH()` is done by the validate_password component. If that component is not installed, the function always returns 0. For information about installing validate_password, see Section 8.4.3, “The Password Validation Component”. To examine or configure the parameters that affect password testing, check or set the system variables implemented by validate_password. See Section 8.4.3.2, “Password Validation Options and Variables”.

The password is subjected to increasingly strict tests and the return value reflects which tests were satisfied, as shown in the following table. In addition, if the validate_password.check_user_name system variable is enabled and the password
matches the user name, `VALIDATE_PASSWORD_STRENGTH()` returns 0 regardless of how other `validate_password` system variables are set.

<table>
<thead>

### 14.14 Locking Functions

This section describes functions used to manipulate user-level locks.

**Table 14.19 Locking Functions**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET_LOCK()</td>
<td>Get a named lock</td>
</tr>
<tr>
<td>IS_FREE_LOCK()</td>
<td>Whether the named lock is free</td>
</tr>
<tr>
<td>IS_USED_LOCK()</td>
<td>Whether the named lock is in use; return connection identifier if true</td>
</tr>
<tr>
<td>RELEASE_ALL_LOCKS()</td>
<td>Release all current named locks</td>
</tr>
<tr>
<td>RELEASE_LOCK()</td>
<td>Release the named lock</td>
</tr>
</tbody>
</table>

- **GET_LOCK(str, timeout)**

  Tries to obtain a lock with a name given by the string `str`, using a timeout of `timeout` seconds. A negative `timeout` value means infinite timeout. The lock is exclusive. While held by one session, other sessions cannot obtain a lock of the same name.

  Returns 1 if the lock was obtained successfully, 0 if the attempt timed out (for example, because another client has previously locked the name), or NULL if an error occurred (such as running out of memory or the thread was killed with `mysqladmin kill`).

  A lock obtained with `GET_LOCK()` is released explicitly by executing `RELEASE_LOCK()` or implicitly when your session terminates (either normally or abnormally). Locks obtained with `GET_LOCK()` are not released when transactions commit or roll back.

  `GET_LOCK()` is implemented using the metadata locking (MDL) subsystem. Multiple simultaneous locks can be acquired and `GET_LOCK()` does not release any existing locks. For example, suppose that you execute these statements:

  ```sql
  SELECT GET_LOCK('lock1',10);
  SELECT GET_LOCK('lock2',10);
  SELECT RELEASE_LOCK('lock2');
  SELECT RELEASE_LOCK('lock1');
  ```

  The second `GET_LOCK()` acquires a second lock and both `RELEASE_LOCK()` calls return 1 (success).

  It is even possible for a given session to acquire multiple locks for the same name. Other sessions cannot acquire a lock with that name until the acquiring session releases all its locks for the name.

  Uniquely named locks acquired with `GET_LOCK()` appear in the Performance Schema `metadata_locks` table. The `OBJECT_TYPE` column says `USER_LEVEL_LOCK` and the
LOCKING FUNCTIONS

The `OBJECT_NAME` column indicates the lock name. In the case that multiple locks are acquired for the same name, only the first lock for the name registers a row in the `metadata_locks` table. Subsequent locks for the name increment a counter in the lock but do not acquire additional metadata locks. The `metadata_locks` row for the lock is deleted when the last lock instance on the name is released.

The capability of acquiring multiple locks means there is the possibility of deadlock among clients. When this happens, the server chooses a caller and terminates its lock-acquisition request with an `ER_USER_LOCK_DEADLOCK` error. This error does not cause transactions to roll back.

MySQL enforces a maximum length on lock names of 64 characters.

`GET_LOCK()` can be used to implement application locks or to simulate record locks. Names are locked on a server-wide basis. If a name has been locked within one session, `GET_LOCK()` blocks any request by another session for a lock with the same name. This enables clients that agree on a given lock name to use the name to perform cooperative advisory locking. But be aware that it also enables a client that is not among the set of cooperating clients to lock a name, either inadvertently or deliberately, and thus prevent any of the cooperating clients from locking that name. One way to reduce the likelihood of this is to use lock names that are database-specific or application-specific. For example, use lock names of the form `db_name.str` or `app_name.str`.

If multiple clients are waiting for a lock, the order in which they acquire it is undefined. Applications should not assume that clients acquire the lock in the same order that they issued the lock requests.

`GET_LOCK()` is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

Since `GET_LOCK()` establishes a lock only on a single `mysqld`, it is not suitable for use with NDB Cluster, which has no way of enforcing an SQL lock across multiple MySQL servers. See Section 25.2.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”, for more information.

Caution

With the capability of acquiring multiple named locks, it is possible for a single statement to acquire a large number of locks. For example:

```
INSERT INTO ... SELECT GET_LOCK(t1.col_name) FROM t1;
```

These types of statements may have certain adverse effects. For example, if the statement fails part way through and rolls back, locks acquired up to the point of failure still exist. If the intent is for there to be a correspondence between rows inserted and locks acquired, that intent is not satisfied. Also, if it is important that locks are granted in a certain order, be aware that result set order may differ depending on which execution plan the optimizer chooses. For these reasons, it may be best to limit applications to a single lock-acquisition call per statement.

A different locking interface is available as either a plugin service or a set of loadable functions. This interface provides lock namespaces and distinct read and write locks, unlike the interface provided by `GET_LOCK()` and related functions. For details, see Section 7.6.9.1, “The Locking Service”.

- **IS_FREE_LOCK(str)**

  Checks whether the lock named `str` is free to use (that is, not locked). Returns 1 if the lock is free (no one is using the lock), 0 if the lock is in use, and NULL if an error occurs (such as an incorrect argument).

  This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- **IS_USED_LOCK(str)**
Checks whether the lock named `str` is in use (that is, locked). If so, it returns the connection identifier of the client session that holds the lock. Otherwise, it returns `NULL`.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- **RELEASE_ALL_LOCKS()**
  
  Releases all named locks held by the current session and returns the number of locks released (0 if there were none).
  
  This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- **RELEASE_LOCK(`str`)**
  
  Releases the lock named by the string `str` that was obtained with `GET_LOCK()`. Returns 1 if the lock was released, 0 if the lock was not established by this thread (in which case the lock is not released), and `NULL` if the named lock did not exist. The lock does not exist if it was never obtained by a call to `GET_LOCK()` or if it has previously been released.
  
  The `DO` statement is convenient to use with `RELEASE_LOCK()`. See Section 15.2.3, “DO Statement”.
  
  This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

### 14.15 Information Functions

**Table 14.20 Information Functions**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>BENCHMARK()</code></td>
<td>Repeatedly execute an expression</td>
</tr>
<tr>
<td><code>CHARSET()</code></td>

</thead>
<tbody>
<tr>
<td>USER()</td>
<td>The user name and host name provided by the client</td>
</tr>
<tr>
<td>VERSION()</td>
<td>Return a string that indicates the MySQL server version</td>
</tr>
</tbody>
</table>

- **BENCHMARK(count, expr)**

  The `BENCHMARK()` function executes the expression `expr` repeatedly `count` times. It may be used to time how quickly MySQL processes the expression. The result value is 0, or `NULL` for inappropriate arguments such as a `NULL` or negative repeat count.

  The intended use is from within the `mysql` client, which reports query execution times:

  ```sql
  mysql> SELECT BENCHMARK(1000000, AES_ENCRYPT('hello', 'goodbye'));
  +---------------------------------------------------+
  | BENCHMARK(1000000, AES_ENCRYPT('hello', 'goodbye')) |
  +---------------------------------------------------+
  |                                                 0 |
  +---------------------------------------------------+
  1 row in set (4.74 sec)
  ```

  The time reported is elapsed time on the client end, not CPU time on the server end. It is advisable to execute `BENCHMARK()` several times, and to interpret the result with regard to how heavily loaded the server machine is.

  `BENCHMARK()` is intended for measuring the runtime performance of scalar expressions, which has some significant implications for the way that you use it and interpret the results:

  - Only scalar expressions can be used. Although the expression can be a subquery, it must return a single column and at most a single row. For example, `BENCHMARK(10, (SELECT * FROM t))` fails if the table `t` has more than one column or more than one row.

  - Executing a `SELECT expr` statement `N` times differs from executing `SELECT BENCHMARK(N, expr)` in terms of the amount of overhead involved. The two have very different execution profiles and you should not expect them to take the same amount of time. The former involves the parser, optimizer, table locking, and runtime evaluation `N` times each. The latter involves only runtime evaluation `N` times, and all the other components just once. Memory structures already allocated are reused, and runtime optimizations such as local caching of results already evaluated for aggregate functions can alter the results. Use of `BENCHMARK()` thus measures performance of the runtime component by giving more weight to that component and removing the “noise” introduced by the network, parser, optimizer, and so forth.

- **CHARSET(str)**

  Returns the character set of the string argument, or `NULL` if the argument is `NULL`.

  ```sql
  mysql> SELECT CHARSET('abc');
  -> 'utf8mb3'
  mysql> SELECT CHARSET(SETUP('abc' USING latin1));
  -> 'latin1'
  mysql> SELECT CHARSET(USER());
  -> 'utf8mb3'
  ```

- **COERCIBILITY(str)**

  Returns the collation coercibility value of the string argument.

  ```sql
  mysql> SELECT COERCIBILITY('abc' COLLATE utf8mb4_swedish_ci);
  -> 0
  mysql> SELECT COERCIBILITY(USER());
  -> 3
  mysql> SELECT COERCIBILITY('abc');
  ```
The return values have the meanings shown in the following table. Lower values have higher precedence.

<table>
<thead>
<tr>
<th>Coercibility</th>
<th>Meaning</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Explicit collation</td>
<td>Value with <code>COLLATE</code> clause</td>
</tr>
<tr>
<td>1</td>
<td>No collation</td>
<td>Concatenation of strings with different collations</td>
</tr>
<tr>
<td>2</td>
<td>Implicit collation</td>
<td>Column value, stored routine parameter or local variable</td>
</tr>
<tr>
<td>3</td>
<td>System constant</td>
<td><code>USER()</code> return value</td>
</tr>
<tr>

</tr>
</tbody>
</table>

For more information, see Section 12.8.4, “Collation Coercibility in Expressions”.

- **COLLATION**(str)

  Returns the collation of the string argument.

  ```
  mysql> SELECT COLLATION('abc');
  -> 'utf8mb4_0900_ai_ci'
  mysql> SELECT COLLATION(_utf8mb4'abc');
  -> 'utf8mb4_0900_ai_ci'
  mysql> SELECT COLLATION(_latin1'abc');
  -> 'latin1_swedish_ci'
  ```

- **CONNECTION_ID()**

  Returns the connection ID (thread ID) for the connection. Every connection has an ID that is unique among the set of currently connected clients.

  The value returned by `CONNECTION_ID()` is the same type of value as displayed in the `ID` column of the Information Schema `PROCESSLIST` table, the `Id` column of `SHOW PROCESSLIST` output, and the `PROCESSLIST_ID` column of the Performance Schema `threads` table.

  ```
  mysql> SELECT CONNECTION_ID();
  -> 23786
  ```

  **Warning**

  Changing the session value of the `pseudo_thread_id` system variable changes the value returned by the `CONNECTION_ID()` function.

- **CURRENT_ROLE()**

  Returns a `utf8mb3` string containing the current active roles for the current session, separated by commas, or `NONE` if there are none. The value reflects the setting of the `sql_quote_show_create` system variable.

  Suppose that an account is granted roles as follows:

  ```
  GRANT 'r1', 'r2' TO 'u1'@'localhost';
  ```
SET DEFAULT ROLE ALL TO 'u1'@'localhost';

In sessions for u1, the initial CURRENT_ROLE() value names the default account roles. Using SET ROLE changes that:

```sql
mysql> SELECT CURRENT_ROLE();
+-------------------+
| CURRENT_ROLE()    |
+-------------------+
| `r1`@`%`,`r2`@`%` |
+-------------------+

mysql> SET ROLE 'r1'; SELECT CURRENT_ROLE();
+----------------+
| CURRENT_ROLE() |
+----------------+
| `r1`@`%`       |
+----------------+
```

- **CURRENT_USER, CURRENT_USER()**

Returns the user name and host name combination for the MySQL account that the server used to authenticate the current client. This account determines your access privileges. The return value is a string in the utf8mb3 character set.

The value of CURRENT_USER() can differ from the value of USER().

```sql
mysql> SELECT USER();
-> 'davida@localhost'

mysql> SELECT * FROM mysql.user;
ERROR 1044: Access denied for user ''@'localhost' to database 'mysql'

mysql> SELECT CURRENT_USER();
-> '@localhost'
```

The example illustrates that although the client specified a user name of davida (as indicated by the value of the USER() function), the server authenticated the client using an anonymous user account.
(as seen by the empty user name part of the `CURRENT_USER()` value). One way this might occur is that there is no account listed in the grant tables for davida.

Within a stored program or view, `CURRENT_USER()` returns the account for the user who defined the object (as given by its `DEFINER` value) unless defined with the `SQL SECURITY INVOKER` characteristic. In the latter case, `CURRENT_USER()` returns the object's invoker.

Triggers and events have no option to define the `SQL SECURITY` characteristic, so for these objects, `CURRENT_USER()` returns the account for the user who defined the object. To return the invoker, use `USER()` or `SESSION_USER()`.

The following statements support use of the `CURRENT_USER()` function to take the place of the name of (and, possibly, a host for) an affected user or a definer; in such cases, `CURRENT_USER()` is expanded where and as needed:

- DROP USER
- RENAME USER
- GRANT
- REVOKE
- CREATE FUNCTION
- CREATE PROCEDURE
- CREATE TRIGGER
- CREATE EVENT
- CREATE VIEW
- ALTER EVENT
- ALTER VIEW
- SET PASSWORD

For information about the implications that this expansion of `CURRENT_USER()` has for replication, see Section 19.5.1.8, “Replication of `CURRENT_USER()`”.

This function can be used for the default value of a `VARCHAR` or `TEXT` column, as shown in the following `CREATE TABLE` statement:

```sql
CREATE TABLE t (c VARCHAR(288) DEFAULT (CURRENT_USER()));
```

- DATABASE()

Returns the default (current) database name as a string in the `utf8mb3` character set. If there is no default database, `DATABASE()` returns `NULL`. Within a stored routine, the default database is the database that the routine is associated with, which is not necessarily the same as the database that is the default in the calling context.

```sql
mysql> SELECT DATABASE();
-> 'test'
```

If there is no default database, `DATABASE()` returns `NULL`. 

2225
Information Functions

• FOUND_ROWS()

Note

The SQL_CALC_FOUND_ROWS query modifier and accompanying FOUND_ROWS() function are deprecated; expect them to be removed in a future version of MySQL. Execute the query with LIMIT, and then a second query with COUNT(*) and without LIMIT to determine whether there are additional rows. For example, instead of these queries:

SELECT SQL_CALC_FOUND_ROWS * FROM tbl_name WHERE id > 100 LIMIT 10;
SELECT FOUND_ROWS();

Use these queries instead:

SELECT * FROM tbl_name WHERE id > 100 LIMIT 10;
SELECT COUNT(*) FROM tbl_name WHERE id > 100;

COUNT(*) is subject to certain optimizations. SQL_CALC_FOUND_ROWS causes some optimizations to be disabled.

A SELECT statement may include a LIMIT clause to restrict the number of rows the server returns to the client. In some cases, it is desirable to know how many rows the statement would have returned without the LIMIT, but without running the statement again. To obtain this row count, include an SQL_CALC_FOUND_ROWS option in the SELECT statement, and then invoke FOUND_ROWS() afterward:

mysql> SELECT SQL_CALC_FOUND_ROWS * FROM tbl_name
      -> WHERE id > 100 LIMIT 10;

mysql> SELECT FOUND_ROWS();

The second SELECT returns a number indicating how many rows the first SELECT would have returned had it been written without the LIMIT clause.

In the absence of the SQL_CALC_FOUND_ROWS option in the most recent successful SELECT statement, FOUND_ROWS() returns the number of rows in the result set returned by that statement. If the statement includes a LIMIT clause, FOUND_ROWS() returns the number of rows up to the limit. For example, FOUND_ROWS() returns 10 or 60, respectively, if the statement includes LIMIT 10 or LIMIT 50, 10.

The row count available through FOUND_ROWS() is transient and not intended to be available past the statement following the SELECT SQL_CALC_FOUND_ROWS statement. If you need to refer to the value later, save it:

mysql> SELECT SQL_CALC_FOUND_ROWS * FROM ... ;

mysql> SET @rows = FOUND_ROWS();

If you are using SELECT SQL_CALC_FOUND_ROWS, MySQL must calculate how many rows are in the full result set. However, this is faster than running the query again without LIMIT, because the result set need not be sent to the client.

SQL_CALC_FOUND_ROWS and FOUND_ROWS() can be useful in situations when you want to restrict the number of rows that a query returns, but also determine the number of rows in the full result set without running the query again. An example is a Web script that presents a paged display
containing links to the pages that show other sections of a search result. Using `FOUND_ROWS()` enables you to determine how many other pages are needed for the rest of the result.

The use of `SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` is more complex for `UNION` statements than for simple `SELECT` statements, because `LIMIT` may occur at multiple places in a `UNION`. It may be applied to individual `SELECT` statements in the `UNION`, or global to the `UNION` result as a whole.

The intent of `SQL_CALC_FOUND_ROWS` for `UNION` is that it should return the row count that would be returned without a global `LIMIT`. The conditions for use of `SQL_CALC_FOUND_ROWS` with `UNION` are:

- The `SQL_CALC_FOUND_ROWS` keyword must appear in the first `SELECT` of the `UNION`.
- The value of `FOUND_ROWS()` is exact only if `UNION ALL` is used. If `UNION` without `ALL` is used, duplicate removal occurs and the value of `FOUND_ROWS()` is only approximate.
- If no `LIMIT` is present in the `UNION`, `SQL_CALC_FOUND_ROWS` is ignored and returns the number of rows in the temporary table that is created to process the `UNION`.

Beyond the cases described here, the behavior of `FOUND_ROWS()` is undefined (for example, its value following a `SELECT` statement that fails with an error).

**Important**

`FOUND_ROWS()` is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

- `ICU_VERSION()`

The version of the International Components for Unicode (ICU) library used to support regular expression operations (see Section 14.8.2, “Regular Expressions”). This function is primarily intended for use in test cases.

- `LAST_INSERT_ID()`, `LAST_INSERT_ID(expr)`

With no argument, `LAST_INSERT_ID()` returns a `BIGINT UNSIGNED` (64-bit) value representing the first automatically generated value successfully inserted for an `AUTO_INCREMENT` column as a result of the most recently executed `INSERT` statement. The value of `LAST_INSERT_ID()` remains unchanged if no rows are successfully inserted.

With an argument, `LAST_INSERT_ID()` returns an unsigned integer, or `NULL` if the argument is `NULL`.

For example, after inserting a row that generates an `AUTO_INCREMENT` value, you can get the value like this:

```sql
mysql> SELECT LAST_INSERT_ID();
-> 195
```

The currently executing statement does not affect the value of `LAST_INSERT_ID()`. Suppose that you generate an `AUTO_INCREMENT` value with one statement, and then refer to `LAST_INSERT_ID()` in a multiple-row `INSERT` statement that inserts rows into a table with its own `AUTO_INCREMENT` column. The value of `LAST_INSERT_ID()` remains stable in the second statement; its value for the second and later rows is not affected by the earlier row insertions. (You should be aware that, if you mix references to `LAST_INSERT_ID()` and `LAST_INSERT_ID(expr)`, the effect is undefined.)

If the previous statement returned an error, the value of `LAST_INSERT_ID()` is undefined. For transactional tables, if the statement is rolled back due to an error, the value of `LAST_INSERT_ID()`
is left undefined. For manual `ROLLBACK`, the value of `LAST_INSERT_ID()` is not restored to that before the transaction; it remains as it was at the point of the `ROLLBACK`.

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects. The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value is seen by statements that follow the procedure call.

- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so statements coming after it do not see a changed value.

The ID that was generated is maintained in the server on a *per-connection basis*. This means that the value returned by the function to a given client is the first `AUTO_INCREMENT` value generated for most recent statement affecting an `AUTO_INCREMENT` column by *that client*. This value cannot be affected by other clients, even if they generate `AUTO_INCREMENT` values of their own. This behavior ensures that each client can retrieve its own ID without concern for the activity of other clients, and without the need for locks or transactions.

The value of `LAST_INSERT_ID()` is not changed if you set the `AUTO_INCREMENT` column of a row to a non-“magic” value (that is, a value that is not `NULL` and not `0`).

**Important**

If you insert multiple rows using a single `INSERT` statement, `LAST_INSERT_ID()` returns the value generated for the *first* inserted row only. The reason for this is to make it possible to reproduce easily the same `INSERT` statement against some other server.

For example:

```sql
mysql> USE test;

mysql> CREATE TABLE t (        id INT AUTO_INCREMENT NOT NULL PRIMARY KEY,        name VARCHAR(10) NOT NULL );

mysql> INSERT INTO t VALUES (NULL, 'Bob');

mysql> SELECT * FROM t;
+----+------+
| id | name |
+----+------+
|  1 | Bob  |
+----+------+

mysql> SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
|                1 |
+------------------+

mysql> INSERT INTO t VALUES
    (NULL, 'Mary'), (NULL, 'Jane'), (NULL, 'Lisa');

mysql> SELECT * FROM t;
+----+------+
| id | name |
+----+------+
|  1 | Bob  |
|  2 | Mary |
|  3 | Jane |
+----+------+
```
Although the second `INSERT` statement inserted three new rows into `t`, the ID generated for the first of these rows was 2, and it is this value that is returned by `LAST_INSERT_ID()` for the following `SELECT` statement.

If you use `INSERT IGNORE` and the row is ignored, the `LAST_INSERT_ID()` remains unchanged from the current value (or 0 is returned if the connection has not yet performed a successful `INSERT`) and, for non-transactional tables, the `AUTO_INCREMENT` counter is not incremented. For InnoDB tables, the `AUTO_INCREMENT` counter is incremented if `innodb_autoinc_lock_mode` is set to 1 or 2, as demonstrated in the following example:
Information Functions

mysql> SHOW CREATE TABLE t;
*************************** 1. row ***************************
Table: t
Create Table: CREATE TABLE `t` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `val` int(11) DEFAULT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `i1` (`val`)
) ENGINE=InnoDB AUTO_INCREMENT=5 DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci

# The LAST_INSERT_ID is unchanged because the previous insert was unsuccessful
mysql> SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
|                1 |
+------------------+

For more information, see Section 17.6.1.6, “AUTO_INCREMENT Handling in InnoDB”.

If `expr` is given as an argument to `LAST_INSERT_ID()`, the value of the argument is returned by the function and is remembered as the next value to be returned by `LAST_INSERT_ID()`. This can be used to simulate sequences:

1. Create a table to hold the sequence counter and initialize it:

```
mysql> CREATE TABLE sequence (id INT NOT NULL);
mysql> INSERT INTO sequence VALUES (0);
```

2. Use the table to generate sequence numbers like this:

```
mysql> UPDATE sequence SET id=LAST_INSERT_ID(id+1);
mysql> SELECT LAST_INSERT_ID();
```

The `UPDATE` statement increments the sequence counter and causes the next call to `LAST_INSERT_ID()` to return the updated value. The `SELECT` statement retrieves that value. The `mysql_insert_id()` C API function can also be used to get the value. See `mysql_insert_id()`.

You can generate sequences without calling `LAST_INSERT_ID()`, but the utility of using the function this way is that the ID value is maintained in the server as the last automatically generated value. It is multi-user safe because multiple clients can issue the `UPDATE` statement and get their own sequence value with the `SELECT` statement (or `mysql_insert_id()`), without affecting or being affected by other clients that generate their own sequence values.

Note that `mysql_insert_id()` is only updated after `INSERT` and `UPDATE` statements, so you cannot use the C API function to retrieve the value for `LAST_INSERT_ID(expr)` after executing other SQL statements like `SELECT` or `SET`.

• `ROLES_GRAPHML()`

Returns a `utf8mb3` string containing a GraphML document representing memory role subgraphs. The `ROLE_ADMIN` privilege (or the deprecated `SUPER` privilege) is required to see content in the `<graphml>` element. Otherwise, the result shows only an empty element:

```
mysql> SELECT ROLES_GRAPHML();
```

2230
Information Functions

- **ROW_COUNT()**

  The `ROW_COUNT()` function returns a value as follows:

  - **DDL statements**: 0. This applies to statements such as `CREATE TABLE` or `DROP TABLE`.
  - **DML statements other than SELECT**: The number of affected rows. This applies to statements such as `UPDATE`, `INSERT`, or `DELETE` (as before), but now also to statements such as `ALTER TABLE` and `LOAD DATA`.
  - **SELECT**: -1 if the statement returns a result set, or the number of rows “affected” if it does not. For example, for `SELECT * FROM t1`, `ROW_COUNT()` returns -1. For `SELECT * FROM t1 INTO OUTFILE 'file_name'`, `ROW_COUNT()` returns the number of rows written to the file.
  - **SIGNAL statements**: 0. For `UPDATE` statements, the affected-rows value by default is the number of rows actually changed. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to `mysqld`, the affected-rows value is the number of rows “found”; that is, matched by the `WHERE` clause.
  - **REPLACE statements**: the affected-rows value is 2 if the new row replaced an old row, because in this case, one row was inserted after the duplicate was deleted.
  - **INSERT ... ON DUPLICATE KEY UPDATE statements**: the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

  The `ROW_COUNT()` value is similar to the value from the `mysql_affected_rows()` C API function and the row count that the `mysql` client displays following statement execution.

```sql
mysql> INSERT INTO t VALUES(1),(2),(3);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT ROW_COUNT();
+-------------+
| ROW_COUNT() |
+-------------+
|            3 |
+-------------+
1 row in set (0.00 sec)

mysql> DELETE FROM t WHERE i IN(1,2);
Query OK, 2 rows affected (0.00 sec)

mysql> SELECT ROW_COUNT();
+-------------+
| ROW_COUNT() |
+-------------+
|            2 |
+-------------+
1 row in set (0.00 sec)
```

**Important**

- `ROW_COUNT()` is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

- **SCHEMA()**

  This function is a synonym for `DATABASE()`.
Spatial Analysis Functions

- **SESSION_USER()**

  **SESSION_USER()** is a synonym for **USER().**

  Like **USER(),** this function can be used for the default value of a **VARCHAR** or **TEXT** column, as shown in the following **CREATE TABLE** statement:

  ```sql
  CREATE TABLE t (c VARCHAR(288) DEFAULT (SESSION_USER()));
  ```

- **SYSTEM_USER()**

  **SYSTEM_USER()** is a synonym for **USER().**

  Note
  
  The **SYSTEM_USER()** function is distinct from the **SYSTEM_USER** privilege. The former returns the current MySQL account name. The latter distinguishes the system user and regular user account categories (see **Section 8.2.11, “Account Categories”**).

  Like **USER(),** this function can be used for the default value of a **VARCHAR** or **TEXT** column, as shown in the following **CREATE TABLE** statement:

  ```sql
  CREATE TABLE t (c VARCHAR(288) DEFAULT (SYSTEM_USER()));
  ```

- **USER()**

  Returns the current MySQL user name and host name as a string in the **utf8mb3** character set.

  ```sql
  mysql> SELECT USER();
  -> 'davida@localhost'
  ```

  The value indicates the user name you specified when connecting to the server, and the client host from which you connected. The value can be different from that of **CURRENT_USER().**

  This function can be used for the default value of a **VARCHAR** or **TEXT** column, as shown in the following **CREATE TABLE** statement:

  ```sql
  CREATE TABLE t (c VARCHAR(288) DEFAULT (USER()));
  ```

- **VERSION()**

  Returns a string that indicates the MySQL server version. The string uses the **utf8mb3** character set. The value might have a suffix in addition to the version number. See the description of the **version** system variable in **Section 7.1.8, ‘Server System Variables’**.

  This function is unsafe for statement-based replication. A warning is logged if you use this function when **binlog_format** is set to **STATEMENT**.

  ```sql
  mysql> SELECT VERSION();
  -> '8.4.0-standard'
  ```

### 14.16 Spatial Analysis Functions

MySQL provides functions to perform various operations on spatial data. These functions can be grouped into several major categories according to the type of operation they perform:

- Functions that create geometries in various formats (WKT, WKB, internal)
- Functions that convert geometries between formats
- Functions that access qualitative or quantitative properties of a geometry
- Functions that describe relations between two geometries
• Functions that create new geometries from existing ones

For general background about MySQL support for using spatial data, see Section 13.4, “Spatial Data Types”.

14.16.1 Spatial Function Reference

The following table lists each spatial function and provides a short description of each one.

### Table 14.21 Spatial Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GeomCollection()</td>
<td>Construct geometry collection from geometries</td>
</tr>
<tr>
<td>GeometryCollection()</td>
<td>Construct geometry collection from geometries</td>
</tr>
<tr>
<td>LineString()</td>
<td>Construct LineString from Point values</td>
</tr>
<tr>
<td>MBRContains()</td>
<td>Whether MBR of one geometry contains MBR of another</td>
</tr>
<tr>
<td>MBRCoveredBy()</td>
<td>Whether one MBR is covered by another</td>
</tr>
<tr>
<td>MBRCovers()</td>
<td>Whether one MBR covers another</td>
</tr>
<tr>
<td>MBRDisjoint()</td>
<td>Whether MBRs of two geometries are disjoint</td>
</tr>
<tr>
<td>MBREquals()</td>
<td>Whether MBRs of two geometries are equal</td>
</tr>
<tr>
<td>MBRIntersects()</td>
<td>Whether MBRs of two geometries intersect</td>
</tr>
<tr>
<td>MBROverlaps()</td>
<td>Whether MBRs of two geometries overlap</td>
</tr>
<tr>
<td>MBRTouches()</td>
<td>Whether MBRs of two geometries touch</td>
</tr>
<tr>
<td>MBRWithin()</td>
<td>Whether MBR of one geometry is within MBR of another</td>
</tr>
<tr>
<td>MultiLineString()</td>
<td>Construct MultiLineString from LineString values</td>
</tr>
<tr>
<td>MultiPoint()</td>
<td>Construct MultiPoint from Point values</td>
</tr>
<tr>
<td>MultiPolygon()</td>
<td>Construct MultiPolygon from Polygon values</td>
</tr>
<tr>
<td>Point()</td>
<td>Construct Point from coordinates</td>
</tr>
<tr>
<td>Polygon()</td>
<td>Construct Polygon from LineString arguments</td>
</tr>
<tr>
<td>ST_Area()</td>
<td>Return Polygon or MultiPolygon area</td>
</tr>
<tr>
<td>ST_AsBinary(), ST_AsWKB()</td>
<td>Convert from internal geometry format to WKB</td>
</tr>
<tr>
<td>ST_AsGeoJSON()</td>
<td>Generate GeoJSON object from geometry</td>
</tr>
<tr>
<td>ST_AsText(), ST_AsWKT()</td>
<td>Convert from internal geometry format to WKT</td>
</tr>
<tr>
<td>ST_Buffer()</td>
<td>Return geometry of points within given distance from geometry</td>
</tr>
<tr>
<td>ST_Buffer_Strategy()</td>
<td>Produce strategy option for ST_Buffer()</td>
</tr>
<tr>
<td>ST_Centroid()</td>
<td>Return centroid as a point</td>
</tr>
<tr>
<td>ST_Collect()</td>
<td>Aggregate spatial values into collection</td>
</tr>
<tr>
<td>ST_Contains()</td>
<td>Whether one geometry contains another</td>
</tr>
<tr>
<td>ST_Centroid()</td>
<td>Return centroid as a point</td>
</tr>
<tr>
<td>ST_Crosses()</td>
<td>Whether one geometry crosses another</td>
</tr>
<tr>
<td>ST_Difference()</td>
<td>Return point set difference of two geometries</td>
</tr>
<tr>
<td>ST_Dimension()</td>
<td>Dimension of geometry</td>
</tr>
<tr>
<td>ST_Disjoint()</td>
<td>Whether one geometry is disjoint from another</td>
</tr>
<tr>
<td>ST_Distance()</td>
<td>The distance of one geometry from another</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ST_Distance_Sphere()</td>
<td>Minimum distance on earth between two geometries</td>
</tr>
<tr>
<td>ST_EndPoint()</td>
<td>End Point of LineString</td>
</tr>
<tr>
<td>ST_Envelope()</td>
<td>Return MBR of geometry</td>
</tr>
<tr>
<td>ST_Equals()</td>
<td>Whether one geometry is equal to another</td>
</tr>
<tr>
<td>ST_ExteriorRing()</td>
<td>Return exterior ring of Polygon</td>
</tr>
<tr>
<td>ST_FrechetDistance()</td>
<td>The discrete Fréchet distance of one geometry from another</td>
</tr>
<tr>
<td>ST_Geohash()</td>
<td>Produce a geohash value</td>
</tr>
<tr>
<td>ST_GeomCollFromText(),</td>
<td>Return geometry collection from WKT</td>
</tr>
<tr>
<td>ST_GeometryCollectionFromText(),</td>
<td></td>
</tr>
<tr>
<td>ST_GeomCollFromTxt()</td>
<td></td>
</tr>
<tr>
<td>ST_GeomCollFromWKB(),</td>
<td>Return geometry collection from WKB</td>
</tr>
<tr>
<td>ST_GeometryCollectionFromWKB()</td>
<td></td>
</tr>
<tr>
<td>ST_GeometryN()</td>
<td>Return N-th geometry from geometry collection</td>
</tr>
<tr>
<td>ST_GeometryType()</td>
<td>Return name of geometry type</td>
</tr>
<tr>
<td>ST_GeomFromGeoJSON()</td>
<td>Generate geometry from GeoJSON object</td>
</tr>
<tr>
<td>ST_GeomFromText(),</td>
<td>Return geometry from WKT</td>
</tr>
<tr>
<td>ST_GeometryFromText()</td>
<td></td>
</tr>
<tr>
<td>ST_GeomFromWKB(),ST_GeometryFromWKB()</td>
<td>The discrete Hausdorff distance of one geometry from another</td>
</tr>
<tr>
<td>ST_HausdorffDistance()</td>
<td></td>
</tr>
<tr>
<td>ST_InteriorRingN()</td>
<td>Return N-th interior ring of Polygon</td>
</tr>
<tr>
<td>ST_Intersection()</td>
<td>Return point set intersection of two geometries</td>
</tr>
<tr>
<td>ST_Intersects()</td>
<td>Whether one geometry intersects another</td>
</tr>
<tr>
<td>ST_IsClosed()</td>
<td>Whether a geometry is closed and simple</td>
</tr>
<tr>
<td>ST_IsEmpty()</td>
<td>Whether a geometry is empty</td>
</tr>
<tr>
<td>ST_IsSimple()</td>
<td>Whether a geometry is simple</td>
</tr>
<tr>
<td>ST_IsValid()</td>
<td>Whether a geometry is valid</td>
</tr>
<tr>
<td>ST_LatLngFromGeohash()</td>
<td>Return latitude from geohash value</td>
</tr>
<tr>
<td>ST_Latitude()</td>
<td>Return latitude of Point</td>
</tr>
<tr>
<td>ST_Length()</td>
<td>Return length of LineString</td>
</tr>
<tr>
<td>ST_LineInterpolatePoint()</td>
<td>The point a given percentage along a LineString</td>
</tr>
<tr>
<td>ST_LineInterpolatePoints()</td>
<td>The points a given percentage along a LineString</td>
</tr>
<tr>
<td>ST_LongFromGeoHash()</td>
<td>Return longitude from geohash value</td>
</tr>
<tr>
<td>ST_Longitude()</td>
<td>Return longitude of Point</td>
</tr>
<tr>
<td>ST_MakeEnvelope()</td>
<td>Rectangle around two points</td>
</tr>
<tr>
<td>ST_MLineFromText(),</td>
<td>Construct MultiLineString from WKT</td>
</tr>
<tr>
<td>ST_MultiLineStringFromText()</td>
<td></td>
</tr>
</tbody>
</table>
### 14.16.2 Argument Handling by Spatial Functions

Spatial values, or geometries, have the properties described in Section 13.4.2.2, “Geometry Class”. The following discussion lists general spatial function argument-handling characteristics. Specific functions or groups of functions may have additional or different argument-handling characteristics, as discussed in the sections where those function descriptions occur. Where that is true, those descriptions take precedence over the general discussion here.
Spatial functions are defined only for valid geometry values. See Section 13.4.4, “Geometry Well-Formedness and Validity”.

Each geometry value is associated with a spatial reference system (SRS), which is a coordinate-based system for geographic locations. See Section 13.4.5, “Spatial Reference System Support”.

The spatial reference identifier (SRID) of a geometry identifies the SRS in which the geometry is defined. In MySQL, the SRID value is an integer associated with the geometry value. The maximum usable SRID value is $2^{32} - 1$. If a larger value is given, only the lower 32 bits are used.

SRID 0 represents an infinite flat Cartesian plane with no units assigned to its axes. To ensure SRID 0 behavior, create geometry values using SRID 0. SRID 0 is the default for new geometry values if no SRID is specified.

For computations on multiple geometry values, all values must be in the same SRS or an error occurs. Thus, spatial functions that take multiple geometry arguments require those arguments to be in the same SRS. If a spatial function returns ER_GIS_DIFFERENT_SRIDS, it means that the geometry arguments were not all in the same SRS. You must modify them to have the same SRS.

A geometry returned by a spatial function is in the SRS of the geometry arguments because geometry values produced by any spatial function inherit the SRID of the geometry arguments.

The Open Geospatial Consortium guidelines require that input polygons already be closed, so unclosed polygons are rejected as invalid rather than being closed.

In MySQL, the only valid empty geometry is represented in the form of an empty geometry collection. Empty geometry collection handling is as follows: An empty WKT input geometry collection may be specified as 'GEOMETRYCOLLECTION()'. This is also the output WKT resulting from a spatial operation that produces an empty geometry collection.

During parsing of a nested geometry collection, the collection is flattened and its basic components are used in various GIS operations to compute results. This provides additional flexibility to users because it is unnecessary to be concerned about the uniqueness of geometry data. Nested geometry collections may be produced from nested GIS function calls without having to be explicitly flattened first.

### 14.16.3 Functions That Create Geometry Values from WKT Values

These functions take as arguments a Well-Known Text (WKT) representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry. For a description of WKT format, see Well-Known Text (WKT) Format.

Functions in this section detect arguments in either Cartesian or geographic spatial reference systems (SRSS), and return results appropriate to the SRS.

**ST_GeomFromText()** accepts a WKT value of any geometry type as its first argument. Other functions provide type-specific construction functions for construction of geometry values of each geometry type.

Functions such as **ST_MPointFromText()** and **ST_GeomFromText()** that accept WKT-format representations of MultiPoint values permit individual points within values to be surrounded by parentheses. For example, both of the following function calls are valid:

```
ST_MPointFromText('MULTIPOINT (1 1, 2 2, 3 3)')
ST_MPointFromText('MULTIPOINT ((1 1), (2 2), (3 3))')
```

Functions such as **ST_GeomFromText()** that accept WKT geometry collection arguments understand both OpenGIS 'GEOMETRYCOLLECTION EMPTY' standard syntax and MySQL 'GEOMETRYCOLLECTION()' nonstandard syntax. Functions such as **ST_AsWKT()** that produce WKT values produce 'GEOMETRYCOLLECTION EMPTY' standard syntax:

```sql
mysql> SET @s1 = ST_GeomFromText('GEOMETRYCOLLECTION()');
mysql> SET @s2 = ST_GeomFromText('GEOMETRYCOLLECTION EMPTY');
mysql> SELECT ST_AsWKT(@s1), ST_AsWKT(@s2);
```
Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any geometry argument is NULL or is not a syntactically well-formed geometry, or if the SRID argument is NULL, the return value is NULL.

- By default, geographic coordinates (latitude, longitude) are interpreted as in the order specified by the spatial reference system of geometry arguments. An optional options argument may be given to override the default axis order. options consists of a list of comma-separated key=value. The only permitted key value is axis-order, with permitted values of lat-long, long-lat and srid-defined (the default).

  If the options argument is NULL, the return value is NULL. If the options argument is invalid, an error occurs to indicate why.

- If an SRID argument refers to an undefined spatial reference system (SRS), an ER_SRS_NOT_FOUND error occurs.

- For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range (-180, 180], an ER_LONGITUDE_OUT_OF_RANGE error occurs.
  - If a latitude value is not in the range [-90, 90], an ER_LATITUDE_OUT_OF_RANGE error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

These functions are available for creating geometries from WKT values:

- ST_GeomCollFromText(wkt [, srid [, options]]),
  ST_GeometryCollectionFromText(wkt [, srid [, options]]),
  ST_GeomCollFromTxt(wkt [, srid [, options]])

  Constructs a GeometryCollection value using its WKT representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

```sql
mysql> SET @g = "MULTILINESTRING((10 10, 11 11), (9 9, 10 10))";
mysql> SELECT ST_AsText(ST_GeomCollFromText(@g));
+--------------------------------------------+
<table>
<thead>
<tr>
<th>ST_AsText(ST_GeomCollFromText(@g))</th>
</tr>
</thead>
<tbody>
<tr>
<td>MULTILINESTRING((10 10,11 11),(9 9,10 10))</td>
</tr>
<tr>
<td>--------------------------------------------</td>
</tr>
</tbody>
</table>
```

- ST_GeomFromText(wkt [, srid [, options]]),
  ST_GeometryFromText(wkt [, srid [, options]]),
  ST_GeomFromTxt(wkt [, srid [, options]])

  Constructs a geometry value of any type using its WKT representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

- ST_LineFromText(wkt [, srid [, options]]),
  ST_LineStringFromText(wkt [, srid [, options]])

  Constructs a LineString value using its WKT representation and SRID.

  These functions handle their arguments as described in the introduction to this section.
• ST_MLineFromText(wkt [, srid [, options]]), ST_MultiLineStringFromText(wkt [, srid [, options]])

Constructs a MultiLineString value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

• ST_MPointFromText(wkt [, srid [, options]]), ST_MultiPointFromText(wkt [, srid [, options]])

Constructs a MultiPoint value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

• ST_MPolyFromText(wkt [, srid [, options]]), ST_MultiPolygonFromText(wkt [, srid [, options]])

Constructs a MultiPolygon value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

• ST_PointFromText(wkt [, srid [, options]])

Constructs a Point value using its WKT representation and SRID.

ST_PointFromText() handles its arguments as described in the introduction to this section.

• ST_PolyFromText(wkt [, srid [, options]]), ST_PolygonFromText(wkt [, srid [, options]])

Constructs a Polygon value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

14.16.4 Functions That Create Geometry Values from WKB Values

These functions take as arguments a BLOB containing a Well-Known Binary (WKB) representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry. For a description of WKB format, see Well-Known Binary (WKB) Format.

Functions in this section detect arguments in either Cartesian or geographic spatial reference systems (SRSs), and return results appropriate to the SRS.

ST_GeomFromWKB() accepts a WKB value of any geometry type as its first argument. Other functions provide type-specific construction functions for construction of geometry values of each geometry type.

Prior to MySQL 8.4, these functions also accepted geometry objects as returned by the functions in Section 14.16.5, “MySQL-Specific Functions That Create Geometry Values”. Geometry arguments are no longer permitted and produce an error. To migrate calls from using geometry arguments to using WKB arguments, follow these guidelines:

• Rewrite constructs such as ST_GeomFromWKB(Point(0, 0)) as Point(0, 0).

• Rewrite constructs such as ST_GeomFromWKB(Point(0, 0), 4326) as ST_SRID(Point(0, 0), 4326) or ST_GeomFromWKB(ST_AsWKB(Point(0, 0)), 4326).

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

• If the WKB or SRID argument is NULL, the return value is NULL.

• By default, geographic coordinates (latitude, longitude) are interpreted as in the order specified by the spatial reference system of geometry arguments. An optional options argument may be given to override the default axis order. options consists of a list of comma-separated key=value.
The only permitted key value is axis-order, with permitted values of lat-long, long-lat and srid-defined (the default).

If the options argument is NULL, the return value is NULL. If the options argument is invalid, an error occurs to indicate why.

• If an SRID argument refers to an undefined spatial reference system (SRS), an ER_SRS_NOT_FOUND error occurs.

• For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:
  • If a longitude value is not in the range (−180, 180], an ER_LLITUDE_OUT_OF_RANGE error occurs.
  • If a latitude value is not in the range [−90, 90], an ER_LATITUDE_OUT_OF_RANGE error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

These functions are available for creating geometries from WKB values:

• ST_GeomCollFromWKB(wkb [, srid [, options]]),
  ST_GeometryCollectionFromWKB(wkb [, srid [, options]])

  Constructs a GeometryCollection value using its WKB representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

• ST_GeomFromWKB(wkb [, srid [, options]]), ST_GeometryFromWKB(wkb [, srid [, options]])

  Constructs a geometry value of any type using its WKB representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

• ST_LineFromWKB(wkb [, srid [, options]]), ST_LineStringFromWKB(wkb [, srid [, options]])

  Constructs a LineString value using its WKB representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

• ST_MLineFromWKB(wkb [, srid [, options]]), ST_MultiLineStringFromWKB(wkb [, srid [, options]])

  Constructs a MultiLineString value using its WKB representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

• ST_MPointFromWKB(wkb [, srid [, options]]), ST_MultiPointFromWKB(wkb [, srid [, options]])

  Constructs a MultiPoint value using its WKB representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

• ST_MPolyFromWKB(wkb [, srid [, options]]), ST_MultiPolygonFromWKB(wkb [, srid [, options]])

  Constructs a MultiPolygon value using its WKB representation and SRID.

  These functions handle their arguments as described in the introduction to this section.
MySQL-Specific Functions That Create Geometry Values

- **ST_PointFromWKB(wkb [, srid [, options]]))**

  Constructs a **Point** value using its WKB representation and SRID.

  **ST_PointFromWKB()** handles its arguments as described in the introduction to this section.

- **ST_PolyFromWKB(wkb [, srid [, options]]), ST_PolygonFromWKB(wkb [, srid [, options]])**

  Constructs a **Polygon** value using its WKB representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

### 14.16.5 MySQL-Specific Functions That Create Geometry Values

MySQL provides a set of useful nonstandard functions for creating geometry values. The functions described in this section are MySQL extensions to the OpenGIS specification.

These functions produce geometry objects from either WKB values or geometry objects as arguments. If any argument is not a proper WKB or geometry representation of the proper object type, the return value is **NULL**.

For example, you can insert the geometry return value from **Point()** directly into a **POINT** column:

```
INSERT INTO t1 (pt_col) VALUES(Point(1,2));
```

- **GeomCollection(g [, g] ...)**

  Constructs a **GeomCollection** value from the geometry arguments.

  **GeomCollection()** returns all the proper geometries contained in the arguments even if a nonsupported geometry is present.

  **GeomCollection()** with no arguments is permitted as a way to create an empty geometry.

  Also, functions such as **ST_GeomFromText()** that accept WKT geometry collection arguments understand both OpenGIS 'GEOMETRYCOLLECTION EMPTY' standard syntax and MySQL 'GEOMETRYCOLLECTION()' nonstandard syntax.

  **GeomCollection()** and **GeometryCollection()** are synonymous, with **GeomCollection()** the preferred function.

- **GeometryCollection(g [, g] ...)**

  Constructs a **GeomCollection** value from the geometry arguments.

  **GeometryCollection()** returns all the proper geometries contained in the arguments even if a nonsupported geometry is present.

  **GeometryCollection()** with no arguments is permitted as a way to create an empty geometry.

  Also, functions such as **ST_GeomFromText()** that accept WKT geometry collection arguments understand both OpenGIS 'GEOMETRYCOLLECTION EMPTY' standard syntax and MySQL 'GEOMETRYCOLLECTION()' nonstandard syntax.

  **GeomCollection()** and **GeometryCollection()** are synonymous, with **GeomCollection()** the preferred function.

- **LineString(pt [, pt] ...)**

  Constructs a **LineString** value from a number of **Point** or WKB **Point** arguments. If the number of arguments is less than two, the return value is **NULL**.

- **MultiLineString(ls [, ls] ...)**
Constructs a `MultiLineString` value using `LineString` or WKB `LineString` arguments.

- `MultiPoint(pt [, pt2] ...)`

Constructs a `MultiPoint` value using `Point` or WKB `Point` arguments.

- `MultiPolygon(poly [, poly] ...)`

Constructs a `MultiPolygon` value from a set of `Polygon` or WKB `Polygon` arguments.

- `Point(x, y)`

Constructs a `Point` using its coordinates.

- `Polygon(ls [, ls] ...)`

Constructs a `Polygon` value from a number of `LineString` or WKB `LineString` arguments. If any argument does not represent a `LinearRing` (that is, not a closed and simple `LineString`), the return value is `NULL`.

14.16.6 Geometry Format Conversion Functions

MySQL supports the functions listed in this section for converting geometry values from internal geometry format to WKT or WKB format, or for swapping the order of X and Y coordinates.

There are also functions to convert a string from WKT or WKB format to internal geometry format. See Section 14.16.3, "Functions That Create Geometry Values from WKT Values", and Section 14.16.4, "Functions That Create Geometry Values from WKB Values".

Functions such as `ST_GeomFromText()` that accept WKT geometry collection arguments understand both OpenGIS 'GEOMETRYCOLLECTION EMPTY' standard syntax and MySQL 'GEOMETRYCOLLECTION()' nonstandard syntax. Another way to produce an empty geometry collection is by calling `GeometryCollection()` with no arguments. Functions such as `ST_AsWKT()` that produce WKT values produce 'GEOMETRYCOLLECTION EMPTY' standard syntax:

```sql
cREATE TABLE `s1` (a GEOMETRYCOLLECTION);

SELECT a, ST_AsWKT(a), ST_AsWKT(a) AS `ST_AsWKT(a)` FROM `s1`;
```

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is `NULL`, the return value is `NULL`.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If any geometry argument is in an undefined spatial reference system, the axes are output in the order they appear in the geometry and an `ER_WARN_SRS_NOT_FOUND_AXIS_ORDER` warning occurs.
- By default, geographic coordinates (latitude, longitude) are interpreted as in the order specified by the spatial reference system of geometry arguments. An optional `options` argument may be given to override the default axis order. `options` consists of a list of comma-separated `key=value`.
Geometry Format Conversion Functions

The only permitted key value is `axis-order`, with permitted values of `lat-long`, `long-lat` and `srid-defined` (the default).

If the `options` argument is `NULL`, the return value is `NULL`. If the `options` argument is invalid, an error occurs to indicate why.

- Otherwise, the return value is non-`NULL`.

These functions are available for format conversions or coordinate swapping:

- `ST_AsBinary(g [, options])`, `ST_AsWKB(g [, options])`

  Converts a value in internal geometry format to its WKB representation and returns the binary result.

  The function return value has geographic coordinates (latitude, longitude) in the order specified by the spatial reference system that applies to the geometry argument. An optional `options` argument may be given to override the default axis order.

  `ST_AsBinary()` and `ST_AsWKB()` handle their arguments as described in the introduction to this section.

  ```
  mysql> SET @g = ST_LineFromText('LINESTRING(0 5,5 10,10 15)', 4326);
  mysql> SELECT ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g)));
  +-----------------------------------------+
  | ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g))) |
  +-----------------------------------------+
  | LINESTRING(5 0,10 5,15 10)              |
  +-----------------------------------------+
  mysql> SELECT ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=long-lat')));
  +----------------------------------------------------------------+
  | ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=long-lat'))) |
  +----------------------------------------------------------------+
  | LINESTRING(0 5,5 10,10 15)                                     |
  +----------------------------------------------------------------+
  mysql> SELECT ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=lat-long')));
  +----------------------------------------------------------------+
  | ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=lat-long'))) |
  +----------------------------------------------------------------+
  | LINESTRING(5 0,10 5,15 10)                                     |
  +----------------------------------------------------------------+
  ```

- `ST_AsText(g [, options])`, `ST_AsWKT(g [, options])`

  Converts a value in internal geometry format to its WKT representation and returns the string result.

  The function return value has geographic coordinates (latitude, longitude) in the order specified by the spatial reference system that applies to the geometry argument. An optional `options` argument may be given to override the default axis order.

  `ST_AsText()` and `ST_AsWKT()` handle their arguments as described in the introduction to this section.

  ```
  mysql> SET @g = 'LineString(1 1,2 2,3 3)';
  mysql> SELECT ST_AsText(ST_GeomFromText(@g));
  +---------------------------------+
  | ST_AsText(ST_GeomFromText(@g)) |
  +---------------------------------+
  | LINESTRING(1 1,2 2,3 3)        |
  +---------------------------------+
  mysql> SELECT ST_AsText(ST_GeomFromText(@g), 'axis-order=long-lat');
  +-------------------------------------------------------------------+
  | ST_AsText(ST_GeomFromText(@g), 'axis-order=long-lat')) |
  +-------------------------------------------------------------------+
  | LINESTRING(1 1,2 2,3 3)               |
  +-------------------------------------------------------------------+
  mysql> SELECT ST_AsText(ST_GeomFromText(@g), 'axis-order=lat-long');
  +-------------------------------------------------------------------+
  | ST_AsText(ST_GeomFromText(@g), 'axis-order=lat-long')) |
  +-------------------------------------------------------------------+
  | LINESTRING(1 1,2 2,3 3)               |
  +-------------------------------------------------------------------+
  ```

Output for `MultiPoint` values includes parentheses around each point. For example:

```
mysql> SELECT ST_AsText(ST_GeomFromText(@mp));
+------------------------------------------+
| ST_AsText(ST_GeomFromText(@mp))          |
+------------------------------------------+
| MULTIPOINT((1 2, 3 4, 5 6))              |
+------------------------------------------+
```
14.16.7 Geometry Property Functions

Each function that belongs to this group takes a geometry value as its argument and returns some quantitative or qualitative property of the geometry. Some functions restrict their argument type. Such functions return NULL if the argument is of an incorrect geometry type. For example, the ST_Area() polygon function returns NULL if the object type is neither Polygon nor MultiPolygon.

14.16.7.1 General Geometry Property Functions

The functions listed in this section do not restrict their argument and accept a geometry value of any type.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is NULL, the return value is NULL.
- If any geometry argument is not a syntactically well-formed geometry, an ER_GIS_INVALID_DATA error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an ER_SRS_NOT_FOUND error occurs.
- If any SRID argument is not within the range of a 32-bit unsigned integer, an ER_DATA_OUT_OF_RANGE error occurs.
- If any SRID argument refers to an undefined SRS, an ER_SRS_NOT_FOUND error occurs.
- Otherwise, the return value is non-NULL.

These functions are available for obtaining geometry properties:

- **ST_Dimension(g)**

  Returns the inherent dimension of the geometry value g. The dimension can be −1, 0, 1, or 2. The meaning of these values is given in Section 13.4.2.2, “Geometry Class”.

  ST_Dimension() handles its arguments as described in the introduction to this section.
### Geometry Property Functions

- **ST_Envelope(g)**

  Returns the minimum bounding rectangle (MBR) for the geometry value \( g \). The result is returned as a `Polygon` value that is defined by the corner points of the bounding box:

  \[
  \text{POLYGON((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))}
  \]

  MySQL>
  ```sql
  SELECT ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,2 2)')));
  +-------------------------------------------------------------------------------------------------+
  | ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,2 2)'))) |
  +-------------------------------------------------------------------------------------------------+
  | POLYGON((1 1,2 1,2 2,1 2,1 1)) |
  +-------------------------------------------------------------------------------------------------+
  ```

  If the argument is a point or a vertical or horizontal line segment, `ST_Envelope()` returns the point or the line segment as its MBR rather than returning an invalid polygon:

  MySQL>
  ```sql
  SELECT ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,1 2)')));
  +-------------------------------------------------------------------------------------------------+
  | ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,1 2)'))) |
  +-------------------------------------------------------------------------------------------------+
  | LINESTRING(1 1,1 2) |
  +-------------------------------------------------------------------------------------------------+
  ```

  `ST_Envelope()` handles its arguments as described in the introduction to this section, with this exception:

  - If the geometry has an SRID value for a geographic spatial reference system (SRS), an `ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS` error occurs.

- **ST_GeometryType(g)**

  Returns a binary string indicating the name of the geometry type of which the geometry instance \( g \) is a member. The name corresponds to one of the instantiable `Geometry` subclasses.

  `ST_GeometryType()` handles its arguments as described in the introduction to this section.

  MySQL>
  ```sql
  SELECT ST_GeometryType(ST_GeomFromText('POINT(1 1)'));
  +-------------------------------------------------+
  | ST_GeometryType(ST_GeomFromText('POINT(1 1)')) |
  +-------------------------------------------------+
  | POINT |
  +-------------------------------------------------+
  ```

- **ST_IsEmpty(g)**

  This function is a placeholder that returns 1 for an empty geometry collection value or 0 otherwise. The only valid empty geometry is represented in the form of an empty geometry collection value. MySQL does not support GIS `EMPTY` values such as `POINT EMPTY`.

  `ST_IsEmpty()` handles its arguments as described in the introduction to this section.

- **ST_IsSimple(g)**

  Returns 1 if the geometry value \( g \) is simple according to the ISO SQL/MM Part 3: Spatial standard. `ST_IsSimple()` returns 0 if the argument is not simple.

  The descriptions of the instantiable geometric classes given under Section 13.4.2, “The OpenGIS Geometry Model” include the specific conditions that cause class instances to be classified as not simple.

  `ST_IsSimple()` handles its arguments as described in the introduction to this section, with this exception:
Geometry Property Functions

• If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range \((-180, 180]\), an `ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE` error occurs.
  - If a latitude value is not in the range \([-90, 90]\), an `ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

• `ST_SRID(g [, srid])`

With a single argument representing a valid geometry object `g`, `ST_SRID()` returns an integer indicating the ID of the spatial reference system (SRS) associated with `g`.

With the optional second argument representing a valid SRID value, `ST_SRID()` returns an object with the same type as its first argument with an SRID value equal to the second argument. This only sets the SRID value of the object; it does not perform any transformation of coordinate values.

`ST_SRID()` handles its arguments as described in the introduction to this section, with this exception:

- For the single-argument syntax, `ST_SRID()` returns the geometry SRID even if it refers to an undefined SRS. An `ER_SRS_NOT_FOUND` error does not occur.

`ST_SRID(g, target_srid)` and `ST_Transform(g, target_srid)` differ as follows:

- `ST_SRID()` changes the geometry SRID value without transforming its coordinates.
- `ST_Transform()` transforms the geometry coordinates in addition to changing its SRID value.

```sql
mysql> SET @g = ST_GeomFromText('LineString(1 1,2 2)', 0);
mysql> SELECT ST_SRID(@g);
+------------------+
| ST_SRID(@g)      |
+------------------+
| 0                |
+------------------+
mysql> SET @g = ST_SRID(@g, 4326);
mysql> SELECT ST_SRID(@g);
+------------------+
| ST_SRID(@g)      |
| 4326             |
+------------------+
```

It is possible to create a geometry in a particular SRID by passing to `ST_SRID()` the result of one of the MySQL-specific functions for creating spatial values, along with an SRID value. For example:

```sql
SET @g1 = ST_SRID(Point(1, 1), 4326);
```

However, that method creates the geometry in SRID 0, then casts it to SRID 4326 (WGS 84). A preferable alternative is to create the geometry with the correct spatial reference system to begin with. For example:

```sql
SET @g1 = ST_PointFromText('POINT(1 1)', 4326);
SET @g1 = ST_GeomFromText('POINT(1 1)', 4326);
```

The two-argument form of `ST_SRID()` is useful for tasks such as correcting or changing the SRS of geometries that have an incorrect SRID.
14.16.7.2 Point Property Functions

A Point consists of X and Y coordinates, which may be obtained using the `ST_X()` and `ST_Y()` functions, respectively. These functions also permit an optional second argument that specifies an X or Y coordinate value, in which case the function result is the Point object from the first argument with the appropriate coordinate modified to be equal to the second argument.

For Point objects that have a geographic spatial reference system (SRS), the longitude and latitude may be obtained using the `ST_Longitude()` and `ST_Latitude()` functions, respectively. These functions also permit an optional second argument that specifies a longitude or latitude value, in which case the function result is the Point object from the first argument with the longitude or latitude modified to be equal to the second argument.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is `NULL`, the return value is `NULL`.
- If any geometry argument is a valid geometry but not a Point object, an `ER_UNEXPECTED_GEOMETRY_TYPE` error occurs.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- If an X or Y coordinate argument is provided and the value is `-inf`, `+inf`, or `NaN`, an `ER_DATA_OUT_OF_RANGE` error occurs.
- If a longitude or latitude value is out of range, an error occurs:
  - If a longitude value is not in the range (-180, 180], an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
  - If a latitude value is not in the range [-90, 90], an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

Otherwise, the return value is non-NULL.

These functions are available for obtaining point properties:

- `ST_Latitude(p [, new_latitude_val])`

With a single argument representing a valid Point object `p` that has a geographic spatial reference system (SRS), `ST_Latitude()` returns the latitude value of `p` as a double-precision number.

With the optional second argument representing a valid latitude value, `ST_Latitude()` returns a Point object like the first argument with its latitude equal to the second argument.

`ST_Latitude()` handles its arguments as described in the introduction to this section, with the addition that if the Point object is valid but does not have a geographic SRS, an `ER_SRS_NOT_GEOGRAPHIC` error occurs.

```sql
mysql> SET @pt = ST_GeomFromText('POINT(45 90)', 4326);
mysql> SELECT ST_Latitude(@pt);
+------------------+
| ST_Latitude(@pt) |
+------------------+
|              45   |
+------------------+
mysql> SELECT ST_AsText(ST_Latitude(@pt, 10));
+---------------------------------+
| ST_AsText(ST_Latitude(@pt, 10)) |
+---------------------------------+
2246```
Geometry Property Functions

- **ST_Longitude(p [, new_longitude_val])**

  With a single argument representing a valid Point object `p` that has a geographic spatial reference system (SRS), `ST_Longitude()` returns the longitude value of `p` as a double-precision number.

  With the optional second argument representing a valid longitude value, `ST_Longitude()` returns a Point object like the first argument with its longitude equal to the second argument.

  `ST_Longitude()` handles its arguments as described in the introduction to this section, with the addition that if the Point object is valid but does not have a geographic SRS, an ER_SRS_NOT_GEOGRAPHIC error occurs.

  ```
  mysql> SET @pt = ST_GeomFromText('POINT(45 90)', 4326);
  mysql> SELECT ST_Longitude(@pt);
  +-------------------+
  | ST_Longitude(@pt) |
  +-------------------+
  |      90           |
  +-------------------+
  mysql> SELECT ST_AsText(ST_Longitude(@pt, 10));
  +----------------------------------+
  | ST_AsText(ST_Longitude(@pt, 10)) |
  +----------------------------------+
  | POINT(45 10)                    |
  +----------------------------------+
  ```

- **ST_X(p [, new_x_val])**

  With a single argument representing a valid Point object `p`, `ST_X()` returns the X-coordinate value of `p` as a double-precision number. The X coordinate is considered to refer to the axis that appears first in the Point spatial reference system (SRS) definition.

  With the optional second argument, `ST_X()` returns a Point object like the first argument with its X coordinate equal to the second argument. If the Point object has a geographic SRS, the second argument must be in the proper range for longitude or latitude values.

  `ST_X()` handles its arguments as described in the introduction to this section.

  ```
  mysql> SELECT ST_X(Point(56.7, 53.34));
  +--------------------------+
  | ST_X(Point(56.7, 53.34)) |
  +--------------------------+
  |                     56.7 |
  +--------------------------+
  mysql> SELECT ST_AsText(ST_X(Point(56.7, 53.34), 10.5));
  +-------------------------------------------+
  | ST_AsText(ST_X(Point(56.7, 53.34), 10.5)) |
  +-------------------------------------------+
  | POINT(10.5 53.34)                         |
  +-------------------------------------------+
  ```
• **ST_Y(p [, new_y_val])**

With a single argument representing a valid *Point* object *p*, *ST_Y()* returns the Y-coordinate value of *p* as a double-precision number. The Y coordinate is considered to refer to the axis that appears second in the *Point* spatial reference system (SRS) definition.

With the optional second argument, *ST_Y()* returns a *Point* object like the first argument with its Y coordinate equal to the second argument. If the *Point* object has a geographic SRS, the second argument must be in the proper range for longitude or latitude values.

*ST_Y()* handles its arguments as described in the introduction to this section.

```sql
mysql> SELECT ST_Y(Point(56.7, 53.34));
+--------------------------+
| ST_Y(Point(56.7, 53.34)) |
| 53.34                    |
+--------------------------+
mysql>
```

### 14.16.7.3 LineString and MultiLineString Property Functions

A *LineString* consists of *Point* values. You can extract particular points of a *LineString*, count the number of points that it contains, or obtain its length.

Some functions in this section also work for *MultiLineString* values.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is *NULL* or any geometry argument is an empty geometry, the return value is *NULL*.
- If any geometry argument is not a syntactically well-formed geometry, an ER_GIS_INVALID_DATA error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an ER_SRS_NOT_FOUND error occurs.
- Otherwise, the return value is non-*NULL*.

These functions are available for obtaining linestring properties:

- **ST_EndPoint(ls)**

  Returns the *Point* that is the endpoint of the *LineString* value *ls*.

  *ST_EndPoint()* handles its arguments as described in the introduction to this section.

  ```sql
  mysql> SET @ls = 'LineString(1,2,3)';
  mysql> SELECT ST_AsText(ST_EndPoint(ST_GeomFromText(@ls)));
  +----------------------------------------------+
  | ST_AsText(ST_EndPoint(ST_GeomFromText(@ls))) |
  | POINT(3)                                     |
  +----------------------------------------------+
  ```

- **ST_IsClosed(ls)**

  For a *LineString* value *ls*, *ST_IsClosed()* returns 1 if *ls* is closed (that is, its *ST_StartPoint()* and *ST_EndPoint()* values are the same).

```sql
mysql> SELECT ST_IsClosed(@ls);
+--------------------+
| ST_IsClosed(@ls)   |
| 1                  |
+--------------------+
```
For a `MultiLineString` value `ls`, `ST_IsClosed()` returns 1 if `ls` is closed (that is, the `ST_StartPoint()` and `ST_EndPoint()` values are the same for each `LineString` in `ls`).

`ST_IsClosed()` returns 0 if `ls` is not closed, and `NULL` if `ls` is `NULL`.

`ST_IsClosed()` handles its arguments as described in the introduction to this section, with this exception:

- If the geometry has an SRID value for a geographic spatial reference system (SRS), an `ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS` error occurs.
• \texttt{ST\_Length(ls [, unit])}

Returns a double-precision number indicating the length of the \texttt{LineString} or \texttt{MultiLineString} value \texttt{ls} in its associated spatial reference system. The length of a \texttt{MultiLineString} value is equal to the sum of the lengths of its elements.

\texttt{ST\_Length()} computes a result as follows:

• If the geometry is a valid \texttt{LineString} in a Cartesian SRS, the return value is the Cartesian length of the geometry.

• If the geometry is a valid \texttt{MultiLineString} in a Cartesian SRS, the return value is the sum of the Cartesian lengths of its elements.

• If the geometry is a valid \texttt{LineString} in a geographic SRS, the return value is the geodetic length of the geometry in that SRS, in meters.

• If the geometry is a valid \texttt{MultiLineString} in a geographic SRS, the return value is the sum of the geodetic lengths of its elements in that SRS, in meters.

\texttt{ST\_Length()} handles its arguments as described in the introduction to this section, with these exceptions:

• If the geometry is not a \texttt{LineString} or \texttt{MultiLineString}, the return value is \texttt{NULL}.

• If the geometry is geometrically invalid, either the result is an undefined length (that is, it can be any number), or an error occurs.

• If the length computation result is \texttt{+inf}, an \texttt{ER\_DATA\_OUT\_OF\_RANGE} error occurs.

• If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:

  • If a longitude value is not in the range \((-180, 180]\), an \texttt{ER\_GEOMETRY\_PARAM\_LONGITUDE\_OUT\_OF\_RANGE} error occurs.

  • If a latitude value is not in the range \([-90, 90]\), an \texttt{ER\_GEOMETRY\_PARAM\_LATITUDE\_OUT\_OF\_RANGE} error occurs.

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

\texttt{ST\_Length()} permits an optional \texttt{unit} argument that specifies the linear unit for the returned length value. These rules apply:

• If a unit is specified but not supported by MySQL, an \texttt{ER\_UNIT\_NOT\_FOUND} error occurs.

• If a supported linear unit is specified and the SRID is 0, an \texttt{ER\_GEOMETRY\_IN\_UNKNOWN\_LENGTH\_UNIT} error occurs.

• If a supported linear unit is specified and the SRID is not 0, the result is in that unit.

• If a unit is not specified, the result is in the unit of the SRS of the geometries, whether Cartesian or geographic. Currently, all MySQL SRSs are expressed in meters.

A unit is supported if it is found in the \texttt{INFORMATION\_SCHEMA ST\_UNITS\_OF\_MEASURE} table. See Section 28.3.37, “The \texttt{INFORMATION\_SCHEMA ST\_UNITS\_OF\_MEASURE} Table”.

```sql
mysql> SET @ls = ST\_GeomFromText('LineString(1 1,2 2,3 3)');
mysql> SELECT ST\_Length(@ls);
+--------------------+
| ST\_Length(@ls)     |
+--------------------+
| 2250               |
```
Geometry Property Functions

• \texttt{ST\_NumPoints(ls)}

Returns the number of \texttt{Point} objects in the \texttt{LineString} value \texttt{ls}.

\texttt{ST\_NumPoints()} handles its arguments as described in the introduction to this section.

• \texttt{ST\_PointN(ls, N)}

Returns the \texttt{N}\textsuperscript{-th} \texttt{Point} in the \texttt{LineString} value \texttt{ls}. Points are numbered beginning with 1.

\texttt{ST\_PointN()} handles its arguments as described in the introduction to this section.

• \texttt{ST\_StartPoint(ls)}

Returns the \texttt{Point} that is the start point of the \texttt{LineString} value \texttt{ls}.

\texttt{ST\_StartPoint()} handles its arguments as described in the introduction to this section.
14.16.7.4 Polygon and MultiPolygon Property Functions

Functions in this section return properties of Polygon or MultiPolygon values.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is NULL or any geometry argument is an empty geometry, the return value is NULL.
- If any geometry argument is not a syntactically well-formed geometry, an ER_GIS_INVALID_DATA error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an ER_SRS_NOT_FOUND error occurs.
- For functions that take multiple geometry arguments, if those arguments are not in the same SRS, an ER_GIS_DIFFERENT_SRIDS error occurs.
- Otherwise, the return value is non-NULL.

These functions are available for obtaining polygon properties:

- **ST_Area({poly|mpoly})**
  Returns a double-precision number indicating the area of the Polygon or MultiPolygon argument, as measured in its spatial reference system.

  **ST_Area()** handles its arguments as described in the introduction to this section, with these exceptions:

  - If the geometry is geometrically invalid, either the result is an undefined area (that is, it can be any number), or an error occurs.
  - If the geometry is valid but is not a Polygon or MultiPolygon object, an ER_UNEXPECTED_GEOMETRY_TYPE error occurs.
  - If the geometry is a valid Polygon in a Cartesian SRS, the result is the Cartesian area of the polygon.
  - If the geometry is a valid MultiPolygon in a Cartesian SRS, the result is the sum of the Cartesian area of the polygons.
  - If the geometry is a valid Polygon in a geographic SRS, the result is the geodetic area of the polygon in that SRS, in square meters.
  - If the geometry is a valid MultiPolygon in a geographic SRS, the result is the sum of geodetic area of the polygons in that SRS, in square meters.
  - If an area computation results in +inf, an ER_DATA_OUT_OF_RANGE error occurs.
  - If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
    - If a longitude value is not in the range (-180, 180], an ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE error occurs.
    - If a latitude value is not in the range [-90, 90], an ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE error occurs.
Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

```sql
mysql> SET @poly = 'Polygon((0 0,0 3,3 0,0 0),(1 1,1 2,2 1,1 1))';
mysql> SELECT ST_Area(ST_GeomFromText(@poly));
+---------------------------------+
| ST_Area(ST_GeomFromText(@poly)) |
| 4                               |
+---------------------------------+

mysql> SET @mpoly = 'MultiPolygon(((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1)))';
mysql> SELECT ST_Area(ST_GeomFromText(@mpoly));
+----------------------------------+
| ST_Area(ST_GeomFromText(@mpoly)) |
| 8                                |
+----------------------------------+
```

- **ST_Centroid**(poly|mpoly)

Returns the mathematical centroid for the Polygon or MultiPolygon argument as a Point. The result is not guaranteed to be on the MultiPolygon.

This function processes geometry collections by computing the centroid point for components of highest dimension in the collection. Such components are extracted and made into a single MultiPolygon, MultiLineString, or MultiPoint for centroid computation.

**ST_Centroid()** handles its arguments as described in the introduction to this section, with these exceptions:

- The return value is NULL for the additional condition that the argument is an empty geometry collection.

- If the geometry has an SRID value for a geographic spatial reference system (SRS), an ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS error occurs.

```sql
mysql> SET @poly = ST_GeomFromText('POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7,5 5))');
mysql> SELECT ST_GeometryType(@poly),ST_AsText(ST_Centroid(@poly));
+------------------------+--------------------------------------------+
| ST_GeometryType(@poly) | ST_AsText(ST_Centroid(@poly))              |
| POLYGON                | POINT(4.958333333333333 4.958333333333333) |
+------------------------+--------------------------------------------+
```

- **ST_ExteriorRing**(poly)

Returns the exterior ring of the Polygon value poly as a LineString.

**ST_ExteriorRing()** handles its arguments as described in the introduction to this section.
Geometry Property Functions

• **ST_InteriorRingN** (poly, N)

Returns the N-th interior ring for the Polygon value poly as a LineString. Rings are numbered beginning with 1.

ST_InteriorRingN() handles its arguments as described in the introduction to this section.

```sql
mysql> SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT ST_AsText(ST_InteriorRingN(ST_GeomFromText(@poly),1));
+-------------------------------------------------------+
| ST_AsText(ST_InteriorRingN(ST_GeomFromText(@poly),1)) |
| LINESTRING(1 1,1 2,2 2,2 1,1 1)                       |
+-------------------------------------------------------+
```

• **ST_NumInteriorRing**, **ST_NumInteriorRings** (poly)

Returns the number of interior rings in the Polygon value poly.

ST_NumInteriorRing() and ST_NumInteriorRings() handle their arguments as described in the introduction to this section.

```sql
mysql> SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT ST_NumInteriorRings(ST_GeomFromText(@poly));
+---------------------------------------------+
| ST_NumInteriorRings(ST_GeomFromText(@poly)) |
|                                           1 |
+---------------------------------------------+
```

14.16.7.5 GeometryCollection Property Functions

These functions return properties of GeometryCollection values.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

• If any argument is NULL or any geometry argument is an empty geometry, the return value is NULL.

• If any geometry argument is not a syntactically well-formed geometry, an ER_GIS_INVALID_DATA error occurs.

• If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an ER_SRS_NOT_FOUND error occurs.

• Otherwise, the return value is non-NULL.

These functions are available for obtaining geometry collection properties:

• **ST_GeometryN** (gc, N)

Returns the N-th geometry in the GeometryCollection value gc. Geometries are numbered beginning with 1.

ST_GeometryN() handles its arguments as described in the introduction to this section.

```sql
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT ST_AsText(ST_GeometryN(ST_GeomFromText(@gc),1));
+-------------------------------------------------+
| ST_AsText(ST_GeometryN(ST_GeomFromText(@gc),1)) |
| POINT(1 1)                                      |
+-------------------------------------------------+
```

• **ST_NumGeometries** (gc)

2254
Spatial Operator Functions

Returns the number of geometries in the `GeometryCollection` value `gc`.

`ST_NumGeometries()` handles its arguments as described in the introduction to this section.

```sql
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT ST_NumGeometries(ST_GeomFromText(@gc));
+----------------------------------------+
| ST_NumGeometries(ST_GeomFromText(@gc)) |
+----------------------------------------+
|                                      2 |
+----------------------------------------+
```

14.16.8 Spatial Operator Functions

OpenGIS proposes a number of functions that can produce geometries. They are designed to implement spatial operators. These functions support all argument type combinations except those that are inapplicable according to the Open Geospatial Consortium specification.

MySQL also implements certain functions that are extensions to OpenGIS, as noted in the function descriptions. In addition, Section 14.16.7, “Geometry Property Functions”, discusses several functions that construct new geometries from existing ones. See that section for descriptions of these functions:

- `ST_Envelope(g)`
- `ST_StartPoint(ls)`
- `ST_EndPoint(ls)`
- `ST_PointN(ls, N)`
- `ST_ExteriorRing(poly)`
- `ST_InteriorRingN(poly, N)`
- `ST_GeometryN(gc, N)`

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is `NULL`, the return value is `NULL`.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- For functions that take multiple geometry arguments, if those arguments are not in the same SRS, an `ER_GIS_DIFFERENT_SRIDS` error occurs.
- If any geometry argument has an SRID value for a geographic SRS and the function does not handle geographic geometries, an `ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS` error occurs.
- For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range (−180, 180], an `ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE` error occurs.
  - If a latitude value is not in the range [−90, 90], an `ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.
Spatial Operator Functions

• Otherwise, the return value is non-NULL.

These spatial operator functions are available:

• `ST_Buffer(g, d [, strategy1 [, strategy2 [, strategy3]]])`

  Returns a geometry that represents all points whose distance from the geometry value `g` is less than or equal to a distance of `d`. The result is in the same SRS as the geometry argument.

  If the geometry argument is empty, `ST_Buffer()` returns an empty geometry.

  If the distance is 0, `ST_Buffer()` returns the geometry argument unchanged:

  ```sql
  mysql> SET @pt = ST_GeomFromText('POINT(0 0)');
  mysql> SELECT ST_AsText(ST_Buffer(@pt, 0));
  +------------------------------+
  | ST_AsText(ST_Buffer(@pt, 0)) |
  +------------------------------+
  | POINT(0 0)                   |
  +------------------------------+
  ```

  If the geometry argument is in a Cartesian SRS:

  • `ST_Buffer()` supports negative distances for `Polygon` and `MultiPolygon` values, and for geometry collections containing `Polygon` or `MultiPolygon` values.

  • If the result is reduced so much that it disappears, the result is an empty geometry.

  • An `ER_WRONG_ARGUMENTS` error occurs for `ST_Buffer()` with a negative distance for `Point`, `MultiPoint`, `LineString`, and `MultiLineString` values, and for geometry collections not containing any `Polygon` or `MultiPolygon` values.

  Point geometries in a geographic SRS are permitted, subject to the following conditions:

  • If the distance is not negative and no strategies are specified, the function returns the geographic buffer of the `Point` in its SRS. The distance argument must be in the SRS distance unit (currently always meters).

  • If the distance is negative or any strategy (except `NULL`) is specified, an `ER_WRONG_ARGUMENTS` error occurs.

  For non-Point geometries, an `ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS` error occurs.

  `ST_Buffer()` permits up to three optional strategy arguments following the distance argument. Strategies influence buffer computation. These arguments are byte string values produced by the `ST_Buffer_Strategy()` function, to be used for point, join, and end strategies:

  • Point strategies apply to `Point` and `MultiPoint` geometries. If no point strategy is specified, the default is `ST_Buffer_Strategy('point_circle', 32)`.

  • Join strategies apply to `LineString`, `MultiLineString`, `Polygon`, and `MultiPolygon` geometries. If no join strategy is specified, the default is `ST_Buffer_Strategy('join_round', 32)`.

  • End strategies apply to `LineString` and `MultiLineString` geometries. If no end strategy is specified, the default is `ST_Buffer_Strategy('end_round', 32)`.

  Up to one strategy of each type may be specified, and they may be given in any order.

  If the buffer strategies are invalid, an `ER_WRONG_ARGUMENTS` error occurs. Strategies are invalid under any of these circumstances:

  • Multiple strategies of a given type (point, join, or end) are specified.
Spatial Operator Functions

- A value that is not a strategy (such as an arbitrary binary string or a number) is passed as a strategy.
- A **Point** strategy is passed and the geometry contains no **Point** or **MultiPoint** values.
- An end or join strategy is passed and the geometry contains no **LineString**, **Polygon**, **MultiLineString** or **MultiPolygon** values.

```sql
mysql> SET @pt = ST_GeomFromText('POINT(0 0)');
mysql> SET @pt_strategy = ST_Buffer_Strategy('point_square');
mysql> SELECT ST_AsText(ST_Buffer(@pt, 2, @pt_strategy));
+--------------------------------------------+
| ST_AsText(ST_Buffer(@pt, 2, @pt_strategy)) |
+--------------------------------------------+
| POLYGON((-2 -2,2 -2,2 2,-2 2,-2 -2))       |
+--------------------------------------------+
```

```sql
mysql> SET @ls = ST_GeomFromText('LINESTRING(0 0,0 5,5 5)');
mysql> SET @end_strategy = ST_Buffer_Strategy('end_flat');
mysql> SELECT ST_AsText(ST_Buffer(@ls, 5, @end_strategy, @join_strategy))
+---------------------------------------------------------------+
| ST_AsText(ST_Buffer(@ls, 5, @end_strategy, @join_strategy))   |
+---------------------------------------------------------------+
| POLYGON((5 5,5 10,0 10,-3.5355339059327373 8.535533905932738, |
| -5 5,-5 0,0 0,5 0,5 5))                                       |
+---------------------------------------------------------------+
```

- **ST_Buffer_Strategy**(strategy [, points_per_circle])

This function returns a strategy byte string for use with **ST_Buffer**() to influence buffer computation.

Information about strategies is available at [Boost.org](http://www.boost.org).

The first argument must be a string indicating a strategy option:

- For point strategies, permitted values are **'point_circle'** and **'point_square'**.
- For join strategies, permitted values are **'join_round'** and **'join_miter'**.
- For end strategies, permitted values are **'end_round'** and **'end_flat'**.

If the first argument is **'point_circle'**, **'join_round'**, **'join_miter'**, or **'end_round'**, the **points_per_circle** argument must be given as a positive numeric value. The maximum **points_per_circle** value is the value of the max_points_in_geometry system variable.

For examples, see the description of **ST_Buffer()**.

**ST_Buffer_Strategy**() handles its arguments as described in the introduction to this section, with these exceptions:

- If any argument is invalid, an **ER_WRONG_ARGUMENTS** error occurs.
- If the first argument is **'point_square'** or **'end_flat'**, the **points_per_circle** argument must not be given or an **ER_WRONG_ARGUMENTS** error occurs.

- **ST_ConvexHull**(g)

Returns a geometry that represents the convex hull of the geometry value **g**.

This function computes a geometry's convex hull by first checking whether its vertex points are colinear. The function returns a linear hull if so, a polygon hull otherwise. This function processes
geometry collections by extracting all vertex points of all components of the collection, creating a `MultiPoint` value from them, and computing its convex hull.

**ST_ConvexHull()** handles its arguments as described in the introduction to this section, with this exception:

- The return value is `NULL` for the additional condition that the argument is an empty geometry collection.

```sql
mysql> SET @g = 'MULTIPOINT(5 0,25 0,15 10,15 25)';
mysql> SELECT ST_AsText(ST_ConvexHull(ST_GeomFromText(@g)));
+-----------------------------------------------+
| ST_AsText(ST_ConvexHull(ST_GeomFromText(@g))) |
+-----------------------------------------------+
| POLYGON((5 0,25 0,15 25,5 0))                 |
+-----------------------------------------------+
```

**ST_Difference(g1, g2)**

Returns a geometry that represents the point set difference of the geometry values `g1` and `g2`. The result is in the same SRS as the geometry arguments.

**ST_Difference()** permits arguments in either a Cartesian or a geographic SRS, and handles its arguments as described in the introduction to this section.

```sql
mysql> SET @g1 = Point(1,1), @g2 = Point(2,2);
mysql> SELECT ST_AsText(ST_Difference(@g1, @g2));
+------------------------------------+
| ST_AsText(ST_Difference(@g1, @g2)) |
+------------------------------------+
| POINT(1 1)                         |
+------------------------------------+
```

**ST_Intersection(g1, g2)**

Returns a geometry that represents the point set intersection of the geometry values `g1` and `g2`. The result is in the same SRS as the geometry arguments.

**ST_Intersection()** permits arguments in either a Cartesian or a geographic SRS, and handles its arguments as described in the introduction to this section.

```sql
mysql> SET @g1 = ST_GeomFromText('LineString(1 1, 3 3)');
mysql> SET @g2 = ST_GeomFromText('LineString(1 3, 3 1)');
mysql> SELECT ST_AsText(ST_Intersection(@g1, @g2));
+--------------------------------------+
| ST_AsText(ST_Intersection(@g1, @g2)) |
+--------------------------------------+
| POINT(2 2)                           |
+--------------------------------------+
```

**ST_LineInterpolatePoint(ls, fractional_distance)**

This function takes a `LineString` geometry and a fractional distance in the range [0.0, 1.0] and returns the `Point` along the `LineString` at the given fraction of the distance from its start point to
its endpoint. It can be used to answer questions such as which Point lies halfway along the road described by the geometry argument.

The function is implemented for LineString geometries in all spatial reference systems, both Cartesian and geographic.

If the fractional_distance argument is 1.0, the result may not be exactly the last point of the LineString argument but a point close to it due to numerical inaccuracies in approximate-value computations.

A related function, ST_LineInterpolatePoints(), takes similar arguments but returns a MultiPoint consisting of Point values along the LineString at each fraction of the distance from its start point to its endpoint. For examples of both functions, see the ST_LineInterpolatePoints() description.

ST_LineInterpolatePoint() handles its arguments as described in the introduction to this section, with these exceptions:

• If the geometry argument is not a LineString, an ER_UNEXPECTED_GEOMETRY_TYPE error occurs.

• If the fractional distance argument is outside the range [0.0, 1.0], an ER_DATA_OUT_OF_RANGE error occurs.

ST_LineInterpolatePoint() is a MySQL extension to OpenGIS.

• ST_LineInterpolatePoints(ls, fractional_distance)

This function takes a LineString geometry and a fractional distance in the range (0.0, 1.0] and returns the MultiPoint consisting of the LineString start point, plus Point values along the LineString at each fraction of the distance from its start point to its endpoint. It can be used to answer questions such as which Point values lie every 10% of the way along the road described by the geometry argument.

The function is implemented for LineString geometries in all spatial reference systems, both Cartesian and geographic.

If the fractional_distance argument divides 1.0 with zero remainder the result may not contain the last point of the LineString argument but a point close to it due to numerical inaccuracies in approximate-value computations.

A related function, ST_LineInterpolatePoint(), takes similar arguments but returns the Point along the LineString at the given fraction of the distance from its start point to its endpoint.

ST_LineInterpolatePoints() handles its arguments as described in the introduction to this section, with these exceptions:

• If the geometry argument is not a LineString, an ER_UNEXPECTED_GEOMETRY_TYPE error occurs.

• If the fractional distance argument is outside the range [0.0, 1.0], an ER_DATA_OUT_OF_RANGE error occurs.

```sql
mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0,0 5,5 5)');
mysql> SELECT ST_AsText(ST_LineInterpolatePoint(@ls1, .5));
+----------------------------------------------+
<p>| ST_AsText(ST_LineInterpolatePoint(@ls1, .5)) |</p>
<table>
<thead>
<tr>
<th>POINT(0 5)</th>
</tr>
</thead>
</table>
mysql> SELECT ST_AsText(ST_LineInterpolatePoint(@ls1, .75));
+-----------------------------------------------+
| ST_AsText(ST_LineInterpolatePoint(@ls1, .75)) |
+-----------------------------------------------+
```
Spatial Operator Functions

**ST_LineInterpolatePoints()** is a MySQL extension to OpenGIS.

- **ST_PointAtDistance(ls, distance)**

This function takes a LineString geometry and a distance in the range \([0.0, \text{ST\_Length}(ls)]\) measured in the unit of the spatial reference system (SRS) of the LineString, and returns the Point along the LineString at that distance from its start point. It can be used to answer questions such as which Point value is 400 meters from the start of the road described by the geometry argument.

The function is implemented for LineString geometries in all spatial reference systems, both Cartesian and geographic.

**ST_PointAtDistance()** handles its arguments as described in the introduction to this section, with these exceptions:

- If the geometry argument is not a LineString, an ER_UNEXPECTED_GEOMETRY_TYPE error occurs.

- If the fractional distance argument is outside the range \([0.0, \text{ST\_Length}(ls)]\), an ER_DATA_OUT_OF_RANGE error occurs.

**ST_SymDifference()** is a MySQL extension to OpenGIS.

- **ST_SymDifference(g1, g2)**

Returns a geometry that represents the point set symmetric difference of the geometry values \(g1\) and \(g2\), which is defined as:

\[
g1 \text{ symdifference } g2 := (g1 \text{ union } g2) \text{ difference } (g1 \text{ intersection } g2)
\]

Or, in function call notation:

\[\text{ST\_SymDifference}(g1, g2) = \text{ST\_Difference}(\text{ST\_Union}(g1, g2), \text{ST\_Intersection}(g1, g2))\]

The result is in the same SRS as the geometry arguments.

**ST_SymDifference()** permits arguments in either a Cartesian or a geographic SRS, and handles its arguments as described in the introduction to this section.

- **ST_Transform(g, target_srid)**
Spatial Operator Functions

Transforms a geometry from one spatial reference system (SRS) to another. The return value is a geometry of the same type as the input geometry with all coordinates transformed to the target SRID, `target_srid`. MySQL supports all SRSs defined by EPSG except for those listed here:

- EPSG 1042 Krovak Modified
- EPSG 1043 Krovak Modified (North Orientated)
- EPSG 9816 Tunisia Mining Grid
- EPSG 9826 Lambert Conic Conformal (West Orientated)

`ST_Transform()` handles its arguments as described in the introduction to this section, with these exceptions:

- Geometry arguments that have an SRID value for a geographic SRS do not produce an error.
- If the geometry or target SRID argument has an SRID value that refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- If the geometry is in an SRS that `ST_Transform()` cannot transform from, an `ER_TRANSFORM_SOURCE_SRS_NOT_SUPPORTED` error occurs.
- If the target SRID is in an SRS that `ST_Transform()` cannot transform to, an `ER_TRANSFORM_TARGET_SRS_NOT_SUPPORTED` error occurs.
- If the geometry is in an SRS that is not WGS 84 and has no TOWGS84 clause, an `ER_TRANSFORM_SOURCE_SRS_MISSING_TOWGS84` error occurs.
- If the target SRID is in an SRS that is not WGS 84 and has no TOWGS84 clause, an `ER_TRANSFORM_TARGET_SRS_MISSING_TOWGS84` error occurs.

`ST_SRID(g, target_srid)` and `ST_Transform(g, target_srid)` differ as follows:

- `ST_SRID()` changes the geometry SRID value without transforming its coordinates.
- `ST_Transform()` transforms the geometry coordinates in addition to changing its SRID value.

```
mysql> SET @p = ST_GeomFromText('POINT(52.381389 13.064444)', 4326);
mysql> SELECT ST_AsText(@p);
+----------------------------+
| ST_AsText(@p)              |
+----------------------------+
| POINT(52.381389 13.064444) |
+----------------------------+
mysql> SET @p = ST_Transform(@p, 4230);
mysql> SELECT ST_AsText(@p);
+---------------------------------------------+
| ST_AsText(@p)                               |
+---------------------------------------------+
| POINT(52.38208611407426 13.065520672345304) |
+---------------------------------------------+
```

- `ST_Union(g1, g2)`

Returns a geometry that represents the point set union of the geometry values $g1$ and $g2$. The result is in the same SRS as the geometry arguments.

`ST_Union()` permits arguments in either a Cartesian or a geographic SRS, and handles its arguments as described in the introduction to this section.

```
mysql> SET @g1 = ST_GeomFromText('LINESTRING(1 1, 3 3)');
mysql> SET @g2 = ST_GeomFromText('LINESTRING(1 3, 3 1)');
mysql> SELECT ST_AsText(ST_Union(@g1, @g2));
```
14.16.9 Functions That Test Spatial Relations Between Geometry Objects

The functions described in this section take two geometries as arguments and return a qualitative or quantitative relation between them.

MySQL implements two sets of functions using function names defined by the OpenGIS specification. One set tests the relationship between two geometry values using precise object shapes, the other set uses object minimum bounding rectangles (MBRs).

14.16.9.1 Spatial Relation Functions That Use Object Shapes

The OpenGIS specification defines the following functions to test the relationship between two geometry values \( g1 \) and \( g2 \), using precise object shapes. The return values 1 and 0 indicate true and false, respectively, except that distance functions return distance values.

Functions in this section detect arguments in either Cartesian or geographic spatial reference systems (SRSs), and return results appropriate to the SRS.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is \texttt{NULL} or any geometry argument is an empty geometry, the return value is \texttt{NULL}.
- If any geometry argument is not a syntactically well-formed geometry, an \texttt{ER_GIS_INVALID_DATA} error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an \texttt{ER_SRS_NOT_FOUND} error occurs.
- For functions that take multiple geometry arguments, if those arguments are not in the same SRS, an \texttt{ER_GIS_DIFFERENT_SRIDS} error occurs.
- If any geometry argument is geometrically invalid, either the result is true or false (it is undefined which), or an error occurs.
- For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range \((-180, 180]\), an \texttt{ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE} error occurs.
  - If a latitude value is not in the range \([-90, 90]\), an \texttt{ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE} error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

- Otherwise, the return value is non-\texttt{NULL}.

Some functions in this section permit a unit argument that specifies the length unit for the return value. Unless otherwise specified, functions handle their unit argument as follows:

- A unit is supported if it is found in the \texttt{INFORMATION_SCHEMA.ST_UNITS_OF_MEASURE} table. See Section 28.3.37, "The \texttt{INFORMATION_SCHEMA.ST_UNITS_OF_MEASURE} Table".
- If a unit is specified but not supported by MySQL, an \texttt{ER_UNIT_NOT_FOUND} error occurs.
- If a supported linear unit is specified and the SRID is 0, an \texttt{ER_GEOMETRY_IN_UNKNOWN_LENGTH_UNIT} error occurs.
Functions That Test Spatial Relations Between Geometry Objects

- If a supported linear unit is specified and the SRID is not 0, the result is in that unit.
- If a unit is not specified, the result is in the unit of the SRS of the geometries, whether Cartesian or geographic. Currently, all MySQL SRSs are expressed in meters.

These object-shape functions are available for testing geometry relationships:

- **ST_Contains**(\(g_1, g_2\))

  Returns 1 or 0 to indicate whether \(g_1\) completely contains \(g_2\). This tests the opposite relationship as **ST_Within()**.

  **ST_Contains()** handles its arguments as described in the introduction to this section.

- **ST_Crosses**(\(g_1, g_2\))

  Two geometries spatially cross if their spatial relation has the following properties:
  - Unless \(g_1\) and \(g_2\) are both of dimension 1: \(g_1\) crosses \(g_2\) if the interior of \(g_2\) has points in common with the interior of \(g_1\), but \(g_2\) does not cover the entire interior of \(g_1\).
  - If both \(g_1\) and \(g_2\) are of dimension 1: If the lines cross each other in a finite number of points (that is, no common line segments, only single points in common).

  This function returns 1 or 0 to indicate whether \(g_1\) spatially crosses \(g_2\).

  **ST_Crosses()** handles its arguments as described in the introduction to this section except that the return value is NULL for these additional conditions:
  - \(g_1\) is of dimension 2 (Polygon or MultiPolygon).
  - \(g_2\) is of dimension 1 (Point or MultiPoint).

- **ST_Disjoint**(\(g_1, g_2\))

  Returns 1 or 0 to indicate whether \(g_1\) is spatially disjoint from (does not intersect) \(g_2\).

  **ST_Disjoint()** handles its arguments as described in the introduction to this section.

- **ST_Distance**(\(g_1, g_2\) [, unit])

  Returns the distance between \(g_1\) and \(g_2\), measured in the length unit of the spatial reference system (SRS) of the geometry arguments, or in the unit of the optional unit argument if that is specified.

  This function processes geometry collections by returning the shortest distance among all combinations of the components of the two geometry arguments.

  **ST_Distance()** handles its geometry arguments as described in the introduction to this section, with these exceptions:
  - **ST_Distance()** detects arguments in a geographic (ellipsoidal) spatial reference system and returns the geodetic distance on the ellipsoid. **ST_Distance()** supports distance calculations for geographic SRS arguments of all geometry types.
  - If any argument is geometrically invalid, either the result is an undefined distance (that is, it can be any number), or an error occurs.
  - If an intermediate or final result produces NaN or a negative number, an ER_GIS_INVALID_DATA error occurs.

  **ST_Distance()** permits specifying the linear unit for the returned distance value with an optional unit argument which **ST_Distance()** handles as described in the introduction to this section.
Functions That Test Spatial Relations Between Geometry Objects

```sql
mysql> SET @g1 = ST_GeomFromText('POINT(1 1)');
mysql> SET @g2 = ST_GeomFromText('POINT(2 2)');
mysql> SELECT ST_Distance(@g1, @g2);
+-----------------------+
| ST_Distance(@g1, @g2) |
+-----------------------+
| 1.4142135623730951    |
+-----------------------+

mysql> SET @g1 = ST_GeomFromText('POINT(1 1)', 4326);
mysql> SET @g2 = ST_GeomFromText('POINT(2 2)', 4326);
mysql> SELECT ST_Distance(@g1, @g2);
+-----------------------+
| ST_Distance(@g1, @g2) |
+-----------------------+
| 156874.3859490455     |
+-----------------------+

mysql> SELECT ST_Distance(@g1, @g2, 'metre');
+--------------------------------+
| ST_Distance(@g1, @g2, 'metre') |
+--------------------------------+
| 156874.3859490455              |
+--------------------------------+

mysql> SELECT ST_Distance(@g1, @g2, 'foot');
+-------------------------------+
| ST_Distance(@g1, @g2, 'foot') |
+-------------------------------+
| 514679.7439273146             |
+-------------------------------+
```

For the special case of distance calculations on a sphere, see the `ST_Distance_Sphere()` function.

- **ST_Equals(g1, g2)**

  Returns 1 or 0 to indicate whether `g1` is spatially equal to `g2`.

  `ST_Equals()` handles its arguments as described in the introduction to this section, except that it does not return `NULL` for empty geometry arguments.

```sql
mysql> SET @g1 = Point(1,1), @g2 = Point(2,2);
mysql> SELECT ST_Equals(@g1, @g1), ST_Equals(@g1, @g2);
+---------------------+---------------------+
| ST_Equals(@g1, @g1) | ST_Equals(@g1, @g2) |
+---------------------+---------------------+
|                   1 |                   0 |
+---------------------+---------------------+
```

- **ST_FrechetDistance(g1, g2 [, unit])**

  Returns the discrete Fréchet distance between two geometries, reflecting how similar the geometries are. The result is a double-precision number measured in the length unit of the spatial reference system (SRS) of the geometry arguments, or in the length unit of the `unit` argument if that argument is given.

  This function implements the discrete Fréchet distance, which means it is restricted to distances between the points of the geometries. For example, given two `LineString` arguments, only the points explicitly mentioned in the geometries are considered. Points on the line segments between these points are not considered.

  `ST_FrechetDistance()` handles its geometry arguments as described in the introduction to this section, with these exceptions:

  - The geometries may have a Cartesian or geographic SRS, but only `LineString` values are supported. If the arguments are in the same Cartesian or geographic SRS, but
either is not a LineString, an ER_NOT_IMPLEMENTED_FOR_CARTESIAN_SRS or ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS error occurs, depending on the SRS type.

ST_FrechetDistance() handles its optional unit argument as described in the introduction to this section.

mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0,0 5,5 5)');
mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 1,0 6,3 3,5 6)');
mysql> SELECT ST_FrechetDistance(@ls1, @ls2);
+--------------------------------+
| ST_FrechetDistance(@ls1, @ls2) |
+--------------------------------+
|             2.8284271247461903   |
+--------------------------------+
mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0,0 5,5 5)', 4326);
mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 1,0 6,3 3,5 6)', 4326);
mysql> SELECT ST_FrechetDistance(@ls1, @ls2);
+--------------------------------+
| ST_FrechetDistance(@ls1, @ls2) |
+--------------------------------+
| 313421.1999416798               |
+--------------------------------+
mysql> SELECT ST_FrechetDistance(@ls1, @ls2, 'foot');
+----------------------------------------+
| ST_FrechetDistance(@ls1, @ls2, 'foot') |
+----------------------------------------+
|                     1028284.7767115477   |
+----------------------------------------+

• ST_HausdorffDistance(g1, g2 [, unit])

Returns the discrete Hausdorff distance between two geometries, reflecting how similar the geometries are. The result is a double-precision number measured in the length unit of the spatial reference system (SRS) of the geometry arguments, or in the length unit of the unit argument if that argument is given.

This function implements the discrete Hausdorff distance, which means it is restricted to distances between the points of the geometries. For example, given two LineString arguments, only the points explicitly mentioned in the geometries are considered. Points on the line segments between these points are not considered.

ST_HausdorffDistance() handles its geometry arguments as described in the introduction to this section, with these exceptions:

• If the geometry arguments are in the same Cartesian or geographic SRS, but are not in a supported combination, an ER_NOT_IMPLEMENTED_FOR_CARTESIAN_SRS or ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS error occurs, depending on the SRS type. These combinations are supported:
  • LineString and LineString
  • Point and MultiPoint
  • LineString and MultiLineString
  • MultiPoint and MultiPoint
  • MultiLineString and MultiLineString

ST_HausdorffDistance() handles its optional unit argument as described in the introduction to this section.

mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0,0 5,5 5)');
mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 1,0 6,3 3,5 6)');
Functions That Test Spatial Relations Between Geometry Objects

• **ST_Intersects**(g1, g2)

  Returns 1 or 0 to indicate whether g1 spatially intersects g2.

  ST_Intersects() handles its arguments as described in the introduction to this section.

• **ST_Overlaps**(g1, g2)

  Two geometries spatially overlap if they intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

  This function returns 1 or 0 to indicate whether g1 spatially overlaps g2.

  ST_Overlaps() handles its arguments as described in the introduction to this section except that the return value is NULL for the additional condition that the dimensions of the two geometries are not equal.

• **ST_Touches**(g1, g2)

  Two geometries spatially touch if their interiors do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

  This function returns 1 or 0 to indicate whether g1 spatially touches g2.

  ST_Touches() handles its arguments as described in the introduction to this section except that the return value is NULL for the additional condition that both geometries are of dimension 0 (Point or MultiPoint).

• **ST_Within**(g1, g2)

  Returns 1 or 0 to indicate whether g1 is spatially within g2. This tests the opposite relationship as ST_Contains().

  ST_Within() handles its arguments as described in the introduction to this section.

14.16.9.2 Spatial Relation Functions That Use Minimum Bounding Rectangles

MySQL provides several MySQL-specific functions that test the relationship between minimum bounding rectangles (MBRs) of two geometries g1 and g2. The return values 1 and 0 indicate true and false, respectively.

The bounding box of a point is interpreted as a point that is both boundary and interior.
The bounding box of a straight horizontal or vertical line is interpreted as a line where the interior of the line is also boundary. The endpoints are boundary points.

If any of the parameters are geometry collections, the interior, boundary, and exterior of those parameters are those of the union of all elements in the collection.

Functions in this section detect arguments in either Cartesian or geographic spatial reference systems (SRSs), and return results appropriate to the SRS.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is NULL or an empty geometry, the return value is NULL.
- If any geometry argument is not a syntactically well-formed geometry, an ER_GIS_INVALID_DATA error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an ER_SRS_NOT_FOUND error occurs.
- For functions that take multiple geometry arguments, if those arguments are not in the same SRS, an ER_GIS_DIFFERENT_SRIDS error occurs.
- If any argument is geometrically invalid, either the result is true or false (it is undefined which), or an error occurs.
- For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range \((-180, 180]\), an ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE error occurs.
  - If a latitude value is not in the range \([-90, 90]\), an ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

- Otherwise, the return value is non-NULL.

These MBR functions are available for testing geometry relationships:

- **MBRContains(g1, g2)**

  Returns 1 or 0 to indicate whether the minimum bounding rectangle of \(g1\) contains the minimum bounding rectangle of \(g2\). This tests the opposite relationship as **MBRWithin()**.

  **MBRContains()** handles its arguments as described in the introduction to this section.

  ```
  mysql> SET @g1 = ST_GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
  mysql> SET @g2 = ST_GeomFromText('Point(1 1)');
  mysql> SELECT MBRContains(@g1, @g2), MBRWithin(@g2, @g1);
  +----------------------+--------------------+
  | MBRContains(@g1, @g2) | MBRWithin(@g2, @g1) |
  +----------------------+--------------------+
  |                    1 |                  1 |
  +----------------------+--------------------+
  ```

  - **MBRCoveredBy(g1, g2)**

    Returns 1 or 0 to indicate whether the minimum bounding rectangle of \(g1\) is covered by the minimum bounding rectangle of \(g2\). This tests the opposite relationship as **MBRCovers()**.

    **MBRCoveredBy()** handles its arguments as described in the introduction to this section.
Functions That Test Spatial Relations Between Geometry Objects

```sql
mysql> SET @g1 = ST_GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = ST_GeomFromText('Point(1 1)');
mysql> SELECT MBRCovers(@g1,@g2), MBRCoveredby(@g1,@g2);
+--------------------+-----------------------+
<table>
<thead>
<tr>
<th>MBRCovers(@g1,@g2)</th>
<th>MBRCoveredby(@g1,@g2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>
+--------------------+-----------------------+
mysql> SELECT MBRCovers(@g2,@g1), MBRCoveredby(@g2,@g1);
+--------------------+-----------------------+
<table>
<thead>
<tr>
<th>MBRCovers(@g2,@g1)</th>
<th>MBRCoveredby(@g2,@g1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>
+--------------------+-----------------------+
```

- **MBRCovers** $(g1, g2)$

  Returns 1 or 0 to indicate whether the minimum bounding rectangle of $g1$ covers the minimum bounding rectangle of $g2$. This tests the opposite relationship as `MBRCoveredBy()`. See the description of `MBRCoveredBy()` for examples.

  `MBRCovers()` handles its arguments as described in the introduction to this section.

- **MBRDisjoint** $(g1, g2)$

  Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries $g1$ and $g2$ are disjoint (do not intersect).

  `MBRDisjoint()` handles its arguments as described in the introduction to this section.

- **MBREquals** $(g1, g2)$

  Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries $g1$ and $g2$ are the same.

  `MBREquals()` handles its arguments as described in the introduction to this section, except that it does not return `NULL` for empty geometry arguments.

- **MBRIntersects** $(g1, g2)$

  Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries $g1$ and $g2$ intersect.

  `MBRIntersects()` handles its arguments as described in the introduction to this section.

- **MBROverlaps** $(g1, g2)$

  Two geometries spatially overlap if they intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

  This function returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries $g1$ and $g2$ overlap.

  `MBROverlaps()` handles its arguments as described in the introduction to this section.

- **MBRTouches** $(g1, g2)$

  Two geometries spatially touch if their interiors do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

  This function returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries $g1$ and $g2$ touch.

  `MBRTouches()` handles its arguments as described in the introduction to this section.
• **MBRWithin**\((g_1, g_2)\)

Returns 1 or 0 to indicate whether the minimum bounding rectangle of \(g_1\) is within the minimum bounding rectangle of \(g_2\). This tests the opposite relationship as **MBRContains()**.

**MBRWithin()** handles its arguments as described in the introduction to this section.

```sql
mysql> SET @g1 = ST_GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = ST_GeomFromText('Polygon((0 0,0 5,5 5,5 0,0 0))');
mysql> SELECT MBRWithin(@g1,@g2), MBRWithin(@g2,@g1);
+--------------------+--------------------+
| MBRWithin(@g1,@g2) | MBRWithin(@g2,@g1) |
+--------------------+--------------------+
|                  1 |                  0 |
+--------------------+--------------------+
```

---

14.16.10 Spatial Geohash Functions

Geohash is a system for encoding latitude and longitude coordinates of arbitrary precision into a text string. Geohash values are strings that contain only characters chosen from "0123456789bcdefghjkmnpqrstuvwxyz".

The functions in this section enable manipulation of geohash values, which provides applications the capabilities of importing and exporting geohash data, and of indexing and searching geohash values.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is **NULL**, the return value is **NULL**.
- If any argument is invalid, an error occurs.
- If any argument has a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range \((-180, 180]\), an **ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE** error occurs.
  - If a latitude value is not in the range \([-90, 90]\), an **ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE** error occurs.

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

- If any point argument does not have SRID 0 or 4326, an **ER_SRS_NOT_FOUND** error occurs. **point** argument SRID validity is not checked.
- If any SRID argument refers to an undefined spatial reference system (SRS), an **ER_SRS_NOT_FOUND** error occurs.
- If any SRID argument is not within the range of a 32-bit unsigned integer, an **ER_DATA_OUT_OF_RANGE** error occurs.
- Otherwise, the return value is non-**NULL**.

These geohash functions are available:

- **ST_GeoHash**(longitude, latitude, max_length), **ST_GeoHash**(point, max_length)

Returns a geohash string in the connection character set and collation.

For the first syntax, the **longitude** must be a number in the range \([-180, 180]\), and the **latitude** must be a number in the range \([-90, 90]\). For the second syntax, a **POINT** value is required, where the X and Y coordinates are in the valid ranges for longitude and latitude, respectively.

The resulting string is no longer than **max_length** characters, which has an upper limit of 100. The string might be shorter than **max_length** characters because the algorithm that creates the
Spatial Geohash Functions

gearthash value continues until it has created a string that is either an exact representation of the location or max_length characters, whichever comes first.

ST_GeHash() handles its arguments as described in the introduction to this section.

\[ \text{SELECT ST_GeHash}(180, 0, 10), \text{ST_GeHash}(-180, -90, 15); \]
\[
+----------------------+-------------------------+
| ST_GeHash(180, 0, 10) | ST_GeHash(-180, -90, 15) |
+----------------------+-------------------------+
| xbpbpbpb           | 000000000000000         |
+----------------------+-------------------------+

• ST_LatFromGeoHash(geohash_str)

Returns the latitude from a geohash string value, as a double-precision number in the range \([-90, 90]\).

The ST_LatFromGeoHash() decoding function reads no more than 433 characters from the geohash_str argument. That represents the upper limit on information in the internal representation of coordinate values. Characters past the 433rd are ignored, even if they are otherwise illegal and produce an error.

ST_LatFromGeoHash() handles its arguments as described in the introduction to this section.

\[ \text{SELECT ST_LatFromGeoHash(ST_GeHash(45, -20, 10));} \]
\[
+------------------------------------------+
| ST_LatFromGeoHash(ST_GeHash(45, -20, 10)) |
+------------------------------------------+
|                                      -20 |
+------------------------------------------+

• ST_LongFromGeoHash(geohash_str)

Returns the longitude from a geohash string value, as a double-precision number in the range \([-180, 180]\).

The remarks in the description of ST_LatFromGeoHash() regarding the maximum number of characters processed from the geohash_str argument also apply to ST_LongFromGeoHash().

ST_LongFromGeoHash() handles its arguments as described in the introduction to this section.

\[ \text{SELECT ST_LongFromGeoHash(ST_GeHash(45, -20, 10));}\]
\[
+-------------------------------------------+
| ST_LongFromGeoHash(ST_GeHash(45, -20, 10)) |
+-------------------------------------------+
|                                        45 |
+-------------------------------------------+

• ST_PointFromGeoHash(geohash_str, srid)

Returns a POINT value containing the decoded geohash value, given a geohash string value.

The X and Y coordinates of the point are the longitude in the range \([-180, 180]\) and the latitude in the range \([-90, 90]\), respectively.

The srid argument is an 32-bit unsigned integer.

The remarks in the description of ST_LatFromGeoHash() regarding the maximum number of characters processed from the geohash_str argument also apply to ST_PointFromGeoHash().

ST_PointFromGeoHash() handles its arguments as described in the introduction to this section.

\[ \text{SELECT ST_AsText(ST_PointFromGeoHash(@gh, 0));}\]
\[
+---------------------------------------+
| ST_AsText(ST_PointFromGeoHash(@gh, 0)) |

| POINT(45 -20)
|
+---------------------------------------+

14.16.11 Spatial GeoJSON Functions
This section describes functions for converting between GeoJSON documents and spatial values.
GeoJSON is an open standard for encoding geometric/geographical features. For more information,
see http://geojson.org. The functions discussed here follow GeoJSON specification revision 1.0.
GeoJSON supports the same geometric/geographic data types that MySQL supports. Feature and
FeatureCollection objects are not supported, except that geometry objects are extracted from them.
CRS support is limited to values that identify an SRID.
MySQL also supports a native JSON data type and a set of SQL functions to enable operations on
JSON values. For more information, see Section 13.5, “The JSON Data Type”, and Section 14.17,
“JSON Functions”.
• ST_AsGeoJSON(g [, max_dec_digits [, options]])
Generates a GeoJSON object from the geometry g. The object string has the connection character
set and collation.
If any argument is NULL, the return value is NULL. If any non-NULL argument is invalid, an error
occurs.
max_dec_digits, if specified, limits the number of decimal digits for coordinates and causes
32
rounding of output. If not specified, this argument defaults to its maximum value of 2 − 1. The
minimum is 0.
options, if specified, is a bitmask. The following table shows the permitted flag values. If the
geometry argument has an SRID of 0, no CRS object is produced even for those flag values that
request one.

Flag Value

Meaning

0

No options. This is the default if options is not
specified.

1

Add a bounding box to the output.

2

Add a short-format CRS URN to the output. The
default format is a short format (EPSG:srid).

4

Add a long-format CRS URN
(urn:ogc:def:crs:EPSG::srid). This flag
overrides flag 2. For example, option values of 5
and 7 mean the same (add a bounding box and a
long-format CRS URN).

mysql> SELECT ST_AsGeoJSON(ST_GeomFromText('POINT(11.11111 12.22222)'),2);
+-------------------------------------------------------------+
| ST_AsGeoJSON(ST_GeomFromText('POINT(11.11111 12.22222)'),2) |
+-------------------------------------------------------------+
| {"type": "Point", "coordinates": [11.11, 12.22]}
|
+-------------------------------------------------------------+

• ST_GeomFromGeoJSON(str [, options [, srid]])
Parses a string str representing a GeoJSON object and returns a geometry.
If any argument is NULL, the return value is NULL. If any non-NULL argument is invalid, an error
occurs.

2271


Spatial GeoJSON Functions

`options`, if given, describes how to handle GeoJSON documents that contain geometries with coordinate dimensions higher than 2. The following table shows the permitted `options` values.

<table>
<thead>
<tr>
<th>Option Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Reject the document and produce an error. This is the default if <code>options</code> is not specified.</td>
</tr>
<tr>
<td>2, 3, 4</td>
<td>Accept the document and strip off the coordinates for higher coordinate dimensions.</td>
</tr>
</tbody>
</table>

`options` values of 2, 3, and 4 currently produce the same effect. If geometries with coordinate dimensions higher than 2 are supported in the future, you can expect these values to produce different effects.

The `srid` argument, if given, must be a 32-bit unsigned integer. If not given, the geometry return value has an SRID of 4326.

If `srid` refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.

For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:

- If a longitude value is not in the range \((-180, 180]\), an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
- If a latitude value is not in the range \([-90, 90]\), an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

GeoJSON geometry, feature, and feature collection objects may have a `crs` property. The parsing function parses named CRS URNs in the `urn:ogc:def:crs:EPSG::srid` and `EPSG:srid` namespaces, but not CRSs given as link objects. Also, `urn:ogc:def:crs:OGC:1.3:CRS84` is recognized as SRID 4326. If an object has a CRS that is not understood, an error occurs, with the exception that if the optional `srid` argument is given, any CRS is ignored even if it is invalid.

If a `crs` member that specifies an SRID different from the top-level object SRID is found at a lower level of the GeoJSON document, an `ER_INVALID_GEOJSON_CRS_NOT_TOP_LEVEL` error occurs.

As specified in the GeoJSON specification, parsing is case-sensitive for the `type` member of the GeoJSON input (`Point`, `LineString`, and so forth). The specification is silent regarding case sensitivity for other parsing, which in MySQL is not case-sensitive.

This example shows the parsing result for a simple GeoJSON object. Observe that the order of coordinates depends on the SRID used.

```sql
mysql> SET @json = '{ "type": "Point", "coordinates": [102.0, 0.0] }';
mysql> SELECT ST_AsText(ST_GeomFromGeoJSON(@json));
+--------------------------------------+
| ST_AsText(ST_GeomFromGeoJSON(@json)) |
+--------------------------------------+
| POINT(0 102)                          |
+--------------------------------------+
mysql> SELECT ST_SRID(ST_GeomFromGeoJSON(@json));
+------------------------------------+
| ST_SRID(ST_GeomFromGeoJSON(@json))  |
+------------------------------------+
| 4326                                |
+------------------------------------+
mysql> SELECT ST_AsText(ST_SRID(ST_GeomFromGeoJSON(@json), 0));
+-------------------------------------------------+
| 2272                                           |
+-------------------------------------------------+
```
14.16.12 Spatial Aggregate Functions

MySQL supports aggregate functions that perform a calculation on a set of values. For general information about these functions, see Section 14.19.1, “Aggregate Function Descriptions”. This section describes the `ST_Collect()` spatial aggregate function.

`ST_Collect()` can be used as a window function, as signified in its syntax description by `[over_clause]`, representing an optional `OVER` clause. `over_clause` is described in Section 14.20.2, “Window Function Concepts and Syntax”, which also includes other information about window function usage.

- `ST_Collect([DISTINCT] g) [over_clause]`
  Aggregates geometry values and returns a single geometry collection value. With the `DISTINCT` option, returns the aggregation of the distinct geometry arguments.

As with other aggregate functions, `GROUP BY` may be used to group arguments into subsets. `ST_Collect()` returns an aggregate value for each subset.

This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 14.20.2, “Window Function Concepts and Syntax”. In contrast to most aggregate functions that support windowing, `ST_Collect()` permits use of `over_clause` together with `DISTINCT`.

`ST_Collect()` handles its arguments as follows:

- `NULL` arguments are ignored.
- If all arguments are `NULL` or the aggregate result is empty, the return value is `NULL`.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- If there are multiple geometry arguments and those arguments are in the same SRS, the return value is in that SRS. If those arguments are not in the same SRS, an `ER_GIS_DIFFERENT_SRIDS_AGGREGATION` error occurs.
- The result is the narrowest `MultiXxx` or `GeometryCollection` value possible, with the result type determined from the non-`NULL` geometry arguments as follows:
  - If all arguments are `Point` values, the result is a `MultiPoint` value.
  - If all arguments are `LineString` values, the result is a `MultiLineString` value.
  - If all arguments are `Polygon` values, the result is a `MultiPolygon` value.
  - Otherwise, the arguments are a mix of geometry types and the result is a `GeometryCollection` value.

This example data set shows hypothetical products by year and location of manufacture:

```sql
CREATE TABLE product {
    year INTEGER,
    product VARCHAR(256),
    location Geometry
}  
```
Spatial Aggregate Functions

INSERT INTO product
  (year, product, location) VALUES
  (2000, "Calculator", ST_GeomFromText('point(60 -24)',4326)),
  (2000, "Computer" , ST_GeomFromText('point(28 -77)',4326)),
  (2000, "Abacus"    , ST_GeomFromText('point(28 -77)',4326)),
  (2000, "TV"       , ST_GeomFromText('point(38  60)',4326)),
  (2001, "Calculator", ST_GeomFromText('point(60 -24)',4326)),
  (2001, "Computer" , ST_GeomFromText('point(28 -77)',4326));

Some sample queries using `ST_Collect()` on the data set:

```sql
mysql> SELECT ST_AsText(ST_Collect(location)) AS result
            FROM product;
+------------------------------------------------------------------+
| result                                                           |
+------------------------------------------------------------------+
| MULTIPOINT((60 -24),(28 -77),(28 -77),(38 60),(60 -24),(28 -77)) |
+------------------------------------------------------------------+

mysql> SELECT ST_AsText(ST_Collect(DISTINCT location)) AS result
            FROM product;
+---------------------------------------+
| result                                |
+---------------------------------------+
| MULTIPOINT((60 -24),(28 -77),(38 60)) |
+---------------------------------------+

mysql> SELECT year, ST_AsText(ST_Collect(location)) AS result
            FROM product GROUP BY year;
+------+------------------------------------------------+
| year | result                                         |
+------+------------------------------------------------+
| 2000 | MULTIPOINT((60 -24),(28 -77),(28 -77),(38 60)) |
| 2001 | MULTIPOINT((60 -24),(28 -77))                  |
+------+------------------------------------------------+

mysql> SELECT year, ST_AsText(ST_Collect(DISTINCT location)) AS result
            FROM product GROUP BY year;
+------+---------------------------------------+
| year | result                                |
+------+---------------------------------------+
| 2000 | MULTIPOINT((60 -24),(28 -77),(38 60)) |
| 2001 | MULTIPOINT((60 -24),(28 -77))         |
+------+---------------------------------------+

# selects nothing
mysql> SELECT ST_Collect(location) AS result
            FROM product WHERE year = 1999;
+--------+
| result |
+--------+
| NULL   |
+--------+

mysql> SELECT ST_AsText(ST_Collect(location)
            OVER (ORDER BY year, product ROWS BETWEEN 1 PRECEDING AND CURRENT ROW))
            AS result
            FROM product;
+-------------------+
| result            |
+-------------------+
| MULTIPOINT((28 -77)) |
| MULTIPOINT((28 -77),(60 -24)) |
| MULTIPOINT((60 -24),(28 -77)) |
| MULTIPOINT((28 -77),(38 60)) |
| MULTIPOINT((38 60),(60 -24)) |
| MULTIPOINT((60 -24),(28 -77)) |
+-------------------+
14.16.13 Spatial Convenience Functions

The functions in this section provide convenience operations on geometry values.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is **NULL**, the return value is **NULL**.
- If any geometry argument is not a syntactically well-formed geometry, an **ER_GIS_INVALID_DATA** error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an **ER_SRS_NOT_FOUND** error occurs.
- For functions that take multiple geometry arguments, if those arguments are not in the same SRS, an **ER_GIS_DIFFERENT_SRIDS** error occurs.
- Otherwise, the return value is non-**NULL**.

These convenience functions are available:

- `ST_Distance_Sphere(g1, g2 [, radius])`

  Returns the minimum spherical distance between `Point` or `MultiPoint` arguments on a sphere, in meters. (For general-purpose distance calculations, see the `ST_Distance()` function.) The optional `radius` argument should be given in meters.

  If both geometry parameters are valid Cartesian `Point` or `MultiPoint` values in SRID 0, the return value is shortest distance between the two geometries on a sphere with the provided radius. If omitted, the default radius is 6,370,986 meters, Point X and Y coordinates are interpreted as longitude and latitude, respectively, in degrees.

  If both geometry parameters are valid `Point` or `MultiPoint` values in a geographic spatial reference system (SRS), the return value is the shortest distance between the two geometries on a sphere with the provided radius. If omitted, the default radius is equal to the mean radius, defined as (2a+b)/3, where a is the semi-major axis and b is the semi-minor axis of the SRS.

  `ST_Distance_Sphere()` handles its arguments as described in the introduction to this section, with these exceptions:

  - Supported geometry argument combinations are `Point` and `Point`, or `Point` and `MultiPoint` (in any argument order). If at least one of the geometries is neither `Point` nor `MultiPoint`, and its SRID is 0, an **ER_NOT_IMPLEMENTED_FOR_CARTESIAN_SRS** error occurs. If at least one of the geometries is neither `Point` nor `MultiPoint`, and its SRID refers to a geographic SRS, an **ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS** error occurs. If any geometry refers to a projected SRS, an **ER_NOT_IMPLEMENTED_FOR_PROJECTED_SRS** error occurs.

  - If any argument has a longitude or latitude that is out of range, an error occurs:
    - If a longitude value is not in the range [−180, 180], an **ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE** error occurs.
    - If a latitude value is not in the range [−90, 90], an **ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE** error occurs.

  Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

  - If the `radius` argument is present but not positive, an **ER_NONPOSITIVE_RADIUS** error occurs.
  - If the distance exceeds the range of a double-precision number, an **ER_STD_OVERFLOW_ERROR** error occurs.
Spatial Convenience Functions

MySQL> SET @pt1 = ST_GeomFromText('POINT(0 0)');
MySQL> SET @pt2 = ST_GeomFromText('POINT(180 0)');
MySQL> SELECT ST_Distance_Sphere(@pt1, @pt2);
+--------------------------------+
| ST_Distance_Sphere(@pt1, @pt2) |
| 20015042.813723423             |
+--------------------------------+

• **ST_IsValid(g)**

Returns 1 if the argument is geometrically valid, 0 if the argument is not geometrically valid. Geometry validity is defined by the OGC specification.

The only valid empty geometry is represented in the form of an empty geometry collection value. **ST_IsValid()** returns 1 in this case. MySQL does not support GIS EMPTY values such as POINT EMPTY.

**ST_IsValid()** handles its arguments as described in the introduction to this section, with this exception:

• If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
  • If a longitude value is not in the range \((-180, 180]\), an **ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE** error occurs.
  • If a latitude value is not in the range \([-90, 90]\), an **ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE** error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.
Spatial Convenience Functions

• **ST_MakeEnvelope**(pt1, pt2)

  Returns the rectangle that forms the envelope around two points, as a Point, LineString, or Polygon.

  Calculations are done using the Cartesian coordinate system rather than on a sphere, spheroid, or on earth.

  Given two points pt1 and pt2, ST_MakeEnvelope() creates the result geometry on an abstract plane like this:
  
  • If pt1 and pt2 are equal, the result is the point pt1.
  • Otherwise, if (pt1, pt2) is a vertical or horizontal line segment, the result is the line segment (pt1, pt2).
  • Otherwise, the result is a polygon using pt1 and pt2 as diagonal points.

  The result geometry has an SRID of 0.

  ST_MakeEnvelope() handles its arguments as described in the introduction to this section, with these exceptions:
  
  • If the arguments are not Point values, an ER_WRONG_ARGUMENTS error occurs.
  • An ER_GIS_INVALID_DATA error occurs for the additional condition that any coordinate value of the two points is infinite or NaN.
  • If any geometry has an SRID value for a geographic spatial reference system (SRS), an ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS error occurs.

  ```sql
  mysql> SET @pt1 = ST_GeomFromText('POINT(0 0)');
  mysql> SET @pt2 = ST_GeomFromText('POINT(1 1)');
  mysql> SELECT ST_AsText(ST_MakeEnvelope(@pt1, @pt2));
  +----------------------------------------+
  | ST_AsText(ST_MakeEnvelope(@pt1, @pt2)) |
  +----------------------------------------+
  | POLYGON((0 0,1 0,1 1,0 1,0 0))         |
  +----------------------------------------+
  ```

• **ST_Simplify**(g, max_distance)

  Simplifies a geometry using the Douglas-Peucker algorithm and returns a simplified value of the same type.

  The geometry may be any geometry type, although the Douglas-Peucker algorithm may not actually process every type. A geometry collection is processed by giving its components one by one to the simplification algorithm, and the returned geometries are put into a geometry collection as result.

  The max_distance argument is the distance (in units of the input coordinates) of a vertex to other segments to be removed. Vertices within this distance of the simplified linestring are removed.

  According to Boost.Geometry, geometries might become invalid as a result of the simplification process, and the process might create self-intersections. To check the validity of the result, pass it to ST_IsValid().

  ST_Simplify() handles its arguments as described in the introduction to this section, with this exception:
  
  • If the max_distance argument is not positive, or is NaN, an ER_WRONG_ARGUMENTS error occurs.

  ```sql
  mysql> SET @g = ST_GeomFromText('LINESTRING(0 0,0 1,1 1,1 2,2 2,2 3,3 3)');
  mysql> SELECT ST_AsText(ST_Simplify(@g, 0.5));
  2277
  ```
• **ST.Validate(g)**

Validates a geometry according to the OGC specification. A geometry can be syntactically well-formed (WKB value plus SRID) but geometrically invalid. For example, this polygon is geometrically invalid:

```
POLYGON((0 0, 0 0, 0 0, 0 0, 0 0))
```

**ST.Validate()** returns the geometry if it is syntactically well-formed and is geometrically valid, **NULL** if the argument is not syntactically well-formed or is not geometrically valid or is **NULL**.

**ST.Validate()** can be used to filter out invalid geometry data, although at a cost. For applications that require more precise results not tainted by invalid data, this penalty may be worthwhile.

If the geometry argument is valid, it is returned as is, except that if an input **Polygon** or **MultiPolygon** has clockwise rings, those rings are reversed before checking for validity. If the geometry is valid, the value with the reversed rings is returned.

The only valid empty geometry is represented in the form of an empty geometry collection value. **ST.Validate()** returns it directly without further checks in this case.

**ST.Validate()** handles its arguments as described in the introduction to this section, with the exceptions listed here:

• If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:

  • If a longitude value is not in the range \((-180, 180]\), an **ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE** error occurs.
  
  • If a latitude value is not in the range \([-90, 90]\), an **ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE** error occurs.

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.
The functions described in this section perform operations on JSON values. For discussion of the JSON data type and additional examples showing how to use these functions, see Section 13.5, “The JSON Data Type”.

For functions that take a JSON argument, an error occurs if the argument is not a valid JSON value. Arguments parsed as JSON are indicated by `json_doc`; arguments indicated by `val` are not parsed.

Functions that return JSON values always perform normalization of these values (see Normalization, Merging, and Autowrapping of JSON Values), and thus orders them. The precise outcome of the sort is subject to change at any time; do not rely on it to be consistent between releases.

A set of spatial functions for operating on GeoJSON values is also available. See Section 14.16.11, “Spatial GeoJSON Functions”.

### 14.17.1 JSON Function Reference

#### Table 14.22 JSON Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Deprecated</th>

MySQL supports two aggregate JSON functions JSON_ARRAYAGG() and JSON_OBJECTAGG(). See Section 14.19, "Aggregate Functions", for descriptions of these.
Functions That Create JSON Values

MySQL also supports “pretty-printing” of JSON values in an easy-to-read format, using the
JSON_PRETTY() function. You can see how much storage space a given JSON value takes
up, and how much space remains for additional storage, using JSON_STORAGE_SIZE() and
JSON_STORAGE_FREE(), respectively. For complete descriptions of these functions, see
Section 14.17.8, “JSON Utility Functions”.

14.17.2 Functions That Create JSON Values
The functions listed in this section compose JSON values from component elements.
• JSON_ARRAY([val[, val] ...])
Evaluates a (possibly empty) list of values and returns a JSON array containing those values.
mysql> SELECT JSON_ARRAY(1, "abc", NULL, TRUE, CURTIME());
+---------------------------------------------+
| JSON_ARRAY(1, "abc", NULL, TRUE, CURTIME()) |
+---------------------------------------------+
| [1, "abc", null, true, "11:30:24.000000"]
|
+---------------------------------------------+

• JSON_OBJECT([key, val[, key, val] ...])
Evaluates a (possibly empty) list of key-value pairs and returns a JSON object containing those
pairs. An error occurs if any key name is NULL or the number of arguments is odd.
mysql> SELECT JSON_OBJECT('id', 87, 'name', 'carrot');
+-----------------------------------------+
| JSON_OBJECT('id', 87, 'name', 'carrot') |
+-----------------------------------------+
| {"id": 87, "name": "carrot"}
|
+-----------------------------------------+

• JSON_QUOTE(string)
Quotes a string as a JSON value by wrapping it with double quote characters and escaping interior
quote and other characters, then returning the result as a utf8mb4 string. Returns NULL if the
argument is NULL.
This function is typically used to produce a valid JSON string literal for inclusion within a JSON
document.
Certain special characters are escaped with backslashes per the escape sequences shown in
Table 14.23, “JSON_UNQUOTE() Special Character Escape Sequences”.
mysql> SELECT JSON_QUOTE('null'), JSON_QUOTE('"null"');
+--------------------+----------------------+
| JSON_QUOTE('null') | JSON_QUOTE('"null"') |
+--------------------+----------------------+
| "null"
| "\"null\""
|
+--------------------+----------------------+
mysql> SELECT JSON_QUOTE('[1, 2, 3]');
+-------------------------+
| JSON_QUOTE('[1, 2, 3]') |
+-------------------------+
| "[1, 2, 3]"
|
+-------------------------+

You can also obtain JSON values by casting values of other types to the JSON type using
CAST(value AS JSON); see Converting between JSON and non-JSON values, for more information.
Two aggregate functions generating JSON values are available. JSON_ARRAYAGG() returns a result
set as a single JSON array, and JSON_OBJECTAGG() returns a result set as a single JSON object. For
more information, see Section 14.19, “Aggregate Functions”.
2281


14.17.3 Functions That Search JSON Values

The functions in this section perform search or comparison operations on JSON values to extract data from them, report whether data exists at a location within them, or report the path to data within them. The `MEMBER OF ()` operator is also documented herein.

- **JSON_CONTAINS(target, candidate[, path])**

  Indicates by returning 1 or 0 whether a given `candidate` JSON document is contained within a `target` JSON document, or—if a `path` argument was supplied—whether the candidate is found at a specific path within the target. Returns `NULL` if any argument is `NULL`, or if the path argument does not identify a section of the target document. An error occurs if `target` or `candidate` is not a valid JSON document, or if the `path` argument is not a valid path expression or contains a * or ** wildcard.

  To check only whether any data exists at the path, use `JSON_CONTAINS_PATH()` instead.

  The following rules define containment:

  - A candidate scalar is contained in a target scalar if and only if they are comparable and are equal. Two scalar values are comparable if they have the same `JSON_TYPE()` types, with the exception that values of types `INTEGER` and `DECIMAL` are also comparable to each other.

  - A candidate array is contained in a target array if and only if every element in the candidate is contained in some element of the target.

  - A candidate nonarray is contained in a target array if and only if the candidate is contained in some element of the target.

  - A candidate object is contained in a target object if and only if for each key in the candidate there is a key with the same name in the target and the value associated with the candidate key is contained in the value associated with the target key.

  Otherwise, the candidate value is not contained in the target document.

  Queries using `JSON_CONTAINS()` on InnoDB tables can be optimized using multi-valued indexes; see Multi-Valued Indexes, for more information.
Functions That Search JSON Values

- **JSON_CONTAINS_PATH**(json_doc, one_or_all, path[, path] ...)

  Returns 0 or 1 to indicate whether a JSON document contains data at a given path or paths. Returns NULL if any argument is NULL. An error occurs if the json_doc argument is not a valid JSON document, any path argument is not a valid path expression, or one_or_all is not 'one' or 'all'.

  To check for a specific value at a path, use JSON_CONTAINS() instead.

  The return value is 0 if no specified path exists within the document. Otherwise, the return value depends on the one_or_all argument:

  - 'one': 1 if at least one path exists within the document, 0 otherwise.
  - 'all': 1 if all paths exist within the document, 0 otherwise.

- **JSON_EXTRACT**(json_doc, path[, path] ...)

  Returns data from a JSON document, selected from the parts of the document matched by the path arguments. Returns NULL if any argument is NULL or no paths locate a value in the document. An error occurs if the json_doc argument is not a valid JSON document or any path argument is not a valid path expression.

  The return value consists of all values matched by the path arguments. If it is possible that those arguments could return multiple values, the matched values are autowrapped as an array, in the order corresponding to the paths that produced them. Otherwise, the return value is the single matched value.
MySQL supports the `->` operator as shorthand for this function as used with 2 arguments where the left hand side is a JSON column identifier (not an expression) and the right hand side is the JSON path to be matched within the column.

- **column->path**

The `->` operator serves as an alias for the `JSON_EXTRACT()` function when used with two arguments, a column identifier on the left and a JSON path (a string literal) on the right that is evaluated against the JSON document (the column value). You can use such expressions in place of column references wherever they occur in SQL statements.

The two `SELECT` statements shown here produce the same output:

```sql
mysql> SELECT c, JSON_EXTRACT(c, "$.id"), g
    -> FROM jemp
    -> WHERE JSON_EXTRACT(c, "$.id") > 1
    -> ORDER BY JSON_EXTRACT(c, "$.name");
+-------------------------------+-----------+------+
<table>
<thead>
<tr>
<th>c</th>
<th>c-&gt;&quot;$.id&quot;</th>
<th>g</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;id&quot;: &quot;3&quot;, &quot;name&quot;: &quot;Barney&quot;}</td>
<td>&quot;3&quot;</td>
<td>3</td>
</tr>
<tr>
<td>{&quot;id&quot;: &quot;4&quot;, &quot;name&quot;: &quot;Betty&quot;}</td>
<td>&quot;4&quot;</td>
<td>4</td>
</tr>
<tr>
<td>{&quot;id&quot;: &quot;2&quot;, &quot;name&quot;: &quot;Wilma&quot;}</td>
<td>&quot;2&quot;</td>
<td>2</td>
</tr>
</tbody>
</table>
+-------------------------------+-----------+------+
3 rows in set (0.00 sec)
```

```sql
mysql> SELECT c, c->"$.id", g
    -> FROM jemp
    -> WHERE c->"$.id" > 1
    -> ORDER BY c->"$.name";
+-------------------------------+-----------+------+
<table>
<thead>
<tr>
<th>c</th>
<th>c-&gt;&quot;$.id&quot;</th>
<th>g</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;id&quot;: &quot;3&quot;, &quot;name&quot;: &quot;Barney&quot;}</td>
<td>&quot;3&quot;</td>
<td>3</td>
</tr>
<tr>
<td>{&quot;id&quot;: &quot;4&quot;, &quot;name&quot;: &quot;Betty&quot;}</td>
<td>&quot;4&quot;</td>
<td>4</td>
</tr>
<tr>
<td>{&quot;id&quot;: &quot;2&quot;, &quot;name&quot;: &quot;Wilma&quot;}</td>
<td>&quot;2&quot;</td>
<td>2</td>
</tr>
</tbody>
</table>
+-------------------------------+-----------+------+
3 rows in set (0.00 sec)
```

This functionality is not limited to `SELECT`, as shown here:

```sql
mysql> ALTER TABLE jemp ADD COLUMN c INT;
Query OK, 0 rows affected (0.68 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

```sql
mysql> UPDATE jemp SET n=1 WHERE c->"$.id" = "4``;  
Query OK, 1 row affected (0.04 sec)  
Rows matched: 1  Changed: 1  Warnings: 0
```
Functions That Search JSON Values

mysql> DELETE FROM jemp WHERE c->"$.id" = "4";
Query OK, 1 row affected (0.04 sec)

mysql> SELECT c, c->"$.id", g, n 
> FROM jemp 
> WHERE JSON_EXTRACT(c, "$\$.id") > 1 
> ORDER BY c->"$.name";

<table>
<thead>
<tr>
<th>c</th>
<th>c-&gt;&quot;$.id&quot;</th>
<th>g</th>
<th>n</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;id&quot;: &quot;3&quot;, &quot;name&quot;: &quot;Barney&quot;}</td>
<td>&quot;3&quot;</td>
<td>3</td>
<td>NULL</td>
</tr>
<tr>
<td>{&quot;id&quot;: &quot;2&quot;, &quot;name&quot;: &quot;Wilma&quot;}</td>
<td>&quot;2&quot;</td>
<td>2</td>
<td>NULL</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------</td>
<td>------</td>
<td>------</td>
</tr>
</tbody>
</table>
2 rows in set (0.00 sec)

(See Indexing a Generated Column to Provide a JSON Column Index, for the statements used to create and populate the table just shown.)

This also works with JSON array values, as shown here:

mysql> CREATE TABLE tj10 (a JSON, b INT);
Query OK, 0 rows affected (0.26 sec)

mysql> INSERT INTO tj10 
> VALUES ("[3,10,5,17,44]", 33), ("[3,10,5,17,22,44,66]", 0);
Query OK, 1 row affected (0.04 sec)

mysql> SELECT a->"$[4]\[1\]" FROM tj10;
+--------------+
<table>
<thead>
<tr>
<th>a-&gt;&quot;$[4][1]&quot;</th>
</tr>
</thead>
<tbody>
<tr>
<td>44</td>
</tr>
<tr>
<td>[22, 44, 66]</td>
</tr>
</tbody>
</table>
+--------------+
2 rows in set (0.00 sec)

mysql> SELECT a->"$[4]\[1\]" FROM tj10 WHERE a->"$[0]" = 3;
+------------------------------+------+
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>{3, 10, 5, 17, 44}</td>
<td>33</td>
</tr>
<tr>
<td>{3, 10, 5, 17, [22, 44, 66]}</td>
<td>0</td>
</tr>
</tbody>
</table>
+------------------------------+------+
2 rows in set (0.00 sec)

Nested arrays are supported. An expression using -> evaluates as NULL if no matching key is found in the target JSON document, as shown here:

mysql> SELECT * FROM tj10 WHERE a->"$[0]\[1\]" IS NOT NULL;
+------------------------------+------+
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>{3, 10, 5, 17, [22, 44, 66]}</td>
<td>0</td>
</tr>
</tbody>
</table>
+------------------------------+------+
mysql> SELECT a->"$[4]\[1\]" FROM tj10;
+--------------+
| a->"$[4]\[1\]" |
|----------------+
| NULL          |
| 44            |
+--------------+
2 rows in set (0.00 sec)

This is the same behavior as seen in such cases when using JSON_EXTRACT():

mysql> SELECT JSON_EXTRACT(a, "$[4]\[1\]") FROM tj10;
+-----------------------------+
| JSON_EXTRACT(a, "$[4]\[1\]" ) |
+-----------------------------+
Functions That Search JSON Values

| NULL
|
| 44
|
+----------------------------+
2 rows in set (0.00 sec)

• column->>path
This is an improved, unquoting extraction operator. Whereas the -> operator simply extracts a value,
the ->> operator in addition unquotes the extracted result. In other words, given a JSON column
value column and a path expression path (a string literal), the following three expressions return
the same value:
• JSON_UNQUOTE( JSON_EXTRACT(column, path) )
• JSON_UNQUOTE(column -> path)
• column->>path
The ->> operator can be used wherever JSON_UNQUOTE(JSON_EXTRACT()) would be allowed.
This includes (but is not limited to) SELECT lists, WHERE and HAVING clauses, and ORDER BY and
GROUP BY clauses.
The next few statements demonstrate some ->> operator equivalences with other expressions in the
mysql client:
mysql> SELECT * FROM jemp WHERE g > 2;
+-------------------------------+------+
| c
| g
|
+-------------------------------+------+
| {"id": "3", "name": "Barney"} |
3 |
| {"id": "4", "name": "Betty"} |
4 |
+-------------------------------+------+
2 rows in set (0.01 sec)
mysql> SELECT c->'$.name' AS name
->
FROM jemp WHERE g > 2;
+----------+
| name
|
+----------+
| "Barney" |
| "Betty" |
+----------+
2 rows in set (0.00 sec)
mysql> SELECT JSON_UNQUOTE(c->'$.name') AS name
->
FROM jemp WHERE g > 2;
+--------+
| name
|
+--------+
| Barney |
| Betty |
+--------+
2 rows in set (0.00 sec)
mysql> SELECT c->>'$.name' AS name
->
FROM jemp WHERE g > 2;
+--------+
| name
|
+--------+
| Barney |
| Betty |
+--------+

2286


Functions That Search JSON Values

See Indexing a Generated Column to Provide a JSON Column Index, for the SQL statements used to create and populate the jemp table in the set of examples just shown.

This operator can also be used with JSON arrays, as shown here:

```sql
mysql> CREATE TABLE tj10 (a JSON, b INT);
Query OK, 0 rows affected (0.26 sec)

mysql> INSERT INTO tj10 VALUES
    -> ('[3,10,5,"x",44]', 33),
    -> ('[3,10,5,17, [22,"y",66]], 0);
Query OK, 2 rows affected (0.04 sec)
Records: 2  Duplicates: 0  Warnings: 0

mysql> SELECT a->"$[3]", a->"$[4][1]" FROM tj10;
+-----------+--------------+
<table>
<thead>
<tr>
<th>a-&gt;&quot;$[3]&quot;</th>
<th>a-&gt;&quot;$[4][1]&quot;</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;x&quot;</td>
<td>NULL</td>
</tr>
<tr>
<td>17</td>
<td>&quot;y&quot;</td>
</tr>
</tbody>
</table>
+-----------+--------------+
2 rows in set (0.00 sec)

mysql> SELECT a->>>"$[3]", a->>>"$[4][1]" FROM tj10;
+------------+---------------+
<table>
<thead>
<tr>
<th>a-&gt;&gt;&gt;&quot;$[3]&quot;</th>
<th>a-&gt;&gt;&gt;&quot;$[4][1]&quot;</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>NULL</td>
</tr>
<tr>
<td>17</td>
<td>y</td>
</tr>
</tbody>
</table>
+------------+---------------+
2 rows in set (0.00 sec)
```

As with `->`, the `->>` operator is always expanded in the output of `EXPLAIN`, as the following example demonstrates:

```sql
mysql> EXPLAIN SELECT c->>'$.name' AS name
    -> FROM jemp WHERE g > 2\G
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: jemp
partitions: NULL
type: range
possible_keys: i
key: i
key_len: 5
ref: NULL
rows: 2
filtered: 100.00
Extra: Using where
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Note
Code: 1003
Message: /* select#1 */ select
json_unquote(json_extract(`jtest`.`jemp`.`c`,'$.name')) AS `name` from
`jtest`.`jemp` where (`jtest`.`jemp`.`g` > 2)
1 row in set (0.00 sec)
```

This is similar to how MySQL expands the `->` operator in the same circumstances.

- `JSON_KEYS(json_doc[, path])`

  Returns the keys from the top-level value of a JSON object as a JSON array, or, if a `path` argument is given, the top-level keys from the selected path. Returns `NULL` if any argument is `NULL`, the
Functions That Search JSON Values

json_doc argument is not an object, or path, if given, does not locate an object. An error occurs
if the json_doc argument is not a valid JSON document or the path argument is not a valid path
expression or contains a * or ** wildcard.
The result array is empty if the selected object is empty. If the top-level value has nested subobjects,
the return value does not include keys from those subobjects.
mysql> SELECT JSON_KEYS('{"a": 1, "b": {"c": 30}}');
+---------------------------------------+
| JSON_KEYS('{"a": 1, "b": {"c": 30}}') |
+---------------------------------------+
| ["a", "b"]
|
+---------------------------------------+
mysql> SELECT JSON_KEYS('{"a": 1, "b": {"c": 30}}', '$.b');
+----------------------------------------------+
| JSON_KEYS('{"a": 1, "b": {"c": 30}}', '$.b') |
+----------------------------------------------+
| ["c"]
|
+----------------------------------------------+

• JSON_OVERLAPS(json_doc1, json_doc2)
Compares two JSON documents. Returns true (1) if the two document have any key-value pairs or
array elements in common. If both arguments are scalars, the function performs a simple equality
test. If either argument is NULL, the function returns NULL.
This function serves as counterpart to JSON_CONTAINS(), which requires all elements of the array
searched for to be present in the array searched in. Thus, JSON_CONTAINS() performs an AND
operation on search keys, while JSON_OVERLAPS() performs an OR operation.
Queries on JSON columns of InnoDB tables using JSON_OVERLAPS() in the WHERE clause can
be optimized using multi-valued indexes. Multi-Valued Indexes, provides detailed information and
examples.
When comparing two arrays, JSON_OVERLAPS() returns true if they share one or more array
elements in common, and false if they do not:
mysql> SELECT JSON_OVERLAPS("[1,3,5,7]", "[2,5,7]");
+---------------------------------------+
| JSON_OVERLAPS("[1,3,5,7]", "[2,5,7]") |
+---------------------------------------+
|
1 |
+---------------------------------------+
1 row in set (0.00 sec)
mysql> SELECT JSON_OVERLAPS("[1,3,5,7]", "[2,6,7]");
+---------------------------------------+
| JSON_OVERLAPS("[1,3,5,7]", "[2,6,7]") |
+---------------------------------------+
|
1 |
+---------------------------------------+
1 row in set (0.00 sec)
mysql> SELECT JSON_OVERLAPS("[1,3,5,7]", "[2,6,8]");
+---------------------------------------+
| JSON_OVERLAPS("[1,3,5,7]", "[2,6,8]") |
+---------------------------------------+
|
0 |
+---------------------------------------+
1 row in set (0.00 sec)

Partial matches are treated as no match, as shown here:
mysql> SELECT JSON_OVERLAPS('[[1,2],[3,4],5]', '[1,[2,3],[4,5]]');
+-----------------------------------------------------+
| JSON_OVERLAPS('[[1,2],[3,4],5]', '[1,[2,3],[4,5]]') |
+-----------------------------------------------------+
|
0 |

2288


Functions That Search JSON Values

+-----------------------------------------------------+
1 row in set (0.00 sec)

When comparing objects, the result is true if they have at least one key-value pair in common.
mysql> SELECT JSON_OVERLAPS('{"a":1,"b":10,"d":10}', '{"c":1,"e":10,"f":1,"d":10}');
+-----------------------------------------------------------------------+
| JSON_OVERLAPS('{"a":1,"b":10,"d":10}', '{"c":1,"e":10,"f":1,"d":10}') |
+-----------------------------------------------------------------------+
|
1 |
+-----------------------------------------------------------------------+
1 row in set (0.00 sec)
mysql> SELECT JSON_OVERLAPS('{"a":1,"b":10,"d":10}', '{"a":5,"e":10,"f":1,"d":20}');
+-----------------------------------------------------------------------+
| JSON_OVERLAPS('{"a":1,"b":10,"d":10}', '{"a":5,"e":10,"f":1,"d":20}') |
+-----------------------------------------------------------------------+
|
0 |
+-----------------------------------------------------------------------+
1 row in set (0.00 sec)

If two scalars are used as the arguments to the function, JSON_OVERLAPS() performs a simple test
for equality:
mysql> SELECT JSON_OVERLAPS('5', '5');
+-------------------------+
| JSON_OVERLAPS('5', '5') |
+-------------------------+
|
1 |
+-------------------------+
1 row in set (0.00 sec)
mysql> SELECT JSON_OVERLAPS('5', '6');
+-------------------------+
| JSON_OVERLAPS('5', '6') |
+-------------------------+
|
0 |
+-------------------------+
1 row in set (0.00 sec)

When comparing a scalar with an array, JSON_OVERLAPS() attempts to treat the scalar as an array
element. In this example, the second argument 6 is interpreted as [6], as shown here:
mysql> SELECT JSON_OVERLAPS('[4,5,6,7]', '6');
+---------------------------------+
| JSON_OVERLAPS('[4,5,6,7]', '6') |
+---------------------------------+
|
1 |
+---------------------------------+
1 row in set (0.00 sec)

The function does not perform type conversions:
mysql> SELECT JSON_OVERLAPS('[4,5,"6",7]', '6');
+-----------------------------------+
| JSON_OVERLAPS('[4,5,"6",7]', '6') |
+-----------------------------------+
|
0 |
+-----------------------------------+
1 row in set (0.00 sec)
mysql> SELECT JSON_OVERLAPS('[4,5,6,7]', '"6"');
+-----------------------------------+
| JSON_OVERLAPS('[4,5,6,7]', '"6"') |
+-----------------------------------+
|
0 |
+-----------------------------------+
1 row in set (0.00 sec)

2289


Functions That Search JSON Values

- JSON_SEARCH(json_doc, one_or_all, search_str[, escape_char[, path] ...])

Returns the path to the given string within a JSON document. Returns NULL if any of the json_doc, search_str, or path arguments are NULL; no path exists within the document; or search_str is not found. An error occurs if the json_doc argument is not a valid JSON document, any path argument is not a valid path expression, one_or_all is not 'one' or 'all', or escape_char is not a constant expression.

The one_or_all argument affects the search as follows:

- 'one': The search terminates after the first match and returns one path string. It is undefined which match is considered first.
- 'all': The search returns all matching path strings such that no duplicate paths are included. If there are multiple strings, they are autowrapped as an array. The order of the array elements is undefined.

Within the search_str search string argument, the % and _ characters work as for the LIKE operator: % matches any number of characters (including zero characters), and _ matches exactly one character.

To specify a literal % or _ character in the search string, precede it by the escape character. The default is \ if the escape_char argument is missing or NULL. Otherwise, escape_char must be a constant that is empty or one character.

For more information about matching and escape character behavior, see the description of LIKE in Section 14.8.1, "String Comparison Functions and Operators". For escape character handling, a difference from the LIKE behavior is that the escape character for JSON_SEARCH() must evaluate to a constant at compile time, not just at execution time. For example, if JSON_SEARCH() is used in a prepared statement and the escape_char argument is supplied using a ? parameter, the parameter value might be constant at execution time, but is not at compile time.

```
mysql> SET @j = '{"abc", [{"k": "10"}, "def"], {"x":"abc"}, {"y":"bcd"}}';

mysql> SELECT JSON_SEARCH(@j, 'one', 'abc');
+-------------------------------+
| JSON_SEARCH(@j, 'one', 'abc') |
+-------------------------------+
| "$[0]"                        |
+-------------------------------+

mysql> SELECT JSON_SEARCH(@j, 'all', 'abc');
+-------------------------------+
| JSON_SEARCH(@j, 'all', 'abc') |
+-------------------------------+
| ["$[0]", "$[2].x"]            |
+-------------------------------+

mysql> SELECT JSON_SEARCH(@j, 'all', 'ghi');
+-------------------------------+
| JSON_SEARCH(@j, 'all', 'ghi') |
+-------------------------------+
| NULL                          |
+-------------------------------+

mysql> SELECT JSON_SEARCH(@j, 'all', '10');
+-------------------------------+
| JSON_SEARCH(@j, 'all', '10') |
+-------------------------------+
| "$[1][0].k"                  |
+-------------------------------+

mysql> SELECT JSON_SEARCH(@j, 'all', '10', NULL, '$');
+-------------------------------+
| JSON_SEARCH(@j, 'all', '10', NULL, '$') |
+-------------------------------+
```
Functions That Search JSON Values

mysql> SELECT JSON_SEARCH(@j, 'all', '10', NULL, '$[*]');
| JSON_SEARCH(@j, 'all', '10', NULL, '$[*]') |
| "$[1][0].k" |
+

mysql> SELECT JSON_SEARCH(@j, 'all', '10', NULL, '$**.k');
| JSON_SEARCH(@j, 'all', '10', NULL, '$**.k') |
| "$[1][0].k" |
+

mysql> SELECT JSON_SEARCH(@j, 'all', '10', NULL, '$[*][0].k');
| JSON_SEARCH(@j, 'all', '10', NULL, '$[*][0].k') |
| "$[1][0].k" |
+

mysql> SELECT JSON_SEARCH(@j, 'all', '10', NULL, '$[1]');
| JSON_SEARCH(@j, 'all', '10', NULL, '$[1]') |
| "$[1][0].k" |
+

mysql> SELECT JSON_SEARCH(@j, 'all', '10', NULL, '$[1][0]');
| JSON_SEARCH(@j, 'all', '10', NULL, '$[1][0]') |
| "$[1][0].k" |
+

mysql> SELECT JSON_SEARCH(@j, 'all', 'abc', NULL, '$[2]');
| JSON_SEARCH(@j, 'all', 'abc', NULL, '$[2]') |

+-------------------------------------------+

For more information about the JSON path syntax supported by MySQL, including rules governing the wildcard operators * and **, see JSON Path Syntax.

• **JSON_VALUE(json_doc, path)**

  Extracts a value from a JSON document at the path given in the specified document, and returns the extracted value, optionally converting it to a desired type. The complete syntax is shown here:

  ```
  JSON_VALUE(json_doc, path [RETURNING type] [on_empty] [on_error])
  ```

  `on_empty`: {NULL | ERROR | DEFAULT value} ON EMPTY

  `on_error`: {NULL | ERROR | DEFAULT value} ON ERROR

  `json_doc` is a valid JSON document. If this is NULL, the function returns NULL.

  `path` is a JSON path pointing to a location in the document. This must be a string literal value.

  `type` is one of the following data types:

  • FLOAT
  • DOUBLE
  • DECIMAL
  • SIGNED
  • UNSIGNED
  • DATE
  • TIME
  • DATETIME
  • YEAR

  YEAR values of one or two digits are not supported.

  • CHAR
  • JSON
Functions That Search JSON Values

The types just listed are the same as the (non-array) types supported by the CAST() function.
If not specified by a RETURNING clause, the JSON_VALUE() function's return type is
VARCHAR(512). When no character set is specified for the return type, JSON_VALUE() uses
utf8mb4 with the binary collation, which is case-sensitive; if utf8mb4 is specified as the character
set for the result, the server uses the default collation for this character set, which is not casesensitive.
When the data at the specified path consists of or resolves to a JSON null literal, the function returns
SQL NULL.
on_empty, if specified, determines how JSON_VALUE() behaves when no data is found at the path
given; this clause takes one of the following values:
• NULL ON EMPTY: The function returns NULL; this is the default ON EMPTY behavior.
• DEFAULT value ON EMPTY: the provided value is returned. The value's type must match that
of the return type.
• ERROR ON EMPTY: The function throws an error.
If used, on_error takes one of the following values with the corresponding outcome when an error
occurs, as listed here:
• NULL ON ERROR: JSON_VALUE() returns NULL; this is the default behavior if no ON ERROR
clause is used.
• DEFAULT value ON ERROR: This is the value returned; its value must match that of the return
type.
• ERROR ON ERROR: An error is thrown.
ON EMPTY, if used, must precede any ON ERROR clause. Specifying them in the wrong order results
in a syntax error.
Error handling.

In general, errors are handled by JSON_VALUE() as follows:

• All JSON input (document and path) is checked for validity. If any of it is not valid, an SQL error is
thrown without triggering the ON ERROR clause.
• ON ERROR is triggered whenever any of the following events occur:
• Attempting to extract an object or an array, such as that resulting from a path that resolves to
multiple locations within the JSON document
• Conversion errors, such as attempting to convert 'asdf' to an UNSIGNED value
• Truncation of values
• A conversion error always triggers a warning even if NULL ON ERROR or DEFAULT ... ON
ERROR is specified.
• The ON EMPTY clause is triggered when the source JSON document (expr) contains no data at
the specified location (path).
Examples.

Two simple examples are shown here:

mysql> SELECT JSON_VALUE('{"fname": "Joe", "lname": "Palmer"}', '$.fname');
+--------------------------------------------------------------+
| JSON_VALUE('{"fname": "Joe", "lname": "Palmer"}', '$.fname') |
+--------------------------------------------------------------+

2293


The statement `SELECT JSON_VALUE(json_doc, path RETURNING type)` is equivalent to the following statement:

```sql
SELECT CAST(
    JSON_UNQUOTE( JSON_EXTRACT(json_doc, path)
) AS type
);
```

`JSON_VALUE()` simplifies creating indexes on JSON columns by making it unnecessary in many cases to create a generated column and then an index on the generated column. You can do this when creating a table `t1` that has a JSON column by creating an index on an expression that uses `JSON_VALUE()` operating on that column (with a path that matches a value in that column), as shown here:

```sql
CREATE TABLE t1(
    j JSON,
    INDEX i1 ( (JSON_VALUE(j, '$.id' RETURNING UNSIGNED)) )
);
```

The following `EXPLAIN` output shows that a query against `t1` employing the index expression in the `WHERE` clause uses the index thus created:

```sql
mysql> EXPLAIN SELECT * FROM t1
    -> WHERE JSON_VALUE(j, '$.id' RETURNING UNSIGNED) = 123
```

```plaintext
id: 1
select_type: SIMPLE
table: t1
partitions: NULL
type: ref
possible_keys: i1
key: i1
key_len: 9
ref: const
rows: 1
filtered: 100.00
Extra: NULL
```

This achieves much the same effect as creating a table `t2` with an index on a generated column (see Indexing a Generated Column to Provide a JSON Column Index), like this one:

```sql
CREATE TABLE t2 {
    j JSON,
    g INT GENERATED ALWAYS AS (j->"$.id"),
    INDEX i1 (g)
};
```

The `EXPLAIN` output for a query against this table, referencing the generated column, shows that the index is used in the same way as for the previous query against table `t1`:

```sql
mysql> EXPLAIN SELECT * FROM t2 WHERE g = 123
```

```plaintext
id: 1
select_type: SIMPLE
table: t2
partitions: NULL
type: ref
possible_keys: i1
```
Functions That Search JSON Values

For information about using indexes on generated columns for indirect indexing of JSON columns, see Indexing a Generated Column to Provide a JSON Column Index.

- **value MEMBER OF(json_array)**

Returns true (1) if value is an element of json_array, otherwise returns false (0). value must be a scalar or a JSON document; if it is a scalar, the operator attempts to treat it as an element of a JSON array. If value or json_array is NULL, the function returns NULL.

Queries using MEMBER_OF() on JSON columns of InnoDB tables in the WHERE clause can be optimized using multi-valued indexes. See Multi-Valued Indexes, for detailed information and examples.

Simple scalars are treated as array values, as shown here:

```sql
mysql> SELECT 17 MEMBER OF('[23, "abc", 17, "ab", 10]');
+-------------------------------------------+
| 17 MEMBER OF('[23, "abc", 17, "ab", 10]') |
+-------------------------------------------+
|                                         1 |
+-------------------------------------------+
1 row in set (0.00 sec)

mysql> SELECT 'ab' MEMBER OF('[23, "abc", 17, "ab", 10]');
+---------------------------------------------+
| 'ab' MEMBER OF('[23, "abc", 17, "ab", 10]') |
+---------------------------------------------+
|                                          1 |
+---------------------------------------------+
1 row in set (0.00 sec)

Partial matches of array element values do not match:

```sql
mysql> SELECT 7 MEMBER OF('[23, "abc", 17, "ab", 10]');
+------------------------------------------+
| 7 MEMBER OF('[23, "abc", 17, "ab", 10]') |
+------------------------------------------+
|                                        0 |
+------------------------------------------+
1 row in set (0.00 sec)

mysql> SELECT 'a' MEMBER OF('[23, "abc", 17, "ab", 10]');
+--------------------------------------------+
| 'a' MEMBER OF('[23, "abc", 17, "ab", 10]') |
+--------------------------------------------+
|                                        0 |
+--------------------------------------------+
1 row in set (0.00 sec)
```

Conversions to and from string types are not performed:

```sql
mysql> SELECT -> 17 MEMBER OF('[23, "abc", 17", "ab", 10]'),
            -> "17" MEMBER OF('[23, "abc", 17", "ab", 10]')
G
*************************** 1. row ***************************
17 MEMBER OF('[23, "abc", 17", "ab", 10]'): 0
"17" MEMBER OF('[23, "abc", 17", "ab", 10]'): 0
```
Functions That Modify JSON Values

1 row in set (0.00 sec)

To use this operator with a value which itself an array, it is necessary to cast it explicitly as a JSON
array. You can do this with CAST(... AS JSON):
mysql> SELECT CAST('[4,5]' AS JSON) MEMBER OF('[[3,4],[4,5]]');
+--------------------------------------------------+
| CAST('[4,5]' AS JSON) MEMBER OF('[[3,4],[4,5]]') |
+--------------------------------------------------+
|
1 |
+--------------------------------------------------+
1 row in set (0.00 sec)

It is also possible to perform the necessary cast using the JSON_ARRAY() function, like this:
mysql> SELECT JSON_ARRAY(4,5) MEMBER OF('[[3,4],[4,5]]');
+--------------------------------------------+
| JSON_ARRAY(4,5) MEMBER OF('[[3,4],[4,5]]') |
+--------------------------------------------+
|
1 |
+--------------------------------------------+
1 row in set (0.00 sec)

Any JSON objects used as values to be tested or which appear in the target array must be coerced
to the correct type using CAST(... AS JSON) or JSON_OBJECT(). In addition, a target array
containing JSON objects must itself be cast using JSON_ARRAY. This is demonstrated in the
following sequence of statements:
mysql> SET @a = CAST('{"a":1}' AS JSON);
Query OK, 0 rows affected (0.00 sec)
mysql> SET @b = JSON_OBJECT("b", 2);
Query OK, 0 rows affected (0.00 sec)
mysql> SET @c = JSON_ARRAY(17, @b, "abc", @a, 23);
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @a MEMBER OF(@c), @b MEMBER OF(@c);
+------------------+------------------+
| @a MEMBER OF(@c) | @b MEMBER OF(@c) |
+------------------+------------------+
|
1 |
1 |
+------------------+------------------+
1 row in set (0.00 sec)

14.17.4 Functions That Modify JSON Values
The functions in this section modify JSON values and return the result.
• JSON_ARRAY_APPEND(json_doc, path, val[, path, val] ...)
Appends values to the end of the indicated arrays within a JSON document and returns the result.
Returns NULL if any argument is NULL. An error occurs if the json_doc argument is not a valid
JSON document or any path argument is not a valid path expression or contains a * or ** wildcard.
The path-value pairs are evaluated left to right. The document produced by evaluating one pair
becomes the new value against which the next pair is evaluated.
If a path selects a scalar or object value, that value is autowrapped within an array and the new value
is added to that array. Pairs for which the path does not identify any value in the JSON document are
ignored.
mysql> SET @j = '["a", ["b", "c"], "d"]';
mysql> SELECT JSON_ARRAY_APPEND(@j, '$[1]', 1);
+----------------------------------+
| JSON_ARRAY_APPEND(@j, '$[1]', 1) |
+----------------------------------+

2296


Functions That Modify JSON Values

<table>
<thead>
<tr>
<th>[&quot;a&quot;, [&quot;b&quot;, &quot;c&quot;, 1], &quot;d&quot;]</th>
</tr>
</thead>

<tr>
<td>JSON_ARRAY_APPEND(@j, '&quot;&quot;, &quot;z&quot;)</td>
</tr>
<tr>
<td>[&quot;a&quot;, 1], &quot;z&quot;]</td>
</tr>
</tbody>
</table>

• JSON_ARRAY_INSERT(json_doc, path, val[, path, val] ...)

Updates a JSON document, inserting into an array within the document and returning the modified document. Returns NULL if any argument is NULL. An error occurs if the json_doc argument is not a valid JSON document or any path argument is not a valid path expression or contains a * or ** wildcard or does not end with an array element identifier.

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

Pairs for which the path does not identify any array in the JSON document are ignored. If a path identifies an array element, the corresponding value is inserted at that element position, shifting any following values to the right. If a path identifies an array position past the end of an array, the value is inserted at the end of the array.

mysql> SET @j = '["a", ["b", [1, 2]], [3, 4]]';
mysql> SELECT JSON_ARRAY_INSERT(@j, '"[1]", "x"');
| JSON_ARRAY_INSERT(@j, '"[1]", "x") |
| ["a", ["b", [1, 2]], [3, 4]] |
mysql> SELECT JSON_ARRAY_INSERT(@j, '"[100]", "x"');
| JSON_ARRAY_INSERT(@j, '"[100]", "x") |
| ["a", ["b", [1, 2]], [3, 4], "x"] |
mysql> SELECT JSON_ARRAY_INSERT(@j, '"[1].b[0]", "x"');
| JSON_ARRAY_INSERT(@j, '"[1].b[0]", "x") |
| ["a", ["b", [1, 2]], [3, 4], ["x"] |
Functions That Modify JSON Values

Earlier modifications affect the positions of the following elements in the array, so subsequent paths in the same `JSON_ARRAY_INSERT()` call should take this into account. In the final example, the second path inserts nothing because the path no longer matches anything after the first insert.

- **JSON_INSERT(json_doc, path, val[, path, val] ...)**

  Inserts data into a JSON document and returns the result. Returns `NULL` if any argument is `NULL`. An error occurs if the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression or contains a `*` or `**` wildcard.

  The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

  A path-value pair for an existing path in the document is ignored and does not overwrite the existing document value. A path-value pair for a nonexisting path in the document adds the value to the document if the path identifies one of these types of values:
  
  - A member not present in an existing object. The member is added to the object and associated with the new value.
  
  - A position past the end of an existing array. The array is extended with the new value. If the existing value is not an array, it is autowrapped as an array, then extended with the new value.

  Otherwise, a path-value pair for a nonexisting path in the document is ignored and has no effect.

  For a comparison of `JSON_INSERT()`, `JSON_REPLACE()`, and `JSON_SET()`, see the discussion of `JSON_SET()`.

- **JSON_MERGE(json_doc, json_doc[, json_doc] ...)**

  Deprecated synonym for `JSON_MERGE_PRESERVE()`.

1 row in set (0.00 sec)
• **JSON_MERGE_PATCH(\(*)\, \left(\ \text{json\_doc}\ \left[, \ \text{json\_doc}\ \right)\ \right)\)**

Performs an RFC 7396 compliant merge of two or more JSON documents and returns the merged result, without preserving members having duplicate keys. Raises an error if at least one of the documents passed as arguments to this function is not valid.

**Note**

For an explanation and example of the differences between this function and **JSON_MERGE_PRESERVE()**, see **JSON_MERGE_PATCH() compared with JSON_MERGE_PRESERVE()**.

**JSON_MERGE_PATCH()** performs a merge as follows:

1. If the first argument is not an object, the result of the merge is the same as if an empty object had been merged with the second argument.

2. If the second argument is not an object, the result of the merge is the second argument.

3. If both arguments are objects, the result of the merge is an object with the following members:
   - All members of the first object which do not have a corresponding member with the same key in the second object.
   - All members of the second object which do not have a corresponding key in the first object, and whose value is not the JSON null literal.
   - All members with a key that exists in both the first and the second object, and whose value in the second object is not the JSON null literal. The values of these members are the results of recursively merging the value in the first object with the value in the second object.

For additional information, see **Normalization, Merging, and Autowrapping of JSON Values**.

```sql
mysql> SELECT JSON_MERGE_PATCH('[1, 2]', '[true, false]');
+---------------------------------------------+
| JSON_MERGE_PATCH('[1, 2]', '[true, false]') |
+---------------------------------------------+
| [true, false]                               |
+---------------------------------------------+

mysql> SELECT JSON_MERGE_PATCH('{"name": "x"}', '{"id": 47}');
+-------------------------------------------------+
| JSON_MERGE_PATCH('{"name": "x"}', '{"id": 47}') |
| {"id": 47, "name": "x"}                       |
+-------------------------------------------------+

mysql> SELECT JSON_MERGE_PATCH('1', 'true');
+-------------------------------+
| JSON_MERGE_PATCH('1', 'true') |
| true                         |
+-------------------------------+

mysql> SELECT JSON_MERGE_PATCH('[1, 2]', '{"id": 47}');
+------------------------------------------+
| JSON_MERGE_PATCH('[1, 2]', '{"id": 47}') |
| {"id": 47}                               |
+------------------------------------------+

mysql> SELECT JSON_MERGE_PATCH('{"a": 1, "b":2 }',
   > '{ "a": 3, "c":4 }');
+---------------------------------------------------------------------+
| JSON_MERGE_PATCH('{"a": 1, "b":2 }',{ "a": 3, "c":4 }') |
| {"a": 3, "b": 2, "c": 4}                                      |
+---------------------------------------------------------------------+
```
Functions That Modify JSON Values

+-----------------------------------------------------------+
mysql> SELECT JSON_MERGE_PATCH('{ "a": 1, "b":2 }','{ "a": 3, "c":4 }',
>
'{ "a": 5, "d":6 }');
+-------------------------------------------------------------------------------+
| JSON_MERGE_PATCH('{ "a": 1, "b":2 }','{ "a": 3, "c":4 }','{ "a": 5, "d":6 }') |
+-------------------------------------------------------------------------------+
| {"a": 5, "b": 2, "c": 4, "d": 6}
|
+-------------------------------------------------------------------------------+

You can use this function to remove a member by specifying null as the value of the same member
in the second argument, as shown here:
mysql> SELECT JSON_MERGE_PATCH('{"a":1, "b":2}', '{"b":null}');
+--------------------------------------------------+
| JSON_MERGE_PATCH('{"a":1, "b":2}', '{"b":null}') |
+--------------------------------------------------+
| {"a": 1}
|
+--------------------------------------------------+

This example shows that the function operates in a recursive fashion; that is, values of members are
not limited to scalars, but rather can themselves be JSON documents:
mysql> SELECT JSON_MERGE_PATCH('{"a":{"x":1}}', '{"a":{"y":2}}');
+----------------------------------------------------+
| JSON_MERGE_PATCH('{"a":{"x":1}}', '{"a":{"y":2}}') |
+----------------------------------------------------+
| {"a": {"x": 1, "y": 2}}
|
+----------------------------------------------------+

JSON_MERGE_PATCH() compared with JSON_MERGE_PRESERVE().
The behavior of
JSON_MERGE_PATCH() is the same as that of JSON_MERGE_PRESERVE(), with the following two
exceptions:
• JSON_MERGE_PATCH() removes any member in the first object with a matching key in the second
object, provided that the value associated with the key in the second object is not JSON null.
• If the second object has a member with a key matching a member in the first object,
JSON_MERGE_PATCH() replaces the value in the first object with the value in the second object,
whereas JSON_MERGE_PRESERVE() appends the second value to the first value.
This example compares the results of merging the same 3 JSON objects, each having a matching
key "a", with each of these two functions:
mysql> SET @x = '{ "a": 1, "b": 2 }',
>
@y = '{ "a": 3, "c": 4 }',
>
@z = '{ "a": 5, "d": 6 }';
mysql> SELECT JSON_MERGE_PATCH(@x, @y, @z)
AS Patch,
->
JSON_MERGE_PRESERVE(@x, @y, @z) AS Preserve\G
*************************** 1. row ***************************
Patch: {"a": 5, "b": 2, "c": 4, "d": 6}
Preserve: {"a": [1, 3, 5], "b": 2, "c": 4, "d": 6}

2300


Functions That Modify JSON Values

- **JSON_MERGE_PRESERVE(json_doc, json_doc[, json_doc] ...)**

  Merges two or more JSON documents and returns the merged result. Returns **NULL** if any argument is **NULL**. An error occurs if any argument is not a valid JSON document.

  Merging takes place according to the following rules. For additional information, see Normalization, Merging, and Autowrapping of JSON Values.

  - Adjacent arrays are merged to a single array.
  - Adjacent objects are merged to a single object.
  - A scalar value is autowrapped as an array and merged as an array.
  - An adjacent array and object are merged by autowrapping the object as an array and merging the two arrays.

  ```
  mysql> SELECT JSON_MERGE_PRESERVE('[1, 2]', '[true, false]');
  +--------------------------------------------------+
  | JSON_MERGE_PRESERVE('[1, 2]', '[true, false]') |
  +--------------------------------------------------+
  | [1, 2, true, false]                             |
  +--------------------------------------------------+
  mysql> SELECT JSON_MERGE_PRESERVE('{"name": "x"}', '{"id": 47}');
  +--------------------------------------------------+
  | JSON_MERGE_PRESERVE('{"name": "x"}', '{"id": 47}') |
  +--------------------------------------------------+
  |{"id": 47, "name": "x"}                         |
  +--------------------------------------------------+
  mysql> SELECT JSON_MERGE_PRESERVE('1', 'true');
  +------------------------+
  | JSON_MERGE_PRESERVE('1', 'true') |
  +------------------------+
  | [1, true]              |
  +------------------------+
  mysql> SELECT JSON_MERGE_PRESERVE('[1, 2]', '{"id": 47}');
  +------------------------+
  | JSON_MERGE_PRESERVE('[1, 2]', '{"id": 47}') |
  +------------------------+
  |[1, 2, {"id": 47}]     |
  +------------------------+
  mysql> SELECT JSON_MERGE_PRESERVE('{ "a": 1, "b": 2 }',
     > '{ "a": 3, "c": 4 }');
  +------------------------+
  | JSON_MERGE_PRESERVE('{ "a": 1, "b": 2 }','{ "a": 3, "c": 4 }') |
  +------------------------+
  |{"a": [1, 3], "b": 2, "c": 4}                 |
  +------------------------+
  mysql> SELECT JSON_MERGE_PRESERVE('{ "a": 1, "b": 2 }', '{ "a": 3, "c": 4 }',
     > '{ "a": 5, "d": 6 }');
  +------------------------+
  | JSON_MERGE_PRESERVE('{ "a": 1, "b": 2 }','{ "a": 3, "c": 4 }','{ "a": 5, "d": 6 }') |
  +------------------------+
  |{"a": [1, 3, 5], "b": 2, "c": 4, "d": 6}     |
  +------------------------+
  ```

  This function is similar to but differs from **JSON_MERGE_PATCH()** in significant respects; see **JSON_MERGE_PATCH()** compared with **JSON_MERGE_PRESERVE()**, for more information.
Functions That Modify JSON Values

- **JSON_REMOVE(json_doc, path[, path] ...)**

  Removes data from a JSON document and returns the result. Returns NULL if any argument is NULL. An error occurs if the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression or is $ or contains a * or ** wildcard.

  The `path` arguments are evaluated left to right. The document produced by evaluating one path becomes the new value against which the next path is evaluated.

  It is not an error if the element to be removed does not exist in the document; in that case, the path does not affect the document.

  mysql> SET @j = '
  | ["a", ["b", "c"], "d"]
  |
  | mysql> SELECT JSON_REMOVE(@j, '$[1]');
  +-------------------------+
  | JSON_REMOVE(@j, '$[1]') |
  +-------------------------+
  | ["a", "d"]              |
  +-------------------------+

- **JSON_REPLACE(json_doc, path, val[, path, val] ...)**

  Replaces existing values in a JSON document and returns the result. Returns NULL if any argument is NULL. An error occurs if the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression or contains a * or ** wildcard.

  The `path-value` pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

  A `path-value` pair for an existing path in the document overwrites the existing document value with the new value. A `path-value` pair for a nonexisting path in the document is ignored and has no effect.

  The optimizer can perform a partial, in-place update of a JSON column instead of removing the old document and writing the new document in its entirety to the column. This optimization can be performed for an update statement that uses the `JSON_REPLACE()` function and meets the conditions outlined in Partial Updates of JSON Values.

  For a comparison of `JSON_INSERT()`, `JSON_REPLACE()`, and `JSON_SET()`, see the discussion of `JSON_SET()`.

  mysql> SET @j = '{ "a": 1, "b": [2, 3]}';
  mysql> SELECT JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]');
  +-----------------------------------------------------+
  | JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]') |
  +-----------------------------------------------------+
  | {"a": 10, "b": [2, 3]}                              |
  +-----------------------------------------------------+

- **JSON_SET(json_doc, path, val[, path, val] ...)**

  Inserts or updates data in a JSON document and returns the result. Returns NULL if `json_doc` or `path` is NULL, or if `path`, when given, does not locate an object. Otherwise, an error occurs if
the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression or contains a `*` or `**` wildcard.

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

A path-value pair for an existing path in the document overwrites the existing document value with the new value. A path-value pair for a nonexisting path in the document adds the value to the document if the path identifies one of these types of values:

- A member not present in an existing object. The member is added to the object and associated with the new value.
- A position past the end of an existing array. The array is extended with the new value. If the existing value is not an array, it is autowrapped as an array, then extended with the new value.

Otherwise, a path-value pair for a nonexisting path in the document is ignored and has no effect.

The optimizer can perform a partial, in-place update of a JSON column instead of removing the old document and writing the new document in its entirety to the column. This optimization can be performed for an update statement that uses the `JSON_SET()` function and meets the conditions outlined in Partial Updates of JSON Values.

The `JSON_SET()`, `JSON_INSERT()`, and `JSON_REPLACE()` functions are related:

- `JSON_SET()` replaces existing values and adds nonexisting values.
- `JSON_INSERT()` inserts values without replacing existing values.
- `JSON_REPLACE()` replaces only existing values.

The following examples illustrate these differences, using one path that does exist in the document (`$.a`) and another that does not exist (`$.c`):

```sql
mysql> SET @j = '{ "a": 1, "b": [2, 3]};
mysql> SELECT JSON_SET(@j, '$.a', 10, '$.c', '[true, false]');
+-------------------------------------------------+
| JSON_SET(@j, '$.a', 10, '$.c', '[true, false]') |
+-------------------------------------------------+
| {"a": 10, "b": [2, 3], "c": [true, false]}    |
+-------------------------------------------------+
mysql> SELECT JSON_INSERT(@j, '$.a', 10, '$.c', '[true, false]');
+----------------------------------------------------+
| JSON_INSERT(@j, '$.a', 10, '$.c', '[true, false]') |
+----------------------------------------------------+
| {"a": 1, "b": [2, 3], "c": [true, false]}        |
+----------------------------------------------------+
mysql> SELECT JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]');
+-----------------------------------------------------+
| JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]') |
+-----------------------------------------------------+
| {"a": 10, "b": [2, 3]}                              |
+-----------------------------------------------------+
```

- `JSON_UNQUOTE(json_val)`

Unquotes JSON value and returns the result as a `utf8mb4` string. Returns `NULL` if the argument is `NULL`. An error occurs if the value starts and ends with double quotes but is not a valid JSON string literal.

Within a string, certain sequences have special meaning unless the `NO_BACKSLASH_ESCAPES` SQL mode is enabled. Each of these sequences begins with a backslash (`\`), known as the escape character. MySQL recognizes the escape sequences shown in Table 14.23, “JSON_UNQUOTE() Special Character Escape Sequences”. For all other escape sequences, backslash is ignored. That
Functions That Modify JSON Values

is, the escaped character is interpreted as if it was not escaped. For example, \x is just x. These sequences are case-sensitive. For example, \b is interpreted as a backspace, but \B is interpreted as B.

### Table 14.23 JSON_UNQUOTE() Special Character Escape Sequences

<table>
<thead>
<tr>
<th>Escape Sequence</th>
<th>Character Represented by Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;</td>
<td>A double quote (&quot;) character</td>
</tr>
<tr>
<td>\b</td>
<td>A backspace character</td>
</tr>
<tr>
<td>\f</td>
<td>A formfeed character</td>
</tr>
<tr>
<td>\n</td>
<td>A newline (linefeed) character</td>
</tr>
<tr>
<td>\r</td>
<td>A carriage return character</td>
</tr>
<tr>
<td>\t</td>
<td>A tab character</td>
</tr>
<tr>
<td>\</td>
<td>A backslash () character</td>
</tr>
<tr>
<td>\uXXXX</td>
<td>UTF-8 bytes for Unicode value XXXX</td>
</tr>
</tbody>
</table>

Two simple examples of the use of this function are shown here:

```
mysql> SET @j = "abc";
mysql> SELECT @j, JSON_UNQUOTE(@j);
+-------+------------------+
| @j    | JSON_UNQUOTE(@j) |
+-------+------------------+
| "abc" | abc              |
+-------+------------------+
```

```
mysql> SET @j = '[1, 2, 3]';
mysql> SELECT @j, JSON_UNQUOTE(@j);
+-----------+------------------+
| @j        | JSON_UNQUOTE(@j) |
+-----------+------------------+
| [1, 2, 3] | [1, 2, 3]        |
+-----------+------------------+
```

The following set of examples shows how JSON_UNQUOTE handles escape sequences with NO_BACKSLASH_ESCAPES disabled and enabled:

```
mysql> SELECT @@sql_mode;
+------------+
| @@sql_mode |
+------------+
|            |
+------------+
```

```
mysql> SELECT JSON_UNQUOTE("\t\u0032");
+------------------+
| JSON_UNQUOTE("\t\u0032") |
+------------------+
| 2                |
+------------------+
```

```
mysql> SET @@sql_mode = 'NO_BACKSLASH_ESCAPES';
mysql> SELECT JSON_UNQUOTE("\t\u0032");
+------------------+
| JSON_UNQUOTE("\t\u0032") |
+------------------+
| \t\u0032          |
+------------------+
```

```
mysql> SELECT JSON_UNQUOTE("\t\u0032");
+------------------+
| JSON_UNQUOTE("\t\u0032") |
+------------------+
| 2                |
+------------------+
```

2304
14.17.5 Functions That Return JSON Value Attributes

The functions in this section return attributes of JSON values.

- **JSON_DEPTH(json_doc)**

  Returns the maximum depth of a JSON document. Returns NULL if the argument is NULL. An error occurs if the argument is not a valid JSON document.

  An empty array, empty object, or scalar value has depth 1. A nonempty array containing only elements of depth 1 or nonempty object containing only member values of depth 1 has depth 2. Otherwise, a JSON document has depth greater than 2.

  ```sql
  mysql> SELECT JSON_DEPTH('{}'), JSON_DEPTH('[]'), JSON_DEPTH('true');
  +------------------+------------------+--------------------+
  | JSON_DEPTH('{}') | JSON_DEPTH('[]')  | JSON_DEPTH('true') |
  +------------------+------------------+--------------------+
  |                1  |                1  |                  1 |
  +------------------+------------------+--------------------+
  mysql> SELECT JSON_DEPTH('[10, 20]'), JSON_DEPTH('[][{}, {}]');
  +------------------------+------------------------+
  | JSON_DEPTH('[10, 20]') | JSON_DEPTH('[][{}, {}]') |
  +------------------------+------------------------+
  |                      2 |                      2 |
  +------------------------+------------------------+
  mysql> SELECT JSON_DEPTH('[10, {"a": 20}]');
  +-----------------------------+
  | JSON_DEPTH('[10, {"a": 20}]') |
  +-----------------------------+
  |                             3 |
  +-----------------------------+
  ```

- **JSON_LENGTH(json_doc[, path])**

  Returns the length of a JSON document, or, if a path argument is given, the length of the value within the document identified by the path. Returns NULL if any argument is NULL or the path argument does not identify a value in the document. An error occurs if the json_doc argument is not a valid JSON document or the path argument is not a valid path expression.

  The length of a document is determined as follows:
  - The length of a scalar is 1.
  - The length of an array is the number of array elements.
  - The length of an object is the number of object members.
  - The length does not count the length of nested arrays or objects.

  ```sql
  mysql> SELECT JSON_LENGTH('[1, 2, {"a": 3}]');
  +-----------------------------+
  | JSON_LENGTH('[1, 2, {"a": 3}]') |
  +-----------------------------+
  |                             3 |
  +-----------------------------+
  mysql> SELECT JSON_LENGTH("{"a": 1, "b": {"c": 30}}");
  +-----------------------------+
  | JSON_LENGTH("{"a": 1, "b": {"c": 30}}") |
  +-----------------------------+
  |                             2 |
  +-----------------------------+
  mysql> SELECT JSON_LENGTH("{"a": 1, "b": {"c": 30}}", 'b.b');
  +-----------------------------+
  | JSON_LENGTH("{"a": 1, "b": {"c": 30}}", 'b.b') |
  +-----------------------------+
  |                             1 |
  +-----------------------------+
  ```
Functions That Return JSON Value Attributes

• JSON_TYPE(json_val)
Returns a utf8mb4 string indicating the type of a JSON value. This can be an object, an array, or a
scalar type, as shown here:
mysql> SET @j = '{"a": [10, true]}';
mysql> SELECT JSON_TYPE(@j);
+---------------+
| JSON_TYPE(@j) |
+---------------+
| OBJECT
|
+---------------+
mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a'));
+------------------------------------+
| JSON_TYPE(JSON_EXTRACT(@j, '$.a')) |
+------------------------------------+
| ARRAY
|
+------------------------------------+
mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a[0]'));
+---------------------------------------+
| JSON_TYPE(JSON_EXTRACT(@j, '$.a[0]')) |
+---------------------------------------+
| INTEGER
|
+---------------------------------------+
mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a[1]'));
+---------------------------------------+
| JSON_TYPE(JSON_EXTRACT(@j, '$.a[1]')) |
+---------------------------------------+
| BOOLEAN
|
+---------------------------------------+

JSON_TYPE() returns NULL if the argument is NULL:
mysql> SELECT JSON_TYPE(NULL);
+-----------------+
| JSON_TYPE(NULL) |
+-----------------+
| NULL
|
+-----------------+

An error occurs if the argument is not a valid JSON value:
mysql> SELECT JSON_TYPE(1);
ERROR 3146 (22032): Invalid data type for JSON data in argument 1
to function json_type; a JSON string or JSON type is required.

For a non-NULL, non-error result, the following list describes the possible JSON_TYPE() return
values:
• Purely JSON types:
• OBJECT: JSON objects
• ARRAY: JSON arrays
• BOOLEAN: The JSON true and false literals
• NULL: The JSON null literal
• Numeric types:
• INTEGER: MySQL TINYINT, SMALLINT, MEDIUMINT and INT and BIGINT scalars
• DOUBLE: MySQL DOUBLE FLOAT scalars
• DECIMAL: MySQL DECIMAL and NUMERIC scalars

JSON Table Functions

• Temporal types:
• DATETIME: MySQL DATETIME and TIMESTAMP scalars
• DATE: MySQL DATE scalars
• TIME: MySQL TIME scalars
• String types:
• STRING: MySQL utf8mb3 character type scalars: CHAR, VARCHAR, TEXT, ENUM, and SET
• Binary types:
• BLOB: MySQL binary type scalars including BINARY, VARBINARY, BLOB, and BIT
• All other types:
• OPAQUE (raw bits)
• JSON_VALID(val)
Returns 0 or 1 to indicate whether a value is valid JSON. Returns NULL if the argument is NULL.
mysql> SELECT JSON_VALID('{"a": 1}');
+------------------------+
| JSON_VALID('{"a": 1}') |
+------------------------+
|
1 |
+------------------------+
mysql> SELECT JSON_VALID('hello'), JSON_VALID('"hello"');
+---------------------+-----------------------+
| JSON_VALID('hello') | JSON_VALID('"hello"') |
+---------------------+-----------------------+
|
0 |
1 |
+---------------------+-----------------------+

14.17.6 JSON Table Functions
This section contains information about JSON functions that convert JSON data to tabular data.
MySQL 8.4 supports one such function, JSON_TABLE().
JSON_TABLE(expr, path COLUMNS (column_list) [AS] alias)
Extracts data from a JSON document and returns it as a relational table having the specified columns.
The complete syntax for this function is shown here:
JSON_TABLE(
expr,
path COLUMNS (column_list)
)
[AS] alias
column_list:
column[, column][, ...]
column:
name FOR ORDINALITY
| name type PATH string path [on_empty] [on_error]
| name type EXISTS PATH string path
| NESTED [PATH] path COLUMNS (column_list)
on_empty:
{NULL | DEFAULT json_string | ERROR} ON EMPTY
on_error:
{NULL | DEFAULT json_string | ERROR} ON ERROR

2307


expr: This is an expression that returns JSON data. This can be a constant (`{"a":1}`), a column (t1.json_data, given table t1 specified prior to JSON_TABLE() in the FROM clause), or a function call (JSON_EXTRACT(t1.json_data,'$.post.comments')).

path: A JSON path expression, which is applied to the data source. We refer to the JSON value matching the path as the row source; this is used to generate a row of relational data. The COLUMNS clause evaluates the row source, finds specific JSON values within the row source, and returns those JSON values as SQL values in individual columns of a row of relational data.

The alias is required. The usual rules for table aliases apply (see Section 11.2, “Schema Object Names”).

This function compares column names in case-insensitive fashion.

JSON_TABLE() supports four types of columns, described in the following list:

1. \texttt{name FOR ORDINALITY}: This type enumerates rows in the COLUMNS clause; the column named \texttt{name} is a counter whose type is \texttt{UNSIGNED INT}, and whose initial value is 1. This is equivalent to specifying a column as \texttt{AUTO_INCREMENT} in a CREATE TABLE statement, and can be used to distinguish parent rows with the same value for multiple rows generated by a \texttt{NESTED [PATH]} clause.

2. \texttt{name type PATH string_path [on_empty] [on_error]}: Columns of this type are used to extract values specified by \texttt{string_path.type} is a MySQL scalar data type (that is, it cannot be an object or array). JSON_TABLE() extracts data as JSON then coerces it to the column type, using the regular automatic type conversion applying to JSON data in MySQL. A missing value triggers the \texttt{on_empty} clause. Saving an object or array triggers the optional \texttt{on_error} clause; this also occurs when an error takes place during coercion from the value saved as JSON to the table column, such as trying to save the string `asd` to an integer column.

3. \texttt{name type EXISTS PATH path}: This column returns 1 if any data is present at the location specified by \texttt{path}, and 0 otherwise. \texttt{type} can be any valid MySQL data type, but should normally be specified as some variety of \texttt{INT}.

4. \texttt{NESTED [PATH] path COLUMNS (column_list)}: This flattens nested objects or arrays in JSON data into a single row along with the JSON values from the parent object or array. Using multiple \texttt{PATH} options allows projection of JSON values from multiple levels of nesting into a single row.

The \texttt{path} is relative to the parent path row path of JSON_TABLE(), or the path of the parent \texttt{NESTED [PATH]} clause in the event of nested paths.

\texttt{on empty}, if specified, determines what JSON_TABLE() does in the event that data is missing (depending on type). This clause is also triggered on a column in a \texttt{NESTED PATH} clause when the latter has no match and a NULL complemented row is produced for it. \texttt{on empty} takes one of the following values:

- \texttt{NULL ON EMPTY}: The column is set to NULL; this is the default behavior.

- \texttt{DEFAULT json_string ON EMPTY}: the provided \texttt{json_string} is parsed as JSON, as long as it is valid, and stored instead of the missing value. Column type rules also apply to the default value.

- \texttt{ERROR ON EMPTY}: An error is thrown.

If used, \texttt{on_error} takes one of the following values with the corresponding result as shown here:

- \texttt{NULL ON ERROR}: The column is set to NULL; this is the default behavior.

- \texttt{DEFAULT json_string ON ERROR}: The \texttt{json_string} is parsed as JSON (provided that it is valid) and stored instead of the object or array.

- \texttt{ERROR ON ERROR}: An error is thrown.
Specifying **ON ERROR** before **ON EMPTY** is nonstandard and deprecated in MySQL: trying to do so causes the server to issue a warning. Expect support for the nonstandard syntax to be removed in a future version of MySQL.

When a value saved to a column is truncated, such as saving 3.14159 in a **DECIMAL(10,1)** column, a warning is issued independently of any **ON ERROR** option. When multiple values are truncated in a single statement, the warning is issued only once.

When the expression and path passed to this function resolve to JSON null, **JSON_TABLE()** returns SQL **NULL**, in accordance with the SQL standard, as shown here:

```sql
mysql> SELECT *
-> FROM
-> JSON_TABLE(
-> '[]
-> $[*]
-> ) COLUMNS( c1 INT PATH '$.c1' ERROR ON ERROR )
-> ) as jt;
+------+
| c1   |
| NULL |
+------+
1 row in set (0.00 sec)
```

The following query demonstrates the use of **ON EMPTY** and **ON ERROR**. The row corresponding to `{"b":1}` is empty for the path `"$.a"`, and attempting to save `[1,2]` as a scalar produces an error; these rows are highlighted in the output shown.

```sql
mysql> SELECT *
-> FROM
-> JSON_TABLE(
-> '[]
-> $[*]
-> ) COLUMNS(
-> rowid FOR ORDINALITY,
-> ac VARCHAR(100) PATH "$a" DEFAULT '111' ON EMPTY DEFAULT '999' ON ERROR,
-> a$ JSON PATH "$a" DEFAULT '{"x": 333}' ON EMPTY,
-> bx INT EXISTS PATH "$b"
-> )
-> ) AS tt;
+-------+------+------------+------+
| rowid | ac   | aj         | bx   |
+-------+------+------------+------+
|     1 | 3    | "3"        |    0 |
|     2 | 2    | 2          |    0 |
|     3 | 111  | {"x": 333} |    1 |
|     4 | 0    | 0          |    0 |
|     5 | 999  | [1, 2]      |    0 |
+-------+------+------------+------+
5 rows in set (0.00 sec)
```

Column names are subject to the usual rules and limitations governing table column names. See Section 11.2, “Schema Object Names”.

All JSON and JSON path expressions are checked for validity; an invalid expression of either type causes an error.

Each match for the **path** preceding the **COLUMNS** keyword maps to an individual row in the result table. For example, the following query gives the result shown here:

```sql
mysql> SELECT *
-> FROM
-> JSON_TABLE(
-> '[]
-> $[*]
-> ) COLUMNS(
-> xval VARCHAR(100) PATH "$x",
-> yval VARCHAR(100) PATH "$y"
-> )
```
The expression "$[*]" matches each element of the array. You can filter the rows in the result by modifying the path. For example, using "$[1]" limits extraction to the second element of the JSON array used as the source, as shown here:

```sql
mysql> SELECT * 
-> FROM
-> JSON_TABLE( 
-> '[["x":2,"y":"8"],{"x":"3","y":"7"},{"x":"4","y":6}]', 
-> "$[1]" COLUMNS( 
-> xval VARCHAR(100) PATH "$.x", 
-> yval VARCHAR(100) PATH "$.y"
-> )
> ) AS jt1;
```

```
+----+----+
| xval | yval |
+----+----+
| 3   | 7   |
+----+----+
```

Within a column definition, "$" passes the entire match to the column; "$x" and "$y" pass only the values corresponding to the keys x and y, respectively, within that match. For more information, see JSON Path Syntax.

**NESTED PATH** (or simply **NESTED; PATH** is optional) produces a set of records for each match in the **COLUMNS** clause to which it belongs. If there is no match, all columns of the nested path are set to **NULL**. This implements an outer join between the topmost clause and **NESTED [PATH]**. An inner join can be emulated by applying a suitable condition in the **WHERE** clause, as shown here:

```sql
mysql> SELECT * 
-> FROM
-> JSON_TABLE( 
-> '[[a: 1, b: [11,111]], {"a": 2, "b": [22,222]}, {"a":3}]', 
-> '$[*]' COLUMNS( 
-> a INT PATH '$.a', 
-> NESTED PATH '$.b[*]' COLUMNS (b INT PATH '$')
-> )
> ) AS jt 
-> WHERE b IS NOT NULL;
```

```
a | b
---+----
1  | 11 
1  | 111
2  | 22 
2  | 222
```

Sibling nested paths—that is, two or more instances of **NESTED [PATH]** in the same **COLUMNS** clause—are processed one after another, one at a time. While one nested path is producing records, columns of any sibling nested path expressions are set to **NULL**. This means that the total number of records for a single match within a single containing **COLUMNS** clause is the sum and not the product of all records produced by **NESTED [PATH]** modifiers, as shown here:

```sql
mysql> SELECT * 
-> FROM
-> JSON_TABLE( 
-> '[["a": 1, "b": [11,111]}, {"a": 2, "b": [22,222]}],
->
```
A FOR ORDINALITY column enumerates records produced by the COLUMNS clause, and can be used to distinguish parent records of a nested path, especially if values in parent records are the same, as can be seen here:

```sql
mysql> SELECT * FROM JSON_TABLE(
    -- Content...
    ) AS jt;
```

The source document contains an array of two elements; each of these elements produces two rows. The values of `apath` and `bpath` are the same over the entire result set; this means that they cannot be used to determine whether `lpath` values came from the same or different parents. The value of the `ord` column remains the same as the set of records having `top_ord` equal to 1, so these two values are from a single object. The remaining two values are from different objects, since they have different values in the `ord` column.

Normally, you cannot join a derived table which depends on columns of preceding tables in the same FROM clause. MySQL, per the SQL standard, makes an exception for table functions; these are considered lateral derived tables. This is implicit, and for this reason is not allowed before `JSON_TABLE()`, also according to the standard.

Suppose you have a table `t1` created and populated using the statements shown here:

```sql
CREATE TABLE t1 (c1 INT, c2 CHAR(1), c3 JSON);
INSERT INTO t1 () VALUES
    ROW(1, 'z', JSON_OBJECT('a', 23, 'b', 27, 'c', 1)),...
```
You can then execute joins, such as this one, in which `JSON_TABLE()` acts as a derived table while at the same time it refers to a column in a previously referenced table:

```sql
SELECT c1, c2, JSON_EXTRACT(c3, '$.*')
FROM t1 AS m
JOIN
JSON_TABLE(
  m.c3,
  '$.*'
  COLUMNS(
    at VARCHAR(10) PATH '$.a' DEFAULT '1' ON EMPTY,
    bt VARCHAR(10) PATH '$.b' DEFAULT '2' ON EMPTY,
    ct VARCHAR(10) PATH '$.c' DEFAULT '3' ON EMPTY
  )
) AS tt
ON m.c1 > tt.at;
```

Attempting to use the `LATERAL` keyword with this query raises `ER_PARSE_ERROR`.

### 14.17.7 JSON Schema Validation Functions

MySQL supports validation of JSON documents against JSON schemas conforming to Draft 4 of the JSON Schema specification. This can be done using either of the functions detailed in this section, both of which take two arguments, a JSON schema, and a JSON document which is validated against the schema. `JSON_SCHEMA_VALID()` returns true if the document validates against the schema, and false if it does not; `JSON_SCHEMA_VALIDATION_REPORT()` provides a report in JSON format on the validation.

Both functions handle null or invalid input as follows:

- If at least one of the arguments is `NULL`, the function returns `NULL`.
- If at least one of the arguments is not valid JSON, the function raises an error (`ER_INVALID_TYPE_FOR_JSON`)
- In addition, if the schema is not a valid JSON object, the function returns `ER_INVALID_JSON_TYPE`.

MySQL supports the `required` attribute in JSON schemas to enforce the inclusion of required properties (see the examples in the function descriptions).

MySQL supports the `id`, `$schema`, `description`, and `type` attributes in JSON schemas but does not require any of these.

MySQL does not support external resources in JSON schemas; using the `$ref` keyword causes `JSON_SCHEMA_VALID()` to fail with `ER_NOT_SUPPORTED_YET`.

**Note**

MySQL supports regular expression patterns in JSON schema, which supports but silently ignores invalid patterns (see the description of `JSON_SCHEMA_VALID()` for an example).

These functions are described in detail in the following list:

- `JSON_SCHEMA_VALID(schema, document)`

  Validates a JSON document against a JSON schema. Both `schema` and `document` are required. The schema must be a valid JSON object; the document must be a valid JSON document. Provided that these conditions are met: If the document validates against the schema, the function returns true (1); otherwise, it returns false (0).
In this example, we set a user variable `@schema` to the value of a JSON schema for geographical coordinates, and another one `@document` to the value of a JSON document containing one such coordinate. We then verify that `@document` validates according to `@schema` by using them as the arguments to `JSON_SCHEMA_VALID()`:

```sql
mysql> SET @schema = ' {
  'id": "http://json-schema.org/geo",
  'schema": "http://json-schema.org/draft-04/schema#",
  'description": "A geographical coordinate",
  'type": "object",
  'properties": {
    'latitude": { 
      'type": "number",
      'minimum": -90,
      'maximum": 90
    },
    'longitude": {
      'type": "number",
      'minimum": -180,
      'maximum": 180
    }
  },
  'required": ["latitude", "longitude"
}
';
Query OK, 0 rows affected (0.01 sec)

mysql> SET @document = '{
  'latitude": 63.444697,
  'longitude": 10.445118
}';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT JSON_SCHEMA_VALID(@schema, @document);
+---------------------------------------+
| JSON_SCHEMA_VALID(@schema, @document) |
| 1                                   |
+---------------------------------------+
1 row in set (0.00 sec)

Since `@schema` contains the `required` attribute, we can set `@document` to a value that is otherwise valid but does not contain the required properties, then test it against `@schema`, like this:

```sql
mysql> SET @document = '{}';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT JSON_SCHEMA_VALID(@schema, @document);
+---------------------------------------+
| JSON_SCHEMA_VALID(@schema, @document) |
| 0                                   |
+---------------------------------------+
1 row in set (0.00 sec)
```

If we now set the value of `@schema` to the same JSON schema but without the `required` attribute, `@document` validates because it is a valid JSON object, even though it contains no properties, as shown here:

```sql
mysql> SET @schema = ' {
  'id": "http://json-schema.org/geo",
  'schema": "http://json-schema.org/draft-04/schema#",
  'description": "A geographical coordinate",
  'type": "object",
  'properties": {
    'latitude": {
      'type": "number",
      'minimum": -90,
      'maximum": 90
    },
    }

mysql> SELECT JSON_SCHEMA_VALID(@schema, @document);
+--------------------------------------------------+
| JSON_SCHEMA_VALID(@schema, @document) |
| 1                                   |
+--------------------------------------------------+
1 row in set (0.00 sec)
```
JSON Schema Validation Functions

```
'"longitude": {
  "type": "number",
  "minimum": -180,
  "maximum": 180
}
};
```

JSON_SCHEMA_VALID() and CHECK constraints. JSON_SCHEMA_VALID() can also be used to enforce CHECK constraints.

Consider the table `geo` created as shown here, with a JSON column `coordinate` representing a point of latitude and longitude on a map, governed by the JSON schema used as an argument in a JSON_SCHEMA_VALID() call which is passed as the expression for a CHECK constraint on this table:

```
mysql> CREATE TABLE geo (coordinate JSON,
-> CHECK(JSON_SCHEMA_VALID('{
-> "type":"object",
-> "properties":{
->  "latitude":{"type":"number", "minimum":-90, "maximum":90},
->  "longitude":{"type":"number", "minimum":-180, "maximum":180}
-> },
-> "required": ["latitude", "longitude"]
-> )',
-> coordinate
-> )
->);
```

Note

Because a MySQL CHECK constraint cannot contain references to variables, you must pass the JSON schema to JSON_SCHEMA_VALID() inline when using it to specify such a constraint for a table.

We assign JSON values representing coordinates to three variables, as shown here:

```
mysql> SET @point1 = '{"latitude":59, "longitude":18}';
Query OK, 0 rows affected (0.00 sec)

mysql> SET @point2 = '{"latitude":91, "longitude":0}';
Query OK, 0 rows affected (0.00 sec)

mysql> SET @point3 = '{"longitude":120}';
Query OK, 0 rows affected (0.00 sec)
```

The first of these values is valid, as can be seen in the following INSERT statement:

```
mysql> INSERT INTO geo VALUES(@point1);
```

2314
The second JSON value is invalid and so fails the constraint, as shown here:

```sql
mysql> INSERT INTO geo VALUES(@point2);
ERROR 3819 (HY000): Check constraint 'geo_chk_1' is violated.
```

You can obtain precise information about the nature of the failure—in this case, that the `latitude` value exceeds the maximum defined in the schema—by issuing a `SHOW WARNINGS` statement:

```sql
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Error
Code: 3934
Message: The JSON document location '#/latitude' failed requirement 'maximum' at JSON Schema location '#/properties/latitude'.
*************************** 2. row ***************************
Level: Error
Code: 3819
Message: Check constraint 'geo_chk_1' is violated.
```

The third coordinate value defined above is also invalid, since it is missing the required `latitude` property. As before, you can see this by attempting to insert the value into the `geo` table, then issuing `SHOW WARNINGS` afterwards:

```sql
mysql> INSERT INTO geo VALUES(@point3);
ERROR 3819 (HY000): Check constraint 'geo_chk_1' is violated.
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Error
Code: 3934
Message: The JSON document location '#' failed requirement 'required' at JSON Schema location '#'.
*************************** 2. row ***************************
Level: Error
Code: 3819
Message: Check constraint 'geo_chk_1' is violated.
```

See Section 15.1.20.6, “CHECK Constraints”, for more information.

JSON Schema has support for specifying regular expression patterns for strings, but the implementation used by MySQL silently ignores invalid patterns. This means that `JSON_SCHEMA_VALID()` can return true even when a regular expression pattern is invalid, as shown here:

```sql
mysql> SELECT JSON_SCHEMA_VALID('["type":"string","pattern":"")', '"abc"');
+---------------------------------------------------------------+
| JSON_SCHEMA_VALID('["type":"string","pattern":"")', '"abc")' | 1 |
+---------------------------------------------------------------+
1 row in set (0.04 sec)
```

### `JSON_SCHEMA_VALIDATION_REPORT(schema, document)`

Validates a JSON `document` against a JSON `schema`. Both `schema` and `document` are required. As with `JSON_VALID_SCHEMA()`, the schema must be a valid JSON object, and the document must be a valid JSON document. Provided that these conditions are met, the function returns a report, as a JSON document, on the outcome of the validation. If the JSON document is considered valid according to the JSON Schema, the function returns a JSON object with one property `valid` having the value "true". If the JSON document fails validation, the function returns a JSON object which includes the properties listed here:

- `valid`: Always "false" for a failed schema validation
**JSON Schema Validation Functions**

- **reason**: A human-readable string containing the reason for the failure
- **schema-location**: A JSON pointer URI fragment identifier indicating where in the JSON schema the validation failed (see Note following this list)
- **document-location**: A JSON pointer URI fragment identifier indicating where in the JSON document the validation failed (see Note following this list)
- **schema-failed-keyword**: A string containing the name of the keyword or property in the JSON schema that was violated

---

**Note**

JSON pointer URI fragment identifiers are defined in [RFC 6901 - JavaScript Object Notation (JSON) Pointer](https://tools.ietf.org/html/rfc6901). (These are not the same as the JSON path notation used by `JSON_EXTRACT()` and other MySQL JSON functions.) In this notation, `#` represents the entire document, and `#/myprop` represents the portion of the document included in the top-level property named `myprop`. See the specification just cited and the examples shown later in this section for more information.

In this example, we set a user variable `@schema` to the value of a JSON schema for geographical coordinates, and another one `@document` to the value of a JSON document containing one such coordinate. We then verify that `@document` validates according to `@schema` by using them as the arguments to `JSON_SCHEMA_VALIDATION_REPORT()`:

```sql
mysql> SET @schema = ' {
    -> "id": "http://json-schema.org/geo",
    -> "$schema": "http://json-schema.org/draft-04/schema#",
    -> "description": "A geographical coordinate",
    -> "type": "object",
    -> "properties": {
      -> "latitude": {
        -> "type": "number",
        -> "minimum": -90,
        -> "maximum": 90
      },
      -> "longitude": {
        -> "type": "number",
        -> "minimum": -180,
        -> "maximum": 180
      }
    },
    -> "required": ["latitude", "longitude"]
  }';
Query OK, 0 rows affected (0.01 sec)

mysql> SET @document = '{
    -> "latitude": 63.444697,
    -> "longitude": 10.445118
  }';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT JSON_SCHEMA_VALIDATION_REPORT(@schema, @document);
+---------------------------------------------------+
<table>
<thead>
<tr>
<th>JSON_SCHEMA_VALIDATION_REPORT(@schema, @document)</th>
</tr>
</thead>
<tbody>
<tr>
<td>{ &quot;valid&quot;: true }</td>
</tr>
</tbody>
</table>
+---------------------------------------------------+
1 row in set (0.00 sec)
```

Now we set `@document` such that it specifies an illegal value for one of its properties, like this:

```sql
mysql> SET @document = '{
    -> "latitude": 63.444697,
    -> "longitude": 310.445118
  }';
Query OK, 0 rows affected (0.00 sec)
```

```sql
mysql> SELECT JSON_SCHEMA_VALIDATION_REPORT(@schema, @document);
+---------------------------------------------------+
<table>
<thead>
<tr>
<th>JSON_SCHEMA_VALIDATION_REPORT(@schema, @document)</th>
</tr>
</thead>
<tbody>
<tr>
<td>[ &quot;reason&quot;: &quot;An illegal value was specified for one of the properties of the coordinate&quot;]</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>[ &quot;schema-location&quot;: &quot;/myprop/longitude&quot;]</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>[ &quot;document-location&quot;: &quot;/myprop/longitude&quot;]</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>[ &quot;schema-failed-keyword&quot;: &quot;longitude&quot;]</td>
</tr>
</tbody>
</table>
+---------------------------------------------------+
1 row in set (0.00 sec)
```
Validation of `@document` now fails when tested with `JSON_SCHEMA_VALIDATION_REPORT()`. The output from the function call contains detailed information about the failure (with the function wrapped by `JSON_PRETTY()` to provide better formatting), as shown here:

```sql
mysql> SELECT JSON_PRETTY(JSON_SCHEMA_VALIDATION_REPORT(@schema, @document))
+--------------------------+-----------------+-------+----------------+-------------------+
| JSON_SCHEMA_VALIDATION_REPORT(@schema, @document) |       |       |       |       |
| {"valid": false, | "reason": "The JSON document location '#/longitude' failed requirement 'maximum' at JSON Schema location '#/properties/longitude', | "schema-location": "#/properties/longitude", | "document-location": "#/longitude", | "schema-failed-keyword": "maximum" } |
| l row in set (0.00 sec) |
```

Since `@schema` contains the `required` attribute, we can set `@document` to a value that is otherwise valid but does not contain the required properties, then test it against `@schema`. The output of `JSON_SCHEMA_VALIDATION_REPORT()` shows that validation fails due to lack of a required element, like this:

```sql
mysql> SET @document = '{}';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT JSON_PRETTY(JSON_SCHEMA_VALIDATION_REPORT(@schema, @document))
+--------------------------+-----------------+-------+----------------+-------------------+
| JSON_SCHEMA_VALIDATION_REPORT(@schema, @document) |       |       |       |       |
| {"valid": false, | "reason": "The JSON document location '#' failed requirement 'required' at JSON Schema location '#', | "schema-location": ", | "document-location": ", | "schema-failed-keyword": "required" } |
| l row in set (0.00 sec) |
```

If we now set the value of `@schema` to the same JSON schema but without the `required` attribute, `@document` validates because it is a valid JSON object, even though it contains no properties, as shown here:

```sql
mysql> SET @schema = '{
  | "id": "http://json-schema.org/geo",
  | "$schema": "http://json-schema.org/draft-04/schema#",
  | "description": "A geographical coordinate",
  | "type": "object",
  | "properties": {
  |   | "latitude": { |
  |   | "type": "number",
  |   | "minimum": -90,
  |   | "maximum": 90
  |   |
  |   | "longitude": { |
  |   | "type": "number",
  |   | "minimum": -180,
  |   | "maximum": 180
  |   |
  |   |   |
  |   |
  | },

Query OK, 0 rows affected (0.00 sec)

mysql> SELECT JSON_SCHEMA_VALIDATION_REPORT(@schema, @document);+
<table>
<thead>
<tr>
<th>JSON_SCHEMA_VALIDATION_REPORT(@schema, @document)</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;valid&quot;: true}</td>
</tr>
<tr>
<td>l row in set (0.00 sec)</td>
</tr>
</tbody>
</table>
This section documents utility functions that act on JSON values, or strings that can be parsed as JSON values. `JSON_PRETTY()` prints out a JSON value in a format that is easy to read. `JSON_STORAGE_SIZE()` and `JSON_STORAGE_FREE()` show, respectively, the amount of storage space used by a given JSON value and the amount of space remaining in a JSON column following a partial update.

- **JSON_PRETTY(json_val)**

  Provides pretty-printing of JSON values similar to that implemented in PHP and by other languages and database systems. The value supplied must be a JSON value or a valid string representation of a JSON value. Extraneous whitespaces and newlines present in this value have no effect on the output. For a `NULL` value, the function returns `NULL`. If the value is not a JSON document, or if it cannot be parsed as one, the function fails with an error.

  Formatting of the output from this function adheres to the following rules:

  - Each array element or object member appears on a separate line, indented by one additional level as compared to its parent.
  - Each level of indentation adds two leading spaces.
  - A comma separating individual array elements or object members is printed before the newline that separates the two elements or members.
  - The key and the value of an object member are separated by a colon followed by a space (`:`).
  - An empty object or array is printed on a single line. No space is printed between the opening and closing brace.
  - Special characters in string scalars and key names are escaped employing the same rules used by the `JSON_QUOTE()` function.

```sql
mysql> SELECT JSON_PRETTY('123'); # scalar
+--------------------+
| JSON_PRETTY('123') |
+--------------------+
| 123                |
+--------------------+
mysql> SELECT JSON_PRETTY('"[1,3,5]"'); # array
+------------------------+
| JSON_PRETTY("[1,3,5]"") |
+------------------------+
| [1, 3, 5]             |
+------------------------+
mysql> SELECT JSON_PRETTY('{"a":"10","b":"15","x":"25"}'); # object
+---------------------------------------------+
| JSON_PRETTY('{"a":"10","b":"15","x":"25"}') |
+---------------------------------------------+
| {"a": "10", "b": "15", "x": "25"}   |
+---------------------------------------------+
mysql> SELECT JSON_PRETTY('[{"a":1,{"key1":
"value1"},"5", "77",
{"key2":["value3", "valueX", "valueY"]
}'); # partial update
+---------------------------------------------+
| JSON_PRETTY('[{"a":1,{"key1":
"value1"},"5", "77",
{"key2":["value3", "valueX", "valueY"]
}'); # partial update
+---------------------------------------------+
```
JSON Utility Functions

For a JSON column value, this function shows how much storage space was freed in its binary representation after it was updated in place using JSON_SET(), JSON_REPLACE(), or JSON_REMOVE(). The argument can also be a valid JSON document or a string which can be parsed as one—either as a literal value or as the value of a user variable—in which case the function returns 0. It returns a positive, nonzero value if the argument is a JSON column value which has been updated as described previously, such that its binary representation takes up less space than it did prior to the update. For a JSON column which has been updated such that its binary representation is the same as or larger than before, or if the update was not able to take advantage of a partial update, it returns 0; it returns NULL if the argument is NULL.

If json_val is not NULL, and neither is a valid JSON document nor can be successfully parsed as one, an error results.

In this example, we create a table containing a JSON column, then insert a row containing a JSON object:

```sql
mysql> CREATE TABLE jtable (jcol JSON);
Query OK, 0 rows affected (0.38 sec)

mysql> INSERT INTO jtable VALUES
-> ('{"a": 10, "b": "wxyz", "c": [true, false]}');
Query OK, 1 row affected (0.04 sec)

mysql> SELECT * FROM jtable;
+----------------------------------------------+
| jcol                                         |
+----------------------------------------------+
| {"a": 10, "b": "wxyz", "c": [true, false]} |
+----------------------------------------------+
1 row in set (0.00 sec)
```

Now we update the column value using JSON_SET() such that a partial update can be performed; in this case, we replace the value pointed to by the c key (the array [true, false]) with one that takes up less space (the integer 1):

```sql
mysql> UPDATE jtable
-> SET jcol = JSON_SET(jcol, "$a", 10, "$b", "wxyz", "$c", 1);
Query OK, 1 row affected (0.03 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT * FROM jtable;
+----------------------------------+
| jcol                             |
+----------------------------------+
| {"a": 10, "b": "wxyz", "c": 1} |
+----------------------------------+
1 row in set (0.00 sec)
```
The effects of successive partial updates on this free space are cumulative, as shown in this example using `JSON_SET()` to reduce the space taken up by the value having key `b` (and making no other changes):

```sql
mysql> UPDATE jtable
    -> SET jcol = JSON_SET(jcol, "$a", 10, "$b", "wx", "$c", 1);
Query OK, 1 row affected (0.03 sec)
Rows matched: 1  Changed: 1  Warnings: 0
mysql> SELECT JSON_STORAGE_FREE(jcol) FROM jtable;
+-------------------------+
| JSON_STORAGE_FREE(jcol) |
+-------------------------+
|                      16 |
+-------------------------+
1 row in set (0.00 sec)
```

Updating the column without using `JSON_SET()`, `JSON_REPLACE()`, or `JSON_REMOVE()` means that the optimizer cannot perform the update in place; in this case, `JSON_STORAGE_FREE()` returns 0, as shown here:

```sql
mysql> UPDATE jtable SET jcol = '{"a": 10, "b": 1}';
Query OK, 1 row affected (0.05 sec)
Rows matched: 1  Changed: 1  Warnings: 0
mysql> SELECT JSON_STORAGE_FREE(jcol) AS Free FROM jtable;
+------+
| 0    |
+------+
1 row in set (0.00 sec)
```

Partial updates of JSON documents can be performed only on column values. For a user variable that stores a JSON value, the value is always completely replaced, even when the update is performed using `JSON_SET()`:

```sql
mysql> SET @j = '{"a": 10, "b": "wxyz", "c": [true, false]}';
Query OK, 0 rows affected (0.00 sec)
mysql> SET @j = JSON_SET(@j, "$a", 10, "$b", "wxyz", "$c", "1");
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @j, JSON_STORAGE_FREE(@j) AS Free;
+----------------------------------+------+
| @j                               | Free |
+----------------------------------+------+
| {"a": 10, "b": "wxyz", "c": "1"} |    0 |
+----------------------------------+------+
1 row in set (0.00 sec)
```

For a JSON literal, this function always returns 0:

```sql
mysql> SELECT JSON_STORAGE_FREE('{"a": 10, "b": "wxyz", "c": "1"}') AS Free;
+------+
| 0    |
+------+
1 row in set (0.00 sec)
```
JSON Utility Functions

• JSON_STORAGE_SIZE(json_val)

This function returns the number of bytes used to store the binary representation of a JSON document. When the argument is a JSON column, this is the space used to store the JSON document as it was inserted into the column, prior to any partial updates that may have been performed on it afterwards. json_val must be a valid JSON document or a string which can be parsed as one. In the case where it is string, the function returns the amount of storage space in the JSON binary representation that is created by parsing the string as JSON and converting it to binary. It returns NULL if the argument is NULL.

An error results when json_val is not NULL, and is not—or cannot be successfully parsed as—a JSON document.

To illustrate this function’s behavior when used with a JSON column as its argument, we create a table named jtable containing a JSON column jcol, insert a JSON value into the table, then obtain the storage space used by this column with JSON_STORAGE_SIZE(), as shown here:

```sql
mysql> CREATE TABLE jtable (jcol JSON);
Query OK, 0 rows affected (0.42 sec)
mysql> INSERT INTO jtable VALUES
    -> ('{"a": 1000, "b": "wxyz", "c": "{1, 3, 5, 7}"}')
Query OK, 1 row affected (0.04 sec)
mysql> SELECT
    -> jcol,
    -> JSON_STORAGE_SIZE(jcol) AS Size,
    -> JSON_STORAGE_FREE(jcol) AS Free
    -> FROM jtable;
+-----------------------------------------------+------+------+
| jcol                                          | Size | Free |
+-----------------------------------------------+------+------+
| {"a": 1000, "b": "wxyz", "c": "{1, 3, 5, 7}"} |   47 |    0 |
+-----------------------------------------------+------+------+
1 row in set (0.00 sec)
```

According to the output of JSON_STORAGE_SIZE(), the JSON document inserted into the column takes up 47 bytes. We also checked the amount of space freed by any previous partial updates of the column using JSON_STORAGE_FREE(); since no updates have yet been performed, this is 0, as expected.

Next we perform an UPDATE on the table that should result in a partial update of the document stored in jcol, and then test the result as shown here:

```sql
mysql> UPDATE jtable SET jcol =
    -> JSON_SET(jcol, ".b", "a");
Query OK, 1 row affected (0.04 sec)
Rows matched: 1  Changed: 1  Warnings: 0
mysql> SELECT
    -> jcol,
    -> JSON_STORAGE_SIZE(jcol) AS Size,
    -> JSON_STORAGE_FREE(jcol) AS Free
    -> FROM jtable;
+--------------------------------------------+------+------+
| jcol                                       | Size | Free |
+--------------------------------------------+------+------+
| {"a": 1000, "b": "a", "c": "{1, 3, 5, 7}"} |   47 |    3 |
+--------------------------------------------+------+------+
```

2321
The value returned by `JSON_STORAGE_FREE()` in the previous query indicates that a partial update of the JSON document was performed, and that this freed 3 bytes of space used to store it. The result returned by `JSON_STORAGE_SIZE()` is unchanged by the partial update.

Partial updates are supported for updates using `JSON_SET()`, `JSON_REPLACE()`, or `JSON_REMOVE()`. The direct assignment of a value to a JSON column cannot be partially updated; following such an update, `JSON_STORAGE_SIZE()` always shows the storage used for the newly-set value:

```sql
mysql> UPDATE jtable
mysql> SET jcol = '{"a": 4.55, "b": "wxyz", "c": [true, false]}';
Query OK, 1 row affected (0.04 sec)
Rows matched: 1  Changed: 1  Warnings: 0
mysql>
```

```sql
SELECT `jcol`, `JSON_STORAGE_SIZE(jcol)` AS Size, `JSON_STORAGE_FREE(jcol)` AS Free
FROM jtable;
+----------------------------------------+-----+-----+
<table>
<thead>
<tr>
<th>jcol</th>
<th>Size</th>
<th>Free</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;a&quot;: 4.55, &quot;b&quot;: &quot;wxyz&quot;, &quot;c&quot;: [true, false]}</td>
<td>56</td>
<td>0</td>
</tr>
</tbody>
</table>
+----------------------------------------+-----+-----+
1 row in set (0.00 sec)
```

A JSON user variable cannot be partially updated. This means that this function always shows the space currently used to store a JSON document in a user variable:

```sql
mysql> SET @j = '[100, "sakila", [1, 3, 5], 425.05]';
Query OK, 0 rows affected (0.00 sec)
mysql>
```

```sql
SELECT @j, `JSON_STORAGE_SIZE(@j)` AS Size;
+------------------------------------+------+
<table>
<thead>
<tr>
<th>@j</th>
<th>Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>[100, &quot;sakila&quot;, [1, 3, 5], 425.05]</td>
<td>45</td>
</tr>
</tbody>
</table>
+------------------------------------+------+
1 row in set (0.00 sec)
```

```sql
mysql> SET @j = JSON_SET(@j, '$[1]', "json");
Query OK, 0 rows affected (0.00 sec)
mysql>
```

```sql
SELECT @j, `JSON_STORAGE_SIZE(@j)` AS Size;
+----------------------------------+------+
<table>
<thead>
<tr>
<th>@j</th>
<th>Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>[100, &quot;json&quot;, [1, 3, 5], 425.05]</td>
<td>43</td>
</tr>
</tbody>
</table>
+----------------------------------+------+
1 row in set (0.00 sec)
```

```sql
mysql> SET @j = JSON_SET(@j, '$[2][0]', JSON_ARRAY(10, 20, 30));
Query OK, 0 rows affected (0.00 sec)
mysql>
```

```sql
SELECT @j, `JSON_STORAGE_SIZE(@j)` AS Size;
+---------------------------------------------+------+
<table>
<thead>
<tr>
<th>@j</th>
<th>Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>[100, &quot;json&quot;, [[10, 20, 30], 3, 5], 425.05]</td>
<td>56</td>
</tr>
</tbody>
</table>
+---------------------------------------------+------+
1 row in set (0.00 sec)
```

For a JSON literal, this function always returns the current storage space used:

```sql
mysql> SELECT
-> `JSON_STORAGE_SIZE('[100, "sakila", [1, 3, 5], 425.05]')` AS A,
-> `JSON_STORAGE_SIZE('{"a": 1000, "b": "a", "c": [1, 3, 5, 7]}')` AS B,
+--------+--------+
<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>2322</td>
<td>72</td>
</tr>
</tbody>
</table>
+--------+--------+
2 rows in set (0.00 sec)
```
14.18 Replication Functions

The functions described in the following sections are used with MySQL Replication.

### 14.18.1 Group Replication Functions

The functions described in the following sections are used with Group Replication.

#### 14.18.1.1 Function which Configures Group Replication Primary

The following function enables you to set a member of a single-primary replication group to take over as the primary. The current primary becomes a read-only secondary, and the specified group member becomes the read-write primary. The function can be used on any member of a replication group running in single-primary mode. This function replaces the usual primary election process; see Section 20.5.1.1, “Changing the Primary”, for more information.

If a standard source to replica replication channel is running on the existing primary member in addition to the Group Replication channels, you must stop that replication channel before you can change the primary member. You can identify the current primary using the `MEMBER_ROLE` column in the Performance Schema `replication_group_members` table.

Any uncommitted transactions that the group is waiting on must be committed, rolled back, or terminated before the operation can complete. You can specify a timeout for transactions that are
Group Replication Functions

running when you use the function. For the timeout to work, all members of the group must be MySQL 
version 8.0.29 or newer.

When the timeout expires, for any transactions that did not yet reach their commit phase, the client 
session is disconnected so that the transaction does not proceed. Transactions that reached their 
commit phase are allowed to complete. When you set a timeout, it also prevents new transactions 
starting on the primary from that point on. Explicitly defined transactions (with a START TRANSACTION 
or BEGIN statement) are subject to the timeout, disconnection, and incoming transaction blocking 
even if they do not modify any data. To allow inspection of the primary while the function is operating, 
single statements that do not modify data, as listed in Permitted Queries Under Consistency Rules, are 
permitted to proceed.

- group_replication_set_as_primary()

  Appoints a specific member of the group as the new primary, overriding any election process.

  Syntax:

  ```
  STRING group_replication_set_as_primary([member_uuid[, timeout]])
  ```

  Arguments:

  - **member_uuid**: A string containing the UUID of the member of the group that you want to become 
    the new primary.

  - **timeout**: An integer specifying a timeout in seconds for transactions that are running on the 
    existing primary when you use the function. You can set a timeout from 0 seconds (immediately) 
    up to 3600 seconds (60 minutes). When you set a timeout, new transactions cannot start on the 
    primary from that point on. There is no default setting for the timeout, so if you do not set it, there is 
    no upper limit to the wait time, and new transactions can start during that time.

  Return value:

  A string containing the result of the operation, for example whether it was successful or not.

  Example:

  ```
  SELECT group_replication_set_as_primary('00371d66-3c45-11ea-804b-080027337932', 300);
  ```

  This function waits for all ongoing transactions and DML operations to finish before electing the 
new primary. In MySQL 8.4, it also waits for the completion of any ongoing DDL statements such as 
ALTER TABLE. Operations that are considered DDL statements for this purpose are listed here:

  - ALTER DATABASE
  - ALTER FUNCTION
  - ALTER INSTANCE
  - ALTER PROCEDURE
  - ALTER SERVER
  - ALTER TABLE
  - ALTER TABLESPACE
  - ALTER USER
  - ALTER VIEW
  - ANALYZE TABLE
Group Replication Functions

- CACHE INDEX
- CHECK TABLE
- CREATE DATABASE
- CREATE FUNCTION
- CREATE INDEX
- CREATE ROLE
- CREATE PROCEDURE
- CREATE SERVER
- CREATE SPATIAL REFERENCE SYSTEM
- CREATE TABLE
- CREATE TABLESPACE
- CREATE TRIGGER
- CREATE USER
- CREATE VIEW
- DROP DATABASE
- DROP FUNCTION
- DROP INDEX
- DROP PROCEDURE
- DROP ROLE
- DROP SERVER
- DROP SPATIAL REFERENCE SYSTEM
- DROP TABLE
- DROP TABLESPACE
- DROP TRIGGER
- DROP USER
- DROP VIEW
- GRANT
- LOAD INDEX
- OPTIMIZE TABLE
- RENAME TABLE
- REPAIR TABLE
14.18.1.2 Functions which Configure the Group Replication Mode

The following functions enable you to control the mode which a replication group is running in, either single-primary or multi-primary mode.

- **group_replication_switch_to_multi_primary_mode()**

  Changes a group running in single-primary mode to multi-primary mode. Must be issued on a member of a replication group running in single-primary mode.

  Syntax:
  
  ```sql
  STRING group_replication_switch_to_multi_primary_mode()
  ```

  This function has no parameters.

  Return value:

  A string containing the result of the operation, for example whether it was successful or not.

  Example:
  
  ```sql
  SELECT group_replication_switch_to_multi_primary_mode()
  ```

  All members which belong to the group become primaries.

  For more information, see Section 20.5.1.2, “Changing the Group Mode”

- **group_replication_switch_to_single_primary_mode()**

  Changes a group running in multi-primary mode to single-primary mode, without the need to stop Group Replication. Must be issued on a member of a replication group running in multi-primary mode. When you change to single-primary mode, strict consistency checks are also disabled on all group members, as required in single-primary mode (`group_replication_enforce_update_everywhere_checks=OFF`).

  Syntax:
  
  ```sql
  STRING group_replication_switch_to_single_primary_mode([str])
  ```

  Arguments:

  - **str**: A string containing the UUID of a member of the group which should become the new single primary. Other members of the group become secondaries.

  Return value:

  A string containing the result of the operation, for example whether it was successful or not.

  Example:
  
  ```sql
  SELECT group_replication_switch_to_single_primary_mode(member_uuid);
  ```

  For more information, see Section 20.5.1.2, “Changing the Group Mode”
The following functions enable you to inspect and configure the maximum number of consensus instances that a group can execute in parallel.

- **group_replication_get_write_concurrency()**
  
  Check the maximum number of consensus instances that a group can execute in parallel.
  
  Syntax:
  ```sql
  INT group_replication_get_write_concurrency()
  ```
  
  This function has no parameters.
  
  Return value:
  The maximum number of consensus instances currently set for the group.
  
  Example:
  ```sql
  SELECT group_replication_get_write_concurrency();
  ```
  
  For more information, see Section 20.5.1.3, “Using Group Replication Group Write Consensus”.

- **group_replication_set_write_concurrency()**
  
  Configures the maximum number of consensus instances that a group can execute in parallel. The `GROUP_REPLICATION_ADMIN` privilege is required to use this function.
  
  Syntax:
  ```sql
  STRING group_replication_set_write_concurrency(instances)
  ```
  
  Arguments:
  - **members**: Sets the maximum number of consensus instances that a group can execute in parallel. Default value is 10, valid values are integers in the range of 10 to 200.
  
  Return value:
  Any resulting error as a string.
  
  Example:
  ```sql
  SELECT group_replication_set_write_concurrency(instances);
  ```
  
  For more information, see Section 20.5.1.3, “Using Group Replication Group Write Consensus”.

### 14.18.1.4 Functions to Inspect and Set the Group Replication Communication Protocol Version

The following functions enable you to inspect and configure the Group Replication communication protocol version that is used by a replication group.

- **Section 20.7.4, “Message Compression”**

- **Section 20.7.5, “Message Fragmentation”**

- **Section 20.7.3, “Single Consensus Leader”**

- **group_replication_get_communication_protocol()**
Inspect the Group Replication communication protocol version that is currently in use for a group.

Syntax:
```
STRING group_replication_get_communication_protocol()
```

This function has no parameters.

Return value:

The oldest MySQL Server version that can join this group and use the group's communication protocol. Note that the `group_replication_get_communication_protocol()` function returns the minimum MySQL version that the group supports, which might differ from the version number that was passed to `group_replication_set_communication_protocol()`, and from the MySQL Server version that is installed on the member where you use the function.

If the protocol cannot be inspected because this server instance does not belong to a replication group, an error is returned as a string.

Example:
```
SELECT group_replication_get_communication_protocol();
```

For more information, see Section 20.5.1.4, “Setting a Group’s Communication Protocol Version”.

• `group_replication_set_communication_protocol()`

Downgrade the Group Replication communication protocol version of a group so that members at earlier releases can join, or upgrade the Group Replication communication protocol version of a group after upgrading MySQL Server on all members. The `GROUP_REPLICATION_ADMIN` privilege is required to use this function, and all existing group members must be online when you issue the statement, with no loss of majority.

Note

For MySQL InnoDB cluster, the communication protocol version is managed automatically whenever the cluster topology is changed using AdminAPI operations. You do not have to use these functions yourself for an InnoDB cluster.

Syntax:
```
STRING group_replication_set_communication_protocol(version)
```

Arguments:

• `version`: For a downgrade, specify the MySQL Server version of the prospective group member that has the oldest installed server version. In this case, the command makes the group fall back to a communication protocol compatible with that server version if possible. The minimum server
version that you can specify is MySQL 5.7.14. For an upgrade, specify the new MySQL Server
version to which the existing group members have been upgraded.

Return value:

A string containing the result of the operation, for example whether it was successful or not.

Example:

```sql
SELECT group_replication_set_communication_protocol("5.7.25");
```

For more information, see Section 20.5.1.4, “Setting a Group’s Communication Protocol Version”.

14.18.1.5 Functions to Set and Reset Group Replication Member Actions

The following functions can be used to enable and disable actions for members of a group to take in
specified situations, and to reset the configuration to the default setting for all member actions. They
can only be used by administrators with the `GROUP_REPLICATION_ADMIN` privilege or the deprecated
`SUPER` privilege.

You configure member actions on the group’s primary using
the `group_replication_enable_member_action` and
`group_replication_disable_member_action` functions. The member actions configuration,
consisting of all the member actions and whether they are enabled or disabled, is then propagated to
other group members and joining members using Group Replication’s group messages. This means
that the group members will all act in the same way when they are in the specified situation, and you
only need to use the function on the primary.

The functions can also be used on a server that is not part of a group, as long as the Group Replication
plugin is installed. In that case, the member actions configuration is not propagated to any other
servers.

The `group_replication_reset_member_actions` function can only be used on a server that
is not part of a group. It resets the member actions configuration to the default settings, and resets its
version number. The server must be writeable (with the `read_only` system variable set to `OFF`) and
have the Group Replication plugin installed.

The available member actions are as follows:

- `mysql_disable_super_read_only_if_primary`

  This member action is taken after a member is elected as the
group’s primary, which is the event `AFTER_PRIMARY_ELECTION`. The member action is enabled by default. You can disable it
using the `group_replication_disable_member_action()` function, and re-enable it using
`group_replication_enable_member_action()`.

  When this member action is enabled and taken, super read-only
mode is disabled on the primary, so that the primary becomes read-
write and accepts updates from a replication source server and from
clients. This is the normal situation.

  When this member action is disabled and not taken, the primary
remains in super read-only mode after election. In this state, it
does not accept updates from any clients, even users who have
the `CONNECTION_ADMIN` or `SUPER` privilege. It does continue to
accept updates performed by replication threads. This setup means
that when a group’s purpose is to provide a secondary backup
to another group for disaster tolerance, you can ensure that the
secondary group remains synchronized with the first.
This member action is taken after a member is elected as the group's primary, which is the event `AFTER_PRIMARY_ELECTION`. The member action is enabled by default. You can disable it using the `group_replication_disable_member_action()` function, and re-enable it using the `group_replication_enable_member_action()` function.

When this member action is enabled, asynchronous connection failover for replicas is active for a replication channel on a Group Replication primary when you set `SOURCE_CONNECTION_AUTO_FAILOVER=1` in the `CHANGE REPLICATION SOURCE TO` statement for the channel. When the feature is active and correctly configured, if the primary that is replicating goes offline or into an error state, the new primary starts replication on the same channel when it is elected. This is the normal situation. For instructions to configure the feature, see Section 19.4.9.2, “Asynchronous Connection Failover for Replicas”.

When this member action is disabled, asynchronous connection failover does not take place for the replicas. If the primary goes offline or into an error state, replication stops for the channel. Note that if there is more than one channel with `SOURCE_CONNECTION_AUTO_FAILOVER=1`, the member action covers all the channels, so they cannot be individually enabled and disabled by this method. Set `SOURCE_CONNECTION_AUTO_FAILOVER=0` to disable an individual channel.

For more information on member actions and how to view the member actions configuration, see Section 20.5.1.5, “Configuring Member Actions”.

- `group_replication_disable_member_action()`

Disable a member action so that the member does not take it in the specified situation. If the server where you use the function is part of a group, it must be the current primary in a group in single-primary mode, and it must be part of the majority. The changed setting is propagated to other group members and joining members, so they will all act in the same way when they are in the specified situation, and you only need to use the function on the primary.

Syntax:

```sql
STRING group_replication_disable_member_action(name, event)
```

Arguments:

- `name`: The name of the member action to disable.
- `event`: The event that triggers the member action.

Return value:

A string containing the result of the operation, for example whether it was successful or not.

Example:

```sql
SELECT group_replication_disable_member_action("mysql_disable_super_read_only_if_primary", "AFTER_PRIMARY_ELECTION")
```

For more information, see Section 20.5.1.5, “Configuring Member Actions”.

- `group_replication_enable_member_action()`
Enable a member action for the member to take in the specified situation. If the server where you use the function is part of a group, it must be the current primary in a group in single-primary mode, and it must be part of the majority. The changed setting is propagated to other group members and joining members, so they will all act in the same way when they are in the specified situation, and you only need to use the function on the primary.

Syntax:

```
STRING group_replication_enable_member_action(name, event)
```

Arguments:

- `name`: The name of the member action to enable.
- `event`: The event that triggers the member action.

Return value:

A string containing the result of the operation, for example whether it was successful or not.

Example:

```
SELECT group_replication_enable_member_action("mysql_disable_super_read_only_if_primary", "AFTER_PRIMARY_ELECTION");
```

For more information, see Section 20.5.1.5, “Configuring Member Actions”.

**group_replication_reset_member_actions()**

Reset the member actions configuration to the default settings, and reset its version number to 1.

The `group_replication_reset_member_actions()` function can only be used on a server that is not currently part of a group. The server must be writeable (with the `read_only` system variable set to `OFF`) and have the Group Replication plugin installed. You can use this function to remove the member actions configuration that a server used when it was part of a group, if you intend to use it as a standalone server with no member actions or different member actions.

Syntax:

```
STRING group_replication_reset_member_actions()
```

Arguments:

None.

Return value:

A string containing the result of the operation, for example whether it was successful or not.

Example:

```
SELECT group_replication_reset_member_actions();
```

For more information, see Section 20.5.1.5, “Configuring Member Actions”.

### 14.18.2 Functions Used with Global Transaction Identifiers (GTIDs)

The functions described in this section are used with GTID-based replication. It is important to keep in mind that all of these functions take string representations of GTID sets as arguments. As such, the GTID sets must always be quoted when used with them. See GTID Sets for more information.
The union of two GTID sets is simply their representations as strings, joined together with an interposed comma. In other words, you can define a very simple function for obtaining the union of two GTID sets, similar to that created here:

```
CREATE FUNCTION GTID_UNION(g1 TEXT, g2 TEXT)
RETURNS TEXT DETERMINISTIC
RETURN CONCAT(g1,',',g2);
```

For more information about GTIDs and how these GTID functions are used in practice, see Section 19.1.3, “Replication with Global Transaction Identifiers”.

### Table 14.26 GTID Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WAIT_FOR_EXECUTED_GTID_SET()</td>
<td>Wait until the given GTIDs have executed on the replica.</td>
</tr>
</tbody>
</table>

**• GTID_SUBSET(set1, set2)**

Given two sets of global transaction identifiers `set1` and `set2`, returns true if all GTIDs in `set1` are also in `set2`. Returns NULL if `set1` or `set2` is NULL. Returns false otherwise.

The GTID sets used with this function are represented as strings, as shown in the following examples:

```sql
mysql> SELECT GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
                           '3E11FA47-71CA-11E1-9E33-C80AA9429562:23-25',
                           '3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25')
```

**• GTID_SUBTRACT(set1, set2)**

Given two sets of global transaction identifiers `set1` and `set2`, returns only those GTIDs from `set1` that are not in `set2`. Returns NULL if `set1` or `set2` is NULL.

All GTID sets used with this function are represented as strings and must be quoted, as shown in these examples:

```sql
mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
                            '3E11FA47-71CA-11E1-9E33-C80AA9429562:23-25',
                            '3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25')
```
Asynchronous Replication Channel Failover Functions

mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
                        -> '3E11FA47-71CA-11E1-9E33-C80AA9429562:23-24') \G
*************************** 1. row ***************************
GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
1 row in set (0.01 sec)

Subtracting a GTID set from itself produces an empty set, as shown here:

mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
                        -> '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57') \G
*************************** 1. row ***************************
GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
               '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57'): 1 row in set (0.00 sec)

• WAIT_FOR_EXECUTED_GTID_SET(gtid_set[, timeout])

Wait until the server has applied all of the transactions whose global transaction identifiers are contained in gtid_set; that is, until the condition GTID_SUBSET(gtid_subset, @@GLOBAL.gtid_executed) holds. See Section 19.1.3.1, “GTID Format and Storage” for a definition of GTID sets.

If a timeout is specified, and timeout seconds elapse before all of the transactions in the GTID set have been applied, the function stops waiting. timeout is optional, and the default timeout is 0 seconds, in which case the function always waits until all of the transactions in the GTID set have been applied. timeout must be greater than or equal to 0; when running in strict SQL mode, a negative timeout value is immediately rejected with an error (ER_WRONG_ARGUMENTS); otherwise the function returns NULL, and raises a warning.

WAIT_FOR_EXECUTED_GTID_SET() monitors all the GTIDs that are applied on the server, including transactions that arrive from all replication channels and user clients. It does not take into account whether replication channels have been started or stopped.

For more information, see Section 19.1.3, “Replication with Global Transaction Identifiers”.

GTID sets used with this function are represented as strings and so must be quoted as shown in the following example:

mysql> SELECT WAIT_FOR_EXECUTED_GTID_SET('3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5');
                         -> 0

For a syntax description for GTID sets, see Section 19.1.3.1, “GTID Format and Storage”.

For WAIT_FOR_EXECUTED_GTID_SET(), the return value is the state of the query, where 0 represents success, and 1 represents timeout. Any other failures generate an error.

gtid_mode cannot be changed to OFF while any client is using this function to wait for GTIDs to be applied.

14.18.3 Asynchronous Replication Channel Failover Functions

The following functions enable you to add or remove replication source servers to or from the source list for a replication channel, as well as clear the source list for a given server.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>asynchnous_connection_failover_add</td>
<td>Add group member source server configuration information to a replication channel source list</td>
</tr>
<tr>
<td>asynchnous_connection_failover_add</td>
<td>Add source server configuration information server to a replication channel source list</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>asynchnous_connection_failover_add</td>
<td>Add group member source server configuration information to a replication channel source list</td>
</tr>
<tr>
<td>asynchnous_connection_failover_add</td>
<td>Add source server configuration information server to a replication channel source list</td>
</tr>
</tbody>
</table>

2334
### Asynchronous Replication Channel Failover Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>asynchronous_connection_failover_delete_managed()</code></td>
<td>Remove a managed group from a replication channel source list</td>
</tr>
<tr>
<td><code>asynchronous_connection_failover_delete_source()</code></td>
<td>Remove a source server from a replication channel source list</td>
</tr>
<tr>
<td><code>asynchronous_connection_failover_reset()</code></td>
<td>Remove all settings relating to group replication asynchronous failover</td>
</tr>
</tbody>
</table>

The asynchronous connection failover mechanism automatically establishes an asynchronous (source to replica) replication connection to a new source from the appropriate list after the existing connection from the replica to its source fails. The connection is also changed if the currently connected source does not have the highest weighted priority in the group. For Group Replication source servers that are defined as part of a managed group, the connection is also failed over to another group member if the currently connected source leaves the group or is no longer in the majority. For more information on the mechanism, see Section 19.4.9, “Switching Sources and Replicas with Asynchronous Connection Failover”.

Source lists are stored in the `mysql.replication_asynchronous_connection_failover` and `mysql.replication_asynchronous_connection_failover_managed` tables, and can be viewed in the Performance Schema `replication_asynchronous_connection_failover` table.

If the replication channel is on a Group Replication primary for a group where failover between replicas is active, the source list is broadcast to all the group members when they join or when it is updated by any method. Failover between replicas is controlled by the `mysql_start_failover_channels_if_primary` member action, which is enabled by default, and can be disabled using the `group_replication_disable_member_action` function.

- `asynchronous_connection_failover_add_managed()`

  Add configuration information for a replication source server that is part of a managed group (a Group Replication group member) to the source list for a replication channel. You only need to add one group member. The replica automatically adds the rest from the current group membership, then keeps the source list updated in line with membership change.

**Syntax:**

```sql
asynchronous_connection_failover_add_managed(channel, managed_type, managed_name, host, port, network_namespace, primary_weight, secondary_weight)
```

**Arguments:**

- **channel**: The replication channel for which this replication source server is part of the source list.
- **managed_type**: The type of managed service that the asynchronous connection failover mechanism must provide for this server. The only value currently accepted is `GroupReplication`.
- **managed_name**: The identifier for the managed group that the server is a part of. For the `GroupReplication` managed service, the identifier is the value of the `group_replication_group_name` system variable.
- **host**: The host name for this replication source server.
- **port**: The port number for this replication source server.
- **network_namespace**: The network namespace for this replication source server. Specify an empty string, as this parameter is reserved for future use.
- **primary_weight**: The priority of this replication source server in the replication channel's source list when it is acting as the primary for the managed group. The weight is from 1 to 100, with 100 being the highest. For the primary, 80 is a suitable weight. The asynchronous connection failover...
Asynchronous Replication Channel Failover Functions

mechanism activates if the currently connected source is not the highest weighted in the group. Assuming that you set up the managed group to give a higher weight to a primary and a lower weight to a secondary, when the primary changes, its weight increases, and the replica changes over the connection to it.

- **secondary_weight**: The priority of this replication source server in the replication channel's source list when it is acting as a secondary in the managed group. The weight is from 1 to 100, with 100 being the highest. For a secondary, 60 is a suitable weight.

Return value:

A string containing the result of the operation, for example whether it was successful or not.

Example:

```sql
SELECT asynchronous_connection_failover_add_managed('channel2', 'GroupReplication', 'aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa', '127.0.0.1', 3310, '', 80, 60);
```

+----------------------------------------------------------------------------------------------------------------------------------------------------+
| asynchronous_connection_failover_add_managed('channel2', 'GroupReplication', 'aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa', '127.0.0.1', 3310, '', 80, 60) |
+----------------------------------------------------------------------------------------------------------------------------------------------------+
| Source managed configuration details successfully inserted.                                                                                         |
+----------------------------------------------------------------------------------------------------------------------------------------------------+

For more information, see Section 19.4.9, “Switching Sources and Replicas with Asynchronous Connection Failover”.

- **asynchronous_connection_failover_add_source()**

Add configuration information for a replication source server to the source list for a replication channel.

Syntax:

```sql
asynchronous_connection_failover_add_source(channel, host, port, network_namespace, weight)
```

Arguments:

- **channel**: The replication channel for which this replication source server is part of the source list.
- **host**: The host name for this replication source server.
- **port**: The port number for this replication source server.
- **network_namespace**: The network namespace for this replication source server. Specify an empty string, as this parameter is reserved for future use.
- **weight**: The priority of this replication source server in the replication channel's source list. The priority is from 1 to 100, with 100 being the highest, and 50 being the default. When the asynchronous connection failover mechanism activates, the source with the highest priority setting among the alternative sources listed in the source list for the channel is chosen for the first connection attempt. If this attempt does not work, the replica tries with all the listed sources in descending order of priority, then starts again from the highest priority source. If multiple sources have the same priority, the replica orders them randomly. The asynchronous connection failover mechanism activates if the source currently connected is not the highest weighted in the group.

Return value:

A string containing the result of the operation, for example whether it was successful or not.

Example:

```sql
SELECT asynchronous_connection_failover_add_source('channel2', '127.0.0.1', 3310, '', 80);
```

+-------------------------------------------------------------------------------------------------+
| asynchronous_connection_failover_add_source('channel2', '127.0.0.1', 3310, '', 80)              |
| Source managed configuration details successfully inserted.                                    |
+-------------------------------------------------------------------------------------------------+
Asynchronous Replication Channel Failover Functions

Source configuration details successfully inserted.

For more information, see Section 19.4.9, “Switching Sources and Replicas with Asynchronous Connection Failover”.

- **asynchronous_connection_failover_delete_managed()**

  Remove an entire managed group from the source list for a replication channel. When you use this function, all the replication source servers defined in the managed group are removed from the channel's source list.

  **Syntax:**
  
  ```plaintext
  asynchronous_connection_failover_delete_managed(channel, managed_name)
  ```

  **Arguments:**

  - **channel**: The replication channel for which this replication source server was part of the source list.
  - **managed_name**: The identifier for the managed group that the server is a part of. For the GroupReplication managed service, the identifier is the value of the `group_replication_group_name` system variable.

  **Return value:**

  A string containing the result of the operation, for example whether it was successful or not.

  **Example:**

  ```sql
  SELECT asynchronous_connection_failover_delete_managed('channel2', 'aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa');
  ```

  Source managed configuration details successfully deleted.

  For more information, see Section 19.4.9, “Switching Sources and Replicas with Asynchronous Connection Failover”.

  2337
• **asynchronous_connection_failover_delete_source()**

Remove configuration information for a replication source server from the source list for a replication channel.

Syntax:

```sql
asynchronous_connection_failover_delete_source(channel, host, port, network_namespace)
```

Arguments:

- **channel**: The replication channel for which this replication source server was part of the source list.
- **host**: The host name for this replication source server.
- **port**: The port number for this replication source server.
- **network_namespace**: The network namespace for this replication source server. Specify an empty string, as this parameter is reserved for future use.

Return value:

A string containing the result of the operation, for example whether it was successful or not.

Example:

```sql
SELECT asynchronous_connection_failover_delete_source('channel2', '127.0.0.1', 3310, '');
```

For more information, see Section 19.4.9, “Switching Sources and Replicas with Asynchronous Connection Failover”.

• **asynchronous_connection_failover_reset()**

Remove all settings relating to the asynchronous connection failover mechanism. The function clears the Performance Schema tables `replication_asynchronous_connection_failover` and `replication_asynchronous_connection_failover Managed`.

`asynchronous_connection_failover_reset()` can be used only on a server that is not currently part of a group, and that does not have any replication channels running. You can use this function to clean up a server that is no longer being used in a managed group.

Syntax:

```sql
STRING asynchronous_connection_failover_reset()
```

Arguments:

None.

Return value:

A string containing the result of the operation, for example whether it was successful or not.

Example:

```sql
mysql> SELECT asynchronous_connection_failover_reset();
```
The functions listed in this section are used for controlling position-based synchronization of source and replica servers in MySQL Replication.

### Table 14.28 Positional Synchronization Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Deprecated</th>
</tr>
</thead>
<tbody>
<tr>
<td>MASTER_POS_WAIT()</td>
<td>Block until the replica has read and applied all updates up to the specified position</td>
<td>Yes</td>
</tr>
<tr>
<td>SOURCE_POS_WAIT()</td>
<td>Block until the replica has read and applied all updates up to the specified position</td>
<td></td>
</tr>
</tbody>
</table>

- **MASTER_POS_WAIT**(log_name, log_pos[, timeout][, channel])
  - Deprecated alias for **SOURCE_POS_WAIT()**.
- **SOURCE_POS_WAIT**(log_name, log_pos[, timeout][, channel])

This function is for control of source-replica synchronization. It blocks until the replica has read and applied all updates up to the specified position in the source’s binary log.

The return value is the number of log events the replica had to wait for to advance to the specified position. The function returns **NULL** if the replication SQL thread is not started, the replica’s source information is not initialized, the arguments are incorrect, or an error occurs. It returns **-1** if the timeout has been exceeded. If the replication SQL thread stops while **SOURCE_POS_WAIT()** is waiting, the function returns **NULL**. If the replica is past the specified position, the function returns immediately.

If the binary log file position has been marked as invalid, the function waits until a valid file position is known. The binary log file position can be marked as invalid when the `CHANGE REPLICATION SOURCE TO` option `GTID_ONLY` is set for the replication channel, and the server is restarted or replication is stopped. The file position becomes valid after a transaction is successfully applied past the given file position. If the applier does not reach the stated position, the function waits until the timeout. Use a **SHOW REPLICA STATUS** statement to check if the binary log file position has been marked as invalid.

On a multithreaded replica, the function waits until expiry of the limit set by the `replica_checkpoint_group` or `replica_checkpoint_period` system variable, when the checkpoint operation is called to update the status of the replica. Depending on the setting for the system variables, the function might therefore return some time after the specified position was reached.

If binary log transaction compression is in use and the transaction payload at the specified position is compressed (as a Transaction_payload_event), the function waits until the whole transaction has been read and applied, and the positions have updated.

If a **timeout** value is specified, **SOURCE_POS_WAIT()** stops waiting when **timeout** seconds have elapsed. **timeout** must be greater than or equal to 0. (When the server is running in strict SQL...
mode, a negative timeout value is immediately rejected with ER_WRONG_ARGUMENTS; otherwise the function returns NULL, and raises a warning.)

The optional channel value enables you to name which replication channel the function applies to. See Section 19.2.2, “Replication Channels” for more information.

This function is unsafe for statement-based replication. A warning is logged if you use this function when binlog_format is set to STATEMENT.

14.19 Aggregate Functions

Aggregate functions operate on sets of values. They are often used with a GROUP BY clause to group values into subsets. This section describes most aggregate functions. For information about aggregate functions that operate on geometry values, see Section 14.16.12, “Spatial Aggregate Functions”.

14.19.1 Aggregate Function Descriptions

This section describes aggregate functions that operate on sets of values. They are often used with a GROUP BY clause to group values into subsets.

Table 14.29 Aggregate Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AVG()</td>
<td>Return the average value of the argument</td>
</tr>
<tr>
<td>BIT_AND()</td>
<td>Return bitwise AND</td>
</tr>
<tr>
<td>BIT_OR()</td>
<td>Return bitwise OR</td>
</tr>
<tr>
<td>BIT_XOR()</td>
<td>Return bitwise XOR</td>
</tr>
<tr>
<td>COUNT()</td>
<td>Return a count of the number of rows returned</td>
</tr>
<tr>
<td>COUNT(DISTINCT)</td>
<td>Return the count of a number of different values</td>
</tr>
<tr>
<td>GROUP_CONCAT()</td>
<td>Return a concatenated string</td>
</tr>
<tr>
<td>JSON_ARRAYAGG()</td>
<td>Return result set as a single JSON array</td>
</tr>
<tr>
<td>JSON_OBJECTAGG()</td>
<td>Return result set as a single JSON object</td>
</tr>
<tr>
<td>MAX()</td>
<td>Return the maximum value</td>
</tr>
<tr>
<td>MIN()</td>
<td>Return the minimum value</td>
</tr>
<tr>
<td>STD()</td>
<td>Return the population standard deviation</td>
</tr>
<tr>
<td>STDDEV()</td>
<td>Return the population standard deviation</td>
</tr>
<tr>
<td>STDDEV_POP()</td>
<td>Return the population standard deviation</td>
</tr>
<tr>
<td>STDDEV_SAMP()</td>
<td>Return the sample standard deviation</td>
</tr>
<tr>
<td>SUM()</td>
<td>Return the sum</td>
</tr>
<tr>
<td>VAR_POP()</td>
<td>Return the population standard variance</td>
</tr>
<tr>
<td>VAR_SAMP()</td>
<td>Return the sample variance</td>
</tr>
<tr>
<td>VARIANCE()</td>
<td>Return the population standard variance</td>
</tr>
</tbody>
</table>

Unless otherwise stated, aggregate functions ignore NULL values.

If you use an aggregate function in a statement containing no GROUP BY clause, it is equivalent to grouping on all rows. For more information, see Section 14.19.3, “MySQL Handling of GROUP BY”.

Most aggregate functions can be used as window functions. Those that can be used this way are signified in their syntax description by [over_clause], representing an optional OVER clause. over_clause is described in Section 14.20.2, “Window Function Concepts and Syntax”, which also includes other information about window function usage.
Aggregate Function Descriptions

For numeric arguments, the variance and standard deviation functions return a **DOUBLE** value. The **SUM()** and **AVG()** functions return a **DECIMAL** value for exact-value arguments (integer or **DECIMAL**), and a **DOUBLE** value for approximate-value arguments (**FLOAT** or **DOUBLE**).

The **SUM()** and **AVG()** aggregate functions do not work with temporal values. (They convert the values to numbers, losing everything after the first nonnumeric character.) To work around this problem, convert to numeric units, perform the aggregate operation, and convert back to a temporal value.

Examples:

```sql
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

Functions such as **SUM()** or **AVG()** that expect a numeric argument cast the argument to a number if necessary. For **SET** or **ENUM** values, the cast operation causes the underlying numeric value to be used.

The **BIT_AND()**, **BIT_OR()**, and **BIT_XOR()** aggregate functions perform bit operations.

MySQL bit functions and operators permit binary string type arguments (**BINARY**, **VARBINARY**, and the **BLOB** types) and return a value of like type, which enables them to take arguments and produce return values larger than 64 bits. For discussion about argument evaluation and result types for bit operations, see the introductory discussion in Section 14.12, “Bit Functions and Operators”.

- **AVG([DISTINCT] expr) [over_clause]**

  Returns the average value of **expr**. The **DISTINCT** option can be used to return the average of the distinct values of **expr**.

  If there are no matching rows, **AVG()** returns **NULL**. The function also returns **NULL** if **expr** is **NULL**.

  This function executes as a window function if **over_clause** is present. **over_clause** is as described in Section 14.20.2, “Window Function Concepts and Syntax”; it cannot be used with **DISTINCT**.

  ```sql
  mysql> SELECT student_name, AVG(test_score)
               FROM student
               GROUP BY student_name;
  ```

- **BIT_AND(expr) [over_clause]**

  Returns the bitwise **AND** of all bits in **expr**.

  The result type depends on whether the function argument values are evaluated as binary strings or numbers:

  - Binary-string evaluation occurs when the argument values have a binary string type, and the argument is not a hexadecimal literal, bit literal, or **NULL** literal. Numeric evaluation occurs otherwise, with argument value conversion to unsigned 64-bit integers as necessary.

  - Binary-string evaluation produces a binary string of the same length as the argument values. If argument values have unequal lengths, an **ER_INVALID_BITWISE_OPERANDS_SIZE** error occurs. If the argument size exceeds 511 bytes, an **ER_INVALID_BITWISE_AGGREGATE_OPERANDS_SIZE** error occurs. Numeric evaluation produces an unsigned 64-bit integer.

  If there are no matching rows, **BIT_AND()** returns a neutral value (all bits set to 1) having the same length as the argument values.

  **NULL** values do not affect the result unless all values are **NULL**. In that case, the result is a neutral value having the same length as the argument values.

  For more information discussion about argument evaluation and result types, see the introductory discussion in Section 14.12, “Bit Functions and Operators”.

2341
If `BIT_AND()` is invoked from within the `mysql` client, binary string results display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 6.5.1, “mysql — The MySQL Command-Line Client”.

This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 14.20.2, “Window Function Concepts and Syntax”.

- **BIT_OR(expr) [over_clause]**

  Returns the bitwise OR of all bits in `expr`.

  The result type depends on whether the function argument values are evaluated as binary strings or numbers:

  - Binary-string evaluation occurs when the argument values have a binary string type, and the argument is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument value conversion to unsigned 64-bit integers as necessary.

  - Binary-string evaluation produces a binary string of the same length as the argument values. If argument values have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. If the argument size exceeds 511 bytes, an `ER_INVALID_BITWISE_AGGREGATE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

  If there are no matching rows, `BIT_OR()` returns a neutral value (all bits set to 0) having the same length as the argument values.

  `NULL` values do not affect the result unless all values are `NULL`. In that case, the result is a neutral value having the same length as the argument values.

  For more information discussion about argument evaluation and result types, see the introductory discussion in Section 14.12, “Bit Functions and Operators”.

  If `BIT_OR()` is invoked from within the `mysql` client, binary string results display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 6.5.1, “mysql — The MySQL Command-Line Client”.

  This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 14.20.2, “Window Function Concepts and Syntax”.

- **BIT_XOR(expr) [over_clause]**

  Returns the bitwise XOR of all bits in `expr`.

  The result type depends on whether the function argument values are evaluated as binary strings or numbers:

  - Binary-string evaluation occurs when the argument values have a binary string type, and the argument is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument value conversion to unsigned 64-bit integers as necessary.

  - Binary-string evaluation produces a binary string of the same length as the argument values. If argument values have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. If the argument size exceeds 511 bytes,
an ER_INVALID_BITWISE_AGGREGATE_OPERANDS_SIZE error occurs. Numeric evaluation produces an unsigned 64-bit integer.

If there are no matching rows, BIT_XOR() returns a neutral value (all bits set to 0) having the same length as the argument values.

NULL values do not affect the result unless all values are NULL. In that case, the result is a neutral value having the same length as the argument values.

For more information discussion about argument evaluation and result types, see the introductory discussion in Section 14.12, “Bit Functions and Operators”.

If BIT_XOR() is invoked from within the mysql client, binary string results display using hexadecimal notation, depending on the value of the --binary-as-hex. For more information about that option, see Section 6.5.1, “mysql — The MySQL Command-Line Client”.

This function executes as a window function if over_clause is present. over_clause is as described in Section 14.20.2, “Window Function Concepts and Syntax”.

• COUNT(expr) [over_clause]

Returns a count of the number of non-NULL values of expr in the rows retrieved by a SELECT statement. The result is a BIGINT value.

If there are no matching rows, COUNT() returns 0. COUNT(NULL) returns 0.

This function executes as a window function if over_clause is present. over_clause is as described in Section 14.20.2, “Window Function Concepts and Syntax”.

```
mysql> SELECT student.student_name, COUNT(*) 
    FROM student, course 
    WHERE student.student_id=course.student_id 
    GROUP BY student_name;
```

COUNT(*) is somewhat different in that it returns a count of the number of rows retrieved, whether or not they contain NULL values.

For transactional storage engines such as InnoDB, storing an exact row count is problematic. Multiple transactions may be occurring at the same time, each of which may affect the count.

InnoDB does not keep an internal count of rows in a table because concurrent transactions might “see” different numbers of rows at the same time. Consequently, SELECT COUNT(*) statements only count rows visible to the current transaction.

```
SELECT COUNT(*) FROM tbl_name query performance for InnoDB tables is optimized for single-threaded workloads if there are no extra clauses such as WHERE or GROUP BY.
```

InnoDB processes SELECT COUNT(*) statements by traversing the smallest available secondary index unless an index or optimizer hint directs the optimizer to use a different index. If a secondary index is not present, InnoDB processes SELECT COUNT(*) statements by scanning the clustered index.

Processing of SELECT COUNT(*) statements takes some time if index records are not entirely in the buffer pool. For a faster count, create a counter table and let your application update it according to the inserts and deletes it does. However, this method may not scale well in situations
 Aggregate Function Descriptions

where thousands of concurrent transactions are initiating updates to the same counter table. If an approximate row count is sufficient, use `SHOW TABLE STATUS`.

**InnoDB** handles `SELECT COUNT(*)` and `SELECT COUNT(1)` operations in the same way. There is no performance difference.

For **MyISAM** tables, `COUNT(*)` is optimized to return very quickly if the `SELECT` retrieves from one table, no other columns are retrieved, and there is no `WHERE` clause. For example:

```sql
mysql> SELECT COUNT(*) FROM student;
```

This optimization only applies to **MyISAM** tables, because an exact row count is stored for this storage engine and can be accessed very quickly. `COUNT(1)` is only subject to the same optimization if the first column is defined as **NOT NULL**.

- `COUNT(DISTINCT expr,[expr...])`

Returns a count of the number of rows with different non-**NULL** `expr` values.

If there are no matching rows, `COUNT(DISTINCT)` returns 0.

```sql
mysql> SELECT COUNT(DISTINCT results) FROM student;
```

In MySQL, you can obtain the number of distinct expression combinations that do not contain **NULL** by giving a list of expressions. In standard SQL, you would have to do a concatenation of all expressions inside `COUNT(DISTINCT ...)`.

- `GROUP_CONCAT(expr)`

This function returns a string result with the concatenated non-**NULL** values from a group. It returns **NULL** if there are no non-**NULL** values. The full syntax is as follows:

```
GROUP_CONCAT([DISTINCT] expr [,expr ...] [ORDER BY {unsigned_integer | col_name | expr} [ASC | DESC] [,col_name ...]] [SEPARATOR str_val])
```

```sql
mysql> SELECT student_name, GROUP_CONCAT(test_score) FROM student GROUP BY student_name;
```

Or:

```sql
mysql> SELECT student_name, GROUP_CONCAT(DISTINCT test_score ORDER BY test_score DESC SEPARATOR '') FROM student GROUP BY student_name;
```

In MySQL, you can get the concatenated values of expression combinations. To eliminate duplicate values, use the **DISTINCT** clause. To sort values in the result, use the **ORDER BY** clause. To sort in reverse order, add the **DESC** (descending) keyword to the name of the column you are sorting by in the **ORDER BY** clause. The default is ascending order; this may be specified explicitly using the **ASC** keyword. The default separator between values in a group is comma (,). To specify a separator explicitly, use **SEPARATOR** followed by the string literal value that should be inserted between group values. To eliminate the separator altogether, specify **SEPARATOR ' '**.

The result is truncated to the maximum length that is given by the `group_concat_max_len` system variable, which has a default value of 1024. The value can be set higher, although the effective maximum length of the return value is constrained by the value of `max_allowed_packet`. The
Aggregate Function Descriptions

Syntax to change the value of `group_concat_max_len` at runtime is as follows, where `val` is an unsigned integer:

```
SET [GLOBAL | SESSION] group_concat_max_len = val;
```

The return value is a nonbinary or binary string, depending on whether the arguments are nonbinary or binary strings. The result type is `TEXT` or `BLOB` unless `group_concat_max_len` is less than or equal to 512, in which case the result type is `VARCHAR` or `VARBINARY`.

If `GROUP_CONCAT()` is invoked from within the `mysql` client, binary string results display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 6.5.1, “mysql — The MySQL Command-Line Client”.

See also `CONCAT()` and `CONCAT_WS()` : Section 14.8, “String Functions and Operators”.

- **JSON_ARRAYAGG**(col_or_expr) [over_clause]

Aggregates a result set as a single JSON array whose elements consist of the rows. The order of elements in this array is undefined. The function acts on a column or an expression that evaluates to a single value. Returns `NULL` if the result contains no rows, or in the event of an error. If `col_or_expr` is `NULL`, the function returns an array of JSON `[null]` elements.

This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 14.20.2, “Window Function Concepts and Syntax”.

```
mysql> SELECT o_id, attribute, value FROM t3;
+----+---------+------+
<table>
<thead>
<tr>
<th>o_id</th>
<th>attribute</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>color</td>
<td>red</td>
</tr>
<tr>
<td>2</td>
<td>fabric</td>
<td>silk</td>
</tr>
<tr>
<td>3</td>
<td>color</td>
<td>green</td>
</tr>
<tr>
<td>3</td>
<td>shape</td>
<td>square</td>
</tr>
</tbody>
</table>
+----+---------+------+
4 rows in set (0.00 sec)
mysql> SELECT o_id, JSON_ARRAYAGG(attribute) AS attributes 
-> FROM t3 GROUP BY o_id;
+----+----------------------------------------+
<table>
<thead>
<tr>
<th>o_id</th>
<th>attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>[&quot;color&quot;, &quot;fabric&quot;]</td>
</tr>
<tr>
<td>3</td>
<td>[&quot;color&quot;, &quot;shape&quot;]</td>
</tr>
</tbody>
</table>
+----+----------------------------------------+
2 rows in set (0.00 sec)
```

- **JSON_OBJECTAGG**(key, value) [over_clause]

Takes two column names or expressions as arguments, the first of these being used as a key and the second as a value, and returns a JSON object containing key-value pairs. Returns `NULL` if the result contains no rows, or in the event of an error. An error occurs if any key name is `NULL` or the number of arguments is not equal to 2.

This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 14.20.2, “Window Function Concepts and Syntax”.

```
mysql> SELECT o_id, attribute, value FROM t3;
+----+---------+------+
<table>
<thead>
<tr>
<th>o_id</th>
<th>attribute</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>color</td>
<td>red</td>
</tr>
<tr>
<td>2</td>
<td>fabric</td>
<td>silk</td>
</tr>
<tr>
<td>3</td>
<td>color</td>
<td>green</td>
</tr>
<tr>
<td>3</td>
<td>shape</td>
<td>square</td>
</tr>
</tbody>
</table>
+----+---------+------+
4 rows in set (0.00 sec)
mysql> SELECT o_id, JSON_OBJECTAGG(attribute) AS attributes 
-> FROM t3 GROUP BY o_id;
+----+----------------------------------------+
<table>
<thead>
<tr>
<th>o_id</th>
<th>attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>[&quot;color&quot;, &quot;fabric&quot;]</td>
</tr>
<tr>
<td>3</td>
<td>[&quot;color&quot;, &quot;shape&quot;]</td>
</tr>
</tbody>
</table>
+----+----------------------------------------+
2 rows in set (0.00 sec)
```
Duplicate key handling. When the result of this function is normalized, values having duplicate keys are discarded. In keeping with the MySQL JSON data type specification that does not permit duplicate keys, only the last value encountered is used with that key in the returned object (“last duplicate key wins”). This means that the result of using this function on columns from a SELECT can depend on the order in which the rows are returned, which is not guaranteed.

When used as a window function, if there are duplicate keys within a frame, only the last value for the key is present in the result. The value for the key from the last row in the frame is deterministic if the ORDER BY specification guarantees that the values have a specific order. If not, the resulting value of the key is nondeterministic.

Consider the following:

```sql
mysql> CREATE TABLE t(c VARCHAR(10), i INT);
Query OK, 0 rows affected (0.33 sec)

mysql> INSERT INTO t VALUES ('key', 3), ('key', 4), ('key', 5);
Query OK, 3 rows affected (0.10 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT c, i FROM t;
+------|------+
| c    | i    |
+------|------+
| key  | 3    |
| key  | 4    |
| key  | 5    |
+------|------+
3 rows in set (0.00 sec)

mysql> SELECT JSON_OBJECTAGG(c, i) FROM t;
+----------------------+
| JSON_OBJECTAGG(c, i) |
+----------------------+
| {"key": 5}          |
+----------------------+
1 row in set (0.00 sec)

mysql> DELETE FROM t;
Query OK, 3 rows affected (0.08 sec)

mysql> INSERT INTO t VALUES ('key', 3), ('key', 5), ('key', 4);
Query OK, 3 rows affected (0.06 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT c, i FROM t;
+------|------+
| c    | i    |
+------|------+
| key  | 3    |
| key  | 5    |
| key  | 4    |
+------|------+
3 rows in set (0.00 sec)

mysql> SELECT JSON_OBJECTAGG(c, i) FROM t;
+----------------------+
| JSON_OBJECTAGG(c, i) |
+----------------------+
```

2346
The key chosen from the last query is nondeterministic. If the query does not use `GROUP BY` (which usually imposes its own ordering regardless) and you prefer a particular key ordering, you can invoke `JSON_OBJECTAGG()` as a window function by including an `OVER` clause with an `ORDER BY` specification to impose a particular order on frame rows. The following examples show what happens with and without `ORDER BY` for a few different frame specifications.

Without `ORDER BY`, the frame is the entire partition:

```sql
mysql> SELECT JSON_OBJECTAGG(c, i)
    ...:     OVER () AS json_object FROM t;
+-------------+
| json_object |
| {"key": 4}  |
| {"key": 4}  |
| {"key": 4}  |
+-------------+
```

With `ORDER BY`, where the frame is the default of `RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW` (in both ascending and descending order):

```sql
mysql> SELECT JSON_OBJECTAGG(c, i)
    ...:     OVER (ORDER BY i) AS json_object FROM t;
+-------------+
| json_object |
| {"key": 3}  |
| {"key": 4}  |
| {"key": 5}  |
+-------------+

mysql> SELECT JSON_OBJECTAGG(c, i)
    ...:     OVER (ORDER BY i DESC) AS json_object FROM t;
+-------------+
| json_object |
| {"key": 5}  |
| {"key": 4}  |
| {"key": 3}  |
+-------------+
```

With `ORDER BY` and an explicit frame of the entire partition:

```sql
mysql> SELECT JSON_OBJECTAGG(c, i)
    ...:     OVER (ORDER BY i
    ...:              ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING)
    ...:     AS json_object
    ...: FROM t;
+-------------+
| json_object |
| {"key": 5}  |
| {"key": 5}  |
| {"key": 5}  |
+-------------+
```

To return a particular key value (such as the smallest or largest), include a `LIMIT` clause in the appropriate query. For example:

```sql
mysql> SELECT JSON_OBJECTAGG(c, i)
    ...:     OVER (ORDER BY i) AS json_object FROM t LIMIT 1;
+-------------+
| json_object |
| {"key": 3}  |
+-------------+
```
### Aggregate Function Descriptions

**mysql>** SELECT JSON_OBJECTAGG(c, i)
  OVER (ORDER BY i DESC) AS json_object FROM t LIMIT 1;

<table>
<thead>
<tr>
<th>json_object</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;key&quot;: 5}</td>
</tr>
</tbody>
</table>

See [Normalization, Merging, and Autowrapping of JSON Values](#), for additional information and examples.

- **MAX([DISTINCT] expr) [over_clause]**

  Returns the maximum value of *expr*. `MAX()` may take a string argument; in such cases, it returns the maximum string value. See [Section 10.3.1, “How MySQL Uses Indexes”](#). The `DISTINCT` keyword can be used to find the maximum of the distinct values of *expr*, however, this produces the same result as omitting `DISTINCT`.

  If there are no matching rows, or if *expr* is `NULL`, `MAX()` returns `NULL`.

  This function executes as a window function if `over_clause` is present. `over_clause` is as described in [Section 14.20.2, “Window Function Concepts and Syntax”](#); it cannot be used with `DISTINCT`.

```sql
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
  FROM student
  GROUP BY student_name;
```

For `MAX()`, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string's relative position in the set. This differs from how `ORDER BY` compares them.

- **MIN([DISTINCT] expr) [over_clause]**

  Returns the minimum value of *expr*. `MIN()` may take a string argument; in such cases, it returns the minimum string value. See [Section 10.3.1, “How MySQL Uses Indexes”](#). The `DISTINCT` keyword can be used to find the minimum of the distinct values of *expr*, however, this produces the same result as omitting `DISTINCT`.

  If there are no matching rows, or if *expr* is `NULL`, `MIN()` returns `NULL`.

  This function executes as a window function if `over_clause` is present. `over_clause` is as described in [Section 14.20.2, “Window Function Concepts and Syntax”](#); it cannot be used with `DISTINCT`.

```sql
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
  FROM student
  GROUP BY student_name;
```

For `MIN()`, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string's relative position in the set. This differs from how `ORDER BY` compares them.

- **STD(expr) [over_clause]**

  Returns the population standard deviation of *expr*. `STD()` is a synonym for the standard SQL function `STDDEV_POP()` provided as a MySQL extension.

  If there are no matching rows, or if *expr* is `NULL`, `STD()` returns `NULL`.

  This function executes as a window function if `over_clause` is present. `over_clause` is as described in [Section 14.20.2, “Window Function Concepts and Syntax”](#).
• **STDDEV**(expr) [over_clause]

  Returns the population standard deviation of expr. STDDEV() is a synonym for the standard SQL function STDDEV_POP(), provided for compatibility with Oracle.

  If there are no matching rows, or if expr is NULL, STDDEV() returns NULL.

  This function executes as a window function if over_clause is present. over_clause is as described in Section 14.20.2, “Window Function Concepts and Syntax”.

• **STDDEV_POP**(expr) [over_clause]

  Returns the population standard deviation of expr (the square root of VAR_POP()). You can also use STD() or STDDEV(), which are equivalent but not standard SQL.

  If there are no matching rows, or if expr is NULL, STDDEV_POP() returns NULL.

  This function executes as a window function if over_clause is present. over_clause is as described in Section 14.20.2, “Window Function Concepts and Syntax”.

• **STDDEV_SAMP**(expr) [over_clause]

  Returns the sample standard deviation of expr (the square root of VAR_SAMP()).

  If there are no matching rows, or if expr is NULL, STDDEV_SAMP() returns NULL.

  This function executes as a window function if over_clause is present. over_clause is as described in Section 14.20.2, “Window Function Concepts and Syntax”.

• **SUM**([DISTINCT] expr) [over_clause]

  Returns the sum of expr. If the return set has no rows, SUM() returns NULL. The DISTINCT keyword can be used to sum only the distinct values of expr.

  If there are no matching rows, or if expr is NULL, SUM() returns NULL.

  This function executes as a window function if over_clause is present. over_clause is as described in Section 14.20.2, “Window Function Concepts and Syntax”; it cannot be used with DISTINCT.

• **VAR_POP**(expr) [over_clause]

  Returns the population standard variance of expr. It considers rows as the whole population, not as a sample, so it has the number of rows as the denominator. You can also use VARIANCE(), which is equivalent but is not standard SQL.

  If there are no matching rows, or if expr is NULL, VAR_POP() returns NULL.

  This function executes as a window function if over_clause is present. over_clause is as described in Section 14.20.2, “Window Function Concepts and Syntax”.

• **VAR_SAMP**(expr) [over_clause]

  Returns the sample variance of expr. That is, the denominator is the number of rows minus one.

  If there are no matching rows, or if expr is NULL, VAR_SAMP() returns NULL.

  This function executes as a window function if over_clause is present. over_clause is as described in Section 14.20.2, “Window Function Concepts and Syntax”.
GROUP BY Modifiers

- **VARIANCE(expr) [over_clause]**

  Returns the population standard variance of `expr`. `VARIANCE()` is a synonym for the standard SQL function `VAR_POP()`, provided as a MySQL extension.

  If there are no matching rows, or if `expr` is `NULL`, `VARIANCE()` returns `NULL`.

  This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 14.20.2, "Window Function Concepts and Syntax".

14.19.2 GROUP BY Modifiers

The **GROUP BY** clause permits a **WITH ROLLUP** modifier that causes summary output to include extra rows that represent higher-level (that is, super-aggregate) summary operations. **ROLLUP** thus enables you to answer questions at multiple levels of analysis with a single query. For example, **ROLLUP** can be used to provide support for OLAP (Online Analytical Processing) operations.

Suppose that a **sales** table has `year`, `country`, `product`, and `profit` columns for recording sales profitability:

```sql
CREATE TABLE sales
(
    year INT,
    country VARCHAR(20),
    product VARCHAR(32),
    profit INT
);
```

To summarize table contents per year, use a simple **GROUP BY** like this:

```sql
mysql> SELECT year, SUM(profit) AS profit
    FROM sales
    GROUP BY year;
```

```
+------+--------+
<table>
<thead>
<tr>
<th>year</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>3010</td>
</tr>
</tbody>
</table>
+------+--------+
```

The output shows the total (aggregate) profit for each year. To also determine the total profit summed over all years, you must add up the individual values yourself or run an additional query. Or you can use **ROLLUP**, which provides both levels of analysis with a single query. Adding a **WITH ROLLUP** modifier to the **GROUP BY** clause causes the query to produce another (super-aggregate) row that shows the grand total over all year values:

```sql
mysql> SELECT year, SUM(profit) AS profit
    FROM sales
    GROUP BY year WITH ROLLUP;
```

```
+------+--------+
<table>
<thead>
<tr>
<th>year</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>3010</td>
</tr>
<tr>
<td>NULL</td>
<td>7535</td>
</tr>
</tbody>
</table>
+------+--------+
```

The **NULL** value in the `year` column identifies the grand total super-aggregate line.

**ROLLUP** has a more complex effect when there are multiple **GROUP BY** columns. In this case, each time there is a change in value in any but the last grouping column, the query produces an extra super-aggregate summary row.

For example, without **ROLLUP**, a summary of the **sales** table based on `year`, `country`, and `product` might look like this, where the output indicates summary values only at the year/country/product level of analysis:
With **ROLLUP** added, the query produces several extra rows:

```
mysql> SELECT year, country, product, SUM(profit) AS profit
    FROM sales
    GROUP BY year, country, product WITH ROLLUP;
```

Now the output includes summary information at four levels of analysis, not just one:

- Following each set of product rows for a given year and country, an extra super-aggregate summary row appears showing the total for all products. These rows have the **product** column set to **NULL**.

- Following each set of rows for a given year, an extra super-aggregate summary row appears showing the total for all countries and products. These rows have the **country** and **products** columns set to **NULL**.

- Finally, following all other rows, an extra super-aggregate summary row appears showing the grand total for all years, countries, and products. This row has the **year**, **country**, and **products** columns set to **NULL**.

The **NULL** indicators in each super-aggregate row are produced when the row is sent to the client. The server looks at the columns named in the **GROUP BY** clause following the leftmost one that has changed value. For any column in the result set with a name that matches any of those names, its value is set to **NULL**. (If you specify grouping columns by column position, the server identifies which columns to set to **NULL** by position.)

Because the **NULL** values in the super-aggregate rows are placed into the result set at such a late stage in query processing, you can test them as **NULL** values only in the **select list** or **HAVING** clause. You cannot test them as **NULL** values in join conditions or the **WHERE** clause to determine which rows
to select. For example, you cannot add `WHERE product IS NULL` to the query to eliminate from the output all but the super-aggregate rows.

The `NULL` values do appear as `NULL` on the client side and can be tested as such using any MySQL client programming interface. However, at this point, you cannot distinguish whether a `NULL` represents a regular grouped value or a super-aggregate value. To test the distinction, use the `GROUPING()` function, described later.

For `GROUP BY ... WITH ROLLUP` queries, to test whether `NULL` values in the result represent super-aggregate values, the `GROUPING()` function is available for use in the select list, `HAVING` clause, and `ORDER BY` clause. For example, `GROUPING(year)` returns 1 when `NULL` in the year column occurs in a super-aggregate row, and 0 otherwise. Similarly, `GROUPING(country)` and `GROUPING(product)` return 1 for super-aggregate `NULL` values in the `country` and `product` columns, respectively:

```
mysql> SELECT
    ...+------+---------+------------+--------+----------+-------------+-------------+
    | year | country | product    | profit | grp_year | grp_country | grp_product |
    +------+---------+------------+--------+----------+-------------+-------------+
    | 2000 | Finland | Computer   |   1500 |        0 |           0 |           0 |
    | 2000 | Finland | Phone      |    100 |        0 |           0 |           0 |
    | 2000 | Finland | NULL       |   1600 |        0 |           0 |           0 |
    | 2000 | India   | Computer   |   1200 |        0 |           0 |           0 |
    | 2000 | India   | NULL       |   1350 |        0 |           0 |           0 |
    | 2000 | USA     | Calculator |     75 |        0 |           0 |           0 |
    | 2000 | USA     | Computer   |   1500 |        0 |           0 |           0 |
    | 2000 | USA     | NULL       |   1575 |        0 |           0 |           0 |
    | 2000 | NULL    | NULL       |   4525 |        0 |           0 |           0 |
    | 2001 | Finland | Phone      |     10 |        0 |           0 |           0 |
    | 2001 | Finland | NULL       |     10 |        0 |           0 |           0 |
    | 2001 | USA     | Calculator |     50 |        0 |           0 |           0 |
    | 2001 | USA     | Computer   |   2700 |        0 |           0 |           0 |
    | 2001 | USA     | TV         |    250 |        0 |           0 |           0 |
    | 2001 | USA     | NULL       |   3010 |        0 |           0 |           0 |
    | 2001 | NULL    | NULL       |   3035 |        0 |           0 |           0 |
    | 2001 | NULL    | NULL       |   7535 |        0 |           0 |           0 |
    +------+---------+------------+--------+----------+-------------+-------------+
```

Instead of displaying the `GROUPING()` results directly, you can use `GROUPING()` to substitute labels for super-aggregate `NULL` values:

```
mysql> SELECT
    ...+---+----------+--------------+--------+
    | year | country  | product      | profit |
    +---+----------+--------------+--------+
    | 2000| Finland  | Computer     | 1500   |
    | 2000| Finland  | Phone        | 100    |
    | 2000| Finland  | All products | 1600   |
    | 2000| India    | Calculator   | 150    |
    | 2000| India    | Computer     | 1200   |
    | 2000| India    | All products | 1350   |
    | 2000| USA      | Calculator   | 75     |
    | 2000| USA      | Computer     | 1500   |
    | 2000| USA      | All products | 1575   |
    | 2000| All countries | All products | 4525   |
    | 2001| Finland  | Phone        | 10     |
    +---+----------+--------------+--------+
```

GROUP BY Modifiers

| 2001 | Finland | All products | 10 |
| 2001 | USA     | Calculator   | 50 |
| 2001 | USA     | Computer     | 2700 |
| 2001 | USA     | TV           | 250 |
| 2001 | USA     | All products | 3000 |
| All years | All countries | All products | 7535 |

With multiple expression arguments, `GROUPING()` returns a result representing a bitmask that combines the results for each expression, with the lowest-order bit corresponding to the result for the rightmost expression. For example, `GROUPING(year, country, product)` is evaluated like this:

```
result for GROUPING(product) + result for GROUPING(country) << 1 + result for GROUPING(year) << 2
```

The result of such a `GROUPING()` is nonzero if any of the expressions represents a super-aggregate `NULL`, so you can return only the super-aggregate rows and filter out the regular grouped rows like this:

```
mysql> SELECT year, country, product, SUM(profit) AS profit
    FROM sales
    GROUP BY year, country, product WITH ROLLUP
    HAVING GROUPING(year, country, product) <> 0;
```

The `sales` table contains no `NULL` values, so all `NULL` values in a `ROLLUP` result represent super-aggregate values. When the data set contains `NULL` values, `ROLLUP` summaries may contain `NULL` values not only in super-aggregate rows, but also in regular grouped rows. `GROUPING()` enables these to be distinguished. Suppose that table `t1` contains a simple data set with two grouping factors for a set of quantity values, where `NULL` indicates something like “other” or “unknown”:

```
mysql> SELECT * FROM t1;
```

A simple `ROLLUP` operation produces these results, in which it is not so easy to distinguish `NULL` values in super-aggregate rows from `NULL` values in regular grouped rows:

```
mysql> SELECT name, size, SUM(quantity) AS quantity
    FROM t1
    GROUP BY name, size WITH ROLLUP;
```
GROUP BY Modifiers

| hoop | small | 15 |
| hoop | NULL | 23 |
| NULL | NULL | 58 |

Using `GROUPING()` to substitute labels for the super-aggregate `NULL` values makes the result easier to interpret:

```
mysql> SELECT
    IF(GROUPING(name) = 1, 'All items', name) AS name,
    IF(GROUPING(size) = 1, 'All sizes', size) AS size,
    SUM(quantity) AS quantity
FROM t1
GROUP BY name, size WITH ROLLUP;
```

Other Considerations When using ROLLUP

The following discussion lists some behaviors specific to the MySQL implementation of ROLLUP.

**ORDER BY** and **ROLLUP** can be used together, which enables the use of **ORDER BY** and **GROUPING()** to achieve a specific sort order of grouped results. For example:

```
mysql> SELECT year, SUM(profit) AS profit
    FROM sales
    GROUP BY year WITH ROLLUP
    ORDER BY GROUPING(year) DESC;
```

In both cases, the super-aggregate summary rows sort with the rows from which they are calculated, and their placement depends on sort order (at the end for ascending sort, at the beginning for descending sort).

**LIMIT** can be used to restrict the number of rows returned to the client. **LIMIT** is applied after **ROLLUP**, so the limit applies against the extra rows added by **ROLLUP**. For example:

```
mysql> SELECT year, country, product, SUM(profit) AS profit
    FROM sales
    GROUP BY year, country, product WITH ROLLUP
    LIMIT 5;
```

Using **LIMIT** with **ROLLUP** may produce results that are more difficult to interpret, because there is less context for understanding the super-aggregate rows.
A MySQL extension permits a column that does not appear in the `GROUP BY` list to be named in the select list. (For information about nonaggregated columns and `GROUP BY`, see Section 14.19.3, “MySQL Handling of GROUP BY”.) In this case, the server is free to choose any value from this nonaggregated column in summary rows, and this includes the extra rows added by `WITH ROLLUP`. For example, in the following query, `country` is a nonaggregated column that does not appear in the `GROUP BY` list and values chosen for this column are nondeterministic:

```
mysql> SELECT year, country, SUM(profit) AS profit
    FROM sales
GROUP BY year WITH ROLLUP;
+-----+-----------+--------+
<table>
<thead>
<tr>
<th>year</th>
<th>country</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>India</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>3010</td>
</tr>
<tr>
<td>NULL</td>
<td>USA</td>
<td>7535</td>
</tr>
</tbody>
</table>
+-----+-----------+--------+
```

This behavior is permitted when the `ONLY_FULL_GROUP_BY` SQL mode is not enabled. If that mode is enabled, the server rejects the query as illegal because `country` is not listed in the `GROUP BY` clause. With `ONLY_FULL_GROUP_BY` enabled, you can still execute the query by using the `ANY_VALUE()` function for nondeterministic-value columns:

```
mysql> SELECT year, ANY_VALUE(country) AS country, SUM(profit) AS profit
    FROM sales
GROUP BY year WITH ROLLUP;
+-----+-----------+--------+
<table>
<thead>
<tr>
<th>year</th>
<th>country</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>India</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>3010</td>
</tr>
<tr>
<td>NULL</td>
<td>USA</td>
<td>7535</td>
</tr>
</tbody>
</table>
+-----+-----------+--------+
```

A rollup column cannot be used as an argument to `MATCH()` (and is rejected with an error) except when called in a `WHERE` clause. See Section 14.9, “Full-Text Search Functions”, for more information.

### 14.19.3 MySQL Handling of GROUP BY

SQL-92 and earlier does not permit queries for which the select list, `HAVING` condition, or `ORDER BY` list refer to nonaggregated columns that are not named in the `GROUP BY` clause. For example, this query is illegal in standard SQL-92 because the nonaggregated `name` column in the select list does not appear in the `GROUP BY`:

```
SELECT o.custid, c.name, MAX(o.payment)
FROM orders AS o, customers AS c
WHERE o.custid = c.custid
GROUP BY o.custid;
```

For the query to be legal in SQL-92, the `name` column must be omitted from the select list or named in the `GROUP BY` clause.

SQL:1999 and later permits such nonaggregates per optional feature T301 if they are functionally dependent on `GROUP BY` columns: If such a relationship exists between `name` and `custid`, the query is legal. This would be the case, for example, were `custid` a primary key of `customers`.

MySQL implements detection of functional dependence. If the `ONLY_FULL_GROUP_BY` SQL mode is enabled (which it is by default), MySQL rejects queries for which the select list, `HAVING` condition, or `ORDER BY` list refer to nonaggregated columns that are neither named in the `GROUP BY` clause nor are functionally dependent on them.

MySQL also permits a nonaggregate column not named in a `GROUP BY` clause when SQL `ONLY_FULL_GROUP_BY` mode is enabled, provided that this column is limited to a single value, as shown in the following example:
MySQL Handling of GROUP BY

```
mysql> CREATE TABLE mytable (  
  ->    id INT UNSIGNED NOT NULL PRIMARY KEY,  
  ->    a VARCHAR(10),  
  ->    b INT  
  -> );

mysql> INSERT INTO mytable  
-> VALUES (1, 'abc', 1000),  
-> (2, 'abc', 2000),  
-> (3, 'def', 4000);

mysql> SET SESSION sql_mode = sys.list_add(@@session.sql_mode, 'ONLY_FULL_GROUP_BY');

mysql> SELECT a, SUM(b) FROM mytable WHERE a = 'abc';
+------+--------+
<table>
<thead>
<tr>
<th>a</th>
<th>SUM(b)</th>
</tr>
</thead>
<tbody>
<tr>
<td>abc</td>
<td>3000</td>
</tr>
</tbody>
</table>
+------+--------+

It is also possible to have more than one nonaggregate column in the SELECT list when employing ONLY_FULL_GROUP_BY. In this case, every such column must be limited to a single value in the WHERE clause, and all such limiting conditions must be joined by logical AND, as shown here:

```
mysql> DROP TABLE IF EXISTS mytable;

mysql> CREATE TABLE mytable (  
  ->    id INT UNSIGNED NOT NULL PRIMARY KEY,  
  ->    a VARCHAR(10),  
  ->    b VARCHAR(10),  
  ->    c INT  
  -> );

mysql> INSERT INTO mytable  
-> VALUES (1, 'abc', 'qrs', 1000),  
-> (2, 'abc', 'tuv', 2000),  
-> (3, 'def', 'qrs', 4000),  
-> (4, 'def', 'tuv', 8000),  
-> (5, 'abc', 'qrs', 16000),  
-> (6, 'def', 'tuv', 32000);

mysql> SELECT @@session.sql_mode;
+---------------------------------------------------------------+
| @@session.sql_mode                                            |
+---------------------------------------------------------------+
| ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,NO_ENGINE_SUBSTITUTION |
+---------------------------------------------------------------+

mysql> SELECT a, b, SUM(c) FROM mytable  
-> WHERE a = 'abc' AND b = 'qrs';
+------+------+--------+
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>SUM(c)</th>
</tr>
</thead>
<tbody>
<tr>
<td>abc</td>
<td>qrs</td>
<td>17000</td>
</tr>
</tbody>
</table>
+------+------+--------+

If ONLY_FULL_GROUP_BY is disabled, a MySQL extension to the standard SQL use of GROUP BY permits the select list, HAVING condition, or ORDER BY list to refer to nonaggregated columns even if the columns are not functionally dependent on GROUP BY columns. This causes MySQL to accept the preceding query. In this case, the server is free to choose any value from each group, so unless they are the same, the values chosen are nondeterministic, which is probably not what you want. Furthermore, the selection of values from each group cannot be influenced by adding an ORDER BY clause. Result set sorting occurs after values have been chosen, and ORDER BY does not affect which value within each group the server chooses. Disabling ONLY_FULL_GROUP_BY is useful primarily when you know that, due to some property of the data, all values in each nonaggregated column not named in the GROUP BY are the same for each group.

You can achieve the same effect without disabling ONLY_FULL_GROUP_BY by using ANY_VALUE() to refer to the nonaggregated column.

2356
MySQL Handling of GROUP BY

The following discussion demonstrates functional dependence, the error message MySQL produces when functional dependence is absent, and ways of causing MySQL to accept a query in the absence of functional dependence.

This query might be invalid with ONLY_FULL_GROUP_BY enabled because the nonaggregated address column in the select list is not named in the GROUP BY clause:

```sql
SELECT name, address, MAX(age) FROM t GROUP BY name;
```

The query is valid if name is a primary key of t or is a unique NOT NULL column. In such cases, MySQL recognizes that the selected column is functionally dependent on a grouping column. For example, if name is a primary key, its value determines the value of address because each group has only one value of the primary key and thus only one row. As a result, there is no randomness in the choice of address value in a group and no need to reject the query.

The query is invalid if name is not a primary key of t or a unique NOT NULL column. In this case, no functional dependency can be inferred and an error occurs:

```sql
mysql> SELECT name, address, MAX(age) FROM t GROUP BY name;
ERROR 1055 (42000): Expression #2 of SELECT list is not in GROUP BY clause and contains nonaggregated column 'mydb.t.address' which is not functionally dependent on columns in GROUP BY clause; this is incompatible with sql_mode=only_full_group_by
```

If you know that, for a given data set, each name value in fact uniquely determines the address value, address is effectively functionally dependent on name. To tell MySQL to accept the query, you can use the ANY_VALUE() function:

```sql
SELECT name, ANY_VALUE(address), MAX(age) FROM t GROUP BY name;
```

Alternatively, disable ONLY_FULL_GROUP_BY.

The preceding example is quite simple, however. In particular, it is unlikely you would group on a single primary key column because every group would contain only one row. For additional examples demonstrating functional dependence in more complex queries, see Section 14.19.4, "Detection of Functional Dependence".

If a query has aggregate functions and no GROUP BY clause, it cannot have nonaggregated columns in the select list, HAVING condition, or ORDER BY list with ONLY_FULL_GROUP_BY enabled:

```sql
mysql> SELECT name, MAX(age) FROM t;
ERROR 1140 (42000): In aggregated query without GROUP BY, expression #1 of SELECT list contains nonaggregated column 'mydb.t.name'; this is incompatible with sql_mode=only_full_group_by
```

Without GROUP BY, there is a single group and it is nondeterministic which name value to choose for the group. Here, too, ANY_VALUE() can be used, if it is immaterial which name value MySQL chooses:

```sql
SELECT ANY_VALUE(name), MAX(age) FROM t;
```

ONLY_FULL_GROUP_BY also affects handling of queries that use DISTINCT and ORDER BY. Consider the case of a table t with three columns c1, c2, and c3 that contains these rows:

<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
<th>c3</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>A</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>B</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>C</td>
</tr>
</tbody>
</table>

Suppose that we execute the following query, expecting the results to be ordered by c3:

```sql
SELECT DISTINCT c1, c2 FROM t ORDER BY c3;
```

To order the result, duplicates must be eliminated first. But to do so, should we keep the first row or the third? This arbitrary choice influences the retained value of c3, which in turn influences ordering
and makes it arbitrary as well. To prevent this problem, a query that has `DISTINCT` and `ORDER BY` is rejected as invalid if any `ORDER BY` expression does not satisfy at least one of these conditions:

- The expression is equal to one in the select list
- All columns referenced by the expression and belonging to the query’s selected tables are elements of the select list

Another MySQL extension to standard SQL permits references in the `HAVING` clause to aliased expressions in the select list. For example, the following query returns `name` values that occur only once in table `orders`:

```
SELECT name, COUNT(name) FROM orders
GROUP BY name
HAVING COUNT(name) = 1;
```

The MySQL extension permits the use of an alias in the `HAVING` clause for the aggregated column:

```
SELECT name, COUNT(name) AS c FROM orders
GROUP BY name
HAVING c = 1;
```

Standard SQL permits only column expressions in `GROUP BY` clauses, so a statement such as this is invalid because `FLOOR(value/100)` is a noncolumn expression:

```
SELECT id, FLOOR(value/100)
FROM tbl_name
GROUP BY id, FLOOR(value/100);
```

MySQL extends standard SQL to permit noncolumn expressions in `GROUP BY` clauses and considers the preceding statement valid.

Standard SQL also does not permit aliases in `GROUP BY` clauses. MySQL extends standard SQL to permit aliases, so another way to write the query is as follows:

```
SELECT id, FLOOR(value/100) AS c
FROM tbl_name
GROUP BY id, c;
```

The alias `c` is considered a column expression in the `GROUP BY` clause.

In the presence of a noncolumn expression in the `GROUP BY` clause, MySQL recognizes equality between that expression and expressions in the select list. This means that with `ONLY_FULL_GROUP_BY` SQL mode enabled, the query containing `GROUP BY id, FLOOR(value/100)` is valid because that same `FLOOR()` expression occurs in the select list. However, MySQL does not try to recognize functional dependence on `GROUP BY` noncolumn expressions, so the following query is invalid with `ONLY_FULL_GROUP_BY` enabled, even though the third selected expression is a simple formula of the `id` column and the `FLOOR()` expression in the `GROUP BY` clause:

```
SELECT id, FLOOR(value/100), id+FLOOR(value/100)
FROM tbl_name
GROUP BY id, FLOOR(value/100);
```

A workaround is to use a derived table:

```
SELECT id, F, id+F
FROM
  (SELECT id, FLOOR(value/100) AS F
   FROM tbl_name
   GROUP BY id, FLOOR(value/100)) AS dt;
```

### 14.19.4 Detection of Functional Dependence

The following discussion provides several examples of the ways in which MySQL detects functional dependencies. The examples use this notation:
Detection of Functional Dependence

\[
\{X\} \rightarrow \{Y\}
\]

Understand this as “\(X\) uniquely determines \(Y\),” which also means that \(Y\) is functionally dependent on \(X\).

The examples use the world database, which can be downloaded from https://dev.mysql.com/doc/index-other.html. You can find details on how to install the database on the same page.

- Functional Dependencies Derived from Keys
- Functional Dependencies Derived from Multiple-Column Keys and from Equalities
- Functional Dependency Special Cases
- Functional Dependencies and Views
- Combinations of Functional Dependencies

**Functional Dependencies Derived from Keys**

The following query selects, for each country, a count of spoken languages:

```sql
SELECT co.Name, COUNT(*)
FROM countrylanguage cl, country co
GROUP BY co.Code;
```

\(co\).\(Code\) is a primary key of \(co\), so all columns of \(co\) are functionally dependent on it, as expressed using this notation:

\[
\{co.\text{Code}\} \rightarrow \{co.*\}
\]

Thus, \(co\).\(name\) is functionally dependent on \(GROUP\ \text{BY}\) columns and the query is valid.

A \textit{UNIQUE} index over a \textit{NOT NULL} column could be used instead of a primary key and the same functional dependence would apply. (This is not true for a \textit{UNIQUE} index that permits \textit{NULL} values because it permits multiple \textit{NULL} values and in that case uniqueness is lost.)

**Functional Dependencies Derived from Multiple-Column Keys and from Equalities**

This query selects, for each country, a list of all spoken languages and how many people speak them:

```sql
SELECT co.Name, cl.Language,
cl.Percentage * co.Population / 100.0 AS SpokenBy
FROM countrylanguage cl, country co
GROUP BY cl.CountryCode, cl.Language;
```

The pair \((cl.\text{CountryCode}, cl.\text{Language})\) is a two-column composite primary key of \(cl\), so that column pair uniquely determines all columns of \(cl\):

\[
\{cl.\text{CountryCode}, cl.\text{Language}\} \rightarrow \{cl.*\}
\]

Moreover, because of the equality in the \textit{WHERE} clause:

\[
\{cl.\text{CountryCode}\} \rightarrow \{co.\text{Code}\}
\]

And, because \(co.\text{Code}\) is primary key of \(co\):

\[
\{co.\text{Code}\} \rightarrow \{co.*\}
\]

“Uniquely determines” relationships are transitive, therefore:

\[
\{cl.\text{CountryCode}, cl.\text{Language}\} \rightarrow \{cl.*,co.*\}
\]

As a result, the query is valid.
Detection of Functional Dependence

As with the previous example, a **UNIQUE** key over **NOT NULL** columns could be used instead of a primary key.

An **INNER JOIN** condition can be used instead of **WHERE**. The same functional dependencies apply:

```sql
SELECT co.Name, cl.Language, 
cl.Percentage * co.Population/100.0 AS SpokenBy 
FROM countrylanguage cl INNER JOIN country co 
GROUP BY cl.CountryCode, cl.Language;
```

**Functional Dependency Special Cases**

Whereas an equality test in a **WHERE** condition or **INNER JOIN** condition is symmetric, an equality test in an outer join condition is not, because tables play different roles.

Assume that referential integrity has been accidentally broken and there exists a row of **countrylanguage** without a corresponding row in **country**. Consider the same query as in the previous example, but with a **LEFT JOIN**:

```sql
SELECT co.Name, cl.Language, 
cl.Percentage * co.Population/100.0 AS SpokenBy 
FROM countrylanguage cl LEFT JOIN country co 
GROUP BY cl.CountryCode, cl.Language;
```

For a given value of **cl.CountryCode**, the value of **co.Code** in the join result is either found in a matching row (determined by **cl.CountryCode**) or is **NULL**-complemented if there is no match (also determined by **cl.CountryCode**). In each case, this relationship applies:

```
{cl.CountryCode} -> {co.Code}
```

**cl.CountryCode** is itself functionally dependent on **{cl.CountryCode, cl.Language}** which is a primary key.

If in the join result **co.Code** is **NULL**-complemented, **co.Name** is as well. If **co.Code** is not **NULL**-complemented, then because **co.Code** is a primary key, it determines **co.Name**. Therefore, in all cases:

```
{co.Code} -> {co.Name}
```

Which yields:

```
{cl.CountryCode, cl.Language} -> {cl.*, co.*}
```

As a result, the query is valid.

However, suppose that the tables are swapped, as in this query:

```sql
SELECT co.Name, cl.Language, 
cl.Percentage * co.Population/100.0 AS SpokenBy 
FROM country co LEFT JOIN countrylanguage cl 
GROUP BY cl.CountryCode, cl.Language;
```

Now this relationship does **not** apply:

```
{cl.CountryCode, cl.Language} -> {cl.*, co.*}
```

Indeed, all **NULL**-complemented rows made for **cl** is put into a single group (they have both **GROUP BY** columns equal to **NULL**), and inside this group the value of **co.Name** can vary. The query is invalid and MySQL rejects it.

Functional dependence in outer joins is thus linked to whether determinant columns belong to the left or right side of the **LEFT JOIN**. Determination of functional dependence becomes more complex if there are nested outer joins or the join condition does not consist entirely of equality comparisons.
Window Functions

Functional Dependencies and Views

Suppose that a view on countries produces their code, their name in uppercase, and how many different official languages they have:

```
CREATE VIEW country2 AS
SELECT co.Code, UPPER(co.Name) AS UpperName,
COUNT(cl.Language) AS OfficialLanguages
FROM country AS co JOIN countrylanguage AS cl
WHERE cl.isOfficial = 'T'
GROUP BY co.Code;
```

This definition is valid because:

```
{co.Code} -> {co.*}
```

In the view result, the first selected column is `co.Code`, which is also the group column and thus determines all other selected expressions:

```
{country2.Code} -> {country2.*}
```

MySQL understands this and uses this information, as described following.

This query displays countries, how many different official languages they have, and how many cities they have, by joining the view with the `city` table:

```
SELECT co2.Code, co2.UpperName, co2.OfficialLanguages,
COUNT(*) AS Cities
FROM country2 AS co2 JOIN city ci
GROUP BY co2.Code;
```

This query is valid because, as seen previously:

```
{co2.Code} -> {co2.*}
```

MySQL is able to discover a functional dependency in the result of a view and use that to validate a query which uses the view. The same would be true if `country2` were a derived table (or common table expression), as in:

```
SELECT co2.Code, co2.UpperName, co2.OfficialLanguages,
COUNT(*) AS Cities
FROM
(
  SELECT co.Code, UPPER(co.Name) AS UpperName,
  COUNT(cl.Language) AS OfficialLanguages
  FROM country AS co JOIN countrylanguage AS cl
  WHERE cl.isOfficial = 'T'
  GROUP BY co.Code
) AS co2
GROUP BY co2.Code;
```

Combinations of Functional Dependencies

MySQL is able to combine all of the preceding types of functional dependencies (key based, equality based, view based) to validate more complex queries.

14.20 Window Functions

MySQL supports window functions that, for each row from a query, perform a calculation using rows related to that row. The following sections discuss how to use window functions, including descriptions of the `OVER` and `WINDOW` clauses. The first section provides descriptions of the nonaggregate window functions. For descriptions of the aggregate window functions, see Section 14.19.1, "Aggregate Function Descriptions".
For information about optimization and window functions, see Section 10.2.1.21, “Window Function Optimization”.

14.20.1 Window Function Descriptions

This section describes nonaggregate window functions that, for each row from a query, perform a calculation using rows related to that row. Most aggregate functions also can be used as window functions; see Section 14.19.1, “Aggregate Function Descriptions”.

For window function usage information and examples, and definitions of terms such as the OVER clause, window, partition, frame, and peer, see Section 14.20.2, “Window Function Concepts and Syntax”.

Table 14.30 Window Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUME_DIST()</td>
<td>Cumulative distribution value</td>
</tr>
<tr>
<td>DENSE_RANK()</td>
<td>Rank of current row within its partition, without gaps</td>
</tr>
<tr>
<td>FIRST_VALUE()</td>
<td>Value of argument from first row of window frame</td>
</tr>
<tr>
<td>LAG()</td>
<td>Value of argument from row lagging current row within partition</td>
</tr>
<tr>
<td>LAST_VALUE()</td>
<td>Value of argument from last row of window frame</td>
</tr>
<tr>
<td>LEAD()</td>
<td>Value of argument from row leading current row within partition</td>
</tr>
<tr>
<td>NTH_VALUE()</td>
<td>Value of argument from N-th row of window frame</td>
</tr>
<tr>
<td>NTILE()</td>
<td>Bucket number of current row within its partition.</td>
</tr>
<tr>
<td>PERCENT_RANK()</td>
<td>Percentage rank value</td>
</tr>
<tr>
<td>RANK()</td>
<td>Rank of current row within its partition, with gaps</td>
</tr>
<tr>
<td>ROW_NUMBER()</td>
<td>Number of current row within its partition</td>
</tr>
</tbody>
</table>

In the following function descriptions, over_clause represents the OVER clause, described in Section 14.20.2, “Window Function Concepts and Syntax”. Some window functions permit a null_treatment clause that specifies how to handle NULL values when calculating results. This clause is optional. It is part of the SQL standard, but the MySQL implementation permits only RESPECT NULLS (which is also the default). This means that NULL values are considered when calculating results. IGNORE NULLS is parsed, but produces an error.

• CUME_DIST() over_clause

Returns the cumulative distribution of a value within a group of values; that is, the percentage of partition values less than or equal to the value in the current row. This represents the number of rows preceding or peer with the current row in the window ordering of the window partition divided by the total number of rows in the window partition. Return values range from 0 to 1.

This function should be used with ORDER BY to sort partition rows into the desired order. Without ORDER BY, all rows are peers and have value \( N/N = 1 \), where \( N \) is the partition size.

over_clause is as described in Section 14.20.2, “Window Function Concepts and Syntax”.

The following query shows, for the set of values in the val column, the CUME_DIST() value for each row, as well as the percentage rank value returned by the similar PERCENT_RANK() function. For reference, the query also displays row numbers using ROW_NUMBER():

```
mysql> SELECT
  val,
  ROW_NUMBER() OVER w AS 'row_number',
```
CUME_DIST() OVER w AS 'cume_dist',
PERCENT_RANK() OVER w AS 'percent_rank'
FROM numbers
WINDOW w AS (ORDER BY val);

+-------+----------+-------------+----------+
<table>
<thead>
<tr>
<th>val</th>
<th>row_number</th>
<th>cume_dist</th>
<th>percent_rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td>0.2222222222222222</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td></td>
<td>0.2222222222222222</td>
<td>0</td>
</tr>

<td></td>
<td>0.3333333333333333</td>
<td>0.25</td>
</tr>
<tr>
<td>3</td>
<td></td>
<td>0.6666666666666666</td>
<td>0.375</td>
</tr>
<tr>
<td>3</td>
<td></td>
<td>0.6666666666666666</td>
<td>0.375</td>
</tr>
<tr>
<td>3</td>
<td></td>
<td>0.6666666666666666</td>
<td>0.375</td>
</tr>
<tr>
<td>4</td>
<td></td>
<td>0.8888888888888888</td>
<td>0.75</td>
</tr>
<tr>
<td>4</td>
<td></td>
<td>0.8888888888888888</td>
<td>0.75</td>
</tr>
<tr>
<td>5</td>
<td></td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

• DENSE_RANK() over_clause

Returns the rank of the current row within its partition, without gaps. Peers are considered ties and receive the same rank. This function assigns consecutive ranks to peer groups; the result is that groups of size greater than one do not produce noncontiguous rank numbers. For an example, see the RANK() function description.

This function should be used with ORDER BY to sort partition rows into the desired order. Without ORDER BY, all rows are peers.

over_clause is as described in Section 14.20.2, “Window Function Concepts and Syntax”.

• FIRST_VALUE(expr) [null_treatment] over_clause

Returns the value of expr from the first row of the window frame.

over_clause is as described in Section 14.20.2, “Window Function Concepts and Syntax”. null_treatment is as described in the section introduction.

The following query demonstrates FIRST_VALUE(), LAST_VALUE(), and two instances of NTH_VALUE():

```mysql
mysql> SELECT time, subject, val,
FIRST_VALUE(val) OVER w AS 'first',
LAST_VALUE(val) OVER w AS 'last',
NTH_VALUE(val, 2) OVER w AS 'second',
NTH_VALUE(val, 4) OVER w AS 'fourth'
FROM observations
WINDOW w AS (PARTITION BY subject ORDER BY time ROWS UNBOUNDED PRECEDING);
```

<table>
<thead>
<tr>
<th>time</th>
<th>subject</th>
<th>val</th>
<th>first</th>
<th>last</th>
<th>second</th>
<th>fourth</th>
</tr>
</thead>
<tbody>
<tr>
<td>07:00:00</td>
<td>st113</td>
<td>10</td>
<td>10</td>
<td>10</td>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>07:15:00</td>
<td>st113</td>
<td>9</td>
<td>10</td>
<td>9</td>
<td>9</td>
<td>NULL</td>
</tr>
<tr>
<td>07:30:00</td>
<td>st113</td>
<td>25</td>
<td>10</td>
<td>25</td>
<td>9</td>
<td>NULL</td>
</tr>
<tr>
<td>07:45:00</td>
<td>st113</td>
<td>20</td>
<td>10</td>
<td>20</td>
<td>9</td>
<td>20</td>
</tr>
<tr>
<td>07:00:00</td>
<td>xh458</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>07:15:00</td>
<td>xh458</td>
<td>10</td>
<td>0</td>
<td>10</td>
<td>10</td>
<td>NULL</td>
</tr>
<tr>
<td>07:30:00</td>
<td>xh458</td>
<td>5</td>
<td>0</td>
<td>5</td>
<td>10</td>
<td>NULL</td>
</tr>
<tr>
<td>07:45:00</td>
<td>xh458</td>
<td>30</td>
<td>0</td>
<td>30</td>
<td>10</td>
<td>30</td>
</tr>
<tr>
<td>08:00:00</td>
<td>xh458</td>
<td>25</td>
<td>0</td>
<td>25</td>
<td>10</td>
<td>30</td>
</tr>
</tbody>
</table>

Each function uses the rows in the current frame, which, per the window definition shown, extends from the first partition row to the current row. For the NTH_VALUE() calls, the current frame does not always include the requested row; in such cases, the return value is NULL.

• LAG(expr [, N[, default]]) [null_treatment] over_clause
Window Function Descriptions

Returns the value of `expr` from the row that lags (precedes) the current row by `N` rows within its partition. If there is no such row, the return value is `default`. For example, if `N` is 3, the return value is `default` for the first three rows. If `N` or `default` are missing, the defaults are 1 and `NULL`, respectively.

`N` must be a literal nonnegative integer. If `N` is 0, `expr` is evaluated for the current row.

`N` cannot be `NULL`, and must be an integer in the range 0 to $2^{63}$, inclusive, in any of the following forms:

- an unsigned integer constant literal
- a positional parameter marker (?)
- a user-defined variable
- a local variable in a stored routine

`over_clause` is as described in Section 14.20.2, “Window Function Concepts and Syntax”. `null_treatment` is as described in the section introduction.

`LAG()` (and the similar `LEAD()` function) are often used to compute differences between rows. The following query shows a set of time-ordered observations and, for each one, the `LAG()` and `LEAD()` values from the adjoining rows, as well as the differences between the current and adjoining rows:

```sql
SELECT t, val,
       LAG(val) OVER w AS 'lag',
       LEAD(val) OVER w AS 'lead',
       val - LAG(val) OVER w AS 'lag diff',
       val - LEAD(val) OVER w AS 'lead diff'
FROM series
WINDOW w AS (ORDER BY t);
```

<table>
<thead>
<tr>
<th>t</th>
<th>val</th>
<th>lag</th>
<th>lead</th>
<th>lag diff</th>
<th>lead diff</th>
</tr>
</thead>
<tbody>
<tr>
<td>12:00:00</td>
<td>100</td>
<td>NULL</td>
<td>125</td>
<td>NULL</td>
<td>-25</td>
</tr>
<tr>
<td>13:00:00</td>
<td>125</td>
<td>100</td>
<td>132</td>
<td>25</td>
<td>-7</td>
</tr>
<tr>
<td>14:00:00</td>
<td>132</td>
<td>125</td>
<td>145</td>
<td>7</td>
<td>-13</td>
</tr>
<tr>
<td>15:00:00</td>
<td>145</td>
<td>132</td>
<td>140</td>
<td>13</td>
<td>-10</td>
</tr>
<tr>
<td>16:00:00</td>
<td>140</td>
<td>145</td>
<td>200</td>
<td>10</td>
<td>-50</td>
</tr>
<tr>
<td>17:00:00</td>
<td>150</td>
<td>140</td>
<td>NULL</td>
<td>50</td>
<td>NULL</td>
</tr>
</tbody>
</table>

In the example, the `LAG()` and `LEAD()` calls use the default `N` and `default` values of 1 and `NULL`, respectively.

The first row shows what happens when there is no previous row for `LAG()`: The function returns the `default` value (in this case, `NULL`). The last row shows the same thing when there is no next row for `LEAD()`.

`LAG()` and `LEAD()` also serve to compute sums rather than differences. Consider this data set, which contains the first few numbers of the Fibonacci series:

```sql
SELECT n FROM fib ORDER BY n;
```

```
+--+
<table>
<thead>
<tr>
<th>n</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>3</td>
</tr>
<tr>
<td>5</td>
</tr>
<tr>
<td>8</td>
</tr>
</tbody>
</table>
```
The following query shows the \texttt{LAG()} and \texttt{LEAD()} values for the rows adjacent to the current row. It also uses those functions to add to the current row value the values from the preceding and following rows. The effect is to generate the next number in the Fibonacci series, and the next number after that:

\begin{verbatim}
mysql> SELECT 
n,  
    LAG(n, 1, 0) OVER w AS 'lag',  
    LEAD(n, 1, 0) OVER w AS 'lead',  
    n + LAG(n, 1, 0) OVER w AS 'next_n',  
    n + LEAD(n, 1, 0) OVER w AS 'next_next_n'
FROM fib
WINDOW w AS (ORDER BY n);
\end{verbatim}

+------+------+------+--------+-------------+
\end{verbatim}

One way to generate the initial set of Fibonacci numbers is to use a recursive common table expression. For an example, see \texttt{Fibonacci Series Generation}.

You cannot use a negative value for the rows argument of this function.

\begin{itemize}
\item \texttt{LAST\_VALUE(expr) [null\_treatment] over\_clause}
\end{itemize}

Returns the value of \texttt{expr} from the last row of the window frame.

\texttt{over\_clause} is as described in Section 14.20.2, "Window Function Concepts and Syntax". \texttt{null\_treatment} is as described in the section introduction.

For an example, see the \texttt{FIRST\_VALUE()} function description.

\begin{itemize}
\item \texttt{LEAD(expr [, N[, default]]) [null\_treatment] over\_clause}
\end{itemize}

Returns the value of \texttt{expr} from the row that leads (follows) the current row by \texttt{N} rows within its partition. If there is no such row, the return value is \texttt{default}. For example, if \texttt{N} is 3, the return
value is `default` for the last three rows. If `N` or `default` are missing, the defaults are 1 and NULL, respectively.

`N` must be a literal nonnegative integer. If `N` is 0, `expr` is evaluated for the current row.

`N` cannot be NULL, and must be an integer in the range 0 to $2^{63}$, inclusive, in any of the following forms:

- an unsigned integer constant literal
- a positional parameter marker (`?`)
- a user-defined variable
- a local variable in a stored routine

`over_clause` is as described in Section 14.20.2, "Window Function Concepts and Syntax". `null_treatment` is as described in the section introduction.

For an example, see the LAG() function description.

Use of a negative value for the rows argument of this function is not permitted.

- `NTH_VALUE(expr, N) [from_first_last] [null_treatment] over_clause`

  Returns the value of `expr` from the `N`-th row of the window frame. If there is no such row, the return value is NULL.

`N` must be a literal positive integer.

`from_first_last` is part of the SQL standard, but the MySQL implementation permits only FROM FIRST (which is also the default). This means that calculations begin at the first row of the window. FROM LAST is parsed, but produces an error. To obtain the same effect as FROM LAST (begin calculations at the last row of the window), use ORDER BY to sort in reverse order.

`over_clause` is as described in Section 14.20.2, "Window Function Concepts and Syntax". `null_treatment` is as described in the section introduction.

For an example, see the FIRST_VALUE() function description.

You cannot use NULL for the row argument of this function.
• **NTILE(N) over_clause**

Divides a partition into \( N \) groups (buckets), assigns each row in the partition its bucket number, and returns the bucket number of the current row within its partition. For example, if \( N \) is 4, `NTILE()` divides rows into four buckets. If \( N \) is 100, `NTILE()` divides rows into 100 buckets.

\( N \) must be a literal positive integer. Bucket number return values range from 1 to \( N \).

\( N \) cannot be `NULL`, and must be an integer in the range 0 to \( 2^{63} \), inclusive, in any of the following forms:

- an unsigned integer constant literal
- a positional parameter marker (`?`)
- a user-defined variable
- a local variable in a stored routine

This function should be used with `ORDER BY` to sort partition rows into the desired order.

`over_clause` is as described in Section 14.20.2, “Window Function Concepts and Syntax”.

The following query shows, for the set of values in the `val` column, the percentile values resulting from dividing the rows into two or four groups. For reference, the query also displays row numbers using `ROW_NUMBER()`:

```
mysql> SELECT val, ROW_NUMBER() OVER w AS 'row_number',
          NTILE(2) OVER w AS 'ntile2',
          NTILE(4) OVER w AS 'ntile4'
FROM numbers
WINDOW w AS (ORDER BY val);
```

<table>
<thead>
<tr>
<th>val</th>
<th>row_number</th>
<th>ntile2</th>
<th>ntile4</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>5</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>6</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td>7</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td>8</td>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>5</td>
<td>9</td>
<td>2</td>
<td>4</td>
</tr>
</tbody>
</table>

The construct `NTILE(NULL)` is not permitted.

• **PERCENT_RANK() over_clause**

Returns the percentage of partition values less than the value in the current row, excluding the highest value. Return values range from 0 to 1 and represent the row relative rank, calculated as the result of this formula, where `rank` is the row rank and `rows` is the number of partition rows:

\[
\frac{\text{rank} - 1}{\text{rows} - 1}
\]

This function should be used with `ORDER BY` to sort partition rows into the desired order. Without `ORDER BY`, all rows are peers.

`over_clause` is as described in Section 14.20.2, “Window Function Concepts and Syntax”.

For an example, see the `CUME_DIST()` function description.
Window Function Concepts and Syntax

- **RANK() over_clause**

Returns the rank of the current row within its partition, with gaps. Peers are considered ties and receive the same rank. This function does not assign consecutive ranks to peer groups if groups of size greater than one exist; the result is noncontiguous rank numbers.

This function should be used with **ORDER BY** to sort partition rows into the desired order. Without **ORDER BY**, all rows are peers.

**over_clause** is as described in Section 14.20.2, “Window Function Concepts and Syntax”.

The following query shows the difference between **RANK()**, which produces ranks with gaps, and **DENSE_RANK()**, which produces ranks without gaps. The query shows rank values for each member of a set of values in the **val** column, which contains some duplicates. **RANK()** assigns peers (the duplicates) the same rank value, and the next greater value has a rank higher by the number of peers minus one. **DENSE_RANK()** also assigns peers the same rank value, but the next higher value has a rank one greater. For reference, the query also displays row numbers using **ROW_NUMBER()**:

```sql
mysql> SELECT
    val,
    ROW_NUMBER() OVER w AS 'row_number',
    RANK() OVER w AS 'rank',
    DENSE_RANK() OVER w AS 'dense_rank'
FROM numbers
WINDOW w AS (ORDER BY val);
```

<table>
<thead>
<tr>
<th>val</th>
<th>row_number</th>
<th>rank</th>
<th>dense_rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>3</td>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>4</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>5</td>
<td>5</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td>6</td>
<td>6</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td>7</td>
<td>7</td>
<td>4</td>
</tr>
<tr>
<td>5</td>
<td>9</td>
<td>9</td>
<td>5</td>
</tr>
</tbody>
</table>

- **ROW_NUMBER() over_clause**

Returns the number of the current row within its partition. Rows numbers range from 1 to the number of partition rows.

**ORDER BY** affects the order in which rows are numbered. Without **ORDER BY**, row numbering is nondeterministic.

**ROW_NUMBER()** assigns peers different row numbers. To assign peers the same value, use **RANK()** or **DENSE_RANK()**. For an example, see the **RANK()** function description.

**over_clause** is as described in Section 14.20.2, “Window Function Concepts and Syntax”.

### 14.20.2 Window Function Concepts and Syntax

This section describes how to use window functions. Examples use the same sales information data set as found in the discussion of the **GROUPING()** function in Section 14.19.2, “GROUP BY Modifiers”:

```sql
mysql> SELECT * FROM sales ORDER BY country, year, product;
```

<table>
<thead>
<tr>
<th>year</th>
<th>country</th>
<th>product</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>Finland</td>
<td>Computer</td>
<td>1500</td>
</tr>
<tr>
<td>2000</td>
<td>Finland</td>
<td>Phone</td>
<td>100</td>
</tr>
<tr>
<td>2001</td>
<td>Finland</td>
<td>Phone</td>
<td>10</td>
</tr>
<tr>
<td>2000</td>
<td>India</td>
<td>Calculator</td>
<td>75</td>
</tr>
<tr>
<td>2000</td>
<td>India</td>
<td>Calculator</td>
<td>75</td>
</tr>
</tbody>
</table>
A window function performs an aggregate-like operation on a set of query rows. However, whereas an aggregate operation groups query rows into a single result row, a window function produces a result for each query row:

- The row for which function evaluation occurs is called the current row.
- The query rows related to the current row over which function evaluation occurs comprise the window for the current row.

For example, using the sales information table, these two queries perform aggregate operations that produce a single global sum for all rows taken as a group, and sums grouped per country:

```sql
mysql> SELECT SUM(profit) AS total_profit
FROM sales;
+--------------+
<table>
<thead>
<tr>
<th>total_profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>7535</td>
</tr>
</tbody>
</table>
+--------------+
mysql> SELECT country, SUM(profit) AS country_profit
FROM sales
GROUP BY country
ORDER BY country;
+---------+----------------+
<table>
<thead>
<tr>
<th>country</th>
<th>country_profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Finland</td>
<td>1610</td>
</tr>
<tr>
<td>India</td>
<td>1350</td>
</tr>
<tr>
<td>USA</td>
<td>4575</td>
</tr>
</tbody>
</table>
+---------+----------------+
```

By contrast, window operations do not collapse groups of query rows to a single output row. Instead, they produce a result for each row. Like the preceding queries, the following query uses `SUM()`, but this time as a window function:

```sql
mysql> SELECT year, country, product, profit,
      SUM(profit) OVER() AS total_profit,
      SUM(profit) OVER(PARTITION BY country) AS country_profit
FROM sales
ORDER BY country, year, product, profit;
+------+---------+------------+--------+--------------+----------------+
<table>
<thead>
<tr>
<th>year</th>
<th>country</th>
<th>product</th>
<th>profit</th>
<th>total_profit</th>
<th>country_profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>Finland</td>
<td>Computer</td>
<td>1500</td>
<td>7535</td>
<td>1610</td>
</tr>
<tr>
<td>2000</td>
<td>Finland</td>
<td>Phone</td>
<td>100</td>
<td>7535</td>
<td>1610</td>
</tr>
<tr>
<td>2001</td>
<td>Finland</td>
<td>Phone</td>
<td>10</td>
<td>7535</td>
<td>1610</td>
</tr>
<tr>
<td>2000</td>
<td>India</td>
<td>Calculator</td>
<td>75</td>
<td>7535</td>
<td>1350</td>
</tr>
<tr>
<td>2000</td>
<td>India</td>
<td>Calculator</td>
<td>75</td>
<td>7535</td>
<td>1350</td>
</tr>
<tr>
<td>2000</td>
<td>India</td>
<td>Computer</td>
<td>1200</td>
<td>7535</td>
<td>1350</td>
</tr>
<tr>
<td>2000</td>
<td>USA</td>
<td>Calculator</td>
<td>75</td>
<td>7535</td>
<td>4575</td>
</tr>
<tr>
<td>2000</td>
<td>USA</td>
<td>Computer</td>
<td>1500</td>
<td>7535</td>
<td>4575</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>Calculator</td>
<td>50</td>
<td>7535</td>
<td>4575</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>Computer</td>
<td>1200</td>
<td>7535</td>
<td>4575</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>TV</td>
<td>150</td>
<td>7535</td>
<td>4575</td>
</tr>
</tbody>
</table>
```
Each window operation in the query is signified by inclusion of an `OVER` clause that specifies how to partition query rows into groups for processing by the window function:

- The first `OVER` clause is empty, which treats the entire set of query rows as a single partition. The window function thus produces a global sum, but does so for each row.

- The second `OVER` clause partitions rows by country, producing a sum per partition (per country). The function produces this sum for each partition row.

Window functions are permitted only in the select list and `ORDER BY` clause. Query result rows are determined from the `FROM` clause, after `WHERE`, `GROUP BY`, and `HAVING` processing, and windowing execution occurs before `ORDER BY`, `LIMIT`, and `SELECT DISTINCT`.

The `OVER` clause is permitted for many aggregate functions, which therefore can be used as window or nonwindow functions, depending on whether the `OVER` clause is present or absent:

```
AVG()
BIT_AND()
BIT_OR()
BIT_XOR()
COUNT()
JSON_ARRAYAGG()
JSON_OBJECTAGG()
MAX()
MIN()
STDDEV_POP(), STDDEV(), STD()
STDDEV_SAMP()
SUM()
VAR_POP(), VARIANCE()
VAR_SAMP()
```

For details about each aggregate function, see Section 14.19.1, “Aggregate Function Descriptions”.

MySQL also supports nonaggregate functions that are used only as window functions. For these, the `OVER` clause is mandatory:

```
CUME_DIST()
DENSE_RANK()
FIRST_VALUE()
LAG()
LAST_VALUE()
LEAD()
NTH_VALUE()
NTILE()
PERCENT_RANK()
RANK()
ROW_NUMBER()
```

For details about each nonaggregate function, see Section 14.20.1, “Window Function Descriptions”.

As an example of one of those nonaggregate window functions, this query uses `ROW_NUMBER()`, which produces the row number of each row within its partition. In this case, rows are numbered per country. By default, partition rows are unordered and row numbering is nondeterministic. To sort partition rows, include an `ORDER BY` clause within the window definition. The query uses unordered and ordered partitions (the `row_num1` and `row_num2` columns) to illustrate the difference between omitting and including `ORDER BY`:

```
mysql> SELECT
          | year | country | product    | profit | row_num1 | row_num2 |
+-------+-------+----------+------------+--------+----------+----------+
| 2000  | Finland | Computer |   1500 |        2 |        1 |
| 2000  | Finland | Phone    |    100 |        1 |        2 |
```
As mentioned previously, to use a window function (or treat an aggregate function as a window function), include an `OVER` clause following the function call. The `OVER` clause has two forms:

\[
\text{over\_clause:} \quad \{\text{OVER (window\_spec)} \mid \text{OVER window\_name}\}
\]

Both forms define how the window function should process query rows. They differ in whether the window is defined directly in the `OVER` clause, or supplied by a reference to a named window defined elsewhere in the query:

- In the first case, the window specification appears directly in the `OVER` clause, between the parentheses.
- In the second case, `window\_name` is the name for a window specification defined by a `WINDOW` clause elsewhere in the query. For details, see Section 14.20.4, “Named Windows”.

For `OVER (window\_spec)` syntax, the window specification has several parts, all optional:

\[
\text{window\_spec:} \quad [\text{window\_name}] \ [\text{partition\_clause}] \ [\text{order\_clause}] \ [\text{frame\_clause}]
\]

If `OVER()` is empty, the window consists of all query rows and the window function computes a result using all rows. Otherwise, the clauses present within the parentheses determine which query rows are used to compute the function result and how they are partitioned and ordered:

- `window\_name`: The name of a window defined by a `WINDOW` clause elsewhere in the query. If `window\_name` appears by itself within the `OVER` clause, it completely defines the window. If partitioning, ordering, or framing clauses are also given, they modify interpretation of the named window. For details, see Section 14.20.4, “Named Windows”.

- `partition\_clause`: A `PARTITION BY` clause indicates how to divide the query rows into groups. The window function result for a given row is based on the rows of the partition that contains the row. If `PARTITION BY` is omitted, there is a single partition consisting of all query rows.

\[\text{partition\_clause:} \quad \text{PARTITION BY expr} \ [, \text{expr}] \ldots\]

Standard SQL requires `PARTITION BY` to be followed by column names only. A MySQL extension is to permit expressions, not just column names. For example, if a table contains a `TIMESTAMP` column named `ts`, standard SQL permits `PARTITION BY ts` but not `PARTITION BY HOUR(ts)`, whereas MySQL permits both.

- `order\_clause`: An `ORDER BY` clause indicates how to sort rows in each partition. Partition rows that are equal according to the `ORDER BY` clause are considered peers. If `ORDER BY` is omitted, partition rows are unordered, with no processing order implied, and all partition rows are peers.
Window Function Frame Specification

$order_clause$ has this syntax:

```sql
$order_clause:
  ORDER BY expr [ASC|DESC] [, expr [ASC|DESC]] ...
```

Each $ORDER BY$ expression optionally can be followed by $ASC$ or $DESC$ to indicate sort direction. The default is $ASC$ if no direction is specified. $NULL$ values sort first for ascending sorts, last for descending sorts.

An $ORDER BY$ in a window definition applies within individual partitions. To sort the result set as a whole, include an $ORDER BY$ at the query top level.

- $frame_clause$: A frame is a subset of the current partition and the frame clause specifies how to define the subset. The frame clause has many subclauses of its own. For details, see Section 14.20.3, “Window Function Frame Specification”.

### 14.20.3 Window Function Frame Specification

The definition of a window used with a window function can include a frame clause. A frame is a subset of the current partition and the frame clause specifies how to define the subset.

Frames are determined with respect to the current row, which enables a frame to move within a partition depending on the location of the current row within its partition. Examples:

- By defining a frame to be all rows from the partition start to the current row, you can compute running totals for each row.
- By defining a frame as extending $N$ rows on either side of the current row, you can compute rolling averages.

The following query demonstrates the use of moving frames to compute running totals within each group of time-ordered $level$ values, as well as rolling averages computed from the current row and the rows that immediately precede and follow it:

```sql
mysql> SELECT
      time, subject, val,
      SUM(val) OVER (PARTITION BY subject ORDER BY time
                    ROWS UNBOUNDED PRECEDING)
      AS running_total,
      AVG(val) OVER (PARTITION BY subject ORDER BY time
                    ROWS BETWEEN 1 PRECEDING AND 1 FOLLOWING)
      AS running_average
      FROM observations;
```

<table>
<thead>
<tr>
<th>time</th>
<th>subject</th>
<th>val</th>
<th>running_total</th>
<th>running_average</th>
</tr>
</thead>
<tbody>
<tr>
<td>07:00:00</td>
<td>st113</td>
<td>10</td>
<td>10</td>
<td>9.5000</td>
</tr>
<tr>
<td>07:15:00</td>
<td>st113</td>
<td>9</td>
<td>19</td>
<td>14.6667</td>
</tr>
<tr>
<td>07:30:00</td>
<td>st113</td>
<td>25</td>
<td>44</td>
<td>18.0000</td>
</tr>
<tr>
<td>07:45:00</td>
<td>st113</td>
<td>20</td>
<td>64</td>
<td>22.5000</td>
</tr>
<tr>
<td>07:00:00</td>
<td>xh458</td>
<td>0</td>
<td>0</td>
<td>5.0000</td>
</tr>
<tr>
<td>07:15:00</td>
<td>xh458</td>
<td>10</td>
<td>10</td>
<td>5.0000</td>
</tr>
<tr>
<td>07:30:00</td>
<td>xh458</td>
<td>5</td>
<td>15</td>
<td>15.0000</td>
</tr>
<tr>
<td>07:45:00</td>
<td>xh458</td>
<td>30</td>
<td>45</td>
<td>20.0000</td>
</tr>
<tr>
<td>08:00:00</td>
<td>xh458</td>
<td>25</td>
<td>70</td>
<td>27.5000</td>
</tr>
</tbody>
</table>

For the $running_average$ column, there is no frame row preceding the first one or following the last. In these cases, $AVG()$ computes the average of the rows that are available.

Aggregate functions used as window functions operate on rows in the current row frame, as do these nonaggregate window functions:

- $FIRST_VALUE()$
- $LAST_VALUE()$
- $NTH_VALUE()$
Window Function Frame Specification

Standard SQL specifies that window functions that operate on the entire partition should have no frame clause. MySQL permits a frame clause for such functions but ignores it. These functions use the entire partition even if a frame is specified:

- CUME_DIST()
- DENSE_RANK()
- LAG()
- LEAD()
- NTILE()
- PERCENT_RANK()
- RANK()
- ROW_NUMBER()

The frame clause, if given, has this syntax:

```sql
frame_clause:
  frame_units frame_extent

frame_units:
  {ROWS | RANGE}
```

In the absence of a frame clause, the default frame depends on whether an `ORDER BY` clause is present, as described later in this section.

The `frame_units` value indicates the type of relationship between the current row and frame rows:

- **ROWS**: The frame is defined by beginning and ending row positions. Offsets are differences in row numbers from the current row number.
- **RANGE**: The frame is defined by rows within a value range. Offsets are differences in row values from the current row value.

The `frame_extent` value indicates the start and end points of the frame. You can specify just the start of the frame (in which case the current row is implicitly the end) or use `BETWEEN` to specify both frame endpoints:

```sql
frame_extent:
  {frame_start | frame_between}

frame_between:
  BETWEEN frame_start AND frame_end

frame_start, frame_end: {
  CURRENT ROW
  | UNBOUNDED PRECEDING
  | UNBOUNDED FOLLOWING
  | expr PRECEDING
  | expr FOLLOWING
}
```

With `BETWEEN` syntax, `frame_start` must not occur later than `frame_end`.

The permitted `frame_start` and `frame_end` values have these meanings:

- **CURRENT ROW**: For ROWS, the bound is the current row. For RANGE, the bound is the peers of the current row.
- **UNBOUNDED PRECEDING**: The bound is the first partition row.
- **UNBOUNDED FOLLOWING**: The bound is the last partition row.
- **expr PRECEDING**: For ROWS, the bound is `expr` rows before the current row. For RANGE, the bound is the rows with values equal to the current row value minus `expr`; if the current row value is NULL, the bound is the peers of the row.

For `expr PRECEDING` (and `expr FOLLOWING`), `expr` can be a ? parameter marker (for use in a prepared statement), a nonnegative numeric literal, or a temporal interval of the form `INTERVAL`
val unit. For INTERVAL expressions, val specifies nonnegative interval value, and unit is a keyword indicating the units in which the value should be interpreted. (For details about the permitted units specifiers, see the description of the DATE_ADD() function in Section 14.7, “Date and Time Functions”.)

RANGE on a numeric or temporal expr requires ORDER BY on a numeric or temporal expression, respectively.

Examples of valid expr PRECEDING and expr FOLLOWING indicators:

| 10 PRECEDING |
| INTERVAL 5 DAY PRECEDING |
| 5 FOLLOWING |
| INTERVAL '2:30' MINUTE_SECOND FOLLOWING |

- expr FOLLOWING: For ROWS, the bound is expr rows after the current row. For RANGE, the bound is the rows with values equal to the current row value plus expr; if the current row value is NULL, the bound is the peers of the row.

For permitted values of expr, see the description of expr PRECEDING.

The following query demonstrates FIRST_VALUE(), LAST_VALUE(), and two instances of NTH_VALUE():

```sql
mysql> SELECT time, subject, val, 
           FIRST_VALUE(val) OVER w AS 'first', 
           LAST_VALUE(val)   OVER w AS 'last', 
           NTH_VALUE(val, 2) OVER w AS 'second', 
           NTH_VALUE(val, 4) OVER w AS 'fourth' 
FROM observations 
WINDOW w AS (PARTITION BY subject ORDER BY time 
ROWS UNBOUNDED PRECEDING); 
```

<table>

</tbody>
</table>

Each function uses the rows in the current frame, which, per the window definition shown, extends from the first partition row to the current row. For the NTH_VALUE() calls, the current frame does not always include the requested row; in such cases, the return value is NULL.

In the absence of a frame clause, the default frame depends on whether an ORDER BY clause is present:

• With ORDER BY: The default frame includes rows from the partition start through the current row, including all peers of the current row (rows equal to the current row according to the ORDER BY clause). The default is equivalent to this frame specification:

RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW

• Without ORDER BY: The default frame includes all partition rows (because, without ORDER BY, all partition rows are peers). The default is equivalent to this frame specification:

RANGE BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING

Because the default frame differs depending on presence or absence of ORDER BY, adding ORDER BY to a query to get deterministic results may change the results. (For example, the values produced by
SUM() might change.) To obtain the same results but ordered per ORDER BY, provide an explicit frame specification to be used regardless of whether ORDER BY is present.

The meaning of a frame specification can be nonobvious when the current row value is NULL. Assuming that to be the case, these examples illustrate how various frame specifications apply:

- **ORDER BY X ASC RANGE BETWEEN 10 FOLLOWING AND 15 FOLLOWING**
  The frame starts at NULL and stops at NULL, thus includes only rows with value NULL.

- **ORDER BY X ASC RANGE BETWEEN 10 FOLLOWING AND UNBOUNDED FOLLOWING**
  The frame starts at NULL and stops at the end of the partition. Because an ASC sort puts NULL values first, the frame is the entire partition.

- **ORDER BY X DESC RANGE BETWEEN 10 FOLLOWING AND UNBOUNDED FOLLOWING**
  The frame starts at NULL and stops at NULL, thus includes only rows with value NULL.

- **ORDER BY X ASC RANGE BETWEEN 10 PRECEDING AND UNBOUNDED FOLLOWING**
  The frame starts at NULL and stops at the end of the partition. Because an ASC sort puts NULL values last, the frame is only the NULL values.

- **ORDER BY X ASC RANGE BETWEEN 10 PRECEDING AND 10 FOLLOWING**
  The frame starts at NULL and stops at NULL, thus includes only rows with value NULL.

- **ORDER BY X ASC RANGE BETWEEN 10 PRECEDING AND 1 PRECEDING**
  The frame starts at NULL and stops at NULL, thus includes only rows with value NULL.

- **ORDER BY X ASC RANGE BETWEEN UNBOUNDED PRECEDING AND 10 FOLLOWING**
  The frame starts at the beginning of the partition and stops at rows with value NULL. Because an ASC sort puts NULL values first, the frame is only the NULL values.

### 14.20.4 Named Windows

Windows can be defined and given names by which to refer to them in OVER clauses. To do this, use a WINDOW clause. If present in a query, the WINDOW clause falls between the positions of the HAVING and ORDER BY clauses, and has this syntax:

```sql
WINDOW window_name AS (window_spec)
[, window_name AS (window_spec)] ...
```

For each window definition, `window_name` is the window name, and `window_spec` is the same type of window specification as given between the parentheses of an OVER clause, as described in Section 14.20.2, “Window Function Concepts and Syntax”:

```sql
window_spec:
 [window_name] [partition_clause] [order_clause] [frame_clause]
```

A WINDOW clause is useful for queries in which multiple OVER clauses would otherwise define the same window. Instead, you can define the window once, give it a name, and refer to the name in the OVER clauses. Consider this query, which defines the same query multiple times:

```sql
SELECT
 val,
 ROW_NUMBER() OVER (ORDER BY val) AS 'row_number',
 RANK() OVER (ORDER BY val) AS 'rank',
 DENSE_RANK() OVER (ORDER BY val) AS 'dense_rank'
FROM numbers;
```
The query can be written more simply by using `WINDOW` to define the window once and referring to the window by name in the `OVER` clauses:

```sql
SELECT
  val,
  ROW_NUMBER() OVER w AS 'row_number',
  RANK() OVER w AS 'rank',
  DENSE_RANK() OVER w AS 'dense_rank'
FROM numbers
WINDOW w AS (ORDER BY val);
```

A named window also makes it easier to experiment with the window definition to see the effect on query results. You need only modify the window definition in the `WINDOW` clause, rather than multiple `OVER` clause definitions.

If an `OVER` clause uses `OVER (window_name ...)` rather than `OVER window_name`, the named window can be modified by the addition of other clauses. For example, this query defines a window that includes partitioning, and uses `ORDER BY` in the `OVER` clauses to modify the window in different ways:

```sql
SELECT
  DISTINCT year, country,
  FIRST_VALUE(year) OVER (w ORDER BY year ASC) AS first,
  FIRST_VALUE(year) OVER (w ORDER BY year DESC) AS last
FROM sales
WINDOW w AS (PARTITION BY country);
```

An `OVER` clause can only add properties to a named window, not modify them. If the named window definition includes a partitioning, ordering, or framing property, the `OVER` clause that refers to the window name cannot also include the same kind of property or an error occurs:

- This construct is permitted because the window definition and the referring `OVER` clause do not contain the same kind of properties:
  ```sql
  OVER (w ORDER BY country)
  ... WINDOW w AS (PARTITION BY country)
  ```

- This construct is not permitted because the `OVER` clause specifies `PARTITION BY` for a named window that already has `PARTITION BY`:
  ```sql
  OVER (w PARTITION BY year)
  ... WINDOW w AS (PARTITION BY country)
  ```

The definition of a named window can itself begin with a `window_name`. In such cases, forward and backward references are permitted, but not cycles:

- This is permitted; it contains forward and backward references but no cycles:
  ```sql
  WINDOW w1 AS (w2), w2 AS (), w3 AS (w1)
  ```

- This is not permitted because it contains a cycle:
  ```sql
  WINDOW w1 AS (w2), w2 AS (w3), w3 AS (w1)
  ```

### 14.20.5 Window Function Restrictions

The SQL standard imposes a constraint on window functions that they cannot be used in `UPDATE` or `DELETE` statements to update rows. Using such functions in a subquery of these statements (to select rows) is permitted.

MySQL does not support these window function features:

- `DISTINCT` syntax for aggregate window functions.
- Nested window functions.
- Dynamic frame endpoints that depend on the value of the current row.
The parser recognizes these window constructs which nevertheless are not supported:

- The `GROUPS` frame units specifier is parsed, but produces an error. Only `ROWS` and `RANGE` are supported.
- The `EXCLUDE` clause for frame specification is parsed, but produces an error.
- `IGNORE NULLS` is parsed, but produces an error. Only `RESPECT NULLS` is supported.
- `FROM LAST` is parsed, but produces an error. Only `FROM FIRST` is supported.

A maximum of 127 windows is supported for a given `SELECT`. Note that a single query may use multiple `SELECT` clauses, and each of these clauses supports up to 127 windows. The number of distinct windows is defined as the sum of the named windows and any implicit windows specified as part of any window function's `OVER` clause. You should also be aware that queries using very large numbers of windows may require increasing the default thread stack size (`thread_stack` system variable).

### 14.21 Performance Schema Functions

MySQL includes built-in SQL functions that format or retrieve Performance Schema data, and that may be used as equivalents for the corresponding `sys` schema stored functions. The built-in functions can be invoked in any schema and require no qualifier, unlike the `sys` functions, which require either a `sys` schema qualifier or that `sys` be the current schema.

#### Table 14.31 Performance Schema Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>FORMAT_BYTES()</code></td>
<td>Convert byte count to value with units</td>
</tr>
<tr>
<td><code>FORMAT_PICO_TIME()</code></td>
<td>Convert time in picoseconds to value with units</td>
</tr>
<tr>
<td><code>PS_CURRENT_THREAD_ID()</code></td>
<td>Performance Schema thread ID for current thread</td>
</tr>
<tr>
<td><code>PS_THREAD_ID()</code></td>
<td>Performance Schema thread ID for given thread</td>
</tr>
</tbody>
</table>

The built-in functions supersede the corresponding `sys` functions, which are deprecated; expect them to be removed in a future version of MySQL. Applications that use the `sys` functions should be adjusted to use the built-in functions instead, keeping in mind some minor differences between the `sys` functions and the built-in functions. For details about these differences, see the function descriptions in this section.

#### `FORMAT_BYTES(count)`

Given a numeric byte count, converts it to human-readable format and returns a string consisting of a value and a units indicator. The string contains the number of bytes rounded to 2 decimal places and a minimum of 3 significant digits. Numbers less than 1024 bytes are represented as whole numbers and are not rounded. Returns `NULL` if `count` is `NULL`.

The units indicator depends on the size of the byte-count argument as shown in the following table.
mysql> SELECT FORMAT_BYTES(512), FORMAT_BYTES(18446644073709551615);
+-------------------+------------------------------------+
| FORMAT_BYTES(512) | FORMAT_BYTES(18446644073709551615) |
| 512 bytes         | 16.00 EiB                           |
+-------------------+------------------------------------+

`FORMAT_BYTES()` may be used instead of the `sys` schema `format_bytes()` function, keeping in mind this difference:

- `FORMAT_BYTES()` uses the EiB units indicator. `sys.format_bytes()` does not.

`FORMAT_PICO_TIME(time_val)`

Given a numeric Performance Schema latency or wait time in picoseconds, converts it to human-readable format and returns a string consisting of a value and a units indicator. The string contains the decimal time rounded to 2 decimal places and a minimum of 3 significant digits. Times under 1 nanosecond are represented as whole numbers and are not rounded.

If `time_val` is `NULL`, this function returns `NULL`.

The units indicator depends on the size of the time-value argument as shown in the following table.

<table>
<thead>
<tr>
<th>Argument Value</th>
<th>Result Units</th>
<th>Result Units Indicator</th>
</tr>
</thead>
<tbody>
<tr>
<td>Up to $10^2 - 1$</td>
<td>picoseconds</td>
<td>ps</td>
</tr>
<tr>
<td>Up to $10^5 - 1$</td>
<td>nanoseconds</td>
<td>ns</td>
</tr>
<tr>
<td>Up to $10^8 - 1$</td>
<td>microseconds</td>
<td>us</td>
</tr>
<tr>
<td>Up to $10^{12} - 1$</td>
<td>milliseconds</td>
<td>ms</td>
</tr>
<tr>
<td>Up to 60×$10^{12} - 1$</td>
<td>seconds</td>
<td>s</td>
</tr>
<tr>
<td>Up to 3.6×$10^{16} - 1$</td>
<td>minutes</td>
<td>min</td>
</tr>
<tr>
<td>Up to 8.64×$10^{16} - 1$</td>
<td>hours</td>
<td>h</td>
</tr>
<tr>
<td>8.64×$10^{16}$ and up</td>
<td>days</td>
<td>d</td>
</tr>
</tbody>
</table>

mysql> SELECT FORMAT_PICO_TIME(3501), FORMAT_PICO_TIME(188732396662000);
+------------------------+-----------------------------------+
| FORMAT_PICO_TIME(3501) | FORMAT_PICO_TIME(188732396662000) |
| 3.50 ns                | 3.15 min                          |
+------------------------+-----------------------------------+

`FORMAT_PICO_TIME()` may be used instead of the `sys` schema `format_time()` function, keeping in mind these differences:

- To indicate minutes, `sys.format_time()` uses the m units indicator, whereas `FORMAT_PICO_TIME()` uses min.

- `sys.format_time()` uses the w (weeks) units indicator. `FORMAT_PICO_TIME()` does not.
Performance Schema Functions

- **PS_CURRENT_THREAD_ID()**

  Returns a **BIGINT UNSIGNED** value representing the Performance Schema thread ID assigned to the current connection.

  The thread ID return value is a value of the type given in the **THREAD_ID** column of Performance Schema tables.

  Performance Schema configuration affects **PS_CURRENT_THREAD_ID()** the same way as for **PS_THREAD_ID()**. For details, see the description of that function.

  ```
  mysql> SELECT PS_CURRENT_THREAD_ID();
  +------------------------+
  | PS_CURRENT_THREAD_ID() |
  +------------------------+
  |                     52 |
  +------------------------+
  mysql> SELECT PS_THREAD_ID(CONNECTION_ID());
  +-------------------------------+
  | PS_THREAD_ID(CONNECTION_ID()) |
  +-------------------------------+
  |                            52 |
  +-------------------------------+
  
  PS_CURRENT_THREAD_ID() may be used as a shortcut for invoking the **sys** schema **ps_thread_id()** function with an argument of NULL or CONNECTION_ID().

- **PS_THREAD_ID(connection_id)**

  Given a connection ID, returns a **BIGINT UNSIGNED** value representing the Performance Schema thread ID assigned to the connection ID, or **NULL** if no thread ID exists for the connection ID. The latter can occur for threads that are not instrumented, or if **connection_id** is **NULL**.

  The connection ID argument is a value of the type given in the **PROCESSLIST_ID** column of the Performance Schema **threads** table or the **Id** column of **SHOW PROCESSLIST** output.

  The thread ID return value is a value of the type given in the **THREAD_ID** column of Performance Schema tables.

  Performance Schema configuration affects **PS_THREAD_ID()** operation as follows. (These remarks also apply to **PS_CURRENT_THREAD_ID()**.)

  - Disabling the **thread_instrumentation** consumer disables statistics from being collected and aggregated at the thread level, but has no effect on **PS_THREAD_ID()**.

  - If **performance_schema_max_thread_instances** is not 0, the Performance Schema allocates memory for thread statistics and assigns an internal ID to each thread for which instance memory is available. If there are threads for which instance memory is not available, **PS_THREAD_ID()** returns **NULL**; in this case, **Performance_schema_thread_instances_lost** is nonzero.

  - If **performance_schema_max_thread_instances** is 0, the Performance Schema allocates no thread memory and **PS_THREAD_ID()** returns **NULL**.

  - If the Performance Schema itself is disabled, **PS_THREAD_ID()** produces an error.

  ```
  mysql> SELECT PS_THREAD_ID(6);
  +-----------------+
  | PS_THREAD_ID(6) |
  +-----------------+
  |              45 |
  +-----------------+
  ```
**PS_THREAD_ID()** may be used instead of the `sys` schema `ps_thread_id()` function, keeping in mind this difference:

- With an argument of `NULL`, `sys.ps_thread_id()` returns the thread ID for the current connection, whereas `PS_THREAD_ID()` returns `NULL`. To obtain the current connection thread ID, use `PS_CURRENT_THREAD_ID()` instead.

## 14.22 Internal Functions

### Table 14.32 Internal Functions

<table>
<thead>
<tr>
<th>Name</th>

</tr>
</tbody>
</table>

- **ANY_VALUE(arg)**

  This function is useful for `GROUP BY` queries when the `ONLY_FULL_GROUP_BY` SQL mode is enabled, for cases when MySQL rejects a query that you know is valid for reasons that MySQL cannot determine. The function return value and type are the same as the return value and type of its argument, but the function result is not checked for the `ONLY_FULL_GROUP_BY` SQL mode.

  For example, if `name` is a nonindexed column, the following query fails with `ONLY_FULL_GROUP_BY` enabled:

  ```sql
  mysql> SELECT name, address, MAX(age) FROM t GROUP BY name;
  ERROR 1055 (42000): Expression #2 of SELECT list is not in GROUP BY clause and contains nonaggregated column 'mydb.t.address' which is not functionally dependent on columns in GROUP BY clause; this is incompatible with sql_mode=only_full_group_by
  ```

  The failure occurs because `address` is a nonaggregated column that is neither named among `GROUP BY` columns nor functionally dependent on them. As a result, the `address` value for rows within each `name` group is nondeterministic. There are multiple ways to cause MySQL to accept the query:

  - Alter the table to make `name` a primary key or a unique `NOT NULL` column. This enables MySQL to determine that `address` is functionally dependent on `name`; that is, `address` is uniquely determined by `name`. (This technique is inapplicable if `NULL` must be permitted as a valid `name` value.)
  
  - Use **ANY_VALUE()** to refer to `address`:

    ```sql
    SELECT name, ANY_VALUE(address), MAX(age) FROM t GROUP BY name;
    ```

    In this case, MySQL ignores the nondeterminism of `address` values within each `name` group and accepts the query. This may be useful if you simply do not care which value of a nonaggregated column is chosen for each group. **ANY_VALUE()** is not an aggregate function, unlike functions such as `SUM()` or `COUNT()`. It simply acts to suppress the test for nondeterminism.

  - Disable `ONLY_FULL_GROUP_BY`. This is equivalent to using **ANY_VALUE()** with `ONLY_FULL_GROUP_BY` enabled, as described in the previous item.

    **ANY_VALUE()** is also useful if functional dependence exists between columns but MySQL cannot determine it. The following query is valid because `age` is functionally dependent on the grouping column `age-1`, but MySQL cannot tell that and rejects the query with `ONLY_FULL_GROUP_BY` enabled:
SELECT age FROM t GROUP BY age-1;

To cause MySQL to accept the query, use \texttt{ANY\_VALUE}():

SELECT \texttt{ANY\_VALUE}(age) FROM t GROUP BY age-1;

\texttt{ANY\_VALUE()} can be used for queries that refer to aggregate functions in the absence of a \texttt{GROUP BY} clause:

\begin{verbatim}
mysql> SELECT name, MAX(age) FROM t;
ERROR 1140 (42000): In aggregated query without \texttt{GROUP BY}, expression #1 of SELECT list contains nonaggregated column 'mydb.t.name'; this is incompatible with \texttt{sql_mode=only\_full\_group\_by}
\end{verbatim}

Without \texttt{GROUP BY}, there is a single group and it is nondeterministic which \texttt{name} value to choose for the group. \texttt{ANY\_VALUE()} tells MySQL to accept the query:

SELECT \texttt{ANY\_VALUE}(name), MAX(age) FROM t;

It may be that, due to some property of a given data set, you know that a selected nonaggregated column is effectively functionally dependent on a \texttt{GROUP BY} column. For example, an application may enforce uniqueness of one column with respect to another. In this case, using \texttt{ANY\_VALUE()} for the effectively functionally dependent column may make sense.

For additional discussion, see Section 14.19.3, “MySQL Handling of \texttt{GROUP BY}”.

- \texttt{BIN\_TO\_UUID(binary\_uuid), BIN\_TO\_UUID(binary\_uuid, swap\_flag)}

\texttt{BIN\_TO\_UUID()} is the inverse of \texttt{UUID\_TO\_BIN()}. It converts a binary UUID to a string UUID and returns the result. The binary value should be a UUID as a \texttt{VARBINARY(16)} value. The return value is a string of five hexadecimal numbers separated by dashes. (For details about this format, see the \texttt{UUID()} function description.) If the UUID argument is \texttt{NULL}, the return value is \texttt{NULL}. If any argument is invalid, an error occurs.

\texttt{BIN\_TO\_UUID()} takes one or two arguments:

- The one-argument form takes a binary UUID value. The UUID value is assumed not to have its time-low and time-high parts swapped. The string result is in the same order as the binary argument.

- The two-argument form takes a binary UUID value and a swap-flag value:

  - If \texttt{swap\_flag} is 0, the two-argument form is equivalent to the one-argument form. The string result is in the same order as the binary argument.

  - If \texttt{swap\_flag} is 1, the UUID value is assumed to have its time-low and time-high parts swapped. These parts are swapped back to their original position in the result value.

For usage examples and information about time-part swapping, see the \texttt{UUID\_TO\_BIN()} function description.

- \texttt{DEFAULT(col\_name)}

Returns the default value for a table column. An error results if the column has no default value.

The use of \texttt{DEFAULT(col\_name)} to specify the default value for a named column is permitted only for columns that have a literal default value, not for columns that have an expression default value.

\begin{verbatim}
mysql> UPDATE t SET i = DEFAULT(i)+1 WHERE id < 100;
\end{verbatim}
• **FORMAT**(X, D)

  Formats the number X to a format like '#,###,###.##', rounded to D decimal places, and returns the result as a string. For details, see Section 14.8, "String Functions and Operators".

• **GROUPING(expr [, expr] ...)**

  For GROUP BY queries that include a WITH ROLLUP modifier, the ROLLUP operation produces super-aggregate output rows where NULL represents the set of all values. The GROUPING() function enables you to distinguish NULL values for super-aggregate rows from NULL values in regular grouped rows.

  GROUPING() is permitted in the select list, HAVING clause, and ORDER BY clause.

  Each argument to GROUPING() must be an expression that exactly matches an expression in the GROUP BY clause. The expression cannot be a positional specifier. For each expression, GROUPING() produces 1 if the expression value in the current row is a NULL representing a super-aggregate value. Otherwise, GROUPING() produces 0, indicating that the expression value is a NULL for a regular result row or is not NULL.

  Suppose that table t1 contains these rows, where NULL indicates something like “other” or “unknown”:

  ```
  mysql> SELECT * FROM t1;
  +-------+-------+----------+
  | name  | size  | quantity |
  +-------+-------+----------+
  | ball  | small | 10       |
  | ball  | large | 20       |
  | ball  | NULL  | 5        |
  | hoop  | small | 15       |
  | hoop  | large | 5        |
  | hoop  | NULL  | 3        |
  +-------+-------+----------+
  ```

  A summary of the table without WITH ROLLUP looks like this:

  ```
  mysql> SELECT name, size, SUM(quantity) AS quantity
                    FROM t1
                    GROUP BY name, size;
  +-------+-------+----------+
  | name  | size  | quantity |
  +-------+-------+----------+
  | ball  | small | 10       |
  | ball  | large | 20       |
  | ball  | NULL  | 5        |
  | hoop  | small | 15       |
  | hoop  | large | 5        |
  | hoop  | NULL  | 3        |
  +-------+-------+----------+
  ```

  The result contains NULL values, but those do not represent super-aggregate rows because the query does not include WITH ROLLUP.

  Adding WITH ROLLUP produces super-aggregate summary rows containing additional NULL values. However, without comparing this result to the previous one, it is not easy to see which NULL values occur in super-aggregate rows and which occur in regular grouped rows:

  ```
  mysql> SELECT name, size, SUM(quantity) AS quantity
                    FROM t1
                    GROUP BY name, size WITH ROLLUP;
  +-------+-------+----------+
  | name  | size  | quantity |
  +-------+-------+----------+
  | ball  | NULL  | 5        |
  | ball  | large | 20       |
  | ball  | small | 10       |
  +-------+-------+----------+
  ```
To distinguish NULL values in super-aggregate rows from those in regular grouped rows, use `GROUPING()`, which returns 1 only for super-aggregate NULL values:

```sql
SELECT name, size, SUM(quantity) AS quantity,
      GROUPING(name) AS grp_name,
      GROUPING(size) AS grp_size
FROM t1
GROUP BY name, size WITH ROLLUP;
```

<table>

<td>ball</td>
<td>NULL</td>
<td>35</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>3</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>hoop</td>
<td>large</td>
<td>5</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>hoop</td>
<td>small</td>
<td>15</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>23</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
<td>58</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

Common uses for `GROUPING()`:

- Substitute a label for super-aggregate NULL values:

```sql
SELECT IF(GROUPING(name) = 1, 'All items', name) AS name,
      IF(GROUPING(size) = 1, 'All sizes', size) AS size,
      SUM(quantity) AS quantity
FROM t1
GROUP BY name, size WITH ROLLUP;
```

<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
<th>quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>ball</td>
<td>NULL</td>
<td>5</td>
</tr>
<tr>
<td>ball</td>
<td>large</td>
<td>20</td>
</tr>
<tr>
<td>ball</td>
<td>small</td>
<td>10</td>
</tr>
<tr>
<td>ball</td>
<td>All sizes</td>
<td>35</td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>3</td>
</tr>
<tr>
<td>hoop</td>
<td>large</td>
<td>5</td>
</tr>
<tr>
<td>hoop</td>
<td>small</td>
<td>15</td>
</tr>
<tr>
<td>All items</td>
<td>All sizes</td>
<td>23</td>
</tr>
</tbody>
</table>

- Return only super-aggregate lines by filtering out the regular grouped lines:

```sql
SELECT name, size, SUM(quantity) AS quantity
FROM t1
GROUP BY name, size WITH ROLLUP
HAVING GROUPING(name) = 1 OR GROUPING(size) = 1;
```

<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
<th>quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>ball</td>
<td>NULL</td>
<td>35</td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>23</td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
<td>58</td>
</tr>
</tbody>
</table>
GROUPING() permits multiple expression arguments. In this case, the GROUPING() return value represents a bitmask combined from the results for each expression, where the lowest-order bit corresponds to the result for the rightmost expression. For example, with three expression arguments, GROUPING(expr1, expr2, expr3) is evaluated like this:

result for GROUPING(expr3) + result for GROUPING(expr2) << 1 + result for GROUPING(expr1) << 2

The following query shows how GROUPING() results for single arguments combine for a multiple-argument call to produce a bitmask value:

```sql
mysql> SELECT name, size, SUM(quantity) AS quantity,
GROUPING(name) AS grp_name,
GROUPING(size) AS grp_size,
GROUPING(name, size) AS grp_all
FROM t1
GROUP BY name, size WITH ROLLUP;
```

<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
<th>quantity</th>
<th>grp_name</th>
<th>grp_size</th>
<th>grp_all</th>
</tr>
</thead>
<tbody>
<tr>
<td>ball</td>
<td>NULL</td>
<td>5</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>ball</td>
<td>large</td>
<td>20</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>ball</td>
<td>small</td>
<td>10</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>ball</td>
<td>NULL</td>
<td>35</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>3</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>hoop</td>
<td>large</td>
<td>5</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>hoop</td>
<td>small</td>
<td>15</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>23</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
<td>58</td>
<td>1</td>
<td>1</td>
<td>3</td>
</tr>
</tbody>
</table>

With multiple expression arguments, the GROUPING() return value is nonzero if any expression represents a super-aggregate value. Multiple-argument GROUPING() syntax thus provides a simpler way to write the earlier query that returned only super-aggregate rows, by using a single multiple-argument GROUPING() call rather than multiple single-argument calls:

```sql
mysql> SELECT name, size, SUM(quantity) AS quantity
FROM t1
GROUP BY name, size WITH ROLLUP
HAVING GROUPING(name, size) <> 0;
```

<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
<th>quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>ball</td>
<td>NULL</td>
<td>35</td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>23</td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
<td>58</td>
</tr>
</tbody>
</table>

Use of GROUPING() is subject to these limitations:

- Do not use subquery GROUP BY expressions as GROUPING() arguments because matching might fail. For example, matching fails for this query:

```sql
mysql> SELECT GROUPING((SELECT MAX(name) FROM t1))
FROM t1
GROUP BY (SELECT MAX(name) FROM t1) WITH ROLLUP;
```

ERROR 3580 (HY000): Argument #1 of GROUPING function is not in GROUP BY

- GROUP BY literal expressions should not be used within a HAVING clause as GROUPING() arguments. Due to differences between when the optimizer evaluates GROUP BY and HAVING,
matching may succeed but GROUPING() evaluation does not produce the expected result. Consider this query:

```sql
SELECT a AS f1, 'w' AS f2
FROM t
GROUP BY f1, f2 WITH ROLLUP
HAVING GROUPING(f2) = 1;
```

GROUPING() is evaluated earlier for the literal constant expression than for the HAVING clause as a whole and returns 0. To check whether a query such as this is affected, use EXPLAIN and look for Impossible having in the Extra column.

For more information about WITH ROLLUP and GROUPING(), see Section 14.19.2, “GROUP BY Modifiers”.

- **INET_ATON(expr)**

  Given the dotted-quad representation of an IPv4 network address as a string, returns an integer that represents the numeric value of the address in network byte order (big endian). INET_ATON() returns NULL if it does not understand its argument, or if expr is NULL.

  ```sql
  mysql> SELECT INET_ATON('10.0.5.9');
  -> 167773449
  ```

  For this example, the return value is calculated as $10 \times 256^3 + 0 \times 256^2 + 5 \times 256 + 9$.

  INET_ATON() may or may not return a non-NULL result for short-form IP addresses (such as '127.1' as a representation of '127.0.0.1'). Because of this, INET_ATON() a should not be used for such addresses.

  **Note**

  To store values generated by INET_ATON(), use an INT UNSIGNED column rather than INT, which is signed. If you use a signed column, values corresponding to IP addresses for which the first octet is greater than 127 cannot be stored correctly. See Section 13.1.7, “Out-of-Range and Overflow Handling”.

- **INET_NTOA(expr)**

  Given a numeric IPv4 network address in network byte order, returns the dotted-quad string representation of the address as a string in the connection character set. INET_NTOA() returns NULL if it does not understand its argument.

  ```sql
  mysql> SELECT INET_NTOA(167773449);
  -> '10.0.5.9'
  ```

- **INET6_ATON(expr)**

  Given an IPv6 or IPv4 network address as a string, returns a binary string that represents the numeric value of the address in network byte order (big endian). Because numeric-format IPv6 addresses require more bytes than the largest integer type, the representation returned by this function has the VARBINARY data type: VARBINARY(16) for IPv6 addresses and VARBINARY(4) for IPv4 addresses. If the argument is not a valid address, or if it is NULL, INET6_ATON() returns NULL.

  The following examples use HEX() to display the INET6_ATON() result in printable form:

  ```sql
  mysql> SELECT HEX(INET6_ATON('fdfe::5a55:caff:fefa:9089'));
  -> 'FDFE0000000000005A55CAFFFEFA9089'
  mysql> SELECT HEX(INET6_ATON('10.0.5.9'));
  ```
**INET6_ATON()** observes several constraints on valid arguments. These are given in the following list along with examples.

- A trailing zone ID is not permitted, as in `fe80::3%1` or `fe80::3%eth0`.
- A trailing network mask is not permitted, as in `2001:45f:3:ba::/64` or `198.51.100.0/24`.
- For values representing IPv4 addresses, only classless addresses are supported. Classful addresses such as `198.51.1` are rejected. A trailing port number is not permitted, as in `198.51.100.2:8080`. Hexadecimal numbers in address components are not permitted, as in `198.0xa0.1.2`. Octal numbers are not supported: `198.51.010.1` is treated as `198.51.10.1`, not `198.51.8.1`. These IPv4 constraints also apply to IPv6 addresses that have IPv4 address parts, such as IPv4-compatible or IPv4-mapped addresses.

To convert an IPv4 address `expr` represented in numeric form as an INT value to an IPv6 address represented in numeric form as a VARBINARY value, use this expression:

\[
\text{INET6_ATON(\text{INET6_NTOA}(\text{expr}))}
\]

For example:

```sql
mysql> SELECT HEX(INET6_ATON(INET6_NTOA(167773449)));
-> '0A000509'
```

If **INET6_ATON()** is invoked from within the **mysql** client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 6.5.1, "mysql — The MySQL Command-Line Client".

**INET6_NTOA(expr)**

Given an IPv6 or IPv4 network address represented in numeric form as a binary string, returns the string representation of the address as a string in the connection character set. If the argument is not a valid address, or if it is NULL, **INET6_NTOA()** returns NULL.

**INET6_NTOA()** has these properties:

- It does not use operating system functions to perform conversions, thus the output string is platform independent.
- The return string has a maximum length of 39 (4 x 8 + 7). Given this statement:

\[
\text{CREATE TABLE t AS SELECT INET6_NTOA(\text{expr}) AS c1;}
\]

The resulting table would have this definition:

\[
\text{CREATE TABLE t (c1 VARCHAR(39) CHARACTER SET utf8mb3 DEFAULT NULL;)
}
\]

- The return string uses lowercase letters for IPv6 addresses.

```sql
mysql> SELECT INET6_NTOA(INET6_ATON('fdfe::5a55:caff:fefa:9089'));
-> 'fdfe::5a55:caff:fefa:9089'
mysql> SELECT INET6_NTOA(INET6_ATON('10.0.5.9'));
-> '10.0.5.9'
mysql> SELECT INET6_NTOA(INET6_ATON('0A000509'));
-> '10.0.5.9'
```

If **INET6_NTOA()** is invoked from within the **mysql** client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 6.5.1, "mysql — The MySQL Command-Line Client".
• **IS_IPV4**(*expr*)

Returns 1 if the argument is a valid IPv4 address specified as a string, 0 otherwise. Returns **NULL** if *expr* is **NULL**.

```sql
mysql> SELECT IS_IPV4('10.0.5.9'), IS_IPV4('10.0.5.256');
-> 1, 0
```

For a given argument, if **IS_IPV4()** returns 1, **INET_ATON()** (and **INET6_ATON()**) returns non-**NULL**. The converse statement is not true: In some cases, **INET_ATON()** returns non-**NULL** when **IS_IPV4()** returns 0.

As implied by the preceding remarks, **IS_IPV4()** is more strict than **INET_ATON()** about what constitutes a valid IPv4 address, so it may be useful for applications that need to perform strong checks against invalid values. Alternatively, use **INET6_ATON()** to convert IPv4 addresses to internal form and check for a **NULL** result (which indicates an invalid address). **INET_ATON()** is equally strong as **IS_IPV4()** about checking IPv4 addresses.

• **IS_IPV4_COMPAT**(*expr*)

This function takes an IPv6 address represented in numeric form as a binary string, as returned by **INET6_ATON()**. It returns 1 if the argument is a valid IPv4-compatible IPv6 address, 0 otherwise (unless *expr* is **NULL**, in which case the function returns **NULL**). IPv4-compatible addresses have the form **::ipv4_address**.

```sql
mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::10.0.5.9'));
-> 1
mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::ffff:10.0.5.9'));
-> 0
```

The IPv4 part of an IPv4-compatible address can also be represented using hexadecimal notation. For example, **198.51.100.1** has this raw hexadecimal value:

```sql
mysql> SELECT HEX(INET6_ATON('198.51.100.1'));
-> 'C6336401'
```

Expressed in IPv4-compatible form, **::198.51.100.1** is equivalent to **::c0a8:0001** or (without leading zeros) **::c0a8:1**

```sql
mysql> SELECT
     -> IS_IPV4_COMPAT(INET6_ATON('::198.51.100.1')),
     -> IS_IPV4_COMPAT(INET6_ATON('::c0a8:0001')),
     -> IS_IPV4_COMPAT(INET6_ATON('::c0a8:1'));
-> 1, 1, 1
```

• **IS_IPV4_MAPPED**(*expr*)

This function takes an IPv6 address represented in numeric form as a binary string, as returned by **INET6_ATON()**. It returns 1 if the argument is a valid IPv4-mapped IPv6 address, 0 otherwise, unless *expr* is **NULL**, in which case the function returns **NULL**. IPv4-mapped addresses have the form **::ffff:ipv4_address**.

```sql
mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::10.0.5.9'));
-> 0
mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::ffff:10.0.5.9'));
-> 1
```

As with **IS_IPV4_COMPAT()** the IPv4 part of an IPv4-mapped address can also be represented using hexadecimal notation:

```sql
mysql> SELECT
     -> IS_IPV4_MAPPED(INET6_ATON('::ffff:198.51.100.1')),
     -> IS_IPV4_MAPPED(INET6_ATON('::ffff:c0a8:0001')),
     -> IS_IPV4_MAPPED(INET6_ATON('::ffff:c0a8:1'));
-> 1, 1, 1
```
**IS_IPV6(expr)**

Returns 1 if the argument is a valid IPv6 address specified as a string, 0 otherwise, unless `expr` is `NULL`, in which case the function returns `NULL`. This function does not consider IPv4 addresses to be valid IPv6 addresses.

```sql
mysql> SELECT IS_IPV6('10.0.5.9'), IS_IPV6('::1');
-> 0, 1
```

For a given argument, if `IS_IPV6()` returns 1, `INET6_ATON()` returns non-`NULL`.

**IS_UUID(string_uuid)**

Returns 1 if the argument is a valid string-format UUID, 0 if the argument is not a valid UUID, and `NULL` if the argument is `NULL`.

"Valid" means that the value is in a format that can be parsed. That is, it has the correct length and contains only the permitted characters (hexadecimal digits in any lettercase and, optionally, dashes and curly braces). This format is most common:

```
aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee
```

These other formats are also permitted:

```
aaaaaaaaabbbbbccccdddeeeeee
{aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee}
```

For the meanings of fields within the value, see the `UUID()` function description.

```sql
mysql> SELECT IS_UUID('6ccd780c-baba-1026-9564-5b8c656024db');
<table>
<thead>
<tr>
<th>IS_UUID('6ccd780c-baba-1026-9564-5b8c656024db')</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>

mysql> SELECT IS_UUID('6cd780c-baba-1026-9564-5b8c656024db');
<table>
<thead>
<tr>
<th>IS_UUID('6cd780c-baba-1026-9564-5b8c656024db')</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
```

```sql
mysql> SELECT IS_UUID('6ccd780c-baba-1026-9564-5b8c656024db');
<table>
<thead>
<tr>
<th>IS_UUID('6ccd780c-baba-1026-9564-5b8c656024db')</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>

mysql> SELECT IS_UUID('6cd780c-baba-1026-9564-5b8c656024db');
<table>
<thead>
<tr>
<th>IS_UUID('6cd780c-baba-1026-9564-5b8c656024db')</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
```
• **NAME_CONST(name, value)**

Returns the given value. When used to produce a result set column, `NAME_CONST()` causes the column to have the given name. The arguments should be constants.

```
mysql> SELECT NAME_CONST('myname', 14);
+--------+
| myname |
+--------+
|     14 |
+--------+
```

This function is for internal use only. The server uses it when writing statements from stored programs that contain references to local program variables, as described in Section 27.7, “Stored Program Binary Logging”. You might see this function in the output from `mysqlbinlog`.

For your applications, you can obtain exactly the same result as in the example just shown by using simple aliasing, like this:

```
mysql> SELECT 14 AS myname;
+--------+
| myname |
+--------+
|     14 |
+--------+
1 row in set (0.00 sec)
```

See Section 15.2.13, “SELECT Statement”, for more information about column aliases.

• **SLEEP(duration)**

Sleeps (pauses) for the number of seconds given by the `duration` argument, then returns 0. The duration may have a fractional part. If the argument is `NULL` or negative, `SLEEP()` produces a warning, or an error in strict SQL mode.

When sleep returns normally (without interruption), it returns 0:

```
mysql> SELECT SLEEP(1000);
+-------------+
| SLEEP(1000) |
+-------------+
|           0 |
+-------------+
```

When `SLEEP()` is the only thing invoked by a query that is interrupted, it returns 1 and the query itself returns no error. This is true whether the query is killed or times out:

• This statement is interrupted using `KILL QUERY` from another session:

```
mysql> SELECT SLEEP(1000);
+-------------+
| SLEEP(1000) |
+-------------+
|           1 |
+-------------+
```

• This statement is interrupted by timing out:

```
mysql> SELECT /*+ MAX_EXECUTION_TIME(1) */ SLEEP(1000);
+-------------+
| SLEEP(1000) |
+-------------+
|           1 |
+-------------+
```

2391
When \texttt{SLEEP()} is only part of a query that is interrupted, the query returns an error:

- This statement is interrupted using \texttt{KILL QUERY} from another session:
  
  \begin{verbatim}
  mysql> SELECT 1 FROM t1 WHERE SLEEP(1000);
  ERROR 1317 (70100): Query execution was interrupted
  \end{verbatim}

- This statement is interrupted by timing out:
  
  \begin{verbatim}
  mysql> SELECT /*+ MAX_EXECUTION_TIME(1000) */ 1 FROM t1 WHERE SLEEP(1000);
  ERROR 3024 (HY000): Query execution was interrupted, maximum statement execution time exceeded
  \end{verbatim}

This function is unsafe for statement-based replication. A warning is logged if you use this function when \texttt{binlog_format} is set to \texttt{STATEMENT}.

- \texttt{UUID()}

  Returns a Universal Unique Identifier (UUID) generated according to RFC 4122, “A Universally Unique IDentifier (UUID) URN Namespace” (http://www.ietf.org/rfc/rfc4122.txt).

  A UUID is designed as a number that is globally unique in space and time. Two calls to \texttt{UUID()} are expected to generate two different values, even if these calls are performed on two separate devices not connected to each other.

  **Warning**

  Although \texttt{UUID()} values are intended to be unique, they are not necessarily unguessable or unpredictable. If unpredictability is required, UUID values should be generated some other way.

  \texttt{UUID()} returns a value that conforms to UUID version 1 as described in RFC 4122. The value is a 128-bit number represented as a \texttt{utf8mb3} string of five hexadecimal numbers in \texttt{aaaaaaaa-bbbbcccc-dddd-eeeeeeeeeeee} format:

  - The first three numbers are generated from the low, middle, and high parts of a timestamp. The high part also includes the UUID version number.
  
  - The fourth number preserves temporal uniqueness in case the timestamp value loses monotonicity (for example, due to daylight saving time).
  
  - The fifth number is an IEEE 802 node number that provides spatial uniqueness. A random number is substituted if the latter is not available (for example, because the host device has no Ethernet card, or it is unknown how to find the hardware address of an interface on the host operating system). In this case, spatial uniqueness cannot be guaranteed. Nevertheless, a collision should have very low probability.

  The MAC address of an interface is taken into account only on FreeBSD, Linux, and Windows. On other operating systems, MySQL uses a randomly generated 48-bit number.

  \begin{verbatim}
  mysql> SELECT UUID();
  \rightarrow '6ccd780c-baba-1026-9564-5b8c656024db'
  \end{verbatim}

  To convert between string and binary UUID values, use the \texttt{UUID_TO_BIN()} and \texttt{BIN_TO_UUID()} functions. To check whether a string is a valid UUID value, use the \texttt{IS_UUID()} function.

  This function is unsafe for statement-based replication. A warning is logged if you use this function when \texttt{binlog_format} is set to \texttt{STATEMENT}.
• **UUID_SHORT()**

Returns a “short” universal identifier as a 64-bit unsigned integer. Values returned by UUID_SHORT() differ from the string-format 128-bit identifiers returned by the UUID() function and have different uniqueness properties. The value of UUID_SHORT() is guaranteed to be unique if the following conditions hold:

- The server_id value of the current server is between 0 and 255 and is unique among your set of source and replica servers
- You do not set back the system time for your server host between mysql restarts
- You invoke UUID_SHORT() on average fewer than 16 million times per second between mysql restarts

The UUID_SHORT() return value is constructed this way:

```
(server_id & 255) << 56
+ (server_startup_time_in_seconds << 24)
+ incremented_variable++;
```

Note

UUID_SHORT() does not work with statement-based replication.

• **UUID_TO_BIN(string_uuid), UUID_TO_BIN(string_uuid, swap_flag)**

Converts a string UUID to a binary UUID and returns the result. (The IS_UUID() function description lists the permitted string UUID formats.) The return binary UUID is a VARBINARY(16) value. If the UUID argument is NULL, the return value is NULL. If any argument is invalid, an error occurs.

UUID_TO_BIN() takes one or two arguments:

- The one-argument form takes a string UUID value. The binary result is in the same order as the string argument.
- The two-argument form takes a string UUID value and a flag value:
  - If swap_flag is 0, the two-argument form is equivalent to the one-argument form. The binary result is in the same order as the string argument.
  - If swap_flag is 1, the format of the return value differs: The time-low and time-high parts (the first and third groups of hexadecimal digits, respectively) are swapped. This moves the more rapidly varying part to the right and can improve indexing efficiency if the result is stored in an indexed column.

Time-part swapping assumes the use of UUID version 1 values, such as are generated by the UUID() function. For UUID values produced by other means that do not follow version 1 format, time-part swapping provides no benefit. For details about version 1 format, see the UUID() function description.

Suppose that you have the following string UUID value:

```
mysql> SET @uuid = '6ccd780c-baba-1026-9564-5b8c656024db';
```

To convert the string UUID to binary with or without time-part swapping, use UUID_TO_BIN():

```sql
mysql> SELECT UUID_SHORT();
-> 92395783831158784
```
To convert a binary UUID returned by `UUID_TO_BIN()` to a string UUID, use `BIN_TO_UUID()`. If you produce a binary UUID by calling `UUID_TO_BIN()` with a second argument of 1 to swap time parts, you should also pass a second argument of 1 to `BIN_TO_UUID()` to unswap the time parts when converting the binary UUID back to a string UUID:

```
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid));
+--------------------------------------+
| BIN_TO_UUID(UUID_TO_BIN(@uuid))      |
| 6ccd780c-baba-1026-9564-5b8c656024db |
+--------------------------------------+
```

If the use of time-part swapping is not the same for the conversion in both directions, the original UUID is not recovered properly:

```
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid,0),1);
+--------------------------------------+
| BIN_TO_UUID(UUID_TO_BIN(@uuid,0),1)  |
| baba1026-780c-6ccd-9564-5b8c656024db |
+--------------------------------------+
```

If `UUID_TO_BIN()` is invoked from within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 6.5.1, “mysql — The MySQL Command-Line Client”.

• VALUES(`col_name`)

In an `INSERT ... ON DUPLICATE KEY UPDATE` statement, you can use the `VALUES(`col_name`)` function in the `UPDATE` clause to refer to column values from the `INSERT`
portion of the statement. In other words, \( \text{VALUES}(col\_name) \) in the \text{UPDATE} clause refers to the value of \( col\_name \) that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The \text{VALUES()} function is meaningful only in the \text{ON DUPLICATE KEY UPDATE} clause of \text{INSERT} statements and returns \text{NULL} otherwise. See Section 15.2.7.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”.

```
mysql> INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
    -> ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

Important
This usage is deprecated, and subject to removal in a future release of MySQL. Use a row alias, or row and column aliases, instead. For more information and examples, see Section 15.2.7.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”.

14.24 Precision Math

MySQL provides support for precision math: numeric value handling that results in extremely accurate results and a high degree control over invalid values. Precision math is based on these two features:

- SQL modes that control how strict the server is about accepting or rejecting invalid data.
- The MySQL library for fixed-point arithmetic.

These features have several implications for numeric operations and provide a high degree of compliance with standard SQL:

- **Precise calculations**: For exact-value numbers, calculations do not introduce floating-point errors. Instead, exact precision is used. For example, MySQL treats a number such as \( .0001 \) as an exact value rather than as an approximation, and summing it 10,000 times produces a result of exactly \( 1 \), not a value that is merely “close” to \( 1 \).

- **Well-defined rounding behavior**: For exact-value numbers, the result of \text{ROUND()} depends on its argument, not on environmental factors such as how the underlying C library works.

- **Platform independence**: Operations on exact numeric values are the same across different platforms such as Windows and Unix.

- **Control over handling of invalid values**: Overflow and division by zero are detectable and can be treated as errors. For example, you can treat a value that is too large for a column as an error rather than having the value truncated to lie within the range of the column's data type. Similarly, you can treat division by zero as an error rather than as an operation that produces a result of \text{NULL}. The choice of which approach to take is determined by the setting of the server SQL mode.

The following discussion covers several aspects of how precision math works, including possible incompatibilities with older applications. At the end, some examples are given that demonstrate how MySQL handles numeric operations precisely. For information about controlling the SQL mode, see Section 7.1.11, “Server SQL Modes”.

14.24.1 Types of Numeric Values

The scope of precision math for exact-value operations includes the exact-value data types (integer and \text{DECIMAL} types) and exact-value numeric literals. Approximate-value data types and numeric literals are handled as floating-point numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: \( 1, 2, 3.4, -5, -6.78, +9.10 \).

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: \( 1.2E3, 1.2E-3, -1.2E3, -1.2E-3 \).
Two numbers that look similar may be treated differently. For example, 2.34 is an exact-value (fixed-point) number, whereas 2.34E0 is an approximate-value (floating-point) number.

The DECIMAL data type is a fixed-point type and calculations are exact. In MySQL, the DECIMAL type has several synonyms: NUMERIC, DEC, FIXED. The integer types also are exact-value types.

The FLOAT and DOUBLE data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with FLOAT or DOUBLE are DOUBLE PRECISION and REAL.

### 14.24.2 DECIMAL Data Type Characteristics

This section discusses the characteristics of the DECIMAL data type (and its synonyms), with particular regard to the following topics:

- Maximum number of digits
- Storage format
- Storage requirements
- The nonstandard MySQL extension to the upper range of DECIMAL columns

The declaration syntax for a DECIMAL column is DECIMAL(M, D). The ranges of values for the arguments are as follows:

- M is the maximum number of digits (the precision). It has a range of 1 to 65.
- D is the number of digits to the right of the decimal point (the scale). It has a range of 0 to 30 and must be no larger than M.

If D is omitted, the default is 0. If M is omitted, the default is 10.

The maximum value of 65 for M means that calculations on DECIMAL values are accurate up to 65 digits. This limit of 65 digits of precision also applies to exact-value numeric literals, so the maximum range of such literals differs from before. (There is also a limit on how long the text of DECIMAL literals can be; see Section 14.24.3, “Expression Handling”.)

Values for DECIMAL columns are stored using a binary format that packs nine decimal digits into 4 bytes. The storage requirements for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires 4 bytes, and any remaining digits left over require some fraction of 4 bytes. The storage required for remaining digits is given by the following table.

<table>
<thead>
<tr>
<th>Leftover Digits</th>
<th>Number of Bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1–2</td>
<td>1</td>
</tr>
<tr>
<td>3–4</td>
<td>2</td>
</tr>
<tr>
<td>5–6</td>
<td>3</td>
</tr>
<tr>
<td>7–9</td>
<td>4</td>
</tr>
</tbody>
</table>

For example, a DECIMAL(18, 9) column has nine digits on either side of the decimal point, so the integer part and the fractional part each require 4 bytes. A DECIMAL(20, 6) column has fourteen integer digits and six fractional digits. The integer digits require four bytes for nine of the digits and 3 bytes for the remaining five digits. The six fractional digits require 3 bytes.

DECIMAL columns do not store a leading + character or – character or leading 0 digits. If you insert +0003.1 into a DECIMAL(5, 1) column, it is stored as 3.1. For negative numbers, a literal – character is not stored.
DECIMAL columns do not permit values larger than the range implied by the column definition. For example, a DECIMAL(3, 0) column supports a range of -999 to 999. A DECIMAL(M, D) column permits up to \( M - D \) digits to the left of the decimal point.

The SQL standard requires that the precision of \( \text{NUMERIC}(M, D) \) be exactly \( M \) digits. For DECIMAL(M, D), the standard requires a precision of at least \( M \) digits but permits more. In MySQL, \( \text{DECIMAL}(M, D) \) and \( \text{NUMERIC}(M, D) \) are the same, and both have a precision of exactly \( M \) digits.

For a full explanation of the internal format of DECIMAL values, see the file strings/decimal.c in a MySQL source distribution. The format is explained (with an example) in the decimal2bin() function.

### 14.24.3 Expression Handling

With precision math, exact-value numbers are used as given whenever possible. For example, numbers in comparisons are used exactly as given without a change in value. In strict SQL mode, for INSERT into a column with an exact data type (DECIMAL or integer), a number is inserted with its exact value if it is within the column range. When retrieved, the value should be the same as what was inserted. (If strict SQL mode is not enabled, truncation for INSERT is permissible.)

Handling of a numeric expression depends on what kind of values the expression contains:

- If any approximate values are present, the expression is approximate and is evaluated using floating-point arithmetic.
- If no approximate values are present, the expression contains only exact values. If any exact value contains a fractional part (a value following the decimal point), the expression is evaluated using DECIMAL exact arithmetic and has a precision of 65 digits. The term “exact” is subject to the limits of what can be represented in binary. For example, \( 1.0/3.0 \) can be approximated in decimal notation as \( .333... \), but not written as an exact number, so \( (1.0/3.0)\times3.0 \) does not evaluate to exactly \( 1.0 \).
- Otherwise, the expression contains only integer values. The expression is exact and is evaluated using integer arithmetic and has a precision the same as BIGINT (64 bits).

If a numeric expression contains any strings, they are converted to double-precision floating-point values and the expression is approximate.

Inserts into numeric columns are affected by the SQL mode, which is controlled by the sql_mode system variable. (See Section 7.1.11, “Server SQL Modes”.) The following discussion mentions strict mode (selected by the STRICT_ALL_TABLES or STRICT_TRANS_TABLES mode values) and ERROR_FOR_DIVISION_BY_ZERO. To turn on all restrictions, you can simply use TRADITIONAL mode, which includes both strict mode values and ERROR_FOR_DIVISION_BY_ZERO:

```sql
SET sql_mode='TRADITIONAL';
```

If a number is inserted into an exact type column (DECIMAL or integer), it is inserted with its exact value if it is within the column range and precision.

If the value has too many digits in the fractional part, rounding occurs and a note is generated. Rounding is done as described in Section 14.24.4, “Rounding Behavior”. Truncation due to rounding of the fractional part is not an error, even in strict mode.

If the value has too many digits in the integer part, it is too large (out of range) and is handled as follows:

- If strict mode is not enabled, the value is truncated to the nearest legal value and a warning is generated.
- If strict mode is enabled, an overflow error occurs.

Underflow is not detected, so underflow handling is undefined.
Rounding Behavior

For inserts of strings into numeric columns, conversion from string to number is handled as follows if the string has nonnumeric contents:

- A string that does not begin with a number cannot be used as a number and produces an error in strict mode, or a warning otherwise. This includes the empty string.
- A string that begins with a number can be converted, but the trailing nonnumeric portion is truncated. If the truncated portion contains anything other than spaces, this produces an error in strict mode, or a warning otherwise.

By default, division by zero produces a result of `NULL` and no warning. By setting the SQL mode appropriately, division by zero can be restricted.

With the `ERROR_FOR_DIVISION_BY_ZERO` SQL mode enabled, MySQL handles division by zero differently:

- If strict mode is not enabled, a warning occurs.
- If strict mode is enabled, inserts and updates involving division by zero are prohibited, and an error occurs.

In other words, inserts and updates involving expressions that perform division by zero can be treated as errors, but this requires `ERROR_FOR_DIVISION_BY_ZERO` in addition to strict mode.

Suppose that we have this statement:

```sql
INSERT INTO t SET i = 1/0;
```

This is what happens for combinations of strict and `ERROR_FOR_DIVISION_BY_ZERO` modes:

<table>
<thead>
<tr>
<th><code>sql_mode</code> Value</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>'' (Default)</td>
<td>No warning, no error; i is set to <code>NULL</code>.</td>
</tr>
<tr>
<td>strict</td>
<td>No warning, no error; i is set to <code>NULL</code>.</td>
</tr>
<tr>
<td><code>ERROR_FOR_DIVISION_BY_ZERO</code></td>
<td>Warning, no error; i is set to <code>NULL</code>.</td>
</tr>
<tr>
<td>strict,<code>ERROR_FOR_DIVISION_BY_ZERO</code></td>
<td>Error condition; no row is inserted.</td>
</tr>
</tbody>
</table>

### 14.24.4 Rounding Behavior

This section discusses precision math rounding for the `ROUND()` function and for inserts into columns with exact-value types (`DECIMAL` and integer).

The `ROUND()` function rounds differently depending on whether its argument is exact or approximate:

- For exact-value numbers, `ROUND()` uses the “round half up” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative. (In other words, it is rounded toward zero.)

- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with a fractional part exactly half way between two integers is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```sql
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+------------+--------------+
| ROUND(2.5) | ROUND(25E-1) |
+------------+--------------+
| 3          |            2 |
```
For inserts into a DECIMAL or integer column, the target is an exact data type, so rounding uses “round half away from zero,” regardless of whether the value to be inserted is exact or approximate:

```sql
mysql> CREATE TABLE t (d DECIMAL(10,0));
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t VALUES(2.5),(2.5E0);
Query OK, 2 rows affected, 2 warnings (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 2

mysql> SHOW WARNINGS;
+-------+------+----------------------------------------+
| Level | Code | Message                                |
+-------+------+----------------------------------------+
| Note  | 1265 | Data truncated for column 'd' at row 1 |
| Note  | 1265 | Data truncated for column 'd' at row 2 |
+-------+------+----------------------------------------+
2 rows in set (0.00 sec)

mysql> SELECT d FROM t;
<table>
<thead>
<tr>
<th>d</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
</tr>
<tr>
<td>3</td>
</tr>
</tbody>
</table>
2 rows in set (0.00 sec)
```

The `SHOW WARNINGS` statement displays the notes that are generated by truncation due to rounding of the fractional part. Such truncation is not an error, even in strict SQL mode (see Section 14.24.3, “Expression Handling”).

### 14.24.5 Precision Math Examples

This section provides some examples that show precision math query results in MySQL. These examples demonstrate the principles described in Section 14.24.3, “Expression Handling”, and Section 14.24.4, “Rounding Behavior”.

**Example 1.** Numbers are used with their exact value as given when possible:

```sql
mysql> SELECT (.1 + .2) = .3;
+----------------+
| (.1 + .2) = .3 |
+----------------+
| 1              |
```

For floating-point values, results are inexact:

```sql
mysql> SELECT (.1E0 + .2E0) = .3E0;
+---------------------+
| (.1E0 + .2E0) = .3E0 |
+---------------------+
| 0                   |
```

Another way to see the difference in exact and approximate value handling is to add a small number to a sum many times. Consider the following stored procedure, which adds .0001 to a variable 1,000 times.

```sql
CREATE PROCEDURE p ()
BEGIN
    DECLARE i INT DEFAULT 0;
    DECLARE d DECIMAL(10,4) DEFAULT 0;
    DECLARE f FLOAT DEFAULT 0;
    WHILE i < 10000 DO
        d = d + .0001;
        f = f + 1;
    END WHILE;
    SELECT d, f;
END
```

...
**Precision Math Examples**

```sql
SET d = d + .0001;
SET f = f + .0001E0;
SET i = i + 1;
END WHILE;
SELECT d, f;
END;
```

The sum for both \(d\) and \(f\) logically should be 1, but that is true only for the decimal calculation. The floating-point calculation introduces small errors:

<table>
<thead>
<tr>
<th>d</th>
<th>f</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.0000</td>
<td>0.99999999999991</td>
</tr>
</tbody>
</table>

**Example 2.** Multiplication is performed with the scale required by standard SQL. That is, for two numbers \(X_1\) and \(X_2\) that have scale \(S_1\) and \(S_2\), the scale of the result is \(S_1 + S_2\):

```sql
mysql> SELECT .01 * .01;
+-----------+
| .01 * .01 |
+-----------+
| 0.0001    |
```

**Example 3.** Rounding behavior for exact-value numbers is well-defined:

Rounding behavior (for example, with the `ROUND()` function) is independent of the implementation of the underlying C library, which means that results are consistent from platform to platform.

- Rounding for exact-value columns (`DECIMAL` and integer) and exact-valued numbers uses the “round half away from zero” rule. A value with a fractional part of .5 or greater is rounded away from zero to the nearest integer, as shown here:

  ```sql
  mysql> SELECT ROUND(2.5), ROUND(-2.5);
  +------------+-------------+
  | ROUND(2.5) | ROUND(-2.5) |
  +------------+-------------+
  | 3          | -3          |
  ```

- Rounding for floating-point values uses the C library, which on many systems uses the “round to nearest even” rule. A value with a fractional part exactly half way between two integers is rounded to the nearest even integer:

  ```sql
  mysql> SELECT ROUND(2.5E0), ROUND(-2.5E0);
  +--------------+---------------+
  | ROUND(2.5E0) | ROUND(-2.5E0) |
  +--------------+---------------+
  |            2 |            -2 |
  ```

**Example 4.** In strict mode, inserting a value that is out of range for a column causes an error, rather than truncation to a legal value.

When MySQL is not running in strict mode, truncation to a legal value occurs:

```sql
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)
```

```sql
mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.01 sec)
```

```sql
mysql> INSERT INTO t SET i = 128;
Query OK, 1 row affected, 1 warning (0.00 sec)
```

```sql
mysql> SELECT i FROM t;
```

2400
However, an error occurs if strict mode is in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 128;
ERROR 1264 (22003): Out of range value adjusted for column 'i' at row 1

mysql> SELECT i FROM t;
Empty set (0.00 sec)
```

**Example 5**: In strict mode and with `ERROR_FOR_DIVISION_BY_ZERO` set, division by zero causes an error, not a result of `NULL`.

In nonstrict mode, division by zero has a result of `NULL`:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT i FROM t;
+------+
| i    |
+------+
| NULL |
+------+
1 row in set (0.03 sec)
```

However, division by zero is an error if the proper SQL modes are in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
ERROR 1365 (22012): Division by 0

mysql> SELECT i FROM t;
Empty set (0.01 sec)
```

**Example 6**: Exact-value literals are evaluated as exact values. Approximate-value literals are evaluated using floating point, but exact-value literals are handled as DECIMAL:

```
mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
Query OK, 1 row affected (0.01 sec)
Records: 1  Duplicates: 0  Warnings: 0

mysql> DESCRIBE t;
+-----------------------+------+-----+---------+-------+
| Field | Type      | Null | Key    | Default | Extra |
|-------|-----------+------|-------|--------|--------|
+-------+-----------+------|-------|--------|--------|
| a     | DECIMAL   |      |       |        |        |
+-------+-----------+------|-------|--------|--------|
| b     | DECIMAL   |      |       |        |        |
+-------+-----------+------|-------|--------|--------|
1 row in set (0.02 sec)
```
Example 7. If the argument to an aggregate function is an exact numeric type, the result is also an exact numeric type, with a scale at least that of the argument.

Consider these statements:

```
mysql> CREATE TABLE t (i INT, d DECIMAL, f FLOAT);
mysql> INSERT INTO t VALUES(1,1,1);
mysql> CREATE TABLE y SELECT AVG(i), AVG(d), AVG(f) FROM t;
```

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type:

```
mysql> DESCRIBE y;
+--------+-----------------------+------+-----+---------+-------+
| Field  | Type                  | Null | Key | Default | Extra |
+--------+-----------------------+------+-----+---------+-------+
| AVG(i) | decimal(14,4)        | YES  |     | NULL    |       |
| AVG(d) | decimal(14,4)        | YES  |     | NULL    |       |
| AVG(f) | double                | YES  |     |         | NULL  |
+--------+-----------------------+------+-----+---------+-------+
```

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type.

15.1 Data Definition Statements

15.1.1 Atomic Data Definition Statement Support

MySQL 8.4 supports atomic Data Definition Language (DDL) statements. This feature is referred to as atomic DDL. An atomic DDL statement combines the data dictionary updates, storage engine operations, and binary log writes associated with a DDL operation into a single, atomic operation. The
operation is either committed, with applicable changes persisted to the data dictionary, storage engine, and binary log, or is rolled back, even if the server halts during the operation.

Note

Atomic DDL is not transactional DDL. DDL statements, atomic or otherwise, implicitly end any transaction that is active in the current session, as if you had done a COMMIT before executing the statement. This means that DDL statements cannot be performed within another transaction, within transaction control statements such as START TRANSACTION ... COMMIT, or combined with other statements within the same transaction.

Atomic DDL is made possible by the MySQL data dictionary, which provides centralized, transactional metadata storage.

The atomic DDL feature is described under the following topics in this section:

- Supported DDL Statements
- Atomic DDL Characteristics
- Storage Engine Support
- Viewing DDL Logs

Supported DDL Statements

The atomic DDL feature supports both table and non-table DDL statements. Table-related DDL operations require storage engine support, whereas non-table DDL operations do not. Currently, only the InnoDB storage engine supports atomic DDL.

- Supported table DDL statements include CREATE, ALTER, and DROP statements for databases, tablespaces, tables, and indexes, and the TRUNCATE TABLE statement.
- Supported non-table DDL statements include:
  - CREATE and DROP statements, and, if applicable, ALTER statements for stored programs, triggers, views, and loadable functions.
  - Account management statements: CREATE, ALTER, DROP, and, if applicable, RENAME statements for users and roles, as well as GRANT and REVOKE statements.

The following statements are not supported by the atomic DDL feature:

- Table-related DDL statements that involve a storage engine other than InnoDB.
- INSTALL PLUGIN and UNINSTALL PLUGIN statements.
- INSTALL COMPONENT and UNINSTALL COMPONENT statements.
- CREATE SERVER, ALTER SERVER, and DROP SERVER statements.

Atomic DDL Characteristics

The characteristics of atomic DDL statements include the following:

- Metadata updates, binary log writes, and storage engine operations, where applicable, are combined into a single atomic operation.
- There are no intermediate commits at the SQL layer during the DDL operation.
- Where applicable:
• The state of data dictionary, routine, event, and loadable function caches is consistent with the status of the DDL operation, meaning that caches are updated to reflect whether or not the DDL operation was completed successfully or rolled back.

• The storage engine methods involved in a DDL operation do not perform intermediate commits, and the storage engine registers itself as part of the DDL operation.

• The storage engine supports redo and rollback of DDL operations, which is performed in the Post-DDL phase of the DDL operation.

• The visible behaviour of DDL operations is atomic.

Storage Engine Support

Currently, only the InnoDB storage engine supports atomic DDL. Storage engines that do not support atomic DDL are exempted from DDL atomicity. DDL operations involving exempted storage engines remain capable of introducing inconsistencies that can occur when operations are interrupted or only partially completed.

To support redo and rollback of DDL operations, InnoDB writes DDL logs to the mysql.innodb_ddl_log table, which is a hidden data dictionary table that resides in the mysql.ibd data dictionary tablespace.

To view DDL logs that are written to the mysql.innodb_ddl_log table during a DDL operation, enable the innodb_print_ddl_logs configuration option. For more information, see Viewing DDL Logs.

Note

The redo logs for changes to the mysql.innodb_ddl_log table are flushed to disk immediately regardless of the innodb_flush_log_at_trx_commit setting. Flushing the redo logs immediately avoids situations where data files are modified by DDL operations but the redo logs for changes to the mysql.innodb_ddl_log table resulting from those operations are not persisted to disk. Such a situation could cause errors during rollback or recovery.

The InnoDB storage engine executes DDL operations in phases. DDL operations such as ALTER TABLE may perform the Prepare and Perform phases multiple times prior to the Commit phase.

1. **Prepare**: Create the required objects and write the DDL logs to the mysql.innodb_ddl_log table. The DDL logs define how to roll forward and roll back the DDL operation.

2. **Perform**: Perform the DDL operation. For example, perform a create routine for a CREATE TABLE operation.

3. **Commit**: Update the data dictionary and commit the data dictionary transaction.

4. **Post-DDL**: Replay and remove DDL logs from the mysql.innodb_ddl_log table. To ensure that rollback can be performed safely without introducing inconsistencies, file operations such as renaming or removing data files are performed in this final phase. This phase also removes dynamic metadata from the mysql.innodb_dynamic_metadata data dictionary table for DROP TABLE, TRUNCATE TABLE, and other DDL operations that rebuild the table.

DDL logs are replayed and removed from the mysql.innodb_ddl_log table during the Post-DDL phase, regardless of whether the DDL operation is committed or rolled back. DDL logs should only remain in the mysql.innodb_ddl_log table if the server is halted during a DDL operation. In this case, the DDL logs are replayed and removed after recovery.

In a recovery situation, a DDL operation may be committed or rolled back when the server is restarted. If the data dictionary transaction that was performed during the Commit phase of a DDL operation is
present in the redo log and binary log, the operation is considered successful and is rolled forward. Otherwise, the incomplete data dictionary transaction is rolled back when InnoDB replays data dictionary redo logs, and the DDL operation is rolled back.

**Viewing DDL Logs**

To view DDL logs that are written to the `mysql.innodb_ddl_log` data dictionary table during atomic DDL operations that involve the InnoDB storage engine, enable `innodb_print_ddl_logs` to have MySQL write the DDL logs to `stderr`. Depending on the host operating system and MySQL configuration, `stderr` may be the error log, terminal, or console window. See Section 7.4.2.2, “Default Error Log Destination Configuration”.

InnoDB writes DDL logs to the `mysql.innodb_ddl_log` table to support redo and rollback of DDL operations. The `mysql.innodb_ddl_log` table is a hidden data dictionary table that resides in the `mysql.ibd` data dictionary tablespace. Like other hidden data dictionary tables, the `mysql.innodb_ddl_log` table cannot be accessed directly in non-debug versions of MySQL. (See Section 16.1, “Data Dictionary Schema”.) The structure of the `mysql.innodb_ddl_log` table corresponds to this definition:

```sql
CREATE TABLE mysql.innodb_ddl_log (  id BIGINT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,  thread_id BIGINT UNSIGNED NOT NULL,  type INT UNSIGNED NOT NULL,  space_id INT UNSIGNED,  page_no INT UNSIGNED,  index_id BIGINT UNSIGNED,  table_id BIGINT UNSIGNED,  old_file_path VARCHAR(512) COLLATE utf8mb4_bin,  new_file_path VARCHAR(512) COLLATE utf8mb4_bin,  KEY(thread_id) );
```

- **id**: A unique identifier for a DDL log record.
- **thread_id**: Each DDL log record is assigned a `thread_id`, which is used to replay and remove DDL logs that belong to a particular DDL operation. DDL operations that involve multiple data file operations generate multiple DDL log records.
- **type**: The DDL operation type. Types include `FREE` (drop an index tree), `DELETE` (delete a file), `RENAME` (rename a file), or `DROP` (drop metadata from the `mysql.innodb_dynamic_metadata` data dictionary table).
- **space_id**: The tablespace ID.
- **page_no**: A page that contains allocation information; an index tree root page, for example.
- **index_id**: The index ID.
- **table_id**: The table ID.
- **old_file_path**: The old tablespace file path. Used by DDL operations that create or drop tablespace files; also used by DDL operations that rename a tablespace.
- **new_file_path**: The new tablespace file path. Used by DDL operations that rename tablespace files.

This example demonstrates enabling `innodb_print_ddl_logs` to view DDL logs written to `stderr` for a CREATE TABLE operation.

```sql
mysql> SET GLOBAL innodb_print_ddl_logs=1;
mysql> CREATE TABLE t1 (c1 INT) ENGINE = InnoDB;
```

```
[Note] [000000] InnoDB: DDL log insert : [DDL record: DELETE SPACE, id=18, thread_id=7, space_id=5, old_file_path=./test/t1.ibd]
[Note] [000000] InnoDB: DDL log delete : by id 18
[Note] [000000] InnoDB: DDL log insert : [DDL record: REMOVE CACHE, id=19, thread_id=7, table_id=1058, new_file_path=test/t1]
```
15.1.2 ALTER DATABASE Statement

```
ALTER DATABASE | SCHEMA | [db_name]  
               alter_option ...  
```

**alter_option:**  
- [DEFAULT] CHARACTER SET [=] charset_name  
- [DEFAULT] COLLATE [=] collation_name  
- [DEFAULT] ENCRYPTION [=] {'Y' | 'N'}  
- READ ONLY [=] {DEFAULT | 0 | 1}

**ALTER DATABASE** enables you to change the overall characteristics of a database. These characteristics are stored in the data dictionary. This statement requires the ALTER privilege on the database. **ALTER SCHEMA** is a synonym for **ALTER DATABASE**.

If the database name is omitted, the statement applies to the default database. In that case, an error occurs if there is no default database.

For any **alter_option** omitted from the statement, the database retains its current option value, with the exception that changing the character set may change the collation and vice versa.

- Character Set and Collation Options
- Encryption Option
- Read Only Option

**Character Set and Collation Options**

The **CHARACTER SET** option changes the default database character set. The **COLLATE** option changes the default database collation. For information about character set and collation names, see Chapter 12, *Character Sets, Collations, Unicode*.

To see the available character sets and collations, use the **SHOW CHARACTER SET** and **SHOW COLLATION** statements, respectively. See Section 15.7.7.4, “SHOW CHARACTER SET Statement”, and Section 15.7.7.5, “SHOW COLLATION Statement”.

A stored routine that uses the database defaults when the routine is created includes those defaults as part of its definition. (In a stored routine, variables with character data types use the database defaults if the character set or collation are not specified explicitly. See Section 15.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”.) If you change the default character set or collation for a database, any stored routines that are to use the new defaults must be dropped and recreated.

**Encryption Option**

The **ENCRYPTION** option, defines the default database encryption, which is inherited by tables created in the database. The permitted values are 'Y' (encryption enabled) and 'N' (encryption disabled).

The mysql system schema cannot be set to default encryption. The existing tables within it are part of the general mysql tablespace, which may be encrypted. The information_schema contains only views. It is not possible to create any tables within it. There is nothing on the disk to encrypt. All tables in the performance_schema use the PERFORMANCE_SCHEMA engine, which is purely in-memory. It is not possible to create any other tables in it. There is nothing on the disk to encrypt.

Only newly created tables inherit the default database encryption. For existing tables associated with the database, their encryption remains unchanged. If the table_encryption_privilege_check
system variable is enabled, the **TABLE_ENCRYPTION_ADMIN** privilege is required to specify a default encryption setting that differs from the value of the **default_table_encryption** system variable. For more information, see Defining an Encryption Default for Schemas and General Tablespaces.

### Read Only Option

The **READ ONLY** option controls whether to permit modification of the database and objects within it. The permitted values are **DEFAULT** or 0 (not read only) and 1 (read only). This option is useful for database migration because a database for which **READ ONLY** is enabled can be migrated to another MySQL instance without concern that the database might be changed during the operation.

With NDB Cluster, making a database read only on one **mysql** server is synchronized to other **mysql** servers in the same cluster, so that the database becomes read only on all **mysql** servers.

The **READ ONLY** option, if enabled, is displayed in the **INFORMATION_SCHEMA SCHEMATA_EXTENSIONS** table. See Section 28.3.32, “The INFORMATION_SCHEMA SCHEMATA_EXTENSIONS Table”.

The **READ ONLY** option cannot be enabled for these system schemas: **mysql**, **information_schema**, **performance_schema**.

In **ALTER DATABASE** statements, the **READ ONLY** option interacts with other instances of itself and with other options as follows:

- An error occurs if multiple instances of **READ ONLY** conflict (for example, **READ ONLY** = 1 **READ ONLY** = 0).
- An **ALTER DATABASE** statement that contains only (nonconflicting) **READ ONLY** options is permitted even for a read-only database.
- A mix of (nonconflicting) **READ ONLY** options with other options is permitted if the read-only state of the database either before or after the statement permits modifications. If the read-only state both before and after prohibits changes, an error occurs.

This statement succeeds whether or not the database is read only:

```
ALTER DATABASE mydb READ ONLY = 0 DEFAULT COLLATE utf8mb4_bin;
```

This statement succeeds if the database is not read only, but fails if it is already read only:

```
ALTER DATABASE mydb READ ONLY = 1 DEFAULT COLLATE utf8mb4_bin;
```

Enabling **READ ONLY** affects all users of the database, with these exceptions that are not subject to read-only checks:

- Statements executed by the server as part of server initialization, restart, upgrade, or replication.
- Statements in a file named at server startup by the **init_file** system variable.
- **TEMPORARY** tables; it is possible to create, alter, drop, and write to **TEMPORARY** tables in a read-only database.
- NDB Cluster non-SQL inserts and updates.

Other than for the excepted operations just listed, enabling **READ ONLY** prohibits write operations to the database and its objects, including their definitions, data, and metadata. The following list details affected SQL statements and operations:

- The database itself:
  - **CREATE DATABASE**
  - **ALTER DATABASE** (except to change the **READ ONLY** option)
• DROP DATABASE

• Views:
  • CREATE VIEW
  • ALTER VIEW
  • DROP VIEW
  • Selecting from views that invoke functions with side effects.
  • Updating updatable views.
  • Statements that create or drop objects in a writable database are rejected if they affect metadata of a view in a read-only database (for example, by making the view valid or invalid).

• Stored routines:
  • CREATE PROCEDURE
  • DROP PROCEDURE
  • CALL (of procedures with side effects)
  • CREATE FUNCTION
  • DROP FUNCTION
  • SELECT (of functions with side effects)
  • For procedures and functions, read-only checks follow prelocking behavior. For CALL statements, read-only checks are done on a per-statement basis, so if some conditionally executed statement writing to a read-only database does not actually execute, the call still succeeds. On the other hand, for a function called within a SELECT, execution of the function body happens in prelocked mode. As long as a some statement within the function writes to a read-only database, execution of the function fails with an error regardless of whether the statement actually executes.

• Triggers:
  • CREATE TRIGGER
  • DROP TRIGGER
  • Trigger invocation.

• Events:
  • CREATE EVENT
  • ALTER EVENT
  • DROP EVENT

• Event execution:
  • Executing an event in the database fails because that would change the last-execution timestamp, which is event metadata stored in the data dictionary. Failure of event execution also has the effect of causing the event scheduler to stop.
  • If an event writes to an object in a read-only database, execution of the event fails with an error, but the event scheduler is not stopped.
• Tables:
  • CREATE TABLE
  • ALTER TABLE
  • CREATE INDEX
  • DROP INDEX
  • RENAME TABLE
  • TRUNCATE TABLE
  • DROP TABLE
  • DELETE
  • INSERT
  • IMPORT TABLE
  • LOAD DATA
  • LOAD XML
  • REPLACE
  • UPDATE

  • For cascading foreign keys where the child table is in a read-only database, updates and deletes on the parent are rejected even if the child table is not directly affected.

  • For a MERGE table such as CREATE TABLE s1.t(i int) ENGINE MERGE UNION (s2.t, s3.t), INSERT_METHOD=..., the following behavior applies:
    • Inserting into the MERGE table (INSERT into s1.t) fails if at least one of s1, s2, s3 is read only, regardless of insert method. The insert is refused even if it would actually end up in a writable table.
    • Dropping the MERGE table (DROP TABLE s1.t) succeeds as long as s1 is not read only. It is permitted to drop a MERGE table that refers to a read-only database.

An ALTER DATABASE statement blocks until all concurrent transactions that have already accessed an object in the database being altered have committed. Conversely, a write transaction accessing an object in a database being altered in a concurrent ALTER DATABASE blocks until the ALTER DATABASE has committed.

If the Clone plugin is used to clone a local or remote data directory, the databases in the clone retain the read-only state they had in the source data directory. The read-only state does not affect the cloning process itself. If it is not desirable to have the same database read-only state in the clone, the option must be changed explicitly for the clone after the cloning process has finished, using ALTER DATABASE operations on the clone.

When cloning from a donor to a recipient, if the recipient has a user database that is read only, cloning fails with an error message. Cloning may be retried after making the database writable.

READ ONLY is permitted for ALTER DATABASE, but not for CREATE DATABASE. However, for a read-only database, the statement produced by SHOW CREATE DATABASE does include READ ONLY=1 within a comment to indicate its read-only status:

```sql
mysql> ALTER DATABASE mydb READ ONLY = 1;
```
ALTER EVENT Statement

If the server executes a `CREATE DATABASE` statement containing such a comment, the server ignores the comment and the `READ ONLY` option is not processed. This has implications for `mysqldump`, which uses `SHOW CREATE DATABASE` to produce `CREATE DATABASE` statements in dump output:

- In a dump file, the `CREATE DATABASE` statement for a read-only database contains the commented `READ ONLY` option.
- The dump file can be restored as usual, but because the server ignores the commented `READ ONLY` option, the restored database is not read only. If the database is to be read only after being restored, you must execute `ALTER DATABASE` manually to make it so.

Suppose that `mydb` is read only and you dump it as follows:

```
$> mysqldump --databases mydb > mydb.sql
```

A restore operation later must be followed by `ALTER DATABASE` if `mydb` should still be read only:

```
$> mysql
mysql>
mysql> SOURCE mydb.sql;
mysql> ALTER DATABASE mydb READ ONLY = 1;
```

MySQL Enterprise Backup is not subject to this issue. It backs up and restores a read-only database like any other, but enables the `READ ONLY` option at restore time if it was enabled at backup time.

`ALTER DATABASE` is written to the binary log, so a change to the `READ ONLY` option on a replication source server also affects replicas. To prevent this from happening, binary logging must be disabled prior to execution of the `ALTER DATABASE` statement. For example, to prepare for migrating a database without affecting replicas, perform these operations:

1. Within a single session, disable binary logging and enable `READ ONLY` for the database:

   ```
   mysql> SET sql_log_bin = OFF;
   mysql> ALTER DATABASE mydb READ ONLY = 1;
   ```

2. Dump the database, for example, with `mysqldump`:

   ```
   $> mysqldump --databases mydb > mydb.sql
   ```

3. Within a single session, disable binary logging and disable `READ ONLY` for the database:

   ```
   mysql> SET sql_log_bin = OFF;
   mysql> ALTER DATABASE mydb READ ONLY = 0;
   ```

15.1.3 ALTER EVENT Statement

```
ALTER
[DEFINER = user]
EVENT event_name
[ON SCHEDULE schedule]
[ON COMPLETION [NOT] PRESERVE]
[RENAME TO new_event_name]
[ENABLE | DISABLE | DISABLE ON {REPLICA | SLAVE}]
[COMMENT 'string']
[DO event_body]
```

The `ALTER EVENT` statement changes one or more of the characteristics of an existing event without the need to drop and recreate it. The syntax for each of the `DEFINER`, `ON SCHEDULE`, `ON COMPLETION`, and `RENAME TO` options is:

- `DEFINER = user` enables or disables triggering of the event.
- `ON SCHEDULE` specifies the schedule for the event.
- `ON COMPLETION` specifies how the event should be handled when it completes.
- `RENAME TO` renames the event.
- `ENABLE | DISABLE | DISABLE ON {REPLICA | SLAVE}` enables or disables the event.
- `COMMENT 'string'` adds a comment to the event.
- `DO event_body` specifies the body of the event.
ALTER EVENT Statement

**COMPLETION, COMMENT, ENABLE / DISABLE, and DO** clauses is exactly the same as when used with CREATE EVENT. (See Section 15.1.13, “CREATE EVENT Statement”.)

Any user can alter an event defined on a database for which that user has the EVENT privilege. When a user executes a successful ALTER EVENT statement, that user becomes the definer for the affected event.

**ALTER EVENT** works only with an existing event:

```
mysql> ALTER EVENT no_such_event
    > ON SCHEDULE
    >   EVERY '2:3' DAY_HOUR;
ERROR 1517 (HY000): Unknown event 'no_such_event'
```

In each of the following examples, assume that the event named `myevent` is defined as shown here:

```
CREATE EVENT myevent
    ON SCHEDULE
    EVERY 6 HOUR
    COMMENT 'A sample comment.'
    DO
    UPDATE myschema.mytable SET mycol = mycol + 1;
```

The following statement changes the schedule for `myevent` from once every six hours starting immediately to once every twelve hours, starting four hours from the time the statement is run:

```
ALTER EVENT myevent
    ON SCHEDULE
    EVERY 12 HOUR
    STARTS CURRENT_TIMESTAMP + INTERVAL 4 HOUR;
```

It is possible to change multiple characteristics of an event in a single statement. This example changes the SQL statement executed by `myevent` to one that deletes all records from `mytable`; it also changes the schedule for the event such that it executes once, one day after this ALTER EVENT statement is run.

```
ALTER EVENT myevent
    ON SCHEDULE
    AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
    DO
    TRUNCATE TABLE myschema.mytable;
```

Specify the options in an ALTER EVENT statement only for those characteristics that you want to change; omitted options keep their existing values. This includes any default values for CREATE EVENT such as ENABLE.

To disable `myevent`, use this ALTER EVENT statement:

```
ALTER EVENT myevent
    DISABLE;
```

The ON SCHEDULE clause may use expressions involving built-in MySQL functions and user variables to obtain any of the timestamp or interval values which it contains. You cannot use stored routines or loadable functions in such expressions, and you cannot use any table references; however, you can use SELECT FROM DUAL. This is true for both ALTER EVENT and CREATE EVENT statements. References to stored routines, loadable functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Although an ALTER EVENT statement that contains another ALTER EVENT statement in its DO clause appears to succeed, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

To rename an event, use the ALTER EVENT statement's RENAME TO clause. This statement renames the event `myevent` to `yourevent`:

```
ALTER EVENT myevent
    RENAME TO yourevent;
```
You can also move an event to a different database using `ALTER EVENT ... RENAME TO ...` and `db_name.event_name` notation, as shown here:

```
ALTER EVENT olddb.myevent
  RENAME TO newdb.myevent;
```

To execute the previous statement, the user executing it must have the `EVENT` privilege on both the `olddb` and `newdb` databases.

**Note**

There is no `RENAME EVENT` statement.

The value `DISABLE ON REPLICA` is used on a replica instead of `ENABLE` or `DISABLE` to indicate an event that was created on the replication source server and replicated to the replica, but that is not executed on the replica. Normally, `DISABLE ON REPLICA` is set automatically as required; however, there are some circumstances under which you may want or need to change it manually. See Section 19.5.1.16, “Replication of Invoked Features”, for more information.

`DISABLE ON REPLICA` replaces `DISABLE ON SLAVE`, which is deprecated, and subject to removal in a future version of MySQL.

### 15.1.4 ALTER FUNCTION Statement

```
ALTER FUNCTION func_name [characteristic ...]

characteristic: {
  COMMENT 'string'
  | LANGUAGE SQL
  | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
}
```

This statement can be used to change the characteristics of a stored function. More than one change may be specified in an `ALTER FUNCTION` statement. However, you cannot change the parameters or body of a stored function using this statement; to make such changes, you must drop and re-create the function using `DROP FUNCTION` and `CREATE FUNCTION`.

You must have the `ALTER ROUTINE` privilege for the function. (That privilege is granted automatically to the function creator.) If binary logging is enabled, the `ALTER FUNCTION` statement might also require the `SUPER` privilege, as described in Section 27.7, “Stored Program Binary Logging”.

### 15.1.5 ALTER INSTANCE Statement

```
ALTER INSTANCE instance_action

instance_action: {
  | {ENABLE|DISABLE} INNODB REDO_LOG
  | ROTATE INNODB MASTER KEY
  | ROTATE BINLOG MASTER KEY
  | RELOAD TLS
  | [FOR CHANNEL {mysql_main | mysql_admin}]
  | [NO ROLLBACK ON ERROR]
  | [RELOAD KEYRING]
}
```

`ALTER INSTANCE` defines actions applicable to a MySQL server instance. The statement supports these actions:

- `ALTER INSTANCE {ENABLE | DISABLE} INNODB REDO_LOG`

  This action enables or disables InnoDB redo logging. Redo logging is enabled by default. This feature is intended only for loading data into a new MySQL instance. The statement is not written to the binary log.
ALTER INSTANCE Statement

Warning

Do not disable redo logging on a production system. While it is permitted to shut down and restart the server while redo logging is disabled, an unexpected server stoppage while redo logging is disabled can cause data loss and instance corruption.

An ALTER INSTANCE [ENABLE|DISABLE] INNODB REDO_LOG operation requires an exclusive backup lock, which prevents other ALTER INSTANCE operations from executing concurrently. Other ALTER INSTANCE operations must wait for the lock to be released before executing.

For more information, see Disabling Redo Logging.

• ALTER INSTANCE ROTATE INNODB MASTER KEY

This action rotates the master encryption key used for InnoDB tablespace encryption. Key rotation requires the ENCRYPTION_KEY_ADMIN or SUPER privilege. To perform this action, a keyring plugin must be installed and configured. For instructions, see Section 8.4.4, “The MySQL Keyring”.

ALTER INSTANCE ROTATE INNODB MASTER KEY supports concurrent DML. However, it cannot be run concurrently with CREATE TABLE ... ENCRYPTION or ALTER TABLE ... ENCRYPTION operations, and locks are taken to prevent conflicts that could arise from concurrent execution of these statements. If one of the conflicting statements is running, it must complete before another can proceed.

ALTER INSTANCE ROTATE INNODB MASTER KEY statements are written to the binary log so that they can be executed on replicated servers.

For additional ALTER INSTANCE ROTATE INNODB MASTER KEY usage information, see Section 17.13, “InnoDB Data-at-Rest Encryption”.

• ALTER INSTANCE ROTATE BINLOG MASTER KEY

This action rotates the binary log master key used for binary log encryption. Key rotation for the binary log master key requires the BINLOG_ENCRYPTION_ADMIN or SUPER privilege. The statement cannot be used if the binlog_encryption system variable is set to OFF. To perform this action, a keyring plugin must be installed and configured. For instructions, see Section 8.4.4, “The MySQL Keyring”.

ALTER INSTANCE ROTATE BINLOG MASTER KEY actions are not written to the binary log and are not executed on replicas. Binary log master key rotation can therefore be carried out in replication environments including a mix of MySQL versions. To schedule regular rotation of the binary log master key on all applicable source and replica servers, you can enable the MySQL Event Scheduler on each server and issue the ALTER INSTANCE ROTATE BINLOG MASTER KEY statement using a CREATE EVENT statement. If you rotate the binary log master key because you suspect that the current or any of the previous binary log master keys might have been compromised, issue the statement on every applicable source and replica server, which enables you to verify immediate compliance.

For additional ALTER INSTANCE ROTATE BINLOG MASTER KEY usage information, including what to do if the process does not complete correctly or is interrupted by an unexpected server halt, see Section 19.3.2, “Encrypting Binary Log Files and Relay Log Files”.

• ALTER INSTANCE RELOAD TLS

This action reconfigures a TLS context from the current values of the system variables that define the context. It also updates the status variables that reflect the active context values. This action requires the CONNECTION_ADMIN privilege. For additional information about reconfiguring the TLS context, including which system and status variables are context-related, see Server-Side Runtime Configuration and Monitoring for Encrypted Connections.
ALTER LOGFILE GROUP Statement

By default, the statement reloads the TLS context for the main connection interface. If the `FOR CHANNEL` clause is given, the statement reloads the TLS context for the named channel: `mysql_main` for the main connection interface, `mysql_admin` for the administrative connection interface. For information about the different interfaces, see Section 7.1.12.1, “Connection Interfaces”. The updated TLS context properties are exposed in the Performance Schema `tls_channel_status` table. See Section 29.12.22.9, “The tls_channel_status Table”.

Updating the TLS context for the main interface may also affect the administrative interface because unless some nondefault TLS value is configured for that interface, it uses the same TLS context as the main interface.

**Note**

When you reload the TLS context, OpenSSL reloads the file containing the CRL (certificate revocation list) as part of the process. If the CRL file is large, the server allocates a large chunk of memory (ten times the file size), which is doubled while the new instance is being loaded and the old one has not yet been released. The process resident memory is not immediately reduced after a large allocation is freed, so if you issue the `ALTER INSTANCE RELOAD TLS` statement repeatedly with a large CRL file, the process resident memory usage may grow as a result of this.

By default, the `RELOAD TLS` action rolls back with an error and has no effect if the configuration values do not permit creation of the new TLS context. The previous context values continue to be used for new connections. If the optional `NO ROLLBACK ON ERROR` clause is given and the new context cannot be created, rollback does not occur. Instead, a warning is generated and encryption is disabled for new connections on the interface to which the statement applies.

`ALTER INSTANCE RELOAD TLS` statements are not written to the binary log (and thus are not replicated). TLS configuration is local and depends on local files not necessarily present on all servers involved.

- **ALTER INSTANCE RELOAD KEYRING**

If a keyring component is installed, this action tells the component to re-read its configuration file and reinitialize any keyring in-memory data. If you modify the component configuration at runtime, the new configuration does not take effect until you perform this action. Keyring reloading requires the `ENCRYPTION_KEY_ADMIN` privilege.

This action enables reconfiguring only the currently installed keyring component. It does not enable changing which component is installed. For example, if you change the configuration for the installed keyring component, `ALTER INSTANCE RELOAD KEYRING` causes the new configuration to take effect. On the other hand, if you change the keyring component named in the server manifest file, `ALTER INSTANCE RELOAD KEYRING` has no effect and the current component remains installed.

`ALTER INSTANCE RELOAD KEYRING` statements are not written to the binary log (and thus are not replicated).

### 15.1.6 ALTER LOGFILE GROUP Statement

```
ALTER LOGFILE GROUP logfile_group
ADD UNDOFILE 'file_name'
[INITIAL_SIZE [=] size]
[WAIT]
ENGINE [=] engine_name
```

This statement adds an UNDO file named 'file_name' to an existing log file group `logfile_group`. An `ALTER LOGFILE GROUP` statement has one and only one `ADD UNDOFILE` clause. No `DROP UNDOFILE` clause is currently supported.
**Note**

All NDB Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and an undo log file with the same name, or an undo log file and a data file with the same name.

The optional `INITIAL_SIZE` parameter sets the UNDO file's initial size in bytes; if not specified, the initial size defaults to 134217728 (128 MB). You may optionally follow `size` with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters `M` (megabytes) or `G` (gigabytes). (Bug #13116514, Bug #16104705, Bug #62858)

On 32-bit systems, the maximum supported value for `INITIAL_SIZE` is 4294967296 (4 GB). (Bug #29186)

The minimum allowed value for `INITIAL_SIZE` is 1048576 (1 MB). (Bug #29574)

**Note**

`WAIT` is parsed but otherwise ignored. This keyword currently has no effect, and is intended for future expansion.

The `ENGINE` clause (required) determines the storage engine which is used by this log file group, with `engine_name` being the name of the storage engine. Currently, the only accepted values for `engine_name` are “NDBCLUSTER” and “NDB”. The two values are equivalent.

Here is an example, which assumes that the log file group `lg_3` has already been created using `CREATE LOGFILE GROUP` (see Section 15.1.16, “CREATE LOGFILE GROUP Statement”):

```sql
ALTER LOGFILE GROUP lg_3
  ADD UNDOFILE 'undo_10.dat'
  INITIAL_SIZE=32M
  ENGINE=NDBCLUSTER;
```

When `ALTER LOGFILE GROUP` is used with `ENGINE = NDBCLUSTER` (alternatively, `ENGINE = NDB`), an undo log file is created on each NDB Cluster data node. You can verify that the undo files were created and obtain information about them by querying the Information Schema `FILES` table. For example:

```sql
mysql> SELECT FILE_NAME, LOGFILE_GROUP_NUMBER, EXTRA
    -> FROM INFORMATION_SCHEMA.FILES
    -> WHERE LOGFILE_GROUP_NAME = 'lg_3';
```

<table>
<thead>
<tr>
<th>FILE_NAME</th>
<th>LOGFILE_GROUP_NUMBER</th>
<th>EXTRA</th>
</tr>
</thead>
<tbody>
<tr>
<td>newdata.dat</td>
<td>0</td>
<td>CLUSTER_NODE=3</td>
</tr>
<tr>
<td>newdata.dat</td>
<td>0</td>

(See Section 28.3.15, “The INFORMATION_SCHEMA FILES Table”.)

Memory used for `UNDO_BUFFER_SIZE` comes from the global pool whose size is determined by the value of the `SharedGlobalMemory` data node configuration parameter. This includes any default value implied for this option by the setting of the `InitialLogFileGroup` data node configuration parameter.

`ALTER LOGFILE GROUP` is useful only with Disk Data storage for NDB Cluster. For more information, see Section 25.6.11, “NDB Cluster Disk Data Tables”.

### 15.1.7 ALTER PROCEDURE Statement

```sql
ALTER PROCEDURE proc_name [characteristic ...]
```
This statement can be used to change the characteristics of a stored procedure. More than one change may be specified in an `ALTER PROCEDURE` statement. However, you cannot change the parameters or body of a stored procedure using this statement; to make such changes, you must drop and re-create the procedure using `DROP PROCEDURE` and `CREATE PROCEDURE`.

You must have the `ALTER ROUTINE` privilege for the procedure. By default, that privilege is granted automatically to the procedure creator. This behavior can be changed by disabling the `automatic_sp_privileges` system variable. See Section 27.2.2, “Stored Routines and MySQL Privileges”.

### 15.1.8 ALTER SERVER Statement

```
ALTER SERVER  server_name
    OPTIONS ( option [, option] ...)  
```

Alters the server information for `server_name`, adjusting any of the options permitted in the `CREATE SERVER` statement. The corresponding fields in the `mysql.servers` table are updated accordingly.

This statement requires the `SUPER` privilege.

For example, to update the `USER` option:

```
ALTER SERVER s OPTIONS (USER 'sally');
```

`ALTER SERVER` causes an implicit commit. See Section 15.3.3, “Statements That Cause an Implicit Commit”.

`ALTER SERVER` is not written to the binary log, regardless of the logging format that is in use.

### 15.1.9 ALTER TABLE Statement

```
ALTER TABLE  tbl_name
    [alter_option [, alter_option] ...]
    [partition_options]
alter_option:  
    table_options
    | ADD [COLUMN]  col_name column_definition
      [FIRST | AFTER col_name]
    | ADD [COLUMN]  (col_name column_definition,...)
    | ADD [INDEX | KEY]  [index_name]
      [index_type]  (key_part,...) [index_option] ...
    | ADD [FULLTEXT | SPATIAL] [INDEX | KEY] [index_name]
      (key_part,...) [index_option] ...
    | ADD [CONSTRAINT [symbol]]  PRIMARY KEY
      [index_type]  (key_part,...) [index_option] ...
    | ADD [CONSTRAINT [symbol]]  UNIQUE [INDEX | KEY]
      [index_name] [index_type]  (key_part,...) [index_option] ...
    | ADD [CONSTRAINT [symbol]]  FOREIGN KEY
      [index_name]  (col_name,...) 
      reference_definition
    | ADD [CONSTRAINT [symbol]]  CHECK ( expr ) [NOT] ENFORCED
    | DROP [CHECK | CONSTRAINT]  symbol
    | ALTER [CHECK | CONSTRAINT] symbol [NOT] ENFORCED
    | ALGORITHM [=]  [DEFAULT | INSTANT | INPLACE | COPY]
    | ALTER [COLUMN]  col_name {  
      SET DEFAULT  (literal | (expr))
      | SET {VISIBLE | INVISIBLE}
      | DROP DEFAULT  
```
ALTER TABLE Statement

ALTER INDEX index_name [VISIBLE | INVISIBLE]
| CHANGE [COLUMN] old_col_name new_col_name column_definition
   [FIRST | AFTER col_name]
| [DEFAULT] CHARACTER SET [=] charset_name [COLLATE [=] collation_name]
| CONVERT TO CHARACTER SET charset_name [COLLATE collation_name]
| {DISABLE | ENABLE} KEYS
| {DISCARD | IMPORT} TABLESPACE
| DROP [COLUMN] col_name
| DROP [INDEX | KEY] index_name
| DROP PRIMARY KEY
| DROP FOREIGN KEY fk_symbol
| FORCE
| LOCK [=] {DEFAULT | NONE | SHARED | EXCLUSIVE}
| MODIFY [COLUMN] col_name column_definition
   [FIRST | AFTER col_name]
| ORDER BY col_name [ , col_name] ...
| RENAME COLUMN old_col_name TO new_col_name
| RENAME [INDEX | KEY] old_index_name TO new_index_name
| RENAME [TO | AS] new_tbl_name
| {WITHOUT | WITH} VALIDATION

partition_options:
    partition_option [partition_option] ...

partition_option: {
    ADD PARTITION (partition_definition)
   | DROP PARTITION partition_names
   | DISCARD PARTITION [partition_names | ALL] TABLESPACE
   | IMPORT PARTITION [partition_names | ALL] TABLESPACE
   | TRUNCATE PARTITION [partition_names | ALL]
   | REORGANIZE PARTITION partition_names INTO (partition_definitions)
   | EXCHANGE PARTITION partition_name WITH TABLE tbl_name [WITH | WITHOUT] VALIDATION
   | ANALYZE PARTITION [partition_names | ALL]
   | CHECK PARTITION [partition_names | ALL]
   | OPTIMIZE PARTITION [partition_names | ALL]
   | REBUILD PARTITION [partition_names | ALL]
   | REPAIR PARTITION [partition_names | ALL]
   | REMOVE PARTITIONING

key_part: {col_name [{(length)}] | (expr)} [ASC | DESC]

index_type:
    USING {BTREE | HASH}

index_option: {

   | DELAY_KEY_WRITE [=] {0 | 1}
   | ENCRYPTION [=] {'Y' | 'N'}
   | ENGINE [=] engine_name

2419
ALTER TABLE changes the structure of a table. For example, you can add or delete columns, create or destroy indexes, change the type of existing columns, or rename columns or the table itself. You can also change characteristics such as the storage engine used for the table or the table comment.

- To use ALTER TABLE, you need ALTER, CREATE, and INSERT privileges for the table. Renaming a table requires ALTER and DROP on the old table, ALTER, CREATE, and INSERT on the new table.

- Following the table name, specify the alterations to be made. If none are given, ALTER TABLE does nothing.

- The syntax for many of the permissible alterations is similar to clauses of the CREATE TABLE statement. column_definition clauses use the same syntax for ADD and CHANGE as for CREATE TABLE. For more information, see Section 15.1.20, “CREATE TABLE Statement”.

- The word COLUMN is optional and can be omitted, except for RENAME COLUMN (to distinguish a column-renaming operation from the RENAME table-renaming operation).

- Multiple ADD, ALTER, DROP, and CHANGE clauses are permitted in a single ALTER TABLE statement, separated by commas. This is a MySQL extension to standard SQL, which permits only one of each clause per ALTER TABLE statement. For example, to drop multiple columns in a single statement, do this:

  ```sql
  ALTER TABLE t2 DROP COLUMN c, DROP COLUMN d;
  ```

- If a storage engine does not support an attempted ALTER TABLE operation, a warning may result. Such warnings can be displayed with SHOW WARNINGS. See Section 15.7.7.41, “SHOW WARNINGS Statement”. For information on troubleshooting ALTER TABLE, see Section B.3.6.1, “Problems with ALTER TABLE”.

- For information about generated columns, see Section 15.1.9.2, “ALTER TABLE and Generated Columns”.

- For usage examples, see Section 15.1.9.3, “ALTER TABLE Examples”.

- InnoDB supports addition of multi-valued indexes on JSON columns using a key_part specification can take the form (CAST json_path AS type ARRAY). See Multi-Valued Indexes, for detailed information regarding multi-valued index creation and usage of, as well as restrictions and limitations on multi-valued indexes.

- With the mysql_info() C API function, you can find out how many rows were copied by ALTER TABLE. See mysql_info().

There are several additional aspects to the ALTER TABLE statement, described under the following topics in this section:

- Table Options
ALTER TABLE Statement

- Performance and Space Requirements
- Concurrency Control
- Adding and Dropping Columns
- Renaming, Redefining, and Reordering Columns
- Primary Keys and Indexes
- Foreign Keys and Other Constraints
- Changing the Character Set
- Importing InnoDB Tables
- Row Order for MyISAM Tables
- Partitioning Options

Table Options

table_options signifies table options of the kind that can be used in the CREATE TABLE statement, such as ENGINE, AUTO_INCREMENT, AVG_ROW_LENGTH, MAX_ROWS, ROW_FORMAT, or TABLESPACE.

For descriptions of all table options, see Section 15.1.20, "CREATE TABLE Statement". However, ALTER TABLE ignores DATA DIRECTORY and INDEX DIRECTORY when given as table options. ALTER TABLE permits them only as partitioning options, and requires that you have the FILE privilege.

Use of table options with ALTER TABLE provides a convenient way of altering single table characteristics. For example:

- If t1 is currently not an InnoDB table, this statement changes its storage engine to InnoDB:

  ```sql
  ALTER TABLE t1 ENGINE = InnoDB;
  ```

- See Section 17.6.1.5, "Converting Tables from MyISAM to InnoDB" for considerations when switching tables to the InnoDB storage engine.

- When you specify an ENGINE clause, ALTER TABLE rebuilds the table. This is true even if the table already has the specified storage engine.

- Running ALTER TABLE tbl_name ENGINE=INNODB on an existing InnoDB table performs a "null" ALTER TABLE operation, which can be used to defragment an InnoDB table, as described in Section 17.11.4, "Defragmenting a Table". Running ALTER TABLE tbl_name FORCE on an InnoDB table performs the same function.

- ALTER TABLE tbl_name ENGINE=INNODB and ALTER TABLE tbl_name FORCE use online DDL. For more information, see Section 17.12, "InnoDB and Online DDL".

- The outcome of attempting to change the storage engine of a table is affected by whether the desired storage engine is available and the setting of the NO ENGINE SUBSTITUTION SQL mode, as described in Section 7.1.11, "Server SQL Modes".

- To prevent inadvertent loss of data, ALTER TABLE cannot be used to change the storage engine of a table to MERGE or BLACKHOLE.

- To change the InnoDB table to use compressed row-storage format:

  ```sql
  ALTER TABLE t1 ROW_FORMAT = COMPRESSED;
  ```

- The ENCRYPTION clause enables or disables page-level data encryption for an InnoDB table. A keyring plugin must be installed and configured to enable encryption.
If the `table_encryption_privilege_check` variable is enabled, the `TABLE_ENCRYPTION_ADMIN` privilege is required to use an `ENCRYPTION` clause with a setting that differs from the default schema encryption setting.

`ENCRYPTION` is also supported for tables residing in general tablespaces.

For tables that reside in general tablespaces, table and tablespace encryption must match.

Altering table encryption by moving a table to a different tablespace or changing the storage engine is not permitted without explicitly specifying an `ENCRYPTION` clause.

Specifying an `ENCRYPTION` clause with a value other than 'N' or '' is not permitted if the table uses a storage engine that does not support encryption. Attempting to create a table without an `ENCRYPTION` clause in an encryption-enabled schema using a storage engine that does not support encryption is also not permitted.

For more information, see Section 17.13, “InnoDB Data-at-Rest Encryption”.

- To reset the current auto-increment value:
  ```sql
  ALTER TABLE t1 AUTO_INCREMENT = 13;
  ```
  You cannot reset the counter to a value less than or equal to the value that is currently in use. For both InnoDB and MyISAM, if the value is less than or equal to the maximum value currently in the `AUTO_INCREMENT` column, the value is reset to the current maximum `AUTO_INCREMENT` column value plus one.

- To change the default table character set:
  ```sql
  ALTER TABLE t1 CHARACTER SET = utf8mb4;
  ```
  See also Changing the Character Set.

- To add (or change) a table comment:
  ```sql
  ALTER TABLE t1 COMMENT = 'New table comment';
  ```

- Use `ALTER TABLE` with the `TABLESPACE` option to move InnoDB tables between existing general tablespaces, file-per-table tablespaces, and the system tablespace. See Moving Tables Between Tablespaces Using ALTER TABLE.

  ```sql
  ALTER TABLE ... TABLESPACE
  ```
  operations always cause a full table rebuild, even if the `TABLESPACE` attribute has not changed from its previous value.

  ```sql
  ALTER TABLE ... TABLESPACE
  ``` syntax does not support moving a table from a temporary tablespace to a persistent tablespace.

  The `DATA DIRECTORY` clause, which is supported with `CREATE TABLE ... TABLESPACE`, is not supported with `ALTER TABLE ... TABLESPACE`, and is ignored if specified.

  For more information about the capabilities and limitations of the `TABLESPACE` option, see CREATE TABLE.

- MySQL NDB Cluster 8.4 supports setting `NDB_TABLE` options for controlling a table's partition balance (fragment count type), read-from-any-replica capability, full replication, or any combination of these, as part of the table comment for an `ALTER TABLE` statement in the same manner as for `CREATE TABLE`, as shown in this example:
  ```sql
  ALTER TABLE t1 COMMENT = "NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RA_BY_NODE";
  ```
  It is also possible to set `NDBCOMMENT` options for columns of `NDB` tables as part of an `ALTER TABLE` statement, like this one:
ALTER TABLE Statement

```sql
ALTER TABLE t1
  CHANGE COLUMN c1 c1 BLOB
  COMMENT = 'NDB_COLUMN=BLOB_INLINE_SIZE=4096,MAX_BLOB_PART_SIZE';
```

Bear in mind that `ALTER TABLE ... COMMENT ...` discards any existing comment for the table. See Setting NDB_TABLE options, for additional information and examples.

- `ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` options are used to specify table, column, and index attributes for primary and secondary storage engines. These options are reserved for future use. Index attributes cannot be altered. An index must be dropped and added back with the desired change, which can be performed in a single `ALTER TABLE` statement.

To verify that the table options were changed as intended, use `SHOW CREATE TABLE`, or query the Information Schema `TABLES` table.

**Performance and Space Requirements**

`ALTER TABLE` operations are processed using one of the following algorithms:

- **COPY**: Operations are performed on a copy of the original table, and table data is copied from the original table to the new table row by row. Concurrent DML is not permitted.

- **INPLACE**: Operations avoid copying table data but may rebuild the table in place. An exclusive metadata lock on the table may be taken briefly during preparation and execution phases of the operation. Typically, concurrent DML is supported.

- **INSTANT**: Operations only modify metadata in the data dictionary. An exclusive metadata lock on the table may be taken briefly during the execution phase of the operation. Table data is unaffected, making operations instantaneous. Concurrent DML is permitted.

For tables using the NDB storage engine, these algorithms work as follows:

- **COPY**: NDB creates a copy of the table and alters it; the NDB Cluster handler then copies the data between the old and new versions of the table. Subsequently, NDB deletes the old table and renames the new one.

  This is sometimes also referred to as a “copying” or “offline” `ALTER TABLE`.

- **INPLACE**: The data nodes make the required changes; the NDB Cluster handler does not copy data or otherwise take part.

  This is sometimes also referred to as a “non-copying” or “online” `ALTER TABLE`.

- **INSTANT**: Not supported by NDB.

See [Section 25.6.12, “Online Operations with ALTER TABLE in NDB Cluster”](#), for more information.

The `ALGORITHM` clause is optional. If the `ALGORITHM` clause is omitted, MySQL uses `ALGORITHM=INSTANT` for storage engines and `ALTER TABLE` clauses that support it. Otherwise, `ALGORITHM=INPLACE` is used. If `ALGORITHM=INPLACE` is not supported, `ALGORITHM=COPY` is used.

**Note**

After adding a column to a partitioned table using `ALGORITHM=INSTANT`, it is no longer possible to perform `ALTER TABLE ... EXCHANGE PARTITION` on the table.

Specifying an `ALGORITHM` clause requires the operation to use the specified algorithm for clauses and storage engines that support it, or fail with an error otherwise. Specifying `ALGORITHM=DEFAULT` is the same as omitting the `ALGORITHM` clause.

`ALTER TABLE` operations that use the `COPY` algorithm wait for other operations that are modifying the table to complete. After alterations are applied to the table copy, data is copied over, the original table
ALTER TABLE Statement

is deleted, and the table copy is renamed to the name of the original table. While the `ALTER TABLE` operation executes, the original table is readable by other sessions (with the exception noted shortly). Updates and writes to the table started after the `ALTER TABLE` operation begins are stalled until the new table is ready, then are automatically redirected to the new table. The temporary copy of the table is created in the database directory of the original table unless it is a `RENAME TO` operation that moves the table to a database that resides in a different directory.

The exception referred to earlier is that `ALTER TABLE` blocks reads (not just writes) at the point where it is ready to clear outdated table structures from the table and table definition caches. At this point, it must acquire an exclusive lock. To do so, it waits for current readers to finish, and blocks new reads and writes.

An `ALTER TABLE` operation that uses the `COPY` algorithm prevents concurrent DML operations. Concurrent queries are still allowed. That is, a table-copying operation always includes at least the concurrency restrictions of `LOCK=SHARED` (allow queries but not DML). You can further restrict concurrency for operations that support the `LOCK` clause by specifying `LOCK=EXCLUSIVE`, which prevents DML and queries. For more information, see `Concurrency Control`.

To force use of the `COPY` algorithm for an `ALTER TABLE` operation that would otherwise not use it, specify `ALGORITHM=COPY` or enable the `old_alter_table` system variable. If there is a conflict between the `old_alter_table` setting and an `ALGORITHM` clause with a value other than `DEFAULT`, the `ALGORITHM` clause takes precedence.

For InnoDB tables, an `ALTER TABLE` operation that uses the `COPY` algorithm on a table that resides in a shared tablespace can increase the amount of space used by the tablespace. Such operations require as much additional space as the data in the table plus indexes. For a table residing in a shared tablespace, the additional space used during the operation is not released back to the operating system as it is for a table that resides in a file-per-table tablespace.

For information about space requirements for online DDL operations, see Section 17.12.3, “Online DDL Space Requirements”.

`ALTER TABLE` operations that support the `INPLACE` algorithm include:

- `ALTER TABLE` operations supported by the InnoDB online DDL feature. See Section 17.12.1, “Online DDL Operations”.
- Renaming a table. MySQL renames files that correspond to the table `tbl_name` without making a copy. (You can also use the `RENAME TABLE` statement to rename tables. See Section 15.1.36, “RENAME TABLE Statement”.) Privileges granted specifically for the renamed table are not migrated to the new name. They must be changed manually.
- Operations that modify table metadata only. These operations are immediate because the server does not touch table contents. Metadata-only operations include:
  - Renaming a column. In NDB Cluster, this operation can also be performed online.
  - Changing the default value of a column (except for NDB tables).
  - Modifying the definition of an `ENUM` or `SET` column by adding new enumeration or set members to the end of the list of valid member values, as long as the storage size of the data type does not change. For example, adding a member to a `SET` column that has 8 members changes the required storage per value from 1 byte to 2 bytes; this requires a table copy. Adding members in the middle of the list causes renumbering of existing members, which requires a table copy.
  - Changing the definition of a spatial column to remove the `SRID` attribute. (Adding or changing an `SRID` attribute requires a rebuild, and cannot be done in place, because the server must verify that all values have the specified `SRID` value.)
  - Changing a column character set, when these conditions apply:
• The column data type is **CHAR**, **VARCHAR**, a **TEXT** type, or **ENUM**.

• The character set change is from **utf8mb3** to **utf8mb4**, or any character set to **binary**.

• There is no index on the column.

• Changing a generated column, when these conditions apply:

  • For **InnoDB** tables, statements that modify generated stored columns but do not change their type, expression, or nullability.

  • For non-**InnoDB** tables, statements that modify generated stored or virtual columns but do not change their type, expression, or nullability.

    An example of such a change is a change to the column comment.

• Renaming an index.

• Adding or dropping a secondary index, for **InnoDB** and **NDB** tables. See Section 17.12.1, “Online DDL Operations”.

• For **NDB** tables, operations that add and drop indexes on variable-width columns. These operations occur online, without table copying and without blocking concurrent DML actions for most of their duration. See Section 25.6.12, “Online Operations with ALTER TABLE in NDB Cluster”.

• Modifying index visibility with an **ALTER INDEX** operation.

• Column modifications of tables containing generated columns that depend on columns with a **DEFAULT** value if the modified columns are not involved in the generated column expressions. For example, changing the **NULL** property of a separate column can be done in place without a table rebuild.

**ALTER TABLE** operations that support the **INSTANT** algorithm include:

• Adding a column. This feature is referred to as “Instant **ADD COLUMN**”. Limitations apply. See Section 17.12.1, “Online DDL Operations”.

• Dropping a column. This feature is referred to as “Instant **DROP COLUMN**”. Limitations apply. See Section 17.12.1, “Online DDL Operations”.

• Adding or dropping a virtual column.

• Adding or dropping a column default value.

• Modifying the definition of an **ENUM** or **SET** column. The same restrictions apply as described above for **ALGORITHM=INSTANT**.

• Changing the index type.

• Renaming a table. The same restrictions apply as described above for **ALGORITHM=INSTANT**.

For more information about operations that support **ALGORITHM=INSTANT**, see Section 17.12.1, “Online DDL Operations”.

**ALTER TABLE** upgrades MySQL 5.5 temporal columns to 5.6 format for **ADD COLUMN**, **CHANGE COLUMN**, **MODIFY COLUMN**, **ADD INDEX**, and **FORCE** operations. This conversion cannot be done using the **INPLACE** algorithm because the table must be rebuilt, so specifying **ALGORITHM=INPLACE** in these cases results in an error. Specify **ALGORITHM=COPY** if necessary.

If an **ALTER TABLE** operation on a multicolumn index used to partition a table by **KEY** changes the order of the columns, it can only be performed using **ALGORITHM=COPY**.
ALTER TABLE Statement

The `WITHOUT VALIDATION` and `WITH VALIDATION` clauses affect whether `ALTER TABLE` performs an in-place operation for virtual generated column modifications. See Section 15.1.9.2, “ALTER TABLE and Generated Columns”.

NDB Cluster 8.4 supports online operations using the same `ALGORITHM=INPLACE` syntax used with the standard MySQL Server. NDB does not allow changing a tablespace online. See Section 25.6.12, “Online Operations with ALTER TABLE in NDB Cluster”, for more information.

When performing a copying `ALTER TABLE`, NDB checks to ensure that no concurrent writes have been made to the affected table. If it finds that any have been made, NDB rejects the `ALTER TABLE` statement and raises `ER_TABLE_DEF_CHANGED`.

`ALTER TABLE with DISCARD ... PARTITION ... TABLESPACE` or `IMPORT ... PARTITION ... TABLESPACE` does not create any temporary tables or temporary partition files.

`ALTER TABLE with ADD PARTITION, DROP PARTITION, COALESCE PARTITION, REBUILD PARTITION, or REORGANIZE PARTITION` does not create temporary tables (except when used with NDB tables); however, these operations can and do create temporary partition files.

`ADD` or `DROP` operations for `RANGE` or `LIST` partitions are immediate operations or nearly so. `ADD` or `COALESCE` operations for `HASH` or `KEY` partitions copy data between all partitions, unless `LINEAR HASH` or `LINEAR KEY` was used; this is effectively the same as creating a new table, although the `ADD` or `COALESCE` operation is performed partition by partition. `REORGANIZE` operations copy only changed partitions and do not touch unchanged ones.

For `MyISAM` tables, you can speed up index re-creation (the slowest part of the alteration process) by setting the `myisam_sort_buffer_size` system variable to a high value.

Concurrency Control

For `ALTER TABLE` operations that support it, you can use the `LOCK` clause to control the level of concurrent reads and writes on a table while it is being altered. Specifying a non-default value for this clause enables you to require a certain amount of concurrent access or exclusivity during the alter operation, and halts the operation if the requested degree of locking is not available.

Only `LOCK = DEFAULT` is permitted for operations that use `ALGORITHM=INSTANT`. The other `LOCK` clause parameters are not applicable.

The parameters for the `LOCK` clause are:

- **LOCK = DEFAULT**
  
  Maximum level of concurrency for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation: Permit concurrent reads and writes if supported. If not, permit concurrent reads if supported. If not, enforce exclusive access.

- **LOCK = NONE**
  
  If supported, permit concurrent reads and writes. Otherwise, an error occurs.

- **LOCK = SHARED**
  
  If supported, permit concurrent reads but block writes. Writes are blocked even if concurrent writes are supported by the storage engine for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation. If concurrent reads are not supported, an error occurs.

- **LOCK = EXCLUSIVE**
  
  Enforce exclusive access. This is done even if concurrent reads/writes are supported by the storage engine for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation.
Adding and Dropping Columns

Use **ADD** to add new columns to a table, and **DROP** to remove existing columns. **DROP col_name** is a MySQL extension to standard SQL.

To add a column at a specific position within a table row, use **FIRST** or **AFTER col_name**. The default is to add the column last.

If a table contains only one column, the column cannot be dropped. If what you intend is to remove the table, use the **DROP TABLE** statement instead.

If columns are dropped from a table, the columns are also removed from any index of which they are a part. If all columns that make up an index are dropped, the index is dropped as well. If you use **CHANGE** or **MODIFY** to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.

For **ALTER TABLE ... ADD**, if the column has an expression default value that uses a nondeterministic function, the statement may produce a warning or error. For further information, see Section 13.6, “Data Type Default Values”, and Section 19.1.3.7, “Restrictions on Replication with GTIDs”.

Renaming, Redefining, and Reordering Columns

The **CHANGE**, **MODIFY**, **RENAME COLUMN**, and **ALTER** clauses enable the names and definitions of existing columns to be altered. They have these comparative characteristics:

- **CHANGE**:
  - Can rename a column and change its definition, or both.
  - Has more capability than **MODIFY** or **RENAME COLUMN**, but at the expense of convenience for some operations. **CHANGE** requires naming the column twice if not renaming it, and requires respecifying the column definition if only renaming it.
  - With **FIRST** or **AFTER**, can reorder columns.

- **MODIFY**:
  - Can change a column definition but not its name.
  - More convenient than **CHANGE** to change a column definition without renaming it.
  - With **FIRST** or **AFTER**, can reorder columns.

- **RENAME COLUMN**:
  - Can change a column name but not its definition.
  - More convenient than **CHANGE** to rename a column without changing its definition.

- **ALTER**: Used only to change a column default value.

**CHANGE** is a MySQL extension to standard SQL. **MODIFY** and **RENAME COLUMN** are MySQL extensions for Oracle compatibility.

To alter a column to change both its name and definition, use **CHANGE**, specifying the old and new names and the new definition. For example, to rename an **INT NOT NULL** column from **a** to **b** and change its definition to use the **BIGINT** data type while retaining the **NOT NULL** attribute, do this:

```
ALTER TABLE t1 CHANGE a b BIGINT NOT NULL;
```
To change a column definition but not its name, use `CHANGE` or `MODIFY`. With `CHANGE`, the syntax requires two column names, so you must specify the same name twice to leave the name unchanged. For example, to change the definition of column `b`, do this:

```
ALTER TABLE t1 CHANGE b b INT NOT NULL;
```

`MODIFY` is more convenient to change the definition without changing the name because it requires the column name only once:

```
ALTER TABLE t1 MODIFY b INT NOT NULL;
```

To change a column name but not its definition, use `CHANGE` or `RENAME COLUMN`. With `CHANGE`, the syntax requires a column definition, so to leave the definition unchanged, you must respecify the definition the column currently has. For example, to rename an `INT NOT NULL` column from `b` to `a`, do this:

```
ALTER TABLE t1 CHANGE b a INT NOT NULL;
```

`RENAME COLUMN` is more convenient to change the name without changing the definition because it requires only the old and new names:

```
ALTER TABLE t1 RENAME COLUMN b TO a;
```

In general, you cannot rename a column to a name that already exists in the table. However, this is sometimes not the case, such as when you swap names or move them through a cycle. If a table has columns named `a`, `b`, and `c`, these are valid operations:

```
-- swap a and b
ALTER TABLE t1 RENAME COLUMN a TO b,
    RENAME COLUMN b TO a;

-- "rotate" a, b, c through a cycle
ALTER TABLE t1 RENAME COLUMN a TO b,
    RENAME COLUMN b TO c,
    RENAME COLUMN c TO a;
```

For column definition changes using `CHANGE` or `MODIFY`, the definition must include the data type and all attributes that should apply to the new column, other than index attributes such as `PRIMARY KEY` or `UNIQUE`. Attributes present in the original definition but not specified for the new definition are not carried forward. Suppose that a column `col1` is defined as `INT UNSIGNED DEFAULT 1 COMMENT 'my column'` and you modify the column as follows, intending to change only `INT` to `BIGINT`:

```
ALTER TABLE t1 MODIFY col1 BIGINT;
```

That statement changes the data type from `INT` to `BIGINT`, but it also drops the `UNSIGNED`, `DEFAULT`, and `COMMENT` attributes. To retain them, the statement must include them explicitly:

```
ALTER TABLE t1 MODIFY col1 BIGINT UNSIGNED DEFAULT 1 COMMENT 'my column';
```

For data type changes using `CHANGE` or `MODIFY`, MySQL tries to convert existing column values to the new type as well as possible.

**Warning**

This conversion may result in alteration of data. For example, if you shorten a string column, values may be truncated. To prevent the operation from succeeding if conversions to the new data type would result in loss of data, enable strict SQL mode before using `ALTER TABLE` (see Section 7.1.11, "Server SQL Modes").

If you use `CHANGE` or `MODIFY` to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.

For columns renamed by `CHANGE` or `RENAME COLUMN`, MySQL automatically renames these references to the renamed column:
ALTER TABLE Statement

- Indexes that refer to the old column, including invisible indexes and disabled MyISAM indexes.
- Foreign keys that refer to the old column.

For columns renamed by CHANGE or RENAME COLUMN, MySQL does not automatically rename these references to the renamed column:

- Generated column and partition expressions that refer to the renamed column. You must use CHANGE to redefine such expressions in the same ALTER TABLE statement as the one that renames the column.
- Views and stored programs that refer to the renamed column. You must manually alter the definition of these objects to refer to the new column name.

To reorder columns within a table, use FIRST and AFTER in CHANGE or MODIFY operations.

ALTER ... SET DEFAULT or ALTER ... DROP DEFAULT specify a new default value for a column or remove the old default value, respectively. If the old default is removed and the column can be NULL, the new default is NULL. If the column cannot be NULL, MySQL assigns a default value as described in Section 13.6, “Data Type Default Values”.

ALTER ... SET VISIBLE and ALTER ... SET INVISIBLE enable column visibility to be changed. See Section 15.1.20.10, “Invisible Columns”.

Primary Keys and Indexes

DROP PRIMARY KEY drops the primary key. If there is no primary key, an error occurs. For information about the performance characteristics of primary keys, especially for InnoDB tables, see Section 10.3.2, “Primary Key Optimization”.

If the sql_require_primary_key system variable is enabled, attempting to drop a primary key produces an error.

If you add a UNIQUE INDEX or PRIMARY KEY to a table, MySQL stores it before any nonunique index to permit detection of duplicate keys as early as possible.

DROP INDEX removes an index. This is a MySQL extension to standard SQL. See Section 15.1.27, “DROP INDEX Statement”. To determine index names, use SHOW INDEX FROM tbl_name.

Some storage engines permit you to specify an index type when creating an index. The syntax for the index_type specifier is USING type_name. For details about USING, see Section 15.1.15, “CREATE INDEX Statement”. The preferred position is after the column list. Expect support for use of the option before the column list to be removed in a future MySQL release.

index_option values specify additional options for an index. USING is one such option. For details about permissible index_option values, see Section 15.1.15, “CREATE INDEX Statement”.

RENAME INDEX old_index_name TO new_index_name renames an index. This is a MySQL extension to standard SQL. The content of the table remains unchanged. old_index_name must be the name of an existing index in the table that is not dropped by the same ALTER TABLE statement. new_index_name is the new index name, which cannot duplicate the name of an index in the resulting table after changes have been applied. Neither index name can be PRIMARY.

If you use ALTER TABLE on a MyISAM table, all nonunique indexes are created in a separate batch (as for REPAIR TABLE). This should make ALTER TABLE much faster when you have many indexes.

For MyISAM tables, key updating can be controlled explicitly. Use ALTER TABLE ... DISABLE KEYS to tell MySQL to stop updating nonunique indexes. Then use ALTER TABLE ... ENABLE KEYS to re-create missing indexes. MyISAM does this with a special algorithm that is much faster than inserting keys one by one, so disabling keys before performing bulk insert operations should give a
ALTER TABLE Statement

considerable speedup. Using `ALTER TABLE ... DISABLE KEYS` requires the `INDEX` privilege in addition to the privileges mentioned earlier.

While the nonunique indexes are disabled, they are ignored for statements such as `SELECT` and `EXPLAIN` that otherwise would use them.

After an `ALTER TABLE` statement, it may be necessary to run `ANALYZE TABLE` to update index cardinality information. See Section 15.7.7.23, “SHOW INDEX Statement”.

The `ALTER INDEX` operation permits an index to be made visible or invisible. An invisible index is not used by the optimizer. Modification of index visibility applies to indexes other than primary keys (either explicit or implicit), and cannot be performed using `ALGORITHM=INSTANT`. This feature is storage engine neutral (supported for any engine). For more information, see Section 10.3.12, “Invisible Indexes”.

Foreign Keys and Other Constraints

The `FOREIGN KEY` and `REFERENCES` clauses are supported by the InnoDB and NDB storage engines, which implement `ADD [CONSTRAINT [symbol]] FOREIGN KEY [index_name] (...) REFERENCES ... (...).` See Section 15.1.20.5, “FOREIGN KEY Constraints”. For other storage engines, the clauses are parsed but ignored.

For `ALTER TABLE`, unlike `CREATE TABLE`, `ADD FOREIGN KEY` ignores `index_name` if given and uses an automatically generated foreign key name. As a workaround, include the `CONSTRAINT` clause to specify the foreign key name:

```
ADD CONSTRAINT name FOREIGN KEY (...) ...
```

Important

MySQL silently ignores inline `REFERENCES` specifications, where the references are defined as part of the column specification. MySQL accepts only `REFERENCES` clauses defined as part of a separate `FOREIGN KEY` specification.

Note

Partitioned InnoDB tables do not support foreign keys. This restriction does not apply to NDB tables, including those explicitly partitioned by `[LINEAR] KEY`. For more information, see Section 26.6.2, “Partitioning Limitations Relating to Storage Engines”.

MySQL Server and NDB Cluster both support the use of `ALTER TABLE` to drop foreign keys:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

Adding and dropping a foreign key in the same `ALTER TABLE` statement is supported for `ALTER TABLE ... ALGORITHM=INPLACE` but not for `ALTER TABLE ... ALGORITHM=COPY`.

The server prohibits changes to foreign key columns that have the potential to cause loss of referential integrity. A workaround is to use `ALTER TABLE ... DROP FOREIGN KEY` before changing the column definition and `ALTER TABLE ... ADD FOREIGN KEY` afterward. Examples of prohibited changes include:

- Changes to the data type of foreign key columns that may be unsafe. For example, changing `VARCHAR(20)` to `VARCHAR(30)` is permitted, but changing it to `VARCHAR(1024)` is not because that alters the number of length bytes required to store individual values.

- Changing a `NULL` column to `NOT NULL` in non-strict mode is prohibited to prevent converting `NULL` values to default non-NULL values, for which there are no corresponding values in the referenced
ALTER TABLE Statement

table. The operation is permitted in strict mode, but an error is returned if any such conversion is required.

.ALTER TABLE tbl_name RENAME new_tbl_name changes internally generated foreign key constraint names and user-defined foreign key constraint names that begin with the string “tbl_name_ibfk_” to reflect the new table name. InnoDB interprets foreign key constraint names that begin with the string “tbl_name_ibfk_” as internally generated names.

.ALTER TABLE permits CHECK constraints for existing tables to be added, dropped, or altered:

• Add a new CHECK constraint:

  .ALTER TABLE tbl_name
  ADD [CONSTRAINT [symbol]] CHECK (expr) [[NOT] ENFORCED];

  The meaning of constraint syntax elements is the same as for CREATE TABLE. See Section 15.1.20.6, “CHECK Constraints”.

• Drop an existing CHECK constraint named symbol:

  .ALTER TABLE tbl_name
  DROP CHECK symbol;

• Alter whether an existing CHECK constraint named symbol is enforced:

  .ALTER TABLE tbl_name
  ALTER CHECK symbol [NOT] ENFORCED;

  The DROP CHECK and ALTER CHECK clauses are MySQL extensions to standard SQL.

.ALTER TABLE permits more general (and SQL standard) syntax for dropping and altering existing constraints of any type, where the constraint type is determined from the constraint name:

• Drop an existing constraint named symbol:

  .ALTER TABLE tbl_name
  DROP CONSTRAINT symbol;

  If the sql_require_primary_key system variable is enabled, attempting to drop a primary key produces an error.

• Alter whether an existing constraint named symbol is enforced:

  .ALTER TABLE tbl_name
  ALTER CONSTRAINT symbol [NOT] ENFORCED;

  Only CHECK constraints can be altered to be unenforced. All other constraint types are always enforced.

The SQL standard specifies that all types of constraints (primary key, unique index, foreign key, check) belong to the same namespace. In MySQL, each constraint type has its own namespace per schema. Consequently, names for each type of constraint must be unique per schema, but constraints of different types can have the same name. When multiple constraints have the same name, DROP CONSTRAINT and ADD CONSTRAINT are ambiguous and an error occurs. In such cases, constraint-specific syntax must be used to modify the constraint. For example, use DROP PRIMARY KEY or DROP FOREIGN KEY to drop a primary key or foreign key.

If a table alteration causes a violation of an enforced CHECK constraint, an error occurs and the table is not modified. Examples of operations for which an error occurs:

• Attempts to add the AUTO_INCREMENT attribute to a column that is used in a CHECK constraint.

• Attempts to add an enforced CHECK constraint or enforce a nonenforced CHECK constraint for which existing rows violate the constraint condition.
ALTER TABLE Statement

- Attempts to modify, rename, or drop a column that is used in a CHECK constraint, unless that constraint is also dropped in the same statement. Exception: If a CHECK constraint refers only to a single column, dropping the column automatically drops the constraint.

ALTER TABLE tbl_name RENAME new_tbl_name changes internally generated and user-defined CHECK constraint names that begin with the string "tbl_name_chk_" to reflect the new table name. MySQL interprets CHECK constraint names that begin with the string "tbl_name_chk_" as internally generated names.

Changing the Character Set

To change the table default character set and all character columns (CHAR, VARCHAR, TEXT) to a new character set, use a statement like this:

ALTER TABLE tbl_name CONVERT TO CHARACTER SET charset_name;

The statement also changes the collation of all character columns. If you specify no COLLATE clause to indicate which collation to use, the statement uses default collation for the character set. If this collation is inappropriate for the intended table use (for example, if it would change from a case-sensitive collation to a case-insensitive collation), specify a collation explicitly.

For a column that has a data type of VARCHAR or one of the TEXT types, CONVERT TO CHARACTER SET changes the data type as necessary to ensure that the new column is long enough to store as many characters as the original column. For example, a TEXT column has two length bytes, which store the byte-length of values in the column, up to a maximum of 65,535. For a latin1 TEXT column, each character requires a single byte, so the column can store up to 65,535 characters. If the column is converted to utf8mb4, each character might require up to 4 bytes, for a maximum possible length of 4 × 65,535 = 262,140 bytes. That length does not fit in a TEXT column's length bytes, so MySQL converts the data type to MEDIUMTEXT, which is the smallest string type for which the length bytes can record a value of 262,140. Similarly, a VARCHAR column might be converted to MEDIUMTEXT.

To avoid data type changes of the type just described, do not use CONVERT TO CHARACTER SET. Instead, use MODIFY to change individual columns. For example:

ALTER TABLE t MODIFY latin1_text_col TEXT CHARACTER SET utf8mb4;
ALTER TABLE t MODIFY latin1_varchar_col VARCHAR(M) CHARACTER SET utf8mb4;

If you specify CONVERT TO CHARACTER SET binary, the CHAR, VARCHAR, and TEXT columns are converted to their corresponding binary string types (BINARY, VARBINARY, BLOB). This means that the columns no longer have a character set and a subsequent CONVERT TO operation does not apply to them.

If charset_name is DEFAULT in a CONVERT TO CHARACTER SET operation, the character set named by the character_set_database system variable is used.

Warning

The CONVERT TO operation converts column values between the original and named character sets. This is not what you want if you have a column in one character set (like latin1) but the stored values actually use some other, incompatible character set (like utf8mb4). In this case, you have to do the following for each such column:

ALTER TABLE t1 CHANGE c1 c1 BLOB;
ALTER TABLE t1 CHANGE c1 c1 TEXT CHARACTER SET utf8mb4;

The reason this works is that there is no conversion when you convert to or from BLOB columns.

To change only the default character set for a table, use this statement:
ALTER TABLE `tbl_name` DEFAULT CHARACTER SET `charset_name`;

The word `DEFAULT` is optional. The default character set is the character set that is used if you do not specify the character set for columns that you add to a table later (for example, with `ALTER TABLE ... ADD column`).

When the `foreign_key_checks` system variable is enabled, which is the default setting, character set conversion is not permitted on tables that include a character string column used in a foreign key constraint. The workaround is to disable `foreign_key_checks` before performing the character set conversion. You must perform the conversion on both tables involved in the foreign key constraint before re-enabling `foreign_key_checks`. If you re-enable `foreign_key_checks` after converting only one of the tables, an `ON DELETE CASCADE` or `ON UPDATE CASCADE` operation could corrupt data in the referencing table due to implicit conversion that occurs during these operations (Bug #45290, Bug #74816).

**Importing InnoDB Tables**

An InnoDB table created in its own file-per-table tablespace can be imported from a backup or from another MySQL server instance using `DISCARD TABLESPACE` and `IMPORT TABLESPACE` clauses. See Section 17.6.1.3, “Importing InnoDB Tables”.

**Row Order for MyISAM Tables**

`ORDER BY` enables you to create the new table with the rows in a specific order. This option is useful primarily when you know that you query the rows in a certain order most of the time. By using this option after major changes to the table, you might be able to get higher performance. In some cases, it might make sorting easier for MySQL if the table is in order by the column that you want to order it by later.

**Note**

The table does not remain in the specified order after inserts and deletes.

`ORDER BY` syntax permits one or more column names to be specified for sorting, each of which optionally can be followed by `ASC` or `DESC` to indicate ascending or descending sort order, respectively. The default is ascending order. Only column names are permitted as sort criteria; arbitrary expressions are not permitted. This clause should be given last after any other clauses.

`ORDER BY` does not make sense for InnoDB tables because InnoDB always orders table rows according to the clustered index.

When used on a partitioned table, `ALTER TABLE ... ORDER BY` orders rows within each partition only.

**Partitioning Options**

`partition_options` signifies options that can be used with partitioned tables for repartitioning, to add, drop, discard, import, merge, and split partitions, and to perform partitioning maintenance.

It is possible for an `ALTER TABLE` statement to contain a `PARTITION BY` or `REMOVE PARTITIONING` clause in an addition to other alter specifications, but the `PARTITION BY` or `REMOVE PARTITIONING` clause must be specified last after any other specifications. The `ADD PARTITION, DROP PARTITION, DISCARD PARTITION, IMPORT PARTITION, COALESCE PARTITION, REORGANIZE PARTITION, EXCHANGE PARTITION, ANALYZE PARTITION, CHECK PARTITION, and REPAIR PARTITION` options cannot be combined with other alter specifications in a single `ALTER TABLE`, since the options just listed act on individual partitions.

For more information about partition options, see Section 15.1.20, “CREATE TABLE Statement”, and Section 15.1.9.1, “ALTER TABLE Partition Operations”. For information about and examples of `ALTER`
TABLE ... EXCHANGE PARTITION statements, see Section 26.3.3, “Exchanging Partitions and Subpartitions with Tables”.

15.1.9.1 ALTER TABLE Partition Operations

Partitioning-related clauses for ALTER TABLE can be used with partitioned tables for repartitioning, to add, drop, discard, import, merge, and split partitions, and to perform partitioning maintenance.

• Simply using a partition_options clause with ALTER TABLE on a partitioned table repartitions the table according to the partitioning scheme defined by the partition_options. This clause always begins with PARTITION BY, and follows the same syntax and other rules as apply to the partition_options clause for CREATE TABLE (for more detailed information, see Section 15.1.20, “CREATE TABLE Statement”), and can also be used to partition an existing table that is not already partitioned. For example, consider a (nonpartitioned) table defined as shown here:

```sql
CREATE TABLE t1 {
    id INT,
    year_col INT
};
```

This table can be partitioned by HASH, using the id column as the partitioning key, into 8 partitions by means of this statement:

```sql
ALTER TABLE t1
    PARTITION BY HASH(id)
    PARTITIONS 8;
```

MySQL supports an ALGORITHM option with [SUB]PARTITION BY [LINEAR] KEY. ALGORITHM=1 causes the server to use the same key-hashing functions as MySQL 5.1 when computing the placement of rows in partitions; ALGORITHM=2 means that the server employs the key-hashing functions implemented and used by default for new KEY partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a MySQL 5.1 server.) Not specifying the option has the same effect as using ALGORITHM=2. This option is intended for use chiefly when upgrading or downgrading [LINEAR] KEY partitioned tables between MySQL 5.1 and later MySQL versions, or for creating tables partitioned by KEY or LINEAR KEY on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server.

The table that results from using an ALTER TABLE ... PARTITION BY statement must follow the same rules as one created using CREATE TABLE ... PARTITION BY. This includes the rules governing the relationship between any unique keys (including any primary key) that the table might have, and the column or columns used in the partitioning expression, as discussed in Section 26.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”. The CREATE TABLE ... PARTITION BY rules for specifying the number of partitions also apply to ALTER TABLE ... PARTITION BY.

The partition_definition clause for ALTER TABLE ADD PARTITION supports the same options as the clause of the same name for the CREATE TABLE statement. (See Section 15.1.20, “CREATE TABLE Statement”, for the syntax and description.) Suppose that you have the partitioned table created as shown here:

```sql
CREATE TABLE t1 {
    id INT,
    year_col INT
}
PARTITION BY RANGE (year_col) {
    PARTITION p0 VALUES LESS THAN (1991),
    PARTITION p1 VALUES LESS THAN (1995),
    PARTITION p2 VALUES LESS THAN (1999)
};
```

You can add a new partition p3 to this table for storing values less than 2002 as follows:

```sql
ALTER TABLE t1 ADD PARTITION (PARTITION p3 VALUES LESS THAN (2002));
```
**DROP PARTITION** can be used to drop one or more **RANGE** or **LIST** partitions. This statement cannot be used with **HASH** or **KEY** partitions; instead, use **COALESCE PARTITION** (see later in this section). Any data that was stored in the dropped partitions named in the `partition_names` list is discarded. For example, given the table `t1` defined previously, you can drop the partitions named `p0` and `p1` as shown here:

```
ALTER TABLE t1 DROP PARTITION p0, p1;
```

**Note**

**DROP PARTITION** does not work with tables that use the **NDB** storage engine. See Section 26.3.1, “Management of RANGE and LIST Partitions”, and Section 25.2.7, “Known Limitations of NDB Cluster”.

**ADD PARTITION** and **DROP PARTITION** do not currently support **IF [NOT] EXISTS**.

The **DISCARD PARTITION ... TABLESPACE** and **IMPORT PARTITION ... TABLESPACE** options extend the **Transportable Tablespace** feature to individual **InnoDB** table partitions. Each **InnoDB** table partition has its own tablespace file (.ibd file). The **Transportable Tablespace** feature makes it easy to copy the tablespaces from a running MySQL server instance to another running instance, or to perform a restore on the same instance. Both options take a comma-separated list of one or more partition names. For example:

```
ALTER TABLE t1 DISCARD PARTITION p2, p3 TABLESPACE;
```

```
ALTER TABLE t1 IMPORT PARTITION p2, p3 TABLESPACE;
```

When running **DISCARD PARTITION ... TABLESPACE** and **IMPORT PARTITION ... TABLESPACE** on subpartitioned tables, both partition and subpartition names are allowed. When a partition name is specified, subpartitions of that partition are included.

The **Transportable Tablespace** feature also supports copying or restoring partitioned **InnoDB** tables. For more information, see Section 17.6.1.3, “Importing InnoDB Tables”.

Renames of partitioned tables are supported. You can rename individual partitions indirectly using **ALTER TABLE ... REORGANIZE PARTITION**; however, this operation copies the partition's data.

To delete rows from selected partitions, use the **TRUNCATE PARTITION** option. This option takes a list of one or more comma-separated partition names. Consider the table `t1` created by this statement:

```
CREATE TABLE t1 (  
id INT,  
year_col INT  
)  
PARTITION BY RANGE (year_col) (  
    PARTITION p0 VALUES LESS THAN (1991),  
    PARTITION p1 VALUES LESS THAN (1995),  
    PARTITION p2 VALUES LESS THAN (1999),  
    PARTITION p3 VALUES LESS THAN (2003),  
    PARTITION p4 VALUES LESS THAN (2007)  
);
```

To delete all rows from partition `p0`, use the following statement:

```
ALTER TABLE t1 TRUNCATE PARTITION p0;
```

The statement just shown has the same effect as the following **DELETE** statement:

```
DELETE FROM t1 WHERE year_col < 1991;
```

When truncating multiple partitions, the partitions do not have to be contiguous: This can greatly simplify delete operations on partitioned tables that would otherwise require very complex **WHERE**
conditions if done with **DELETE** statements. For example, this statement deletes all rows from partitions **p1** and **p3**:

```
ALTER TABLE t1 TRUNCATE PARTITION p1, p3;
```

An equivalent **DELETE** statement is shown here:

```
DELETE FROM t1 WHERE
 (year_col >= 1991 AND year_col < 1995)
 OR
 (year_col >= 2003 AND year_col < 2007);
```

If you use the **ALL** keyword in place of the list of partition names, the statement acts on all table partitions.

**TRUNCATE PARTITION** merely deletes rows; it does not alter the definition of the table itself, or of any of its partitions.

To verify that the rows were dropped, check the **INFORMATION_SCHEMA.PARTITIONS** table, using a query such as this one:

```
SELECT PARTITION_NAME, TABLE_ROWS
 FROM INFORMATION_SCHEMA.PARTITIONS
 WHERE TABLE_NAME = 't1';
```

**COALESCE PARTITION** can be used with a table that is partitioned by **HASH** or **KEY** to reduce the number of partitions by **number**. Suppose that you have created table **t2** as follows:

```
CREATE TABLE t2 (
    name VARCHAR (30),
    started DATE
) PARTITION BY HASH( YEAR(started) )
PARTITIONS 6;
```

To reduce the number of partitions used by **t2** from 6 to 4, use the following statement:

```
ALTER TABLE t2 COALESCE PARTITION 2;
```

The data contained in the last **number** partitions is merged into the remaining partitions. In this case, partitions 4 and 5 are merged into the first 4 partitions (the partitions numbered 0, 1, 2, and 3).

To change some but not all the partitions used by a partitioned table, you can use **REORGANIZE PARTITION**. This statement can be used in several ways:

- To merge a set of partitions into a single partition. This is done by naming several partitions in the **partition_names** list and supplying a single definition for **partition_definition**.

- To split an existing partition into several partitions. Accomplish this by naming a single partition for **partition_names** and providing multiple **partition_definitions**.

- To change the ranges for a subset of partitions defined using **VALUES LESS THAN** or the value lists for a subset of partitions defined using **VALUES IN**.

**Note**

For partitions that have not been explicitly named, MySQL automatically provides the default names **p0, p1, p2**, and so on. The same is true with regard to subpartitions.

For more detailed information about and examples of **ALTER TABLE ... REORGANIZE PARTITION** statements, see Section 26.3.1, “Management of RANGE and LIST Partitions”.
ALTER TABLE Statement

• To exchange a table partition or subpartition with a table, use the `ALTER TABLE ... EXCHANGE PARTITION` statement—that is, to move any existing rows in the partition or subpartition to the nonpartitioned table, and any existing rows in the nonpartitioned table to the table partition or subpartition.

Once one or more columns have been added to a partitioned table using `ALGORITHM=INSTANT`, it is no longer possible to exchange partitions with that table.

For usage information and examples, see Section 26.3.3, “Exchanging Partitions and Subpartitions with Tables”.

• Several options provide partition maintenance and repair functionality analogous to that implemented for nonpartitioned tables by statements such as `CHECK TABLE` and `REPAIR TABLE` (which are also supported for partitioned tables; for more information, see Section 15.7.3, “Table Maintenance Statements”). These include `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, and `REPAIR PARTITION`. Each of these options takes a `partition_names` clause consisting of one or more names of partitions, separated by commas. The partitions must already exist in the target table. You can also use the `ALL` keyword in place of `partition_names`, in which case the statement acts on all table partitions. For more information and examples, see Section 26.3.4, “Maintenance of Partitions”.

InnoDB does not currently support per-partition optimization; `ALTER TABLE ... OPTIMIZE PARTITION` causes the entire table to rebuilt and analyzed, and an appropriate warning to be issued. (Bug #11751825, Bug #42822) To work around this problem, use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead.

The `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, and `REPAIR PARTITION` options are not supported for tables which are not partitioned.

• `REMOVE PARTITIONING` enables you to remove a table’s partitioning without otherwise affecting the table or its data. This option can be combined with other `ALTER TABLE` options such as those used to add, drop, or rename columns or indexes.

• Using the `ENGINE` option with `ALTER TABLE` changes the storage engine used by the table without affecting the partitioning. The target storage engine must provide its own partitioning handler. Only the InnoDB and NDB storage engines have native partitioning handlers.

It is possible for an `ALTER TABLE` statement to contain a `PARTITION BY` or `REMOVE PARTITIONING` clause in an addition to other alter specifications, but the `PARTITION BY` or `REMOVE PARTITIONING` clause must be specified last after any other specifications.

The `ADD PARTITION`, `DROP PARTITION`, `COALESCE PARTITION`, `REORGANIZE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, and `REPAIR PARTITION` options cannot be combined with other specifications in a single `ALTER TABLE`, since the options just listed act on individual partitions. For more information, see Section 15.1.9.1, “ALTER TABLE Partition Operations”.

Only a single instance of any one of the following options can be used in a given `ALTER TABLE` statement: `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `TRUNCATE PARTITION`, `EXCHANGE PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, `REMOVE PARTITIONING`.

For example, the following two statements are invalid:

```
ALTER TABLE t1 ANALYZE PARTITION p1, ANALYZE PARTITION p2;
ALTER TABLE t1 ANALYZE PARTITION p1, CHECK PARTITION p2;
```

In the first case, you can analyze partitions `p1` and `p2` of table `t1` concurrently using a single statement with a single `ANALYZE PARTITION` option that lists both of the partitions to be analyzed, like this:

```
ALTER TABLE t1 ANALYZE PARTITION p1, p2;
```
ALTER TABLE Statement

In the second case, it is not possible to perform ANALYZE and CHECK operations on different partitions of the same table concurrently. Instead, you must issue two separate statements, like this:

```sql
ALTER TABLE t1 ANALYZE PARTITION p1;
ALTER TABLE t1 CHECK PARTITION p2;
```

REBUILD operations are currently unsupported for subpartitions. The REBUILD keyword is expressly disallowed with subpartitions, and causes ALTER TABLE to fail with an error if so used.

CHECK PARTITION and REPAIR PARTITION operations fail when the partition to be checked or repaired contains any duplicate key errors.

For more information about these statements, see Section 26.3.4, “Maintenance of Partitions”.

15.1.9.2 ALTER TABLE and Generated Columns

ALTER TABLE operations permitted for generated columns are ADD, MODIFY, and CHANGE.

- Generated columns can be added.
  ```sql
  CREATE TABLE t1 (c1 INT);
  ALTER TABLE t1 ADD COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) STORED;
  ```

- The data type and expression of generated columns can be modified.
  ```sql
  CREATE TABLE t1 (c1 INT, c2 INT GENERATED ALWAYS AS (c1 + 1) STORED);
  ALTER TABLE t1 MODIFY COLUMN c2 TINYINT GENERATED ALWAYS AS (c1 + 5) STORED;
  ```

- Generated columns can be renamed or dropped, if no other column refers to them.
  ```sql
  CREATE TABLE t1 (c1 INT, c2 INT GENERATED ALWAYS AS (c1 + 1) STORED);
  ALTER TABLE t1 CHANGE c2 c3 INT GENERATED ALWAYS AS (c1 + 1) STORED;
  ALTER TABLE t1 DROP COLUMN c3;
  ```

- Virtual generated columns cannot be altered to stored generated columns, or vice versa. To work around this, drop the column, then add it with the new definition.
  ```sql
  CREATE TABLE t1 (c1 INT, c2 INT GENERATED ALWAYS AS (c1 + 1) VIRTUAL);
  ALTER TABLE t1 DROP COLUMN c2;
  ALTER TABLE t1 ADD COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) STORED;
  ```

- Nongenerated columns can be altered to stored but not virtual generated columns.
  ```sql
  CREATE TABLE t1 (c1 INT, c2 INT);
  ALTER TABLE t1 MODIFY COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) STORED;
  ```

- Stored but not virtual generated columns can be altered to nongenerated columns. The stored generated values become the values of the nongenerated column.
  ```sql
  CREATE TABLE t1 (c1 INT, c2 INT GENERATED ALWAYS AS (c1 + 1) STORED);
  ALTER TABLE t1 MODIFY COLUMN c2 INT;
  ```

- ADD COLUMN is not an in-place operation for stored columns (done without using a temporary table) because the expression must be evaluated by the server. For stored columns, indexing changes are done in place, and expression changes are not done in place. Changes to column comments are done in place.

- For non-partitioned tables, ADD COLUMN and DROP COLUMN are in-place operations for virtual columns. However, adding or dropping a virtual column cannot be performed in place in combination with other ALTER TABLE operations.

For partitioned tables, ADD COLUMN and DROP COLUMN are not in-place operations for virtual columns.

- InnoDB supports secondary indexes on virtual generated columns. Adding or dropping a secondary index on a virtual generated column is an in-place operation. For more information, see Section 15.1.20.9, “Secondary Indexes and Generated Columns”.
• When a **VIRTUAL** generated column is added to a table or modified, it is not ensured that data being calculated by the generated column expression is not out of range for the column. This can lead to inconsistent data being returned and unexpectedly failed statements. To permit control over whether validation occurs for such columns, **ALTER TABLE** supports **WITHOUT VALIDATION** and **WITH VALIDATION** clauses:

• With **WITHOUT VALIDATION** (the default if neither clause is specified), an in-place operation is performed (if possible), data integrity is not checked, and the statement finishes more quickly. However, later reads from the table might report warnings or errors for the column if values are out of range.

• With **WITH VALIDATION**, **ALTER TABLE** copies the table. If an out-of-range or any other error occurs, the statement fails. Because a table copy is performed, the statement takes longer.

**WITHOUT VALIDATION** and **WITH VALIDATION** are permitted only with **ADD COLUMN**, **CHANGE COLUMN**, and **MODIFY COLUMN** operations. Otherwise, an **ER_WRONG_USAGE** error occurs.

• If expression evaluation causes truncation or provides incorrect input to a function, the **ALTER TABLE** statement terminates with an error and the DDL operation is rejected.

• An **ALTER TABLE** statement that changes the default value of a column **col_name** may also change the value of a generated column expression that refers to the column using **col_name**, which may change the value of a generated column expression that refers to the column using **DEFAULT(col_name)**. For this reason, **ALTER TABLE** operations that change the definition of a column cause a table rebuild if any generated column expression uses **DEFAULT()**.

### 15.1.9.3 ALTER TABLE Examples

Begin with a table **t1** created as shown here:

```sql
CREATE TABLE t1 (a INTEGER, b CHAR(10));
```

To rename the table from **t1** to **t2**:

```sql
ALTER TABLE t1 RENAME t2;
```

To change column **a** from **INTEGER** to **TINYINT NOT NULL** (leaving the name the same), and to change column **b** from **CHAR(10)** to **CHAR(20)** as well as renaming it from **b** to **c**:

```sql
ALTER TABLE t2 MODIFY a TINYINT NOT NULL, CHANGE b c CHAR(20);
```

To add a new **TIMESTAMP** column named **d**:

```sql
ALTER TABLE t2 ADD d TIMESTAMP;
```

To add an index on column **d** and a **UNIQUE** index on column **a**:

```sql
ALTER TABLE t2 ADD INDEX (d), ADD UNIQUE (a);
```

To remove column **c**:

```sql
ALTER TABLE t2 DROP COLUMN c;
```

To add a new **AUTO_INCREMENT** integer column named **c**:

```sql
ALTER TABLE t2 ADD c INT UNSIGNED NOT NULL AUTO_INCREMENT, ADD PRIMARY KEY (c);
```

We indexed **c** (as a **PRIMARY KEY**) because **AUTO_INCREMENT** columns must be indexed, and we declare **c** as **NOT NULL** because primary key columns cannot be **NULL**.

For **NDB** tables, it is also possible to change the storage type used for a table or column. For example, consider an **NDB** table created as shown here:
ALTER TABLE Statement

```sql
mysql> CREATE TABLE t1 (c1 INT) TABLESPACE ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.27 sec)
```

To convert this table to disk-based storage, you can use the following `ALTER TABLE` statement:

```sql
mysql> ALTER TABLE t1 TABLESPACE ts_1 STORAGE DISK;
Query OK, 0 rows affected (2.99 sec)
```

```sql
mysql> SHOW CREATE TABLE t1
```

```
Table: t1
Create Table: CREATE TABLE `t1` (``c1`` int(11) DEFAULT NULL) /*!50100 TABLESPACE ts_1 STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
1 row in set (0.01 sec)
```

It is not necessary that the tablespace was referenced when the table was originally created; however, the tablespace must be referenced by the `ALTER TABLE`:

```sql
mysql> CREATE TABLE t2 (c1 INT) ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.00 sec)
```

```sql
mysql> ALTER TABLE t2 STORAGE DISK;
ERROR 1005 (HY000): Can't create table 'c.#sql-1750_3' (errno: 140)
```

```sql
mysql> ALTER TABLE t2 TABLESPACE ts_1 STORAGE DISK;
Query OK, 0 rows affected (3.42 sec)
```

```sql
mysql> SHOW CREATE TABLE t2
```

```
Table: t2
Create Table: CREATE TABLE `t2` (``c1`` int(11) DEFAULT NULL) /*!50100 TABLESPACE ts_1 STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
1 row in set (0.01 sec)
```

To change the storage type of an individual column, you can use `ALTER TABLE ... MODIFY [COLUMN]`. For example, suppose you create an NDB Cluster Disk Data table with two columns, using this `CREATE TABLE` statement:

```sql
mysql> CREATE TABLE t3 (c1 INT, c2 INT) TABLESPACE ts_1 STORAGE DISK ENGINE NDB;
Query OK, 0 rows affected (1.34 sec)
```

To change column `c2` from disk-based to in-memory storage, include a `STORAGE MEMORY` clause in the column definition used by the `ALTER TABLE` statement, as shown here:

```sql
mysql> ALTER TABLE t3 MODIFY c2 INT STORAGE MEMORY;
Query OK, 0 rows affected (3.14 sec)
```

```sql
mysql> SHOW CREATE TABLE t3
```

```
Table: t3
Create Table: CREATE TABLE `t3` (``c1`` int(11) DEFAULT NULL,``c2`` int(11) /*!50120 STORAGE MEMORY */ DEFAULT NULL) /*!50100 TABLESPACE ts_1 STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
1 row in set (0.01 sec)
```

To change column `c2` from in-memory to disk-based storage, include a `STORAGE DISK` clause in a similar fashion.

Column `c1` uses disk-based storage, since this is the default for the table (determined by the table-level `STORAGE DISK` clause in the `CREATE TABLE` statement). However, column `c2` uses in-memory storage, as can be seen here in the output of `SHOW CREATE TABLE`:

```sql
mysql> SHOW CREATE TABLE t3
```

```
Table: t3
Create Table: CREATE TABLE `t3` (``c1`` int(11) DEFAULT NULL,``c2`` int(11) /*!50100 TABLESPACE ts_1 STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
1 row in set (0.02 sec)
```
When you add an `AUTO_INCREMENT` column, column values are filled in with sequence numbers automatically. For `MyISAM` tables, you can set the first sequence number by executing `SET INSERT_ID=value` before `ALTER TABLE` or by using the `AUTO_INCREMENT=value` table option.

With `MyISAM` tables, if you do not change the `AUTO_INCREMENT` column, the sequence number is not affected. If you drop an `AUTO_INCREMENT` column and then add another `AUTO_INCREMENT` column, the numbers are resequenced beginning with 1.

When replication is used, adding an `AUTO_INCREMENT` column to a table might not produce the same ordering of the rows on the replica and the source. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the source and replica, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to the table `t1`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```sql
CREATE TABLE t2 (id INT AUTO_INCREMENT PRIMARY KEY)
SELECT * FROM t1 ORDER BY col1, col2;
```

This assumes that the table `t1` has columns `col1` and `col2`.

This set of statements also produces a new table `t2` identical to `t1`, with the addition of an `AUTO_INCREMENT` column:

```sql
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

**Important**

To guarantee the same ordering on both source and replica, all columns of `t1` must be referenced in the `ORDER BY` clause.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```sql
DROP TABLE t1;
ALTER TABLE t2 RENAME t1;
```

### 15.1.10 ALTER TABLESPACE Statement

This statement is used with `NDB` and `InnoDB` tablespaces. It can be used to add a new data file to, or to drop a data file from an `NDB` tablespace. It can also be used to rename an `NDB` Cluster Disk Data tablespace, rename an `InnoDB` general tablespace, encrypt an `InnoDB` general tablespace, or mark an `InnoDB` undo tablespace as active or inactive.

The `UNDO` keyword is used with the `SET {ACTIVE | INACTIVE}` clause to mark an `InnoDB` undo tablespace as active or inactive. For more information, see Section 17.6.3.4, “Undo Tablespaces”.

---

2441
The **ADD DATAFILE** variant enables you to specify an initial size for an **NDB** Disk Data tablespace using an **INITIAL_SIZE** clause, where *size* is measured in bytes; the default value is 134217728 (128 MB). You may optionally follow *size* with a one-letter abbreviation for an order of magnitude, similar to those used in my.cnf. Generally, this is one of the letters M (megabytes) or G (gigabytes).

On 32-bit systems, the maximum supported value for **INITIAL_SIZE** is 4294967296 (4 GB). (Bug #29186)

**INITIAL_SIZE** is rounded, explicitly, as for **CREATE TABLESPACE**.

Once a data file has been created, its size cannot be changed; however, you can add more data files to an **NDB** tablespace using additional **ALTER TABLESPACE ... ADD DATAFILE** statements.

When **ALTER TABLESPACE ... ADD DATAFILE** is used with **ENGINE = NDB**, a data file is created on each Cluster data node, but only one row is generated in the Information Schema **FILES** table. See the description of this table, as well as Section 25.6.11.1, “NDB Cluster Disk Data Objects”, for more information. **ADD DATAFILE** is not supported with **InnoDB** tablespaces.

Using **DROP DATAFILE** with **ALTER TABLESPACE** drops the data file ‘*file_name*’ from an **NDB** tablespace. You cannot drop a data file from a tablespace which is in use by any table; in other words, the data file must be empty (no extents used). See Section 25.6.11.1, “NDB Cluster Disk Data Objects”. In addition, any data file to be dropped must previously have been added to the tablespace with **CREATE TABLESPACE** or **ALTER TABLESPACE.DROP DATAFILE** is not supported with **InnoDB** tablespaces.

**WAIT** is parsed but otherwise ignored. It is intended for future expansion.

The **ENGINE** clause, which specifies the storage engine used by the tablespace, is deprecated, since the tablespace storage engine is known by the data dictionary, making the **ENGINE** clause obsolete. In MySQL 8.4, it is supported in the following two cases only:

- **ALTER TABLESPACE** *tablespace_name* ADD DATAFILE ‘*file_name*’
  
  ```
  ENGINE={NDB|NDBCLUSTER}
  ```

- **ALTER UNDO TABLESPACE** *tablespace_name* SET {ACTIVE|INACTIVE}
  
  ```
  ENGINE=INNODB
  ```

You should expect the eventual removal of **ENGINE** from these statements as well, in a future version of MySQL.

**RENAME TO** operations are implicitly performed in autocommit mode, regardless of the value of **autocommit**.

A **RENAME TO** operation cannot be performed while **LOCK TABLES** or **FLUSH TABLES WITH READ LOCK** is in effect for tables that reside in the tablespace.

Exclusive **metadata locks** are taken on tables that reside in a general tablespace while the tablespace is renamed, which prevents concurrent DDL. Concurrent DML is supported.

The **CREATE TABLESPACE** privilege is required to rename an **InnoDB** general tablespace.

The **AUTOEXTEND_SIZE** option defines the amount by which **InnoDB** extends the size of a tablespace when it becomes full. The setting must be a multiple of 4MB. The default setting is 0, which causes the tablespace to be extended according to the implicit default behavior. For more information, see Section 17.6.3.9, “Tablespace AUTOEXTEND_SIZE Configuration”.

The **ENCRYPTION** clause enables or disables page-level data encryption for an **InnoDB** general tablespace or the **mysql** system tablespace.

A keyring plugin must be installed and configured before encryption can be enabled.
If the `table_encryption_privilege_check` variable is enabled, the `TABLE_ENCRYPTION_ADMIN` privilege is required to alter a general tablespace with an `ENCRYPTION` clause setting that differs from the `default_table_encryption` setting.

Enabling encryption for a general tablespace fails if any table in the tablespace belongs to a schema defined with `DEFAULT_ENCRYPTION='N'`. Similarly, disabling encryption fails if any table in the general tablespace belongs to a schema defined with `DEFAULT_ENCRYPTION='Y'`.

If an `ALTER TABLESPACE` statement executed on a general tablespace does not include an `ENCRYPTION` clause, the tablespace retains its current encryption status, regardless of the `default_table_encryption` setting.

When a general tablespace or the `mysql` system tablespace is encrypted, all tables residing in the tablespace are encrypted. Likewise, a table created in an encrypted tablespace is encrypted.

The `INPLACE` algorithm is used when altering the `ENCRYPTION` attribute of a general tablespace or the `mysql` system tablespace. The `INPLACE` algorithm permits concurrent DML on tables that reside in the tablespace. Concurrent DDL is blocked.

For more information, see Section 17.13, “InnoDB Data-at-Rest Encryption”.

The `ENGINE_ATTRIBUTE` option is used to specify tablespace attributes for primary storage engines. The option is reserved for future use.

The value assigned to this option is a string literal containing a valid JSON document or an empty string (`""`). Invalid JSON is rejected.

```sql
ALTER TABLESPACE ts1 ENGINE_ATTRIBUTE='{"key":"value"}';
```

`ENGINE_ATTRIBUTE` values can be repeated without error. In this case, the last specified value is used.

`ENGINE_ATTRIBUTE` values are not checked by the server, nor are they cleared when the table's storage engine is changed.

It is not permitted to alter an individual element of a JSON attribute value. You can only add or replace an attribute.

### 15.1.11 ALTER VIEW Statement

```sql
ALTER
    [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
    [DEFINER = user]
    [SQL SECURITY { DEFINER | INVOKER }]
VIEW view_name
    [(column_list)]
AS select_statement
    [WITH [CASCADED | LOCAL] CHECK OPTION]
```

This statement changes the definition of a view, which must exist. The syntax is similar to that for `CREATE VIEW` (see Section 15.1.23, “CREATE VIEW Statement”). This statement requires the `CREATE VIEW` and `DROP` privileges for the view, and some privilege for each column referred to in the `SELECT` statement. `ALTER VIEW` is permitted only to the definer or users with the `SET_ANY_DEFINER` or `ALLOW_NONEXISTENT_DEFINER` privilege.

### 15.1.12 CREATE DATABASE Statement

```sql
CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
    [create_option] ...
```

`create_option`: [DEFAULT] {

- `CHARACTER SET [=] charset_name`
- `COLLATE [=] collation_name`
- `ENCRYPTION [=] {'Y' | 'N'}`

2443
CREATE DATABASE creates a database with the given name. To use this statement, you need the CREATE privilege for the database. CREATE SCHEMA is a synonym for CREATE DATABASE.

An error occurs if the database exists and you did not specify IF NOT EXISTS.

CREATE DATABASE is not permitted within a session that has an active LOCK TABLES statement.

Each create_option specifies a database characteristic. Database characteristics are stored in the data dictionary.

- The CHARACTER SET option specifies the default database character set. The COLLATE option specifies the default database collation. For information about character set and collation names, see Chapter 12, Character Sets, Collations, Unicode.

To see the available character sets and collations, use the the SHOW CHARACTER SET and SHOW COLLATION statements, respectively. See Section 15.7.7.4, “SHOW CHARACTER SET Statement”, and Section 15.7.7.5, “SHOW COLLATION Statement”.

- The ENCRYPTION option defines the default database encryption, which is inherited by tables created in the database. The permitted values are 'Y' (encryption enabled) and 'N' (encryption disabled). If the ENCRYPTION option is not specified, the value of the default_table_encryption system variable defines the default database encryption. If the table_encryption_privilege_check system variable is enabled, the TABLE_ENCRYPTION_ADMIN privilege is required to specify a default encryption setting that differs from the default_table_encryption setting. For more information, see Defining an Encryption Default for Schemas and General Tablespaces.

A database in MySQL is implemented as a directory containing files that correspond to tables in the database. Because there are no tables in a database when it is initially created, the CREATE DATABASE statement creates only a directory under the MySQL data directory. Rules for permissible database names are given in Section 11.2, “Schema Object Names”. If a database name contains special characters, the name for the database directory contains encoded versions of those characters as described in Section 11.2.4, “Mapping of Identifiers to File Names”.

Creating a database directory by manually creating a directory under the data directory (for example, with mkdir) is unsupported in MySQL 8.4.

When you create a database, let the server manage the directory and the files in it. Manipulating database directories and files directly can cause inconsistencies and unexpected results.

MySQL has no limit on the number of databases. The underlying file system may have a limit on the number of directories.

You can also use the mysqladmin program to create databases. See Section 6.5.2, “mysqladmin — A MySQL Server Administration Program”.

15.1.13 CREATE EVENT Statement

```
CREATE EVENT [DEFINER = user] EVENT [IF NOT EXISTS] event_name
ON SCHEDULE schedule
[ON COMPLETION [NOT] PRESERVE]
[ENABLE | DISABLE | DISABLE ON {REPLICA | SLAVE}]
[COMMENT 'string']
DO event_body;
```

The `ON SCHEDULE` clause specifies the schedule of the event. The `event_body` is the body of the event, which can include `AT timestamp [+ INTERVAL interval]`...
CREATE EVENT Statement

EVERY interval

[STARTS timestamp [+ INTERVAL interval] ...]

[ENDS timestamp [+ INTERVAL interval] ...]

interval:

<table>
<thead>
<tr>
<th>quantity</th>
<th>YEAR</th>
<th>QUARTER</th>
<th>MONTH</th>
<th>DAY</th>
<th>HOUR</th>
<th>MINUTE</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>WEEK</td>
<td>SECOND</td>
<td>YEAR_MONTH</td>
<td>DAY_HOUR</td>
<td>DAY_MINUTE</td>
<td>DAY_SECOND</td>
</tr>
</tbody>
</table>

This statement creates and schedules a new event. The event does not run unless the Event Scheduler is enabled. For information about checking Event Scheduler status and enabling it if necessary, see Section 27.4.2, “Event Scheduler Configuration”.

CREATE EVENT requires the EVENT privilege for the schema in which the event is to be created. If the DEFINER clause is present, the privileges required depend on the user value, as discussed in Section 27.6, “Stored Object Access Control”.

The minimum requirements for a valid CREATE EVENT statement are as follows:

- The keywords CREATE EVENT plus an event name, which uniquely identifies the event in a database schema.

- An ON SCHEDULE clause, which determines when and how often the event executes.

- A DO clause, which contains the SQL statement to be executed by an event.

This is an example of a minimal CREATE EVENT statement:

```
CREATE EVENT myevent
ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
DO
  UPDATE myschema.mytable SET mycol = mycol + 1;
```

The previous statement creates an event named myevent. This event executes once—one hour following its creation—by running an SQL statement that increments the value of the myschema.mytable table’s mycol column by 1.

The event_name must be a valid MySQL identifier with a maximum length of 64 characters. Event names are not case-sensitive, so you cannot have two events named myevent and MyEvent in the same schema. In general, the rules governing event names are the same as those for names of stored routines. See Section 11.2, “Schema Object Names”.

An event is associated with a schema. If no schema is indicated as part of event_name, the default (current) schema is assumed. To create an event in a specific schema, qualify the event name with a schema using schema_name.event_name syntax.

The DEFINER clause specifies the MySQL account to be used when checking access privileges at event execution time. If the DEFINER clause is present, the user value should be a MySQL account specified as 'user_name'@'host_name'. CURRENT_USER, or CURRENT_USER(). The permitted user values depend on the privileges you hold, as discussed in Section 27.6, “Stored Object Access Control”. Also see that section for additional information about event security.

If the DEFINER clause is omitted, the default definer is the user who executes the CREATE EVENT statement. This is the same as specifying DEFINER = CURRENT_USER explicitly.

Within an event body, the CURRENT_USER function returns the account used to check privileges at event execution time, which is the DEFINER user. For information about user auditing within events, see Section 8.2.23, “SQL-Based Account Activity Auditing”.

IF NOT EXISTS has the same meaning for CREATE EVENT as for CREATE TABLE: If an event named event_name already exists in the same schema, no action is taken, and no error results. (However, a warning is generated in such cases.)
CREATE EVENT Statement

The `ON SCHEDULE` clause determines when, how often, and for how long the `event_body` defined for the event repeats. This clause takes one of two forms:

- **AT timestamp** is used for a one-time event. It specifies that the event executes one time only at the date and time given by `timestamp`, which must include both the date and time, or must be an expression that resolves to a datetime value. You may use a value of either the `DATETIME` or `TIMESTAMP` type for this purpose. If the date is in the past, a warning occurs, as shown here:

  ```sql
  mysql> SELECT NOW();
  +---------------------+
  | NOW()               |
  +---------------------+
  | 2006-02-10 23:59:01 |
  +---------------------+
  1 row in set (0.04 sec)
  mysql>
  CREATE EVENT e_totals
  -> ON SCHEDULE AT '2006-02-10 23:59:00'
  -> DO INSERT INTO test.totals VALUES (NOW());
  Query OK, 0 rows affected, 1 warning (0.00 sec)
  mysql>
  SHOW WARNINGS\G
  *************************** 1. row ***************************
  Level: Note
  Code: 1588
  Message: Event execution time is in the past and ON COMPLETION NOT PRESERVE is set. The event was dropped immediately after creation.
  ```

- **EVERY** clause may be used to repeat actions at a regular interval. The `EVERY` keyword is followed by an `interval` as described in the previous discussion of the `AT` keyword. (The `+ INTERVAL` is not used with `EVERY`.) For example, `EVERY 6 WEEK` means “every six weeks”.

  ```sql
  CREATE EVENT e_totals
  -> EVERY 6 WEEK
  -> DO INSERT INTO test.totals VALUES (NOW());
  Query OK, 0 rows affected, 1 warning (0.00 sec)
  mysql>
  SHOW WARNINGS\G
  *************************** 1. row ***************************
  Level: Note
  Code: 1588
  Message: Event execution time is in the past and ON COMPLETION NOT PRESERVE is set. The event was dropped immediately after creation.
  ```

You may use **CURRENT_TIMESTAMP** to specify the current date and time. In such a case, the event acts as soon as it is created.

To create an event which occurs at some point in the future relative to the current date and time—such as that expressed by the phrase “three weeks from now”—you can use the optional clause `+ INTERVAL interval`. The `interval` portion consists of two parts, a quantity and a unit of time, and follows the syntax rules described in Temporal Intervals, except that you cannot use any units keywords that involving microseconds when defining an event. With some interval types, complex time units may be used. For example, “two minutes and ten seconds” can be expressed as `+ INTERVAL '2:10' MINUTE_SECOND`.

An `EVERY` clause may contain an optional `STARTS` clause. The `STARTS` keyword is followed by a `timestamp` value that tells MySQL when the event should begin repeating, and may also use `+ INTERVAL interval` to specify an amount of time “from now”. For example, `EVERY 3 MONTH STARTS CURRENT_TIMESTAMP + INTERVAL 1 WEEK` means “every three months, beginning one week from now”.

Although `+ INTERVAL` clauses are not permitted in an `EVERY` clause, you can use the same complex time units permitted in a `+ INTERVAL`.

An `EVERY` clause may contain an optional `ENDS` clause. The `ENDS` keyword is followed by a `timestamp` value that tells MySQL when the event should stop repeating. You may also use `+ INTERVAL interval` to specify an amount of time “from now”.

An `EVERY` clause may contain an optional `STARTS` clause. The `STARTS` keyword is followed by a `timestamp` value that indicates when the action should begin repeating, and may also use `+ INTERVAL interval` to specify an amount of time “from now”. For example, `EVERY 3 MONTH STARTS CURRENT_TIMESTAMP + INTERVAL 1 WEEK` means “every three months, beginning one week from now”. Similarly, you can express “every two weeks, beginning six hours and fifteen minutes from now” as `EVERY 2 WEEK STARTS CURRENT_TIMESTAMP + INTERVAL '6:15' HOUR_MINUTE`. Not specifying `STARTS` is the same as using `STARTS CURRENT_TIMESTAMP`—that is, the action specified for the event begins repeating immediately upon creation of the event.

An `EVERY` clause may contain an optional `ENDS` clause. The `ENDS` keyword is followed by a `timestamp` value that tells MySQL when the event should stop repeating. You may also use `+ INTERVAL interval` to specify an amount of time “from now”. For example, `EVERY 3 MONTH STARTS CURRENT_TIMESTAMP + INTERVAL 1 WEEK` means “every three months, beginning one week from now”.
CREATE EVENT Statement

INTERVAL interval with ENDS; for instance, EVERY 12 HOUR STARTS CURRENT_TIMESTAMP + INTERVAL 30 MINUTE ENDS CURRENT_TIMESTAMP + INTERVAL 4 WEEK is equivalent to “every twelve hours, beginning thirty minutes from now, and ending four weeks from now”. Not using ENDS means that the event continues executing indefinitely.

ENDS supports the same syntax for complex time units as STARTS does.

You may use STARTS, ENDS, both, or neither in an EVERY clause.

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the GET_LOCK() function, or row or table locking.

The ON SCHEDULE clause may use expressions involving built-in MySQL functions and user variables to obtain any of the timestamp or interval values which it contains. You may not use stored functions or loadable functions in such expressions, nor may you use any table references; however, you may use SELECT FROM DUAL. This is true for both CREATE EVENT and ALTER EVENT statements. References to stored functions, loadable functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Times in the ON SCHEDULE clause are interpreted using the current session time_zone value. This becomes the event time zone; that is, the time zone that is used for event scheduling and is in effect within the event as it executes. These times are converted to UTC and stored along with the event time zone internally. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. For additional information about representation of event times, see Section 27.4.4, “Event Metadata”. See also Section 15.7.7.19, “SHOW EVENTS Statement”, and Section 28.3.14, “The INFORMATION_SCHEMA EVENTS Table”.

Normally, once an event has expired, it is immediately dropped. You can override this behavior by specifying ON COMPLETION PRESERVE. Using ON COMPLETION NOT PRESERVE merely makes the default nonpersistent behavior explicit.

You can create an event but prevent it from being active using the DISABLE keyword. Alternatively, you can use ENABLE to make explicit the default status, which is active. This is most useful in conjunction with ALTER EVENT (see Section 15.1.3, “ALTER EVENT Statement”).

A third value may also appear in place of ENABLE or DISABLE; DISABLE ON REPLICA is set for the status of an event on a replica to indicate that the event was created on the replication source server and replicated to the replica, but is not executed on the replica. See Section 19.5.1.16, “Replication of Invoked Features”.

DISABLE ON REPLICA replaces DISABLE ON SLAVE, which is deprecated, and thus subject to removal in a future version of MySQL.

You may supply a comment for an event using a COMMENT clause. comment may be any string of up to 64 characters that you wish to use for describing the event. The comment text, being a string literal, must be surrounded by quotation marks.

The DO clause specifies an action carried by the event, and consists of an SQL statement. Nearly any valid MySQL statement that can be used in a stored routine can also be used as the action statement for a scheduled event. (See Section 27.8, “Restrictions on Stored Programs”.) For example, the following event e_hourly deletes all rows from the sessions table once per hour, where this table is part of the site_activity schema:

```sql
CREATE EVENT e_hourly
ON SCHEDULE EVERY 1 HOUR
COMMENT 'Clears out sessions table each hour.'
DO
DELETE FROM site_activity.sessions;
```
MySQL stores the `sql_mode` system variable setting in effect when an event is created or altered, and always executes the event with this setting in force, regardless of the current server SQL mode when the event begins executing.

A `CREATE EVENT` statement that contains an `ALTER EVENT` statement in its `DO` clause appears to succeed; however, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

**Note**

Statements such as `SELECT` or `SHOW` that merely return a result set have no effect when used in an event; the output from these is not sent to the MySQL Monitor, nor is it stored anywhere. However, you can use statements such as `SELECT ... INTO` and `INSERT INTO ... SELECT` that store a result. (See the next example in this section for an instance of the latter.)

The schema to which an event belongs is the default schema for table references in the `DO` clause. Any references to tables in other schemas must be qualified with the proper schema name.

As with stored routines, you can use compound-statement syntax in the `DO` clause by using the `BEGIN` and `END` keywords, as shown here:

```sql
delimiter |
CREATE EVENT e_daily
ON SCHEDULE EVERY 1 DAY
COMMENT 'Saves total number of sessions then clears the table each day'
DO
BEGIN
    INSERT INTO site_activity.totals (time, total)
    SELECT CURRENT_TIMESTAMP, COUNT(*)
    FROM site_activity.sessions;
    DELETE FROM site_activity.sessions;
END |
delimiter;
```

This example uses the `delimiter` command to change the statement delimiter. See Section 27.1, “Defining Stored Programs”.

More complex compound statements, such as those used in stored routines, are possible in an event. This example uses local variables, an error handler, and a flow control construct:

```sql
delimiter |
CREATE EVENT e
ON SCHEDULE EVERY 5 SECOND
DO
BEGIN
    DECLARE v INTEGER;
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION BEGIN END;
    SET v = 0;
    WHILE v < 5 DO
        INSERT INTO t1 VALUES (0);
        UPDATE t2 SET s1 = s1 + 1;
        SET v = v + 1;
    END WHILE;
END |
delimiter;
```

There is no way to pass parameters directly to or from events; however, it is possible to invoke a stored routine with parameters within an event:
CREATE FUNCTION Statement

CREATE EVENT e_call_myproc
ON SCHEDULE
  AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
DO CALL myproc(5, 27);

If an event's definer has privileges sufficient to set global system variables (see Section 7.1.9.1, “System Variable Privileges”), the event can read and write global variables. As granting such privileges entails a potential for abuse, extreme care must be taken in doing so.

Generally, any statements that are valid in stored routines may be used for action statements executed by events. For more information about statements permissible within stored routines, see Section 27.2.1, “Stored Routine Syntax”. It is not possible to create an event as part of a stored routine or to create an event by another event.

15.1.14 CREATE FUNCTION Statement

The CREATE FUNCTION statement is used to create stored functions and loadable functions:

- For information about creating stored functions, see Section 15.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”.
- For information about creating loadable functions, see Section 15.7.4.1, “CREATE FUNCTION Statement for Loadable Functions”.

15.1.15 CREATE INDEX Statement

CREATE [UNIQUE | FULLTEXT | SPATIAL] INDEX index_name
  [index_type]
  ON tbl_name (key_part,...)
  [index_option]
  [algorithm_option | lock_option] ...

key_part: {col_name [(length)] | (expr)} [ASC | DESC]

index_option: {
  KEY_BLOCK_SIZE [=] value
  | index_type
  WITH PARSER parser_name
  | COMMENT 'string'
  | {VISIBLE | INVISIBLE}
  | ENGINE_ATTRIBUTE [=] 'string'
  | SECONDARY_ENGINE_ATTRIBUTE [=] 'string'
}

index_type:
  USING {BTREE | HASH}

algorithm_option:
  ALGORITHM [=] {DEFAULT | INPLACE | COPY}

lock_option:
  LOCK [=] {DEFAULT | NONE | SHARED | EXCLUSIVE}

Normally, you create all indexes on a table at the time the table itself is created with CREATE TABLE. See Section 15.1.20, “CREATE TABLE Statement”. This guideline is especially important for InnoDB tables, where the primary key determines the physical layout of rows in the data file. CREATE INDEX enables you to add indexes to existing tables.

CREATE INDEX is mapped to an ALTER TABLE statement to create indexes. See Section 15.1.9, “ALTER TABLE Statement”. CREATE INDEX cannot be used to create a PRIMARY KEY; use ALTER TABLE instead. For more information about indexes, see Section 10.3.1, “How MySQL Uses Indexes”.

InnoDB supports secondary indexes on virtual columns. For more information, see Section 15.1.20.9, “Secondary Indexes and Generated Columns”.

When the innodb_stats_persistent setting is enabled, run the ANALYZE TABLE statement for an InnoDB table after creating an index on that table.
The `expr` for a `key_part` specification can also take the form `(CAST json_expression AS type ARRAY)` to create a multi-valued index on a JSON column. See Multi-Valued Indexes.

An index specification of the form `(key_part1, key_part2, ...)` creates an index with multiple key parts. Index key values are formed by concatenating the values of the given key parts. For example `(col1, col2, col3)` specifies a multiple-column index with index keys consisting of values from `col1`, `col2`, and `col3`.

A `key_part` specification can end with `ASC` or `DESC` to specify whether index values are stored in ascending or descending order. The default is ascending if no order specifier is given. `ASC` and `DESC` are not supported for HASH indexes, multi-valued indexes or SPATIAL indexes.

The following sections describe different aspects of the `CREATE INDEX` statement:

- Column Prefix Key Parts
- Functional Key Parts
- Unique Indexes
- Full-Text Indexes
- Multi-Valued Indexes
- Spatial Indexes
- Index Options
- Table Copying and Locking Options

**Column Prefix Key Parts**

For string columns, indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length:

- Prefixes can be specified for CHAR, VARCHAR, BINARY, and VARBINARY key parts.
- Prefixes must be specified for BLOB and TEXT key parts. Additionally, BLOB and TEXT columns can be indexed only for InnoDB, MyISAM, and BLACKHOLE tables.
- Prefix limits are measured in bytes. However, prefix lengths for index specifications in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements are interpreted as number of characters for nonbinary string types (CHAR, VARCHAR, TEXT) and number of bytes for binary string types (BINARY, VARBINARY, BLOB). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

Prefix support and lengths of prefixes (where supported) are storage engine dependent. For example, a prefix can be up to 767 bytes long for InnoDB tables that use the REDUNDANT or COMPACT row format. The prefix length limit is 3072 bytes for InnoDB tables that use the DYNAMIC or COMPRESSED row format. For MyISAM tables, the prefix length limit is 1000 bytes. The NDB storage engine does not support prefixes (see Section 25.2.7.6, “Unsupported or Missing Features in NDB Cluster”).

If a specified index prefix exceeds the maximum column data type size, `CREATE INDEX` handles the index as follows:

- For a nonunique index, either an error occurs (if strict SQL mode is enabled), or the index length is reduced to lie within the maximum column data type size and a warning is produced (if strict SQL mode is not enabled).
- For a unique index, an error occurs regardless of SQL mode because reducing the index length might enable insertion of nonunique entries that do not meet the specified uniqueness requirement.
The statement shown here creates an index using the first 10 characters of the `name` column (assuming that `name` has a nonbinary string type):

```sql
CREATE INDEX part_of_name ON customer (name(10));
```

If names in the column usually differ in the first 10 characters, lookups performed using this index should not be much slower than using an index created from the entire `name` column. Also, using column prefixes for indexes can make the index file much smaller, which could save a lot of disk space and might also speed up `INSERT` operations.

### Functional Key Parts

A “normal” index indexes column values or prefixes of column values. For example, in the following table, the index entry for a given `t1` row includes the full `col1` value and a prefix of the `col2` value consisting of its first 10 characters:

```sql
CREATE TABLE t1 (
  col1 VARCHAR(10),
  col2 VARCHAR(20),
  INDEX (col1, col2(10))
);
```

Functional key parts that index expression values can also be used in place of column or column prefix values. Use of functional key parts enables indexing of values not stored directly in the table. Examples:

```sql
CREATE TABLE t1 (col1 INT, col2 INT, INDEX func_index ((ABS(col1))));
CREATE INDEX idx1 ON t1 ((col1 + col2));
CREATE INDEX idx2 ON t1 ((col1 + col2), (col1 - col2), col1);
ALTER TABLE t1 ADD INDEX ((col1 * 40) DESC);
```

An index with multiple key parts can mix nonfunctional and functional key parts.

`ASC` and `DESC` are supported for functional key parts.

Functional key parts must adhere to the following rules. An error occurs if a key part definition contains disallowed constructs.

- In index definitions, enclose expressions within parentheses to distinguish them from columns or column prefixes. For example, this is permitted; the expressions are enclosed within parentheses:

  ```sql
  INDEX ((col1 + col2), (col3 - col4))
  ```

  This produces an error; the expressions are not enclosed within parentheses:

  ```sql
  INDEX (col1 + col2, col3 - col4)
  ```

- A functional key part cannot consist solely of a column name. For example, this is not permitted:

  ```sql
  INDEX ((col1), (col2))
  ```

  Instead, write the key parts as nonfunctional key parts, without parentheses:

  ```sql
  INDEX (col1, col2)
  ```

- A functional key part expression cannot refer to column prefixes. For a workaround, see the discussion of `SUBSTRING()` and `CAST()` later in this section.

- Functional key parts are not permitted in foreign key specifications.

For `CREATE TABLE ... LIKE`, the destination table preserves functional key parts from the original table.

Functional indexes are implemented as hidden virtual generated columns, which has these implications:
• Each functional key part counts against the limit on total number of table columns; see Section 10.4.7, “Limits on Table Column Count and Row Size”.

• Functional key parts inherit all restrictions that apply to generated columns. Examples:
  • Only functions permitted for generated columns are permitted for functional key parts.
  • Subqueries, parameters, variables, stored functions, and loadable functions are not permitted.

For more information about applicable restrictions, see Section 15.1.20.8, “CREATE TABLE and Generated Columns”, and Section 15.1.9.2, “ALTER TABLE and Generated Columns”.

• The virtual generated column itself requires no storage. The index itself takes up storage space as any other index.

UNIQUE is supported for indexes that include functional key parts. However, primary keys cannot include functional key parts. A primary key requires the generated column to be stored, but functional key parts are implemented as virtual generated columns, not stored generated columns.

SPATIAL and FULLTEXT indexes cannot have functional key parts.

If a table contains no primary key, InnoDB automatically promotes the first UNIQUE NOT NULL index to the primary key. This is not supported for UNIQUE NOT NULL indexes that have functional key parts.

Nonfunctional indexes raise a warning if there are duplicate indexes. Indexes that contain functional key parts do not have this feature.

To remove a column that is referenced by a functional key part, the index must be removed first. Otherwise, an error occurs.

Although nonfunctional key parts support a prefix length specification, this is not possible for functional key parts. The solution is to use SUBSTRING() (or CAST(), as described later in this section). For a functional key part containing the SUBSTRING() function to be used in a query, the WHERE clause must contain SUBSTRING() with the same arguments. In the following example, only the second SELECT is able to use the index because that is the only query in which the arguments to SUBSTRING() match the index specification:

```
CREATE TABLE tbl (  
    col1 LONGTEXT,  
    INDEX idx1 ((SUBSTRING(col1, 1, 10)))  
);  
SELECT * FROM tbl WHERE SUBSTRING(col1, 1, 9) = '123456789';  
SELECT * FROM tbl WHERE SUBSTRING(col1, 1, 10) = '1234567890';
```

Functional key parts enable indexing of values that cannot be indexed otherwise, such as JSON values. However, this must be done correctly to achieve the desired effect. For example, this syntax does not work:

```
CREATE TABLE employees (  
    data JSON,  
    INDEX ((data->>'$.name'))  
);  
```

The syntax fails because:

• The ->> operator translates into JSON_UNQUOTE(JSON_EXTRACT(...)).

• JSON_UNQUOTE() returns a value with a data type of LONGTEXT, and the hidden generated column thus is assigned the same data type.

• MySQL cannot index LONGTEXT columns specified without a prefix length on the key part, and prefix lengths are not permitted in functional key parts.

To index the JSON column, you could try using the CAST() function as follows:
CREATE TABLE employees (  
data JSON,  
INDEX ((CAST(data->>'$.name' AS CHAR(30)))))
);

The hidden generated column is assigned the `VARCHAR(30)` data type, which can be indexed. But this approach produces a new issue when trying to use the index:

- `CAST()` returns a string with the collation `utf8mb4_0900_ai_ci` (the server default collation).
- `JSON_UNQUOTE()` returns a string with the collation `utf8mb4_bin` (hard coded).

As a result, there is a collation mismatch between the indexed expression in the preceding table definition and the `WHERE` clause expression in the following query:

```
SELECT * FROM employees WHERE data->>'$.name' = 'James';
```

The index is not used because the expressions in the query and the index differ. To support this kind of scenario for functional key parts, the optimizer automatically strips `CAST()` when looking for an index to use, but only if the collation of the indexed expression matches that of the query expression. For an index with a functional key part to be used, either of the following two solutions work (although they differ somewhat in effect):

- **Solution 1.** Assign the indexed expression the same collation as `JSON_UNQUOTE()`:

  ```
  CREATE TABLE employees (  
data JSON,  
INDEX idx ((CAST(data->>'$.name' AS CHAR(30)) COLLATE utf8mb4_bin)))
  );
  INSERT INTO employees VALUES  
  ('{"name": "james", "salary": 9000 }'),  
  ('{"name": "James", "salary": 10000 }'),  
  ('{"name": "Mary", "salary": 12000 }'),  
  ('{"name": "Peter", "salary": 8000 }');
  SELECT * FROM employees WHERE data->>'$.name' = 'James';
  ```

  The `->>` operator is the same as `JSON_UNQUOTE(JSON_EXTRACT(...))`, and `JSON_UNQUOTE()` returns a string with collation `utf8mb4_bin`. The comparison is thus case-sensitive, and only one row matches:

  ```
  +------------------------------------+  
  | data                               |  
  +------------------------------------+  
  | {"name": "James", "salary": 10000} |  
  +------------------------------------+  
  ```

- **Solution 2.** Specify the full expression in the query:

  ```
  CREATE TABLE employees (  
data JSON,  
INDEX idx ((CAST(data->>'$.name' AS CHAR(30)))))
  );
  INSERT INTO employees VALUES  
  ('{"name": "james", "salary": 9000 }'),  
  ('{"name": "James", "salary": 10000 }'),  
  ('{"name": "Mary", "salary": 12000 }'),  
  ('{"name": "Peter", "salary": 8000 }');
  SELECT * FROM employees WHERE CAST(data->>'$.name' AS CHAR(30)) = 'James';
  ```

  `CAST()` returns a string with collation `utf8mb4_0900_ai_ci`, so the comparison case-insensitive and two rows match:

  ```
  +------------------------------------+  
  | data                               |  
  +------------------------------------+  
  | {"name": "james", "salary": 9000} |  
  | {"name": "James", "salary": 10000} |  
  +------------------------------------+  
  ```
Be aware that although the optimizer supports automatically stripping `CAST()` with indexed generated columns, the following approach does not work because it produces a different result with and without an index (Bug#27337092):

```sql
mysql> CREATE TABLE employees (  
  data JSON,  
  generated_col VARCHAR(30) AS (CAST(data->>'$.name' AS CHAR(30)))  
);  
Query OK, 0 rows affected, 1 warning (0.03 sec)
```

```sql
mysql> INSERT INTO employees (data)  
VALUES ('{"name": "james"}', '{"name": "James"}');  
Query OK, 2 rows affected, 1 warning (0.01 sec)  
Records: 2  Duplicates: 0  Warnings: 1
```

```sql
mysql> SELECT * FROM employees WHERE data->>'$.name' = 'James';  
+-------------------+---------------+  
| data              | generated_col |  
| +-------------------+---------------+  
| {"name": "James"} | James         |  
+-------------------+---------------+  
1 row in set (0.00 sec)
```

```sql
mysql> ALTER TABLE employees ADD INDEX idx (generated_col);  
Query OK, 0 rows affected, 1 warning (0.03 sec)  
Records: 0  Duplicates: 0  Warnings: 1
```

```sql
mysql> SELECT * FROM employees WHERE data->>'$.name' = 'James';  
+-------------------+---------------+  
| data              | generated_col |  
| +-------------------+---------------+  
| {"name": "james"} | james         |  
| {"name": "James"} | James         |  
+-------------------+---------------+  
2 rows in set (0.01 sec)
```

### Unique Indexes

A **UNIQUE** index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. If you specify a prefix value for a column in a **UNIQUE** index, the column values must be unique within the prefix length. A **UNIQUE** index permits multiple **NULL** values for columns that can contain **NULL**.

If a table has a **PRIMARY KEY** or **UNIQUE NOT NULL** index that consists of a single column that has an integer type, you can use `_rowid` to refer to the indexed column in **SELECT** statements, as follows:

- `_rowid` refers to the **PRIMARY KEY** column if there is a **PRIMARY KEY** consisting of a single integer column. If there is a **PRIMARY KEY** but it does not consist of a single integer column, `_rowid` cannot be used.
- Otherwise, `_rowid` refers to the column in the first **UNIQUE NOT NULL** index if that index consists of a single integer column. If the first **UNIQUE NOT NULL** index does not consist of a single integer column, `_rowid` cannot be used.

### Full-Text Indexes

**FULLTEXT** indexes are supported only for InnoDB and MyISAM tables and can include only **CHAR**, **VARCHAR**, and **TEXT** columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See Section 14.9, "Full-Text Search Functions", for details of operation.

### Multi-Valued Indexes

InnoDB supports multi-valued indexes. A multi-valued index is a secondary index defined on a column that stores an array of values. A "normal" index has one index record for each data record (1:1). A multi-valued index can have multiple index records for a single data record (N:1). Multi-valued indexes
CREATE INDEX Statement

are intended for indexing JSON arrays. For example, a multi-valued index defined on the array of zip codes in the following JSON document creates an index record for each zip code, with each index record referencing the same data record.

```
{
  "user":"Bob",
  "user_id":31,
  "zipcode": [94477, 94536]
}
```

Creating multi-valued Indexes

You can create a multi-valued index in a CREATE TABLE, ALTER TABLE, or CREATE INDEX statement. This requires using `CAST(... AS ... ARRAY)` in the index definition, which casts same-typed scalar values in a JSON array to an SQL data type array. A virtual column is then generated transparently with the values in the SQL data type array; finally, a functional index (also referred to as a virtual index) is created on the virtual column. It is the functional index defined on the virtual column of values from the SQL data type array that forms the multi-valued index.

The examples in the following list show the three different ways in which a multi-valued index `zips` can be created on an array `.zipcode` on a JSON column `custinfo` in a table named `customers`. In each case, the JSON array is cast to an SQL data type array of UNSIGNED integer values.

- **CREATE TABLE only:**

  ```
  CREATE TABLE customers (
    id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    modified DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    custinfo JSON,
    INDEX zips( (CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY)) )
  );
  ```

- **CREATE TABLE plus ALTER TABLE:**

  ```
  CREATE TABLE customers (
    id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    modified DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    custinfo JSON
  );
  ALTER TABLE customers ADD INDEX zips( (CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY)) );
  ```

- **CREATE TABLE plus CREATE INDEX:**

  ```
  CREATE TABLE customers (
    id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    modified DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    custinfo JSON
  );
  CREATE INDEX zips ON customers ( (CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY)) );
  ```

A multi-valued index can also be defined as part of a composite index. This example shows a composite index that includes two single-valued parts (for the `id` and `modified` columns), and one multi-valued part (for the `custinfo` column):

```
CREATE TABLE customers (
    id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    modified DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    custinfo JSON
  );
ALTER TABLE customers ADD INDEX comp(id, modified,
    (CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY)) );
```

Only one multi-valued key part can be used in a composite index. The multi-valued key part may be used in any order relative to the other parts of the key. In other words, the `ALTER TABLE` statement
CREATE INDEX Statement

just shown could have used comp(id, (CAST(custinfo->'$.zipcode' AS UNSIGNED
ARRAY), modified)) (or any other ordering) and still have been valid.

Using multi-valued Indexes
The optimizer uses a multi-valued index to fetch records when the following functions are specified in a
WHERE clause:
• MEMBER OF()
• JSON_CONTAINS()
• JSON_OVERLAPS()
We can demonstrate this by creating and populating the customers table using the following CREATE
TABLE and INSERT statements:
mysql> CREATE TABLE customers (
->
id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->
modified DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
->
custinfo JSON
->
);
Query OK, 0 rows affected (0.51 sec)
mysql> INSERT INTO customers VALUES
->
(NULL, NOW(), '{"user":"Jack","user_id":37,"zipcode":[94582,94536]}'),
->
(NULL, NOW(), '{"user":"Jill","user_id":22,"zipcode":[94568,94507,94582]}'),
->
(NULL, NOW(), '{"user":"Bob","user_id":31,"zipcode":[94477,94507]}'),
->
(NULL, NOW(), '{"user":"Mary","user_id":72,"zipcode":[94536]}'),
->
(NULL, NOW(), '{"user":"Ted","user_id":56,"zipcode":[94507,94582]}');
Query OK, 5 rows affected (0.07 sec)
Records: 5 Duplicates: 0 Warnings: 0

First we execute three queries on the customers table, one each using MEMBER OF(),
JSON_CONTAINS(), and JSON_OVERLAPS(), with the result from each query shown here:
mysql> SELECT * FROM customers
->
WHERE 94507 MEMBER OF(custinfo->'$.zipcode');
+----+---------------------+-------------------------------------------------------------------+
| id | modified
| custinfo
|
+----+---------------------+-------------------------------------------------------------------+
| 2 | 2019-06-29 22:23:12 | {"user": "Jill", "user_id": 22, "zipcode": [94568, 94507, 94582]} |
| 3 | 2019-06-29 22:23:12 | {"user": "Bob", "user_id": 31, "zipcode": [94477, 94507]}
|
|
+----+---------------------+-------------------------------------------------------------------+
3 rows in set (0.00 sec)
mysql> SELECT * FROM customers
->
WHERE JSON_CONTAINS(custinfo->'$.zipcode', CAST('[94507,94582]' AS JSON));
+----+---------------------+-------------------------------------------------------------------+
| id | modified
| custinfo
|
+----+---------------------+-------------------------------------------------------------------+
| 2 | 2019-06-29 22:23:12 | {"user": "Jill", "user_id": 22, "zipcode": [94568, 94507, 94582]} |
|
+----+---------------------+-------------------------------------------------------------------+
2 rows in set (0.00 sec)
mysql> SELECT * FROM customers
->
WHERE JSON_OVERLAPS(custinfo->'$.zipcode', CAST('[94507,94582]' AS JSON));
+----+---------------------+-------------------------------------------------------------------+
| id | modified
| custinfo
|
+----+---------------------+-------------------------------------------------------------------+
| 1 | 2019-06-29 22:23:12 | {"user": "Jack", "user_id": 37, "zipcode": [94582, 94536]}
|
| 2 | 2019-06-29 22:23:12 | {"user": "Jill", "user_id": 22, "zipcode": [94568, 94507, 94582]} |
| 3 | 2019-06-29 22:23:12 | {"user": "Bob", "user_id": 31, "zipcode": [94477, 94507]}
|
|
+----+---------------------+-------------------------------------------------------------------+
4 rows in set (0.00 sec)

Next, we run EXPLAIN on each of the previous three queries:

2456


None of the three queries just shown are able to use any keys. To solve this problem, we can add a multi-valued index on the `zipcode` array in the `JSON` column (```, like this:

```sql
ALTER TABLE customers
ADD INDEX zips (CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY));
```

When we run the previous `EXPLAIN` statements again, we can now observe that the queries can (and do) use the index `zips` that was just created:

```sql
EXPLAIN
WHERE 94507 MEMBER OF(custinfo->'$.zipcode');
```

```sql
EXPLAIN
WHERE JSON_CONTAINS(custinfo->'$.zipcode', CAST('[94507,94582]' AS JSON));
```

```sql
WHERE JSON_OVERLAPS(custinfo->'$.zipcode', CAST('[94507,94582]' AS JSON));
```

A multi-valued index can be defined as a unique key. If defined as a unique key, attempting to insert a value already present in the multi-valued index returns a duplicate key error. If duplicate values are already present, attempting to add a unique multi-valued index fails, as shown here:

```sql
ALTER TABLE customers DROP INDEX zips;
```
CREATE INDEX Statement

Records: 0  Duplicates: 0  Warnings: 0

mysql> ALTER TABLE customers
-> ADD UNIQUE INDEX zips((CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY)));
ERROR 1062 (23000): Duplicate entry '94507,' for key 'customers.zips'

mysql> ALTER TABLE customers
-> ADD INDEX zips((CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY)));
Query OK, 0 rows affected (0.36 sec)
Records: 0  Duplicates: 0  Warnings: 0

Characteristics of Multi-Valued Indexes

Multi-valued indexes have the additional characteristics listed here:

• DML operations that affect multi-valued indexes are handled in the same way as DML operations that affect a normal index, with the only difference being that there may be more than one insert or update for a single clustered index record.

• Nullability and multi-valued indexes:
  • If a multi-valued key part has an empty array, no entries are added to the index, and the data record is not accessible by an index scan.
  • If multi-valued key part generation returns a NULL value, a single entry containing NULL is added to the multi-valued index. If the key part is defined as NOT NULL, an error is reported.
  • If the typed array column is set to NULL, the storage engine stores a single record containing NULL that points to the data record.
  • JSON null values are not permitted in indexed arrays. If any returned value is NULL, it is treated as a JSON null and an Invalid JSON value error is reported.

• Because multi-valued indexes are virtual indexes on virtual columns, they must adhere to the same rules as secondary indexes on virtual generated columns.

• Index records are not added for empty arrays.

Limitations and Restrictions on Multi-valued Indexes

Multi-valued indexes are subject to the limitations and restrictions listed here:

• Only one multi-valued key part is permitted per multi-valued index. However, the CAST(... AS ... ARRAY) expression can refer to multiple arrays within a JSON document, as shown here:

  \[
  \text{CAST(data->'$.arr[*][*]' AS UNSIGNED ARRAY)}
  \]

  In this case, all values matching the JSON expression are stored in the index as a single flat array.

• An index with a multi-valued key part does not support ordering and therefore cannot be used as a primary key. For the same reason, a multi-valued index cannot be defined using the ASC or DESC keyword.

• A multi-valued index cannot be a covering index.

• The maximum number of values per record for a multi-valued index is determined by the amount of data than can be stored on a single undo log page, which is 65221 bytes (64K minus 315 bytes for overhead), which means that the maximum total length of key values is also 65221 bytes. The maximum number of keys depends on various factors, which prevents defining a specific limit. Tests have shown a multi-valued index to permit as many as 1604 integer keys per record, for example. When the limit is reached, an error similar to the following is reported: ERROR 3905 (HY000): Exceeded max number of values per record for multi-valued index 'idx' by 1 value(s).
CREATE INDEX Statement

- The only type of expression that is permitted in a multi-valued key part is a JSON expression. The expression need not reference an existing element in a JSON document inserted into the indexed column, but must itself be syntactically valid.

- Because index records for the same clustered index record are dispersed throughout a multi-valued index, a multi-valued index does not support range scans or index-only scans.

- Multi-valued indexes are not permitted in foreign key specifications.

- Index prefixes cannot be defined for multi-valued indexes.

- Multi-valued indexes cannot be defined on data cast as BINARY (see the description of the CAST() function).

- Online creation of a multi-value index is not supported, which means the operation uses ALGORITHM=COPY. See Performance and Space Requirements.

- Character sets and collations other than the following two combinations of character set and collation are not supported for multi-valued indexes:
  1. The binary character set with the default binary collation
  2. The utf8mb4 character set with the default utf8mb4_0900_as_cs collation.

- As with other indexes on columns of InnoDB tables, a multi-valued index cannot be created with USING HASH; attempting to do so results in a warning: This storage engine does not support the HASH index algorithm, storage engine default was used instead. (USING BTREE is supported as usual.)

Spatial Indexes

The MyISAM, InnoDB, NDB, and ARCHIVE storage engines support spatial columns such as POINT and GEOMETRY. (Section 13.4, “Spatial Data Types”, describes the spatial data types.) However, support for spatial column indexing varies among engines. Spatial and nonspatial indexes on spatial columns are available according to the following rules.

Spatial indexes on spatial columns have these characteristics:

- Available only for InnoDB and MyISAM tables. Specifying SPATIAL_INDEX for other storage engines results in an error.

- An index on a spatial column must be a SPATIAL index. The SPATIAL keyword is thus optional but implicit for creating an index on a spatial column.

- Available for single spatial columns only. A spatial index cannot be created over multiple spatial columns.

- Indexed columns must be NOT NULL.

- Column prefix lengths are prohibited. The full width of each column is indexed.

- Not permitted for a primary key or unique index.

Nonspatial indexes on spatial columns (created with INDEX, UNIQUE, or PRIMARY KEY) have these characteristics:

- Permitted for any storage engine that supports spatial columns except ARCHIVE.

- Columns can be NULL unless the index is a primary key.

- The index type for a non-SPATIAL index depends on the storage engine. Currently, B-tree is used.

- Permitted for a column that can have NULL values only for InnoDB, MyISAM, and MEMORY tables.
Index Options

Following the key part list, index options can be given. An `index_option` value can be any of the following:

- **KEY_BLOCK_SIZE [=] value**

  For *MyISAM* tables, `KEY_BLOCK_SIZE` optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A `KEY_BLOCK_SIZE` value specified for an individual index definition overrides a table-level `KEY_BLOCK_SIZE` value.

  `KEY_BLOCK_SIZE` is not supported at the index level for *InnoDB* tables. See Section 15.1.20, “CREATE TABLE Statement”.

- **index_type**

  Some storage engines permit you to specify an index type when creating an index. For example:

  ```sql
  CREATE TABLE lookup (id INT) ENGINE = MEMORY;
  CREATE INDEX id_index ON lookup (id) USING BTREE;
  ```

  Table 15.1, “Index Types Per Storage Engine” shows the permissible index type values supported by different storage engines. Where multiple index types are listed, the first one is the default when no index type specifier is given. Storage engines not listed in the table do not support an `index_type` clause in index definitions.

<table>
<thead>
<tr>
<th>Storage Engine</th>
<th>Permissible Index Types</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>InnoDB</em></td>
<td>BTREE</td>
</tr>
<tr>
<td><em>MyISAM</em></td>
<td>BTREE</td>
</tr>
<tr>
<td>MEMORY/HEAP</td>
<td>HASH, BTREE</td>
</tr>
<tr>
<td><em>NDB</em></td>
<td>HASH, BTREE (see note in text)</td>
</tr>
</tbody>
</table>

  The `index_type` clause cannot be used for FULLTEXT INDEX specifications. Full-text index implementation is storage-engine dependent. Spatial indexes are implemented as R-tree indexes.

  If you specify an index type that is not valid for a given storage engine, but another index type is available that the engine can use without affecting query results, the engine uses the available type. The parser recognizes `RTREE` as a type name. This is permitted only for SPATIAL indexes.

  `BTREE` indexes are implemented by the *NDB* storage engine as T-tree indexes.

**Note**

For indexes on *NDB* table columns, the `USING` option can be specified only for a unique index or primary key. `USING HASH` prevents the creation of an ordered index; otherwise, creating a unique index or primary key on an *NDB* table automatically results in the creation of both an ordered index and a hash index, each of which indexes the same set of columns.

For unique indexes that include one or more NULL columns of an *NDB* table, the hash index can be used only to look up literal values, which means that `IS [NOT] NULL` conditions require a full scan of the table. One workaround is to make sure that a unique index using one or more NULL columns on such a table is always created in such a way that it includes the ordered index; that is, avoid employing `USING HASH` when creating the index.
If you specify an index type that is not valid for a given storage engine, but another index type is available that the engine can use without affecting query results, the engine uses the available type. The parser recognizes `RTREE` as a type name, but currently this cannot be specified for any storage engine.

**Note**

Use of the `index_type` option before the `ON tbl_name` clause is deprecated; expect support for use of the option in this position to be removed in a future MySQL release. If an `index_type` option is given in both the earlier and later positions, the final option applies.

`TYPE type_name` is recognized as a synonym for `USING type_name`. However, `USING` is the preferred form.

The following tables show index characteristics for the storage engines that support the `index_type` option.

**Table 15.2 InnoDB Storage Engine Index Characteristics**

</tr>
</tbody>
</table>

Table note:

1. **USING HASH** prevents creation of an implicit ordered index.

- **WITH PARSER parser_name**

This option can be used only with **FULLTEXT** indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. **InnoDB** and **MyISAM** support full-text parser plugins. If you have a **MyISAM** table with an associated full-text parser plugin, you can convert the table to **InnoDB** using **ALTER TABLE**. See **Full-Text Parser Plugins** and **Writing Full-Text Parser Plugins** for more information.

- **COMMENT 'string'**

Index definitions can include an optional comment of up to 1024 characters.

The **MERGE_THRESHOLD** for index pages can be configured for individual indexes using the **index_option COMMENT** clause of the **CREATE INDEX** statement. For example:

```sql
CREATE TABLE t1 (id INT);
CREATE INDEX id_index ON t1 (id) COMMENT 'MERGE_THRESHOLD=40';
```

If the page-full percentage for an index page falls below the **MERGE_THRESHOLD** value when a row is deleted or when a row is shortened by an update operation, **InnoDB** attempts to merge the index page with a neighboring index page. The default **MERGE_THRESHOLD** value is 50, which is the previously hardcoded value.

**MERGE_THRESHOLD** can also be defined at the index level and table level using **CREATE TABLE** and **ALTER TABLE** statements. For more information, see **Section 17.8.11, “Configuring the Merge Threshold for Index Pages”**.

- **VISIBLE, INVISIBLE**

Specify index visibility. Indexes are visible by default. An invisible index is not used by the optimizer. Specification of index visibility applies to indexes other than primary keys (either explicit or implicit). For more information, see **Section 10.3.12, “Invisible Indexes”**.
• The `ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` are used to specify index attributes for primary and secondary storage engines. The options are reserved for future use.

The value assigned to this option is a string literal containing a valid JSON document or an empty string (''). Invalid JSON is rejected.

```sql
CREATE INDEX i1 ON t1 (c1) ENGINE_ATTRIBUTE='{"key":"value"}';
```

`ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` values can be repeated without error. In this case, the last specified value is used.

`ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` values are not checked by the server, nor are they cleared when the table's storage engine is changed.

**Table Copying and Locking Options**

`ALGORITHM` and `LOCK` clauses may be given to influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the same meaning as for the `ALTER TABLE` statement. For more information, see Section 15.1.9, "ALTER TABLE Statement".

NDB Cluster supports online operations using the same `ALGORITHM=INPLACE` syntax used with the standard MySQL Server. See Section 25.6.12, "Online Operations with ALTER TABLE in NDB Cluster", for more information.

**15.1.16 CREATE LOGFILE GROUP Statement**

```sql
CREATE LOGFILE GROUP logfile_group
    ADD UNDOFILE 'undo_file'
    [INITIAL_SIZE [=] initial_size]
    [UNDO_BUFFER_SIZE [=] undo_buffer_size]
    [REDO_BUFFER_SIZE [=] redo_buffer_size]
    [NODEGROUP [=] nodegroup_id]
    [WAIT]
    [COMMENT [=] 'string']
    ENGINE [=] engine_name
```

This statement creates a new log file group named `logfile_group` having a single undo file named 'undo_file'. A `CREATE LOGFILE GROUP` statement has one and only one `ADD UNDOFILE` clause. For rules covering the naming of log file groups, see Section 11.2, "Schema Object Names".

**Note**

All NDB Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group with the same name, or a tablespace and a data file with the same name.

There can be only one log file group per NDB Cluster instance at any given time.

The optional `INITIAL_SIZE` parameter sets the undo file's initial size; if not specified, it defaults to 128M (128 megabytes). The optional `UNDO_BUFFER_SIZE` parameter sets the size used by the undo buffer for the log file group; The default value for `UNDO_BUFFER_SIZE` is 8M (eight megabytes); this value cannot exceed the amount of system memory available. Both of these parameters are specified in bytes. You may optionally follow either or both of these with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters `M` (for megabytes) or `G` (for gigabytes).

Memory used for `UNDO_BUFFER_SIZE` comes from the global pool whose size is determined by the value of the `SharedGlobalMemory` data node configuration parameter. This includes any default value implied for this option by the setting of the `InitialLogFileGroup` data node configuration parameter.
The maximum permitted for `UNDO_BUFFER_SIZE` is 629145600 (600 MB).

On 32-bit systems, the maximum supported value for `INITIAL_SIZE` is 4294967296 (4 GB). (Bug #29186)

The minimum allowed value for `INITIAL_SIZE` is 1048576 (1 MB).

The `ENGINE` option determines the storage engine to be used by this log file group, with `engine_name` being the name of the storage engine. This must be `NDB` (or `NDBCLUSTER`). If `ENGINE` is not set, MySQL tries to use the engine specified by the `default_storage_engine` server system variable. In any case, if the engine is not specified as `NDB` or `NDBCLUSTER`, the `CREATE LOGFILE GROUP` statement appears to succeed but actually fails to create the log file group, as shown here:

```
mysql> CREATE LOGFILE GROUP lg1
    -> ADD UNDOFILE 'undo.dat' INITIAL_SIZE = 10M;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-------+------+-------------------------------------------------------------------------------------------------------------------+
| Level | Code | Message                                                                                                             |
+-------+------+-------------------------------------------------------------------------------------------------------------------+
| Error | 1478 | Table storage engine 'InnoDB' does not support the create option 'TABLESPACE or LOGFILE GROUP'                     |
+-------+------+-------------------------------------------------------------------------------------------------------------------+
1 row in set (0.00 sec)
```

```
mysql> DROP LOGFILE GROUP lg1 ENGINE = NDB;
ERROR 1529 (HY000): Failed to drop LOGFILE GROUP
```

```
mysql> CREATE LOGFILE GROUP lg1
    -> ADD UNDOFILE 'undo.dat' INITIAL_SIZE = 10M
    -> ENGINE = NDB;
Query OK, 0 rows affected (2.97 sec)
```

The fact that the `CREATE LOGFILE GROUP` statement does not actually return an error when a storage engine other than `NDB` is specified, but rather appears to succeed, is a known issue which we hope to address in a future version of NDB Cluster.

`REDO_BUFFER_SIZE`, `NODEGROUP`, `WAIT`, and `COMMENT` are parsed but ignored, and so have no effect in MySQL 8.4. These options are intended for future expansion.

When used with `ENGINE [=] NDB`, a log file group and associated undo log file are created on each Cluster data node. You can verify that the undo files were created and obtain information about them by querying the Information Schema `FILES` table. For example:

```
mysql> SELECT LOGFILE_GROUP_NAME, LOGFILE_GROUP_NUMBER, EXTRA
    -> FROM INFORMATION_SCHEMA.FILES
    -> WHERE FILE_NAME = 'undo_10.dat';
+--------------------+----------------+----------------+
| LOGFILE_GROUP_NAME | LOGFILE_GROUP_NUMBER | EXTRA          |
+--------------------+----------------+----------------+
| lg_3               |                   11 | CLUSTER_NODE=3 |
| lg_3               |                   11 | CLUSTER_NODE=4 |
+--------------------+----------------+----------------+
2 rows in set (0.06 sec)
```

`CREATE LOGFILE GROUP` is useful only with Disk Data storage for NDB Cluster. See Section 25.6.11, “NDB Cluster Disk Data Tables”.

### 15.1.17 CREATE PROCEDURE and CREATE FUNCTION Statements

```
CREATE
    [DEFINER = user]
PROCEDURE [IF NOT EXISTS] sp_name ([proc_parameter[,....]])
    [characteristic ...] routine_body
```

```
CREATE
    [DEFINER = user]
FUNCTION [IF NOT EXISTS] sp_name ([func_parameter[,....]])
```
CREATE PROCEDURE and CREATE FUNCTION Statements

```
RETURNS type
[characteristic ...] routine_body

proc_parameter:
  [ IN | OUT | INOUT ] param_name type

func_parameter:
  param_name type

type:
  Any valid MySQL data type

characteristic: {
  COMMENT 'string'
  | LANGUAGE SQL
  | [NOT] DETERMINISTIC
  | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
}

routine_body:
  SQL routine
```

These statements are used to create a stored routine (a stored procedure or function). That is, the specified routine becomes known to the server. By default, a stored routine is associated with the default database. To associate the routine explicitly with a given database, specify the name as `db_name.sp_name` when you create it.

The `CREATE FUNCTION` statement is also used in MySQL to support loadable functions. See Section 15.7.4.1, “CREATE FUNCTION Statement for Loadable Functions”. A loadable function can be regarded as an external stored function. Stored functions share their namespace with loadable functions. See Section 11.2.5, “Function Name Parsing and Resolution”, for the rules describing how the server interprets references to different kinds of functions.

To invoke a stored procedure, use the `CALL` statement (see Section 15.2.1, “CALL Statement”). To invoke a stored function, refer to it in an expression. The function returns a value during expression evaluation.

`CREATE PROCEDURE` and `CREATE FUNCTION` require the `CREATE ROUTINE` privilege. If the `DEFINER` clause is present, the privileges required depend on the `user` value, as discussed in Section 27.6, “Stored Object Access Control”. If binary logging is enabled, `CREATE FUNCTION` might require the `SUPER` privilege, as discussed in Section 27.7, “Stored Program Binary Logging”.

By default, MySQL automatically grants the `ALTER ROUTINE` and `EXECUTE` privileges to the routine creator. This behavior can be changed by disabling the `automatic_sp_privileges` system variable. See Section 27.2.2, “Stored Routines and MySQL Privileges”.

The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at routine execution time, as described later in this section.

If the routine name is the same as the name of a built-in SQL function, a syntax error occurs unless you use a space between the name and the following parenthesis when defining the routine or invoking it later. For this reason, avoid using the names of existing SQL functions for your own stored routines.

The `IGNORE_SPACE` SQL mode applies to built-in functions, not to stored routines. It is always permissible to have spaces after a stored routine name, regardless of whether `IGNORE_SPACE` is enabled.

`IF NOT EXISTS` prevents an error from occurring if there already exists a routine with the same name. This option is supported with both `CREATE FUNCTION` and `CREATE PROCEDURE`.

If a built-in function with the same name already exists, attempting to create a stored function with `CREATE FUNCTION ... IF NOT EXISTS` succeeds with a warning indicating that it has the same name as a native function; this is no different than when performing the same `CREATE FUNCTION` statement without specifying `IF NOT EXISTS`. 
If a loadable function with the same name already exists, attempting to create a stored function using `IF NOT EXISTS` succeeds with a warning. This is the same as without specifying `IF NOT EXISTS`.

See Function Name Resolution, for more information.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of `()` should be used. Parameter names are not case-sensitive.

Each parameter is an `IN` parameter by default. To specify otherwise for a parameter, use the keyword `OUT` or `INOUT` before the parameter name.

Note

Specifying a parameter as `IN`, `OUT`, or `INOUT` is valid only for a `PROCEDURE`. For a `FUNCTION`, parameters are always regarded as `IN` parameters.

An `IN` parameter passes a value into a procedure. The procedure might modify the value, but the modification is not visible to the caller when the procedure returns. An `OUT` parameter passes a value from the procedure back to the caller. Its initial value is `NULL` within the procedure, and its value is visible to the caller when the procedure returns. An `INOUT` parameter is initialized by the caller, can be modified by the procedure, and any change made by the procedure is visible to the caller when the procedure returns.

For each `OUT` or `INOUT` parameter, pass a user-defined variable in the `CALL` statement that invokes the procedure so that you can obtain its value when the procedure returns. If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an `OUT` or `INOUT` parameter. If you are calling the procedure from within a trigger, you can also pass `NEW.col_name` as an `OUT` or `INOUT` parameter.

For information about the effect of unhandled conditions on procedure parameters, see Section 15.6.7.8, “Condition Handling and OUT or INOUT Parameters”.

Routine parameters cannot be referenced in statements prepared within the routine; see Section 27.8, “Restrictions on Stored Programs”.

The following example shows a simple stored procedure that, given a country code, counts the number of cities for that country that appear in the `city` table of the `world` database. The country code is passed using an `IN` parameter, and the city count is returned using an `OUT` parameter:

```sql
mysql> delimiter //
mysql> CREATE PROCEDURE citycount (IN country CHAR(3), OUT cities INT)
    BEGIN
    SELECT COUNT(*) INTO cities FROM world.city
    WHERE CountryCode = country;
    END//
Query OK, 0 rows affected (0.01 sec)
mysql> delimiter ;
mysql> CALL citycount('JPN', @cities); -- cities in Japan
Query OK, 1 row affected (0.00 sec)
mysql> SELECT @cities;
+---------+
| @cities |
| 248     |
+---------+
1 row in set (0.00 sec)
mysql> CALL citycount('FRA', @cities); -- cities in France
Query OK, 1 row affected (0.00 sec)
mysql> SELECT @cities;
+---------+
| @cities |
| 2466    |
+---------+
1 row in set (0.00 sec)
```
CREATE PROCEDURE and CREATE FUNCTION Statements

The example uses the `mysql` client `delimiter` command to change the statement delimiter from `;` to `//` while the procedure is being defined. This enables the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself. See Section 27.1, “Defining Stored Programs”.

The `RETURNS` clause may be specified only for a `FUNCTION`, for which it is mandatory. It indicates the return type of the function, and the function body must contain a `RETURN value` statement. If the `RETURN` statement returns a value of a different type, the value is coerced to the proper type. For example, if a function specifies an `ENUM` or `SET` value in the `RETURNS` clause, but the `RETURN` statement returns an integer, the value returned from the function is the string for the corresponding `ENUM` member of set of `SET` members.

The following example function takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal ; statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
mysql> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT hello('world');
+----------------+
| hello('world') |
+----------------+
| Hello, world! |
+----------------+
1 row in set (0.00 sec)
```

Parameter types and function return types can be declared to use any valid data type. The `COLLATE` attribute can be used if preceded by a `CHARACTER SET` specification.

The `routine_body` consists of a valid SQL routine statement. This can be a simple statement such as `SELECT` or `INSERT`, or a compound statement written using `BEGIN` and `END`. Compound statements can contain declarations, loops, and other control structure statements. The syntax for these statements is described in Section 15.6, “Compound Statement Syntax”. In practice, stored functions tend to use compound statements, unless the body consists of a single `RETURN` statement.

MySQL permits routines to contain DDL statements, such as `CREATE` and `DROP`. MySQL also permits stored procedures (but not stored functions) to contain SQL transaction statements such as `COMMIT`. Stored functions may not contain statements that perform explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to permit them.

Statements that return a result set can be used within a stored procedure but not within a stored function. This prohibition includes `SELECT` statements that do not have an INTO `var_list` clause and other statements such as `SHOW`, `EXPLAIN`, and `CHECK TABLE`. For statements that can be determined at function definition time to return a result set, a `Not allowed to return a result set` error occurs (`ER_SP_NO_RETSET`). For statements that can be determined only at runtime to return a result set, a `PROCEDURE %s can't return a result set in the given context` error occurs (`ER_SP_BADSELECT`).

`USE` statements within stored routines are not permitted. When a routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). The causes the routine to have the given default database while it executes. References to objects in databases other than the routine default database should be qualified with the appropriate database name.
CREATE PROCEDURE and CREATE FUNCTION Statements

For additional information about statements that are not permitted in stored routines, see Section 27.8, "Restrictions on Stored Programs".

For information about invoking stored procedures from within programs written in a language that has a MySQL interface, see Section 15.2.1, "CALL Statement".

MySQL stores the `sql_mode` system variable setting in effect when a routine is created or altered, and always executes the routine with this setting in force, regardless of the current server SQL mode when the routine begins executing.

The switch from the SQL mode of the invoker to that of the routine occurs after evaluation of arguments and assignment of the resulting values to routine parameters. If you define a routine in strict SQL mode but invoke it in nonstrict mode, assignment of arguments to routine parameters does not take place in strict mode. If you require that expressions passed to a routine be assigned in strict SQL mode, you should invoke the routine with strict mode in effect.

The `COMMENT` characteristic is a MySQL extension, and may be used to describe the stored routine. This information is displayed by the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements.

The `LANGUAGE` characteristic indicates the language in which the routine is written. The server ignores this characteristic; only SQL routines are supported.

A routine is considered “deterministic” if it always produces the same result for the same input parameters, and “not deterministic” otherwise. If neither `DETERMINISTIC` nor `NOT DETERMINISTIC` is given in the routine definition, the default is `NOT DETERMINISTIC`. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.

Assessment of the nature of a routine is based on the “honesty” of the creator: MySQL does not check that a routine declared `DETERMINISTIC` is free of statements that produce nondeterministic results. However, misdeclaring a routine might affect results or affect performance. Declaring a nondeterministic routine as `DETERMINISTIC` might lead to unexpected results by causing the optimizer to make incorrect execution plan choices. Declaring a deterministic routine as `NONDETERMINISTIC` might diminish performance by causing available optimizations not to be used.

If binary logging is enabled, the `DETERMINISTIC` characteristic affects which routine definitions MySQL accepts. See Section 27.7, “Stored Program Binary Logging”.

A routine that contains the `NOW()` function (or its synonyms) or `RAND()` is nondeterministic, but it might still be replication-safe. For `NOW()`, the binary log includes the timestamp and replicates correctly. `RAND()` also replicates correctly as long as it is called only a single time during the execution of a routine. (You can consider the routine execution timestamp and random number seed as implicit inputs that are identical on the source and replica.)

Several characteristics provide information about the nature of data use by the routine. In MySQL, these characteristics are advisory only. The server does not use them to constrain what kinds of statements a routine is permitted to execute.

- `CONTAINS SQL` indicates that the routine does not contain statements that read or write data. This is the default if none of these characteristics is given explicitly. Examples of such statements are `SET @x = 1` or `DO RELEASE_LOCK('abc')`, which execute but neither read nor write data.
- `NO SQL` indicates that the routine contains no SQL statements.
- `READS SQL DATA` indicates that the routine contains statements that read data (for example, `SELECT`), but not statements that write data.
- `MODIFIES SQL DATA` indicates that the routine contains statements that may write data (for example, `INSERT` or `DELETE`).

The `SQL SECURITY` characteristic can be `DEFINER` or `INVOKER` to specify the security context; that is, whether the routine executes using the privileges of the account named in the routine `DEFINER` clause
or the user who invokes it. This account must have permission to access the database with which
the routine is associated. The default value is DEFINER. The user who invokes the routine must have
the EXECUTE privilege for it, as must the DEFINER account if the routine executes in definer security
context.

The DEFINER clause specifies the MySQL account to be used when checking access privileges at
routine execution time for routines that have the SQL SECURITY DEFINER characteristic.

If the DEFINER clause is present, the user value should be a MySQL account specified as
'user_name'@'host_name', CURRENT_USER, or CURRENT_USER(). The permitted user values
depend on the privileges you hold, as discussed in Section 27.6, “Stored Object Access Control”. Also
see that section for additional information about stored routine security.

If the DEFINER clause is omitted, the default definer is the user who executes the CREATE
PROCEDURE or CREATE FUNCTION statement. This is the same as specifying DEFINER =
CURRENT_USER explicitly.

Within the body of a stored routine that is defined with the SQL SECURITY DEFINER characteristic,
the CURRENT_USER function returns the routine’s DEFINER value. For information about user auditing
within stored routines, see Section 8.2.23, “SQL-Based Account Activity Auditing”.

Consider the following procedure, which displays a count of the number of MySQL accounts listed in
the mysql.user system table:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
BEGIN
  SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure is assigned a DEFINER account of 'admin'@'localhost' no matter which user
defines it. It executes with the privileges of that account no matter which user invokes it (because the
default security characteristic is DEFINER). The procedure succeeds or fails depending on whether
invoker has the EXECUTE privilege for it and 'admin'@'localhost' has the SELECT privilege for the
mysql.user table.

Now suppose that the procedure is defined with the SQL SECURITY INVOKER characteristic:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
SQL SECURITY INVOKER
BEGIN
  SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure still has a DEFINER of 'admin'@'localhost', but in this case, it executes with the
privileges of the invoking user. Thus, the procedure succeeds or fails depending on whether the
invoker has the EXECUTE privilege for it and the SELECT privilege for the mysql.user table.

By default, when a routine with the SQL SECURITY DEFINER characteristic is executed, MySQL
Server does not set any active roles for the MySQL account named in the DEFINER clause, only the
default roles. The exception is if the activate_all_roles_on_login system variable is enabled, in
which case MySQL Server sets all roles granted to the DEFINER user, including mandatory roles. Any
privileges granted through roles are therefore not checked by default when the CREATE PROCEDURE
or CREATE FUNCTION statement is issued. For stored programs, if execution should occur with roles
different from the default, the program body can execute SET ROLE to activate the required roles. This
must be done with caution since the privileges assigned to roles can be changed.

The server handles the data type of a routine parameter, local routine variable created with DECLARE,
or function return value as follows:

- Assignments are checked for data type mismatches and overflow. Conversion and overflow
  problems result in warnings, or errors in strict SQL mode.
- Only scalar values can be assigned. For example, a statement such as SET x = (SELECT 1, 2)
  is invalid.
CREATE SERVER Statement

- For character data types, if `CHARACTER SET` is included in the declaration, the specified character set and its default collation is used. If the `COLLATE` attribute is also present, that collation is used rather than the default collation.

  If `CHARACTER SET` and `COLLATE` are not present, the database character set and collation in effect at routine creation time are used. To avoid having the server use the database character set and collation, provide an explicit `CHARACTER SET` and a `COLLATE` attribute for character data parameters.

  If you alter the database default character set or collation, stored routines that are to use the new database defaults must be dropped and recreated.

The database character set and collation are given by the value of the `character_set_database` and `collation_database` system variables. For more information, see Section 12.3.3, “Database Character Set and Collation”.

### 15.1.18 CREATE SERVER Statement

```
CREATE SERVER server_name
    FOREIGN DATA WRAPPER wrapper_name
    OPTIONS (option [, option] ...)
```

**Option:**

- `HOST character-literal`
- `DATABASE character-literal`
- `USER character-literal`
- `PASSWORD character-literal`
- `SOCKET character-literal`
- `OWNER character-literal`
- `PORT numeric-literal`

This statement creates the definition of a server for use with the `FEDERATED` storage engine. The `CREATE SERVER` statement creates a new row in the `servers` table in the `mysql` database. This statement requires the `SUPER` privilege.

The `server_name` should be a unique reference to the server. Server definitions are global within the scope of the server, it is not possible to qualify the server definition to a specific database. The `server_name` has a maximum length of 64 characters (names longer than 64 characters are silently truncated), and is case-insensitive. You may specify the name as a quoted string.

The `wrapper_name` is an identifier and may be quoted with single quotation marks.

For each `option` you must specify either a character literal or numeric literal. Character literals are UTF-8, support a maximum length of 64 characters and default to a blank (empty) string. String literals are silently truncated to 64 characters. Numeric literals must be a number between 0 and 9999, default value is 0.

**Note**

The `OWNER` option is currently not applied, and has no effect on the ownership or operation of the server connection that is created.

The `CREATE SERVER` statement creates an entry in the `mysql.servers` table that can later be used with the `CREATE TABLE` statement when creating a `FEDERATED` table. The options that you specify are used to populate the columns in the `mysql.servers` table. The table columns are `Server_name`, `Host`, `Db`, `Username`, `Password`, `Port` and `Socket`.

For example:

```
CREATE SERVER s
    FOREIGN DATA WRAPPER mysql
    OPTIONS (USER 'Remote', HOST '198.51.100.106', DATABASE 'test');
```
CREATE SPATIAL REFERENCE SYSTEM Statement

Be sure to specify all options necessary to establish a connection to the server. The user name, host name, and database name are mandatory. Other options might be required as well, such as password.

The data stored in the table can be used when creating a connection to a FEDERATED table:

```
CREATE TABLE t (s1 INT) ENGINE=FEDERATED CONNECTION='s';
```

For more information, see Section 18.8, “The FEDERATED Storage Engine”.

CREATE SERVER causes an implicit commit. See Section 15.3.3, “Statements That Cause an Implicit Commit”.

CREATE SERVER is not written to the binary log, regardless of the logging format that is in use.

15.1.19 CREATE SPATIAL REFERENCE SYSTEM Statement

```
CREATE OR REPLACE SPATIAL REFERENCE SYSTEM
   srid srs_attribute ...;

CREATE SPATIAL REFERENCE SYSTEM
   [IF NOT EXISTS]
   srid srs_attribute ...

srs_attribute: {  
   NAME 'srs_name'
   | DEFINITION 'definition'
   | ORGANIZATION 'org_name' IDENTIFIED BY org_id
   | DESCRIPTION 'description'
}

srid, org_id: 32-bit unsigned integer
```

This statement creates a spatial reference system (SRS) definition and stores it in the data dictionary. It requires the SUPER privilege. The resulting data dictionary entry can be inspected using the INFORMATION_SCHEMA.SPATIAL_REFERENCE_SYSTEMS table.

SRID values must be unique, so if neither OR REPLACE nor IF NOT EXISTS is specified, an error occurs if an SRS definition with the given srid value already exists.

With CREATE OR REPLACE syntax, any existing SRS definition with the same SRID value is replaced, unless the SRID value is used by some column in an existing table. In that case, an error occurs. For example:

```
mysql> CREATE OR REPLACE SPATIAL REFERENCE SYSTEM 4326 ...;
ERROR 3716 (SR005): Can't modify SRID 4326. There is at least one column depending on it.
```

To identify which column or columns use the SRID, use this query, replacing 4326 with the SRID of the definition you are trying to create:

```
SELECT * FROM INFORMATION_SCHEMA.ST_GEOMETRY_COLUMNS WHERE SRS_ID=4326;
```

With CREATE ... IF NOT EXISTS syntax, any existing SRS definition with the same SRID value causes the new definition to be ignored and a warning occurs.

SRID values must be in the range of 32-bit unsigned integers, with these restrictions:

- SRID 0 is a valid SRID but cannot be used with CREATE SPATIAL REFERENCE SYSTEM.
- If the value is in a reserved SRID range, a warning occurs. Reserved ranges are [0, 32767] (reserved by EPSG), [60,000,000, 69,999,999] (reserved by EPSG), and [2,000,000,000, 2,147,483,647] (reserved by MySQL). EPSG stands for the European Petroleum Survey Group.
- Users should not create SRSs with SRIDs in the reserved ranges. Doing so runs the risk of the SRIDs conflicting with future SRS definitions distributed with MySQL, with the result that the new system-provided SRSs are not installed for MySQL upgrades or that the user-defined SRSs are overwritten.
CREATE SPATIAL REFERENCE SYSTEM Statement

Attributes for the statement must satisfy these conditions:
• Attributes can be given in any order, but no attribute can be given more than once.
• The NAME and DEFINITION attributes are mandatory.
• The NAME srs_name attribute value must be unique. The combination of the ORGANIZATION
org_name and org_id attribute values must be unique.
• The NAME srs_name attribute value and ORGANIZATION org_name attribute value cannot be
empty or begin or end with whitespace.
• String values in attribute specifications cannot contain control characters, including newline.
• The following table shows the maximum lengths for string attribute values.
Table 15.6 CREATE SPATIAL REFERENCE SYSTEM Attribute Lengths

DESCRIPTION

2048

Here is an example CREATE SPATIAL REFERENCE SYSTEM statement. The DEFINITION value is
reformatted across multiple lines for readability. (For the statement to be legal, the value actually must
be given on a single line.)
CREATE SPATIAL REFERENCE SYSTEM 4120
NAME 'Greek'
ORGANIZATION 'EPSG' IDENTIFIED BY 4120
DEFINITION
'GEOGCS["Greek",DATUM["Greek",SPHEROID["Bessel 1841",
6377397.155,299.1528128,AUTHORITY["EPSG","7004"]],
AUTHORITY["EPSG","6120"]],PRIMEM["Greenwich",0,
AUTHORITY["EPSG","8901"]],UNIT["degree",0.017453292519943278,
AUTHORITY["EPSG","9122"]],AXIS["Lat",NORTH],AXIS["Lon",EAST],
AUTHORITY["EPSG","4120"]]';

The grammar for SRS definitions is based on the grammar defined in OpenGIS Implementation
Specification: Coordinate Transformation Services, Revision 1.00, OGC 01-009, January 12, 2001,
Section 7.2. This specification is available at http://www.opengeospatial.org/standards/ct.
MySQL incorporates these changes to the specification:
• Only the <horz cs> production rule is implemented (that is, geographic and projected SRSs).
• There is an optional, nonstandard <authority> clause for <parameter>. This makes it possible
to recognize projection parameters by authority instead of name.
• The specification does not make AXIS clauses mandatory in GEOGCS spatial reference system
definitions. However, if there are no AXIS clauses, MySQL cannot determine whether a definition
has axes in latitude-longitude order or longitude-latitude order. MySQL enforces the nonstandard
requirement that each GEOGCS definition must include two AXIS clauses. One must be NORTH or
SOUTH, and the other EAST or WEST. The AXIS clause order determines whether the definition has
axes in latitude-longitude order or longitude-latitude order.
• SRS definitions may not contain newlines.
If an SRS definition specifies an authority code for the projection (which is recommended), an error
occurs if the definition is missing mandatory parameters. In this case, the error message indicates what
the problem is. The projection methods and mandatory parameters that MySQL supports are shown

2472


The following table shows the projection methods that MySQL supports. MySQL permits unknown projection methods but cannot check the definition for mandatory parameters and cannot convert spatial data to or from an unknown projection. For detailed explanations of how each projection works, including formulas, see EPSG Guidance Note 7-2.

</table>

The following table shows the projection parameters that MySQL recognizes. Recognition occurs primarily by authority code. If there is no authority code, MySQL falls back to case-insensitive string matching on the parameter name. For details about each parameter, look it up by code in the EPSG Online Registry.

CREATE TABLE statement creates a table with the given name. You must have the CREATE privilege for the table.

By default, tables are created in the default database, using the InnoDB storage engine. An error occurs if the table exists, if there is no default database, or if the database does not exist.

MySQL has no limit on the number of tables. The underlying file system may have a limit on the number of files that represent tables. Individual storage engines may impose engine-specific constraints. InnoDB permits up to 4 billion tables.

For information about the physical representation of a table, see Section 15.1.20.1, “Files Created by CREATE TABLE”.

There are several aspects to the CREATE TABLE statement, described under the following topics in this section:

- Table Name
- Temporary Tables
- Table Cloning and Copying
- Column Data Types and Attributes
- Indexes, Foreign Keys, and CHECK Constraints
- Table Options
- Table Partitioning

**Table Name**

- `tbl_name`

The table name can be specified as `db_name.tbl_name` to create the table in a specific database. This works regardless of whether there is a default database, assuming that the database exists. If you use quoted identifiers, quote the database and table names separately. For example, write `mydb.` just before `mytbl`, not `mydb.mytbl`.

Rules for permissible table names are given in Section 11.2, “Schema Object Names”.

- IF NOT EXISTS

Prevents an error from occurring if the table exists. However, there is no verification that the existing table has a structure identical to that indicated by the CREATE TABLE statement.

**Temporary Tables**

You can use the TEMPORARY keyword when creating a table. A TEMPORARY table is visible only within the current session, and is dropped automatically when the session is closed. For more information, see Section 15.1.20.2, “CREATE TEMPORARY TABLE Statement”.

**Table Cloning and Copying**

- LIKE
Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```
CREATE TABLE new_tbl LIKE orig_tbl;
```

For more information, see Section 15.1.20.3, “CREATE TABLE ... LIKE Statement”.

- `[AS] query_expression

To create one table from another, add a `SELECT` statement at the end of the `CREATE TABLE` statement:

```
CREATE TABLE new_tbl AS SELECT * FROM orig_tbl;
```

For more information, see Section 15.1.20.4, “CREATE TABLE ... SELECT Statement”.

- `IGNORE` | `REPLACE`

The `IGNORE` and `REPLACE` options indicate how to handle rows that duplicate unique key values when copying a table using a `SELECT` statement.

For more information, see Section 15.1.20.4, “CREATE TABLE ... SELECT Statement”.

### Column Data Types and Attributes

There is a hard limit of 4096 columns per table, but the effective maximum may be less for a given table and depends on the factors discussed in Section 10.4.7, “Limits on Table Column Count and Row Size”.

- `data_type`

  `data_type` represents the data type in a column definition. For a full description of the syntax available for specifying column data types, as well as information about the properties of each type, see Chapter 13, `Data Types`.

  - `AUTO_INCREMENT` applies only to integer types.

  - Character data types (`CHAR`, `VARCHAR`, the `TEXT` types, `ENUM`, `SET`, and any synonyms) can include `CHARACTER SET` to specify the character set for the column. `CHARSET` is a synonym for `CHARACTER SET`. A collation for the character set can be specified with the `COLLATE` attribute, along with any other attributes. For details, see Chapter 12, `Character Sets, Collations, Unicode`. Example:

    ```
    CREATE TABLE t (c CHAR(20) CHARACTER SET utf8mb4 COLLATE utf8mb4_bin);
    ```

  MySQL 8.4 interprets length specifications in character column definitions in characters. Lengths for `BINARY` and `VARBINARY` are in bytes.

  - For `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` columns, indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length. `BLOB` and `TEXT` columns also can be indexed, but a prefix length `must` be given. Prefix lengths are given in characters for nonbinary string types and in bytes for binary string types. That is, index entries consist of the first `length` characters of each column value for `CHAR`, `VARCHAR`, and `TEXT` columns, and the first `length` bytes of each column value for `BINARY`, `VARBINARY`, and `BLOB` columns. Indexing only a prefix of column values like this can make the index file much smaller. For additional information about index prefixes, see Section 15.1.15, “CREATE INDEX Statement”.

    Only the `InnoDB` and `MyISAM` storage engines support indexing on `BLOB` and `TEXT` columns. For example:

    ```
    CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
    ```
If a specified index prefix exceeds the maximum column data type size, CREATE TABLE handles the index as follows:

- For a nonunique index, either an error occurs (if strict SQL mode is enabled), or the index length is reduced to lie within the maximum column data type size and a warning is produced (if strict SQL mode is not enabled).

- For a unique index, an error occurs regardless of SQL mode because reducing the index length might enable insertion of nonunique entries that do not meet the specified uniqueness requirement.

 JSON columns cannot be indexed. You can work around this restriction by creating an index on a generated column that extracts a scalar value from the JSON column. See Indexing a Generated Column to Provide a JSON Column Index, for a detailed example.

- **NOT NULL | NULL**

If neither NULL nor NOT NULL is specified, the column is treated as though NULL had been specified.

In MySQL 8.4, only the InnoDB, MyISAM, and MEMORY storage engines support indexes on columns that can have NULL values. In other cases, you must declare indexed columns as NOT NULL or an error results.

- **DEFAULT**

Specifies a default value for a column. For more information about default value handling, including the case that a column definition includes no explicit DEFAULT value, see Section 13.6, “Data Type Default Values”.

If the NO_ZERO_DATE or NO_ZERO_IN_DATE SQL mode is enabled and a date-valued default is not correct according to that mode, CREATE TABLE produces a warning if strict SQL mode is not enabled and an error if strict mode is enabled. For example, with NO_ZERO_IN_DATE enabled, c1 DATE DEFAULT '2010-00-00' produces a warning.

- **VISIBLE, INVISIBLE**

Specify column visibility. The default is VISIBLE if neither keyword is present. A table must have at least one visible column. Attempting to make all columns invisible produces an error. For more information, see Section 15.1.20.10, “Invisible Columns”.

- **AUTO_INCREMENT**

An integer column can have the additional attribute AUTO_INCREMENT. When you insert a value of NULL (recommended) or 0 into an indexed AUTO_INCREMENT column, the column is set to the next sequence value. Typically this is value+1, where value is the largest value for the column currently in the table. AUTO_INCREMENT sequences begin with 1.

To retrieve an AUTO_INCREMENT value after inserting a row, use the LAST_INSERT_ID() SQL function or the mysql_insert_id() C API function. See Section 14.15, “Information Functions”, and mysql_insert_id().

If the NO_AUTO_VALUE_ON_ZERO SQL mode is enabled, you can store 0 in AUTO_INCREMENT columns as 0 without generating a new sequence value. See Section 7.1.11, “Server SQL Modes”.

There can be only one AUTO_INCREMENT column per table, it must be indexed, and it cannot have a DEFAULT value. An AUTO_INCREMENT column works properly only if it contains only positive values. Inserting a negative number is regarded as inserting a very large positive number. This is done to avoid precision problems when numbers “wrap” over from positive to negative and also to ensure that you do not accidentally get an AUTO_INCREMENT column that contains 0.
For MySQL tables, you can specify an AUTO_INCREMENT secondary column in a multiple-column key. See Section 5.6.9, "Using AUTO_INCREMENT".

To make MySQL compatible with some ODBC applications, you can find the AUTO_INCREMENT value for the last inserted row with the following query:

```sql
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

This method requires that `sql_auto_is_null` variable is not set to 0. See Section 7.1.8, "Server System Variables".

For information about InnoDB and AUTO_INCREMENT, see Section 17.6.1.6, "AUTO_INCREMENT Handling in InnoDB". For information about AUTO_INCREMENT and MySQL Replication, see Section 19.5.1.1, "Replication and AUTO_INCREMENT".

**COMMENT**

A comment for a column can be specified with the `COMMENT` option, up to 1024 characters long. The comment is displayed by the `SHOW CREATE TABLE` and `SHOW FULL COLUMNS` statements. It is also shown in the `COLUMN_COMMENT` column of the Information Schema `COLUMNS` table.

**COLUMN_FORMAT**

In NDB Cluster, it is also possible to specify a data storage format for individual columns of NDB tables using `COLUMN_FORMAT`. Permissible column formats are FIXED, DYNAMIC, and DEFAULT. FIXED is used to specify fixed-width storage, DYNAMIC permits the column to be variable-width, and DEFAULT causes the column to use fixed-width or variable-width storage as determined by the column's data type (possibly overridden by a `ROW_FORMAT` specifier).

For NDB tables, the default value for `COLUMN_FORMAT` is FIXED.

In NDB Cluster, the maximum possible offset for a column defined with `COLUMN_FORMAT=FIXED` is 8188 bytes. For more information and possible workarounds, see Section 25.2.7.5, "Limits Associated with Database Objects in NDB Cluster".

`COLUMN_FORMAT` currently has no effect on columns of tables using storage engines other than NDB. MySQL 8.4 silently ignores `COLUMN_FORMAT`.

**ENGINE_ATTRIBUTE** and **SECONDARY_ENGINE_ATTRIBUTE** options are used to specify column attributes for primary and secondary storage engines. The options are reserved for future use.

The value assigned to this option is a string literal containing a valid JSON document or an empty string (""). Invalid JSON is rejected.

```sql
CREATE TABLE t1 (c1 INT ENGINE_ATTRIBUTE='{"key":"value"}');
```

`ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` values can be repeated without error. In this case, the last specified value is used.

`ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` values are not checked by the server, nor are they cleared when the table’s storage engine is changed.

**STORAGE**

For NDB tables, it is possible to specify whether the column is stored on disk or in memory by using a `STORAGE` clause. `STORAGE DISK` causes the column to be stored on disk, and `STORAGE MEMORY` causes in-memory storage to be used. The `CREATE TABLE` statement used must still include a `TABLESPACE` clause:

```sql
mysql> CREATE TABLE t1 {
  -> c1 INT STORAGE DISK,
  -> c2 INT STORAGE MEMORY
```
ERROR 1005 (HY000): Can't create table 'c.t1' (errno: 140)

mysql> CREATE TABLE t1 {
  -> c1 INT STORAGE DISK,
  -> c2 INT STORAGE MEMORY
  -> TABLESPACE ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.06 sec)

For **NDB** tables, **STORAGE DEFAULT** is equivalent to **STORAGE MEMORY**.

The **STORAGE** clause has no effect on tables using storage engines other than **NDB**. The **STORAGE** keyword is supported only in the build of **mysql** that is supplied with NDB Cluster; it is not recognized in any other version of MySQL, where any attempt to use the **STORAGE** keyword causes a syntax error.

- **GENERATED ALWAYS**

  Used to specify a generated column expression. For information about generated columns, see Section 15.1.20.8, “CREATE TABLE and Generated Columns”.

  **Stored generated columns** can be indexed. **InnoDB** supports secondary indexes on virtual generated columns. See Section 15.1.20.9, “Secondary Indexes and Generated Columns”.

**Indexes, Foreign Keys, and CHECK Constraints**

Several keywords apply to creation of indexes, foreign keys, and **CHECK** constraints. For general background in addition to the following descriptions, see Section 15.1.15, “CREATE INDEX Statement”, Section 15.1.20.5, “FOREIGN KEY Constraints”, and Section 15.1.20.6, “CHECK Constraints”.

- **CONSTRAINT symbol**

  The **CONSTRAINT symbol** clause may be given to name a constraint. If the clause is not given, or a **symbol** is not included following the **CONSTRAINT** keyword, MySQL automatically generates a constraint name, with the exception noted below. The **symbol** value, if used, must be unique per schema (database), per constraint type. A duplicate **symbol** results in an error. See also the discussion about length limits of generated constraint identifiers at Section 11.2.1, “Identifier Length Limits”.

  **Note**

  If the **CONSTRAINT symbol** clause is not given in a foreign key definition, or a **symbol** is not included following the **CONSTRAINT** keyword, MySQL automatically generates a constraint name.

  The SQL standard specifies that all types of constraints (primary key, unique index, foreign key, check) belong to the same namespace. In MySQL, each constraint type has its own namespace per schema. Consequently, names for each type of constraint must be unique per schema, but constraints of different types can have the same name.

- **PRIMARY KEY**

  A unique index where all key columns must be defined as **NOT NULL**. If they are not explicitly declared as **NOT NULL**, MySQL declares them so implicitly (and silently). A table can have only one **PRIMARY KEY**. The name of a **PRIMARY KEY** is always **PRIMARY**, which thus cannot be used as the name for any other kind of index.

  If you do not have a **PRIMARY KEY** and an application asks for the **PRIMARY KEY** in your tables, MySQL returns the first **UNIQUE** index that has no **NULL** columns as the **PRIMARY KEY**.
In InnoDB tables, keep the PRIMARY_KEY short to minimize storage overhead for secondary indexes. Each secondary index entry contains a copy of the primary key columns for the corresponding row. (See Section 17.6.2.1, “Clustered and Secondary Indexes”.)

In the created table, a PRIMARY_KEY is placed first, followed by all UNIQUE indexes, and then the nonunique indexes. This helps the MySQL optimizer to prioritize which index to use and also more quickly to detect duplicated UNIQUE keys.

A PRIMARY_KEY can be a multiple-column index. However, you cannot create a multiple-column index using the PRIMARY_KEY key attribute in a column specification. Doing so only marks that single column as primary. You must use a separate PRIMARY_KEY(key_part, ...) clause.

If a table has a PRIMARY_KEY or UNIQUE NOT NULL index that consists of a single column that has an integer type, you can use _rowid to refer to the indexed column in SELECT statements, as described in Unique Indexes.

In MySQL, the name of a PRIMARY_KEY is PRIMARY. For other indexes, if you do not assign a name, the index is assigned the same name as the first indexed column, with an optional suffix (_2, _3, ...) to make it unique. You can see index names for a table using SHOW INDEX FROM tbl_name. See Section 15.7.7.23, “SHOW INDEX Statement”.

- **KEY | INDEX**

  KEY is normally a synonym for INDEX. The key attribute PRIMARY_KEY can also be specified as just KEY when given in a column definition. This was implemented for compatibility with other database systems.

- **UNIQUE**

  A UNIQUE index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a UNIQUE index permits multiple NULL values for columns that can contain NULL. If you specify a prefix value for a column in a UNIQUE index, the column values must be unique within the prefix length.

  If a table has a PRIMARY_KEY or UNIQUE NOT NULL index that consists of a single column that has an integer type, you can use _rowid to refer to the indexed column in SELECT statements, as described in Unique Indexes.

- **FULLTEXT**

  A FULLTEXT index is a special type of index used for full-text searches. Only the InnoDB and MyISAM storage engines support FULLTEXT indexes. They can be created only from CHAR, VARCHAR, and TEXT columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See Section 14.9, “Full-Text Search Functions”, for details of operation. A WITH_PARSER clause can be specified as an index_option value to associate a parser plugin with the index if full-text indexing and searching operations need special handling. This clause is valid only for FULLTEXT indexes. InnoDB and MyISAM support full-text parser plugins. See Full-Text Parser Plugins and Writing Full-Text Parser Plugins for more information.

- **SPATIAL**

  You can create SPATIAL indexes on spatial data types. Spatial types are supported only for InnoDB and MyISAM tables, and indexed columns must be declared as NOT NULL. See Section 13.4, “Spatial Data Types”.
CREATE TABLE Statement

- **FOREIGN KEY**

MySQL supports foreign keys, which let you cross-reference related data across tables, and foreign key constraints, which help keep this spread-out data consistent. For definition and option information, see reference_definition and reference_option.

Partitioned tables employing the InnoDB storage engine do not support foreign keys. See Section 26.6, “Restrictions and Limitations on Partitioning”, for more information.

- **CHECK**

The CHECK clause enables the creation of constraints to be checked for data values in table rows. See Section 15.1.20.6, “CHECK Constraints”.

- **key_part**

  - A key_part specification can end with ASC or DESC to specify whether index values are stored in ascending or descending order. The default is ascending if no order specifier is given.

  - Prefixes, defined by the length attribute, can be up to 767 bytes long for InnoDB tables that use the REDUNDANT or COMPACT row format. The prefix length limit is 3072 bytes for InnoDB tables that use the DYNAMIC or COMPRESSED row format. For MyISAM tables, the prefix length limit is 1000 bytes.

Prefix limits are measured in bytes. However, prefix lengths for index specifications in CREATE TABLE, ALTER TABLE, and CREATE INDEX statements are interpreted as number of characters for nonbinary string types (CHAR, VARCHAR, TEXT) and number of bytes for binary string types (BINARY, VARBINARY, BLOB). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

  - The expr for a key_part specification can take the form (CAST json_path AS type ARRAY) to create a multi-valued index on a JSON column. Multi-Valued Indexes, provides detailed information regarding creation of, usage of, and restrictions and limitations on multi-valued indexes.

- **index_type**

Some storage engines permit you to specify an index type when creating an index. The syntax for the index_type specifier is USING type_name.

Example:

```sql
CREATE TABLE lookup
  (id INT, INDEX USING BTREE (id)) ENGINE = MEMORY;
```

The preferred position for USING is after the index column list. It can be given before the column list, but support for use of the option in that position is deprecated and you should expect it to be removed in a future MySQL release.

- **index_option**

  - index_option values specify additional options for an index.

  - **KEY_BLOCK_SIZE**

For MyISAM tables, KEY_BLOCK_SIZE optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A KEY_BLOCK_SIZE value specified for an individual index definition overrides the table-level KEY_BLOCK_SIZE value.

For information about the table-level KEY_BLOCK_SIZE attribute, see Table Options.
CREATE TABLE Statement

- WITH PARSER

  The WITH PARSER option can be used only with FULLTEXT indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. InnoDB and MyISAM support full-text parser plugins. If you have a MyISAM table with an associated full-text parser plugin, you can convert the table to InnoDB using ALTER TABLE.

- COMMENT

  Index definitions can include an optional comment of up to 1024 characters.

  You can set the InnoDB MERGE_THRESHOLD value for an individual index using the index_option COMMENT clause. See Section 17.8.11, “Configuring the Merge Threshold for Index Pages”.

- VISIBLE, INVISIBLE

  Specify index visibility. Indexes are visible by default. An invisible index is not used by the optimizer. Specification of index visibility applies to indexes other than primary keys (either explicit or implicit). For more information, see Section 10.3.12, “Invisible Indexes”.

- ENGINE_ATTRIBUTE and SECONDARY_ENGINE_ATTRIBUTE options are used to specify index attributes for primary and secondary storage engines. The options are reserved for future use.

  For more information about permissible index_option values, see Section 15.1.15, “CREATE INDEX Statement”. For more information about indexes, see Section 10.3.1, “How MySQL Uses Indexes”.

- reference_definition

  For reference_definition syntax details and examples, see Section 15.1.20.5, “FOREIGN KEY Constraints”.

  InnoDB and NDB tables support checking of foreign key constraints. The columns of the referenced table must always be explicitly named. Both ON DELETE and ON UPDATE actions on foreign keys are supported. For more detailed information and examples, see Section 15.1.20.5, “FOREIGN KEY Constraints”.

  For other storage engines, MySQL Server parses and ignores the FOREIGN KEY syntax in CREATE TABLE statements.

Important

For users familiar with the ANSI/ISO SQL Standard, please note that no storage engine, including InnoDB, recognizes or enforces the MATCH clause used in referential integrity constraint definitions. Use of an explicit MATCH clause does not have the specified effect, and also causes ON DELETE and ON UPDATE clauses to be ignored. For these reasons, specifying MATCH should be avoided.

The MATCH clause in the SQL standard controls how NULL values in a composite (multiple-column) foreign key are handled when comparing to a primary key. InnoDB essentially implements the semantics defined by MATCH SIMPLE, which permit a foreign key to be all or partially NULL. In that case, the (child table) row containing such a foreign key is permitted to be inserted, and does not match any row in the referenced (parent) table. It is possible to implement other semantics using triggers.

Additionally, MySQL requires that the referenced columns be indexed for performance. However, InnoDB does not enforce any requirement that the
CREATE TABLE Statement

referenced columns be declared **UNIQUE** or **NOT NULL**. The handling of foreign key references to nonunique keys or keys that contain **NULL** values is not well defined for operations such as **UPDATE** or **DELETE, CASCADE**. You are advised to use foreign keys that reference only keys that are both **UNIQUE** (or **PRIMARY**) and **NOT NULL**.

MySQL parses but ignores “inline **REFERENCES** specifications” (as defined in the SQL standard) where the references are defined as part of the column specification. MySQL accepts **REFERENCES** clauses only when specified as part of a separate **FOREIGN KEY** specification. For more information, see Section 1.7.2.3, “FOREIGN KEY Constraint Differences”.

• **reference_option**

For information about the **RESTRICT**, **CASCADE**, **SET NULL**, **NO ACTION**, and **SET DEFAULT** options, see Section 15.1.20.5, “FOREIGN KEY Constraints”.

Table Options

Table options are used to optimize the behavior of the table. In most cases, you do not have to specify any of them. These options apply to all storage engines unless otherwise indicated. Options that do not apply to a given storage engine may be accepted and remembered as part of the table definition. Such options then apply if you later use **ALTER TABLE** to convert the table to use a different storage engine.

• **ENGINE**

Specifies the storage engine for the table, using one of the names shown in the following table. The engine name can be unquoted or quoted. The quoted name ‘**DEFAULT**’ is recognized but ignored.

<table>
<thead>
<tr>
<th>Storage Engine</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>InnoDB</td>
<td>Transaction-safe tables with row locking and foreign keys. The default storage engine for new tables. See Chapter 17, <em>The InnoDB Storage Engine</em>, and in particular Section 17.1, “Introduction to InnoDB” if you have MySQL experience but are new to InnoDB.</td>
</tr>
<tr>
<td>MyISAM</td>
<td>The binary portable storage engine that is primarily used for read-only or read-mostly workloads. See Section 18.2, “The MyISAM Storage Engine”.</td>
</tr>
<tr>
<td>MEMORY</td>
<td>The data for this storage engine is stored only in memory. See Section 18.3, “The MEMORY Storage Engine”.</td>
</tr>
<tr>
<td>CSV</td>
<td>Tables that store rows in comma-separated values format. See Section 18.4, “The CSV Storage Engine”.</td>
</tr>
<tr>
<td>ARCHIVE</td>
<td>The archiving storage engine. See Section 18.5, “The ARCHIVE Storage Engine”.</td>
</tr>
<tr>
<td>EXAMPLE</td>
<td>An example engine. See Section 18.9, “The EXAMPLE Storage Engine”.</td>
</tr>
<tr>
<td>FEDERATED</td>
<td>Storage engine that accesses remote tables. See Section 18.8, “The FEDERATED Storage Engine”.</td>
</tr>
<tr>
<td>HEAP</td>
<td>This is a synonym for <strong>MEMORY</strong>.</td>
</tr>
</tbody>
</table>
CREATE TABLE Statement

<table>
<thead>
<tr>
<th>Storage Engine</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MERGE</td>
<td>A collection of MyISAM tables used as one table. Also known as MRG_MyISAM. See Section 18.7, “The MERGE Storage Engine”.</td>
</tr>
<tr>
<td>NDB</td>
<td>Clustered, fault-tolerant, memory-based tables, supporting transactions and foreign keys. Also known as NDBCLUSTER. See Chapter 25, MySQL NDB Cluster 8.4.</td>
</tr>
</tbody>
</table>

By default, if a storage engine is specified that is not available, the statement fails with an error. You can override this behavior by removing NO_ENGINE_SUBSTITUTION from the server SQL mode (see Section 7.1.11, “Server SQL Modes”) so that MySQL allows substitution of the specified engine with the default storage engine instead. Normally in such cases, this is InnoDB, which is the default value for the default_storage_engine system variable. When NO_ENGINE_SUBSTITUTION is disabled, a warning occurs if the storage engine specification is not honored.

- **AUTOEXTEND_SIZE**

  Defines the amount by which InnoDB extends the size of the tablespace when it becomes full. The setting must be a multiple of 4MB. The default setting is 0, which causes the tablespace to be extended according to the implicit default behavior. For more information, see Section 17.6.3.9, “Tablespace AUTOEXTEND_SIZE Configuration”.

- **AUTO_INCREMENT**

  The initial AUTO_INCREMENT value for the table. In MySQL 8.4, this works for MyISAM, MEMORY, InnoDB, and ARCHIVE tables. To set the first auto-increment value for engines that do not support the AUTO_INCREMENT table option, insert a “dummy” row with a value one less than the desired value after creating the table, and then delete the dummy row.

  For engines that support the AUTO_INCREMENT table option in CREATE TABLE statements, you can also use ALTER TABLE tbl_name AUTO_INCREMENT = N to reset the AUTO_INCREMENT value. The value cannot be set lower than the maximum value currently in the column.

- **AVG_ROW_LENGTH**

  An approximation of the average row length for your table. You need to set this only for large tables with variable-size rows.

  When you create a MyISAM table, MySQL uses the product of the MAX_ROWS and AVG_ROW_LENGTH options to decide how big the resulting table is. If you don't specify either option, the maximum size for MyISAM data and index files is 256TB by default. (If your operating system does not support files that large, table sizes are constrained by the file size limit.) If you want to keep down the pointer sizes to make the index smaller and faster and you don't really need big files, you can decrease the default pointer size by setting the myisam_data_pointer_size system variable. (See Section 7.1.8, “Server System Variables”.) If you want all your tables to be able to grow above the default limit and are willing to have your tables slightly slower and larger than necessary, you can increase the default pointer size by setting this variable. Setting the value to 7 permits table sizes up to 65,536TB.

- **[DEFAULT] CHARACTER SET**

  Specifies a default character set for the table. CHARSET is a synonym for CHARACTER SET. If the character set name is DEFAULT, the database character set is used.

- **CHECKSUM**

  Set this to 1 if you want MySQL to maintain a live checksum for all rows (that is, a checksum that MySQL updates automatically as the table changes). This makes the table a little slower to update,
but also makes it easier to find corrupted tables. The CHECKSUM TABLE statement reports the checksum. (MyISAM only.)

- **[DEFAULT] COLLATE**

  Specifies a default collation for the table.

- **COMMENT**

  A comment for the table, up to 2048 characters long.

You can set the InnoDB MERGE_THRESHOLD value for a table using the `table_option COMMENT` clause. See Section 17.8.11, “Configuring the Merge Threshold for Index Pages”.

**Setting NDB_TABLE options.** The table comment in a CREATE TABLE that creates an NDB table or an ALTER TABLE statement which alters one can also be used to specify one to four of the NDB_TABLE options NOLOGGING, READ_BACKUP, PARTITION_BALANCE, or FULLY_REPLICATED as a set of name-value pairs, separated by commas if need be, immediately following the string NDB_TABLE= that begins the quoted comment text. An example statement using this syntax is shown here (emphasized text):

```sql
CREATE TABLE t1 (
  c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  c2 VARCHAR(100),
  c3 VARCHAR(100)
) ENGINE=NDB
COMMENT="NDB_TABLE=READ_BACKUP=0, PARTITION_BALANCE=FOR_RP_BY_NODE";
```

Spaces are not permitted within the quoted string. The string is case-insensitive.

The comment is displayed as part of the output of SHOW CREATE TABLE. The text of the comment is also available as the TABLE_COMMENT column of the MySQL Information Schema TABLES table.

This comment syntax is also supported with ALTER TABLE statements for NDB tables. Keep in mind that a table comment used with ALTER TABLE replaces any existing comment which the table might have had previously.

Setting the MERGE_THRESHOLD option in table comments is not supported for NDB tables (it is ignored).

For complete syntax information and examples, see Section 15.1.20.12, “Setting NDB Comment Options”.

- **COMPRESSION**

  The compression algorithm used for page level compression for InnoDB tables. Supported values include Zlib, LZ4, and None. The COMPRESSION attribute was introduced with the transparent page compression feature. Page compression is only supported with InnoDB tables that reside in file-per-table tablespaces, and is only available on Linux and Windows platforms that support sparse files and hole punching. For more information, see Section 17.9.2, “InnoDB Page Compression”.

- **CONNECTION**

  The connection string for a FEDERATED table.

  **Note**

  Older versions of MySQL used a COMMENT option for the connection string.
CREATE TABLE Statement

- DATA DIRECTORY, INDEX DIRECTORY

For InnoDB, the DATA DIRECTORY='directory' clause permits creating tables outside of the data directory. The innodb_file_per_table variable must be enabled to use the DATA DIRECTORY clause. The full directory path must be specified, and known to InnoDB. For more information, see Section 17.6.1.2, “Creating Tables Externally”.

When creating MyISAM tables, you can use the DATA DIRECTORY='directory' clause, the INDEX DIRECTORY='directory' clause, or both. They specify where to put a MyISAM table’s data file and index file, respectively. Unlike InnoDB tables, MySQL does not create subdirectories that correspond to the database name when creating a MyISAM table with a DATA DIRECTORY or INDEX DIRECTORY option. Files are created in the directory that is specified.

You must have the FILE privilege to use the DATA DIRECTORY or INDEX DIRECTORY table option.

Important
Table-level DATA DIRECTORY and INDEX DIRECTORY options are ignored for partitioned tables. (Bug #32091)

These options work only when you are not using the --skip-symbolic-links option. Your operating system must also have a working, thread-safe realpath() call. See Section 10.12.2.2, “Using Symbolic Links for MyISAM Tables on Unix”, for more complete information.

If a MyISAM table is created with no DATA DIRECTORY option, the .MYD file is created in the database directory. By default, if MyISAM finds an existing .MYD file in this case, it overwrites it. The same applies to .MYI files for tables created with no INDEX DIRECTORY option. To suppress this behavior, start the server with the --keep_files_on_create option, in which case MyISAM does not overwrite existing files and returns an error instead.

If a MyISAM table is created with a DATA DIRECTORY or INDEX DIRECTORY option and an existing .MYD or .MYI file is found, MyISAM always returns an error, and does not overwrite a file in the specified directory.

Important
You cannot use path names that contain the MySQL data directory with DATA DIRECTORY or INDEX DIRECTORY. This includes partitioned tables and individual table partitions. (See Bug #32167.)

- DELAY_KEY_WRITE

Set this to 1 if you want to delay key updates for the table until the table is closed. See the description of the delay_key_write system variable in Section 7.1.8, “Server System Variables”. (MyISAM only.)

- ENCRYPTION

The ENCRYPTION clause enables or disables page-level data encryption for an InnoDB table. A keyring plugin must be installed and configured before encryption can be enabled. The ENCRYPTION clause can be specified when creating a table in an a file-per-table tablespace, or when creating a table in a general tablespace.

A table inherits the default schema encryption if an ENCRYPTION clause is not specified. If the table_encryption_privilege_check variable is enabled, the TABLE_ENCRYPTION_ADMIN privilege is required to create a table with an ENCRYPTION clause setting that differs from the default schema encryption. When creating a table in a general tablespace, table and tablespace encryption must match.

Specifying an ENCRYPTION clause with a value other than 'N' or '' is not permitted when using a storage engine that does not support encryption.
For more information, see Section 17.13, “InnoDB Data-at-Rest Encryption”.

- The `ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` options are used to specify table attributes for primary and secondary storage engines. The options are reserved for future use.

  The value assigned to either of these options must be a string literal containing a valid JSON document or an empty string (""). Invalid JSON is rejected.

  ```
  CREATE TABLE t1 (c1 INT) ENGINE_ATTRIBUTE='{"key":"value"}';
  ```

  `ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` values can be repeated without error. In this case, the last specified value is used.

  `ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` values are not checked by the server, nor are they cleared when the table’s storage engine is changed.

- `INSERT_METHOD`

  If you want to insert data into a `MERGE` table, you must specify with `INSERT_METHOD` the table into which the row should be inserted. `INSERT_METHOD` is an option useful for `MERGE` tables only. Use a value of `FIRST` or `LAST` to have inserts go to the first or last table, or a value of `NO` to prevent inserts. See Section 18.7, “The MERGE Storage Engine”.

- `KEY_BLOCK_SIZE`

  For `MyISAM` tables, `KEY_BLOCK_SIZE` optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A `KEY_BLOCK_SIZE` value specified for an individual index definition overrides the table-level `KEY_BLOCK_SIZE` value.

  For `InnoDB` tables, `KEY_BLOCK_SIZE` specifies the page size in kilobytes to use for compressed `InnoDB` tables. The `KEY_BLOCK_SIZE` value is treated as a hint; a different size could be used by `InnoDB` if necessary. `KEY_BLOCK_SIZE` can only be less than or equal to the `innodb_page_size` value. A value of 0 represents the default compressed page size, which is half of the `innodb_page_size` value. Depending on `innodb_page_size`, possible `KEY_BLOCK_SIZE` values include 0, 1, 2, 4, 8, and 16. See Section 17.9.1, “InnoDB Table Compression” for more information.

  Oracle recommends enabling `innodb_strict_mode` when specifying `KEY_BLOCK_SIZE` for `InnoDB` tables. When `innodb_strict_mode` is enabled, specifying an invalid `KEY_BLOCK_SIZE` value returns an error. If `innodb_strict_mode` is disabled, an invalid `KEY_BLOCK_SIZE` value results in a warning, and the `KEY_BLOCK_SIZE` option is ignored.

  The `Create_options` column in response to `SHOW TABLE STATUS` reports the actual `KEY_BLOCK_SIZE` used by the table, as does `SHOW CREATE TABLE`.

  `InnoDB` only supports `KEY_BLOCK_SIZE` at the table level.

  `KEY_BLOCK_SIZE` is not supported with `32KB` and `64KB` `innodb_page_size` values. `InnoDB` table compression does not support these pages sizes.

  `InnoDB` does not support the `KEY_BLOCK_SIZE` option when creating temporary tables.
**CREATE TABLE Statement**

- **MAX_ROWS**

  The maximum number of rows you plan to store in the table. This is not a hard limit, but rather a hint to the storage engine that the table must be able to store at least this many rows.

  **Important**
  
  The use of `MAX_ROWS` with `NDB` tables to control the number of table partitions is deprecated. It remains supported in later versions for backward compatibility, but is subject to removal in a future release. Use `PARTITION_BALANCE` instead; see Setting `NDB_TABLE` options.

  The `NDB` storage engine treats this value as a maximum. If you plan to create very large NDB Cluster tables (containing millions of rows), you should use this option to ensure that `NDB` allocates sufficient number of index slots in the hash table used for storing hashes of the table's primary keys by setting `MAX_ROWS = 2 * rows`, where `rows` is the number of rows that you expect to insert into the table.

  The maximum `MAX_ROWS` value is 4294967295; larger values are truncated to this limit.

- **MIN_ROWS**

  The minimum number of rows you plan to store in the table. The `MEMORY` storage engine uses this option as a hint about memory use.

- **PACK_KEYS**

  Takes effect only with `MyISAM` tables. Set this option to 1 if you want to have smaller indexes. This usually makes updates slower and reads faster. Setting the option to 0 disables all packing of keys. Setting it to `DEFAULT` tells the storage engine to pack only long `CHAR`, `VARCHAR`, `BINARY`, or `VARBINARY` columns.

  If you do not use `PACK_KEYS`, the default is to pack strings, but not numbers. If you use `PACK_KEYS=1`, numbers are packed as well.

  When packing binary number keys, MySQL uses prefix compression:

  - Every key needs one extra byte to indicate how many bytes of the previous key are the same for the next key.
  - The pointer to the row is stored in high-byte-first order directly after the key, to improve compression.

  This means that if you have many equal keys on two consecutive rows, all following “same” keys usually only take two bytes (including the pointer to the row). Compare this to the ordinary case where the following keys take `storage_size_for_key + pointer_size` (where the pointer size is usually 4). Conversely, you get a significant benefit from prefix compression only if you have many numbers that are the same. If all keys are totally different, you use one byte more per key, if the key is not a key that can have `NULL` values. (In this case, the packed key length is stored in the same byte that is used to mark if a key is `NULL`.)

- **PASSWORD**

  This option is unused.

- **ROW_FORMAT**

  Defines the physical format in which the rows are stored.

  When creating a table with `strict mode` disabled, the storage engine’s default row format is used if the specified row format is not supported. The actual row format of the table is reported in the
Row_format column in response to SHOW TABLE STATUS. The Create_options column shows the row format that was specified in the CREATE TABLE statement, as does SHOW CREATE TABLE.

Row format choices differ depending on the storage engine used for the table.

For InnoDB tables:

- The default row format is defined by innodb_default_row_format, which has a default setting of DYNAMIC. The default row format is used when the ROW_FORMAT option is not defined or when ROW_FORMAT=DEFAULT is used.

  If the ROW_FORMAT option is not defined, or if ROW_FORMAT=DEFAULT is used, operations that rebuild a table also silently change the row format of the table to the default defined by innodb_default_row_format. For more information, see Defining the Row Format of a Table.

- For more efficient InnoDB storage of data types, especially BLOB types, use the DYNAMIC Row Format for requirements associated with the DYNAMIC row format.

- To enable compression for InnoDB tables, specify ROW_FORMAT=COMPRESSED. The ROW_FORMAT=COMPRESSED option is not supported when creating temporary tables. See Section 17.9, “InnoDB Table and Page Compression” for requirements associated with the COMPRESSED row format.

- The row format used in older versions of MySQL can still be requested by specifying the REDUNDANT row format.

- When you specify a non-default ROW_FORMAT clause, consider also enabling the innodb_strict_mode configuration option.

- ROW_FORMAT=FIXED is not supported. If ROW_FORMAT=FIXED is specified while innodb_strict_mode is disabled, InnoDB issues a warning and assumes ROW_FORMAT=DYNAMIC. If ROW_FORMAT=FIXED is specified while innodb_strict_mode is enabled, which is the default, InnoDB returns an error.

- For additional information about InnoDB row formats, see Section 17.10, “InnoDB Row Formats”.

For MyISAM tables, the option value can be FIXED or DYNAMIC for static or variable-length row format. myisampack sets the type to COMPRESSED. See Section 18.2.3, “MyISAM Table Storage Formats”.

For NDB tables, the default ROW_FORMAT is DYNAMIC.

- START TRANSACTION

  This is an internal-use table option, used to permit CREATE TABLE ... SELECT to be logged as a single, atomic transaction in the binary log when using row-based replication with a storage engine that supports atomic DDL. Only BINLOG, COMMIT, and ROLLBACK statements are permitted after CREATE TABLE ... START TRANSACTION. For related information, see Section 15.1.1, “Atomic Data Definition Statement Support”.

- STATS_AUTO_RECALC

  Specifies whether to automatically recalculate persistent statistics for an InnoDB table. The value DEFAULT causes the persistent statistics setting for the table to be determined by the innodb_stats_auto_recalc configuration option. The value 1 causes statistics to be recalculated when 10% of the data in the table has changed. The value 0 prevents automatic recalculation for this table; with this setting, issue an ANALYZE TABLE statement to recalculate the statistics after making substantial changes to the table. For more information about the persistent statistics feature, see Section 17.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”.

- STATS_PERSISTENT
Specifies whether to enable persistent statistics for an InnoDB table. The value DEFAULT causes the persistent statistics setting for the table to be determined by the innodb_stats_persistent configuration option. The value 1 enables persistent statistics for the table, while the value 0 turns off this feature. After enabling persistent statistics through a CREATE TABLE or ALTER TABLE statement, issue an ANALYZE TABLE statement to calculate the statistics, after loading representative data into the table. For more information about the persistent statistics feature, see Section 17.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”.

- **STATS_SAMPLE_PAGES**
  The number of index pages to sample when estimating cardinality and other statistics for an indexed column, such as those calculated by ANALYZE TABLE. For more information, see Section 17.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”.

- **TABLESPACE**
  The TABLESPACE clause can be used to create an InnoDB table in an existing general tablespace, a file-per-table tablespace, or the system tablespace.

  CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name

  The general tablespace that you specify must exist prior to using the TABLESPACE clause. For information about general tablespaces, see Section 17.6.3.3, “General Tablespaces”.

  The tablespace_name is a case-sensitive identifier. It may be quoted or unquoted. The forward slash character ("/") is not permitted. Names beginning with “innodb_” are reserved for special use.

  To create a table in the system tablespace, specify innodb_system as the tablespace name.

  CREATE TABLE tbl_name ... TABLESPACE [=] innodb_system

  Using TABLESPACE [=] innodb_system, you can place a table of any uncompressed row format in the system tablespace regardless of the innodb_file_per_table setting. For example, you can add a table with ROW_FORMAT=DYNAMIC to the system tablespace using TABLESPACE [=] innodb_system.

  To create a table in a file-per-table tablespace, specify innodb_file_per_table as the tablespace name.

  CREATE TABLE tbl_name ... TABLESPACE [=] innodb_file_per_table

  **Note**
  If innodb_file_per_table is enabled, you need not specify TABLESPACE=innodb_file_per_table to create an InnoDB file-per-table tablespace. InnoDB tables are created in file-per-table tablespaces by default when innodb_file_per_table is enabled.

  The DATA DIRECTORY clause is permitted with CREATE TABLE ...
  TABLESPACE=innodb_file_per_table but is otherwise not supported for use in combination with the TABLESPACE clause. The directory specified in a DATA DIRECTORY clause must be known to InnoDB. For more information, see Using the DATA DIRECTORY Clause.

  **Note**
  Support for TABLESPACE = innodb_file_per_table and TABLESPACE = innodb_temporary clauses with CREATE TEMPORARY TABLE is deprecated; expect it to be removed in a future version of MySQL.

  The STORAGE table option is employed only with NDB tables. STORAGE determines the type of storage used, and can be either of DISK or MEMORY.
TABLESPACE ... STORAGE DISK assigns a table to an NDB Cluster Disk Data tablespace. STORAGE DISK cannot be used in CREATE TABLE unless preceded by TABLESPACE tablespace_name.

For STORAGE MEMORY, the tablespace name is optional, thus, you can use TABLESPACE tablespace_name STORAGE MEMORY or simply STORAGE MEMORY to specify explicitly that the table is in-memory.

See Section 25.6.11, “NDB Cluster Disk Data Tables”, for more information.

• UNION

Used to access a collection of identical MyISAM tables as one. This works only with MERGE tables. See Section 18.7, “The MERGE Storage Engine”.

You must have SELECT, UPDATE, and DELETE privileges for the tables you map to a MERGE table.

Note
Formerly, all tables used had to be in the same database as the MERGE table itself. This restriction no longer applies.

Table Partitioning

partition_options can be used to control partitioning of the table created with CREATE TABLE.

Not all options shown in the syntax for partition_options at the beginning of this section are available for all partitioning types. Please see the listings for the following individual types for information specific to each type, and see Chapter 26, Partitioning, for more complete information about the workings of and uses for partitioning in MySQL, as well as additional examples of table creation and other statements relating to MySQL partitioning.

Partitions can be modified, merged, added to tables, and dropped from tables. For basic information about the MySQL statements to accomplish these tasks, see Section 15.1.9, “ALTER TABLE Statement”. For more detailed descriptions and examples, see Section 26.3, “Partition Management”.

• PARTITION BY

If used, a partition_options clause begins with PARTITION BY. This clause contains the function that is used to determine the partition; the function returns an integer value ranging from 1 to num, where num is the number of partitions. (The maximum number of user-defined partitions which a table may contain is 1024; the number of subpartitions—discussed later in this section—is included in this maximum.)

Note
The expression (expr) used in a PARTITION BY clause cannot refer to any columns not in the table being created; such references are specifically not permitted and cause the statement to fail with an error. (Bug #29444)

• HASH(expr)

Hashes one or more columns to create a key for placing and locating rows. expr is an expression using one or more table columns. This can be any valid MySQL expression (including MySQL functions) that yields a single integer value. For example, these are both valid CREATE TABLE statements using PARTITION BY HASH:

CREATE TABLE t1 (col1 INT, col2 CHAR(5))
PARTITION BY HASH(col1);

CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATETIME)
PARTITION BY HASH ( YEAR(col3) );
You may not use either `VALUES LESS THAN` or `VALUES IN` clauses with `PARTITION BY HASH`.

`PARTITION BY HASH` uses the remainder of `expr` divided by the number of partitions (that is, the modulus). For examples and additional information, see Section 26.2.4, “HASH Partitioning”.

The `LINEAR` keyword entails a somewhat different algorithm. In this case, the number of the partition in which a row is stored is calculated as the result of one or more logical `AND` operations. For discussion and examples of linear hashing, see Section 26.2.4.1, “LINEAR HASH Partitioning”.

- **KEY(`column_list`)**

  This is similar to `HASH`, except that MySQL supplies the hashing function so as to guarantee an even data distribution. The `column_list` argument is simply a list of 1 or more table columns (maximum: 16). This example shows a simple table partitioned by key, with 4 partitions:

  ```sql
  CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
  PARTITION BY KEY(col3)
  PARTITIONS 4;
  ```

  For tables that are partitioned by key, you can employ linear partitioning by using the `LINEAR` keyword. This has the same effect as with tables that are partitioned by `HASH`. That is, the partition number is found using the `&` operator rather than the modulus (see Section 26.2.4.1, “LINEAR HASH Partitioning”, and Section 26.2.5, “KEY Partitioning”, for details). This example uses linear partitioning by key to distribute data between 5 partitions:

  ```sql
  CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
  PARTITION BY LINEAR KEY(col3)
  PARTITIONS 5;
  ```

  The `ALGORITHM={1 | 2}` option is supported with `PARTITION BY [LINEAR] KEY`. `ALGORITHM=1` causes the server to use the same key-hashing functions as MySQL 5.1; `ALGORITHM=2` means that the server employs the key-hashing functions implemented and used by default for new `KEY` partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a MySQL 5.1 server.) Not specifying the option has the same effect as using `ALGORITHM=2`. This option is intended for use chiefly when upgrading or downgrading `[LINEAR] KEY` partitioned tables between MySQL 5.1 and later MySQL versions, or for creating tables partitioned by `KEY` or `LINEAR KEY` on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server. For more information, see Section 15.1.9.1, “ALTER TABLE Partition Operations”.

  `mysqldump` writes this option encased in versioned comments.

  `ALGORITHM=1` is shown when necessary in the output of `SHOW CREATE TABLE` using versioned comments in the same manner as `mysqldump`. `ALGORITHM=2` is always omitted from `SHOW CREATE TABLE` output, even if this option was specified when creating the original table.

  You may not use either `VALUES LESS THAN` or `VALUES IN` clauses with `PARTITION BY KEY`.

- **RANGE(`expr`)**

  In this case, `expr` shows a range of values using a set of `VALUES LESS THAN` operators. When using range partitioning, you must define at least one partition using `VALUES LESS THAN`. You cannot use `VALUES IN` with range partitioning.

  **Note**

  For tables partitioned by `RANGE`, `VALUES LESS THAN` must be used with either an integer literal value or an expression that evaluates to a single integer value. In MySQL 8.4, you can overcome this limitation in a table that
CREATE TABLE Statement is defined using `PARTITION BY RANGE COLUMNS`, as described later in this section.

Suppose that you have a table that you wish to partition on a column containing year values, according to the following scheme.

<table>
<thead>
<tr>
<th>Partition Number</th>
<th>Years Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1990 and earlier</td>
</tr>
<tr>
<td>1</td>
<td>1991 to 1994</td>
</tr>
<tr>
<td>2</td>
<td>1995 to 1998</td>
</tr>
<tr>
<td>3</td>
<td>1999 to 2002</td>
</tr>
<tr>
<td>4</td>
<td>2003 to 2005</td>
</tr>
<tr>
<td>5</td>
<td>2006 and later</td>
</tr>
</tbody>
</table>

A table implementing such a partitioning scheme can be realized by the `CREATE TABLE` statement shown here:

```sql
CREATE TABLE t1 (
    year_col  INT,
    some_data INT
) PARTITION BY RANGE (year_col) (
    PARTITION p0 VALUES LESS THAN (1991),
    PARTITION p1 VALUES LESS THAN (1995),
    PARTITION p2 VALUES LESS THAN (1999),
    PARTITION p3 VALUES LESS THAN (2002),
    PARTITION p4 VALUES LESS THAN (2006),
    PARTITION p5 VALUES LESS THAN MAXVALUE
);
```

`PARTITION ... VALUES LESS THAN ...` statements work in a consecutive fashion. `VALUES LESS THAN MAXVALUE` works to specify “leftover” values that are greater than the maximum value otherwise specified.

`VALUES LESS THAN` clauses work sequentially in a manner similar to that of the `case` portions of a `switch ... case` block (as found in many programming languages such as C, Java, and PHP). That is, the clauses must be arranged in such a way that the upper limit specified in each successive `VALUES LESS THAN` is greater than that of the previous one, with the one referencing `MAXVALUE` coming last of all in the list.

- **RANGE COLUMNS(column_list)**

This variant on `RANGE` facilitates partition pruning for queries using range conditions on multiple columns (that is, having conditions such as `WHERE a = 1 AND b < 10` or `WHERE a = 1 AND b = 10 AND c < 10`). It enables you to specify value ranges in multiple columns by using a list of columns in the `COLUMNS` clause and a set of column values in each `PARTITION ... VALUES LESS THAN (value_list)` partition definition clause. (In the simplest case, this set consists of a single column.) The maximum number of columns that can be referenced in the `column_list` and `value_list` is 16.

The `column_list` used in the `COLUMNS` clause may contain only names of columns; each column in the list must be one of the following MySQL data types: the integer types; the string types; and time or date column types. Columns using `BLOB`, `TEXT`, `SET`, `ENUM`, `BIT`, or spatial data types are not permitted; columns that use floating-point number types are also not permitted. You also may not use functions or arithmetic expressions in the `COLUMNS` clause.

The `VALUES LESS THAN` clause used in a partition definition must specify a literal value for each column that appears in the `COLUMNS()` clause; that is, the list of values used for each `VALUES LESS THAN` clause must contain the same number of values as there are columns listed in the
**COLUMNS clause.** An attempt to use more or fewer values in a `VALUES LESS THAN` clause than there are in the `COLUMNS` clause causes the statement to fail with the error *Inconsistency in usage of column lists for partitioning...*. You cannot use `NULL` for any value appearing in `VALUES LESS THAN`. It is possible to use `MAXVALUE` more than once for a given column other than the first, as shown in this example:

```sql
CREATE TABLE rc (
    a INT NOT NULL,
    b INT NOT NULL
)
PARTITION BY RANGE COLUMNS(a,b) (
    PARTITION p0 VALUES LESS THAN (10,5),
    PARTITION p1 VALUES LESS THAN (20,10),
    PARTITION p2 VALUES LESS THAN (50,MAXVALUE),
    PARTITION p3 VALUES LESS THAN (65,MAXVALUE),
    PARTITION p4 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);
```

Each value used in a `VALUES LESS THAN` value list must match the type of the corresponding column exactly; no conversion is made. For example, you cannot use the string `'1'` for a value that matches a column that uses an integer type (you must use the numeral `1` instead), nor can you use the numeral `1` for a value that matches a column that uses a string type (in such a case, you must use a quoted string: `'1'`).

For more information, see Section 26.2.1, “RANGE Partitioning”, and Section 26.4, “Partition Pruning”.

- **LIST(expr)**

  This is useful when assigning partitions based on a table column with a restricted set of possible values, such as a state or country code. In such a case, all rows pertaining to a certain state or country can be assigned to a single partition, or a partition can be reserved for a certain set of states or countries. It is similar to `RANGE`, except that only `VALUES IN` may be used to specify permissible values for each partition.

  `VALUES IN` is used with a list of values to be matched. For instance, you could create a partitioning scheme such as the following:

  ```sql
  CREATE TABLE client_firms (
      id   INT,
      name VARCHAR(35)
  )
PARTITION BY LIST (id) (
    PARTITION r0 VALUES IN (1, 5, 9, 13, 17, 21),
    PARTITION r1 VALUES IN (2, 6, 10, 14, 18, 22),
    PARTITION r2 VALUES IN (3, 7, 11, 15, 19, 23),
    PARTITION r3 VALUES IN (4, 8, 12, 16, 20, 24)
  );
  ```

  When using list partitioning, you must define at least one partition using `VALUES IN`. You cannot use `VALUES LESS THAN` with `PARTITION BY LIST`.

  **Note**

  For tables partitioned by `LIST`, the value list used with `VALUES IN` must consist of integer values only. In MySQL 8.4, you can overcome this limitation using partitioning by `LIST COLUMNS`, which is described later in this section.

  - **LIST COLUMNS(column_list)**

    This variant on `LIST` facilitates partition pruning for queries using comparison conditions on multiple columns (that is, having conditions such as `WHERE a = 5 AND b = 5` or `WHERE a = 1 AND b = 10 AND c = 5`). It enables you to specify values in multiple columns by using a list of
columns in the `COLUMNS` clause and a set of column values in each `PARTITION ... VALUES IN (value_list)` partition definition clause.

The rules governing regarding data types for the column list used in `LIST COLUMNS(column_list)` and the value list used in `VALUES IN(value_list)` are the same as those for the column list used in `RANGE COLUMNS(column_list)` and the value list used in `VALUES LESS THAN(value_list)`, respectively, except that in the `VALUES IN` clause, `MAXVALUE` is not permitted, and you may use `NULL`.

There is one important difference between the list of values used for `VALUES IN` with `PARTITION BY LIST COLUMNS` as opposed to when it is used with `PARTITION BY LIST`. When used with `PARTITION BY LIST COLUMNS`, each element in the `VALUES IN` clause must be a set of column values; the number of values in each set must be the same as the number of columns used in the `COLUMNS` clause, and the data types of these values must match those of the columns (and occur in the same order). In the simplest case, the set consists of a single column. The maximum number of columns that can be used in the `column_list` and in the elements making up the `value_list` is 16.

The table defined by the following `CREATE TABLE` statement provides an example of a table using `LIST COLUMNS` partitioning:

```sql
CREATE TABLE lc (  
a INT NULL,
b INT NULL
)  
PARTITION BY LIST COLUMNS(a,b) (  
    PARTITION p0 VALUES IN( (0,0), (NULL,NULL) ),
    PARTITION p1 VALUES IN( (0,1), (0,2), (0,3), (1,1), (1,2) ),
    PARTITION p2 VALUES IN( (1,0), (2,0), (2,1), (3,0), (3,1) ),
    PARTITION p3 VALUES IN( (1,3), (2,2), (2,3), (3,2), (3,3) )
);
```

- **PARTITIONS num**

The number of partitions may optionally be specified with a `PARTITIONS num` clause, where `num` is the number of partitions. If both this clause and any `PARTITION` clauses are used, `num` must be equal to the total number of any partitions that are declared using `PARTITION` clauses.

**Note**

Whether or not you use a `PARTITIONS` clause in creating a table that is partitioned by `RANGE` or `LIST`, you must still include at least one `PARTITION VALUES` clause in the table definition (see below).

- **SUBPARTITION BY**

A partition may optionally be divided into a number of subpartitions. This can be indicated by using the optional `SUBPARTITION BY` clause. Subpartitioning may be done by `HASH` or `KEY`. Either of these may be `LINEAR`. These work in the same way as previously described for the equivalent partitioning types. (It is not possible to subpartition by `LIST` or `RANGE`.)

The number of subpartitions can be indicated using the `SUBPARTITIONS` keyword followed by an integer value.

- **Rigorous checking of the value used in PARTITIONS or SUBPARTITIONS clauses is applied and this value must adhere to the following rules:**
  - The value must be a positive, nonzero integer.
  - No leading zeros are permitted.
  - The value must be an integer literal, and cannot not be an expression. For example, `PARTITIONS 0.2E+01` is not permitted, even though `0.2E+01` evaluates to `2` (Bug #15890)
CREATE TABLE Statement

• **partition_definition**

Each partition may be individually defined using a **partition_definition** clause. The individual parts making up this clause are as follows:

• **PARTITION** *partition_name*

  Specifies a logical name for the partition.

• **VALUES**

  For range partitioning, each partition must include a **VALUES LESS THAN** clause; for list partitioning, you must specify a **VALUES IN** clause for each partition. This is used to determine which rows are to be stored in this partition. See the discussions of partitioning types in Chapter 26, **Partitioning**, for syntax examples.

• **[STORAGE] ENGINE**

  MySQL accepts a **[STORAGE] ENGINE** option for both **PARTITION** and **SUBPARTITION**. Currently, the only way in which this option can be used is to set all partitions or all subpartitions to the same storage engine, and an attempt to set different storage engines for partitions or subpartitions in the same table raises the error **ERROR 1469 (HY000): The mix of handlers in the partitions is not permitted in this version of MySQL**.

• **COMMENT**

  An optional **COMMENT** clause may be used to specify a string that describes the partition. Example:

  ```
  COMMENT = 'Data for the years previous to 1999'
  ```

  The maximum length for a partition comment is 1024 characters.

• **DATA DIRECTORY** and **INDEX DIRECTORY**

  **DATA DIRECTORY** and **INDEX DIRECTORY** may be used to indicate the directory where, respectively, the data and indexes for this partition are to be stored. Both the **data_dir** and the **index_dir** must be absolute system path names.

  The directory specified in a **DATA DIRECTORY** clause must be known to **InnoDB**. For more information, see **Using the DATA DIRECTORY Clause**.

  You must have the **FILE** privilege to use the **DATA DIRECTORY** or **INDEX DIRECTORY** partition option.

  Example:

  ```sql
  CREATE TABLE th (id INT, name VARCHAR(30), adate DATE)
  PARTITION BY LIST(YEAR(adate))
      DATA DIRECTORY = '/var/appdata/95/data'
      INDEX DIRECTORY = '/var/appdata/95/idx',
      DATA DIRECTORY = '/var/appdata/96/data'
      INDEX DIRECTORY = '/var/appdata/96/idx',
      DATA DIRECTORY = '/var/appdata/97/data'
      INDEX DIRECTORY = '/var/appdata/97/idx',
      DATA DIRECTORY = '/var/appdata/98/data'
      INDEX DIRECTORY = '/var/appdata/98/idx'
  )
  ```
CREATE TABLE Statement

DATA DIRECTORY and INDEX DIRECTORY behave in the same way as in the CREATE TABLE statement’s table_option clause as used for MyISAM tables.

One data directory and one index directory may be specified per partition. If left unspecified, the data and indexes are stored by default in the table’s database directory.

The DATA DIRECTORY and INDEX DIRECTORY options are ignored for creating partitioned tables if NO_DIR_IN_CREATE is in effect.

- MAX_ROWS and MIN_ROWS

May be used to specify, respectively, the maximum and minimum number of rows to be stored in the partition. The values for max_number_of_rows and min_number_of_rows must be positive integers. As with the table-level options with the same names, these act only as “suggestions” to the server and are not hard limits.

- TABLESPACE

May be used to designate an InnoDB file-per-table tablespace for the partition by specifying TABLESPACE `innodb_file_per_table`. All partitions must belong to the same storage engine.

Placing InnoDB table partitions in shared InnoDB tablespaces is not supported. Shared tablespaces include the InnoDB system tablespace and general tablespaces.

- subpartition_definition

The partition definition may optionally contain one or more subpartition_definition clauses. Each of these consists at a minimum of the SUBPARTITION name, where name is an identifier for the subpartition. Except for the replacement of the PARTITION keyword with SUBPARTITION, the syntax for a subpartition definition is identical to that for a partition definition.

Subpartitioning must be done by HASH or KEY, and can be done only on RANGE or LIST partitions. See Section 26.2.6, “Subpartitioning”.

Partitioning by Generated Columns

Partitioning by generated columns is permitted. For example:

```sql
CREATE TABLE t1 (  
s1 INT,  
s2 INT AS (EXP(s1)) STORED
)  
PARTITION BY LIST (s2) (  
  PARTITION p1 VALUES IN (1)
);
```

Partitioning sees a generated column as a regular column, which enables workarounds for limitations on functions that are not permitted for partitioning (see Section 26.6.3, “Partitioning Limitations Relating to Functions”). The preceding example demonstrates this technique: EXP() cannot be used directly in the PARTITION BY clause, but a generated column defined using EXP() is permitted.

15.1.20.1 Files Created by CREATE TABLE

For an InnoDB table created in a file-per-table tablespace or general tablespace, table data and associated indexes are stored in a .ibd file in the database directory. When an InnoDB table is created in the system tablespace, table data and indexes are stored in the ibdata* files that represent the system tablespace. The innodb_file_per_table option controls whether tables are created in file-per-table tablespaces or the system tablespace, by default. The TABLESPACE option can be used to place a table in a file-per-table tablespace, general tablespace, or the system tablespace, regardless of the innodb_file_per_table setting.
For **MyISAM** tables, the storage engine creates data and index files. Thus, for each **MyISAM** table `tbl_name`, there are two disk files.

<table>
<thead>
<tr>
<th>File</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>tbl_name.MYD</code></td>
<td>Data file</td>
</tr>
<tr>
<td><code>tbl_name.MYI</code></td>
<td>Index file</td>
</tr>
</tbody>
</table>

Chapter 18, *Alternative Storage Engines*, describes what files each storage engine creates to represent tables. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in Section 11.2.4, “Mapping of Identifiers to File Names”.

15.1.20.2 CREATE TEMPORARY TABLE Statement

You can use the **TEMPORARY** keyword when creating a table. A **TEMPORARY** table is visible only within the current session, and is dropped automatically when the session is closed. This means that two different sessions can use the same temporary table name without conflicting with each other or with an existing non-**TEMPORARY** table of the same name. (The existing table is hidden until the temporary table is dropped.)

**InnoDB** does not support compressed temporary tables. When `innodb_strict_mode` is enabled (the default), `CREATE TEMPORARY TABLE` returns an error if `ROW_FORMAT=COMPRESSED` or `KEY_BLOCK_SIZE` is specified. If `innodb_strict_mode` is disabled, warnings are issued and the temporary table is created using a non-compressed row format. The `innodb_file_per-table` option does not affect the creation of **InnoDB** temporary tables.

`CREATE TABLE` causes an implicit commit, except when used with the **TEMPORARY** keyword. See Section 15.3.3, “Statements ThatCause an Implicit Commit”.

**TEMPORARY** tables have a very loose relationship with databases (schemas). Dropping a database does not automatically drop any **TEMPORARY** tables created within that database.

To create a temporary table, you must have the **CREATE TEMPORARY TABLES** privilege. After a session has created a temporary table, the server performs no further privilege checks on the table. The creating session can perform any operation on the table, such as `DROP TABLE`, `INSERT`, `UPDATE`, or `SELECT`.

One implication of this behavior is that a session can manipulate its temporary tables even if the current user has no privilege to create them. Suppose that the current user does not have the **CREATE TEMPORARY TABLES** privilege but is able to execute a definer-context stored procedure that executes with the privileges of a user who does have **CREATE TEMPORARY TABLES** and that creates a temporary table. While the procedure executes, the session uses the privileges of the defining user. After the procedure returns, the effective privileges revert to those of the current user, which can still see the temporary table and perform any operation on it.

You cannot use `CREATE TEMPORARY TABLE ... LIKE` to create an empty table based on the definition of a table that resides in the **mysql** tablespace, **InnoDB** system tablespace (**innodb_system**), or a general tablespace. The tablespace definition for such a table includes a **TABLESPACE** attribute that defines the tablespace where the table resides, and the aforementioned tablespaces do not support temporary tables. To create a temporary table based on the definition of such a table, use this syntax instead:

```sql
CREATE TEMPORARY TABLE new_tbl SELECT * FROM orig_tbl LIMIT 0;
```

**Note**

Support for **TABLESPACE = innodb_file_per_table** and **TABLESPACE = innodb_temporary** clauses with `CREATE TEMPORARY TABLE` is deprecated; expect it to be removed in a future version of MySQL.

15.1.20.3 CREATE TABLE ... LIKE Statement
Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```sql
CREATE TABLE new_tbl LIKE orig_tbl;
```

The copy is created using the same version of the table storage format as the original table. The `SELECT` privilege is required on the original table.

`LIKE` works only for base tables, not for views.

**Important**

You cannot execute `CREATE TABLE` or `CREATE TABLE ... LIKE` while a `LOCK TABLES` statement is in effect.

`CREATE TABLE ... LIKE` makes the same checks as `CREATE TABLE`. This means that if the current SQL mode is different from the mode in effect when the original table was created, the table definition might be considered invalid for the new mode and cause the statement to fail.

For `CREATE TABLE ... LIKE`, the destination table preserves generated column information from the original table.

For `CREATE TABLE ... LIKE`, the destination table preserves expression default values from the original table.

For `CREATE TABLE ... LIKE`, the destination table preserves CHECK constraints from the original table, except that all the constraint names are generated.

`CREATE TABLE ... LIKE` does not preserve any `DATA DIRECTORY` or `INDEX DIRECTORY` table options that were specified for the original table, or any foreign key definitions.

If the original table is a `TEMPORARY` table, `CREATE TABLE ... LIKE` does not preserve `TEMPORARY`. To create a `TEMPORARY` destination table, use `CREATE TEMPORARY TABLE ... LIKE`.

`CREATE TABLE ... LIKE` operations apply all `ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` values to the new table.

### 15.1.20.4 CREATE TABLE ... SELECT Statement

You can create one table from another by adding a `SELECT` statement at the end of the `CREATE TABLE` statement:

```sql
CREATE TABLE new_tbl [AS] SELECT * FROM orig_tbl;
```

MySQL creates new columns for all elements in the `SELECT`. For example:

```sql
mysql> CREATE TABLE test (a INT NOT NULL AUTO_INCREMENT,
  
  | PRIMARY KEY (a), KEY(b))
  
  ENGINE=InnoDB SELECT b,c FROM test2;
```

This creates an InnoDB table with three columns, a, b, and c. The `ENGINE` option is part of the `CREATE TABLE` statement, and should not be used following the `SELECT`; this would result in a syntax error. The same is true for other `CREATE TABLE` options such as `CHARSET`.

Notice that the columns from the `SELECT` statement are appended to the right side of the table, not overlapped onto it. Take the following example:

```sql
mysql> SELECT * FROM foo;
```

<table>
<thead>
<tr>
<th>n</th>
<th>l</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
</tr>
<tr>
<td>---</td>
<td></td>
</tr>
</tbody>
</table>
For each row in table `foo`, a row is inserted in `bar` with the values from `foo` and default values for the new columns.

In a table resulting from `CREATE TABLE ... SELECT`, columns named only in the `CREATE TABLE` part come first. Columns named in both parts or only in the `SELECT` part come after that. The data type of `SELECT` columns can be overridden by also specifying the column in the `CREATE TABLE` part.

For storage engines that support both atomic DDL and foreign key constraints, creation of foreign keys is not permitted in `CREATE TABLE ... SELECT` statements when row-based replication is in use. Foreign key constraints can be added later using `ALTER TABLE`.

You can precede the `SELECT` by `IGNORE` or `REPLACE` to indicate how to handle rows that duplicate unique key values. With `IGNORE`, rows that duplicate an existing row on a unique key value are discarded. With `REPLACE`, new rows replace rows that have the same unique key value. If neither `IGNORE` nor `REPLACE` is specified, duplicate unique key values result in an error. For more information, see The Effect of `IGNORE` on Statement Execution.

You can also use a `VALUES` statement in the `SELECT` part of `CREATE TABLE ... SELECT`; the `VALUES` portion of the statement must include a table alias using an `AS` clause. To name the columns coming from `VALUES`, supply column aliases with the table alias; otherwise, the default column names `column_0, column_1, column_2, ...`, are used.

Otherwise, naming of columns in the table thus created follows the same rules as described previously in this section. Examples:
CREATE TABLE Statement

mysql> CREATE TABLE tv4 (a INT, b INT, c INT);
mysql> SELECT * FROM (VALUES ROW(1,3,5), ROW(2,4,6)) AS v(x,y,z);

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>c</th>
<th>x</th>
<th>y</th>
<th>z</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>1</td>
<td>3</td>
<td>5</td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>2</td>
<td>4</td>
<td>6</td>
</tr>
</tbody>
</table>

mysql> CREATE TABLE tv5 (a INT, b INT, c INT);
mysql> SELECT * FROM (VALUES ROW(1,3,5), ROW(2,4,6)) AS v(a,b,c);

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3</td>
<td>5</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>6</td>
</tr>
</tbody>
</table>

When selecting all columns and using the default column names, you can omit `SELECT *`, so the statement just used to create table `tv1` can also be written as shown here:

mysql> CREATE TABLE tv1 VALUES ROW(1,3,5), ROW(2,4,6);

mysql> TABLE tv1;

<table>
<thead>
<tr>
<th>column_0</th>
<th>column_1</th>
<th>column_2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3</td>
<td>5</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>6</td>
</tr>
</tbody>
</table>

When using `VALUES` as the source of the `SELECT`, all columns are always selected into the new table, and individual columns cannot be selected as they can be when selecting from a named table; each of the following statements produces an error (`ER_OPERAND_COLUMNS`):

CREATE TABLE txv
    SELECT (x,z) FROM (VALUES ROW(1,3,5), ROW(2,4,6)) AS v(x,y,z);

CREATE TABLE txv (a INT, c INT)
    SELECT (x,z) FROM (VALUES ROW(1,3,5), ROW(2,4,6)) AS v(x,y,z);

Similarly, you can use a `TABLE` statement in place of the `SELECT`. This follows the same rules as with `VALUES`; all columns of the source table and their names in the source table are always inserted into the new table. Examples:

mysql> TABLE t1;

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>6</td>
<td>7</td>
</tr>
<tr>
<td>10</td>
<td>-4</td>
</tr>
<tr>
<td>14</td>
<td>6</td>
</tr>
</tbody>
</table>

mysql> CREATE TABLE tt1 TABLE t1;

mysql> TABLE tt1;

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>6</td>
<td>7</td>
</tr>
<tr>
<td>10</td>
<td>-4</td>
</tr>
<tr>
<td>14</td>
<td>6</td>
</tr>
</tbody>
</table>

mysql> CREATE TABLE tt2 (x INT) TABLE t1;

mysql> TABLE tt2;

+----+----|
<table>
<thead>
<tr>
<th>x</th>
<th>y</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>3</td>
<td>5</td>
</tr>
<tr>
<td>4</td>

</tr>
</tbody>
</table>

Because the ordering of the rows in the underlying SELECT statements cannot always be determined, CREATE TABLE ... IGNORE SELECT and CREATE TABLE ... REPLACE SELECT statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using MIXED mode. See also Section 19.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

CREATE TABLE ... SELECT does not automatically create any indexes for you. This is done intentionally to make the statement as flexible as possible. If you want to have indexes in the created table, you should specify these before the SELECT statement:

```sql
mysql> CREATE TABLE bar (UNIQUE (n)) SELECT n FROM foo;
```

For CREATE TABLE ... SELECT, the destination table does not preserve information about whether columns in the selected-from table are generated columns. The SELECT part of the statement cannot assign values to generated columns in the destination table.

For CREATE TABLE ... SELECT, the destination table does preserve expression default values from the original table.

Some conversion of data types might occur. For example, the AUTO_INCREMENT attribute is not preserved, and VARCHAR columns can become CHAR columns. Retrained attributes are NULL (or NOT NULL) and, for those columns that have them, CHARACTER SET, COLLATION, COMMENT, and the DEFAULT clause.

When creating a table with CREATE TABLE ... SELECT, make sure to alias any function calls or expressions in the query. If you do not, the CREATE statement might fail or result in undesirable column names.

```sql
CREATE TABLE artists_and_works
    SELECT artist.name, COUNT(work.artist_id) AS number_of_works
    FROM artist LEFT JOIN work ON artist.id = work.artist_id
    GROUP BY artist.id;
```

You can also explicitly specify the data type for a column in the created table:

```sql
CREATE TABLE foo (a TINYINT NOT NULL) SELECT b+1 AS a FROM bar;
```

For CREATE TABLE ... SELECT, if IF NOT EXISTS is given and the target table exists, nothing is inserted into the destination table, and the statement is not logged.

To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts during CREATE TABLE ... SELECT. For more information, see Section 15.1.1, “Atomic Data Definition Statement Support”.

You cannot use FOR UPDATE as part of the SELECT in a statement such as CREATE TABLE new_table SELECT ... FROM old_table ... If you attempt to do so, the statement fails.

CREATE TABLE ... SELECT operations apply ENGINE_ATTRIBUTE and SECONDARY_ENGINE_ATTRIBUTE values to columns only. Table and index ENGINE_ATTRIBUTE and SECONDARY_ENGINE_ATTRIBUTE values are not applied to the new table unless specified explicitly.

15.1.20.5 FOREIGN KEY Constraints

MySQL supports foreign keys, which permit cross-referencing related data across tables, and foreign key constraints, which help keep the related data consistent.
A foreign key relationship involves a parent table that holds the initial column values, and a child table with column values that reference the parent column values. A foreign key constraint is defined on the child table.

The essential syntax for defining a foreign key constraint in a `CREATE TABLE` or `ALTER TABLE` statement includes the following:

```
[CONSTRAINT [symbol]] FOREIGN KEY
[index_name] (col_name, ...)
REFERENCES tbl_name (col_name, ...)
[ON DELETE reference_option]
[ON UPDATE reference_option]

reference_option:
    RESTRICT | CASCADE | SET NULL | NO ACTION | SET DEFAULT
```

Foreign key constraint usage is described under the following topics in this section:

- **Identifiers**
- **Conditions and Restrictions**
- **Referential Actions**
- **Foreign Key Constraint Examples**
- **Adding Foreign Key Constraints**
- **Dropping Foreign Key Constraints**
- **Foreign Key Checks**
- **Locking**
- **Foreign Key Definitions and Metadata**
- **Foreign Key Errors**

**Identifiers**

Foreign key constraint naming is governed by the following rules:

- **The** `CONSTRAINT symbol` **value is used, if defined.**

- **If the** `CONSTRAINT symbol` **clause is not defined, or a symbol is not included following the** `CONSTRAINT` **keyword, a constraint name name is generated automatically.**

  If the `CONSTRAINT symbol` clause is not defined, or a symbol is not included following the `CONSTRAINT` keyword, both InnoDB and NDB storage engines ignore `FOREIGN_KEY index_name`.  

- **The** `CONSTRAINT symbol` **value, if defined, must be unique in the database. A duplicate symbol results in an error similar to:** `ERROR 1005 (HY000): Can't create table 'test.fk1' (errno: 121)`.  

- **NDB Cluster stores foreign key names using the same lettercase with which they are created.**

Table and column identifiers in a `FOREIGN KEY ... REFERENCES` clause can be quoted within backticks (``). Alternatively, double quotation marks (") can be used if the `ANSI_QUOTES` SQL mode is enabled. The `lower_case_table_names` system variable setting is also taken into account.

**Conditions and Restrictions**

Foreign key constraints are subject to the following conditions and restrictions:
CREATE TABLE Statement

- Parent and child tables must use the same storage engine, and they cannot be defined as temporary tables.

- Creating a foreign key constraint requires the REFERENCES privilege on the parent table.

- Corresponding columns in the foreign key and the referenced key must have similar data types. The size and sign of fixed precision types such as INTEGER and DECIMAL must be the same. The length of string types need not be the same. For nonbinary (character) string columns, the character set and collation must be the same.

- MySQL supports foreign key references between one column and another within a table. (A column cannot have a foreign key reference to itself.) In these cases, a “child table record” refers to a dependent record within the same table.

- MySQL requires indexes on foreign keys and referenced keys so that foreign key checks can be fast and not require a table scan. In the referencing table, there must be an index where the foreign key columns are listed as the first columns in the same order. Such an index is created on the referencing table automatically if it does not exist. This index might be silently dropped later if you create another index that can be used to enforce the foreign key constraint. index_name, if given, is used as described previously.

- Previously, InnoDB allowed a foreign key to reference any index column or group of columns, even a non-unique index or partial index, an extension of standard SQL. This is still allowed for backwards compatibility, but is now deprecated; in addition, it must be enabled by setting restrict_fk_on_non_standard_key. If this is done, there must still be an index in the referenced table where the referenced columns are the first columns in the same order. Hidden columns that InnoDB adds to an index are also considered in such cases (see Section 17.6.2.1, “Clustered and Secondary Indexes”). You should expect support for use of nonstandard keys to be removed in a future version of MySQL, and migrate away from their use.

- NDB always requires an explicit unique key (or primary key) on any column referenced as a foreign key.

- Index prefixes on foreign key columns are not supported. Consequently, BLOB and TEXT columns cannot be included in a foreign key because indexes on those columns must always include a prefix length.

- InnoDB does not currently support foreign keys for tables with user-defined partitioning. This includes both parent and child tables.

  This restriction does not apply for NDB tables that are partitioned by KEY or LINEAR KEY (the only user partitioning types supported by the NDB storage engine); these may have foreign key references or be the targets of such references.

- A table in a foreign key relationship cannot be altered to use another storage engine. To change the storage engine, you must drop any foreign key constraints first.

- A foreign key constraint cannot reference a virtual generated column.

For information about how the MySQL implementation of foreign key constraints differs from the SQL standard, see Section 1.7.2.3, “FOREIGN KEY Constraint Differences”.

**Referential Actions**

When an UPDATE or DELETE operation affects a key value in the parent table that has matching rows in the child table, the result depends on the referential action specified by the ON UPDATE and ON DELETE subclauses of the FOREIGN KEY clause. Referential actions include:

- **CASCADE**: Delete or update the row from the parent table and automatically delete or update the matching rows in the child table. Both ON DELETE CASCADE and ON UPDATE CASCADE are supported. Between two tables, do not define several ON UPDATE CASCADE clauses that act on the same column in the parent table or in the child table.
If a FOREIGN KEY clause is defined on both tables in a foreign key relationship, making both tables a parent and child, an ON UPDATE CASCADE or ON DELETE CASCADE subclause defined for one FOREIGN KEY clause must be defined for the other in order for cascading operations to succeed. If an ON UPDATE CASCADE or ON DELETE CASCADE subclause is only defined for one FOREIGN KEY clause, cascading operations fail with an error.

Note
Cascaded foreign key actions do not activate triggers.

- **SET NULL**: Delete or update the row from the parent table and set the foreign key column or columns in the child table to NULL. Both ON DELETE SET NULL and ON UPDATE SET NULL clauses are supported.

  If you specify a SET NULL action, make sure that you have not declared the columns in the child table as NOT NULL.

- **RESTRICT**: Rejects the delete or update operation for the parent table. Specifying RESTRICT (or NO ACTION) is the same as omitting the ON DELETE or ON UPDATE clause.

- **NO ACTION**: A keyword from standard SQL. For InnoDB, this is equivalent to RESTRICT; the delete or update operation for the parent table is immediately rejected if there is a related foreign key value in the referenced table. NDB supports deferred checks, and NO ACTION specifies a deferred check; when this is used, constraint checks are not performed until commit time. Note that for NDB tables, this causes all foreign key checks made for both parent and child tables to be deferred.

- **SET DEFAULT**: This action is recognized by the MySQL parser, but both InnoDB and NDB reject table definitions containing ON DELETE SET DEFAULT or ON UPDATE SET DEFAULT clauses.

For storage engines that support foreign keys, MySQL rejects any INSERT or UPDATE operation that attempts to create a foreign key value in a child table if there is no matching candidate key value in the parent table.

For an ON DELETE or ON UPDATE that is not specified, the default action is always NO ACTION.

As the default, an ON DELETE NO ACTION or ON UPDATE NO ACTION clause that is specified explicitly does not appear in SHOW CREATE TABLE output or in tables dumped with mysqldump. RESTRICT, which is an equivalent non-default keyword, appears in SHOW CREATE TABLE output and in tables dumped with mysqldump.

For NDB tables, ON UPDATE CASCADE is not supported where the reference is to the parent table's primary key.

For NDB tables, ON DELETE CASCADE is not supported where the child table contains one or more columns of any of the TEXT or BLOB types. (Bug #89511, Bug #27484882)

InnoDB performs cascading operations using a depth-first search algorithm on the records of the index that corresponds to the foreign key constraint.

A foreign key constraint on a stored generated column cannot use CASCADE, SET NULL, or SET DEFAULT as ON UPDATE referential actions, nor can it use SET NULL or SET DEFAULT as ON DELETE referential actions.

A foreign key constraint on the base column of a stored generated column cannot use CASCADE, SET NULL, or SET DEFAULT as ON UPDATE or ON DELETE referential actions.

**Foreign Key Constraint Examples**

This simple example relates parent and child tables through a single-column foreign key:

```sql
CREATE TABLE parent {
```
This is a more complex example in which a `product_order` table has foreign keys for two other tables. One foreign key references a two-column index in the `product` table. The other references a single-column index in the `customer` table:

```sql
CREATE TABLE product (  
category INT NOT NULL, id INT NOT NULL,  
price DECIMAL,  
PRIMARY KEY(category, id)  
) ENGINE=INNODB;

CREATE TABLE customer (  
id INT NOT NULL,  
PRIMARY KEY (id)  
) ENGINE=INNODB;

CREATE TABLE product_order (  
nr INT NOT NULL AUTO_INCREMENT,  
product_category INT NOT NULL,  
product_id INT NOT NULL,  
customer_id INT NOT NULL,  
PRIMARY KEY(nr),  
INDEX (product_category, product_id),  
INDEX (customer_id),  
FOREIGN KEY (product_category, product_id)  
REFERENCES product(category, id)  
ON UPDATE CASCADE ON DELETE RESTRICT,  
FOREIGN KEY (customer_id)  
REFERENCES customer(id)  
) ENGINE=INNODB;
```

**Adding Foreign Key Constraints**

You can add a foreign key constraint to an existing table using the following `ALTER TABLE` syntax:

```sql
ALTER TABLE tbl_name  
ADD [CONSTRAINT [symbol]] FOREIGN KEY  
[index_name] (col_name, ...)  
REFERENCES tbl_name (col_name,...)  
[ON DELETE reference_option]  
[ON UPDATE reference_option]
```

The foreign key can be self referential (referring to the same table). When you add a foreign key constraint to a table using `ALTER TABLE`, remember to first create an index on the column(s) referenced by the foreign key.

**Dropping Foreign Key Constraints**

You can drop a foreign key constraint using the following `ALTER TABLE` syntax:

```sql
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

If the `FOREIGN KEY` clause defined a `CONSTRAINT` name when you created the constraint, you can refer to that name to drop the foreign key constraint. Otherwise, a constraint name was generated.
CREATE TABLE Statement

Internally, and you must use that value. To determine the foreign key constraint name, use `SHOW CREATE TABLE`:

```sql
mysql> SHOW CREATE TABLE child
```

```
*************************** 1. row ***************************
Table: child
Create Table: CREATE TABLE `child` (
 `id` int DEFAULT NULL,
 `parent_id` int DEFAULT NULL,
KEY `par_ind` (`parent_id`),
CONSTRAINT `child_ibfk_1` FOREIGN KEY (`parent_id`)
REFERENCES `parent` (`id`) ON DELETE CASCADE
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
```

Adding and dropping a foreign key in the same `ALTER TABLE` statement is supported for `ALTER TABLE ... ALGORITHM=INPLACE`. It is not supported for `ALTER TABLE ... ALGORITHM=COPY`.

Foreign Key Checks

In MySQL, InnoDB and NDB tables support checking of foreign key constraints. Foreign key checking is controlled by the `foreign_key_checks` variable, which is enabled by default. Typically, you leave this variable enabled during normal operation to enforce referential integrity. The `foreign_key_checks` variable has the same effect on NDB tables as it does for InnoDB tables.

The `foreign_key_checks` variable is dynamic and supports both global and session scopes. For information about using system variables, see Section 7.1.9, “Using System Variables”.

Disabling foreign key checking is useful when:

- Dropping a table that is referenced by a foreign key constraint. A referenced table can only be dropped after `foreign_key_checks` is disabled. When you drop a table, constraints defined on the table are also dropped.

- Reloading tables in different order than required by their foreign key relationships. For example, `mysqldump` produces correct definitions of tables in the dump file, including foreign key constraints for child tables. To make it easier to reload dump files for tables with foreign key relationships, `mysqldump` automatically includes a statement in the dump output that disables `foreign_key_checks`. This enables you to import the tables in any order in case the dump file contains tables that are not correctly ordered for foreign keys. Disabling `foreign_key_checks` also speeds up the import operation by avoiding foreign key checks.

- Executing `LOAD DATA` operations, to avoid foreign key checking.

- Performing an `ALTER TABLE` operation on a table that has a foreign key relationship.

When `foreign_key_checks` is disabled, foreign key constraints are ignored, with the following exceptions:

- Recreating a table that was previously dropped returns an error if the table definition does not conform to the foreign key constraints that reference the table. The table must have the correct column names and types. It must also have indexes on the referenced keys. If these requirements are not satisfied, MySQL returns Error 1005 that refers to errno: 150 in the error message, which means that a foreign key constraint was not correctly formed.

- Altering a table returns an error (errno: 150) if a foreign key definition is incorrectly formed for the altered table.

- Dropping an index required by a foreign key constraint. The foreign key constraint must be removed before dropping the index.

- Creating a foreign key constraint where a column references a nonmatching column type.
Disabling `foreign_key_checks` has these additional implications:

- It is permitted to drop a database that contains tables with foreign keys that are referenced by tables outside the database.
- It is permitted to drop a table with foreign keys referenced by other tables.
- Enabling `foreign_key_checks` does not trigger a scan of table data, which means that rows added to a table while `foreign_key_checks` is disabled are not checked for consistency when `foreign_key_checks` is re-enabled.

### Locking

MySQL extends metadata locks, as necessary, to tables that are related by a foreign key constraint. Extending metadata locks prevents conflicting DML and DDL operations from executing concurrently on related tables. This feature also enables updates to foreign key metadata when a parent table is modified. In earlier MySQL releases, foreign key metadata, which is owned by the child table, could not be updated safely.

If a table is locked explicitly with `LOCK TABLES`, any tables related by a foreign key constraint are opened and locked implicitly. For foreign key checks, a shared read-only lock (`LOCK TABLES READ`) is taken on related tables. For cascading updates, a shared-nothing write lock (`LOCK TABLES WRITE`) is taken on related tables that are involved in the operation.

### Foreign Key Definitions and Metadata

To view a foreign key definition, use `SHOW CREATE TABLE`:

```
mysql> SHOW CREATE TABLE child
+-------------------------------+-------------------+
| Table: child                 |
| Create Table: CREATE TABLE `child` ( |
+-------------------------------+-------------------+
| `id` int DEFAULT NULL,       |
| `parent_id` int DEFAULT NULL,|
| KEY `par_ind` (`parent_id`), |
| CONSTRAINT `child_ibfk_1` FOREIGN KEY (`parent_id`) |
| REFERENCES `parent` (`id`) ON DELETE CASCADE |
+-------------------------------+-------------------+
ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
```

You can obtain information about foreign keys from the Information Schema `KEY_COLUMN_USAGE` table. An example of a query against this table is shown here:

```
mysql> SELECT TABLE_SCHEMA, TABLE_NAME, COLUMN_NAME, CONSTRAINT_NAME FROM INFORMATION_SCHEMA.KEY_COLUMN_USAGE WHERE REFERENCED_TABLE_SCHEMA IS NOT NULL;
```

You can obtain information specific to InnoDB foreign keys from the `INNODB_FOREIGN` and `INNODB_FOREIGN_COLS` tables. Example queries are show here:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FOREIGN
```

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FOREIGN_COLS
```
CREATE TABLE Statement

**Foreign Key Errors**

In the event of a foreign key error involving InnoDB tables (usually Error 150 in the MySQL Server), information about the latest foreign key error can be obtained by checking `SHOW ENGINE INNODB STATUS` output.

```
mysql> SHOW ENGINE INNODB STATUS;
```

```
LATEST FOREIGN KEY ERROR
------------------------
2018-04-12 14:57:24 0x7f97a9c91700 Transaction:
TRANSACTION 7717, ACTIVE 0 sec inserting
mysql tables in use 1, locked 1
4 lock struct(s), heap size 1136, 3 row lock(s), undo log entries 14
MySQL thread id 8, OS thread handle 140289365317376, query id 14
localhost root update
INSERT INTO child VALUES (NULL, 1), (NULL, 2), (NULL, 3), (NULL, 4), (NULL, 5), (NULL, 6)
Foreign key constraint fails for table `test`.'child':
 CONSTRAINT `child_ibfk_1` FOREIGN KEY (`parent_id`) REFERENCES `parent` (`id`) ON DELETE CASCADE ON UPDATE CASCADE
Trying to add in child table, in index par_ind tuple:
DATA TUPLE: 2 fields;
0: len 4; hex 80000003; asc ;;
1: len 4; hex 80000003; asc ;;
But in parent table `test`.'parent', in index PRIMARY,
the closest match we can find is record:
PHYSICAL RECORD: n_fields 3; compact format; info bits 0
0: len 4; hex 80000004; asc ;;
1: len 6; hex 00000001e19; asc ;;
2: len 7; hex 81000001110137; asc 7;;
```

**Warning**

If a user has table-level privileges for all parent tables, `ER_NO_REFERENCED_ROW_2` and `ER_ROW_IS_REFERENCED_2` error messages for foreign key operations expose information about parent tables. If a user does not have table-level privileges for all parent tables, more generic error messages are displayed instead (`ER_NO_REFERENCED_ROW` and `ER_ROW_IS_REFERENCED`).

An exception is that, for stored programs defined to execute with `DEFINER` privileges, the user against which privileges are assessed is the user in the program `DEFINER` clause, not the invoking user. If that user has table-level parent table privileges, parent table information is still displayed. In this case, it is the responsibility of the stored program creator to hide the information by including appropriate condition handlers.

### 15.1.20.6 CHECK Constraints

`CREATE TABLE` permits the core features of table and column `CHECK` constraints, for all storage engines. `CREATE TABLE` permits the following `CHECK` constraint syntax, for both table constraints and column constraints:

```
[CONSTRAINT [symbol:]] CHECK (expr) [[NOT] ENFORCED]
```

The optional `symbol` specifies a name for the constraint. If omitted, MySQL generates a name from the table name, a literal `_chk_`, and an ordinal number (1, 2, 3, ...). Constraint names have a maximum length of 64 characters. They are case-sensitive, but not accent-sensitive.

`expr` specifies the constraint condition as a boolean expression that must evaluate to `TRUE` or `UNKNOWN` (for `NULL` values) for each row of the table. If the condition evaluates to `FALSE`, it fails and...
a constraint violation occurs. The effect of a violation depends on the statement being executed, as
described later in this section.

The optional enforcement clause indicates whether the constraint is enforced:

- If omitted or specified as **ENFORCED**, the constraint is created and enforced.
- If specified as **NOT ENFORCED**, the constraint is created but not enforced.

A **CHECK** constraint is specified as either a table constraint or column constraint:

- A table constraint does not appear within a column definition and can refer to any table column or
columns. Forward references are permitted to columns appearing later in the table definition.
- A column constraint appears within a column definition and can refer only to that column.

Consider this table definition:

```sql
CREATE TABLE t1
(
  CHECK (c1 <> c2),
  c1 INT CHECK (c1 > 10),
  c2 INT CONSTRAINT c2_positive CHECK (c2 > 0),
  c3 INT CHECK (c3 < 100),
  CONSTRAINT c1_nonzero CHECK (c1 <> 0),
  CHECK (c1 > c3)
);
```

The definition includes table constraints and column constraints, in named and unnamed formats:

- The first constraint is a table constraint: It occurs outside any column definition, so it can (and does)
  refer to multiple table columns. This constraint contains forward references to columns not defined
  yet. No constraint name is specified, so MySQL generates a name.
- The next three constraints are column constraints: Each occurs within a column definition, and
  thus can refer only to the column being defined. One of the constraints is named explicitly. MySQL
  generates a name for each of the other two.
- The last two constraints are table constraints. One of them is named explicitly. MySQL generates a
  name for the other one.

As mentioned, MySQL generates a name for any **CHECK** constraint specified without one. To see the
names generated for the preceding table definition, use **SHOW CREATE TABLE**:

```
mysql> SHOW CREATE TABLE t1;
```

```
Table: t1
+---------------+-----------------------------------+------------+
| Create Table: | CREATE TABLE `t1` (               |
| `c1` int(11)  | DEFAULT NULL,                    |
| `c2` int(11)  | DEFAULT NULL,                    |
| `c3` int(11)  | DEFAULT NULL,                    |
| CONSTRAINT    | `c1_nonzero` CHECK ('c1' <> 0)), |
| `c2_positive` | CHECK ('c2' > 0)),               |
| CONSTRAINT    | `t1_chk_1` CHECK ('c1' <> 'c2)'),|
| `t1_chk_2`    | CHECK ('c1' > 10)),              |
| CONSTRAINT    | `t1_chk_3` CHECK ('c3' < 100)),   |
| CONSTRAINT    | `t1_chk_4` CHECK ('c1' > 'c3'))); |
+---------------+-----------------------------------+------------+
```

The SQL standard specifies that all types of constraints (primary key, unique index, foreign key, check)
belong to the same namespace. In MySQL, each constraint type has its own namespace per schema
(database). Consequently, **CHECK** constraint names must be unique per schema; no two tables in
the same schema can share a **CHECK** constraint name. (Exception: A **TEMPORARY** table hides a
non-**TEMPORARY** table of the same name, so it can have the same **CHECK** constraint names as well.)

Beginning generated constraint names with the table name helps ensure schema uniqueness because
table names also must be unique within the schema.
**CHECK** condition expressions must adhere to the following rules. An error occurs if an expression contains disallowed constructs.

- Nongenerated and generated columns are permitted, except columns with the **AUTO_INCREMENT** attribute and columns in other tables.
- Literals, deterministic built-in functions, and operators are permitted. A function is deterministic if, given the same data in tables, multiple invocations produce the same result, independently of the connected user. Examples of functions that are nondeterministic and fail this definition: `CONNECTION_ID()`, `CURRENT_USER()`, `NOW()`.
- Stored functions and loadable functions are not permitted.
- Stored procedure and function parameters are not permitted.
- Variables (system variables, user-defined variables, and stored program local variables) are not permitted.
- Subqueries are not permitted.

Foreign key referential actions (**ON UPDATE**, **ON DELETE**) are prohibited on columns used in **CHECK** constraints. Likewise, **CHECK** constraints are prohibited on columns used in foreign key referential actions.

**CHECK** constraints are evaluated for **INSERT**, **UPDATE**, **REPLACE**, **LOAD DATA**, and **LOAD XML** statements and an error occurs if a constraint evaluates to **FALSE**. If an error occurs, handling of changes already applied differs for transactional and nontransactional storage engines, and also depends on whether strict SQL mode is in effect, as described in *Strict SQL Mode*.

**CHECK** constraints are evaluated for **INSERT IGNORE**, **UPDATE IGNORE**, **LOAD DATA ... IGNORE**, and **LOAD XML ... IGNORE** statements and a warning occurs if a constraint evaluates to **FALSE**. The insert or update for any offending row is skipped.

If the constraint expression evaluates to a data type that differs from the declared column type, implicit coercion to the declared type occurs according to the usual MySQL type-conversion rules. See *Section 14.3, “Type Conversion in Expression Evaluation”*. If type conversion fails or results in a loss of precision, an error occurs.

**Note**

Constraint expression evaluation uses the SQL mode in effect at evaluation time. If any component of the expression depends on the SQL mode, different results may occur for different uses of the table unless the SQL mode is the same during all uses.

The Information Schema **CHECK_CONSTRAINTS** table provides information about **CHECK** constraints defined on tables. See *Section 28.3.5, “The INFORMATION_SCHEMA CHECK_CONSTRAINTS Table”*.

### 15.1.20.7 Silent Column Specification Changes

In some cases, MySQL silently changes column specifications from those given in a **CREATE TABLE** or **ALTER TABLE** statement. These might be changes to a data type, to attributes associated with a data type, or to an index specification.

All changes are subject to the internal row-size limit of 65,535 bytes, which may cause some attempts at data type changes to fail. See *Section 10.4.7, “Limits on Table Column Count and Row Size”*.

- Columns that are part of a **PRIMARY KEY** are made **NOT NULL** even if not declared that way.
- Trailing spaces are automatically deleted from **ENUM** and **SET** member values when the table is created.
CREATE TABLE Statement

• MySQL maps certain data types used by other SQL database vendors to MySQL types. See Section 13.9, “Using Data Types from Other Database Engines”.

• If you include a USING clause to specify an index type that is not permitted for a given storage engine, but there is another index type available that the engine can use without affecting query results, the engine uses the available type.

• If strict SQL mode is not enabled, a VARCHAR column with a length specification greater than 65535 is converted to TEXT, and a VARBINARY column with a length specification greater than 65535 is converted to BLOB. Otherwise, an error occurs in either of these cases.

• Specifying the CHARACTER SET binary attribute for a character data type causes the column to be created as the corresponding binary data type: CHAR becomes BINARY, VARCHAR becomes VARBINARY, and TEXT becomes BLOB. For the ENUM and SET data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

```
CREATE TABLE t
(
  c1 VARCHAR(10) CHARACTER SET binary,
  c2 TEXT CHARACTER SET binary,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

The resulting table has this definition:

```
CREATE TABLE t
(
  c1 VARBINARY(10),
  c2 BLOB,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

To see whether MySQL used a data type other than the one you specified, issue a DESCRIBE or SHOW CREATE TABLE statement after creating or altering the table.

Certain other data type changes can occur if you compress a table using myisampack. See Section 18.2.3.3, “Compressed Table Characteristics”.

15.1.20.8 CREATE TABLE and Generated Columns

CREATE TABLE supports the specification of generated columns. Values of a generated column are computed from an expression included in the column definition.

Generated columns are also supported by the NDB storage engine.

The following simple example shows a table that stores the lengths of the sides of right triangles in the sidea and sideb columns, and computes the length of the hypotenuse in sidec (the square root of the sums of the squares of the other sides):

```
CREATE TABLE triangle
(
  sidea DOUBLE,
  sideb DOUBLE,
  sidec DOUBLE AS (SQRT(sidea * sidea + sideb * sideb))
);
```

```
INSERT INTO triangle (sidea, sideb) VALUES(1,1),(3,4),(6,8);
```

Selecting from the table yields this result:

```
mysql> SELECT * FROM triangle;
+-------+-------+--------------------+
<table>
<thead>
<tr>
<th>sidea</th>
<th>sideb</th>
<th>sidec</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1.4142135623730951</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>5</td>
</tr>
<tr>
<td>6</td>
<td>8</td>
<td>10</td>
</tr>
</tbody>
</table>
+-------+-------+--------------------+
```
Any application that uses the triangle table has access to the hypotenuse values without having to specify the expression that calculates them.

Generated column definitions have this syntax:

```
col_name data_type [GENERATED ALWAYS] AS (expr)
[VIRTUAL | STORED] [NOT NULL | NULL]
[UNIQUE {KEY}] [{PRIMARY} {KEY}]
[COMMENT 'string']
```

AS (expr) indicates that the column is generated and defines the expression used to compute column values. AS may be preceded by GENERATED ALWAYS to make the generated nature of the column more explicit. Constructs that are permitted or prohibited in the expression are discussed later.

The VIRTUAL or STORED keyword indicates how column values are stored, which has implications for column use:

- **VIRTUAL**: Column values are not stored, but are evaluated when rows are read, immediately after any BEFORE triggers. A virtual column takes no storage.

  InnoDB supports secondary indexes on virtual columns. See Section 15.1.20.9, “Secondary Indexes and Generated Columns”.

- **STORED**: Column values are evaluated and stored when rows are inserted or updated. A stored column does require storage space and can be indexed.

The default is VIRTUAL if neither keyword is specified.

It is permitted to mix VIRTUAL and STORED columns within a table.

Other attributes may be given to indicate whether the column is indexed or can be NULL, or provide a comment.

Generated column expressions must adhere to the following rules. An error occurs if an expression contains disallowed constructs.

- Literals, deterministic built-in functions, and operators are permitted. A function is deterministic if, given the same data in tables, multiple invocations produce the same result, independently of the connected user. Examples of functions that are nondeterministic and fail this definition: CONNECTION_ID(), CURRENT_USER(), NOW().

- Stored functions and loadable functions are not permitted.

- Stored procedure and function parameters are not permitted.

- Variables (system variables, user-defined variables, and stored program local variables) are not permitted.

- Subqueries are not permitted.

- A generated column definition can refer to other generated columns, but only those occurring earlier in the table definition. A generated column definition can refer to any base (nongenerated) column in the table whether its definition occurs earlier or later.

- The AUTO_INCREMENT attribute cannot be used in a generated column definition.

- An AUTO_INCREMENT column cannot be used as a base column in a generated column definition.

- If expression evaluation causes truncation or provides incorrect input to a function, the CREATE TABLE statement terminates with an error and the DDL operation is rejected.

If the expression evaluates to a data type that differs from the declared column type, implicit coercion to the declared type occurs according to the usual MySQL type-conversion rules. See Section 14.3, "Type Conversion in Expression Evaluation".
If a generated column uses the `TIMESTAMP` data type, the setting for `explicit_defaults_for_timestamp` is ignored. In such cases, if this variable is disabled then `NULL` is not converted to `CURRENT_TIMESTAMP`. If the column is also declared as `NOT NULL`, attempting to insert `NULL` is explicitly rejected with `ER_BAD_NULL_ERROR`.

**Note**

Expression evaluation uses the SQL mode in effect at evaluation time. If any component of the expression depends on the SQL mode, different results may occur for different uses of the table unless the SQL mode is the same during all uses.

For `CREATE TABLE ... LIKE`, the destination table preserves generated column information from the original table.

For `CREATE TABLE ... SELECT`, the destination table does not preserve information about whether columns in the selected-from table are generated columns. The `SELECT` part of the statement cannot assign values to generated columns in the destination table.

Partitioning by generated columns is permitted. See Table Partitioning.

A foreign key constraint on a stored generated column cannot use `CASCADE`, `SET NULL`, or `SET DEFAULT` as `ON UPDATE` referential actions, nor can it use `SET NULL` or `SET DEFAULT` as `ON DELETE` referential actions.

A foreign key constraint on the base column of a stored generated column cannot use `CASCADE`, `SET NULL`, or `SET DEFAULT` as `ON UPDATE` or `ON DELETE` referential actions.

A foreign key constraint cannot reference a virtual generated column.

Triggers cannot use `NEW.col_name` or use `OLD.col_name` to refer to generated columns.

For `INSERT`, `REPLACE`, and `UPDATE`, if a generated column is inserted into, replaced, or updated explicitly, the only permitted value is `DEFAULT`.

A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is `DEFAULT`.

Generated columns have several use cases, such as these:

- Virtual generated columns can be used as a way to simplify and unify queries. A complicated condition can be defined as a generated column and referred to from multiple queries on the table to ensure that all of them use exactly the same condition.

- Stored generated columns can be used as a materialized cache for complicated conditions that are costly to calculate on the fly.

- Generated columns can simulate functional indexes: Use a generated column to define a functional expression and index it. This can be useful for working with columns of types that cannot be indexed directly, such as `JSON` columns; see Indexing a Generated Column to Provide a JSON Column Index, for a detailed example.

For stored generated columns, the disadvantage of this approach is that values are stored twice; once as the value of the generated column and once in the index.

- If a generated column is indexed, the optimizer recognizes query expressions that match the column definition and uses indexes from the column as appropriate during query execution, even if a query does not refer to the column directly by name. For details, see Section 10.3.11, “Optimizer Use of Generated Column Indexes”.

**Example:**
Suppose that a table `t1` contains `first_name` and `last_name` columns and that applications frequently construct the full name using an expression like this:

```sql
SELECT CONCAT(first_name, ' ', last_name) AS full_name FROM t1;
```

One way to avoid writing out the expression is to create a view `v1` on `t1`, which simplifies applications by enabling them to select `full_name` directly without using an expression:

```sql
CREATE VIEW v1 AS
SELECT *, CONCAT(first_name, ' ', last_name) AS full_name FROM t1;
SELECT full_name FROM v1;
```

A generated column also enables applications to select `full_name` directly without the need to define a view:

```sql
CREATE TABLE t1 (
  first_name VARCHAR(10),
  last_name VARCHAR(10),
  full_name VARCHAR(255) AS (CONCAT(first_name, ' ', last_name))
);
SELECT full_name FROM t1;
```

### 15.1.20.9 Secondary Indexes and Generated Columns

**InnoDB** supports secondary indexes on virtual generated columns. Other index types are not supported. A secondary index defined on a virtual column is sometimes referred to as a “virtual index”.

A secondary index may be created on one or more virtual columns or on a combination of virtual columns and regular columns or stored generated columns. Secondary indexes that include virtual columns may be defined as **UNIQUE**.

When a secondary index is created on a virtual generated column, generated column values are materialized in the records of the index. If the index is a **covering index** (one that includes all the columns retrieved by a query), generated column values are retrieved from materialized values in the index structure instead of computed “on the fly”.

There are additional write costs to consider when using a secondary index on a virtual column due to computation performed when materializing virtual column values in secondary index records during **INSERT** and **UPDATE** operations. Even with additional write costs, secondary indexes on virtual columns may be preferable to generated **stored** columns, which are materialized in the clustered index, resulting in larger tables that require more disk space and memory. If a secondary index is not defined on a virtual column, there are additional costs for reads, as virtual column values must be computed each time the column's row is examined.

Values of an indexed virtual column are MVCC-logged to avoid unnecessary recomputation of generated column values during rollback or during a purge operation. The data length of logged values is limited by the index key limit of 767 bytes for **COMPACT** and **REDUNDANT** row formats, and 3072 bytes for **DYNAMIC** and **COMPRESSED** row formats.

Adding or dropping a secondary index on a virtual column is an in-place operation.

### Indexing a Generated Column to Provide a JSON Column Index

As noted elsewhere, **JSON** columns cannot be indexed directly. To create an index that references such a column indirectly, you can define a generated column that extracts the information that should be indexed, then create an index on the generated column, as shown in this example:

```sql
mysql> CREATE TABLE jemp (
  c JSON,
  g INT GENERATED ALWAYS AS (c->"$.id"),
  INDEX i (g)
);
Query OK, 0 rows affected (0.28 sec)
```

2518
CREATE TABLE Statement

mysql> INSERT INTO jemp (c) VALUES
   > (json_object("id", "1", "name", "Fred")), (json_object("id", "2", "name", "Wilma")),
   > (json_object("id", "3", "name", "Barney")), (json_object("id", "4", "name", "Betty"));
Query OK, 4 rows affected (0.04 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT c->>'$.name' AS name
   > FROM jemp WHERE g > 2;

+--------+
| name   |
+--------+
| Barney |
| Betty  |
+--------+
2 rows in set (0.00 sec)

mysql> EXPLAIN SELECT c->>'$.name' AS name
   > FROM jemp WHERE g > 2

*************************** 1. row ***************************
  id: 1
  select_type: SIMPLE
  table: jemp
  partitions: NULL
  type: range
  possible_keys: i
    key: i
    key_len: 5
    ref: NULL
  rows: 2
  filtered: 100.00
  Extra: Using where
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS

*************************** 1. row ***************************
  Level: Note
  Code: 1003
  Message: /* select#1 */ select json_unquote(json_extract(`test`.`jemp`.`c`,'$.name')) AS `name` from `test`.`jemp` where (`test`.`jemp`.`g` > 2)
1 row in set (0.00 sec)

(We have wrapped the output from the last statement in this example to fit the viewing area.)

When you use EXPLAIN on a SELECT or other SQL statement containing one or more expressions that use the -> or ->> operator, these expressions are translated into their equivalents using JSON_EXTRACT() and (if needed) JSON_UNQUOTE() instead, as shown here in the output from SHOW WARNINGS immediately following this EXPLAIN statement:

mysql> EXPLAIN SELECT c->>'$.name' AS name
   > FROM jemp WHERE g > 2 ORDER BY c->>'$.name'

*************************** 1. row ***************************
  id: 1
  select_type: SIMPLE
  table: jemp
  partitions: NULL
  type: range
  possible_keys: i
    key: i
    key_len: 5
    ref: NULL
  rows: 2
  filtered: 100.00
  Extra: Using where; Using filesort
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS

*************************** 1. row ***************************
  Level: Note
  Code: 1003
  Message: /* select#1 */ select json_unquote(json_extract('test'.`jemp`.'c',`$.name')) AS `name` from `test`.`jemp` where (`test`.`jemp`.`g` > 2)
CREATE TABLE Statement
`c->>"$.name"` from `test`.`jemp` where (`test`.`jemp`.`g` > 2) order by json_extract(`test`.`jemp`,'$.c','$.name')
1 row in set (0.00 sec)

See the descriptions of the -> and --> operators, as well as those of the JSON_EXTRACT() and JSON_UNQUOTE() functions, for additional information and examples.

This technique also can be used to provide indexes that indirectly reference columns of other types that cannot be indexed directly, such as GEOMETRY columns.

It is also possible to create an index on a JSON column using the JSON_VALUE() function with an expression that can be used to optimize queries employing the expression. See the description of that function for more information and examples.

**JSON columns and indirect indexing in NDB Cluster**

It is also possible to use indirect indexing of JSON columns in MySQL NDB Cluster, subject to the following conditions:

1. **NDB** handles a JSON column value internally as a BLOB. This means that any NDB table having one or more JSON columns must have a primary key, else it cannot be recorded in the binary log.

2. The **NDB** storage engine does not support indexing of virtual columns. Since the default for generated columns is VIRTUAL, you must specify explicitly the generated column to which to apply the indirect index as STORED.

The **CREATE TABLE** statement used to create the table **jempn** shown here is a version of the **jemp** table shown previously, with modifications making it compatible with NDB:

```sql
CREATE TABLE jempn (  a BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,  c JSON DEFAULT NULL,  g INT GENERATED ALWAYS AS (c->"$.id") STORED,  INDEX i (g) ) ENGINE=NDB;
```

We can populate this table using the following INSERT statement:

```sql
INSERT INTO jempn (c) VALUES  ('{"id": "1", "name": "Fred"}'),  ('{"id": "2", "name": "Wilma"}'),  ('{"id": "3", "name": "Barney"}'),  ('{"id": "4", "name": "Betty"}');
```

Now **NDB** can use index **i**, as shown here:

```sql
mysql> EXPLAIN SELECT c->"$.name" AS name -> FROM jempn WHERE g > 2\G  *************************** 1. row ***************************  id: 1  select_type: SIMPLE  table: jempn  partitions: p0,p1,p2,p3  type: range  possible_keys: i  key: i  key_len: 5  ref: NULL  rows: 3  filtered: 100.00  Extra: Using pushed condition (`test`.`jempn`.'g' > 2)
1 row in set, 1 warning (0.01 sec)
```

```sql
mysql> SHOW WARNINGS\G  *************************** 1. row ***************************  Level: Note  Code: 1003  Message: /* select#1 */ select
```
15.1.20.10 Invisible Columns

MySQL 8.4 supports invisible columns. An invisible column is normally hidden to queries, but can be accessed if explicitly referenced.

As an illustration of when invisible columns may be useful, suppose that an application uses SELECT * queries to access a table, and must continue to work without modification even if the table is altered to add a new column that the application does not expect to be there. In a SELECT * query, the * evaluates to all table columns, except those that are invisible, so the solution is to add the new column as an invisible column. The column remains “hidden” from SELECT * queries, and the application continues to work as previously. A newer version of the application can refer to the invisible column if necessary by explicitly referencing it.

The following sections detail how MySQL treats invisible columns.

• DDL Statements and Invisible Columns
• DML Statements and Invisible Columns
• Invisible Column Metadata
• The Binary Log and Invisible Columns

DDL Statements and Invisible Columns

Columns are visible by default. To explicitly specify visibility for a new column, use a VISIBLE or INVISIBLE keyword as part of the column definition for CREATE TABLE or ALTER TABLE:

CREATE TABLE t1 (  
i INT,  
j DATE INVISIBLE  
) ENGINE = InnoDB;
ALTER TABLE t1 ADD COLUMN k INT INVISIBLE;

To alter the visibility of an existing column, use a VISIBLE or INVISIBLE keyword with one of the ALTER TABLE column-modification clauses:

ALTER TABLE t1 CHANGE COLUMN j j DATE VISIBLE;
ALTER TABLE t1 MODIFY COLUMN j DATE INVISIBLE;
ALTER TABLE t1 ALTER COLUMN j SET VISIBLE;

A table must have at least one visible column. Attempting to make all columns invisible produces an error.

Invisible columns support the usual column attributes: NULL, NOT NULL, AUTO_INCREMENT, and so forth.

Generated columns can be invisible.

Index definitions can name invisible columns, including definitions for PRIMARY KEY and UNIQUE indexes. Although a table must have at least one visible column, an index definition need not have any visible columns.

An invisible column dropped from a table is dropped in the usual way from any index definition that names the column.

Foreign key constraints can be defined on invisible columns, and foreign key constraints can reference invisible columns.
CHECK constraints can be defined on invisible columns. For new or modified rows, violation of a CHECK constraint on an invisible column produces an error.

CREATE TABLE ... LIKE includes invisible columns, and they are invisible in the new table.

CREATE TABLE ... SELECT does not include invisible columns, unless they are explicitly referenced in the SELECT part. However, even if explicitly referenced, a column that is invisible in the existing table is visible in the new table:

```sql
mysql> CREATE TABLE t1 (col1 INT, col2 INT INVISIBLE);
mysql> CREATE TABLE t2 AS SELECT col1, col2 FROM t1;
mysql> SHOW CREATE TABLE t2
+--------------------------+-----------+---------+---------------+-------------------+-------------------+------------+-----------+---------------+-------------------+-------------------+-------------------+
| Name | Type | Engine | Tablespace | Data Dictionary | Raw | InnoDB | Other | InnoDB | Other | InnoDB | Other | InnoDB | Other |
+--------------------------+-----------+---------+---------------+-------------------+-------------------+------------+-----------+---------------+-------------------+-------------------+-------------------+
| t2 | CREATE TABLE `t2` (`col1` int DEFAULT NULL, `col2` int DEFAULT NULL) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci |
```

If invisibility should be preserved, provide a definition for the invisible column in the CREATE TABLE part of the CREATE TABLE ... SELECT statement:

```sql
mysql> CREATE TABLE t1 (col1 INT, col2 INT INVISIBLE);
mysql> CREATE TABLE t2 (col2 INT INVISIBLE) AS SELECT col1, col2 FROM t1;
mysql> SHOW CREATE TABLE t2
+--------------------------+-----------+---------+---------------+-------------------+-------------------+------------+-----------+---------------+-------------------+-------------------+-------------------+
| Name | Type | Engine | Tablespace | Data Dictionary | Raw | InnoDB | Other | InnoDB | Other | InnoDB | Other | InnoDB | Other |
+--------------------------+-----------+---------+---------------+-------------------+-------------------+------------+-----------+---------------+-------------------+-------------------+-------------------+
| t2 | CREATE TABLE `t2` (`col1` int DEFAULT NULL, `col2` int DEFAULT NULL) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci |
```

Views can refer to invisible columns by explicitly referencing them in the SELECT statement that defines the view. Changing a column’s visibility subsequent to defining a view that references the column does not change view behavior.

**DML Statements and Invisible Columns**

For SELECT statements, an invisible column is not part of the result set unless explicitly referenced in the select list. In a select list, the * and tbl_name.* shorthands do not include invisible columns. Natural joins do not include invisible columns.

Consider the following statement sequence:

```sql
mysql> CREATE TABLE t1 (col1 INT, col2 INT INVISIBLE);
mysql> INSERT INTO t1 (col1, col2) VALUES(1, 2), (3, 4);
mysql> SELECT * FROM t1;
+-----+
| col1 |
+-----+
| 1 |
| 3 |

mysql> SELECT col1, col2 FROM t1;
+-------+-------+
| col1  | col2  |
+-------+-------+
| 1     | 2     |
| 3     | 4     |
```

The first SELECT does not reference the invisible column col2 in the select list (because * does not include invisible columns), so col2 does not appear in the statement result. The second SELECT explicitly references col2, so the column appears in the result.
The statement `TABLE t1` produces the same output as the first `SELECT` statement. Since there is no way to specify columns in a `TABLE` statement, `TABLE` never displays invisible columns.

For statements that create new rows, an invisible column is assigned its implicit default value unless explicitly referenced and assigned a value. For information about implicit defaults, see Implicit Default Handling.

For `INSERT` (and `REPLACE`, for non-replaced rows), implicit default assignment occurs with a missing column list, an empty column list, or a nonempty column list that does not include the invisible column:

```
CREATE TABLE t1 (col1 INT, col2 INT INVISIBLE);
INSERT INTO t1 VALUES(...);
INSERT INTO t1 () VALUES(...);
INSERT INTO t1 (col1) VALUES(...);
```

For the first two `INSERT` statements, the `VALUES()` list must provide a value for each visible column and no invisible column. For the third `INSERT` statement, the `VALUES()` list must provide the same number of values as the number of named columns; the same is true when you use `VALUES ROW()` rather than `VALUES()`.

For `LOAD DATA` and `LOAD XML`, implicit default assignment occurs with a missing column list or a nonempty column list that does not include the invisible column. Input rows should not include a value for the invisible column.

To assign a value other than the implicit default for the preceding statements, explicitly name the invisible column in the column list and provide a value for it.

```
INSERT INTO ... SELECT * and REPLACE INTO ... SELECT * do not include invisible columns because * does not include invisible columns. Implicit default assignment occurs as described previously.
```

For statements that insert or ignore new rows, or that replace or modify existing rows, based on values in a `PRIMARY KEY` or `UNIQUE` index, MySQL treats invisible columns the same as visible columns: Invisible columns participate in key value comparisons. Specifically, if a new row has the same value as an existing row for a unique key value, these behaviors occur whether the index columns are visible or invisible:

- With the `IGNORE` modifier, `INSERT`, `LOAD DATA`, and `LOAD XML` ignore the new row.
- `REPLACE` replaces the existing row with the new row. With the `REPLACE` modifier, `LOAD DATA` and `LOAD XML` do the same.
- `INSERT ... ON DUPLICATE KEY UPDATE` updates the existing row.

To update invisible columns for `UPDATE` statements, name them and assign a value, just as for visible columns.

### Invisible Column Metadata

Information about whether a column is visible or invisible is available from the `EXTRA` column of the Information Schema `COLUMNS` table or `SHOW COLUMNS` output. For example:

```
mysql> SELECT TABLE_NAME, COLUMN_NAME, EXTRA
FROM INFORMATION_SCHEMA.COLUMNS
WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 't1';
```

```
+------------+-------------+-----------+
| TABLE_NAME | COLUMN_NAME | EXTRA     |
+------------+-------------+-----------+
| t1         | i           |           |
| t1         | j           |           |
| t1         | k           | INVISIBLE |
+------------+-------------+-----------+
```

Columns are visible by default, so in that case, `EXTRA` displays no visibility information. For invisible columns, `EXTRA` displays `INVISIBLE`. 
SHOW CREATE TABLE displays invisible columns in the table definition, with the INVISIBLE keyword in a version-specific comment:

```sql
mysql> SHOW CREATE TABLE t1
+--------------------------+
<table>
<thead>
<tr>
<th>Table</th>
</tr>
</thead>
<tbody>
<tr>
<td>t1</td>
</tr>
</tbody>
</table>
| Create Table: CREATE TABLE `t1` {
  `i` int DEFAULT NULL,  
  `j` int DEFAULT NULL,  
  `k` int DEFAULT NULL /*!80023 INVISIBLE */
} ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
```

mysqldump uses SHOW CREATE TABLE, so they include invisible columns in dumped table definitions. They also include invisible column values in dumped data.

Reloading a dump file into an older version of MySQL that does not support invisible columns causes the version-specific comment to be ignored, which creates any invisible columns as visible.

### The Binary Log and Invisible Columns

MySQL treats invisible columns as follows with respect to events in the binary log:

- Table-creation events include the INVISIBLE attribute for invisible columns.
- Invisible columns are treated like visible columns in row events. They are included if needed according to the `binlog_row_image` system variable setting.
- When row events are applied, invisible columns are treated like visible columns in row events.
- Invisible columns are treated like visible columns when computing writesets. In particular, writesets include indexes defined on invisible columns.
- The `mysqlbinlog` command includes visibility in column metadata.

### 15.1.20.11 Generated Invisible Primary Keys

MySQL 8.4 supports generated invisible primary keys for any InnoDB table that is created without an explicit primary key. When the `sql_generate_invisible_primary_key` server system variable is set to ON, the MySQL server automatically adds a generated invisible primary key (GIPK) to any such table. This setting has no effect on tables created using any other storage engine than InnoDB.

By default, the value of `sql_generate_invisible_primary_key` is OFF, meaning that the automatic addition of GIPKs is disabled. To illustrate how this affects table creation, we begin by creating two identical tables, neither having a primary key, the only difference being that the first (table `auto_0`) is created with `sql_generate_invisible_primary_key` set to OFF, and the second (`auto_1`) after setting it to ON, as shown here:

```sql
mysql> SELECT @@sql_generate_invisible_primary_key;
+--------------------------------------+
<table>
<thead>
<tr>
<th>@@sql_generate_invisible_primary_key</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
+--------------------------------------+
1 row in set (0.00 sec)

mysql> CREATE TABLE auto_0 (c1 VARCHAR(50), c2 INT);
Query OK, 0 rows affected (0.02 sec)

mysql> SET sql_generate_invisible_primary_key=ON;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@sql_generate_invisible_primary_key;
+--------------------------------------+
<table>
<thead>
<tr>
<th>@@sql_generate_invisible_primary_key</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
+--------------------------------------+
```

```sql
mysql> CREATE TABLE auto_1 (c1 VARCHAR(50), c2 INT);
Query OK, 0 rows affected (0.02 sec)

mysql> SET sql_generate_invisible_primary_key=ON;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@sql_generate_invisible_primary_key;
+--------------------------------------+
<table>
<thead>
<tr>
<th>@@sql_generate_invisible_primary_key</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
+--------------------------------------+
```
CREATE TABLE Statement

```sql
mysql> CREATE TABLE auto_1 (c1 VARCHAR(50), c2 INT);
Query OK, 0 rows affected (0.04 sec)
```

Compare the output of these `SHOW CREATE TABLE` statements to see the difference in how the tables were actually created:

```sql
mysql> SHOW CREATE TABLE auto_0\G
*************************** 1. row ***************************
Table: auto_0
Create Table: CREATE TABLE `auto_0` (`c1` varchar(50) DEFAULT NULL, `c2` int DEFAULT NULL)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
1 row in set (0.00 sec)

mysql> SHOW CREATE TABLE auto_1\G
*************************** 1. row ***************************
Table: auto_1
Create Table: CREATE TABLE `auto_1` (`my_row_id` bigint unsigned NOT NULL AUTO_INCREMENT /*!80023 INVISIBLE */, `c1` varchar(50) DEFAULT NULL, `c2` int DEFAULT NULL,
PRIMARY KEY (`my_row_id`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
1 row in set (0.00 sec)
```

Since `auto_1` had no primary key specified by the `CREATE TABLE` statement used to create it, setting `sql_generate_invisible_primary_key = ON` causes MySQL to add both the invisible column `my_row_id` to this table and a primary key on that column. Since `sql_generate_invisible_primary_key` was `OFF` at the time that `auto_0` was created, no such additions were performed on that table.

When a primary key is added to a table by the server, the column and key name is always `my_row_id`. For this reason, when enabling generated invisible primary keys in this way, you cannot create a table having a column named `my_row_id` unless the table creation statement also specifies an explicit primary key. (You are not required to name the column or key `my_row_id` in such cases.)

`my_row_id` is an invisible column, which means it is not shown in the output of `SELECT *` or `TABLE`; the column must be selected explicitly by name. See Section 15.1.20.10, “Invisible Columns”.

When GIPKs are enabled, a generated primary key cannot be altered other than to switch it between `VISIBLE` and `INVISIBLE`. To make the generated invisible primary key on `auto_1` visible, execute this `ALTER TABLE` statement:

```sql
mysql> ALTER TABLE auto_1 ALTER COLUMN my_row_id SET VISIBLE;
Query OK, 0 rows affected (0.02 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> SHOW CREATE TABLE auto_1\G
*************************** 1. row ***************************
Table: auto_1
Create Table: CREATE TABLE `auto_1` (`my_row_id` bigint unsigned NOT NULL AUTO_INCREMENT /*!80023 VISIBLE */, `c1` varchar(50) DEFAULT NULL, `c2` int DEFAULT NULL,
PRIMARY KEY (`my_row_id`)
) ENGINE=InnoDB AUTO_INCREMENT=4 DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
1 row in set (0.01 sec)
```

To make this generated primary key invisible again, issue `ALTER TABLE auto_1 ALTER COLUMN my_row_id SET INVISIBLE`.

A generated invisible primary key is always invisible by default.

Whenever GIPKs are enabled, you cannot drop a generated primary key if either of the following 2 conditions would result:

---

2525
• The table is left with no primary key.
• The primary key is dropped, but not the primary key column.

The effects of `sql_generate_invisible_primary_key` apply to tables using the InnoDB storage engine only. You can use an `ALTER TABLE` statement to change the storage engine used by a table that has a generated invisible primary key; in this case, the primary key and column remain in place, but the table and key no longer receive any special treatment.

By default, GIPKs are shown in the output of `SHOW CREATE TABLE`, `SHOW COLUMNS`, and `SHOW INDEX`, and are visible in the Information Schema `COLUMNS` and `STATISTICS` tables. You can cause generated invisible primary keys to be hidden instead in such cases by setting the `show_gipk_in_create_table_and_information_schema` system variable to `OFF`. By default, this variable is `ON`, as shown here:

```
mysql> SELECT @@show_gipk_in_create_table_and_information_schema;
+----------------------------------------------------+
| @@show_gipk_in_create_table_and_information_schema |
+----------------------------------------------------+
|                                                  1 |
+----------------------------------------------------+
1 row in set (0.00 sec)
```

As can be seen from the following query against the `COLUMNS` table, `my_row_id` is visible among the columns of `auto_1`:

```
mysql> SELECT COLUMN_NAME, ORDINAL_POSITION, DATA_TYPE, COLUMN_KEY
    -> FROM INFORMATION_SCHEMA.COLUMNS
    -> WHERE TABLE_NAME = "auto_1";
+-------------+----------------+-----------+------------+
| COLUMN_NAME | ORDINAL_POSITION | DATA_TYPE | COLUMN_KEY |
| my_row_id   |                1 | bigint    | PRI        |
| c1          |                2 | varchar   |            |
| c2          |                3 | int       |            |
+-------------+----------------+-----------+------------+
3 rows in set (0.01 sec)
```

After `show_gipk_in_create_table_and_information_schema` is set to `OFF`, `my_row_id` can no longer be seen in the `COLUMNS` table, as shown here:

```
mysql> SET show_gipk_in_create_table_and_information_schema = OFF;
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SELECT @@show_gipk_in_create_table_and_information_schema;
+----------------------------------------------------+
| @@show_gipk_in_create_table_and_information_schema |
+----------------------------------------------------+
|                                                  0 |
+----------------------------------------------------+
1 row in set (0.00 sec)
```

```
mysql> SELECT COLUMN_NAME, ORDINAL_POSITION, DATA_TYPE, COLUMN_KEY
    -> FROM INFORMATION_SCHEMA.COLUMNS
    -> WHERE TABLE_NAME = "auto_1";
+-------------+----------------+-----------+------------+
| COLUMN_NAME | ORDINAL_POSITION | DATA_TYPE | COLUMN_KEY |
| c1          |                2 | varchar   |            |
| c2          |                3 | int       |            |
+-------------+----------------+-----------+------------+
2 rows in set (0.00 sec)
```

The setting for `sql_generate_invisible_primary_key` is not replicated, and is ignored by replication applier threads. This means that the setting of this variable on the source has no effect on the replica. You can cause the replica to add a GIPK for tables replicated without primary keys on a given replication channel using `REQUIRE_TABLE_PRIMARY_KEY_CHECK = GENERATE` as part of a `CHANGE REPLICATION SOURCE TO` statement.
GIPKs work with row-based replication of `CREATE TABLE ... SELECT`; the information written to the binary log for this statement in such cases includes the GIPK definition, and thus is replicated correctly. Statement-based replication of `CREATE TABLE ... SELECT` is not supported with `sql_generate_invisible_primary_key = ON`.

When creating or importing backups of installations where GIPKs are in use, it is possible to exclude generated invisible primary key columns and values. The `--skip-generated-invisible-primary-key` option for `mysqldump` causes GIPK information to be excluded in the program's output.

### 15.1.20.12 Setting NDB Comment Options

- **NDB_COLUMN Options**
- **NDB_TABLE Options**

It is possible to set a number of options specific to NDB Cluster in the table comment or column comments of an NDB table. Table-level options for controlling read from any replica and partition balance can be embedded in a table comment using `NDB_TABLE`.

`NDB_COLUMN` can be used in a column comment to set the size of the blob parts table column used for storing parts of blob values by NDB to its maximum. This works for `BLOB`, `MEDIUMBLOB`, `LONGBLOB`, `TEXT`, `MEDIUMTEXT`, `LONGTEXT`, and `JSON` columns. A column comment can also be used to control the inline size of a blob column. `NDB_COLUMN` comments do not support `TINYBLOB` or `TINYTEXT` columns, since these have an inline part (only) of fixed size, and no separate parts to store elsewhere.

`NDB_TABLE` can be used in a table comment to set options relating to partition balance and whether the table is fully replicated, among others.

The remainder of this section describes these options and their use.

**NDB_COLUMN Options**

In NDB Cluster, a column comment in a `CREATE TABLE` or `ALTER TABLE` statement can also be used to specify an `NDB_COLUMN` option. NDB supports two column comment options: `BLOB_INLINE_SIZE` and `MAX_BLOB_PART_SIZE`. Syntax for these options is shown here:

```
COMMENT 'NDB_COLUMN=speclist'

speclist := spec[,spec]

spec :=
  BLOB_INLINE_SIZE=value |
  MAX_BLOB_PART_SIZE=[=0|1]
```

`BLOB_INLINE_SIZE` specifies the number of bytes to be stored inline by the column; its expected value is an integer in the range 1 - 29980, inclusive. Setting a value greater than 29980 raises an error; setting a value less than 1 is allowed, but causes the default inline size for the column type to be used.

You should be aware that the maximum value for this option is actually the maximum number of bytes that can be stored in one row of an NDB table; every column in the row contributes to this total.

You should also keep in mind, especially when working with `TEXT` columns, that the value set by `MAX_BLOB_PART_SIZE` or `BLOB_INLINE_SIZE` represents column size in bytes. It does not indicate the number of characters, which varies according to the character set and collation used by the column.

To see the effects of this option, first create a table with two `BLOB` columns, one (`b1`) with no extra options, and another (`b2`) with a setting for `BLOB_INLINE_SIZE`, as shown here:

```
mysql> CREATE TABLE t1 (  
  -> a INT NOT NULL PRIMARY KEY,  
  -> b1 BLOB,  
  -> b2 BLOB COMMENT 'NDB_COLUMN=BLOB_INLINE_SIZE=8000'
```

### NDB_TABLE Options

It is possible to set a number of options specific to NDB Cluster in the table comment of an NDB table. Table-level options for controlling read from any replica and partition balance can be embedded in a table comment using `NDB_TABLE`.

NDB supports two table comment options: `MAX_READ_PART_SIZE` and `PARTITION_BALANCE`. Syntax for these options is shown here:

```
COMMENT 'NDB_TABLE=optlist'

optlist := opt[=value[,...opt]]

opt :=
  MAX_READ_PART_SIZE=value |
  PARTITION_BALANCE[=on/off]
```

`MAX_READ_PART_SIZE` specifies the maximum size of a read operation from a partition; its expected value is a positive integer. Setting a value that exceeds available space on a disk raises an error. Setting a negative value is allowed, but causes the default value (the maximum amount of data that can be read from a partition) to be used.

You should be aware that the maximum value for this option is actually the maximum number of bytes that can be read from one replica; every partition in the replica contributes to this total.

You should also keep in mind, especially when working with `TEXT` columns, that the value set by `PARTITION_BALANCE` represents column size in bytes. It does not indicate the number of characters, which varies according to the character set and collation used by the column.

To see the effects of this option, first create a table with two `TEXT` columns, one (`t1`) with no extra options, and another (`t2`) with a setting for `PARTITION_BALANCE`, as shown here:

```
mysql> CREATE TABLE t2 (  
  -> a INT NOT NULL PRIMARY KEY,  
  -> t1 TEXT,  
  -> t2 TEXT COMMENT 'NDB_TABLE=PARTITION_BALANCE=5000'
```
CREATE TABLE Statement

You can see the `BLOB_INLINE_SIZE` settings for the `BLOB` columns by querying the `ndbinfo.blobs` table, like this:

```sql
mysql> SELECT
      -> column_name AS 'Column Name',
      -> inline_size AS 'Inline Size',
      -> part_size AS 'Blob Part Size'
      -> FROM ndbinfo.blobs
      -> WHERE table_name = 't1';
+-------------+-------------+----------------+
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Inline Size</th>
<th>Blob Part Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>b1</td>
<td>256</td>
<td>2000</td>
</tr>
<tr>
<td>b2</td>
<td>8000</td>
<td>2000</td>
</tr>
</tbody>
</table>
+-------------+-------------+----------------+
2 rows in set (0.01 sec)
```

You can also check the output from the `ndb_desc` utility, as shown here, with the relevant lines displayed using emphasized text:

```
$> ndb_desc -d test t1
-- t --
Version: 1
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 3
Number of primary keys: 1
Length of frm data: 945
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
PartitionCount: 2
FragmentCount: 2
PartitionBalance: FOR_RP_BY_LDM
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options: readbackup
HashMap: DEFAULT-HASHMAP-3840-2
-- Attributes --
a Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY
b1 Blob(256,2000,0) NULL AT=MEDIUM_VAR ST=MEMORY BV=2 BT=NDB$BLOB_64_1
b2 Blob(8000,2000,0) NULL AT=MEDIUM_VAR ST=MEMORY BV=2 BT=NDB$BLOB_64_2
-- Indexes --
PRIMARY KEY(a) - UniqueHashIndex
PRIMARY(a) - OrderedIndex
```

For `MAX_BLOB_PART_SIZE`, the = sign and the value following it are optional. Using any value other than 0 or 1 results in a syntax error.

The effect of using `MAX_BLOB_PART_SIZE` in a column comment is to set the blob part size of a `TEXT` or `BLOB` column to the maximum number of bytes supported for this by `NDB` (13948). This option can be applied to any blob column type supported by MySQL except `TINYBLOB` or `TINYTEXT` (`BLOB`, `MEDIUMBLOB`, `LONGBLOB`, `TEXT`, `MEDIUMTEXT`, `LONGTEXT`). Unlike `BLOB_INLINE_SIZE`, `MAX_BLOB_PART_SIZE` has no effect on `JSON` columns.

To see the effects of this option, we first run the following SQL statement in the `mysql` client to create a table with two `BLOB` columns, one (`c1`) with no extra options, and another (`c2`) with `MAX_BLOB_PART_SIZE`:

```sql
mysql> CREATE TABLE test.t2 ( c1
```
CREATE TABLE Statement

```sql
-> p INT PRIMARY KEY,
-> c1 BLOB,$
-> c2 BLOB COMMENT 'NDB_COLUMN=MAX_BLOB_PART_SIZE'
) ENGINE NDB;
```

Query OK, 0 rows affected (0.32 sec)

From the system shell, run the `ndb_desc` utility to obtain information about the table just created, as shown in this example:

```shell
$> ndb_desc -d test t2
-- t --
Version: 1
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 3
Number of primary keys: 1
Length of frm data: 324
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
HashMap: DEFAULT-HASHMAP-3840-2
-- Attributes --
p Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY
c1 Blob(256,2000,0) NULL AT=MEDIUM_VAR ST=MEMORY BV=2 BT=NDB$BLOB_22_1
c2 Blob(256,13948,0) NULL AT=MEDIUM_VAR ST=MEMORY BV=2 BT=NDB$BLOB_22_2
-- Indexes --
PRIMARY KEY(p) - UniqueHashIndex
PRIMARY(p) - OrderedIndex
```

Column information in the output is listed under `Attributes`; for columns `c1` and `c2` it is displayed here in emphasized text. For `c1`, the blob part size is 2000, the default value; for `c2`, it is 13948, as set by `MAX_BLOB_PART_SIZE`.

You can also query the `ndbinfo.blobs` table to see this, as shown here:

```sql
mysql> SELECT
-> column_name AS 'Column Name',
-> inline_size AS 'Inline Size',
-> part_size AS 'Blob Part Size'
-> FROM ndbinfo.blobs
-> WHERE table_name = 't2';
+-------------+-------------+----------------+
| Column Name | Inline Size | Blob Part Size |
+-------------+-------------+----------------+
| c1          |         256 |           2000 |
| c2          |         256 |          13948 |
+-------------+-------------+----------------+
2 rows in set (0.00 sec)
```

You can change the blob part size for a given blob column of an NDB table using an `ALTER TABLE` statement such as this one, and verifying the changes afterwards using `SHOW CREATE TABLE`:

```sql
mysql> ALTER TABLE test.t2
->    DROP COLUMN c1,
->     ADD COLUMN c1 BLOB COMMENT 'NDB_COLUMN=MAX_BLOB_PART_SIZE',
->     CHANGE COLUMN c2 c2 BLOB AFTER c1;
Query OK, 0 rows affected (0.47 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

```sql
mysql> SHOW CREATE TABLE test.t2\G
*************************** 1. row ***************************
Table: t
```

2529
CREATE TABLE Statement

Create Table: CREATE TABLE `t2` ( 
  `p` int(11) NOT NULL, 
  `c1` blob COMMENT 'NDB_COLUMN=MAX_BLOB_PART_SIZE', 
  `c2` blob, 
  PRIMARY KEY (`p`) 
) ENGINE=ndbcluster DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
1 row in set (0.00 sec)

mysql> EXIT
Bye

The output of ndb_desc shows that the blob part sizes of the columns have been changed as expected:

$> ndb_desc -d test t2
-- t --
Version: 16777220
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 3
Number of primary keys: 1
Length of frm data: 324
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
HashMap: DEFAULT-HASHMAP-3840-2
-- Attributes --
p Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY
c1 Blob(256,13948,0) NULL AT=MEDIUM_VAR ST=MEMORY BV=2 BT=NDB$BLOB_26_1
c2 Blob(256,2000,0) NULL AT=MEDIUM_VAR ST=MEMORY BV=2 BT=NDB$BLOB_26_2
-- Indexes --
PRIMARY KEY(p) - UniqueHashIndex
PRIMARY(p) - OrderedIndex

You can also see the change by running the query against ndbinfo.blobs again:

mysql> SELECT
  -> column_name AS 'Column Name',
  -> inline_size AS 'Inline Size',
  -> part_size AS 'Blob Part Size'
  -> FROM ndbinfo.blobs
  -> WHERE table_name = 't2';
+-------------+-------------+----------------+
| Column Name | Inline Size | Blob Part Size |
+-------------+-------------+----------------+
| c1          |         256 |          13948 |
| c2          |         256 |           2000 |
+-------------+-------------+----------------+
2 rows in set (0.00 sec)

It is possible to set both BLOB_INLINE_SIZE and MAX_BLOB_PART_SIZE for a blob column, as shown in this CREATE TABLE statement:

mysql> CREATE TABLE test.t3 ( 
  -> p INT NOT NULL PRIMARY KEY,
  -> c1 JSON,
  -> c2 JSON COMMENT 'NDB_COLUMN=BLOB_INLINE_SIZE=5000,MAX_BLOB_PART_SIZE' 
) ENGINE NDB;
Query OK, 0 rows affected (0.28 sec)

Querying the blobs table shows us that the statement worked as expected:

mysql> SELECT
You can also verify that the statement worked by checking the output of `ndb_desc`.

Changing a column's blob part size must be done using a copying `ALTER TABLE`; this operation cannot be performed online (see Section 25.6.12, “Online Operations with ALTER TABLE in NDB Cluster”).

For more information about how NDB stores columns of blob types, see String Type Storage Requirements.

**NDB_TABLE Options**

For an NDB Cluster table, the table comment in a `CREATE TABLE` or `ALTER TABLE` statement can also be used to specify an `NDB_TABLE` option, which consists of one or more name-value pairs, separated by commas if need be, following the string `NDB_TABLE=`. Complete syntax for names and values syntax is shown here:

```
COMMENT="NDB_TABLE=
ndb_table_option[,ndb_table_option[,...]]"
```

```
ndb_table_option: ( 
    NOLOGGING={1 | 0} 
    | READ_BACKUP={1 | 0} 
    | PARTITION_BALANCE={FOR_RP_BY_NODE | FOR_RA_BY_NODE | FOR_RP_BY_LDM 
                      | FOR_RA_BY_LDM | FOR_RA_BY_LDM_X_2 
                      | FOR_RA_BY_LDM_X_3 | FOR_RA_BY_LDM_X_4} 
    | FULLY_REPLICATED={1 | 0} 
)
```

Spaces are not permitted within the quoted string. The string is case-insensitive.

The four `NDB` table options that can be set as part of a comment in this way are described in more detail in the next few paragraphs.

**NOLOGGING**: By default, NDB tables are logged, and checkpointed. This makes them durable to whole cluster failures. Using `NOLOGGING` when creating or altering a table means that this table is not redo logged or included in local checkpoints. In this case, the table is still replicated across the data nodes for high availability, and updated using transactions, but changes made to it are not recorded in the data node's redo logs, and its content is not checkpointed to disk; when recovering from a cluster failure, the cluster retains the table definition, but none of its rows—that is, the table is empty.

Using such nonlogging tables reduces the data node's demands on disk I/O and storage, as well as CPU for checkpointing CPU. This may be suitable for short-lived data which is frequently updated, and where the loss of all data in the unlikely event of a total cluster failure is acceptable.

It is also possible to use the `ndb_table_no_logging` system variable to cause any NDB tables created or altered while this variable is in effect to behave as though it had been created with the `NOLOGGING` comment. Unlike when using the comment directly, there is nothing in this case in the output of `SHOW CREATE TABLE` to indicate that it is a nonlogging table. Using the table comment approach is recommended since it offers per-table control of the feature, and this aspect of the table schema is embedded in the table creation statement where it can be found easily by SQL-based tools.

**READ_BACKUP**: Setting this option to 1 has the same effect as though `ndb_read_backup` were enabled; enables reading from any replica. Doing so greatly improves the performance of reads from
the table at a relatively small cost to write performance. 1 is the default for READ_BACKUP, and the
default for ndb_read_backup is ON (previously, read from any replica was disabled by default).

You can set READ_BACKUP for an existing table online, using an ALTER TABLE statement similar to
one of those shown here:

```
ALTER TABLE ... ALGORITHM=INPLACE, COMMENT="NDB_TABLE=READ_BACKUP=1";
ALTER TABLE ... ALGORITHM=INPLACE, COMMENT="NDB_TABLE=READ_BACKUP=0";
```

For more information about the ALGORITHM option for ALTER TABLE, see Section 25.6.12, “Online
Operations with ALTER TABLE in NDB Cluster”.

PARTITION_BALANCE: Provides additional control over assignment and placement of partitions. The
following four schemes are supported:

1. **FOR_RP_BY_NODE**: One partition per node.
   Only one LDM on each node stores a primary partition. Each partition is stored in the same LDM
   (same ID) on all nodes.

2. **FOR_RA_BY_NODE**: One partition per node group.
   Each node stores a single partition, which can be either a primary replica or a backup replica. Each
   partition is stored in the same LDM on all nodes.

3. **FOR_RP_BY_LDM**: One partition for each LDM on each node; the default.
   This is the setting used if READ_BACKUP is set to 1.

4. **FOR_RA_BY_LDM**: One partition per LDM in each node group.
   These partitions can be primary or backup partitions.

5. **FOR_RA_BY_LDM_X_2**: Two partitions per LDM in each node group.
   These partitions can be primary or backup partitions.

6. **FOR_RA_BY_LDM_X_3**: Three partitions per LDM in each node group.
   These partitions can be primary or backup partitions.

7. **FOR_RA_BY_LDM_X_4**: Four partitions per LDM in each node group.
   These partitions can be primary or backup partitions.

PARTITION_BALANCE is the preferred interface for setting the number of partitions per table. Using
MAX_ROWS to force the number of partitions is deprecated but continues to be supported for backward
compatibility; it is subject to removal in a future release of MySQL NDB Cluster. (Bug #81759, Bug
#23544301)

FULLY_REPLICATED controls whether the table is fully replicated, that is, whether each data node
has a complete copy of the table. To enable full replication of the table, use FULLY_REPLICATED=1.

This setting can also be controlled using the ndb_fully_replicated system variable.
Setting it to ON enables the option by default for all new NDB tables; the default is OFF. The
ndb_data_node_neighbour system variable is also used for fully replicated tables, to ensure that
when a fully replicated table is accessed, we access the data node which is local to this MySQL Server.

An example of a CREATE TABLE statement using such a comment when creating an NDB table is
shown here:

```
mysql> CREATE TABLE t1 (}
CREATE TABLESPACE Statement

CREATE [UNDO] TABLESPACE tablespace_name

The comment is displayed as part of the output of `SHOW CREATE TABLE`. The text of the comment is also available from querying the MySQL Information Schema `TABLES` table, as in this example:

```sql
mysql> SELECT TABLE_NAME, TABLE_SCHEMA, TABLE_COMMENT
FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_NAME="t1"\G
*************************** 1. row ***************************
TABLE_NAME: t1
TABLE_SCHEMA: test
TABLE_COMMENT: NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RP_BY_NODE
1 row in set (0.01 sec)
```

This comment syntax is also supported with `ALTER TABLE` statements for NDB tables, as shown here:

```sql
mysql> ALTER TABLE t1 COMMENT="NDB_TABLE=PARTITION_BALANCE=FOR_RA_BY_NODE";
Query OK, 0 rows affected (0.40 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

The `TABLE_COMMENT` column displays the comment that is required to re-create the table as it is following the `ALTER TABLE` statement, like this:

```sql
mysql> SELECT TABLE_NAME, TABLE_SCHEMA, TABLE_COMMENT
FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_NAME="t1";
*************************** 1. row ***************************
TABLE_NAME: t1
TABLE_SCHEMA: test
TABLE_COMMENT: NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RP_BY_NODE
1 row in set (0.01 sec)
```

Keep in mind that a table comment used with `ALTER TABLE` replaces any existing comment which the table might have.

```sql
mysql> ALTER TABLE t1 COMMENT="NDB_TABLE=PARTITION_BALANCE=FOR_RA_BY_NODE";
Query OK, 0 rows affected (0.40 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

You can also see the value of the `PARTITION_BALANCE` option in the output of `ndb_desc`. `ndb_desc` also shows whether the `READ_BACKUP` and `FULLY_REPLICATED` options are set for the table. See the description of this program for more information.

15.1.21 CREATE TABLESPACE Statement

CREATE [UNDO] TABLESPACE tablespace_name
CREATE TABLESPACE Statement

**InnoDB and NDB:**

- ADD DATAFILE 'file_name'
- AUTOEXTEND_SIZE [=] value

**InnoDB only:**

- FILE_BLOCK_SIZE = value
- ENCRYPTION [=] {'Y' | 'N'}

**NDB only:**

- USE LOGFILE GROUP logfile_group
- EXTENT_SIZE [=] extent_size
- INITIAL_SIZE [=] initial_size
- MAX_SIZE [=] max_size
- NODEGROUP [=] nodegroup_id
- WAIT
- COMMENT [=] 'string'

**InnoDB and NDB:**

- ENGINE [=] engine_name

**Reserved for future use:**

- ENGINE_ATTRIBUTE [=] 'string'

This statement is used to create a tablespace. The precise syntax and semantics depend on the storage engine used. In standard MySQL releases, this is always an **InnoDB** tablespace. MySQL NDB Cluster also supports tablespaces using the **NDB** storage engine.

- **Considerations for InnoDB**
- **Considerations for NDB Cluster**
- **Options**
- **Notes**
- **InnoDB Examples**
- **NDB Example**

**Considerations for InnoDB**

The **CREATE TABLESPACE** syntax is used to create general tablespaces or undo tablespaces. The **UNDO** keyword must be specified to create an undo tablespace.

A general tablespace is a shared tablespace. It can hold multiple tables, and supports all table row formats. General tablespaces can be created in a location relative to or independent of the data directory.

After creating an **InnoDB** general tablespace, use **CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name** or **ALTER TABLE tbl_name TABLESPACE [=] tablespace_name** to add tables to the tablespace. For more information, see Section 17.6.3.3, “General Tablespaces”.

Undo tablespaces contain undo logs. Undo tablespaces can be created in a chosen location by specifying a fully qualified data file path. For more information, see Section 17.6.3.4, “Undo Tablespaces”.

**Considerations for NDB Cluster**

This statement is used to create a tablespace, which can contain one or more data files, providing storage space for NDB Cluster Disk Data tables (see Section 25.6.11, “NDB Cluster Disk Data Tables”). One data file is created and added to the tablespace using this statement. Additional data files may be added to the tablespace by using the **ALTER TABLESPACE** statement (see Section 15.1.10, “ALTER TABLESPACE Statement”).
CREATE TABLESPACE Statement

Note
All NDB Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group with the same name, or a tablespace and a data file with the same name.

A log file group of one or more UNDO log files must be assigned to the tablespace to be created with the USE LOGFILE GROUP clause. logfile_group must be an existing log file group created with CREATE LOGFILE GROUP (see Section 15.1.16, “CREATE LOGFILE GROUP Statement”). Multiple tablespaces may use the same log file group for UNDO logging.

When setting EXTENT_SIZE or INITIAL_SIZE, you may optionally follow the number with a one-letter abbreviation for an order of magnitude, similar to those used in my.cnf. Generally, this is one of the letters M (for megabytes) or G (for gigabytes).

INITIAL_SIZE and EXTENT_SIZE are subject to rounding as follows:

- EXTENT_SIZE is rounded up to the nearest whole multiple of 32K.
- INITIAL_SIZE is rounded down to the nearest whole multiple of 32K; this result is rounded up to the nearest whole multiple of EXTENT_SIZE (after any rounding).

Note
NDB reserves 4% of a tablespace for data node restart operations. This reserved space cannot be used for data storage.

The rounding just described is done explicitly, and a warning is issued by the MySQL Server when any such rounding is performed. The rounded values are also used by the NDB kernel for calculating INFORMATION_SCHEMA.FILES column values and other purposes. However, to avoid an unexpected result, we suggest that you always use whole multiples of 32K in specifying these options.

When CREATE TABLESPACE is used with ENGINE [=] NDB, a tablespace and associated data file are created on each Cluster data node. You can verify that the data files were created and obtain information about them by querying the Information Schema FILES table. (See the example later in this section.)

(See Section 28.3.15, “The INFORMATION_SCHEMA FILES Table”.)

Options

- ADD_DATAFILE: Defines the name of a tablespace data file. This option is always required when creating an NDB tablespace; for InnoDB, it is required only when creating an undo tablespace. The file_name, including any specified path, must be quoted with single or double quotation marks. File names (not counting the file extension) and directory names must be at least one byte in length. Zero length file names and directory names are not supported.

Because there are considerable differences in how InnoDB and NDB treat data files, the two storage engines are covered separately in the discussion that follows.

InnoDB data files. An InnoDB tablespace supports only a single data file, whose name must include an .ibd extension.

To place an InnoDB general tablespace data file in a location outside of the data directory, include a fully qualified path or a path relative to the data directory. Only a fully qualified path is permitted for undo tablespaces. If you do not specify a path, a general tablespace is created in the data directory. An undo tablespace created without specifying a path is created in the directory defined by the innodb_undo_directory variable. If innodb_undo_directory is not set, undo tablespaces are created in the data directory.
To avoid conflicts with implicitly created file-per-table tablespaces, creating an InnoDB general tablespace in a subdirectory under the data directory is not supported. When creating a general tablespace or undo tablespace outside of the data directory, the directory must exist and must be known to InnoDB prior to creating the tablespace. To make a directory known to InnoDB, add it to the innodb_directories value or to one of the variables whose values are appended to the value of innodb_directories. innodb_directories is a read-only variable. Configuring it requires restarting the server.

If the ADD DATAFILE clause is not specified when creating an InnoDB tablespace, a tablespace data file with a unique file name is created implicitly. The unique file name is a 128 bit UUID formatted into five groups of hexadecimal numbers separated by dashes (aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeee). A file extension is added if required by the storage engine. An .ibd file extension is added for InnoDB general tablespace data files. In a replication environment, the data file name created on the replication source server is not the same as the data file name created on the replica.

The ADD DATAFILE clause does not permit circular directory references when creating an InnoDB tablespace. For example, the circular directory reference (/../) in the following statement is not permitted:

```sql
CREATE TABLESPACE ts1 ADD DATAFILE ts1.ibd 'any_directory/../ts1.ibd';
```

An exception to this restriction exists on Linux, where a circular directory reference is permitted if the preceding directory is a symbolic link. For example, the data file path in the example above is permitted if any_directory is a symbolic link. (It is still permitted for data file paths to begin with './'.)

**NDB data files.** An NDB tablespace supports multiple data files which can have any legal file names; more data files can be added to an NDB Cluster tablespace following its creation by using an ALTER TABLESPACE statement.

An NDB tablespace data file is created by default in the data node file system directory—that is, the directory named ndb_nodeid_fs/TS under the data node's data directory (DataDir), where nodeid is the data node's NodeId. To place the data file in a location other than the default, include an absolute directory path or a path relative to the default location. If the directory specified does not exist, NDB attempts to create it; the system user account under which the data node process is running must have the appropriate permissions to do so.

![Note](image)

When determining the path used for a data file, NDB does not expand the ~ (tilde) character.

When multiple data nodes are run on the same physical host, the following considerations apply:

- You cannot specify an absolute path when creating a data file.
- It is not possible to create tablespace data files outside the data node file system directory, unless each data node has a separate data directory.
- If each data node has its own data directory, data files can be created anywhere within this directory.
- If each data node has its own data directory, it may also be possible to create a data file outside the node's data directory using a relative path, as long as this path resolves to a unique location on the host file system for each data node running on that host.
- **FILE_BLOCK_SIZE:** This option—which is specific to InnoDB general tablespaces, and is ignored by NDB—defines the block size for the tablespace data file. Values can be specified in bytes or kilobytes. For example, an 8 kilobyte file block size can be specified as 8192 or 8K. If
you do not specify this option, **FILE_BLOCK_SIZE** defaults to the **innodb_page_size** value. **FILE_BLOCK_SIZE** is required when you intend to use the tablespace for storing compressed InnoDB tables (**ROW_FORMAT=COMPRESSED**). In this case, you must define the tablespace **FILE_BLOCK_SIZE** when creating the tablespace.

If **FILE_BLOCK_SIZE** is equal the **innodb_page_size** value, the tablespace can contain only tables having an uncompressed row format (**COMPACT, REDUNDANT, and DYNAMIC**). Tables with a **COMPRESSED** row format have a different physical page size than uncompressed tables. Therefore, compressed tables cannot coexist in the same tablespace as uncompressed tables.

For a general tablespace to contain compressed tables, **FILE_BLOCK_SIZE** must be specified, and the **FILE_BLOCK_SIZE** value must be a valid compressed page size in relation to the **innodb_page_size** value. Also, the physical page size of the compressed table (**KEY_BLOCK_SIZE**) must be equal to **FILE_BLOCK_SIZE**/1024. For example, if **innodb_page_size=16K**, and **FILE_BLOCK_SIZE=8K**, the **KEY_BLOCK_SIZE** of the table must be 8. For more information, see Section 17.6.3.3, “General Tablespaces”.

- **USE LOGFILE GROUP**: Required for NDB, this is the name of a log file group previously created using **CREATE LOGFILE GROUP**. Not supported for InnoDB, where it fails with an error.

- **EXTENT_SIZE**: This option is specific to NDB, and is not supported by InnoDB, where it fails with an error. **EXTENT_SIZE** sets the size, in bytes, of the extents used by any files belonging to the tablespace. The default value is 1M. The minimum size is 32K, and theoretical maximum is 2G, although the practical maximum size depends on a number of factors. In most cases, changing the extent size does not have any measurable effect on performance, and the default value is recommended for all but the most unusual situations.

  An **extent** is a unit of disk space allocation. One extent is filled with as much data as that extent can contain before another extent is used. In theory, up to 65,535 (64K) extents may used per data file; however, the recommended maximum is 32,768 (32K). The recommended maximum size for a single data file is 32G—that is, 32K extents × 1 MB per extent. In addition, once an extent is allocated to a given partition, it cannot be used to store data from a different partition; an extent cannot store data from more than one partition. This means, for example that a tablespace having a single datafile whose **INITIAL_SIZE** (described in the following item) is 256 MB and whose **EXTENT_SIZE** is 128M has just two extents, and so can be used to store data from at most two different disk data table partitions.

  You can see how many extents remain free in a given data file by querying the Information Schema **FILES** table, and so derive an estimate for how much space remains free in the file. For further discussion and examples, see Section 28.3.15, “The INFORMATION_SCHEMA FILES Table”.

- **INITIAL_SIZE**: This option is specific to NDB, and is not supported by InnoDB, where it fails with an error.

  The **INITIAL_SIZE** parameter sets the total size in bytes of the data file that was specific using **ADD DATATFILE**. Once this file has been created, its size cannot be changed; however, you can add more data files to the tablespace using **ALTER TABLESPACE ... ADD DATATFILE**.

  **INITIAL_SIZE** is optional; its default value is 134217728 (128 MB).

  On 32-bit systems, the maximum supported value for **INITIAL_SIZE** is 4294967296 (4 GB).

- **AUTOEXTEND_SIZE**: Defines the amount by which InnoDB extends the size of the tablespace when it becomes full. The setting must be a multiple of 4MB. The default setting is 0, which causes the tablespace to be extended according to the implicit default behavior. For more information, see Section 17.6.3.9, “Tablespace AUTOEXTEND_SIZE Configuration”.

  Has no effect in any release of MySQL NDB Cluster, regardless of the storage engine used.

- **MAX_SIZE**: Currently ignored by MySQL; reserved for possible future use. Has no effect in any release of MySQL or MySQL NDB Cluster, regardless of the storage engine used.
• **NODEGROUP**: Currently ignored by MySQL; reserved for possible future use. Has no effect in any release of MySQL or MySQL NDB Cluster, regardless of the storage engine used.

• **WAIT**: Currently ignored by MySQL; reserved for possible future use. Has no effect in any release of MySQL or MySQL NDB Cluster, regardless of the storage engine used.

• **COMMENT**: Currently ignored by MySQL; reserved for possible future use. Has no effect in any release of MySQL or MySQL NDB Cluster, regardless of the storage engine used.

• The **ENCRYPTION** clause enables or disables page-level data encryption for an InnoDB general tablespace.

  If the **ENCRYPTION** clause is not specified, the `default_table_encryption` setting controls whether encryption is enabled. The **ENCRYPTION** clause overrides the `default_table_encryption` setting. However, if the `table_encryption_privilege_check` variable is enabled, the **TABLE_ENCRYPTION_ADMIN** privilege is required to use an **ENCRYPTION** clause setting that differs from the `default_table_encryption` setting.

  A keyring plugin must be installed and configured before an encryption-enabled tablespace can be created.

  When a general tablespace is encrypted, all tables residing in the tablespace are encrypted. Likewise, a table created in an encrypted tablespace is encrypted.

  For more information, see Section 17.13, “InnoDB Data-at-Rest Encryption”

• **ENGINE**: Defines the storage engine which uses the tablespace, where **engine_name** is the name of the storage engine. Currently, only the InnoDB storage engine is supported by standard MySQL 8.4 releases. MySQL NDB Cluster supports both NDB and InnoDB tablespaces. The value of the `default_storage_engine` system variable is used for **ENGINE** if the option is not specified.

• The **ENGINE_ATTRIBUTE** option is used to specify tablespace attributes for primary storage engines. The option is reserved for future use.

  The value assigned to this option must be a string literal containing a valid JSON document or an empty string (''). Invalid JSON is rejected.

  ```sql
  CREATE TABLESPACE ts1 ENGINE_ATTRIBUTE='{"key":"value"}';
  ```

  **ENGINE_ATTRIBUTE** values can be repeated without error. In this case, the last specified value is used.

  **ENGINE_ATTRIBUTE** values are not checked by the server, nor are they cleared when the table's storage engine is changed.

**Notes**

• For the rules covering the naming of MySQL tablespaces, see Section 11.2, “Schema Object Names”. In addition to these rules, the slash character (“/”) is not permitted, nor can you use names beginning with `innodb_`, as this prefix is reserved for system use.

• Creation of temporary general tablespaces is not supported.

• General tablespaces do not support temporary tables.

• The **TABLESPACE** option may be used with **CREATE TABLE** or **ALTER TABLE** to assign an InnoDB table partition or subpartition to a file-per-table tablespace. All partitions must belong to the same storage engine. Assigning table partitions to shared InnoDB tablespaces is not supported. Shared tablespaces include the InnoDB system tablespace and general tablespaces.

• General tablespaces support the addition of tables of any row format using **CREATE TABLE ... TABLESPACE.innodb_file_per_table** does not need to be enabled.
CREATE TABLESPACE Statement

• `innodb_strict_mode` is not applicable to general tablespaces. Tablespace management rules are strictly enforced independently of `innodb_strict_mode`. If `CREATE TABLESPACE` parameters are incorrect or incompatible, the operation fails regardless of the `innodb_strict_mode` setting. When a table is added to a general tablespace using `CREATE TABLE ... TABLESPACE` or `ALTER TABLE ... TABLESPACE`, `innodb_strict_mode` is ignored but the statement is evaluated as if `innodb_strict_mode` is enabled.

• Use `DROP TABLESPACE` to remove a tablespace. All tables must be dropped from a tablespace using `DROP TABLE` prior to dropping the tablespace. Before dropping an NDB Cluster tablespace you must also remove all its data files using one or more `ALTER TABLESPACE ... DROP DATATFILE` statements. See Section 25.6.11.1, “NDB Cluster Disk Data Objects”.

• All parts of an InnoDB table added to an InnoDB general tablespace reside in the general tablespace, including indexes and BLOB pages.

For an NDB table assigned to a tablespace, only those columns which are not indexed are stored on disk, and actually use the tablespace data files. Indexes and indexed columns for all NDB tables are always kept in memory.

• Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace .ibd data file which can only be used for new InnoDB data. Space is not released back to the operating system as it is for file-per-table tablespaces.

• A general tablespace is not associated with any database or schema.

• `ALTER TABLE ... DISCARD TABLESPACE` and `ALTER TABLE ... IMPORT TABLESPACE` are not supported for tables that belong to a general tablespace.

• The server uses tablespace-level metadata locking for DDL that references general tablespaces. By comparison, the server uses table-level metadata locking for DDL that references file-per-table tablespaces.

• A generated or existing tablespace cannot be changed to a general tablespace.

• There is no conflict between general tablespace names and file-per-table tablespace names. The “/” character, which is present in file-per-table tablespace names, is not permitted in general tablespace names.

• `mysqldump` does not dump InnoDB `CREATE TABLESPACE` statements.

InnoDB Examples

This example demonstrates creating a general tablespace and adding three uncompressed tables of different row formats.

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' ENGINE=INNODB;
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=REDUNDANT;
mysql> CREATE TABLE t2 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=CMPACT;
mysql> CREATE TABLE t3 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=DYNAMIC;
```

This example demonstrates creating a general tablespace and adding a compressed table. The example assumes a default `innodb_page_size` value of 16K. The `FILE_BLOCK_SIZE` of 8192 requires that the compressed table have a `KEY_BLOCK_SIZE` of 8.

```
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE = 8192 ENGINE=InnoDB;
mysql> CREATE TABLE t4 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED KEY_BLOCK_SIZE=8;
```

This example demonstrates creating a general tablespace without specifying the `ADD DATAFILE` clause, which is optional:
CREATE TABLESPACE `ts3` ENGINE=INNODB;

This example demonstrates creating an undo tablespace:

CREATE UNDO TABLESPACE undo_003 ADD DATAFILE 'undo_003.ibu';

NDB Example

Suppose that you wish to create an NDB Cluster Disk Data tablespace named `myts` using a datafile named `mydata-1.dat`. An NDB tablespace always requires the use of a log file group consisting of one or more undo log files. For this example, we first create a log file group named `mylg` that contains one undo long file named `myundo-1.dat`, using the `CREATE LOGFILE GROUP` statement shown here:

mysql> CREATE LOGFILE GROUP mylg
  ->  ADD UNDOFILE 'myundo-1.dat'
  ->  ENGINE=NDB;
Query OK, 0 rows affected (3.29 sec)

Now you can create the tablespace previously described using the following statement:

mysql> CREATE TABLESPACE myts
  ->  ADD DATAFILE 'mydata-1.dat'
  ->  USE LOGFILE GROUP mylg
  ->  ENGINE=NDB;
Query OK, 0 rows affected (2.98 sec)

You can now create a Disk Data table using a `CREATE TABLE` statement with the `TABLESPACE` and `STORAGE DISK` options, similar to what is shown here:

mysql> CREATE TABLE mytable (                  
  ->  id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY, 
  ->  lname VARCHAR(50) NOT NULL, 
  ->  fname VARCHAR(50) NOT NULL, 
  ->  dob DATE NOT NULL, 
  ->  joined DATE NOT NULL, 
  ->  INDEX(last_name, first_name) 
  -> ) TABLESPACE myts STORAGE DISK 
  ->  ENGINE=NDB;
Query OK, 0 rows affected (1.41 sec)

It is important to note that only the `dob` and `joined` columns from `mytable` are actually stored on disk, due to the fact that the `id`, `lname`, and `fname` columns are all indexed.

As mentioned previously, when `CREATE TABLESPACE` is used with `ENGINE [=] NDB`, a tablespace and its associated data file are created on each NDB Cluster data node. You can verify that the data files were created and obtain information about them by querying the Information Schema `FILES` table, as shown here:

mysql> SELECT FILE_NAME, FILE_TYPE, LOGFILE_GROUP_NAME, STATUS, EXTRA
  ->  FROM INFORMATION_SCHEMA.FILES
  ->  WHERE TABLESPACE_NAME = 'myts';
+--------------+------------+--------------------+--------+----------------+
<table>
<thead>
<tr>
<th>file_name</th>
<th>file_type</th>
<th>logfile_group_name</th>
<th>status</th>
<th>extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>mydata-1.dat</td>
<td>DATAFILE</td>
<td>mylg</td>
<td>NORMAL</td>
<td>CLUSTER_NODE=5</td>
</tr>
<tr>
<td>mydata-1.dat</td>
<td>DATAFILE</td>
<td>mylg</td>
<td>NORMAL</td>
<td>CLUSTER_NODE=6</td>
</tr>
<tr>
<td>NULL</td>
<td>TABLESPACE</td>
<td>mylg</td>
<td>NORMAL</td>
<td>NULL</td>
</tr>
</tbody>
</table>
+--------------+------------+--------------------+--------+----------------+
3 rows in set (0.01 sec)

For additional information and examples, see Section 25.6.11.1, “NDB Cluster Disk Data Objects”.

15.1.22 CREATE TRIGGER Statement
CREATE TRIGGER Statement

```
[DEFINER = user]
TRIGGER [IF NOT EXISTS] trigger_name
    trigger_time trigger_event
    ON tbl_name FOR EACH ROW
    [trigger_order]
    trigger_body

trigger_time: { BEFORE | AFTER }
trigger_event: { INSERT | UPDATE | DELETE }
trigger_order: { Follows | Precedes } other_trigger_name
```

This statement creates a new trigger. A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. The trigger becomes associated with the table named `tbl_name`, which must refer to a permanent table. You cannot associate a trigger with a `TEMPORARY` table or a view.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

`IF NOT EXISTS` prevents an error from occurring if a trigger having the same name, on the same table, exists in the same schema.

This section describes `CREATE TRIGGER` syntax. For additional discussion, see Section 27.3.1, “Trigger Syntax and Examples”.

`CREATE TRIGGER` requires the `TRIGGER` privilege for the table associated with the trigger. If the `DEFINER` clause is present, the privileges required depend on the `user` value, as discussed in Section 27.6, “Stored Object Access Control”. If binary logging is enabled, `CREATE TRIGGER` might require the `SUPER` privilege, as discussed in Section 27.7, “Stored Program Binary Logging”.

The `DEFINER` clause determines the security context to be used when checking access privileges at trigger activation time, as described later in this section.

`trigger_time` is the trigger action time. It can be `BEFORE` or `AFTER` to indicate that the trigger activates before or after each row to be modified.

Basic column value checks occur prior to trigger activation, so you cannot use `BEFORE` triggers to convert values inappropriate for the column type to valid values.

`trigger_event` indicates the kind of operation that activates the trigger. These `trigger_event` values are permitted:

- `INSERT`: The trigger activates whenever a new row is inserted into the table (for example, through `INSERT`, `LOAD DATA`, and `REPLACE` statements).
- `UPDATE`: The trigger activates whenever a row is modified (for example, through `UPDATE` statements).
- `DELETE`: The trigger activates whenever a row is deleted from the table (for example, through `DELETE` and `REPLACE` statements). `DROP TABLE` and `TRUNCATE TABLE` statements on the table do not activate this trigger, because they do not use `DELETE`. Dropping a partition does not activate `DELETE` triggers, either.

The `trigger_event` does not represent a literal type of SQL statement that activates the trigger so much as it represents a type of table operation. For example, an `INSERT` trigger activates not only for `INSERT` statements but also `LOAD DATA` statements because both statements insert rows into a table.

A potentially confusing example of this is the `INSERT INTO ... ON DUPLICATE KEY UPDATE ...` syntax: a `BEFORE INSERT` trigger activates for every row, followed by either an `AFTER INSERT` trigger or both the `BEFORE UPDATE` and `AFTER UPDATE` triggers, depending on whether there was a duplicate key for the row.
CREATE TRIGGER Statement

Note
Cascaded foreign key actions do not activate triggers.

It is possible to define multiple triggers for a given table that have the same trigger event and action time. For example, you can have two BEFORE UPDATE triggers for a table. By default, triggers that have the same trigger event and action time activate in the order they were created. To affect trigger order, specify a trigger_order clause that indicates follows or precedes and the name of an existing trigger that also has the same trigger event and action time. With precedes, the new trigger activates after the existing trigger. With follows, the new trigger activates before the existing trigger.

trigger_body is the statement to execute when the trigger activates. To execute multiple statements, use the BEGIN ... END compound statement construct. This also enables you to use the same statements that are permitted within stored routines. See Section 15.6.1, “BEGIN ... END Compound Statement”. Some statements are not permitted in triggers; see Section 27.8, “Restrictions on Stored Programs”.

Within the trigger body, you can refer to columns in the subject table (the table associated with the trigger) by using the aliases OLD and NEW. OLD.col_name refers to a column of an existing row before it is updated or deleted. NEW.col_name refers to the column of a new row to be inserted or an existing row after it is updated.

Triggers cannot use NEW.col_name or use OLD.col_name to refer to generated columns. For information about generated columns, see Section 15.1.20.8, “CREATE TABLE and Generated Columns”.

MySQL stores the sql_mode system variable setting in effect when a trigger is created, and always executes the trigger body with this setting in force, regardless of the current server SQL mode when the trigger begins executing.

The DEFINER clause specifies the MySQL account to be used when checking access privileges at trigger activation time. If the DEFINER clause is present, the user value should be a MySQL account specified as 'user_name'@'host_name', CURRENT_USER, or CURRENT_USER(). The permitted user values depend on the privileges you hold, as discussed in Section 27.6, “Stored Object Access Control”. Also see that section for additional information about trigger security.

If the DEFINER clause is omitted, the default definer is the user who executes the CREATE TRIGGER statement. This is the same as specifying DEFINER = CURRENT_USER explicitly.

MySQL takes the DEFINER user into account when checking trigger privileges as follows:

• At CREATE TRIGGER time, the user who issues the statement must have the TRIGGER privilege.

• At trigger activation time, privileges are checked against the DEFINER user. This user must have these privileges:

  • The TRIGGER privilege for the subject table.

  • The SELECT privilege for the subject table if references to table columns occur using OLD.col_name or NEW.col_name in the trigger body.

  • The UPDATE privilege for the subject table if table columns are targets of SET NEW.col_name = value assignments in the trigger body.

  • Whatever other privileges normally are required for the statements executed by the trigger.

Within a trigger body, the CURRENT_USER function returns the account used to check privileges at trigger activation time. This is the DEFINER user, not the user whose actions caused the trigger to be activated. For information about user auditing within triggers, see Section 8.2.23, “SQL-Based Account Activity Auditing”.

2542
CREATE VIEW Statement

If you use LOCK TABLES to lock a table that has triggers, the tables used within the trigger are also locked, as described in LOCK TABLES and Triggers.

For additional discussion of trigger use, see Section 27.3.1, “Trigger Syntax and Examples”.

15.1.23 CREATE VIEW Statement

CREATE
[OR REPLACE]
[ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
[DEFINER = user]
[SQL SECURITY { DEFINER | INVOKER }]
VIEW view_name [(column_list)]
AS select_statement
[WITH [CASCADED | LOCAL] CHECK OPTION]

The CREATE VIEW statement creates a new view, or replaces an existing view if the OR REPLACE clause is given. If the view does not exist, CREATE OR REPLACE VIEW is the same as CREATE VIEW. If the view does exist, CREATE OR REPLACE VIEW replaces it.

For information about restrictions on view use, see Section 27.9, “Restrictions on Views”.

The select_statement is a SELECT statement that provides the definition of the view. (Selecting from the view selects, in effect, using the SELECT statement.) The select_statement can select from base tables or from other views. The SELECT statement can use a VALUES statement as its source, or can be replaced with a TABLE statement, as with CREATE TABLE ... SELECT.

The view definition is “frozen” at creation time and is not affected by subsequent changes to the definitions of the underlying tables. For example, if a view is defined as SELECT * on a table, new columns added to the table later do not become part of the view, and columns dropped from the table result in an error when selecting from the view.

The ALGORITHM clause affects how MySQL processes the view. The DEFINER and SQL SECURITY clauses specify the security context to be used when checking access privileges at view invocation time. The WITH CHECK OPTION clause can be given to constrain inserts or updates to rows in tables referenced by the view. These clauses are described later in this section.

The CREATE VIEW statement requires the CREATE VIEW privilege for the view, and some privilege for each column selected by the SELECT statement. For columns used elsewhere in the SELECT statement, you must have the DROP privilege for the view. If the DEFINER clause is present, the privileges required depend on the user value, as discussed in Section 27.6, “Stored Object Access Control”.

When a view is referenced, privilege checking occurs as described later in this section.

A view belongs to a database. By default, a new view is created in the default database. To create the view explicitly in a given database, use db_name.view_name syntax to qualify the view name with the database name:

CREATE VIEW test.v AS SELECT * FROM t;

Unqualified table or view names in the SELECT statement are also interpreted with respect to the default database. A view can refer to tables or views in other databases by qualifying the table or view name with the appropriate database name.

Within a database, base tables and views share the same namespace, so a base table and a view cannot have the same name.

Columns retrieved by the SELECT statement can be simple references to table columns, or expressions that use functions, constant values, operators, and so forth.

A view must have unique column names with no duplicates, just like a base table. By default, the names of the columns retrieved by the SELECT statement are used for the view column names.
CREATE VIEW Statement

To define explicit names for the view columns, specify the optional column_list clause as a list of comma-separated identifiers. The number of names in column_list must be the same as the number of columns retrieved by the SELECT statement.

A view can be created from many kinds of SELECT statements. It can refer to base tables or other views. It can use joins, UNION, and subqueries. The SELECT need not even refer to any tables:

```
CREATE VIEW v_today (today) AS SELECT CURRENT_DATE;
```

The following example defines a view that selects two columns from another table as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+------+-------+-------+
<table>
<thead>
<tr>
<th>qty</th>
<th>price</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>50</td>
<td>150</td>
</tr>
</tbody>
</table>
+------+-------+-------+
```

A view definition is subject to the following restrictions:

- The SELECT statement cannot refer to system variables or user-defined variables.
- Within a stored program, the SELECT statement cannot refer to program parameters or local variables.
- The SELECT statement cannot refer to prepared statement parameters.
- Any table or view referred to in the definition must exist. If, after the view has been created, a table or view that the definition refers to is dropped, use of the view results in an error. To check a view definition for problems of this kind, use the CHECK TABLE statement.
- The definition cannot refer to a TEMPORARY table, and you cannot create a TEMPORARY view.
- You cannot associate a trigger with a view.
- Aliases for column names in the SELECT statement are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).

ORDER BY is permitted in a view definition, but it is ignored if you select from a view using a statement that has its own ORDER BY.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a LIMIT clause, and you select from the view using a statement that has its own LIMIT clause, it is undefined which limit applies. This same principle applies to options such as ALL, DISTINCT, or SQL_SMALL_RESULT that follow the SELECT keyword, and to clauses such as INTO, FOR UPDATE, FOR SHARE, LOCK IN SHARE MODE, and PROCEDURE.

The results obtained from a view may be affected if you change the query processing environment by changing system variables:

```
mysql> CREATE VIEW v (mycol) AS SELECT 'abc';
Query OK, 0 rows affected (0.01 sec)
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT "mycol" FROM v;
+-------+
| mycol |
+-------+
```
The `DEFINER` and `SQL SECURITY` clauses determine which MySQL account to use when checking access privileges for the view when a statement is executed that references the view. The valid `SQL SECURITY` characteristic values are `DEFINER` (the default) and `INVOKER`. These indicate that the required privileges must be held by the user who defined or invoked the view, respectively.

If the `DEFINER` clause is present, the `user` value should be a MySQL account specified as `user_name'@'host_name`, `CURRENT_USER`, or `CURRENT_USER()`. The permitted `user` values depend on the privileges you hold, as discussed in Section 27.6, “Stored Object Access Control”. Also see that section for additional information about view security.

If the `DEFINER` clause is omitted, the default definer is the user who executes the `CREATE VIEW` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

Within a view definition, the `CURRENT_USER` function returns the view's `DEFINER` value by default. For views defined with the `SQL SECURITY INVOKER` characteristic, `CURRENT_USER` returns the account for the view's invoker. For information about user auditing within views, see Section 8.2.23, “SQL-Based Account Activity Auditing”.

Within a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, `CURRENT_USER` returns the routine's `DEFINER` value. This also affects a view defined within such a routine, if the view definition contains a `DEFINER` value of `CURRENT_USER`.

MySQL checks view privileges like this:

- At view definition time, the view creator must have the privileges needed to use the top-level objects accessed by the view. For example, if the view definition refers to table columns, the creator must have some privilege for each column in the select list of the definition, and the `SELECT` privilege for each column used elsewhere in the definition. If the definition refers to a stored function, only the privileges needed to invoke the function can be checked. The privileges required at function invocation time can be checked only as it executes: For different invocations, different execution paths within the function might be taken.

- The user who references a view must have appropriate privileges to access it (`SELECT` to select from it, `INSERT` to insert into it, and so forth.)

- When a view has been referenced, privileges for objects accessed by the view are checked against the privileges held by the view `DEFINER` account or invoker, depending on whether the `SQL SECURITY` characteristic is `DEFINER` or `INVOKER`, respectively.

- If reference to a view causes execution of a stored function, privilege checking for statements executed within the function depend on whether the function `SQL SECURITY` characteristic is `DEFINER` or `INVOKER`. If the security characteristic is `DEFINER`, the function runs with the privileges of the `DEFINER` account. If the characteristic is `INVOKER`, the function runs with the privileges determined by the view's `SQL SECURITY` characteristic.

Example: A view might depend on a stored function, and that function might invoke other stored routines. For example, the following view invokes a stored function `f()`:

```sql
CREATE VIEW v AS SELECT * FROM t WHERE t.id = f(t.name);
```
Suppose that \( f() \) contains a statement such as this:

```sql
IF name IS NULL then
  CALL p1();
ELSE
  CALL p2();
END IF;
```

The privileges required for executing statements within \( f() \) need to be checked when \( f() \) executes. This might mean that privileges are needed for \( p1() \) or \( p2() \), depending on the execution path within \( f() \). Those privileges must be checked at runtime, and the user who must possess the privileges is determined by the SQL SECURITY values of the view \( v \) and the function \( f() \).

The **DEFINER** and SQL SECURITY clauses for views are extensions to standard SQL. In standard SQL, views are handled using the rules for SQL SECURITY DEFINER. The standard says that the definer of the view, which is the same as the owner of the view's schema, gets applicable privileges on the view (for example, SELECT) and may grant them. MySQL has no concept of a schema “owner”, so MySQL adds a clause to identify the definer. The **DEFINER** clause is an extension where the intent is to have what the standard has; that is, a permanent record of who defined the view. This is why the default **DEFINER** value is the account of the view creator.

The optional **ALGORITHM** clause is a MySQL extension to standard SQL. It affects how MySQL processes the view. **ALGORITHM** takes three values: MERGE, TEMPTABLE, or UNDEFINED. For more information, see Section 27.5.2, “View Processing Algorithms”, as well as Section 10.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”.

Some views are updatable. That is, you can use them in statements such as **UPDATE**, **DELETE**, or **INSERT** to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable.

A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is **DEFAULT**. For information about generated columns, see Section 15.1.20.8, “CREATE TABLE and Generated Columns”.

The **WITH CHECK OPTION** clause can be given for an updatable view to prevent inserts or updates to rows except those for which the **WHERE** clause in the **select_statement** is true.

In a **WITH CHECK OPTION** clause for an updatable view, the **LOCAL** and **CASCADED** keywords determine the scope of check testing when the view is defined in terms of another view. The **LOCAL** keyword restricts the **CHECK OPTION** only to the view being defined. **CASCADED** causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is **CASCADED**.

For more information about updatable views and the **WITH CHECK OPTION** clause, see Section 27.5.3, “Updatable and Insertable Views”, and Section 27.5.4, “The View WITH CHECK OPTION Clause”.

### 15.1.24 DROP DATABASE Statement

**DROP DATABASE** drops all tables in the database and deletes the database. Be very careful with this statement! To use **DROP DATABASE**, you need the **DROP** privilege on the database. **DROP SCHEMA** is a synonym for **DROP DATABASE**.

The **IF EXISTS** clause is used to prevent an error from occurring if the database does not exist.

---

**Important**

When a database is dropped, privileges granted specifically for the database are not automatically dropped. They must be dropped manually. See Section 15.7.1.6, “GRANT Statement”.

**IF EXISTS** is used to prevent an error from occurring if the database does not exist.
If the default database is dropped, the default database is unset (the `DATABASE()` function returns `NULL`).

If you use `DROP DATABASE` on a symbolically linked database, both the link and the original database are deleted.

`DROP DATABASE` returns the number of tables that were removed.

The `DROP DATABASE` statement removes from the given database directory those files and directories that MySQL itself may create during normal operation. This includes all files with the extensions shown in the following list:

- `.BAK`
- `.DAT`
- `.HSH`
- `.MRG`
- `.MYD`
- `.MYI`
- `.cfg`
- `.db`
- `.ibd`
- `.ndb`

If other files or directories remain in the database directory after MySQL removes those just listed, the database directory cannot be removed. In this case, you must remove any remaining files or directories manually and issue the `DROP DATABASE` statement again.

Dropping a database does not remove any `TEMPORARY` tables that were created in that database. `TEMPORARY` tables are automatically removed when the session that created them ends. See Section 15.1.20.2, “CREATE TEMPORARY TABLE Statement”.

You can also drop databases with `mysqladmin`. See Section 6.5.2, “mysqladmin — A MySQL Server Administration Program”.

### 15.1.25 DROP EVENT Statement

```
DROP EVENT [IF EXISTS] event_name
```

This statement drops the event named `event_name`. The event immediately ceases being active, and is deleted completely from the server.

If the event does not exist, the error `ERROR 1517 (HY000): Unknown event 'event_name'` results. You can override this and cause the statement to generate a warning for nonexistent events instead using `IF EXISTS`.

This statement requires the `EVENT` privilege for the schema to which the event to be dropped belongs.

### 15.1.26 DROP FUNCTION Statement

The `DROP FUNCTION` statement is used to drop stored functions and loadable functions:

- For information about dropping stored functions, see Section 15.1.29, “DROP PROCEDURE and DROP FUNCTION Statements”.
For information about dropping loadable functions, see Section 15.7.4.2, “DROP FUNCTION Statement for Loadable Functions”.

15.1.27 DROP INDEX Statement

DROP INDEX index_name ON tbl_name

[algorithm_option | lock_option] ...

algorithm_option:
  ALGORITHM [=] {DEFAULT | INPLACE | COPY}

lock_option:
  LOCK [=] {DEFAULT | NONE | SHARED | EXCLUSIVE}

DROP INDEX drops the index named index_name from the table tbl_name. This statement is mapped to an ALTER TABLE statement to drop the index. See Section 15.1.9, “ALTER TABLE Statement”.

To drop a primary key, the index name is always PRIMARY, which must be specified as a quoted identifier because PRIMARY is a reserved word:

DROP INDEX `PRIMARY` ON t;

Indexes on variable-width columns of NDB tables are dropped online; that is, without any table copying. The table is not locked against access from other NDB Cluster API nodes, although it is locked against other operations on the same API node for the duration of the operation. This is done automatically by the server whenever it determines that it is possible to do so; you do not have to use any special SQL syntax or server options to cause it to happen.

ALGORITHM and LOCK clauses may be given to influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the same meaning as for the ALTER TABLE statement. For more information, see Section 15.1.9, “ALTER TABLE Statement”.

MySQL NDB Cluster supports online operations using the same ALGORITHM=INPLACE syntax supported in the standard MySQL Server. See Section 25.6.12, “Online Operations with ALTER TABLE in NDB Cluster”, for more information.

15.1.28 DROP LOGFILE GROUP Statement

DROP LOGFILE GROUP logfile_group ENGINE [=] engine_name

This statement drops the log file group named logfile_group. The log file group must already exist or an error results. (For information on creating log file groups, see Section 15.1.16, “CREATE LOGFILE GROUP Statement”.)

Important
Before dropping a log file group, you must drop all tablespaces that use that log file group for UNDO logging.

The required ENGINE clause provides the name of the storage engine used by the log file group to be dropped. The only permitted values for engine_name are NDB and NDBCLUSTER.

DROP LOGFILE GROUP is useful only with Disk Data storage for NDB Cluster. See Section 25.6.11, “NDB Cluster Disk Data Tables”.

15.1.29 DROP PROCEDURE and DROP FUNCTION Statements

DROP {PROCEDURE | FUNCTION} [IF EXISTS] sp_name
DROP SERVER Statement

These statements are used to drop a stored routine (a stored procedure or function). That is, the specified routine is removed from the server. (DROP FUNCTION is also used to drop loadable functions; see Section 15.7.4.2, “DROP FUNCTION Statement for Loadable Functions”.)

To drop a stored routine, you must have the ALTER ROUTINE privilege for it. (If the automatic_sp_privileges system variable is enabled, that privilege and EXECUTE are granted automatically to the routine creator when the routine is created and dropped from the creator when the routine is dropped. See Section 27.2.2, “Stored Routines and MySQL Privileges”.)

In addition, if the definer of the routine has the SYSTEM_USER privilege, the user dropping it must also have this privilege.

The IF EXISTS clause is a MySQL extension. It prevents an error from occurring if the procedure or function does not exist. A warning is produced that can be viewed with SHOW WARNINGS.

DROP FUNCTION is also used to drop loadable functions (see Section 15.7.4.2, “DROP FUNCTION Statement for Loadable Functions”).

15.1.30 DROP SERVER Statement

DROP SERVER [ IF EXISTS ] server_name

Drops the server definition for the server named server_name. The corresponding row in the mysql.servers table is deleted. This statement requires the SUPER privilege.

Dropping a server for a table does not affect any FEDERATED tables that used this connection information when they were created. See Section 15.1.18, “CREATE SERVER Statement”.

DROP SERVER causes an implicit commit. See Section 15.3.3, “Statements That Cause an Implicit Commit”.

DROP SERVER is not written to the binary log, regardless of the logging format that is in use.

15.1.31 DROP SPATIAL REFERENCE SYSTEM Statement

DROP SPATIAL REFERENCE SYSTEM [IF EXISTS] srid

srid: 32-bit unsigned integer

This statement removes a spatial reference system (SRS) definition from the data dictionary. It requires the SUPER privilege.

Example:

DROP SPATIAL REFERENCE SYSTEM 4120;

If no SRS definition with the SRID value exists, an error occurs unless IF EXISTS is specified. In that case, a warning occurs rather than an error.

If the SRID value is used by some column in an existing table, an error occurs. For example:

mysql> DROP SPATIAL REFERENCE SYSTEM 4326;
ERROR 3716 (SR005): Can't modify SRID 4326. There is at least one column depending on it.

To identify which column or columns use the SRID, use this query:

SELECT * FROM INFORMATION_SCHEMA.ST_GEOMETRY_COLUMNS WHERE SRS_ID=4326;

SRID values must be in the range of 32-bit unsigned integers, with these restrictions:

- SRID 0 is a valid SRID but cannot be used with DROP SPATIAL REFERENCE SYSTEM.
DROP TABLE Statement

- If the value is in a reserved SRID range, a warning occurs. Reserved ranges are [0, 32767] (reserved by EPSG), [60,000,000, 69,999,999] (reserved by EPSG), and [2,000,000,000, 2,147,483,647] (reserved by MySQL). EPSG stands for the European Petroleum Survey Group.

- Users should not drop SRSs with SRIDs in the reserved ranges. If system-installed SRSs are dropped, the SRS definitions may be recreated for MySQL upgrades.

15.1.32 DROP TABLE Statement

```
DROP [TEMPORARY] TABLE [IF EXISTS]
  tbl_name [, tbl_name] ... [RESTRICT | CASCADE]
```

DROP TABLE removes one or more tables. You must have the DROP privilege for each table.

Be careful with this statement! For each table, it removes the table definition and all table data. If the table is partitioned, the statement removes the table definition, all its partitions, all data stored in those partitions, and all partition definitions associated with the dropped table.

Dropping a table also drops any triggers for the table.

DROP TABLE causes an implicit commit, except when used with the TEMPORARY keyword. See Section 15.3.3, "Statements That Cause an Implicit Commit".

Important

When a table is dropped, privileges granted specifically for the table are not automatically dropped. They must be dropped manually. See Section 15.7.1.6, "GRANT Statement".

If any tables named in the argument list do not exist, DROP TABLE behavior depends on whether the IF EXISTS clause is given:

- Without IF EXISTS, the statement fails with an error indicating which nonexisting tables it was unable to drop, and no changes are made.

- With IF EXISTS, no error occurs for nonexisting tables. The statement drops all named tables that do exist, and generates a NOTE diagnostic for each nonexistent table. These notes can be displayed with SHOW WARNINGS. See Section 15.7.7.41, "SHOW WARNINGS Statement".

IF EXISTS can also be useful for dropping tables in unusual circumstances under which there is an entry in the data dictionary but no table managed by the storage engine. (For example, if an abnormal server exit occurs after removal of the table from the storage engine but before removal of the data dictionary entry.)

The TEMPORARY keyword has the following effects:

- The statement drops only TEMPORARY tables.

- The statement does not cause an implicit commit.

- No access rights are checked. A TEMPORARY table is visible only with the session that created it, so no check is necessary.

Including the TEMPORARY keyword is a good way to prevent accidentally dropping non-TEMPORARY tables.

The RESTRICT and CASCADE keywords do nothing. They are permitted to make porting easier from other database systems.

DROP TABLE is not supported with all innodb_force_recovery settings. See Section 17.20.3, "Forcing InnoDB Recovery".
15.1.33 DROP TABLESPACE Statement

```sql
DROP [UNDO] TABLESPACE `tablespace_name`
```

This statement drops a tablespace that was previously created using `CREATE TABLESPACE`. It is supported by the NDB and InnoDB storage engines.

The `UNDO` keyword must be specified to drop an undo tablespace. Only undo tablespaces created using `CREATE UNDO TABLESPACE` syntax can be dropped. An undo tablespace must be in an empty state before it can be dropped. For more information, see Section 17.6.3.4, “Undo Tablespaces”.

`tablespace_name` is a case-sensitive identifier in MySQL.

For an InnoDB general tablespace, all tables must be dropped from the tablespace prior to a `DROP TABLESPACE` operation. If the tablespace is not empty, `DROP TABLESPACE` returns an error.

An NDB tablespace to be dropped must not contain any data files; in other words, before you can drop an NDB tablespace, you must first drop each of its data files using `ALTER TABLESPACE ... DROP DATAFILE`.

Notes

- A general InnoDB tablespace is not deleted automatically when the last table in the tablespace is dropped. The tablespace must be dropped explicitly using `DROP TABLESPACE tablespace_name`.

- A `DROP DATABASE` operation can drop tables that belong to a general tablespace but it cannot drop the tablespace, even if the operation drops all tables that belong to the tablespace. The tablespace must be dropped explicitly using `DROP TABLESPACE tablespace_name`.

- Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace .ibd data file which can only be used for new InnoDB data. Space is not released back to the operating system as it is for file-per-table tablespaces.

InnoDB Examples

This example demonstrates how to drop an InnoDB general tablespace. The general tablespace `ts1` is created with a single table. Before dropping the tablespace, the table must be dropped.

```sql
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 Engine=InnoDB;
mysql> DROP TABLE t1;
mysql> DROP TABLESPACE ts1;
```

This example demonstrates dropping an undo tablespace. An undo tablespace must be in an empty state before it can be dropped. For more information, see Section 17.6.3.4, “Undo Tablespaces”.

```sql
mysql> DROP UNDO TABLESPACE undo_003;
```

NDB Example

This example shows how to drop an NDB tablespace `myts` having a data file named `mydata-1.dat` after first creating the tablespace, and assumes the existence of a log file group named `mylg` (see Section 15.1.16, “CREATE LOGFILE GROUP Statement”).

```sql
mysql> CREATE TABLESPACE myts
    -> ADD DATAFILE 'mydata-1.dat'
    -> USE LOGFILE GROUP mylg
    -> ENGINE=NDB;
```
You must remove all data files from the tablespace using `ALTER TABLESPACE`, as shown here, before it can be dropped:

```sql
mysql> ALTER TABLESPACE myts
-> DROP DATAFILE 'mydata-1.dat';
```
```
mysql> DROP TABLESPACE myts;
```

### 15.1.34 DROP TRIGGER Statement

```sql
DROP TRIGGER [IF EXISTS] [schema_name.]trigger_name
```

This statement drops a trigger. The schema (database) name is optional. If the schema is omitted, the trigger is dropped from the default schema. `DROP TRIGGER` requires the `TRIGGER` privilege for the table associated with the trigger.

Use `IF EXISTS` to prevent an error from occurring for a trigger that does not exist. A `NOTE` is generated for a nonexistent trigger when using `IF EXISTS`. See Section 15.7.7.41, “SHOW WARNINGS Statement”.

Triggers for a table are also dropped if you drop the table.

### 15.1.35 DROP VIEW Statement

```sql
DROP VIEW [IF EXISTS] view_name [, view_name] ... [RESTRICT | CASCADE]
```

`DROP VIEW` removes one or more views. You must have the `DROP` privilege for each view.

If any views named in the argument list do not exist, the statement fails with an error indicating by name which nonexistent views it was unable to drop, and no changes are made.

#### Note

In MySQL 8.3 and earlier, `DROP VIEW` returns an error if any views named in the argument list do not exist, but also drops all views in the list that do exist. Due to the change in behavior in MySQL 8.4, a partially completed `DROP VIEW` operation on a MySQL 8.3 replication source server fails when replicated on a MySQL 8.4 replica. To avoid this failure scenario, use `IF EXISTS` syntax in `DROP VIEW` statements to prevent an error from occurring for views that do not exist. For more information, see Section 15.1.1, “Atomic Data Definition Statement Support”.

The `IF EXISTS` clause prevents an error from occurring for views that don't exist. When this clause is given, a `NOTE` is generated for each nonexistent view. See Section 15.7.7.41, “SHOW WARNINGS Statement”.

`RESTRICT` and `CASCADE`, if given, are parsed and ignored.

### 15.1.36 RENAME TABLE Statement

```sql
RENAME TABLE tbl_name TO new_tbl_name [, tbl_name2 TO new_tbl_name2] ... 
```

`RENAME TABLE` renames one or more tables. You must have `ALTER` and `DROP` privileges for the original table, and `CREATE` and `INSERT` privileges for the new table.

For example, to rename a table named `old_table` to `new_table`, use this statement:

```sql
RENAME TABLE old_table TO new_table;
```

That statement is equivalent to the following `ALTER TABLE` statement:
RENAME TABLE Statement

```
ALTER TABLE old_table RENAME new_table;
```

**RENAME TABLE**, unlike **ALTER TABLE**, can rename multiple tables within a single statement:

```
RENAME TABLE old_table1 TO new_table1,
  old_table2 TO new_table2,
  old_table3 TO new_table3;
```

Renaming operations are performed left to right. Thus, to swap two table names, do this (assuming that a table with the intermediary name `tmp_table` does not already exist):

```
RENAME TABLE old_table TO tmp_table,
  new_table TO old_table,
  tmp_table TO new_table;
```

Metadata locks on tables are acquired in name order, which in some cases can make a difference in operation outcome when multiple transactions execute concurrently. See Section 10.11.4, “Metadata Locking”.

You can rename tables locked with a `LOCK TABLES` statement, provided that they are locked with a `WRITE` lock or are the product of renaming `WRITE`-locked tables from earlier steps in a multiple-table rename operation. For example, this is permitted:

```
LOCK TABLE old_table1 WRITE;
RENAME TABLE old_table1 TO new_table1,
  new_table1 TO new_table2;
```

This is not permitted:

```
LOCK TABLE old_table1 READ;
RENAME TABLE old_table1 TO new_table1,
  new_table1 TO new_table2;
```

With the transaction table locking conditions satisfied, the rename operation is done atomically; no other session can access any of the tables while the rename is in progress.

If any errors occur during a **RENAME TABLE**, the statement fails and no changes are made.

You can use **RENAME TABLE** to move a table from one database to another:

```
RENAME TABLE current_db.tbl_name TO other_db.tbl_name;
```

Using this method to move all tables from one database to a different one in effect renames the database (an operation for which MySQL has no single statement), except that the original database continues to exist, albeit with no tables.

Like **RENAME TABLE, ALTER TABLE ... RENAME** can also be used to move a table to a different database. Regardless of the statement used, if the rename operation would move the table to a database located on a different file system, the success of the outcome is platform specific and depends on the underlying operating system calls used to move table files.

If a table has triggers, attempts to rename the table into a different database fail with a `Trigger in wrong schema (ER_TRG_IN_WRONG_SCHEMA)` error.

An unencrypted table can be moved to an encryption-enabled database and vice versa. However, if the `table_encryption_privilege_check` variable is enabled, the `TABLE_ENCRYPTION_ADMIN` privilege is required if the table encryption setting differs from the default database encryption.

To rename **TEMPORARY** tables, **RENAME TABLE** does not work. Use **ALTER TABLE** instead.

**RENAME TABLE** works for views, except that views cannot be renamed into a different database.

Any privileges granted specifically for a renamed table or view are not migrated to the new name. They must be changed manually.
RENAME TABLE `tbl_name` TO `new_tbl_name` changes internally generated foreign key constraint names and user-defined foreign key constraint names that begin with the string "tbl_name_ibfk_" to reflect the new table name. InnoDB interprets foreign key constraint names that begin with the string "tbl_name_ibfk_" as internally generated names.

Foreign key constraint names that point to the renamed table are automatically updated unless there is a conflict, in which case the statement fails with an error. A conflict occurs if the renamed constraint name already exists. In such cases, you must drop and re-create the foreign keys for them to function properly.

RENAME TABLE `tbl_name` TO `new_tbl_name` changes internally generated and user-defined CHECK constraint names that begin with the string "tbl_name_chk_" to reflect the new table name. MySQL interprets CHECK constraint names that begin with the string "tbl_name_chk_" as internally generated names. Example:

```sql
mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
Table: t1
Create Table: CREATE TABLE `t1` (  'i1' int(11) DEFAULT NULL,  'i2' int(11) DEFAULT NULL,  CONSTRAINT `t1_chk_1` CHECK ((`i1` > 0)),  CONSTRAINT `t1_chk_2` CHECK ((`i2` < 0))
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
1 row in set (0.02 sec)

mysql> RENAME TABLE t1 TO t3;
Query OK, 0 rows affected (0.03 sec)

mysql> SHOW CREATE TABLE t3\G
*************************** 1. row ***************************
Table: t3
Create Table: CREATE TABLE `t3` (  'i1' int(11) DEFAULT NULL,  'i2' int(11) DEFAULT NULL,  CONSTRAINT `t3_chk_1` CHECK ((`i1` > 0)),  CONSTRAINT `t3_chk_2` CHECK ((`i2` < 0))
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
1 row in set (0.01 sec)
```

15.1.37 TRUNCATE TABLE Statement

TRUNCATE [TABLE] `tbl_name`

TRUNCATE TABLE empties a table completely. It requires the DROP privilege. Logically, TRUNCATE TABLE is similar to a DELETE statement that deletes all rows, or a sequence of DROP TABLE and CREATE TABLE statements.

To achieve high performance, TRUNCATE TABLE bypasses the DML method of deleting data. Thus, it does not cause ON DELETE triggers to fire, it cannot be performed for InnoDB tables with parent-child foreign key relationships, and it cannot be rolled back like a DML operation. However, TRUNCATE TABLE operations on tables that use an atomic DDL-supported storage engine are either fully committed or rolled back if the server halts during their operation. For more information, see Section 15.1.1, “Atomic Data Definition Statement Support”.

Although TRUNCATE TABLE is similar to DELETE, it is classified as a DDL statement rather than a DML statement. It differs from DELETE in the following ways:

- Truncate operations drop and re-create the table, which is much faster than deleting rows one by one, particularly for large tables.
- Truncate operations cause an implicit commit, and so cannot be rolled back. See Section 15.3.3, “Statements That Cause an Implicit Commit”.
- Truncation operations cannot be performed if the session holds an active table lock.
Data Manipulation Statements

- **TRUNCATE TABLE** fails for an InnoDB table or NDB table if there are any FOREIGN KEY constraints from other tables that reference the table. Foreign key constraints between columns of the same table are permitted.

- Truncation operations do not return a meaningful value for the number of deleted rows. The usual result is “0 rows affected,” which should be interpreted as “no information.”

- As long as the table definition is valid, the table can be re-created as an empty table with TRUNCATE TABLE, even if the data or index files have become corrupted.

- Any AUTO_INCREMENT value is reset to its start value. This is true even for MyISAM and InnoDB, which normally do not reuse sequence values.

- When used with partitioned tables, **TRUNCATE TABLE** preserves the partitioning; that is, the data and index files are dropped and re-created, while the partition definitions are unaffected.

- The **TRUNCATE TABLE** statement does not invoke ON DELETE triggers.

- Truncating a corrupted InnoDB table is supported.

**TRUNCATE TABLE** is treated for purposes of binary logging and replication as DDL rather than DML, and is always logged as a statement.

**TRUNCATE TABLE** for a table closes all handlers for the table that were opened with **HANDLER OPEN**.

**TRUNCATE TABLE** can be used with Performance Schema summary tables, but the effect is to reset the summary columns to 0 or NULL, not to remove rows. See Section 29.12.20, “Performance Schema Summary Tables”.

Truncating an InnoDB table that resides in a file-per-table tablespace drops the existing tablespace and creates a new one. If the tablespace was created with an earlier version and resides in an unknown directory, InnoDB creates the new tablespace in the default location and writes the following warning to the error log: **The DATA DIRECTORY location must be in a known directory.** The DATA DIRECTORY location will be ignored and the file will be put into the default datadir location. Known directories are those defined by the datadir, innodb_data_home_dir, and innodb_directories variables. To have **TRUNCATE TABLE** create the tablespace in its current location, add the directory to the innodb_directories setting before running **TRUNCATE TABLE**.

### 15.2 Data Manipulation Statements

#### 15.2.1 CALL Statement

**CALL** sp_name([parameter[,...]])

CALL sp_name()

The **CALL** statement invokes a stored procedure that was defined previously with **CREATE PROCEDURE**.

Stored procedures that take no arguments can be invoked without parentheses. That is, **CALL p()** and **CALL p** are equivalent.

**CALL** can pass back values to its caller using parameters that are declared as **OUT** or **INOUT** parameters. When the procedure returns, a client program can also obtain the number of rows affected for the final statement executed within the routine: At the SQL level, call the **ROW_COUNT()** function; from the C API, call the **mysql_affected_rows()** function.

For information about the effect of unhandled conditions on procedure parameters, see Section 15.6.7.8, “Condition Handling and OUT or INOUT Parameters”.

To get back a value from a procedure using an **OUT** or **INOUT** parameter, pass the parameter by means of a user variable, and then check the value of the variable after the procedure returns. (If you
are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an **IN** or **INOUT** parameter.) For an **INOUT** parameter, initialize its value before passing it to the procedure. The following procedure has an **OUT** parameter that the procedure sets to the current server version, and an **INOUT** value that the procedure increments by one from its current value:

```
DELIMITER //
CREATE PROCEDURE p (OUT ver_param VARCHAR(25), INOUT incr_param INT)
BEGIN
  # Set value of OUT parameter
  SELECT VERSION() INTO ver_param;
  # Increment value of INOUT parameter
  SET incr_param = incr_param + 1;
END //
DELIMITER ;
```

Before calling the procedure, initialize the variable to be passed as the **INOUT** parameter. After calling the procedure, you can see that the values of the two variables are set or modified:

```
mysql> SET @increment = 10;
mysql> CALL p(@version, @increment);
mysql> SELECT @version, @increment;
+----------+------------+
<table>
<thead>
<tr>
<th>@version</th>
<th>@increment</th>
</tr>
</thead>
<tbody>
<tr>
<td>8.4.0</td>
<td>11</td>
</tr>
</tbody>
</table>
+----------+------------+
```

In prepared **CALL** statements used with **PREPARE** and **EXECUTE**, placeholders can be used for **IN** parameters, **OUT**, and **INOUT** parameters. These types of parameters can be used as follows:

```
mysql> SET @increment = 10;
mysql> PREPARE s FROM 'CALL p(?, ?)';
mysql> EXECUTE s USING @version, @increment;
mysql> SELECT @version, @increment;
+----------+------------+
<table>
<thead>
<tr>
<th>@version</th>
<th>@increment</th>
</tr>
</thead>
<tbody>
<tr>
<td>8.4.0</td>
<td>11</td>
</tr>
</tbody>
</table>
+----------+------------+
```

To write C programs that use the **CALL** SQL statement to execute stored procedures that produce result sets, the **CLIENT_MULTI_RESULTS** flag must be enabled. This is because each **CALL** returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. **CLIENT_MULTI_RESULTS** must also be enabled if **CALL** is used to execute any stored procedure that contains prepared statements. It cannot be determined when such a procedure is loaded whether those statements produce result sets, so it is necessary to assume that they do so.

**CLIENT_MULTI_RESULTS** can be enabled when you call `mysql_real_connect()`, either explicitly by passing the **CLIENT_MULTI_RESULTS** flag itself, or implicitly by passing **CLIENT_MULTI_STATEMENTS** (which also enables **CLIENT_MULTI_RESULTS**). **CLIENT_MULTI_RESULTS** is enabled by default.

To process the result of a **CALL** statement executed using **mysql_query()** or `mysql_real_query()`, use a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see **Multiple Statement Execution Support**.

C programs can use the prepared-statement interface to execute **CALL** statements and access **OUT** and **INOUT** parameters. This is done by processing the result of a **CALL** statement using a loop that calls `mysql_stmt_next_result()` to determine whether there are more results. For an example, see **Prepared CALL Statement Support**. Languages that provide a MySQL interface can use prepared **CALL** statements to directly retrieve **OUT** and **INOUT** procedure parameters.
DELETE Statement

Metadata changes to objects referred to by stored programs are detected and cause automatic reparsing of the affected statements when the program is next executed. For more information, see Section 10.10.3, “Caching of Prepared Statements and Stored Programs”.

15.2.2 DELETE Statement

DELETE is a DML statement that removes rows from a table.

A DELETE statement can start with a WITH clause to define common table expressions accessible within the DELETE. See Section 15.2.20, “WITH (Common Table Expressions)”.

Single-Table Syntax

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE] FROM tbl_name [[AS] tbl_alias]
    [PARTITION (partition_name [, partition_name] ...)]
    [WHERE where_condition]
    [ORDER BY ...]
    [LIMIT row_count]
```

The DELETE statement deletes rows from `tbl_name` and returns the number of deleted rows. To check the number of deleted rows, call the `ROW_COUNT()` function described in Section 14.15, “Information Functions”.

Main Clauses

The conditions in the optional WHERE clause identify which rows to delete. With no WHERE clause, all rows are deleted.

`where_condition` is an expression that evaluates to true for each row to be deleted. It is specified as described in Section 15.2.13, “SELECT Statement”.

If the ORDER BY clause is specified, the rows are deleted in the order that is specified. The LIMIT clause places a limit on the number of rows that can be deleted. These clauses apply to single-table deletes, but not multi-table deletes.

Multiple-Table Syntax

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE] FROM tbl_name[.*] [, tbl_name[.*]] ... [WHERE where_condition]

DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
    FROM table_references
    [WHERE where_condition]

DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
    FROM tbl_name[.*] [, tbl_name[.*]] ... [USING table_references]
    [WHERE where_condition]
```

Privileges

You need the DELETE privilege on a table to delete rows from it. You need only the SELECT privilege for any columns that are only read, such as those named in the WHERE clause.

Performance

When you do not need to know the number of deleted rows, the TRUNCATE TABLE statement is a faster way to empty a table than a DELETE statement with no WHERE clause. Unlike DELETE, TRUNCATE TABLE cannot be used within a transaction or if you have a lock on the table. See Section 15.1.37, “TRUNCATE TABLE Statement” and Section 15.3.6, “LOCK TABLES and UNLOCK TABLES Statements”.

The speed of delete operations may also be affected by factors discussed in Section 10.2.5.3, “Optimizing DELETE Statements”. 
DELETE Statement

To ensure that a given DELETE statement does not take too much time, the MySQL-specific LIMIT row_count clause for DELETE specifies the maximum number of rows to be deleted. If the number of rows to delete is larger than the limit, repeat the DELETE statement until the number of affected rows is less than the LIMIT value.

Subqueries

You cannot delete from a table and select from the same table in a subquery.

Partitioned Table Support

DELETE supports explicit partition selection using the PARTITION clause, which takes a list of the comma-separated names of one or more partitions or subpartitions (or both) from which to select rows to be dropped. Partitions not included in the list are ignored. Given a partitioned table t with a partition named p0, executing the statement DELETE FROM t PARTITION (p0) has the same effect on the table as executing ALTER TABLE t TRUNCATE PARTITION (p0); in both cases, all rows in partition p0 are dropped.

PARTITION can be used along with a WHERE condition, in which case the condition is tested only on rows in the listed partitions. For example, DELETE FROM t PARTITION (p0) WHERE c < 5 deletes rows only from partition p0 for which the condition c < 5 is true; rows in any other partitions are not checked and thus not affected by the DELETE.

The PARTITION clause can also be used in multiple-table DELETE statements. You can use up to one such option per table named in the FROM option.

For more information and examples, see Section 26.5, “Partition Selection”.

Auto-Increment Columns

If you delete the row containing the maximum value for an AUTO_INCREMENT column, the value is not reused for a MyISAM or InnoDB table. If you delete all rows in the table with DELETE FROM tbl_name (without a WHERE clause) in autocommit mode, the sequence starts over for all storage engines except InnoDB and MyISAM. There are some exceptions to this behavior for InnoDB tables, as discussed in Section 17.6.1.6, “AUTO_INCREMENT Handling in InnoDB”.

For MyISAM tables, you can specify an AUTO_INCREMENT secondary column in a multiple-column key. In this case, reuse of values deleted from the top of the sequence occurs even for MyISAM tables. See Section 5.6.9, “Using AUTO_INCREMENT”.

Modifiers

The DELETE statement supports the following modifiers:

• If you specify the LOW_PRIORITY modifier, the server delays execution of the DELETE until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE).

• For MyISAM tables, if you use the QUICK modifier, the storage engine does not merge index leaves during delete, which may speed up some kinds of delete operations.

• The IGNORE modifier causes MySQL to ignore ignorable errors during the process of deleting rows. (Errors encountered during the parsing stage are processed in the usual manner.) Errors that are ignored due to the use of IGNORE are returned as warnings. For more information, see The Effect of IGNORE on Statement Execution.

Order of Deletion

If the DELETE statement includes an ORDER BY clause, rows are deleted in the order specified by the clause. This is useful primarily in conjunction with LIMIT. For example, the following statement finds
DELETE Statement

rows matching the WHERE clause, sorts them by timestamp_column, and deletes the first (oldest) one:

```sql
DELETE FROM somelog WHERE user = 'jcole'
ORDER BY timestamp_column LIMIT 1;
```

ORDER BY also helps to delete rows in an order required to avoid referential integrity violations.

**InnoDB Tables**

If you are deleting many rows from a large table, you may exceed the lock table size for an InnoDB table. To avoid this problem, or simply to minimize the time that the table remains locked, the following strategy (which does not use DELETE at all) might be helpful:

1. Select the rows not to be deleted into an empty table that has the same structure as the original table:

   ```sql
   INSERT INTO t_copy SELECT * FROM t WHERE ... ;
   ```

2. Use RENAME TABLE to atomically move the original table out of the way and rename the copy to the original name:

   ```sql
   RENAME TABLE t TO t_old, t_copy TO t;
   ```

3. Drop the original table:

   ```sql
   DROP TABLE t_old;
   ```

No other sessions can access the tables involved while RENAME TABLE executes, so the rename operation is not subject to concurrency problems. See Section 15.1.36, “RENAME TABLE Statement”.

**MyISAM Tables**

In MyISAM tables, deleted rows are maintained in a linked list and subsequent INSERT operations reuse old row positions. To reclaim unused space and reduce file sizes, use the OPTIMIZE TABLE statement or the myisamchk utility to reorganize tables. OPTIMIZE TABLE is easier to use, but myisamchk is faster. See Section 15.7.3.4, “OPTIMIZE TABLE Statement”, and Section 6.6.4, “myisamchk — MyISAM Table-Maintenance Utility”.

The QUICK modifier affects whether index leaves are merged for delete operations. DELETE QUICK is most useful for applications where index values for deleted rows are replaced by similar index values from rows inserted later. In this case, the holes left by deleted values are reused.

DELETE QUICK is not useful when deleted values lead to underfilled index blocks spanning a range of index values for which new inserts occur again. In this case, use of QUICK can lead to wasted space in the index that remains unreclaimed. Here is an example of such a scenario:

1. Create a table that contains an indexed AUTO_INCREMENT column.

2. Insert many rows into the table. Each insert results in an index value that is added to the high end of the index.

3. Delete a block of rows at the low end of the column range using DELETE QUICK.

In this scenario, the index blocks associated with the deleted index values become underfilled but are not merged with other index blocks due to the use of QUICK. They remain underfilled when new inserts occur, because new rows do not have index values in the deleted range. Furthermore, they remain underfilled even if you later use DELETE without QUICK, unless some of the deleted index values happen to lie in index blocks within or adjacent to the underfilled blocks. To reclaim unused index space under these circumstances, use OPTIMIZE TABLE.

If you are going to delete many rows from a table, it might be faster to use DELETE QUICK followed by OPTIMIZE TABLE. This rebuilds the index rather than performing many index block merge operations.
**Multi-Table Deletes**

You can specify multiple tables in a `DELETE` statement to delete rows from one or more tables depending on the condition in the `WHERE` clause. You cannot use `ORDER BY` or `LIMIT` in a multiple-table `DELETE`. The `table_references` clause lists the tables involved in the join, as described in Section 15.2.13.2, "JOIN Clause".

For the first multiple-table syntax, only matching rows from the tables listed before the `FROM` clause are deleted. For the second multiple-table syntax, only matching rows from the tables listed in the `FROM` clause (before the `USING` clause) are deleted. The effect is that you can delete rows from many tables at the same time and have additional tables that are used only for searching:

```sql
DELETE t1, t2 FROM t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

Or:

```sql
DELETE FROM t1, t2 USING t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

These statements use all three tables when searching for rows to delete, but delete matching rows only from tables `t1` and `t2`.

The preceding examples use `INNER JOIN`, but multiple-table `DELETE` statements can use other types of join permitted in `SELECT` statements, such as `LEFT JOIN`. For example, to delete rows that exist in `t1` that have no match in `t2`, use a `LEFT JOIN`:

```sql
DELETE t1 FROM t1 LEFT JOIN t2 ON t1.id=t2.id WHERE t2.id IS NULL;
```

The syntax permits `.*` after each `tbl_name` for compatibility with Access.

If you use a multiple-table `DELETE` statement involving InnoDB tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, you should delete from a single table and rely on the `ON DELETE` capabilities that InnoDB provides to cause the other tables to be modified accordingly.

> **Note**

If you declare an alias for a table, you must use the alias when referring to the table:

```sql
DELETE t1 FROM test AS t1, test2 WHERE ...
```

Table aliases in a multiple-table `DELETE` should be declared only in the `table_references` part of the statement. Elsewhere, alias references are permitted but not alias declarations.

**Correct:**

```sql
DELETE a1, a2 FROM t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;
```

```sql
DELETE FROM a1, a2 USING t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;
```

**Incorrect:**

```sql
DELETE t1 AS a1, t2 AS a2 FROM t1 INNER JOIN t2
WHERE a1.id=a2.id;
```

```sql
DELETE FROM t1 AS a1, t2 AS a2 USING t1 INNER JOIN t2
WHERE a1.id=a2.id;
```

Table aliases are also supported for single-table `DELETE` statements.
15.2.3 DO Statement

**DO** expr [ , expr ] ...

**DO** executes the expressions but does not return any results. In most respects, **DO** is shorthand for **SELECT** expr, ..., but has the advantage that it is slightly faster when you do not care about the result.

**DO** is useful primarily with functions that have side effects, such as **RELEASE_LOCK()**.

Example: This **SELECT** statement pauses, but also produces a result set:

```sql
mysql> SELECT SLEEP(5);
+----------+
<table>
<thead>
<tr>
<th>SLEEP(5)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
+----------+
1 row in set (5.02 sec)
```

**DO**, on the other hand, pauses without producing a result set:

```sql
mysql> DO SLEEP(5);
Query OK, 0 rows affected (4.99 sec)
```

This could be useful, for example in a stored function or trigger, which prohibit statements that produce result sets.

**DO** only executes expressions. It cannot be used in all cases where **SELECT** can be used. For example, **DO id FROM t1** is invalid because it references a table.

15.2.4 EXCEPT Clause

```sql
query_expression_body EXCEPT [ ALL | DISTINCT ] query_expression_body
[ EXCEPT [ ALL | DISTINCT ] query_expression_body ]
[ ... ]
```

**query_expression_body:**
See Section 15.2.14, "Set Operations with UNION, INTERSECT, and EXCEPT"

**EXCEPT** limits the result from the first query block to those rows which are (also) not found in the second. As with **UNION** and **INTERSECT**, either query block can make use of any of **SELECT**, **TABLE**, or **VALUES**. An example using the tables **a**, **b**, and **c** defined in Section 15.2.8, “INTERSECT Clause”, is shown here:

```sql
mysql> TABLE a EXCEPT TABLE b;
+----+----+
<table>
<thead>
<tr>
<th>m</th>
<th>n</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>3</td>
</tr>
</tbody>
</table>
+----+----+
1 row in set (0.00 sec)

mysql> TABLE a EXCEPT TABLE c;
+----+----+
<table>
<thead>
<tr>
<th>m</th>
<th>n</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
</tr>
</tbody>
</table>
+----+----+
2 rows in set (0.00 sec)

mysql> TABLE b EXCEPT TABLE c;
+----+----+
<table>
<thead>
<tr>
<th>m</th>
<th>n</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
</tr>
</tbody>
</table>
+----+----+
```
As with `UNION` and `INTERSECT`, if neither `DISTINCT` nor `ALL` is specified, the default is `DISTINCT`. According to [MySQL documentation](https://dev.mysql.com/doc/refman/8.0/en/except.html), `DISTINCT` removes duplicates found on either side of the relation, as shown here:

```sql
mysql> TABLE c EXCEPT DISTINCT TABLE a;
+------+------+
| m    | n    |
+------+------+
|    1 |    3 |
+------+------+
1 row in set (0.00 sec)

mysql> TABLE c EXCEPT ALL TABLE a;
+------+------+
| m    | n    |
| 1    | 3    |
| 1    | 3    |
+------+------+
2 rows in set (0.00 sec)
```

(The first statement has the same effect as `TABLE c EXCEPT TABLE a`.)

Unlike `UNION` or `INTERSECT`, `EXCEPT` is not commutative—that is, the result depends on the order of the operands, as shown here:

```sql
mysql> TABLE a EXCEPT TABLE c;
+------+------+
| m    | n    |
| 1    | 2    |
| 2    | 3    |
+------+------+
2 rows in set (0.00 sec)

mysql> TABLE c EXCEPT TABLE a;
+------+------+
| m    | n    |
+------+------+
| 1    | 3    |
+------+------+
1 row in set (0.00 sec)
```

As with `UNION`, the result sets to be compared must have the same number of columns. Result set column types are also determined as for `UNION`.

### 15.2.5 HANDLER Statement

The `HANDLER` statement provides direct access to table storage engine interfaces. It is available for InnoDB and MyISAM tables.

The `HANDLER ... OPEN` statement opens a table, making it accessible using subsequent `HANDLER ... READ` statements. This table object is not shared by other sessions and is not closed until the session calls `HANDLER ... CLOSE` or the session terminates.
If you open the table using an alias, further references to the open table with other `HANDLER` statements must use the alias rather than the table name. If you do not use an alias, but open the table using a table name qualified by the database name, further references must use the unqualified table name. For example, for a table opened using `mydb.mytable`, further references must use `mytable`.

The first `HANDLER ... READ` syntax fetches a row where the index specified satisfies the given values and the `WHERE` condition is met. If you have a multiple-column index, specify the index column values as a comma-separated list. Either specify values for all the columns in the index, or specify values for a leftmost prefix of the index columns. Suppose that an index `my_idx` includes three columns named `col_a`, `col_b`, and `col_c`, in that order. The `HANDLER` statement can specify values for all three columns in the index, or for the columns in a leftmost prefix. For example:

```sql
HANDLER ... READ my_idx = (col_a_val,col_b_val,col_c_val) ...
HANDLER ... READ my_idx = (col_a_val,col_b_val) ...
HANDLER ... READ my_idx = (col_a_val) ...
```

To employ the `HANDLER` interface to refer to a table's PRIMARY KEY, use the quoted identifier `"PRIMARY"`:

```sql
HANDLER tbl_name READ "PRIMARY" ...
```

The second `HANDLER ... READ` syntax fetches a row from the table in index order that matches the `WHERE` condition.

The third `HANDLER ... READ` syntax fetches a row from the table in natural row order that matches the `WHERE` condition. It is faster than `HANDLER tbl_name READ index_name` when a full table scan is desired. Natural row order is the order in which rows are stored in a MyISAM table data file. This statement works for InnoDB tables as well, but there is no such concept because there is no separate data file.

Without a `LIMIT` clause, all forms of `HANDLER ... READ` fetch a single row if one is available. To return a specific number of rows, include a `LIMIT` clause. It has the same syntax as for the `SELECT` statement. See Section 15.2.13, “SELECT Statement”.

`HANDLER ... CLOSE` closes a table that was opened with `HANDLER ... OPEN`.

There are several reasons to use the `HANDLER` interface instead of normal `SELECT` statements:

- `HANDLER` is faster than `SELECT`:
  - A designated storage engine handler object is allocated for the `HANDLER ... OPEN`. The object is reused for subsequent `HANDLER` statements for that table; it need not be reinitialized for each one.
  - There is less parsing involved.
  - There is no optimizer or query-checking overhead.
  - The handler interface does not have to provide a consistent look of the data (for example, dirty reads are permitted), so the storage engine can use optimizations that `SELECT` does not normally permit.
  - `HANDLER` makes it easier to port to MySQL applications that use a low-level ISAM-like interface.
  - `HANDLER` enables you to traverse a database in a manner that is difficult (or even impossible) to accomplish with `SELECT`. The `HANDLER` interface is a more natural way to look at data when working with applications that provide an interactive user interface to the database.

`HANDLER` is a somewhat low-level statement. For example, it does not provide consistency. That is, `HANDLER ... OPEN` does not take a snapshot of the table, and does not lock the table. This means that after a `HANDLER ... OPEN` statement is issued, table data can be modified (by the current session or other sessions) and these modifications might be only partially visible to `HANDLER ... NEXT` or `HANDLER ... PREV` scans.
An open handler can be closed and marked for reopen, in which case the handler loses its position in the table. This occurs when both of the following circumstances are true:

- Any session executes `FLUSH TABLES` or DDL statements on the handler's table.
- The session in which the handler is open executes non-`HANDLER` statements that use tables.

`TRUNCATE TABLE` for a table closes all handlers for the table that were opened with `HANDLER OPEN`.

If a table is flushed with `FLUSH TABLES tbl_name WITH READ LOCK` was opened with `HANDLER`, the handler is implicitly flushed and loses its position.

### 15.2.6 IMPORT TABLE Statement

```
IMPORT TABLE Statement
```

An open handler can be closed and marked for reopen, in which case the handler loses its position in the table. This occurs when both of the following circumstances are true:

- Any session executes `FLUSH TABLES` or DDL statements on the handler's table.
- The session in which the handler is open executes non-`HANDLER` statements that use tables.

`TRUNCATE TABLE` for a table closes all handlers for the table that were opened with `HANDLER OPEN`.

If a table is flushed with `FLUSH TABLES tbl_name WITH READ LOCK` was opened with `HANDLER`, the handler is implicitly flushed and loses its position.

The `IMPORT TABLE` statement imports MyISAM tables based on information contained in `.sdi` (serialized dictionary information) metadata files. `IMPORT TABLE` requires the `FILE` privilege to read the `.sdi` and table content files, and the `CREATE` privilege for the table to be created.

Tables can be exported from one server using `mysqldump` to write a file of SQL statements and imported into another server using `mysql` to process the dump file. `IMPORT TABLE` provides a faster alternative using the ‘raw’ table files.

Prior to import, the files that provide the table content must be placed in the appropriate schema directory for the import server, and the `.sdi` file must be located in a directory accessible to the server. For example, the `.sdi` file can be placed in the directory named by the `secure_file_priv` system variable, or (if `secure_file_priv` is empty) in a directory under the server data directory.

The following example describes how to export MyISAM tables named `employees` and `managers` from the `hr` schema of one server and import them into the `hr` schema of another server. The example uses these assumptions (to perform a similar operation on your own system, modify the path names as appropriate):

- For the export server, `export_basedir` represents its base directory, and its data directory is `export_basedir/data`.
- For the import server, `import_basedir` represents its base directory, and its data directory is `import_basedir/data`.
- Table files are exported from the export server into the `/tmp/export` directory and this directory is secure (not accessible to other users).
- The import server uses `/tmp/mysql-files` as the directory named by its `secure_file_priv` system variable.

To export tables from the export server, use this procedure:

1. Ensure a consistent snapshot by executing this statement to lock the tables so that they cannot be modified during export:

   ```sql
   mysql> FLUSH TABLES hr.employees, hr.managers WITH READ LOCK;
   ```

   While the lock is in effect, the tables can still be used, but only for read access.

2. At the file system level, copy the `.sdi` and table content files from the `hr` schema directory to the secure export directory:

   - The `.sdi` file is located in the `hr` schema directory, but might not have exactly the same basename as the table name. For example, the `.sdi` files for the `employees` and `managers` tables might be named `employees_125.sdi` and `managers_238.sdi`. 
IMPORT TABLE Statement

• For a MyISAM table, the content files are its .MYD data file and .MYI index file.

Given those file names, the copy commands look like this:

```
$> cd export_basedir/data/hr
$> cp employees_125.sdi /tmp/export
$> cp managers_238.sdi /tmp/export
$> cp employees.{MYD,MYI} /tmp/export
$> cp managers.{MYD,MYI} /tmp/export
```

3. Unlock the tables:

```
mysql> UNLOCK TABLES;
```

To import tables into the import server, use this procedure:

1. The import schema must exist. If necessary, execute this statement to create it:

```
mysql> CREATE SCHEMA hr;
```

2. At the file system level, copy the .sdi files to the import server secure_file_priv directory, /tmp/mysql-files. Also, copy the table content files to the hr schema directory:

```
$> cd /tmp/export
$> cp employees_125.sdi /tmp/mysql-files
$> cp managers_238.sdi /tmp/mysql-files
$> cp employees.{MYD,MYI} import_basedir/data/hr
$> cp managers.{MYD,MYI} import_basedir/data/hr
```

3. Import the tables by executing an IMPORT TABLE statement that names the .sdi files:

```
mysql> IMPORT TABLE FROM '/tmp/mysql-files/employees.sdi',
   '/tmp/mysql-files/managers.sdi';
```

The .sdi file need not be placed in the import server directory named by the secure_file_priv system variable if that variable is empty; it can be in any directory accessible to the server, including the schema directory for the imported table. If the .sdi file is placed in that directory, however, it may be rewritten; the import operation creates a new .sdi file for the table, which overwrites the old .sdi file if the operation uses the same file name for the new file.

Each sdi_file value must be a string literal that names the .sdi file for a table or is a pattern that matches .sdi files. If the string is a pattern, any leading directory path and the .sdi file name suffix must be given literally. Pattern characters are permitted only in the base name part of the file name:

• ? matches any single character

• * matches any sequence of characters, including no characters

Using a pattern, the previous IMPORT TABLE statement could have been written like this (assuming that the /tmp/mysql-files directory contains no other .sdi files matching the pattern):

```
IMPORT TABLE FROM '/tmp/mysql-files/*.*.sdi';
```

To interpret the location of .sdi file path names, the server uses the same rules for IMPORT TABLE as the server-side rules for LOAD DATA (that is, the non-LOCAL rules). See Section 15.2.9, "LOAD DATA Statement", paying particular attention to the rules used to interpret relative path names.

IMPORT TABLE fails if the .sdi or table files cannot be located. After importing a table, the server attempts to open it and reports as warnings any problems detected. To attempt a repair to correct any reported issues, use REPAIR TABLE.

IMPORT TABLE is not written to the binary log.
Restrictions and Limitations

**IMPORT TABLE** applies only to non-TEMPORARY MyISAM tables. It does not apply to tables created with a transactional storage engine, tables created with `CREATE TEMPORARY TABLE`, or views.

An `.sdi` file used in an import operation must be generated on a server with the same data dictionary version and sdi version as the import server. The version information of the generating server is found in the `.sdi` file:

```json
{
   "mysql_version_id":80019,
   "dd_version":80017,
   "sdi_version":80016,
   ...
}
```

To determine the data dictionary and sdi version of the import server, you can check the `.sdi` file of a recently created table on the import server.

The table data and index files must be placed in the schema directory for the import server prior to the import operation, unless the table as defined on the export server uses the `DATA DIRECTORY` or `INDEX DIRECTORY` table options. In that case, modify the import procedure using one of these alternatives before executing the **IMPORT TABLE** statement:

- Put the data and index files into the same directory on the import server host as on the export server host, and create symlinks in the import server schema directory to those files.
- Put the data and index files into an import server host directory different from that on the export server host, and create symlinks in the import server schema directory to those files. In addition, modify the `.sdi` file to reflect the different file locations.
- Put the data and index files into the schema directory on the import server host, and modify the `.sdi` file to remove the data and index directory table options.

Any collation IDs stored in the `.sdi` file must refer to the same collations on the export and import servers.

Trigger information for a table is not serialized into the table `.sdi` file, so triggers are not restored by the import operation.

Some edits to an `.sdi` file are permissible prior to executing the **IMPORT TABLE** statement, whereas others are problematic or may even cause the import operation to fail:

- Changing the data directory and index directory table options is required if the locations of the data and index files differ between the export and import servers.
- Changing the schema name is required to import the table into a different schema on the import server than on the export server.
- Changing schema and table names may be required to accommodate differences between file system case-sensitivity semantics on the export and import servers or differences in `lower_case_table_names` settings. Changing the table names in the `.sdi` file may require renaming the table files as well.
- In some cases, changes to column definitions are permitted. Changing data types is likely to cause problems.

### 15.2.7 INSERT Statement

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name
[PARTITION (partition_name [, partition_name] ...)]
[(col_name [, col_name] ...)]
```
**INSERT Statement**

{ {VALUES | VALUE} (value_list) [, {value_list}] ... }  
[AS row_alias[(col_alias [, col_alias] ...)]]  
[ON DUPLICATE KEY UPDATE assignment_list]

**INSERT** [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]  
[INTO] tbl_name  
[PARTITION (partition_name [, partition_name] ...)]  
SET assignment_list  
[AS row_alias[(col_alias [, col_alias] ...)]]  
[ON DUPLICATE KEY UPDATE assignment_list]

**INSERT** [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]  
[INTO] tbl_name  
[PARTITION (partition_name [, partition_name] ...)]  
[(col_name [, col_name] ...)]  
{ SELECT ...  
| TABLE table_name  
| VALUES row_constructor_list  
}  
[ON DUPLICATE KEY UPDATE assignment_list]

**value:**  
{ expr | DEFAULT}

**value_list:**  
value [, value] ...

**row_constructor_list:**  
ROW(value_list) [, ROW(value_list)] [, ...]

**assignment:**  
col_name =  
{ row_alias.[.]col_name  
| tbl_name.[.]col_name  
| row_alias.[.]col_alias}

**assignment_list:**  
assignment [, assignment] ...

**INSERT** inserts new rows into an existing table. The **INSERT ... VALUES, INSERT ... VALUES ROW()**, and **INSERT ... SET** forms of the statement insert rows based on explicitly specified values. The **INSERT ... SELECT** form inserts rows selected from another table or tables. You can also use **INSERT ... TABLE** to insert rows from a single table. **INSERT** with an **ON DUPLICATE KEY UPDATE** clause enables existing rows to be updated if a row to be inserted would cause a duplicate value in a **UNIQUE** index or **PRIMARY KEY**. A row alias with one or more optional column aliases can be used with **ON DUPLICATE KEY UPDATE** to refer to the row to be inserted.

For additional information about **INSERT ... SELECT** and **INSERT ... ON DUPLICATE KEY UPDATE**, see Section 15.2.7.1, “**INSERT ... SELECT Statement**”, and Section 15.2.7.2, “**INSERT ... ON DUPLICATE KEY UPDATE Statement**”.

In MySQL 8.4, the **DELAYED** keyword is accepted but ignored by the server. For the reasons for this, see Section 15.2.7.3, “**INSERT DELAYED Statement**”.

Inserting into a table requires the **INSERT** privilege for the table. If the **ON DUPLICATE KEY UPDATE** clause is used and a duplicate key causes an **UPDATE** to be performed instead, the statement requires the **UPDATE** privilege for the columns to be updated. For columns that are read but not modified you need only the **SELECT** privilege (such as for a column referenced only on the right hand side of an **col_name=expr** assignment in an **ON DUPLICATE KEY UPDATE** clause).

When inserting into a partitioned table, you can control which partitions and subpartitions accept new rows. The **PARTITION** clause takes a list of the comma-separated names of one or more partitions or subpartitions (or both) of the table. If any of the rows to be inserted by a given **INSERT** statement do not match one of the partitions listed, the **INSERT** statement fails with the error **Found a row not matching the given partition set**. For more information and examples, see Section 26.5, “**Partition Selection**”.

2567
**tbl_name** is the table into which rows should be inserted. Specify the columns for which the statement provides values as follows:

- Provide a parenthesized list of comma-separated column names following the table name. In this case, a value for each named column must be provided by the **VALUES** list, **VALUES ROW()** list, or **SELECT** statement. For the **INSERT TABLE** form, the number of columns in the source table must match the number of columns to be inserted.

- If you do not specify a list of column names for **INSERT ... VALUES** or **INSERT ... SELECT**, values for every column in the table must be provided by the **VALUES** list, **SELECT** statement, or **TABLE** statement. If you do not know the order of the columns in the table, use **DESCRIBE tbl_name** to find out.

- A **SET** clause indicates columns explicitly by name, together with the value to assign each one.

Column values can be given in several ways:

- If strict SQL mode is not enabled, any column not explicitly given a value is set to its default (explicit or implicit) value. For example, if you specify a column list that does not name all the columns in the table, unnamed columns are set to their default values. Default value assignment is described in Section 13.6, “Data Type Default Values”.

  If strict SQL mode is enabled, an **INSERT** statement generates an error if it does not specify an explicit value for every column that has no default value. See Section 7.1.11, “Server SQL Modes”.

- If both the column list and the **VALUES** list are empty, **INSERT** creates a row with each column set to its default value:

  ```sql
  INSERT INTO tbl_name () VALUES();
  ```

  If strict mode is not enabled, MySQL uses the implicit default value for any column that has no explicitly defined default. If strict mode is enabled, an error occurs if any column has no default value.

- Use the keyword **DEFAULT** to set a column explicitly to its default value. This makes it easier to write **INSERT** statements that assign values to all but a few columns, because it enables you to avoid writing an incomplete **VALUES** list that does not include a value for each column in the table. Otherwise, you must provide the list of column names corresponding to each value in the **VALUES** list.

- If a generated column is inserted into explicitly, the only permitted value is **DEFAULT**. For information about generated columns, see Section 15.1.20.8, “CREATE TABLE and Generated Columns”.

- In expressions, you can use **DEFAULT(col_name)** to produce the default value for column **col_name**.

- Type conversion of an expression **expr** that provides a column value might occur if the expression data type does not match the column data type. Conversion of a given value can result in different inserted values depending on the column type. For example, inserting the string '1999.0e-2' into an **INT**, **FLOAT**, **DECIMAL(10,6)**, or **YEAR** column inserts the value 1999, 19.9921, 19.992100, or 1999, respectively. The value stored in the **INT** and **YEAR** columns is 1999 because the string-to-number conversion looks only at as much of the initial part of the string as may be considered a valid integer or year. For the **FLOAT** and **DECIMAL** columns, the string-to-number conversion considers the entire string a valid numeric value.

- An expression **expr** can refer to any column that was set earlier in a value list. For example, you can do this because the value for **col2** refers to **col1**, which has previously been assigned:

  ```sql
  INSERT INTO tbl_name (col1,col2) VALUES(15,col1*2);
  ```

  But the following is not legal, because the value for **col1** refers to **col2**, which is assigned after **col1**:

  ```sql
  INSERT INTO tbl_name (col1,col2) VALUES(col2*2,15);
  ```
An exception occurs for columns that contain `AUTO_INCREMENT` values. Because `AUTO_INCREMENT` values are generated after other value assignments, any reference to an `AUTO_INCREMENT` column in the assignment returns a 0.

**INSERT** statements that use **VALUES** syntax can insert multiple rows. To do this, include multiple lists of comma-separated column values, with lists enclosed within parentheses and separated by commas. Example:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3), (4,5,6), (7,8,9);
```

Each values list must contain exactly as many values as are to be inserted per row. The following statement is invalid because it contains one list of nine values, rather than three lists of three values each:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3,4,5,6,7,8,9);
```

**VALUE** is a synonym for **VALUES** in this context. Neither implies anything about the number of values lists, nor about the number of values per list. Either may be used whether there is a single values list or multiple lists, and regardless of the number of values per list.

**INSERT** statements using **VALUES ROW()** syntax can also insert multiple rows. In this case, each value list must be contained within a **ROW()** (row constructor), like this:

```
INSERT INTO tbl_name (a,b,c) VALUES ROW(1,2,3), ROW(4,5,6), ROW(7,8,9);
```

The affected-rows value for an **INSERT** can be obtained using the **ROW_COUNT()** SQL function or the **mysql_affected_rows()** C API function. See Section 14.15, "Information Functions", and **mysql_affected_rows()**.

If you use **INSERT ... VALUES** or **INSERT ... VALUES ROW()** with multiple value lists, or **INSERT ... SELECT** or **INSERT ... TABLE**, the statement returns an information string in this format:

```
Records: N1 Duplicates: N2 Warnings: N3
```

If you are using the C API, the information string can be obtained by invoking the **mysql_info()** function. See **mysql_info()**.

**Records** indicates the number of rows processed by the statement. (This is not necessarily the number of rows actually inserted because **Duplicates** can be nonzero.) **Duplicates** indicates the number of rows that could not be inserted because they would duplicate some existing unique index value. **Warnings** indicates the number of attempts to insert column values that were problematic in some way. Warnings can occur under any of the following conditions:

- Inserting **NULL** into a column that has been declared **NOT NULL**. For multiple-row **INSERT** statements or **INSERT INTO ... SELECT** statements, the column is set to the implicit default value for the column data type. This is 0 for numeric types, the empty string (""") for string types, and the ‘zero’ value for date and time types. **INSERT INTO ... SELECT** statements are handled the same way as multiple-row inserts because the server does not examine the result set from the **SELECT** to see whether it returns a single row. (For a single-row **INSERT**, no warning occurs when **NULL** is inserted into a **NOT NULL** column. Instead, the statement fails with an error.)

- Setting a numeric column to a value that lies outside the column range. The value is clipped to the closest endpoint of the range.

- Assigning a value such as `'10.34 a'` to a numeric column. The trailing nonnumeric text is stripped off and the remaining numeric part is inserted. If the string value has no leading numeric part, the column is set to 0.
• Inserting a string into a string column (**CHAR, VARCHAR, TEXT**, or **BLOB**) that exceeds the column maximum length. The value is truncated to the column maximum length.

• Inserting a value into a date or time column that is illegal for the data type. The column is set to the appropriate zero value for the type.

• For **INSERT** examples involving **AUTO_INCREMENT** column values, see Section 5.6.9, “Using **AUTO_INCREMENT**”.

If **INSERT** inserts a row into a table that has an **AUTO_INCREMENT** column, you can find the value used for that column by using the **LAST_INSERT_ID()** SQL function or the **mysql_insert_id()** C API function.

**Note**

These two functions do not always behave identically. The behavior of **INSERT** statements with respect to **AUTO_INCREMENT** columns is discussed further in Section 14.15, “Information Functions”, and mysql_insert_id().

The **INSERT** statement supports the following modifiers:

• If you use the **LOW_PRIORITY** modifier, execution of the **INSERT** is delayed until no other clients are reading from the table. This includes other clients that began reading while existing clients are reading, and while the **INSERT LOW_PRIORITY** statement is waiting. It is possible, therefore, for a client that issues an **INSERT LOW_PRIORITY** statement to wait for a very long time.

  **LOW_PRIORITY** affects only storage engines that use only table-level locking (such as **MyISAM, MEMORY, and MERGE**).

  **Note**

  **LOW_PRIORITY** should normally not be used with **MyISAM** tables because doing so disables concurrent inserts. See Section 10.11.3, “Concurrent Inserts”.

• If you specify **HIGH_PRIORITY**, it overrides the effect of the **--low-priority-updates** option if the server was started with that option. It also causes concurrent inserts not to be used. See Section 10.11.3, “Concurrent Inserts”.

  **HIGH_PRIORITY** affects only storage engines that use only table-level locking (such as **MyISAM, MEMORY, and MERGE**).

• If you use the **IGNORE** modifier, ignorable errors that occur while executing the **INSERT** statement are ignored. For example, without **IGNORE**, a row that duplicates an existing **UNIQUE** index or **PRIMARY KEY** value in the table causes a duplicate-key error and the statement is aborted. With **IGNORE**, the row is discarded and no error occurs. Ignored errors generate warnings instead.

  **IGNORE** has a similar effect on inserts into partitioned tables where no partition matching a given value is found. Without **IGNORE**, such **INSERT** statements are aborted with an error. When **INSERT IGNORE** is used, the insert operation fails silently for rows containing the unmatched value, but inserts rows that are matched. For an example, see Section 26.2.2, “LIST Partitioning”.

  Data conversions that would trigger errors abort the statement if **IGNORE** is not specified. With **IGNORE**, invalid values are adjusted to the closest values and inserted; warnings are produced but the statement does not abort. You can determine with the **mysql_info()** C API function how many rows were actually inserted into the table.

  For more information, see The Effect of **IGNORE** on Statement Execution.

You can use **REPLACE** instead of **INSERT** to overwrite old rows. **REPLACE** is the counterpart to **INSERT IGNORE** in the treatment of new rows that contain unique key values that duplicate
old rows: The new rows replace the old rows rather than being discarded. See Section 15.2.12, “REPLACE Statement”.

- If you specify ON DUPLICATE KEY UPDATE, and a row is inserted that would cause a duplicate value in a UNIQUE index or PRIMARY KEY, an UPDATE of the old row occurs. The affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the CLIENT_FOUND_ROWS flag to the mysql_real_connect() C API function when connecting to mysqld, the affected-rows value is 1 (not 0) if an existing row is set to its current values. See Section 15.2.7.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”.

- INSERT DELAYED was deprecated in MySQL 5.6, and is scheduled for eventual removal. In MySQL 8.4, the DELAYED modifier is accepted but ignored. Use INSERT (without DELAYED) instead. See Section 15.2.7.3, “INSERT DELAYED Statement”.

15.2.7.1 INSERT ... SELECT Statement

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name
[PARTITION (partition_name [, partition_name] ...)]
[(col_name [, col_name] ...)]
| SELECT ...
| TABLE table_name
| VALUES row_constructor_list
| [ON DUPLICATE KEY UPDATE assignment_list]
```

With INSERT ... SELECT, you can quickly insert many rows into a table from the result of a SELECT statement, which can select from one or many tables. For example:

```
INSERT INTO tbl_temp2 (fld_id)
SELECT tbl_temp1.fld_order_id
FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

TABLE statement in place of SELECT, as shown here:

```
INSERT INTO ta TABLE tb;
```

TABLE tb is equivalent to SELECT * FROM tb. It can be useful when inserting all columns from the source table into the target table, and no filtering with WHERE is required. In addition, the rows from TABLE can be ordered by one or more columns using ORDER BY, and the number of rows inserted can be limited using a LIMIT clause. For more information, see Section 15.2.16, “TABLE Statement”.

The following conditions hold for INSERT ... SELECT statements, and, except where noted, for INSERT ... TABLE as well:

- Specify IGNORE to ignore rows that would cause duplicate-key violations.
The target table of the `INSERT` statement may appear in the `FROM` clause of the `SELECT` part of the query, or as the table named by `TABLE`. However, you cannot insert into a table and select from the same table in a subquery.

When selecting from and inserting into the same table, MySQL creates an internal temporary table to hold the rows from the `SELECT` and then inserts those rows into the target table. However, you cannot use `INSERT INTO t ... SELECT ... FROM t` when `t` is a `TEMPORARY` table, because `TEMPORARY` tables cannot be referred to twice in the same statement. For the same reason, you cannot use `INSERT INTO t ... TABLE t` when `t` is a temporary table. See Section 10.4.4, “Internal Temporary Table Use in MySQL”, and Section B.3.6.2, “TEMPORARY Table Problems”.

- `AUTO_INCREMENT` columns work as usual.
- To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts for `INSERT ... SELECT` or `INSERT ... TABLE` statements (see Section 10.11.3, “Concurrent Inserts”).
- To avoid ambiguous column reference problems when the `SELECT` and the `INSERT` refer to the same table, provide a unique alias for each table used in the `SELECT` part, and qualify column names in that part with the appropriate alias. The `TABLE` statement does not support aliases.

You can explicitly select which partitions or subpartitions (or both) of the source or target table (or both) are to be used with a `PARTITION` clause following the name of the table. When `PARTITION` is used with the name of the source table in the `SELECT` portion of the statement, rows are selected only from the partitions or subpartitions named in its partition list. When `PARTITION` is used with the name of the target table for the `INSERT` portion of the statement, it must be possible to insert all rows selected into the partitions or subpartitions named in the partition list following the option. Otherwise, the `INSERT ... SELECT` statement fails. For more information and examples, see Section 26.5, “Partition Selection”.

`TABLE` does not support a `PARTITION` clause.

For `INSERT ... SELECT` statements, see Section 15.2.7.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement” for conditions under which the `SELECT` columns can be referred to in an `ON DUPLICATE KEY UPDATE` clause. This also works for `INSERT ... TABLE`.

The order in which a `SELECT` or `TABLE` statement with no `ORDER BY` clause returns rows is nondeterministic. This means that, when using replication, there is no guarantee that such a `SELECT` returns rows in the same order on the source and the replica, which can lead to inconsistencies between them. To prevent this from occurring, always write `INSERT ... SELECT` or `INSERT ... TABLE` statements that are to be replicated using an `ORDER BY` clause that produces the same row order on the source and the replica. See also Section 19.5.1.18, “Replication and LIMIT”.

Due to this issue, `INSERT ... SELECT ON DUPLICATE KEY UPDATE` and `INSERT IGNORE ... SELECT` statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using `MIXED` mode. (Bug #11758262, Bug #50439)

See also Section 19.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

### 15.2.7.2 INSERT ... ON DUPLICATE KEY UPDATE Statement

If you specify an `ON DUPLICATE KEY UPDATE` clause and a row to be inserted would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row occurs. For example, if column `a` is declared as `UNIQUE` and contains the value `1`, the following two statements have similar effect:

```sql
INSERT INTO t1 (a,b,c) VALUES (1,2,3)
```
**INSERT Statement**

```sql
ON DUPLICATE KEY UPDATE c=c+1;

UPDATE t1 SET c=c+1 WHERE a=1;
```

The effects are not quite identical: For an InnoDB table where `a` is an auto-increment column, the `INSERT` statement increases the auto-increment value but the `UPDATE` does not.

If column `b` is also unique, the `INSERT` is equivalent to this `UPDATE` statement instead:

```sql
UPDATE t1 SET c=c+1 WHERE a=1 OR b=2 LIMIT 1;
```

If `a=1 OR b=2` matches several rows, only one row is updated. In general, you should try to avoid using an `ON DUPLICATE KEY UPDATE` clause on tables with multiple unique indexes.

With `ON DUPLICATE KEY UPDATE`, the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag to the `mysql_real_connect()` C API function when connecting to `mysqld`, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

If a table contains an `AUTO_INCREMENT` column and `INSERT ... ON DUPLICATE KEY UPDATE` inserts or updates a row, the `LAST_INSERT_ID()` function returns the `AUTO_INCREMENT` value.

The `ON DUPLICATE KEY UPDATE` clause can contain multiple column assignments, separated by commas.

In assignment value expressions in the `ON DUPLICATE KEY UPDATE` clause, you can use the `VALUES(col_name)` function to refer to column values from the `INSERT` portion of the `INSERT ... ON DUPLICATE KEY UPDATE` statement. In other words, `VALUES(col_name)` in the `ON DUPLICATE KEY UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in the `ON DUPLICATE KEY UPDATE` clause or `INSERT` statements and returns `NULL` otherwise. Example:

```sql
INSERT INTO t1 (a,b,c) VALUES (1,2,3),(4,5,6)
ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

That statement is identical to the following two statements:

```sql
INSERT INTO t1 (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=3;
INSERT INTO t1 (a,b,c) VALUES (4,5,6)
ON DUPLICATE KEY UPDATE c=9;
```

**Note**

The use of `VALUES()` to refer to the new row and columns is deprecated, and subject to removal in a future version of MySQL. Instead, use row and column aliases, as described in the next few paragraphs of this section.

It is possible to use an alias for the row, with, optionally, one or more of its columns to be inserted, following the `VALUES` or `SET` clause, and preceded by the `AS` keyword. Using the row alias `new`, the statement shown previously using `VALUES()` to access the new column values can be written in the form shown here:

```sql
INSERT INTO t1 (a,b,c) VALUES (1,2,3),(4,5,6) AS new
ON DUPLICATE KEY UPDATE c = new.a+new.b;
```

If, in addition, you use the column aliases `m`, `n`, and `p`, you can omit the row alias in the assignment clause and write the same statement like this:

```sql
INSERT INTO t1 (a,b,c) VALUES (1,2,3),(4,5,6) AS new(m,n,p)
ON DUPLICATE KEY UPDATE c = m+n;
```

When using column aliases in this fashion, you must still use a row alias following the `VALUES` clause, even if you do not make direct use of it in the assignment clause.
An `INSERT ... SELECT ... ON DUPLICATE KEY UPDATE` statement that uses `VALUES()` in the `UPDATE` clause, like this one, throws a warning:

```sql
INSERT INTO t1
SELECT c, c+d FROM t2
ON DUPLICATE KEY UPDATE b = VALUES(b);
```

You can eliminate such warnings by using a subquery instead, like this:

```sql
INSERT INTO t1
SELECT * FROM (SELECT c, c+d AS e FROM t2) AS dt
ON DUPLICATE KEY UPDATE b = e;
```

You can also use row and column aliases with a `SET` clause, as mentioned previously. Employing `SET` instead of `VALUES` in the two `INSERT ... ON DUPLICATE KEY UPDATE` statements just shown can be done as shown here:

```sql
INSERT INTO t1 SET a=1,b=2,c=3 AS new
ON DUPLICATE KEY UPDATE c = new.a+new.b;
```

```sql
INSERT INTO t1 SET a=1,b=2,c=3 AS new(m,n,p)
ON DUPLICATE KEY UPDATE c = m+n;
```

The row alias must not be the same as the name of the table. If column aliases are not used, or if they are the same as the column names, they must be distinguished using the row alias in the `ON DUPLICATE KEY UPDATE` clause. Column aliases must be unique with regard to the row alias to which they apply (that is, no column aliases referring to columns of the same row may be the same).

For `INSERT ... SELECT` statements, these rules apply regarding acceptable forms of `SELECT` query expressions that you can refer to in an `ON DUPLICATE KEY UPDATE` clause:

- References to columns from queries on a single table, which may be a derived table.
- References to columns from queries on a join over multiple tables.
- References to columns from `DISTINCT` queries.
- References to columns in other tables, as long as the `SELECT` does not use `GROUP BY`. One side effect is that you must qualify references to nonunique column names.

References to columns from a `UNION` are not supported. To work around this restriction, rewrite the `UNION` as a derived table so that its rows can be treated as a single-table result set. For example, this statement produces an error:

```sql
INSERT INTO t1 (a, b)
SELECT c, d FROM t2
UNION
SELECT e, f FROM t3
ON DUPLICATE KEY UPDATE b = b + c;
```

Instead, use an equivalent statement that rewrites the `UNION` as a derived table:

```sql
INSERT INTO t1 (a, b)
SELECT * FROM
(SELECT c, d FROM t2
UNION
SELECT e, f FROM t3) AS dt
ON DUPLICATE KEY UPDATE b = b + c;
```

The technique of rewriting a query as a derived table also enables references to columns from `GROUP BY` queries.

Because the results of `INSERT ... SELECT` statements depend on the ordering of rows from the `SELECT` and this order cannot always be guaranteed, it is possible when logging `INSERT ... SELECT ON DUPLICATE KEY UPDATE` statements for the source and the replica to diverge.
Thus, **INSERT ... SELECT ON DUPLICATE KEY UPDATE** statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using MIXED mode. An **INSERT ... ON DUPLICATE KEY UPDATE** statement against a table having more than one unique or primary key is also marked as unsafe. (Bug #11765650, Bug #58637)

See also Section 19.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

### 15.2.7.3 INSERT DELAYED Statement

**INSERT DELAYED ...**

The **DELAYED** option for the **INSERT** statement is a MySQL extension to standard SQL. In previous versions of MySQL, it can be used for certain kinds of tables (such as **MyISAM**), such that when a client uses **INSERT DELAYED**, it gets an okay from the server at once, and the row is queued to be inserted when the table is not in use by any other thread.

**DELAYED** inserts and replaces were deprecated in MySQL 5.6. In MySQL 8.4, **DELAYED** is not supported. The server recognizes but ignores the **DELAYED** keyword, handles the insert as a nondelayed insert, and generates an **ER_WARN_LEGACY_SYNTAX_CONVERTED** warning: **INSERT DELAYED** is no longer supported. The statement was converted to **INSERT**. The **DELAYED** keyword is scheduled for removal in a future release.

### 15.2.8 INTERSECT Clause

```
query_expression_body INTERSECT [ALL | DISTINCT] query_expression_body
  [INTERSECT [ALL | DISTINCT] query_expression_body]
[...]
```

**query_expression_body:**

See Section 15.2.14, “Set Operations with UNION, INTERSECT, and EXCEPT”

**INTERSECT** limits the result from multiple query blocks to those rows which are common to all. Example:

```sql
mysql> TABLE a;
+------+------+
| m    | n    |
+------+------+
|    1 |    2 |
|    2 |    3 |
|    3 |    4 |
+------+------+
3 rows in set (0.00 sec)

mysql> TABLE b;
+------+------+
| m    | n    |
+------+------+
|    1 |    2 |
|    1 |    3 |
|    3 |    4 |
+------+------+
3 rows in set (0.00 sec)

mysql> TABLE c;
+------+------+
| m    | n    |
+------+------+
|    1 |    3 |
|    1 |    3 |
|    3 |    4 |
+------+------+
3 rows in set (0.00 sec)

mysql> TABLE a INTERSECT TABLE b;
```
As with \texttt{UNION} and \texttt{EXCEPT}, if neither \texttt{DISTINCT} nor \texttt{ALL} is specified, the default is \texttt{DISTINCT}.

\texttt{DISTINCT} can remove duplicates from either side of the intersection, as shown here:

\begin{verbatim}
mysql> TABLE c INTERSECT DISTINCT TABLE c;
+------+------+
| m    | n    |
+------+------+
| 1    | 3    |
| 3    | 4    |
+------+------+
2 rows in set (0.00 sec)
mysql> TABLE c INTERSECT ALL TABLE c;
+------+------+
| m    | n    |
+------+------+
| 1    | 3    |
| 1    | 3    |
| 3    | 4    |
+------+------+
3 rows in set (0.00 sec)
\end{verbatim}

(\texttt{TABLE c INTERSECT TABLE c} is the equivalent of the first of the two statements just shown.)

As with \texttt{UNION}, the operands must have the same number of columns. Result set column types are also determined as for \texttt{UNION}.

\texttt{INTERSECT} has greater precedence than and is evaluated before \texttt{UNION} and \texttt{EXCEPT}, so that the two statements shown here are equivalent:

\begin{verbatim}
TABLE r EXCEPT TABLE s INTERSECT TABLE t;
TABLE r EXCEPT (TABLE s INTERSECT TABLE t);
\end{verbatim}

For \texttt{INTERSECT ALL}, the maximum supported number of duplicates of any unique row in the left hand table is \texttt{4294967295}.

\subsection*{15.2.9 LOAD DATA Statement}

\begin{verbatim}
LOAD DATA
[LOW_PRIORITY | CONCURRENT] [LOCAL]
INFILE 'file_name'
[REPLACE | IGNORE]
INTO TABLE \textit{tbl_name}
[PARTITION (\textit{partition_name} [, \textit{partition_name}] ...)]
[CHARACTER SET \textit{charset_name}]
[\{FIELDS | COLUMNS\]
[TERMINATED BY 'string']
[\{OPTIONALLY\} ENCLOSED BY 'char']
[ESCAPED BY 'char']
]
[LINES
\end{verbatim}
The **LOAD DATA** statement reads rows from a text file into a table at a very high speed. The file can be read from the server host or the client host, depending on whether the **LOCAL** modifier is given. **LOCAL** also affects data interpretation and error handling.

**LOAD DATA** is the complement of **SELECT ... INTO OUTFILE**. (See Section 15.2.13.1, “SELECT ... INTO Statement”.) To write data from a table to a file, use **SELECT ... INTO OUTFILE**. To read the file back into a table, use **LOAD DATA**. The syntax of the **FIELDS** and **LINES** clauses is the same for both statements.

The **mysqlimport** utility provides another way to load data files; it operates by sending a **LOAD DATA** statement to the server. See Section 6.5.5, “mysqlimport — A Data Import Program”.

For information about the efficiency of **INSERT** versus **LOAD DATA** and speeding up **LOAD DATA**, see Section 10.2.5.1, “Optimizing **INSERT** Statements”.

- **Non-LOCAL Versus LOCAL Operation**
- **Input File Character Set**
- **Input File Location**
- **Security Requirements**
- **Duplicate-Key and Error Handling**
- **Index Handling**
- **Field and Line Handling**
- **Column List Specification**
- **Input Preprocessing**
- **Column Value Assignment**
- **Partitioned Table Support**
- **Concurrency Considerations**
- **Statement Result Information**
- **Replication Considerations**
- **Miscellaneous Topics**

**Non-LOCAL Versus LOCAL Operation**

The **LOCAL** modifier affects these aspects of **LOAD DATA**, compared to non-**LOCAL** operation:

- It changes the expected location of the input file; see **Input File Location**.
- It changes the statement security requirements; see **Security Requirements**.
- It has the same effect as the **IGNORE** modifier on the interpretation of input file contents and error handling; see **Duplicate-Key and Error Handling**, and **Column Value Assignment**.
**LOAD DATA Statement**

**LOCAL** works only if the server and your client both have been configured to permit it. For example, if `mysqld` was started with the `local_infile` system variable disabled, **LOCAL** produces an error. See Section 8.1.6, “Security Considerations for LOAD DATA LOCAL”.

**Input File Character Set**

The file name must be given as a literal string. On Windows, specify backslashes in path names as forward slashes or doubled backslashes. The server interprets the file name using the character set indicated by the `character_set_filesystem` system variable.

By default, the server interprets the file contents using the character set indicated by the `character_set_database` system variable. If the file contents use a character set different from this default, it is a good idea to specify that character set by using the `CHARACTER SET` clause. A character set of `binary` specifies “no conversion.”

**SET NAMES** and the setting of `character_set_client` do not affect interpretation of file contents.

**LOAD DATA** interprets all fields in the file as having the same character set, regardless of the data types of the columns into which field values are loaded. For proper interpretation of the file, you must ensure that it was written with the correct character set. For example, if you write a data file with `mysqldump -T` or by issuing a `SELECT ... INTO OUTFILE` statement in `mysql`, be sure to use a `--default-character-set` option to write output in the character set to be used when the file is loaded with **LOAD DATA**.

**Note**

It is not possible to load data files that use the `ucs2`, `utf16`, `utf16le`, or `utf32` character set.

**Input File Location**

These rules determine the **LOAD DATA** input file location:

- If **LOCAL** is not specified, the file must be located on the server host. The server reads the file directly, locating it as follows:
  - If the file name is an absolute path name, the server uses it as given.
  - If the file name is a relative path name with leading components, the server looks for the file relative to its data directory.
  - If the file name has no leading components, the server looks for the file in the database directory of the default database.

- If **LOCAL** is specified, the file must be located on the client host. The client program reads the file, locating it as follows:
  - If the file name is an absolute path name, the client program uses it as given.
  - If the file name is a relative path name, the client program looks for the file relative to its invocation directory.

When **LOCAL** is used, the client program reads the file and sends its contents to the server. The server creates a copy of the file in the directory where it stores temporary files. See Section B.3.3.5, “Where MySQL Stores Temporary Files”. Lack of sufficient space for the copy in this directory can cause the **LOAD DATA LOCAL** statement to fail.

The non-**LOCAL** rules mean that the server reads a file named as `./myfile.txt` relative to its data directory, whereas it reads a file named as `myfile.txt` from the database directory of the default database. For example, if the following **LOAD DATA** statement is executed while `db1` is the default database,
database, the server reads the file data.txt from the database directory for db1, even though the statement explicitly loads the file into a table in the db2 database:

```sql
LOAD DATA INFILE 'data.txt' INTO TABLE db2.my_table;
```

**Note**
The server also uses the non-LOCAL rules to locate .sdi files for the IMPORT TABLE statement.

### Security Requirements

For a non-LOCAL load operation, the server reads a text file located on the server host, so these security requirements must be satisfied:

- You must have the FILE privilege. See Section 8.2.2, “Privileges Provided by MySQL”.
- The operation is subject to the secure_file_priv system variable setting:
  - If the variable value is a nonempty directory name, the file must be located in that directory.
  - If the variable value is empty (which is insecure), the file need only be readable by the server.

For a LOCAL load operation, the client program reads a text file located on the client host. Because the file contents are sent over the connection by the client to the server, using LOCAL is a bit slower than when the server accesses the file directly. On the other hand, you do not need the FILE privilege, and the file can be located in any directory the client program can access.

### Duplicate-Key and Error Handling

The REPLACE and IGNORE modifiers control handling of new (input) rows that duplicate existing table rows on unique key values (PRIMARY KEY or UNIQUE index values):

- With REPLACE, new rows that have the same value as a unique key value in an existing row replace the existing row. See Section 15.2.12, “REPLACE Statement”.
- With IGNORE, new rows that duplicate an existing row on a unique key value are discarded. For more information, see The Effect of IGNORE on Statement Execution.

The LOCAL modifier has the same effect as IGNORE. This occurs because the server has no way to stop transmission of the file in the middle of the operation.

If none of REPLACE, IGNORE, or LOCAL is specified, an error occurs when a duplicate key value is found, and the rest of the text file is ignored.

In addition to affecting duplicate-key handling as just described, IGNORE and LOCAL also affect error handling:

- With neither IGNORE nor LOCAL, data-interpretation errors terminate the operation.
- With IGNORE or LOCAL, data-interpretation errors become warnings and the load operation continues, even if the SQL mode is restrictive. For examples, see Column Value Assignment.

### Index Handling

To ignore foreign key constraints during the load operation, execute a SET foreign_key_checks = 0 statement before executing LOAD DATA.

If you use LOAD DATA on an empty MyISAM table, all nonunique indexes are created in a separate batch (as for REPAIR TABLE). Normally, this makes LOAD DATA much faster when you have many
indexes. In some extreme cases, you can create the indexes even faster by turning them off with
`ALTER TABLE ... DISABLE KEYS` before loading the file into the table and re-creating the indexes
with `ALTER TABLE ... ENABLE KEYS` after loading the file. See Section 10.2.5.1, “Optimizing
INSERT Statements”.

Field and Line Handling

For both the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements, the syntax of the `FIELDS`
and `LINES` clauses is the same. Both clauses are optional, but `FIELDS` must precede `LINES` if both
are specified.

If you specify a `FIELDS` clause, each of its subclauses (`TERMINATED BY`, `[OPTIONALLY] ENCLOSED
BY`, and `ESCAPED BY`) is also optional, except that you must specify at least one of them. Arguments
to these clauses are permitted to contain only ASCII characters.

If you specify no `FIELDS` or `LINES` clause, the defaults are the same as if you had written this:

```
FIELDS TERMINATED BY '	' ENCLOSED BY '' ESCAPED BY '\'
LINES TERMINATED BY '
' STARTING BY ''
```

Backslash is the MySQL escape character within strings in SQL statements. Thus, to specify a literal
backslash, you must specify two backslashes for the value to be interpreted as a single backslash. The
escape sequences `	` and `
` specify tab and newline characters, respectively.

In other words, the defaults cause `LOAD DATA` to act as follows when reading input:

- Look for line boundaries at newlines.
- Do not skip any line prefix.
- Break lines into fields at tabs.
- Do not expect fields to be enclosed within any quoting characters.
- Interpret characters preceded by the escape character \ as escape sequences. For example,
  \t, \n, and \\ signify tab, newline, and backslash, respectively. See the discussion of `FIELDS
  ESCAPED BY` later for the full list of escape sequences.

Conversely, the defaults cause `SELECT ... INTO OUTFILE` to act as follows when writing output:

- Write tabs between fields.
- Do not enclose fields within any quoting characters.
- Use \ to escape instances of tab, newline, or \ that occur within field values.
- Write newlines at the ends of lines.

Note

For a text file generated on a Windows system, proper file reading might require
`LINES TERMINATED BY '\r\n'` because Windows programs typically use
two characters as a line terminator. Some programs, such as WordPad, might
use \r as a line terminator when writing files. To read such files, use `LINES
TERMINATED BY '\r'`.

If all the input lines have a common prefix that you want to ignore, you can use `LINES STARTING BY
'prefix_string'` to skip the prefix and anything before it. If a line does not include the prefix, the
entire line is skipped. Suppose that you issue the following statement:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test
  FIELDS TERMINATED BY ',' LINES STARTING BY 'xxx';
```
If the data file looks like this:

```
xxx"abc",1
something xxx"def",2
"ghi",3
```

The resulting rows are ("abc",1) and ("def",2). The third row in the file is skipped because it does not contain the prefix.

The **IGNORE number LINES** clause can be used to ignore lines at the start of the file. For example, you can use **IGNORE 1 LINES** to skip an initial header line containing column names:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test IGNORE 1 LINES;
```

When you use **SELECT ... INTO OUTFILE** in tandem with **LOAD DATA** to write data from a database into a file and then read the file back into the database later, the field- and line-handling options for both statements must match. Otherwise, **LOAD DATA** does not interpret the contents of the file properly. Suppose that you use **SELECT ... INTO OUTFILE** to write a file with fields delimited by commas:

```
SELECT * INTO OUTFILE 'data.txt'
  FIELDS TERMINATED BY ','
  FROM table2;
```

To read the comma-delimited file, the correct statement is:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
  FIELDS TERMINATED BY ',';
```

If instead you tried to read the file with the statement shown following, it would not work because it instructs **LOAD DATA** to look for tabs between fields:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
  FIELDS TERMINATED BY '\t';
```

The likely result is that each input line would be interpreted as a single field.

**LOAD DATA** can be used to read files obtained from external sources. For example, many programs can export data in comma-separated values (CSV) format, such that lines have fields separated by commas and enclosed within double quotation marks, with an initial line of column names. If the lines in such a file are terminated by carriage return/newline pairs, the statement shown here illustrates the field- and line-handling options you would use to load the file:

```
LOAD DATA INFILE 'data.txt' INTO TABLE tbl_name
  FIELDS TERMINATED BY ',' ENCLOSED BY '"'
  LINES TERMINATED BY '\n'
  IGNORE 1 LINES;
```

If the input values are not necessarily enclosed within quotation marks, use **OPTIONALLY** before the **ENCLOSED BY** option.

Any of the field- or line-handling options can specify an empty string ("''). If not empty, the **FIELDS [OPTIONALLY] ENCLOSED BY** and **FIELDS ESCAPED BY** values must be a single character. The **FIELDS TERMINATED BY**, **LINES STARTING BY**, and **LINES TERMINATED BY** values can be more than one character. For example, to write lines that are terminated by carriage return/linefeed pairs, or to read a file containing such lines, specify a **LINES TERMINATED BY '\r\n'** clause.

To read a file containing jokes that are separated by lines consisting of %, you can do this:

```
CREATE TABLE jokes
  (a INT NOT NULL AUTO_INCREMENT PRIMARY KEY, 
   joke TEXT NOT NULL);
LOAD DATA INFILE '/tmp/jokes.txt' INTO TABLE jokes
  FIELDS TERMINATED BY '\';
```
LINES TERMINATED BY '\n\$\n' (joke);

FIELDS [OPTIONALLY] ENCLOSED BY controls quoting of fields. For output (SELECT ... INTO OUTFILE), if you omit the word OPTIONALLY, all fields are enclosed by the ENCLOSED BY character. An example of such output (using a comma as the field delimiter) is shown here:

"1", "a string", "100.20"
"2", "a string containing a , comma", "102.20"
"3", "a string containing a " quote", "102.20"
"4", "a string containing a ", quote and comma", "102.20"

If you specify OPTIONALLY, the ENCLOSED BY character is used only to enclose values from columns that have a string data type (such as CHAR, BINARY, TEXT, or ENUM):

1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a " quote",102.20
4,"a string containing a ", quote and comma",102.20

Occurrences of the ENCLOSED BY character within a field value are escaped by prefixing them with the ESCAPED BY character. Also, if you specify an empty ESCAPED BY value, it is possible to inadvertently generate output that cannot be read properly by LOAD DATA. For example, the preceding output just shown would appear as follows if the escape character is empty. Observe that the second field in the fourth line contains a comma following the quote, which (erroneously) appears to terminate the field:

1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a " quote",102.20
4,"a string containing a ", quote and comma",102.20

For input, the ENCLOSED BY character, if present, is stripped from the ends of field values. (This is true regardless of whether OPTIONALLY is specified; OPTIONALLY has no effect on input interpretation.) Occurrences of the ENCLOSED BY character preceded by the ESCAPED BY character are interpreted as part of the current field value.

If the field begins with the ENCLOSED BY character, instances of that character are recognized as terminating a field value only if followed by the field or line TERMINATED BY sequence. To avoid ambiguity, occurrences of the ENCLOSED BY character within a field value can be doubled and are interpreted as a single instance of the character. For example, if ENCLOSED BY '"' is specified, quotation marks are handled as shown here:

"The ""BIG"" boss" -> The "BIG" boss
The "BIG" boss   -> The "BIG" boss
The ""BIG"" boss  -> The ""BIG"" boss

FIELDS ESCAPED BY controls how to read or write special characters:

- For input, if the FIELDS ESCAPED BY character is not empty, occurrences of that character are stripped and the following character is taken literally as part of a field value. Some two-character sequences that are exceptions, where the first character is the escape character. These sequences are shown in the following table (using \ for the escape character). The rules for NULL handling are described later in this section.

<table>
<thead>
<tr>
<th>Character</th>
<th>Escape Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>\0</td>
<td>An ASCII NUL (X'00') character</td>
</tr>
<tr>
<td>\b</td>
<td>A backspace character</td>
</tr>
<tr>
<td>\n</td>
<td>A newline (linefeed) character</td>
</tr>
<tr>
<td>\r</td>
<td>A carriage return character</td>
</tr>
<tr>
<td>\t</td>
<td>A tab character.</td>
</tr>
<tr>
<td>\z</td>
<td>ASCII 26 (Control+Z)</td>
</tr>
</tbody>
</table>
LOAD DATA Statement

<table>
<thead>
<tr>
<th>Character</th>
<th>Escape Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>\N</td>
<td>NULL</td>
</tr>
</tbody>
</table>

For more information about \-escape syntax, see Section 11.1.1, “String Literals”.

If the FIELDS ESCAPED BY character is empty, escape-sequence interpretation does not occur.

- For output, if the FIELDS ESCAPED BY character is not empty, it is used to prefix the following characters on output:
  - The FIELDS ESCAPED BY character.
  - The FIELDS [OPTIONALLY] ENCLOSED BY character.
  - The first character of the FIELDS TERMINATED BY and LINES TERMINATED BY values, if the ENCLOSED BY character is empty or unspecified.
  - ASCII 0 (what is actually written following the escape character is ASCII 0, not a zero-valued byte).

If the FIELDS ESCAPED BY character is empty, no characters are escaped and NULL is output as NULL, not \N. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

In certain cases, field- and line-handling options interact:

- If LINES TERMINATED BY is an empty string and FIELDS TERMINATED BY is nonempty, lines are also terminated with FIELDS TERMINATED BY.

- If the FIELDS TERMINATED BY and FIELDS ENCLOSED BY values are both empty (""), a fixed-row (nondelimited) format is used. With fixed-row format, no delimiters are used between fields (but you can still have a line terminator). Instead, column values are read and written using a field width wide enough to hold all values in the field. For TINYINT, SMALLINT, MEDIUMINT, INT, and BIGINT, the field widths are 4, 6, 8, 11, and 20, respectively, no matter what the declared display width is.

LINES TERMINATED BY is still used to separate lines. If a line does not contain all fields, the rest of the columns are set to their default values. If you do not have a line terminator, you should set this to ''. In this case, the text file must contain all fields for each row.

Fixed-row format also affects handling of NULL values, as described later.

**Note**

Fixed-size format does not work if you are using a multibyte character set.

Handling of NULL values varies according to the FIELDS and LINES options in use:

- For the default FIELDS and LINES values, NULL is written as a field value of \N for output, and a field value of \N is read as NULL for input (assuming that the ESCAPED BY character is \\).

- If FIELDS ENCLOSED BY is not empty, a field containing the literal word NULL as its value is read as a NULL value. This differs from the word NULL enclosed within FIELDS ENCLOSED BY characters, which is read as the string 'NULL'.

- If FIELDS ESCAPED BY is empty, NULL is written as the word NULL.

- With fixed-row format (which is used when FIELDS TERMINATED BY and FIELDS ENCLOSED BY are both empty), NULL is written as an empty string. This causes both NULL values and empty strings in the table to be indistinguishable when written to the file because both are written as empty strings. If you need to be able to tell the two apart when reading the file back in, you should not use fixed-row format.
LOAD DATA Statement

An attempt to load NULL into a NOT NULL column produces either a warning or an error according to the rules described in Column Value Assignment.

Some cases are not supported by LOAD DATA:

- Fixed-size rows (FIELDS TERMINATED BY and FIELDS ENCLOSED BY both empty) and BLOB or TEXT columns.

- If you specify one separator that is the same as or a prefix of another, LOAD DATA cannot interpret the input properly. For example, the following FIELDS clause would cause problems:

  FIELDS TERMINATED BY '"' ENCLOSED BY '"'

- If FIELDS ESCAPED BY is empty, a field value that contains an occurrence of FIELDS ENCLOSED BY or LINES TERMINATED BY followed by the FIELDS TERMINATED BY value causes LOAD DATA to stop reading a field or line too early. This happens because LOAD DATA cannot properly determine where the field or line value ends.

Column List Specification

The following example loads all columns of the persondata table:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata;
```

By default, when no column list is provided at the end of the LOAD DATA statement, input lines are expected to contain a field for each table column. If you want to load only some of a table’s columns, specify a column list:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata
  (col_name_or_user_var [, col_name_or_user_var] ...);
```

You must also specify a column list if the order of the fields in the input file differs from the order of the columns in the table. Otherwise, MySQL cannot tell how to match input fields with table columns.

Input Preprocessing

Each instance of col_name_or_user_var in LOAD DATA syntax is either a column name or a user variable. With user variables, the SET clause enables you to perform preprocessing transformations on their values before assigning the result to columns.

User variables in the SET clause can be used in several ways. The following example uses the first input column directly for the value of t1.column1, and assigns the second input column to a user variable that is subjected to a division operation before being used for the value of t1.column2:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, @var1)
  SET column2 = @var1/100;
```

The SET clause can be used to supply values not derived from the input file. The following statement sets column3 to the current date and time:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, column2)
  SET column3 = CURRENT_TIMESTAMP;
```

You can also discard an input value by assigning it to a user variable and not assigning the variable to any table column:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, @dummy, column2, @dummy, column3);
```
LOAD DATA Statement

Use of the column/variable list and SET clause is subject to the following restrictions:

- Assignments in the SET clause should have only column names on the left hand side of assignment operators.

- You can use subqueries in the right hand side of SET assignments. A subquery that returns a value to be assigned to a column may be a scalar subquery only. Also, you cannot use a subquery to select from the table that is being loaded.

- Lines ignored by an IGNORE number LINES clause are not processed for the column/variable list or SET clause.

- User variables cannot be used when loading data with fixed-row format because user variables do not have a display width.

Column Value Assignment

To process an input line, LOAD DATA splits it into fields and uses the values according to the column/variable list and the SET clause, if they are present. Then the resulting row is inserted into the table. If there are BEFORE INSERT or AFTER INSERT triggers for the table, they are activated before or after inserting the row, respectively.

Interpretation of field values and assignment to table columns depends on these factors:

- The SQL mode (the value of the sql_mode system variable). The mode can be nonrestrictive, or restrictive in various ways. For example, strict SQL mode can be enabled, or the mode can include values such as NO_ZERO_DATE or NO_ZERO_IN_DATE.

- Presence or absence of the IGNORE and LOCAL modifiers.

Those factors combine to produce restrictive or nonrestrictive data interpretation by LOAD DATA:

- Data interpretation is restrictive if the SQL mode is restrictive and neither the IGNORE nor the LOCAL modifier is specified. Errors terminate the load operation.

- Data interpretation is nonrestrictive if the SQL mode is nonrestrictive or the IGNORE or LOCAL modifier is specified. (In particular, either modifier if specified overrides a restrictive SQL mode when the REPLACE modifier is omitted.) Errors become warnings and the load operation continues.

Restrictive data interpretation uses these rules:

- Too many or too few fields results an error.

- Assigning NULL (that is, \N) to a non-NULL column results in an error.

- A value that is out of range for the column data type results in an error.

- Invalid values produce errors. For example, a value such as 'x' for a numeric column results in an error, not conversion to 0.

By contrast, nonrestrictive data interpretation uses these rules:

- If an input line has too many fields, the extra fields are ignored and the number of warnings is incremented.

- If an input line has too few fields, the columns for which input fields are missing are assigned their default values. Default value assignment is described in Section 13.6, “Data Type Default Values”.

- Assigning NULL (that is, \N) to a non-NULL column results in assignment of the implicit default value for the column data type. Implicit default values are described in Section 13.6, “Data Type Default Values”.

2585
• Invalid values produce warnings rather than errors, and are converted to the “closest” valid value for
the column data type. Examples:

• A value such as 'x' for a numeric column results in conversion to 0.

• An out-of-range numeric or temporal value is clipped to the closest endpoint of the range for the
column data type.

• An invalid value for a DATETIME, DATE, or TIME column is inserted as the implicit default value,
regardless of the SQL mode NO_ZERO_DATE setting. The implicit default is the appropriate
“zero” value for the type ('0000-00-00 00:00:00', '0000-00-00', or '00:00:00'). See
Section 13.2, “Date and Time Data Types”.

• LOAD DATA interprets an empty field value differently from a missing field:

• For string types, the column is set to the empty string.

• For numeric types, the column is set to 0.

• For date and time types, the column is set to the appropriate “zero” value for the type. See
Section 13.2, “Date and Time Data Types”.

These are the same values that result if you assign an empty string explicitly to a string, numeric, or
date or time type explicitly in an INSERT or UPDATE statement.

TIMESTAMP columns are set to the current date and time only if there is a NULL value for the column
(that is, \n) and the column is not declared to permit NULL values, or if the TIMESTAMP column default
value is the current timestamp and it is omitted from the field list when a field list is specified.

LOAD DATA regards all input as strings, so you cannot use numeric values for ENUM or SET columns
the way you can with INSERT statements. All ENUM and SET values must be specified as strings.

BIT values cannot be loaded directly using binary notation (for example, b'011010'). To work around
this, use the SET clause to strip off the leading b' and trailing ' and perform a base-2 to base-10
conversion so that MySQL loads the values into the BIT column properly:

```bash
$> cat /tmp/bit_test.txt
b'10'
b'1111111'
$> mysql test
mysql> LOAD DATA INFILE '/tmp/bit_test.txt'
    INTO TABLE bit_test (@var1)
    SET b = CAST(CONV(MID(@var1, 3, LENGTH(@var1)-3), 2, 10) AS UNSIGNED);
Query OK, 2 rows affected (0.00 sec)
Records: 2  Deleted: 0  Skipped: 0  Warnings: 0
mysql>
```

```bash
mysql> SELECT BIN(b+0) FROM bit_test;
+---------+
<table>
<thead>
<tr>
<th>BIN(b+0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
</tr>
<tr>
<td>1111111</td>
</tr>
</tbody>
</table>
+---------+
2 rows in set (0.00 sec)
```

For BIT values in 0b binary notation (for example, 0b011010), use this SET clause instead to strip off
the leading 0b:

```sql
SET b = CAST(CONV(MID(@var1, 3, LENGTH(@var1)-2), 2, 10) AS UNSIGNED)
```

Partitioned Table Support

LOAD DATA supports explicit partition selection using the PARTITION clause with a list of one or
more comma-separated names of partitions, subpartitions, or both. When this clause is used, if any
rows from the file cannot be inserted into any of the partitions or subpartitions named in the list, the
statement fails with the error **Found a row not matching the given partition set.** For more information and examples, see Section 26.5, “Partition Selection”.

**Concurrency Considerations**

With the `LOW_PRIORITY` modifier, execution of the `LOAD DATA` statement is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

With the `CONCURRENT` modifier and a `MyISAM` table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other threads can retrieve data from the table while `LOAD DATA` is executing. This modifier affects the performance of `LOAD DATA` a bit, even if no other thread is using the table at the same time.

**Statement Result Information**

When the `LOAD DATA` statement finishes, it returns an information string in the following format:

```
Records: 1  Deleted: 0  Skipped: 0  Warnings: 0
```

Warnings occur under the same circumstances as when values are inserted using the `INSERT` statement (see Section 15.2.7, “INSERT Statement”), except that `LOAD DATA` also generates warnings when there are too few or too many fields in the input row.

You can use `SHOW WARNINGS` to get a list of the first `max_error_count` warnings as information about what went wrong. See Section 15.7.7.41, “SHOW WARNINGS Statement”.

If you are using the C API, you can get information about the statement by calling the `mysql_info()` function. See `mysql_info()`.

**Replication Considerations**

`LOAD DATA` is considered unsafe for statement-based replication. If you use `LOAD DATA` with `binlog_format=STATEMENT`, each replica on which the changes are to be applied creates a temporary file containing the data. This temporary file is not encrypted, even if binary log encryption is active on the source. If encryption is required, use row-based or mixed binary logging format instead, for which replicas do not create the temporary file. For more information on the interaction between `LOAD DATA` and replication, see Section 19.5.1.19, “Replication and LOAD DATA”.

**Miscellaneous Topics**

On Unix, if you need `LOAD DATA` to read from a pipe, you can use the following technique (the example loads a listing of the `/` directory into the table `db1.t1`):

```
mkfifo /mysql/data/db1/ls.dat
chmod 666 /mysql/data/db1/ls.dat
find / -ls > /mysql/data/db1/ls.dat &
mysql -e "LOAD DATA INFILE 'ls.dat' INTO TABLE t1" db1
```

Here you must run the command that generates the data to be loaded and the `mysql` commands either on separate terminals, or run the data generation process in the background (as shown in the preceding example). If you do not do this, the pipe blocks until data is read by the `mysql` process.

### 15.2.10 LOAD XML Statement

```
LOAD XML
  [LOW_PRIORITY | CONCURRENT] [LOCAL]
  INFILE 'file_name'
  [REPLACE | IGNORE]
  INTO TABLE [db_name.]tbl_name
  [CHARACTER SET charset_name]
  [ROWS IDENTIFIED BY '<tagname>']
  [IGNORE number [LINES | ROWS]]
```
The **LOAD XML** statement reads data from an XML file into a table. The *file_name* must be given as a literal string. The *tagname* in the optional **ROWS IDENTIFIED BY** clause must also be given as a literal string, and must be surrounded by angle brackets (< and >).

**LOAD XML** acts as the complement of running the `mysql` client in XML output mode (that is, starting the client with the `--xml` option). To write data from a table to an XML file, you can invoke the `mysql` client with the `--xml` and `-e` options from the system shell, as shown here:

```
$> mysql --xml -e 'SELECT * FROM mydb.mytable' > file.xml
```

To read the file back into a table, use **LOAD XML**. By default, the `<row>` element is considered to be the equivalent of a database table row; this can be changed using the **ROWS IDENTIFIED BY** clause.

This statement supports three different XML formats:

- **Column names as attributes and column values as attribute values:**

  ```xml
  <row column1="value1" column2="value2" .../>
  ```

- **Column names as tags and column values as the content of these tags:**

  ```xml
  <row>
  <column1>value1</column1>
  <column2>value2</column2>
  </row>
  ```

- **Column names are the *name* attributes of `<field>` tags, and values are the contents of these tags:**

  ```xml
  <row>
  <field name='column1'>value1</field>
  <field name='column2'>value2</field>
  </row>
  ```

This is the format used by other MySQL tools, such as `mysqldump`.

All three formats can be used in the same XML file; the import routine automatically detects the format for each row and interprets it correctly. Tags are matched based on the tag or attribute name and the column name.

The following clauses work essentially the same way for **LOAD XML** as they do for **LOAD DATA**:

- **LOW_PRIORITY** or **CONCURRENT**
- **LOCAL**
- **REPLACE** or **IGNORE**
- **CHARACTER SET**
- **SET**

See Section 15.2.9, “LOAD DATA Statement”, for more information about these clauses.

*(field_name_or_user_var, ...)* is a list of one or more comma-separated XML fields or user variables. The name of a user variable used for this purpose must match the name of a field from the XML file, prefixed with @. You can use field names to select only desired fields. User variables can be employed to store the corresponding field values for subsequent re-use.

The **IGNORE number LINES** or **IGNORE number ROWS** clause causes the first *number* rows in the XML file to be skipped. It is analogous to the **LOAD DATA** statement's **IGNORE ... LINES** clause.
Suppose that we have a table named `person`, created as shown here:

```sql
USE test;
CREATE TABLE person (
    person_id INT NOT NULL PRIMARY KEY,
    fname VARCHAR(40) NULL,
    lname VARCHAR(40) NULL,
    created TIMESTAMP
);
```

Suppose further that this table is initially empty.

Now suppose that we have a simple XML file `person.xml`, whose contents are as shown here:

```xml
<list>
    <person person_id="1" fname="Kapek" lname="Sainnouine"/>
    <person person_id="2" fname="Sajon" lname="Rondela"/>
    <person person_id="3"><fname>Likame</fname><lname>Örrtmons</lname></person>
    <person person_id="4"><fname>Slar</fname><lname>Manlanth</lname></person>
    <person><field name="person_id">5</field><field name="fname">Stoma</field><field name="lname">Nilu</field></person>
    <person><field name="person_id">6</field><field name="fname">Nirtam</field><field name="lname">Sklöd</field></person>
    <person person_id="7"><fname>Sungam</fname><lname>Dubbåd</lname></person>
    <person person_id="8" fname="Sraref" lname="Encmelt"/>
</list>
```

Each of the permissible XML formats discussed previously is represented in this example file.

To import the data in `person.xml` into the `person` table, you can use this statement:

```sql
mysql> LOAD XML LOCAL INFILE 'person.xml'
    --> INTO TABLE person
    --> ROWS IDENTIFIED BY '<person>';
Query OK, 8 rows affected (0.00 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0
```

Here, we assume that `person.xml` is located in the MySQL data directory. If the file cannot be found, the following error results:

```
ERROR 2 (HY000): File '/person.xml' not found (Errcode: 2)
```

The `ROWS IDENTIFIED BY '<person>'` clause means that each `<person>` element in the XML file is considered equivalent to a row in the table into which the data is to be imported. In this case, this is the `person` table in the `test` database.

As can be seen by the response from the server, 8 rows were imported into the `test.person` table. This can be verified by a simple `SELECT` statement:

```sql
mysql> SELECT * FROM person;
+-----------+--------+------------+---------------------+
<table>
<thead>
<tr>
<th>person_id</th>
<th>fname</th>
<th>lname</th>
<th>created</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Kapek</td>
<td>Sainnouine</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>2</td>
<td>Sajon</td>
<td>Rondela</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>3</td>
<td>Likame</td>
<td>Örrtmons</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>4</td>
<td>Slar</td>
<td>Manlanth</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>5</td>
<td>Stoma</td>
<td>Nilu</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>6</td>
<td>Nirtam</td>
<td>Sklöd</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>7</td>
<td>Sungam</td>
<td>Dubbåd</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>8</td>
<td>Sraref</td>
<td>Encmelt</td>
<td>2007-07-13 16:18:47</td>
</tr>
</tbody>
</table>
+-----------+--------+------------+---------------------+
8 rows in set (0.00 sec)
```

This shows, as stated earlier in this section, that any or all of the 3 permitted XML formats may appear in a single file and be read using `LOAD XML`.
The inverse of the import operation just shown—that is, dumping MySQL table data into an XML file—can be accomplished using the `mysql` client from the system shell, as shown here:

```
$> mysql --xml -e "SELECT * FROM test.person" > person-dump.xml
$> cat person-dump.xml
<resultset statement="SELECT * FROM test.person" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <row>
    <field name="person_id">1</field>
    <field name="fname">Kapek</field>
    <field name="lname">Sainnouine</field>
  </row>
  <row>
    <field name="person_id">2</field>
    <field name="fname">Sajon</field>
    <field name="lname">Rondela</field>
  </row>
  <row>
    <field name="person_id">3</field>
    <field name="fname">Likema</field>
    <field name="lname">Örrtmons</field>
  </row>
  <row>
    <field name="person_id">4</field>
    <field name="fname">Slar</field>
    <field name="lname">Manlanth</field>
  </row>
  <row>
    <field name="person_id">5</field>
    <field name="fname">Stoma</field>
    <field name="lname">Nilu</field>
  </row>
  <row>
    <field name="person_id">6</field>
    <field name="fname">Nirtam</field>
    <field name="lname">Sklöd</field>
  </row>
  <row>
    <field name="person_id">7</field>
    <field name="fname">Sungam</field>
    <field name="lname">Dulbåd</field>
  </row>
  <row>
    <field name="person_id">8</field>
    <field name="fname">Sreraf</field>
    <field name="lname">Encmelt</field>
  </row>
</resultset>
```

Note

The `--xml` option causes the `mysql` client to use XML formatting for its output; the `-e` option causes the client to execute the SQL statement immediately following the option. See Section 6.5.1, “mysql — The MySQL Command-Line Client”.

You can verify that the dump is valid by creating a copy of the `person` table and importing the dump file into the new table, like this:

```
mysql> USE test;
mysql> CREATE TABLE person2 LIKE person;
Query OK, 0 rows affected (0.00 sec)
```
LOAD XML Statement

mysql> LOAD XML LOCAL INFILE 'person-dump.xml'
    -> INTO TABLE person2;
Query OK, 8 rows affected (0.01 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT * FROM person2;
+-----------+--------+------------+---------------------+
| person_id | fname  | lname      | created             |
+-----------+--------+------------+---------------------+
|         1 | Kapek  | Sainnouine | 2007-07-13 16:18:47 |
|         2 | Sajon  | Rondela    | 2007-07-13 16:18:47 |
|         3 | Likema | Örrtmons   | 2007-07-13 16:18:47 |
|         4 | Slar   | Manlanth   | 2007-07-13 16:18:47 |
|         5 | Stoma  | Nilu       | 2007-07-13 16:18:47 |
|         6 | Nirtam | Sklöd      | 2007-07-13 16:18:47 |
|         7 | Sungam | Dulbåd     | 2007-07-13 16:18:47 |
|         8 | Sreraf | Encmelt    | 2007-07-13 16:18:47 |
+-----------+--------+------------+---------------------+
8 rows in set (0.00 sec)

There is no requirement that every field in the XML file be matched with a column in the corresponding table. Fields which have no corresponding columns are skipped. You can see this by first emptying the `person2` table and dropping the `created` column, then using the same `LOAD XML` statement we just employed previously, like this:

mysql> TRUNCATE person2;
Query OK, 8 rows affected (0.26 sec)

mysql> ALTER TABLE person2 DROP COLUMN created;
Query OK, 0 rows affected (0.52 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SHOW CREATE TABLE person2\G
*************************** 1. row ***************************
Table: person2
Create Table: CREATE TABLE `person2` (  `person_id` int NOT NULL,  `fname` varchar(40) DEFAULT NULL,  `lname` varchar(40) DEFAULT NULL,  PRIMARY KEY (`person_id`) ) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
1 row in set (0.00 sec)

mysql> LOAD XML LOCAL INFILE 'person-dump.xml'
    -> INTO TABLE person2;
Query OK, 8 rows affected (0.01 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT * FROM person2;
+-----------+--------+------------+
| person_id | fname  | lname      |
+-----------+--------+------------+
|         1 | Kapek  | Sainnouine |
|         2 | Sajon  | Rondela    |
|         3 | Likema | Örrtmons   |
|         4 | Slar   | Manlanth   |
|         5 | Stoma  | Nilu       |
|         6 | Nirtam | Sklöd      |
|         7 | Sungam | Dulbåd     |
|         8 | Sreraf | Encmelt    |
+-----------+--------+------------+
8 rows in set (0.00 sec)

The order in which the fields are given within each row of the XML file does not affect the operation of `LOAD XML`; the field order can vary from row to row, and is not required to be in the same order as the corresponding columns in the table.

As mentioned previously, you can use a `(field_name_or_user_var, ...)` list of one or more XML fields (to select desired fields only) or user variables (to store the corresponding field values for
User variables can be especially useful when you want to insert data from an XML file into table columns whose names do not match those of the XML fields. To see how this works, we first create a table named `individual` whose structure matches that of the `person` table, but whose columns are named differently:

```
mysql> CREATE TABLE individual (  
    -> individual_id INT NOT NULL PRIMARY KEY,
    -> name1 VARCHAR(40) NULL,
    -> name2 VARCHAR(40) NULL,
    -> made TIMESTAMP
    -> );
Query OK, 0 rows affected (0.42 sec)
```

In this case, you cannot simply load the XML file directly into the table, because the field and column names do not match:

```
mysql> LOAD XML INFILE '../bin/person-dump.xml' INTO TABLE test.individual;
ERROR 1263 (22004): Column set to default value; NULL supplied to NOT NULL column 'individual_id' at row 1
```

This happens because the MySQL server looks for field names matching the column names of the target table. You can work around this problem by selecting the field values into user variables, then setting the target table's columns equal to the values of those variables using `SET`. You can perform both of these operations in a single statement, as shown here:

```
mysql> LOAD XML INFILE '../bin/person-dump.xml'
    -> INTO TABLE test.individual (@person_id, @fname, @lname, @created)
    -> SET individual_id=@person_id, name1=@fname, name2=@lname, made=@created;
Query OK, 8 rows affected (0.05 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0
```

The names of the user variables must match those of the corresponding fields from the XML file, with the addition of the required @ prefix to indicate that they are variables. The user variables need not be listed or assigned in the same order as the corresponding fields.

Using a `ROWS IDENTIFIED BY '<tagname>'` clause, it is possible to import data from the same XML file into database tables with different definitions. For this example, suppose that you have a file named `address.xml` which contains the following XML:

```
<?xml version="1.0"?>

<list>
    <person person_id="1">
        <fname>Robert</fname>
        <lname>Jones</lname>
        <address address_id="1" street="Mill Creek Road" zip="45365" city="Sidney"/>
    </person>

    <person person_id="2">
        <fname>Mary</fname>
        <lname>Smith</lname>
        <address address_id="3" street="River Road" zip="80239" city="Denver"/>
    </person>
</list>
```
You can again use the `test.person` table as defined previously in this section, after clearing all the existing records from the table and then showing its structure as shown here:

```
mysql< TRUNCATE person;
Query OK, 0 rows affected (0.04 sec)
```

```
mysql< SHOW CREATE TABLE person;
*************************** 1. row ***************************
  Table: person
  Create Table: CREATE TABLE `person` (  `person_id` int(11) NOT NULL,  `fname` varchar(40) DEFAULT NULL,  `lname` varchar(40) DEFAULT NULL,  `created` timestamp NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,  PRIMARY KEY (`person_id`))
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
1 row in set (0.00 sec)
```

Now create an `address` table in the `test` database using the following `CREATE TABLE` statement:

```
CREATE TABLE address (  address_id INT NOT NULL PRIMARY KEY,  person_id INT NULL,  street VARCHAR(40) NULL,  zip INT NULL,  city VARCHAR(40) NULL,  created TIMESTAMP);
```

To import the data from the XML file into the `person` table, execute the following `LOAD XML` statement, which specifies that rows are to be specified by the `<person>` element, as shown here:

```
mysql> LOAD XML LOCAL INFILE 'address.xml'  -> INTO TABLE person  -> ROWS IDENTIFIED BY '<person>';  Query OK, 2 rows affected (0.00 sec)  Records: 2  Deleted: 0  Skipped: 0  Warnings: 0
```

You can verify that the records were imported using a `SELECT` statement:

```
mysql> SELECT * FROM person;
+----------+--------+-------+---------------------+
<table>
<thead>
<tr>
<th>person_id</th>
<th>fname</th>
<th>lname</th>
<th>created</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Robert</td>
<td>Jones</td>
<td>2007-07-24 17:37:06</td>
</tr>
<tr>
<td>2</td>
<td>Mary</td>
<td>Smith</td>
<td>2007-07-24 17:37:06</td>
</tr>
</tbody>
</table>
+-----------+--------+-------+---------------------+
2 rows in set (0.00 sec)
```

Since the `<address>` elements in the XML file have no corresponding columns in the `person` table, they are skipped.

To import the data from the `<address>` elements into the `address` table, use the `LOAD XML` statement shown here:

```
mysql> LOAD XML LOCAL INFILE 'address.xml'  -> INTO TABLE address  -> ROWS IDENTIFIED BY '<address>';  Query OK, 3 rows affected (0.00 sec)  Records: 3  Deleted: 0  Skipped: 0  Warnings: 0
```

You can see that the data was imported using a `SELECT` statement such as this one:

```
mysql> SELECT * FROM address;
+------------+-----------+-----------------+-------+--------------+---------------------+
<table>
<thead>
<tr>
<th>address_id</th>
<th>person_id</th>
<th>street</th>
<th>zip</th>
<th>city</th>
<th>created</th>
</tr>
</thead>
<tbody>
<tr>
<td>22593</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>22594</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>22595</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
</tr>
</tbody>
</table>
+------------+-----------+-----------------+-------+--------------+---------------------+
3 rows in set (0.00 sec)
```
The data from the `<address>` element that is enclosed in XML comments is not imported. However, since there is a `person_id` column in the `address` table, the value of the `person_id` attribute from the parent `<person>` element for each `<address>` is imported into the `address` table.

**Security Considerations.** As with the `LOAD DATA` statement, the transfer of the XML file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server’s choosing rather than the file named by the client in the `LOAD XML` statement. Such a server could access any file on the client host to which the client user has read access.

In a Web environment, clients usually connect to MySQL from a Web server. A user that can run any command against the MySQL server can use `LOAD XML LOCAL` to read any files to which the Web server process has read access. In this environment, the client with respect to the MySQL server is actually the Web server, not the remote program being run by the user who connects to the Web server.

You can disable loading of XML files from clients by starting the server with `--local-infile=0` or `--local-infile=OFF`. This option can also be used when starting the `mysql` client to disable `LOAD XML` for the duration of the client session.

To prevent a client from loading XML files from the server, do not grant the `FILE` privilege to the corresponding MySQL user account, or revoke this privilege if the client user account already has it.

---

### 15.2.11 Parenthesized Query Expressions

**parenthesized_query_expression**:

```
( query_expression [ order_by_clause ] [ limit_clause ] )
[ order_by_clause ]
[ limit_clause ]
[ into_clause ]
```

**query_expression**:

```
query_block [ set_op query_block [ set_op query_block ... ]] 
[ order_by_clause ]
[ limit_clause ]
[ into_clause ]
```

**query_block**:

```
SELECT ... | TABLE | VALUES
```

**order_by_clause**:

```
ORDER BY as for SELECT
```

**limit_clause**:

```
LIMIT as for SELECT
```
Parenthesized Query Expressions

into_clause:
INTO as for SELECT

set_op:
UNION | INTERSECT | EXCEPT

MySQL 8.4 supports parenthesized query expressions according to the preceding syntax. At its simplest, a parenthesized query expression contains a single SELECT or other statement returning a result set and no following optional clauses:

(SELECT 1);
(SELECT * FROM INFORMATION_SCHEMA.SCHEMATA WHERE SCHEMA_NAME = 'mysql');

TABLE t;
VALUES ROW(2, 3, 4), ROW(1, -2, 3);

A parenthesized query expression can also contain queries linked by one or more set operations such as UNION, and end with any or all of the optional clauses:

mysql> (SELECT 1 AS result UNION SELECT 2);
+--------+
| result |
+--------+
|      1 |
|      2 |
+--------+
mysql> (SELECT 1 AS result UNION SELECT 2) LIMIT 1;
+--------+
| result |
+--------+
|      1 |
+--------+
mysql> (SELECT 1 AS result UNION SELECT 2) LIMIT 1 OFFSET 1;
+--------+
| result |
+--------+
|      2 |
+--------+
mysql> (SELECT 1 AS result UNION SELECT 2) ORDER BY result DESC LIMIT 1;
+--------+
| result |
+--------+
|      2 |
+--------+
mysql> (SELECT 1 AS result UNION SELECT 2) ORDER BY result DESC LIMIT 1 OFFSET 1;
+--------+
| result |
+--------+
|      1 |
+--------+
mysql> (SELECT 1 AS result UNION SELECT 2 UNION SELECT 3) ORDER BY result LIMIT 1 OFFSET 1 INTO @var;

mysql> SELECT @var;
+------+
| @var |
+------+
|    2 |
+------+

INTERSECT acts before UNION and EXCEPT, so that the following two statements are equivalent:

SELECT a FROM t1 EXCEPT SELECT b FROM t2 INTERSECT SELECT c FROM t3;
SELECT a FROM t1 EXCEPT (SELECT b FROM t2 INTERSECT SELECT c FROM t3);

Parenthesized query expressions are also used as query expressions, so a query expression, usually composed of query blocks, may also consist of parenthesized query expressions:
Query blocks may have trailing ORDER BY and LIMIT clauses, which are applied before the outer set operation, ORDER BY, and LIMIT.

You cannot have a query block with a trailing ORDER BY or LIMIT without wrapping it in parentheses but parentheses may be used for enforcement in various ways:

- To enforce LIMIT on each query block:
  \[(SELECT 1 LIMIT 1) UNION (VALUES ROW(2) LIMIT 1)\];
  \[(VALUES ROW(1), ROW(2) LIMIT 2) EXCEPT (SELECT 2 LIMIT 1)\];

- To enforce LIMIT on both query blocks and the entire query expression:
  \[(SELECT 1 LIMIT 1) UNION (SELECT 2 LIMIT 1) LIMIT 1;\]

- To enforce LIMIT on the entire query expression (with no parentheses):
  VALUES ROW(1), ROW(2) INTERSECT VALUES ROW(2), ROW(1) LIMIT 1;

- Hybrid enforcement: LIMIT on the first query block and on the entire query expression:
  \[(SELECT 1 LIMIT 1) UNION SELECT 2 LIMIT 1;\]

The syntax described in this section is subject to certain restrictions:

- A trailing INTO clause for a query expression is not permitted if there is another INTO clause inside parentheses.

- An ORDER BY or LIMIT within a parenthesized query expression which is also applied in the outer query is handled in accordance with the SQL standard.

Nested parenthesized query expressions are permitted. The maximum level of nesting supported is 63; this is after any simplifications or merges have been performed by the parser.

An example of such a statement is shown here:

```
mysql> (SELECT 'a' UNION SELECT 'b' LIMIT 2) LIMIT 3;
+---+
| a |
+---+
| a |
| b |
+---+
2 rows in set (0.00 sec)
```

You should be aware that, when collapsing parenthesized expression bodies, MySQL follows SQL standard semantics, so that a higher outer limit cannot override an inner lower one. For example, (SELECT ... LIMIT 5) LIMIT 10 can return no more than five rows.

15.2.12 REPLACE Statement

```sql
REPLACE [LOW_PRIORITY | DELAYED]
[INTO] tbl_name
[PARTITION (partition_name [, partition_name] ...)]
[(col_name [, col_name] ...)]
{ {VALUES | VALUE} (value_list) [, (value_list)] ... |
  VALUES row_constructor_list
}
```

```sql
REPLACE [LOW_PRIORITY | DELAYED]
[INTO] tbl_name
[PARTITION (partition_name [, partition_name] ...)]
SET assignment_list
```
REPLACE Statement

REPLACE [LOW_PRIORITY | DELAYED]
    [INTO] tbl_name
    [PARTITION (partition_name [, partition_name] ...)]
    [(col_name [, col_name] ...)]
    [SELECT ... | TABLE table_name]

value:
    {expr | DEFAULT}
value_list:
    value [, value] ...
row_constructor_list:
    ROW(value_list)[, ROW(value_list)][, ...]

assignment:
    col_name = value
assignment_list:
    assignment [, assignment] ...

REPLACE works exactly like INSERT, except that if an old row in the table has the same value as a new row for a PRIMARY KEY or a UNIQUE index, the old row is deleted before the new row is inserted. See Section 15.2.7, “INSERT Statement”.

REPLACE is a MySQL extension to the SQL standard. It either inserts, or deletes and inserts. For another MySQL extension to standard SQL—that either inserts or updates—see Section 15.2.7.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”.

DELAYED inserts and replaces were deprecated in MySQL 5.6. In MySQL 8.4, DELAYED is not supported. The server recognizes but ignores the DELAYED keyword, handles the replace as a nondelayed replace, and generates an ER_WARN_LEGACY_SYNTAX_CONVERTED warning: REPLACE DELAYED is no longer supported. The statement was converted to REPLACE. The DELAYED keyword is scheduled for removal in a future release.

Note

REPLACE makes sense only if a table has a PRIMARY KEY or UNIQUE index. Otherwise, it becomes equivalent to INSERT, because there is no index to be used to determine whether a new row duplicates another.

Values for all columns are taken from the values specified in the REPLACE statement. Any missing columns are set to their default values, just as happens for INSERT. You cannot refer to values from the current row and use them in the new row. If you use an assignment such as SET col_name = col_name + 1, the reference to the column name on the right hand side is treated as DEFAULT(col_name), so the assignment is equivalent to SET col_name = DEFAULT(col_name) + 1.

You can specify the column values that REPLACE attempts to insert using VALUES ROW().

To use REPLACE, you must have both the INSERT and DELETE privileges for the table.

If a generated column is replaced explicitly, the only permitted value is DEFAULT. For information about generated columns, see Section 15.1.20.8, “CREATE TABLE and Generated Columns”.

REPLACE supports explicit partition selection using the PARTITION clause with a list of comma-separated names of partitions, subpartitions, or both. As with INSERT, if it is not possible to insert the new row into any of these partitions or subpartitions, the REPLACE statement fails with the error Found a row not matching the given partition set. For more information and examples, see Section 26.5, “Partition Selection”.

The REPLACE statement returns a count to indicate the number of rows affected. This is the sum of the rows deleted and inserted. If the count is 1 for a single-row REPLACE, a row was inserted and no rows...
were deleted. If the count is greater than 1, one or more old rows were deleted before the new row was inserted. It is possible for a single row to replace more than one old row if the table contains multiple unique indexes and the new row duplicates values for different old rows in different unique indexes.

The affected-rows count makes it easy to determine whether REPLACE only added a row or whether it also replaced any rows: Check whether the count is 1 (added) or greater (replaced).

If you are using the C API, the affected-rows count can be obtained using the mysql_affected_rows() function.

You cannot replace into a table and select from the same table in a subquery.

MySQL uses the following algorithm for REPLACE (and LOAD DATA ... REPLACE):

1. Try to insert the new row into the table
2. While the insertion fails because a duplicate-key error occurs for a primary key or unique index:
   a. Delete from the table the conflicting row that has the duplicate key value
   b. Try again to insert the new row into the table

It is possible that in the case of a duplicate-key error, a storage engine may perform the REPLACE as an update rather than a delete plus insert, but the semantics are the same. There are no user-visible effects other than a possible difference in how the storage engine increments Handler_xxx status variables.

Because the results of REPLACE ... SELECT statements depend on the ordering of rows from the SELECT and this order cannot always be guaranteed, it is possible when logging these statements for the source and the replica to diverge. For this reason, REPLACE ... SELECT statements are flagged as unsafe for statement-based replication. such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using MIXED mode. See also Section 19.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

MySQL 8.4 supports TABLE as well as SELECT with REPLACE, just as it does with INSERT. See Section 15.2.7.1, “INSERT ... SELECT Statement”, for more information and examples.

When modifying an existing table that is not partitioned to accommodate partitioning, or, when modifying the partitioning of an already partitioned table, you may consider altering the table’s primary key (see Section 26.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”). You should be aware that, if you do this, the results of REPLACE statements may be affected, just as they would be if you modified the primary key of a nonpartitioned table. Consider the table created by the following CREATE TABLE statement:

```sql
CREATE TABLE test (  
id INT UNSIGNED NOT NULL AUTO_INCREMENT,  
data VARCHAR(64) DEFAULT NULL,  
ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,  
PRIMARY KEY (id)  
);
```

When we create this table and run the statements shown in the mysql client, the result is as follows:

```sql
mysql> REPLACE INTO test VALUES (1, 'Old', '2014-08-20 18:47:00');  
Query OK, 1 row affected (0.04 sec)

mysql> REPLACE INTO test VALUES (1, 'New', '2014-08-20 18:47:42');  
Query OK, 2 rows affected (0.04 sec)

mysql> SELECT * FROM test;  
+----+------+---------------------+
<table>
<thead>
<tr>
<th>id</th>
<th>data</th>
<th>ts</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Old</td>
<td>2014-08-20 18:47:00</td>
</tr>
<tr>
<td>1</td>
<td>New</td>
<td>2014-08-20 18:47:42</td>
</tr>
</tbody>
</table>
```
Now we create a second table almost identical to the first, except that the primary key now covers 2 columns, as shown here (emphasized text):

```sql
CREATE TABLE test2 {
  id INT UNSIGNED NOT NULL AUTO_INCREMENT,
  data VARCHAR(64) DEFAULT NULL,
  ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  PRIMARY KEY (id, ts)
};
```

When we run on `test2` the same two `REPLACE` statements as we did on the original `test` table, we obtain a different result:

```sql
mysql> REPLACE INTO test2 VALUES (1, 'Old', '2014-08-20 18:47:00');
Query OK, 1 row affected (0.05 sec)

mysql> REPLACE INTO test2 VALUES (1, 'New', '2014-08-20 18:47:42');
Query OK, 1 row affected (0.06 sec)

mysql> SELECT * FROM test2;
+----+-----+---------------------+
<table>
<thead>
<tr>
<th>id</th>
<th>data</th>
<th>ts</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Old</td>
<td>2014-08-20 18:47:00</td>
</tr>
<tr>
<td>1</td>
<td>New</td>
<td>2014-08-20 18:47:42</td>
</tr>
</tbody>
</table>
+----+-----+---------------------+
2 rows in set (0.00 sec)
```

This is due to the fact that, when run on `test2`, both the `id` and `ts` column values must match those of an existing row for the row to be replaced; otherwise, a row is inserted.

### 15.2.13 SELECT Statement

```sql
SELECT [ALL | DISTINCT | DISTINCTROW]
       [HIGH_PRIORITY]
       [STRAIGHT_JOIN]
       [SQL_SMALL_RESULT] [SQL_BIG_RESULT] [SQL_BUFFER_RESULT]
       [SQL_NO_CACHE] [SQL_CALC_FOUND_ROWS]
[select_expr [, select_expr] ...]
[into_option]
FROM table_references
       [PARTITION partition_list]]
WHERE where_condition
GROUP BY [col_name | expr [position], ... [WITH ROLLUP]]
HAVING where_condition
WINDOW window_name AS (window_spec)
[, window_name AS (window_spec)] ...]
ORDER BY [col_name | expr [position]
[ASC | DESC], ... [WITH ROLLUP]]
LIMIT [offset,] row_count | row_count OFFSET offset]
[into_option]
FOR [UPDATE | SHARE]
    [OF tbl_name [, tbl_name] ...]
    [NOWAIT | SKIP LOCKED]
    | LOCK IN SHARE MODE]
[into_option]

into_option: {
  INTO OUTFILE 'file_name'
  [CHARACTER SET charset_name]
  export_options
  | INTO DUMPFILE 'file_name'
  | INTO var_name [, var_name] ...
}
```
**SELECT** is used to retrieve rows selected from one or more tables, and can include **UNION** operations and subqueries. **INTERSECT** and **EXCEPT** operations are also supported. The **UNION**, **INTERSECT**, and **EXCEPT** operators are described in more detail later in this section. See also Section 15.2.15, “Subqueries”.

A **SELECT** statement can start with a **WITH** clause to define common table expressions accessible within the **SELECT**. See Section 15.2.20, “WITH (Common Table Expressions)”.

The most commonly used clauses of **SELECT** statements are these:

- Each **select_expr** indicates a column that you want to retrieve. There must be at least one **select_expr**.

- **table_references** indicates the table or tables from which to retrieve rows. Its syntax is described in Section 15.2.13.2, “JOIN Clause”.

- **SELECT** supports explicit partition selection using the **PARTITION** clause with a list of partitions or subpartitions (or both) following the name of the table in a **table_reference** (see Section 15.2.13.2, “JOIN Clause”). In this case, rows are selected only from the partitions listed, and any other partitions of the table are ignored. For more information and examples, see Section 26.5, “Partition Selection”.

- The **WHERE** clause, if given, indicates the condition or conditions that rows must satisfy to be selected. **where_condition** is an expression that evaluates to true for each row to be selected. The statement selects all rows if there is no **WHERE** clause.

  In the **WHERE** expression, you can use any of the functions and operators that MySQL supports, except for aggregate (group) functions. See Section 11.5, “Expressions”, and Chapter 14, Functions and Operators.

**SELECT** can also be used to retrieve rows computed without reference to any table.

For example:

```sql
mysql> SELECT 1 + 1;
-> 2
```

You are permitted to specify **DUAL** as a dummy table name in situations where no tables are referenced:

```sql
mysql> SELECT 1 + 1 FROM DUAL;
-> 2
```

**DUAL** is purely for the convenience of people who require that all **SELECT** statements should have **FROM** and possibly other clauses. MySQL may ignore the clauses. MySQL does not require **FROM** **DUAL** if no tables are referenced.

In general, clauses used must be given in exactly the order shown in the syntax description. For example, a **HAVING** clause must come after any **GROUP BY** clause and before any **ORDER BY** clause. The **INTO** clause, if present, can appear in any position indicated by the syntax description, but within a given statement can appear only once, not in multiple positions. For more information about **INTO**, see Section 15.2.13.1, “SELECT ... INTO Statement”.

The list of **select_expr** terms comprises the select list that indicates which columns to retrieve. Terms specify a column or expression or can use **-shorthand**:

- A select list consisting only of a single unqualified **-shorthand** can be used as shorthand to select all columns from all tables:

  ```sql
  SELECT * FROM t1 INNER JOIN t2 ...
  ```

- **tbl_name.** can be used as a qualified shorthand to select all columns from the named table:
SELECT t1.*, t2.* FROM t1 INNER JOIN t2 ...

• If a table has invisible columns, * and tbl_name.* do not include them. To be included, invisible columns must be referenced explicitly.

• Use of an unqualified * with other items in the select list may produce a parse error. For example:

  SELECT id, * FROM t1

  To avoid this problem, use a qualified tbl_name.* reference:

  SELECT id, t1.* FROM t1

  Use qualified tbl_name.* references for each table in the select list:

  SELECT AVG(tbl_name.*), t1.* FROM t1 ...

The following list provides additional information about other SELECT clauses:

• A select_expr can be given an alias using AS alias_name. The alias is used as the expression’s column name and can be used in GROUP BY, ORDER BY, or HAVING clauses. For example:

  SELECT CONCAT(last_name,' ',first_name) AS full_name
  FROM mytable ORDER BY full_name;

  The AS keyword is optional when aliasing a select_expr with an identifier. The preceding example could have been written like this:

  SELECT CONCAT(last_name,' ',first_name) full_name
  FROM mytable ORDER BY full_name;

  However, because the AS is optional, a subtle problem can occur if you forget the comma between two select_expr expressions: MySQL interprets the second as an alias name. For example, in the following statement, columnb is treated as an alias name:

  SELECT columna columnb FROM mytable;

  For this reason, it is good practice to be in the habit of using AS explicitly when specifying column aliases.

  It is not permissible to refer to a column alias in a WHERE clause, because the column value might not yet be determined when the WHERE clause is executed. See Section B.3.4.4, “Problems with Column Aliases”.

• The FROM table_references clause indicates the table or tables from which to retrieve rows. If you name more than one table, you are performing a join. For information on join syntax, see Section 15.2.13.2, “JOIN Clause”. For each table specified, you can optionally specify an alias.

  tbl_name [[AS] alias] [index_hint]

  The use of index hints provides the optimizer with information about how to choose indexes during query processing. For a description of the syntax for specifying these hints, see Section 10.9.4, “Index Hints”.

  You can use SET max_seeks_for_key=value as an alternative way to force MySQL to prefer key scans instead of table scans. See Section 7.1.8, “Server System Variables”.

• You can refer to a table within the default database as tbl_name, or as db_name.tbl_name to specify a database explicitly. You can refer to a column as col_name, tbl_name.col_name, or db_name.tbl_name.col_name. You need not specify a tbl_name or db_name.tbl_name prefix for a column reference unless the reference would be ambiguous. See Section 11.2.2, “Identifier Qualifiers”, for examples of ambiguity that require the more explicit column reference forms.
• A table reference can be aliased using `tbl_name AS alias_name` or `tbl_name alias_name`. These statements are equivalent:

```sql
SELECT t1.name, t2.salary FROM employee AS t1, info AS t2
    WHERE t1.name = t2.name;

SELECT t1.name, t2.salary FROM employee t1, info t2
    WHERE t1.name = t2.name;
```

• Columns selected for output can be referred to in `ORDER BY` and `GROUP BY` clauses using column names, column aliases, or column positions. Column positions are integers and begin with 1:

```sql
SELECT college, region, seed FROM tournament
    ORDER BY region, seed;

SELECT college, region AS r, seed AS s FROM tournament
    ORDER BY r, s;

SELECT college, region, seed FROM tournament
    ORDER BY 2, 3;
```

To sort in reverse order, add the `DESC` (descending) keyword to the name of the column in the `ORDER BY` clause that you are sorting by. The default is ascending order; this can be specified explicitly using the `ASC` keyword.

If `ORDER BY` occurs within a parenthesized query expression and also is applied in the outer query, the results are undefined and may change in a future version of MySQL.

Use of column positions is deprecated because the syntax has been removed from the SQL standard.

• When you use `ORDER BY` or `GROUP BY` to sort a column in a `SELECT`, the server sorts values using only the initial number of bytes indicated by the `max_sort_length` system variable.

• MySQL extends the use of `GROUP BY` to permit selecting fields that are not mentioned in the `GROUP BY` clause. If you are not getting the results that you expect from your query, please read the description of `GROUP BY` found in Section 14.19, “Aggregate Functions”.

• The `HAVING` clause, like the `WHERE` clause, specifies selection conditions. The `WHERE` clause specifies conditions on columns in the select list, but cannot refer to aggregate functions. The `HAVING` clause specifies conditions on groups, typically formed by the `GROUP BY` clause. The query result includes only groups satisfying the `HAVING` conditions. (If no `GROUP BY` is present, all rows implicitly form a single aggregate group.)

The `HAVING` clause is applied nearly last, just before items are sent to the client, with no optimization. (`LIMIT` is applied after `HAVING`.)

The SQL standard requires that `HAVING` must reference only columns in the `GROUP BY` clause or columns used in aggregate functions. However, MySQL supports an extension to this behavior, and permits `HAVING` to refer to columns in the `SELECT` list and columns in outer subqueries as well.

If the `HAVING` clause refers to a column that is ambiguous, a warning occurs. In the following statement, `col12` is ambiguous because it is used as both an alias and a column name:

```sql
SELECT COUNT(col11) AS col12 FROM t GROUP BY col12 HAVING col12 = 2;
```

Preference is given to standard SQL behavior, so if a `HAVING` column name is used both in `GROUP BY` and as an aliased column in the select column list, preference is given to the column in the `GROUP BY` column.

• Do not use `HAVING` for items that should be in the `WHERE` clause. For example, do not write the following:

```sql
SELECT col_name FROM tbl_name HAVING col_name > 0;
```
SELECT Statement

Write this instead:

```sql
SELECT col_name FROM tbl_name WHERE col_name > 0;
```

- The **HAVING** clause can refer to aggregate functions, which the **WHERE** clause cannot:

```sql
SELECT user, MAX(salary) FROM users
    GROUP BY user HAVING MAX(salary) > 10;
```

(This did not work in some older versions of MySQL.)

- MySQL permits duplicate column names. That is, there can be more than one `select_expr` with the same name. This is an extension to standard SQL. Because MySQL also permits `GROUP BY` and `HAVING` to refer to `select_expr` values, this can result in an ambiguity:

```sql
SELECT 12 AS a, a FROM t GROUP BY a;
```

In that statement, both columns have the name `a`. To ensure that the correct column is used for grouping, use different names for each `select_expr`.

- The **WINDOW** clause, if present, defines named windows that can be referred to by window functions. For details, see Section 14.20.4, “Named Windows”.

MySQL resolves unqualified column or alias references in `ORDER BY` clauses by searching in the `select_expr` values, then in the columns of the tables in the `FROM` clause. For `GROUP BY` or `HAVING` clauses, it searches the `FROM` clause before searching in the `select_expr` values. (For `GROUP BY` and `HAVING`, this differs from the pre-MySQL 5.0 behavior that used the same rules as for `ORDER BY`.)

- The **LIMIT** clause can be used to constrain the number of rows returned by the **SELECT** statement. `LIMIT` takes one or two numeric arguments, which must both be nonnegative integer constants, with these exceptions:

  - Within prepared statements, `LIMIT` parameters can be specified using `?` placeholder markers.
  - Within stored programs, `LIMIT` parameters can be specified using integer-valued routine parameters or local variables.

With two arguments, the first argument specifies the offset of the first row to return, and the second specifies the maximum number of rows to return. The offset of the initial row is 0 (not 1):

```sql
SELECT * FROM tbl LIMIT 5,10;  # Retrieve rows 6-15
```

To retrieve all rows from a certain offset up to the end of the result set, you can use some large number for the second parameter. This statement retrieves all rows from the 96th row to the last:

```sql
SELECT * FROM tbl LIMIT 95,18446744073709551615;
```

With one argument, the value specifies the number of rows to return from the beginning of the result set:

```sql
SELECT * FROM tbl LIMIT 5;     # Retrieve first 5 rows
```

In other words, `LIMIT row_count` is equivalent to `LIMIT 0, row_count`.

For prepared statements, you can use placeholders. The following statements return one row from the `tbl` table:

```sql
SET @a=1;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?';
EXECUTE STMT USING @a;
```

The following statements return the second to sixth rows from the `tbl` table:
For compatibility with PostgreSQL, MySQL also supports the \texttt{LIMIT row\_count OFFSET offset} syntax.

If \texttt{LIMIT} occurs within a parenthesized query expression and also is applied in the outer query, the results are undefined and may change in a future version of MySQL.

- The \texttt{SELECT ... INTO} form of \texttt{SELECT} enables the query result to be written to a file or stored in variables. For more information, see Section 15.2.13.1, "SELECT ... INTO Statement".

- If you use \texttt{FOR UPDATE} with a storage engine that uses page or row locks, rows examined by the query are write-locked until the end of the current transaction.

You cannot use \texttt{FOR UPDATE} as part of the \texttt{SELECT} in a statement such as \texttt{CREATE TABLE new\_table SELECT ... FROM old\_table ...(If you attempt to do so, the statement is rejected with the error Can't update table 'old\_table' while 'new\_table' is being created.)}

\texttt{FOR SHARE} and \texttt{LOCK IN SHARE MODE} set shared locks that permit other transactions to read the examined rows but not to update or delete them. \texttt{FOR SHARE} and \texttt{LOCK IN SHARE MODE} are equivalent. However, \texttt{FOR SHARE}, like \texttt{FOR UPDATE}, supports \texttt{NOWAIT}, \texttt{SKIP LOCKED}, and \texttt{OF tbl\_name} options. \texttt{FOR SHARE} is a replacement for \texttt{LOCK IN SHARE MODE}, but \texttt{LOCK IN SHARE MODE} remains available for backward compatibility.

\texttt{NOWAIT} causes a \texttt{FOR UPDATE} or \texttt{FOR SHARE} query to execute immediately, returning an error if a row lock cannot be obtained due to a lock held by another transaction.

\texttt{SKIP LOCKED} causes a \texttt{FOR UPDATE} or \texttt{FOR SHARE} query to execute immediately, excluding rows from the result set that are locked by another transaction.

\texttt{NOWAIT} and \texttt{SKIP LOCKED} options are unsafe for statement-based replication.

\begin{quote}
\textbf{Note}

Queries that skip locked rows return an inconsistent view of the data. \texttt{SKIP LOCKED} is therefore not suitable for general transactional work. However, it may be used to avoid lock contention when multiple sessions access the same queue-like table.

\texttt{OF tbl\_name} applies \texttt{FOR UPDATE} and \texttt{FOR SHARE} queries to named tables. For example:

\texttt{SELECT * FROM t1, t2 FOR SHARE OF t1 FOR UPDATE OF t2;}

All tables referenced by the query block are locked when \texttt{OF tbl\_name} is omitted. Consequently, using a locking clause without \texttt{OF tbl\_name} in combination with another locking clause returns an error. Specifying the same table in multiple locking clauses returns an error. If an alias is specified as the table name in the \texttt{SELECT} statement, a locking clause may only use the alias. If the \texttt{SELECT} statement does not specify an alias explicitly, the locking clause may only specify the actual table name.

For more information about \texttt{FOR UPDATE} and \texttt{FOR SHARE}, see Section 17.7.2.4, "Locking Reads". For additional information about \texttt{NOWAIT} and \texttt{SKIP LOCKED} options, see Locking Read Concurrency with \texttt{NOWAIT} and \texttt{SKIP LOCKED}.

Following the \texttt{SELECT} keyword, you can use a number of modifiers that affect the operation of the statement. \texttt{HIGH\_PRIORITY}, \texttt{STRAIGHT\_JOIN}, and modifiers beginning with \texttt{SQL\_} are MySQL extensions to standard SQL.
• The **ALL** and **DISTINCT** modifiers specify whether duplicate rows should be returned. **ALL** (the default) specifies that all matching rows should be returned, including duplicates. **DISTINCT** specifies removal of duplicate rows from the result set. It is an error to specify both modifiers. **DISTINCTROW** is a synonym for **DISTINCT**. **DISTINCT** can be used with a query that also uses **WITH ROLLUP**.

• **HIGH_PRIORITY** gives the **SELECT** higher priority than a statement that updates a table. You should use this only for queries that are very fast and must be done at once. A **SELECT HIGH_PRIORITY** query that is issued while the table is locked for reading runs even if there is an update statement waiting for the table to be free. This affects only storage engines that use only table-level locking (such as **MyISAM**, **MEMORY**, and **MERGE**).

**HIGH_PRIORITY** cannot be used with **SELECT** statements that are part of a **UNION**.

• **STRAIGHT_JOIN** forces the optimizer to join the tables in the order in which they are listed in the **FROM** clause. You can use this to speed up a query if the optimizer joins the tables in nonoptimal order. **STRAIGHT_JOIN** also can be used in the **table_references** list. See Section 15.2.13.2, “JOIN Clause”.

**STRAIGHT_JOIN** does not apply to any table that the optimizer treats as a **const** or **system** table. Such a table produces a single row, is read during the optimization phase of query execution, and references to its columns are replaced with the appropriate column values before query execution proceeds. These tables appear first in the query plan displayed by **EXPLAIN**. See Section 10.8.1, “Optimizing Queries with EXPLAIN”. This exception may not apply to **const** or **system** tables that are used on the **NULL**-complemented side of an outer join (that is, the right-side table of a **LEFT JOIN** or the left-side table of a **RIGHT JOIN**).

• **SQL_BIG_RESULT** or **SQL_SMALL_RESULT** can be used with **GROUP BY** or **DISTINCT** to tell the optimizer that the result set has many rows or is small, respectively. For **SQL_BIG_RESULT**, MySQL directly uses disk-based temporary tables if they are created, and prefers sorting to using a temporary table with a key on the **GROUP BY** elements. For **SQL_SMALL_RESULT**, MySQL uses in-memory temporary tables to store the resulting table instead of using sorting. This should not normally be needed.

• **SQL_BUFFER_RESULT** forces the result to be put into a temporary table. This helps MySQL free the table locks early and helps in cases where it takes a long time to send the result set to the client. This modifier can be used only for top-level **SELECT** statements, not for subqueries or following **UNION**.

• **SQL_CALC_FOUND_ROWS** tells MySQL to calculate how many rows there would be in the result set, disregarding any **LIMIT** clause. The number of rows can then be retrieved with **SELECT FOUND_ROWS()**. See Section 14.15, “Information Functions”.

Note

The **SQL_CALC_FOUND_ROWS** query modifier and accompanying **FOUND_ROWS()** function are deprecated; expect them to be removed in a future version of MySQL. See the description of **FOUND_ROWS()** for information about an alternative strategy.

• The **SQL_CACHE** and **SQL_NO_CACHE** modifiers were used with the query cache prior to MySQL 8.4. The query cache was removed in MySQL 8.4. The **SQL_CACHE** modifier was removed as well. **SQL_NO_CACHE** is deprecated, and has no effect; expect it to be removed in a future MySQL release.

### 15.2.13.1 SELECT ... INTO Statement

The **SELECT ... INTO** form of **SELECT** enables a query result to be stored in variables or written to a file:
• **SELECT ... INTO var_list** selects column values and stores them into variables.

• **SELECT ... INTO OUTFILE** writes the selected rows to a file. Column and line terminators can be specified to produce a specific output format.

• **SELECT ... INTO DUMPFILE** writes a single row to a file without any formatting.

A given **SELECT** statement can contain at most one **INTO** clause, although as shown by the **SELECT** syntax description (see Section 15.2.13, “SELECT Statement”), the **INTO** can appear in different positions:

• **Before FROM.** Example:

```sql
SELECT * INTO @myvar FROM t1;
```

• **Before a trailing locking clause.** Example:

```sql
SELECT * FROM t1 INTO @myvar FOR UPDATE;
```

• **At the end of the SELECT.** Example:

```sql
SELECT * FROM t1 FOR UPDATE INTO @myvar;
```

The **INTO** position at the end of the statement is the preferred position. The position before a locking clause is deprecated; expect support for it to be removed in a future version of MySQL. In other words, **INTO** after **FROM** but not at the end of the **SELECT** produces a warning.

An **INTO** clause should not be used in a nested **SELECT** because such a **SELECT** must return its result to the outer context. There are also constraints on the use of **INTO** within **UNION** statements; see Section 15.2.18, “UNION Clause”.

For the **INTO var_list** variant:

• **var_list** names a list of one or more variables, each of which can be a user-defined variable, stored procedure or function parameter, or stored program local variable. (Within a prepared **SELECT ... INTO var_list** statement, only user-defined variables are permitted; see Section 15.6.4.2, “Local Variable Scope and Resolution”.)

• The selected values are assigned to the variables. The number of variables must match the number of columns. The query should return a single row. If the query returns no rows, a warning with error code 1329 occurs (No data), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (Result consisted of more than one row). If it is possible that the statement may retrieve multiple rows, you can use **LIMIT 1** to limit the result set to a single row.

```sql
SELECT id, data INTO @x, @y FROM test.t1 LIMIT 1;
```

**INTO var_list** can also be used with a **TABLE** statement, subject to these restrictions:

• The number of variables must match the number of columns in the table.

• If the table contains more than one row, you must use **LIMIT 1** to limit the result set to a single row. **LIMIT 1** must precede the **INTO** keyword.

An example of such a statement is shown here:

```sql
TABLE employees ORDER BY lname DESC LIMIT 1
    INTO @id, @fname, @lname, @hired, @separated, @job_code, @store_id;
```

You can also select values from a **VALUES** statement that generates a single row into a set of user variables. In this case, you must employ a table alias, and you must assign each value from the value list to a variable. Each of the two statements shown here is equivalent to **SET @x=2, @y=4, @z=8**:

```sql
SELECT * FROM (VALUES ROW(2,4,8)) AS t INTO @x,@y,@z;
```
User variable names are not case-sensitive. See Section 11.4, “User-Defined Variables”.

The `SELECT ... INTO OUTFILE 'file_name'` form of `SELECT` writes the selected rows to a file. The file is created on the server host, so you must have the `FILE` privilege to use this syntax. `file_name` cannot be an existing file, which among other things prevents files such as `/etc/passwd` and database tables from being modified. The `character_set_filesystem` system variable controls the interpretation of the file name.

The `SELECT ... INTO OUTFILE` statement is intended to enable dumping a table to a text file on the server host. To create the resulting file on some other host, `SELECT ... INTO OUTFILE` normally is unsuitable because there is no way to write a path to the file relative to the server host file system, unless the location of the file on the remote host can be accessed using a network-mapped path on the server host file system.

Alternatively, if the MySQL client software is installed on the remote host, you can use a client command such as `mysql -e "SELECT ..." > file_name` to generate the file on that host.

`SELECT ... INTO OUTFILE` is the complement of `LOAD DATA`. Column values are written converted to the character set specified in the `CHARACTER SET` clause. If no such clause is present, values are dumped using the `binary` character set. In effect, there is no character set conversion.

If a result set contains columns in several character sets, so is the output data file, and it may not be possible to reload the file correctly.

The syntax for the `export_options` part of the statement consists of the same `FIELDS` and `LINES` clauses that are used with the `LOAD DATA` statement. For information about the `FIELDS` and `LINES` clauses, including their default values and permissible values, see Section 15.2.9, “LOAD DATA Statement”.

`FIELDS ESCAPED BY` controls how to write special characters. If the `FIELDS ESCAPED BY` character is not empty, it is used when necessary to avoid ambiguity as a prefix that precedes following characters on output:

- The `FIELDS ESCAPED BY` character
- The `FIELDS [OPTIONALLY] ENCLOSED BY` character
- The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values
- ASCII `NULL` (the zero-valued byte; what is actually written following the escape character is ASCII 0, not a zero-valued byte)

The `FIELDS TERMINATED BY`, `ENCLOSED BY`, `ESCAPED BY`, or `LINES TERMINATED BY` characters must be escaped so that you can read the file back in reliably. ASCII `NULL` is escaped to make it easier to view with some pagers.

The resulting file need not conform to SQL syntax, so nothing else need be escaped.

If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

`INTO OUTFILE` can also be used with a `TABLE` statement when you want to dump all columns of a table into a text file. In this case, the ordering and number of rows can be controlled using `ORDER BY` and `LIMIT`; these clauses must precede `INTO OUTFILE`. `TABLE ... INTO OUTFILE` supports the same `export_options` as does `SELECT ... INTO OUTFILE`, and it is subject to the same restrictions on writing to the file system. An example of such a statement is shown here:

```sql
SELECT * FROM (VALUES ROW(2,4,8)) AS t(a,b,c) INTO @x,@y,@z;

TABLE employees ORDER BY lname LIMIT 1000
INTO OUTFILE '/tmp/employee_data.1.txt'
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"', ESCAPED BY '\'
LINES TERMINATED BY '\n';
```
You can also use `SELECT ... INTO OUTFILE` with a `VALUES` statement to write values directly into a file. An example is shown here:

```sql
SELECT * FROM (VALUES ROW(1,2,3),ROW(4,5,6),ROW(7,8,9)) AS t
INTO OUTFILE '/tmp/select-values.txt';
```

You must use a table alias; column aliases are also supported, and can optionally be used to write values only from desired columns. You can also use any or all of the export options supported by `SELECT ... INTO OUTFILE` to format the output to the file.

Here is an example that produces a file in the comma-separated values (CSV) format used by many programs:

```sql
SELECT a,b,a+b INTO OUTFILE '/tmp/result.txt'
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
LINES TERMINATED BY '
'
FROM test_table;
```

If you use `INTO DUMPFILE` instead of `INTO OUTFILE`, MySQL writes only one row into the file, without any column or line termination and without performing any escape processing. This is useful for selecting a `BLOB` value and storing it in a file.

`TABLE` also supports `INTO DUMPFILE`. If the table contains more than one row, you must also use `LIMIT 1` to limit the output to a single row. `INTO DUMPFILE` can also be used with `SELECT * FROM (VALUES ROW()[, ...]) AS table_alias [LIMIT 1]`. See Section 15.2.19, “VALUES Statement”.

```
Note
Any file created by `INTO OUTFILE` or `INTO DUMPFILE` is owned by the operating system user under whose account `mysqld` runs. (You should *never* run `mysqld` as `root` for this and other reasons.) The umask for file creation is 0640; you must have sufficient access privileges to manipulate the file contents.

If the `secure_file_priv` system variable is set to a nonempty directory name, the file to be written must be located in that directory.
```

In the context of `SELECT ... INTO` statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For additional information, see Section 27.4.5, “Event Scheduler Status”.

Support is provided for periodic synchronization of output files written to by `SELECT INTO OUTFILE` and `SELECT INTO DUMPFILE`, enabled by setting the `select_into_disk_sync` server system variable introduced in that version. Output buffer size and optional delay can be set using, respectively, `select_into_buffer_size` and `select_into_disk_sync_delay`. For more information, see the descriptions of these system variables.

### 15.2.13.2 JOIN Clause

MySQL supports the following `JOIN` syntax for the `table_references` part of `SELECT` statements and multiple-table `DELETE` and `UPDATE` statements:

```
table_references:
  escaped_table_reference [, escaped_table_reference] ...

escaped_table_reference: {
  table_reference
  | { OJ table_reference }
}

table_reference: {
  table_factor
  | joined_table
}
```
A table reference is also known as a join expression.

A table reference (when it refers to a partitioned table) may contain a `PARTITION` clause, including a list of comma-separated partitions, subpartitions, or both. This option follows the name of the table and precedes any alias declaration. The effect of this option is that rows are selected only from the listed partitions or subpartitions. Any partitions or subpartitions not named in the list are ignored. For more information and examples, see Section 26.5, “Partition Selection”.

The syntax of `table_factor` is extended in MySQL in comparison with standard SQL. The standard accepts only `table_reference`, not a list of them inside a pair of parentheses. This is a conservative extension if each comma in a list of `table_reference` items is considered as equivalent to an inner join. For example:

```
SELECT * FROM t1 LEFT JOIN (t2, t3, t4) ON (t2.a = t1.a AND t3.b = t1.b AND t4.c = t1.c)
```

is equivalent to:

```
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4) ON (t2.a = t1.a AND t3.b = t1.b AND t4.c = t1.c)
```

In MySQL, `JOIN`, `CROSS JOIN`, and `INNER JOIN` are syntactic equivalents (they can replace each other). In standard SQL, they are not equivalent. `INNER JOIN` is used with an `ON` clause, `CROSS JOIN` is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. MySQL also supports nested joins. See Section 10.2.1.8, “Nested Join Optimization”.

Index hints can be specified to affect how the MySQL optimizer makes use of indexes. For more information, see Section 10.9.4, “Index Hints”. Optimizer hints and the `optimizer_switch` system variable are other ways to influence optimizer use of indexes. See Section 10.9.3, “Optimizer Hints”, and Section 10.9.2, “Switchable Optimizations”.

---

### SELECT Statement

```
SELECT Statement

```
The following list describes general factors to take into account when writing joins:

- A table reference can be aliased using `tbl_name AS alias_name` or `tbl_name alias_name`:

  ```sql
  SELECT t1.name, t2.salary
  FROM employee AS t1 INNER JOIN info AS t2 ON t1.name = t2.name;
  SELECT t1.name, t2.salary
  FROM employee t1 INNER JOIN info t2 ON t1.name = t2.name;
  ```

- A `table_subquery` is also known as a derived table or subquery in the `FROM` clause. See Section 15.2.15.8, “Derived Tables”. Such subqueries must include an alias to give the subquery result a table name, and may optionally include a list of table column names in parentheses. A trivial example follows:

  ```sql
  SELECT * FROM (SELECT 1, 2, 3) AS t1;
  ```

- The maximum number of tables that can be referenced in a single join is 61. This includes a join handled by merging derived tables and views in the `FROM` clause into the outer query block (see Section 10.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”).

- `INNER JOIN` and `,` (comma) are semantically equivalent in the absence of a join condition: both produce a Cartesian product between the specified tables (that is, each and every row in the first table is joined to each and every row in the second table).

  However, the precedence of the comma operator is less than that of `INNER JOIN`, `CROSS JOIN`, `LEFT JOIN`, and so on. If you mix comma joins with the other join types when there is a join condition, an error of the form `Unknown column 'col_name' in 'on clause'` may occur. Information about dealing with this problem is given later in this section.

- The `search_condition` used with `ON` is any conditional expression of the form that can be used in a `WHERE` clause. Generally, the `ON` clause serves for conditions that specify how to join tables, and the `WHERE` clause restricts which rows to include in the result set.

- If there is no matching row for the right table in the `ON` or `USING` part in a `LEFT JOIN`, a row with all columns set to `NULL` is used for the right table. You can use this fact to find rows in a table that have no counterpart in another table:

  ```sql
  SELECT left_tbl.*
  FROM left_tbl LEFT JOIN right_tbl ON left_tbl.id = right_tbl.id
  WHERE right_tbl.id IS NULL;
  ```

  This example finds all rows in `left_tbl` with an `id` value that is not present in `right_tbl` (that is, all rows in `left_tbl` with no corresponding row in `right_tbl`). See Section 10.2.1.9, “Outer Join Optimization”.

- The `USING(join_column_list)` clause names a list of columns that must exist in both tables. If tables `a` and `b` both contain columns `c1`, `c2`, and `c3`, the following join compares corresponding columns from the two tables:

  ```sql
  a LEFT JOIN b USING (c1, c2, c3)
  ```

- The `NATURAL [LEFT] JOIN` of two tables is defined to be semantically equivalent to an `INNER JOIN` or a `LEFT JOIN` with a `USING` clause that names all columns that exist in both tables.

- `RIGHT JOIN` works analogously to `LEFT JOIN`. To keep code portable across databases, it is recommended that you use `LEFT JOIN` instead of `RIGHT JOIN`.

- The `{ OJ ... }` syntax shown in the join syntax description exists only for compatibility with ODBC. The curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

  ```sql
  SELECT left_tbl.*
  ```
SELECT Statement

You can use other types of joins within (OJ ...), such as INNER JOIN or RIGHT OUTER JOIN. This helps with compatibility with some third-party applications, but is not official ODBC syntax.

- STRAIGHT_JOIN is similar to JOIN, except that the left table is always read before the right table. This can be used for those (few) cases for which the join optimizer processes the tables in a suboptimal order.

Some join examples:

```sql
SELECT * FROM table1, table2;
SELECT * FROM table1 INNER JOIN table2 ON table1.id = table2.id;
SELECT * FROM table1 LEFT JOIN table2 ON table1.id = table2.id;
SELECT * FROM table1 LEFT JOIN table2 USING (id);
SELECT * FROM table1 LEFT JOIN table2 ON table1.id = table2.id
LEFT JOIN table3 ON table2.id = table3.id;
```

Natural joins and joins with USING, including outer join variants, are processed according to the SQL:2003 standard:

- Redundant columns of a NATURAL join do not appear. Consider this set of statements:

```sql
CREATE TABLE t1 (i INT, j INT);
CREATE TABLE t2 (k INT, j INT);
INSERT INTO t1 VALUES(1, 1);
INSERT INTO t2 VALUES(1, 1);
SELECT * FROM t1 NATURAL JOIN t2;
SELECT * FROM t1 JOIN t2 USING (j);
```

In the first SELECT statement, column j appears in both tables and thus becomes a join column, so, according to standard SQL, it should appear only once in the output, not twice. Similarly, in the second SELECT statement, column j is named in the USING clause and should appear only once in the output, not twice.

Thus, the statements produce this output:

```
<table>
<thead>
<tr>
<th>j</th>
<th>i</th>
<th>k</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>
```

Redundant column elimination and column ordering occurs according to standard SQL, producing this display order:

- First, coalesced common columns of the two joined tables, in the order in which they occur in the first table
- Second, columns unique to the first table, in order in which they occur in that table
- Third, columns unique to the second table, in order in which they occur in that table
The single result column that replaces two common columns is defined using the coalesce operation. That is, for two \( t1.a \) and \( t2.a \) the resulting single join column \( a \) is defined as \( a = \text{COALESCE}(t1.a, t2.a) \), where:

\[
\text{COALESCE}(x, y) = \begin{cases} 
\text{CASE WHEN } x \text{ IS NOT NULL THEN } x \text{ ELSE } y \end{cases}
\]

If the join operation is any other join, the result columns of the join consist of the concatenation of all columns of the joined tables.

A consequence of the definition of coalesced columns is that, for outer joins, the coalesced column contains the value of the non-NULL column if one of the two columns is always NULL. If neither or both columns are NULL, both common columns have the same value, so it doesn’t matter which one is chosen as the value of the coalesced column. A simple way to interpret this is to consider that a coalesced column of an outer join is represented by the common column of the inner table of a \textbf{JOIN}. Suppose that the tables \( t1(a, b) \) and \( t2(a, c) \) have the following contents:

\[
t1 \quad t2
\begin{array}{ccc}
1 & x & z \\
2 & y & w \\
\end{array}
\]

Then, for this join, column \( a \) contains the values of \( t1.a \):

```
mysql> SELECT * FROM t1 NATURAL LEFT JOIN t2;
+------+------+------+
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>x</td>
<td>NULL</td>
</tr>
<tr>
<td>2</td>
<td>y</td>
<td>z</td>
</tr>
</tbody>
</table>
+------+------+------+
```

By contrast, for this join, column \( a \) contains the values of \( t2.a \):

```
mysql> SELECT * FROM t1 NATURAL RIGHT JOIN t2;
+------+------+------+
<table>
<thead>
<tr>
<th>a</th>
<th>c</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>z</td>
<td>y</td>
</tr>
<tr>
<td>3</td>
<td>w</td>
<td>NULL</td>
</tr>
</tbody>
</table>
+------+------+------+
```

Compare those results to the otherwise equivalent queries with \textbf{JOIN ... ON}:

```
mysql> SELECT * FROM t1 LEFT JOIN t2 ON (t1.a = t2.a);
+------+------+------+
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>a</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>x</td>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>2</td>
<td>y</td>
<td>2</td>
<td>z</td>
</tr>
</tbody>
</table>
+------+------+------+
```

```
mysql> SELECT * FROM t1 RIGHT JOIN t2 ON (t1.a = t2.a);
+------+------+------+
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>a</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>y</td>
<td>2</td>
<td>z</td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
<td>3</td>
<td>w</td>
</tr>
</tbody>
</table>
+------+------+------+
```

- A \textbf{USING} clause can be rewritten as an \textbf{ON} clause that compares corresponding columns. However, although \textbf{USING} and \textbf{ON} are similar, they are not quite the same. Consider the following two queries:

```sql
a LEFT JOIN b USING (c1, c2, c3)
```
The **SELECT Statement**

A **LEFT JOIN** on a c1 = b.c1 AND a.c2 = b.c2 AND a.c3 = b.c3

With respect to determining which rows satisfy the join condition, both joins are semantically identical.

With respect to determining which columns to display for **SELECT * expansion**, the two joins are not semantically identical. The **USING** join selects the coalesced value of corresponding columns, whereas the **ON** join selects all columns from all tables. For the **USING** join, **SELECT * selects these values:**

\[
\text{COALESCE}(a.c1, b.c1), \text{COALESCE}(a.c2, b.c2), \text{COALESCE}(a.c3, b.c3)
\]

For the **ON** join, **SELECT * selects these values:**

\[
a.c1, a.c2, a.c3, b.c1, b.c2, b.c3
\]

With an inner join, **COALESCE(a.c1, b.c1)** is the same as either **a.c1** or **b.c1** because both columns have the same value. With an outer join (such as **LEFT JOIN**), one of the two columns can be **NULL**. That column is omitted from the result.

- An **ON** clause can refer only to its operands.

**Example:**

```sql
CREATE TABLE t1 (i1 INT);
CREATE TABLE t2 (i2 INT);
CREATE TABLE t3 (i3 INT);
SELECT * FROM t1 JOIN t2 ON (i1 = i3) JOIN t3;
```

The statement fails with an **Unknown column 'i3' in 'on clause'** error because **i3** is a column in **t3**, which is not an operand of the **ON** clause. To enable the join to be processed, rewrite the statement as follows:

```sql
SELECT * FROM t1 JOIN t2 JOIN t3 ON (i1 = i3);
```

- **JOIN** has higher precedence than the comma operator (**,**), so the join expression **t1, t2 JOIN t3** is interpreted as \((t1, (t2 JOIN t3))\), not as \(((t1, t2) JOIN t3)\). This affects statements that use an **ON** clause because that clause can refer only to columns in the operands of the join, and the precedence affects interpretation of what those operands are.

**Example:**

```sql
CREATE TABLE t1 (i1 INT, j1 INT);
CREATE TABLE t2 (i2 INT, j2 INT);
CREATE TABLE t3 (i3 INT, j3 INT);
INSERT INTO t1 VALUES(1, 1);
INSERT INTO t2 VALUES(1, 1);
INSERT INTO t3 VALUES(1, 1);
SELECT * FROM t1, t2 JOIN t3 ON (t1.i1 = t3.i3);
```

The **JOIN** takes precedence over the comma operator, so the operands for the **ON clause are t2 and t3**. Because **t1.i1** is not a column in either of the operands, the result is an **Unknown column 't1.i1' in 'on clause'** error.

To enable the join to be processed, use either of these strategies:

- Group the first two tables explicitly with parentheses so that the operands for the **ON clause are \((t1, t2)\) and \(t3\):**

  ```sql
  SELECT * FROM (t1, t2) JOIN t3 ON (t1.i1 = t3.i3);
  ```
Set Operations with UNION, INTERSECT, and EXCEPT

- Avoid the use of the comma operator and use `JOIN` instead:

  ```sql
  SELECT * FROM t1 JOIN t2 JOIN t3 ON (t1.i1 = t3.i3);
  ```

  The same precedence interpretation also applies to statements that mix the comma operator with `INNER JOIN`, `CROSS JOIN`, `LEFT JOIN`, and `RIGHT JOIN`, all of which have higher precedence than the comma operator.

- A MySQL extension compared to the SQL:2003 standard is that MySQL permits you to qualify the common (coalesced) columns of `NATURAL` or `USING` joins, whereas the standard disallows that.

15.2.14 Set Operations with UNION, INTERSECT, and EXCEPT

- Result Set Column Names and Data Types
- Set Operations with TABLE and VALUES Statements
- Set Operations using DISTINCT and ALL
- Set Operations with ORDER BY and LIMIT
- Limitations of Set Operations

SQL set operations combine the results of multiple query blocks into a single result. A `query block`, sometimes also known as a `simple table`, is any SQL statement that returns a result set, such as `SELECT`. MySQL 8.4 also supports `TABLE` and `VALUES` statements. See the individual descriptions of these statements elsewhere in this chapter for additional information.

The SQL standard defines the following three set operations:

- **UNION**: Combine all results from two query blocks into a single result, omitting any duplicates.
- **INTERSECT**: Combine only those rows which the results of two query blocks have in common, omitting any duplicates.
- **EXCEPT**: For two query blocks $A$ and $B$, return all results from $A$ which are not also present in $B$, omitting any duplicates.

  (Some database systems, such as Oracle, use `MINUS` for the name of this operator. This is not supported in MySQL.)

MySQL supports `UNION`, `INTERSECT`, and `EXCEPT`.

Each of these set operators supports an `ALL` modifier. When the `ALL` keyword follows a set operator, this causes duplicates to be included in the result. See the following sections covering the individual operators for more information and examples.

All three set operators also support a `DISTINCT` keyword, which suppresses duplicates in the result. Since this is the default behavior for set operators, it is usually not necessary to specify `DISTINCT` explicitly.

In general, query blocks and set operations can be combined in any number and order. A greatly simplified representation is shown here:

```
query_block [set_op query_block] [set_op query_block] ...
query_block:
  SELECT | TABLE | VALUES
set_op:
  UNION | INTERSECT | EXCEPT
```

This can be represented more accurately, and in greater detail, like this:
You should be aware that \texttt{INTERSECT} is evaluated before \texttt{UNION} or \texttt{EXCEPT}. This means that, for example, \texttt{TABLE x UNION TABLE y INTERSECT TABLE z} is always evaluated as \texttt{TABLE x UNION (TABLE y INTERSECT TABLE z)}. See Section 15.2.8, “INTERSECT Clause”, for more information.

In addition, you should keep in mind that, while the \texttt{UNION} and \texttt{INTERSECT} set operators are commutative (ordering is not significant), \texttt{EXCEPT} is not (order of operands affects the outcome). In other words, all of the following statements are true:

- \texttt{TABLE x UNION TABLE y} and \texttt{TABLE y UNION TABLE x} produce the same result, although the ordering of the rows may differ. You can force them to be the same using \texttt{ORDER BY}; see Set Operations with ORDER BY and LIMIT.

- \texttt{TABLE x INTERSECT TABLE y} and \texttt{TABLE y INTERSECT TABLE x} return the same result.

- \texttt{TABLE x EXCEPT TABLE y} and \texttt{TABLE y EXCEPT TABLE x} do not yield the same result. See Section 15.2.4, “EXCEPT Clause”, for an example.

More information and examples can be found in the sections that follow.

\section*{Result Set Column Names and Data Types}

The column names for the result of a set operation are taken from the column names of the first query block. Example:

\begin{verbatim}
mysql> CREATE TABLE t1 (x INT, y INT);
Query OK, 0 rows affected (0.04 sec)

mysql> INSERT INTO t1 VALUES ROW(4,-2), ROW(5,9);
Query OK, 2 rows affected (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 0

mysql> CREATE TABLE t2 (a INT, b INT);
Query OK, 0 rows affected (0.04 sec)

mysql> INSERT INTO t2 VALUES ROW(1,2), ROW(3,4);
Query OK, 2 rows affected (0.01 sec)
Records: 2  Duplicates: 0  Warnings: 0

mysql> TABLE t1 UNION TABLE t2;

\begin{tabular}{ll}
<table>
<thead>
<tr>
<th>x</th>
<th>y</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>-2</td>
</tr>
<tr>
<td>5</td>
<td>9</td>
</tr>
</tbody>
</table>
\end{tabular}
\end{verbatim}
Set Operations with UNION, INTERSECT, and EXCEPT

This is true for **UNION**, **EXCEPT**, and **INTERSECT** queries.

Selected columns listed in corresponding positions of each query block should have the same data type. For example, the first column selected by the first statement should have the same type as the first column selected by the other statements. If the data types of corresponding result columns do not match, the types and lengths of the columns in the result take into account the values retrieved by all of the query blocks. For example, the column length in the result set is not constrained to the length of the value from the first statement, as shown here:

```sql
mysql> SELECT REPEAT('a',1) UNION SELECT REPEAT('b',20);
+----------------------+
| REPEAT('a',1)        |
+----------------------+
| a                    |
| bbbbbbbbbbbbbbbbbbbbb |
+----------------------+
```

Set Operations with TABLE and VALUES Statements

You can also use a **TABLE** statement or **VALUES** statement wherever you can employ the equivalent **SELECT** statement. Assume that tables **t1** and **t2** are created and populated as shown here:

```sql
CREATE TABLE t1 (x INT, y INT);
INSERT INTO t1 VALUES ROW(4,-2),ROW(5,9);
CREATE TABLE t2 (a INT, b INT);
INSERT INTO t2 VALUES ROW(1,2),ROW(3,4);
```

The preceding being the case, and disregarding the column names in the output of the queries beginning with **VALUES**, all of the following **UNION** queries yield the same result:

```sql
SELECT * FROM t1 UNION SELECT * FROM t2;
 TABLE t1 UNION SELECT * FROM t2;
 VALUES ROW(4,-2), ROW(5,9) UNION SELECT * FROM t2;
 SELECT * FROM t1 UNION TABLE t2;
 TABLE t1 UNION TABLE t2;
 VALUES ROW(4,-2), ROW(5,9) UNION TABLE t2;
 SELECT * FROM t1 UNION VALUES ROW(4,-2),ROW(5,9); 
 TABLE t1 UNION VALUES ROW(4,-2),ROW(5,9); 
 VALUES ROW(4,-2), ROW(5,9) UNION VALUES ROW(4,-2),ROW(5,9); 
```

To force the column names to be the same, wrap the query block on the left-hand side in a **SELECT** statement, and use aliases, like this:

```sql
mysql> SELECT * FROM (TABLE t2) AS t(x,y) UNION TABLE t1;
+------+------+
| x    | y    |
+------+------+
| 1    | 2    |
| 3    | 4    |
| 4    | -2   |
| 5    | 9    |
```
Set Operations with UNION, INTERSECT, and EXCEPT

Set Operations using DISTINCT and ALL

By default, duplicate rows are removed from results of set operations. The optional DISTINCT keyword has the same effect but makes it explicit. With the optional ALL keyword, duplicate-row removal does not occur and the result includes all matching rows from all queries in the union.

You can mix ALL and DISTINCT in the same query. Mixed types are treated such that a set operation using DISTINCT overrides any such operation using ALL to its left. A DISTINCT set can be produced explicitly by using DISTINCT with UNION, INTERSECT, or EXCEPT, or implicitly by using the set operations with no following DISTINCT or ALL keyword.

Set operations work the same way when one or more TABLE statements, VALUES statements, or both, are used to generate the set.

Set Operations with ORDER BY and LIMIT

To apply an ORDER BY or LIMIT clause to an individual query block used as part of a union, intersection, or other set operation, parenthesize the query block, placing the clause inside the parentheses, like this:

{(SELECT a FROM t1 WHERE a=10 AND b=1 ORDER BY a LIMIT 10) UNION (SELECT a FROM t2 WHERE a=11 AND b=2 ORDER BY a LIMIT 10)} INTERSECT (TABLE t1 ORDER BY a LIMIT 10) UNION (TABLE t2 ORDER BY a LIMIT 10);

Use of ORDER BY for individual query blocks or statements implies nothing about the order in which the rows appear in the final result because the rows produced by a set operation are by default unordered. Therefore, ORDER BY in this context typically is used in conjunction with LIMIT, to determine the subset of the selected rows to retrieve, even though it does not necessarily affect the order of those rows in the final result. If ORDER BY appears without LIMIT within a query block, it is optimized away because it has no effect in any case.

To use an ORDER BY or LIMIT clause to sort or limit the entire result of a set operation, place the ORDER BY or LIMIT after the last statement:

SELECT a FROM t1 EXCEPT SELECT a FROM t2 WHERE a=11 AND b=2 ORDER BY a LIMIT 10; TABLE t1 UNION TABLE t2 ORDER BY a LIMIT 10;

If one or more individual statements make use of ORDER BY, LIMIT, or both, and, in addition, you wish to apply an ORDER BY, LIMIT, or both to the entire result, then each such individual statement must be enclosed in parentheses.

{(SELECT a FROM t1 WHERE a=10 AND b=1) EXCEPT (SELECT a FROM t2 WHERE a=11 AND b=2) ORDER BY a LIMIT 10) UNION (TABLE t1 ORDER BY a LIMIT 10) UNION TABLE t2 ORDER BY a LIMIT 10;
A statement with no ORDER BY or LIMIT clause does need to be parenthesized; replacing TABLE t2 with (TABLE t2) in the second statement of the two just shown does not alter the result of the UNION.

You can also use ORDER BY and LIMIT with VALUES statements in set operations, as shown in this example using the mysql client:

```
mysql> VALUES ROW(4,-2), ROW(5,9), ROW(-1,3)
    -> UNION
    -> VALUES ROW(1,2), ROW(3,4), ROW(-1,3)
    -> ORDER BY column_0 DESC LIMIT 3;
+----------+----------+
<table>
<thead>
<tr>
<th>column_0</th>
<th>column_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>9</td>
</tr>
<tr>
<td>4</td>
<td>-2</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
</tr>
</tbody>
</table>
+----------+----------+
3 rows in set (0.00 sec)
```

(You should keep in mind that neither TABLE statements nor VALUES statements accept a WHERE clause.)

This kind of ORDER BY cannot use column references that include a table name (that is, names in tbl_name.col_name format). Instead, provide a column alias in the first query block, and refer to the alias in the ORDER BY clause. (You can also refer to the column in the ORDER BY clause using its column position, but such use of column positions is deprecated, and thus subject to eventual removal in a future MySQL release.)

If a column to be sorted is aliased, the ORDER BY clause must refer to the alias, not the column name. The first of the following statements is permitted, but the second fails with an Unknown column 'a' in 'order clause' error:

```
(SELECT a AS b FROM t) UNION (SELECT ...) ORDER BY b;
(SELECT a AS b FROM t) UNION (SELECT ...) ORDER BY a;
```

To cause rows in a UNION result to consist of the sets of rows retrieved by each query block one after the other, select an additional column in each query block to use as a sort column and add an ORDER BY clause that sorts on that column following the last query block:

```
(SELECT 1 AS sort_col, col1a, col1b, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col;
```

To maintain sort order within individual results, add a secondary column to the ORDER BY clause:

```
(SELECT 1 AS sort_col, col1a, col1b, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col, col1a;
```

Use of an additional column also enables you to determine which query block each row comes from. Extra columns can provide other identifying information as well, such as a string that indicates a table name.

Limitations of Set Operations

Set operations in MySQL are subject to some limitations, which are described in the next few paragraphs.

Set operations including SELECT statements have the following limitations:

- **HIGH_PRIORITY** in the first SELECT has no effect. HIGH_PRIORITY in any subsequent SELECT produces a syntax error.
- Only the last SELECT statement can use an INTO clause. However, the entire UNION result is written to the INTO output destination.
These two `UNION` variants containing `INTO` are deprecated; you should expect support for them to be removed in a future version of MySQL:

- In the trailing query block of a query expression, use of `INTO` before `FROM` produces a warning. Example:

  ```sql
  ... UNION SELECT * INTO 'file_name' FROM table_name;
  ```

- In a parenthesized trailing block of a query expression, use of `INTO` (regardless of its position relative to `FROM`) produces a warning. Example:

  ```sql
  ... UNION (SELECT * INTO 'file_name' FROM table_name);
  ```

Those variants are deprecated because they are confusing, as if they collect information from the named table rather than the entire query expression (the `UNION`).

Set operations with an aggregate function in an `ORDER BY` clause are rejected with `ER_AGGREGATE_ORDER_FOR_UNION`. Although the error name might suggest that this is exclusive to `UNION` queries, the preceding is also true for `EXCEPT` and `INTERSECT` queries, as shown here:

```sql
mysql> TABLE t1 INTERSECT TABLE t2 ORDER BY MAX(x);
ERROR 3028 (HY000): Expression #1 of ORDER BY contains aggregate function and applies to a UNION, EXCEPT or INTERSECT
```

A locking clause (such as `FOR UPDATE` or `LOCK IN SHARE MODE`) applies to the query block it follows. This means that, in a `SELECT` statement used with set operations, a locking clause can be used only if the query block and locking clause are enclosed in parentheses.

### 15.2.15 Subqueries

A subquery is a `SELECT` statement within another statement.

All subquery forms and operations that the SQL standard requires are supported, as well as a few features that are MySQL-specific.

Here is an example of a subquery:

```sql
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

In this example, `SELECT * FROM t1 ...` is the outer query (or outer statement), and `(SELECT column1 FROM t2)` is the subquery. We say that the subquery is nested within the outer query, and in fact it is possible to nest subqueries within other subqueries, to a considerable depth. A subquery must always appear within parentheses.

The main advantages of subqueries are:

- They allow queries that are *structured* so that it is possible to isolate each part of a statement.
- They provide alternative ways to perform operations that would otherwise require complex joins and unions.
- Many people find subqueries more readable than complex joins or unions. Indeed, it was the innovation of subqueries that gave people the original idea of calling the early SQL “Structured Query Language.”

Here is an example statement that shows the major points about subquery syntax as specified by the SQL standard and supported in MySQL:

```sql
DELETE FROM t1
WHERE s11 > ANY
  (SELECT COUNT(*) /* no hint */ FROM t2
  WHERE NOT EXISTS
  (SELECT * FROM t3
  WHERE ROW(5*t2.s1,77) =
```

2619
A subquery can return a scalar (a single value), a single row, a single column, or a table (one or more rows of one or more columns). These are called scalar, column, row, and table subqueries. Subqueries that return a particular kind of result often can be used only in certain contexts, as described in the following sections.

There are few restrictions on the type of statements in which subqueries can be used. A subquery can contain many of the keywords or clauses that an ordinary SELECT can contain: DISTINCT, GROUP BY, ORDER BY, LIMIT, joins, index hints, UNION constructs, comments, functions, and so on. TABLE and VALUES statements can be used in subqueries. Subqueries using VALUES are generally more verbose versions of subqueries that can be rewritten more compactly using set notation, or with SELECT or TABLE syntax; assuming that table ts is created using the statement CREATE TABLE ts VALUES ROW(2), ROW(4), ROW(6), the statements shown here are all equivalent:

```sql
SELECT * FROM tt
  WHERE b > ANY (VALUES ROW(2), ROW(4), ROW(6));

SELECT * FROM tt
  WHERE b > ANY (SELECT * FROM ts);

SELECT * FROM tt
  WHERE b > ANY (TABLE ts);
```

Examples of TABLE subqueries are shown in the sections that follow.

A subquery's outer statement can be any one of: SELECT, INSERT, UPDATE, DELETE, SET, or DO.

For information about how the optimizer handles subqueries, see Section 10.2.2, "Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions". For a discussion of restrictions on subquery use, including performance issues for certain forms of subquery syntax, see Section 15.2.15.12, "Restrictions on Subqueries".

15.2.15.1 The Subquery as Scalar Operand

In its simplest form, a subquery is a scalar subquery that returns a single value. A scalar subquery is a simple operand, and you can use it almost anywhere a single column value or literal is legal, and you can expect it to have those characteristics that all operands have: a data type, a length, an indication that it can be NULL, and so on. For example:

```sql
CREATE TABLE t1 (s1 INT, s2 CHAR(5) NOT NULL);
INSERT INTO t1 VALUES(100, 'abcde');
SELECT (SELECT s2 FROM t1);
```

The subquery in this SELECT returns a single value (‘abcde’) that has a data type of CHAR, a length of 5, a character set and collation equal to the defaults in effect at CREATE TABLE time, and an indication that the value in the column can be NULL. Nullability of the value selected by a scalar subquery is not copied because if the subquery result is empty, the result is NULL. For the subquery just shown, if t1 were empty, the result would be NULL even though s2 is NOT NULL.

There are a few contexts in which a scalar subquery cannot be used. If a statement permits only a literal value, you cannot use a subquery. For example, LIMIT requires literal integer arguments, and LOAD DATA requires a literal string file name. You cannot use subqueries to supply these values.

When you see examples in the following sections that contain the rather spartan construct (SELECT column1 FROM t1), imagine that your own code contains much more diverse and complex constructions.

Suppose that we make two tables:

```sql
CREATE TABLE t1 (s1 INT);
```
INSERT INTO t1 VALUES (1);
CREATE TABLE t2 (s1 INT);
INSERT INTO t2 VALUES (2);

Then perform a SELECT:

SELECT (SELECT s1 FROM t2) FROM t1;

The result is 2 because there is a row in t2 containing a column s1 that has a value of 2.

The preceding query can also be written like this, using TABLE:

SELECT (TABLE t2) FROM t1;

A scalar subquery can be part of an expression, but remember the parentheses, even if the subquery is an operand that provides an argument for a function. For example:

SELECT UPPER((SELECT s1 FROM t1)) FROM t2;

The same result can be obtained using SELECT UPPER((TABLE t1)) FROM t2.

15.2.15.2 Comparisons Using Subqueries

The most common use of a subquery is in the form:

```
non_subquery_operand comparison_operator (subquery)
```

Where `comparison_operator` is one of these operators:

```
=  >  <  >=  <=  <>  !=  <=>
```

For example:

```sql
... WHERE 'a' = (SELECT column1 FROM t1)
```

MySQL also permits this construct:

```
non_subquery_operand LIKE (subquery)
```

At one time the only legal place for a subquery was on the right side of a comparison, and you might still find some old DBMSs that insist on this.

Here is an example of a common-form subquery comparison that you cannot do with a join. It finds all the rows in table t1 for which the column1 value is equal to a maximum value in table t2:

```
SELECT * FROM t1
WHERE column1 = (SELECT MAX(column2) FROM t2);
```

Here is another example, which again is impossible with a join because it involves aggregating for one of the tables. It finds all rows in table t1 containing a value that occurs twice in a given column:

```
SELECT * FROM t1 AS t
WHERE 2 = (SELECT COUNT(*) FROM t1 WHERE t1.id = t.id);
```

For a comparison of the subquery to a scalar, the subquery must return a scalar. For a comparison of the subquery to a row constructor, the subquery must be a row subquery that returns a row with the same number of values as the row constructor. See Section 15.2.15.5, “Row Subqueries”.

15.2.15.3 Subqueries with ANY, IN, or SOME

Syntax:

```
operand comparison_operator ANY (subquery)
operand IN (subquery)
```
Subqueries

**operand comparison_operator SOME (subquery)**

Where *comparison_operator* is one of these operators:

- =  >  <  >=  <=  <>  !=

The *ANY* keyword, which must follow a comparison operator, means “return TRUE if the comparison is TRUE for ANY of the values in the column that the subquery returns.” For example:

```sql
SELECT s1 FROM t1 WHERE s1 > ANY (SELECT s1 FROM t2);
```

Suppose that there is a row in table *t1* containing (10). The expression is TRUE if table *t2* contains (21,14,7) because there is a value 7 in *t2* that is less than 10. The expression is FALSE if table *t2* contains (20,10), or if table *t2* is empty. The expression is *unknown* (that is, NULL) if table *t2* contains (NULL,NULL,NULL).

When used with a subquery, the word *IN* is an alias for *ANY*. Thus, these two statements are the same:

```sql
SELECT s1 FROM t1 WHERE s1 = ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 IN (SELECT s1 FROM t2);
```

*IN* and = *ANY* are not synonyms when used with an expression list. *IN* can take an expression list, but = *ANY* cannot. See Section 14.4.2, “Comparison Functions and Operators”.

*NOT IN* is not an alias for <> *ANY*, but for <> *ALL*. See Section 15.2.15.4, “Subqueries with ALL”.

The word *SOME* is an alias for *ANY*. Thus, these two statements are the same:

```sql
SELECT s1 FROM t1 WHERE s1 <> ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 <> SOME (SELECT s1 FROM t2);
```

Use of the word *SOME* is rare, but this example shows why it might be useful. To most people, the English phrase “a is not equal to any b” means “there is no b which is equal to a,” but that is not what is meant by the SQL syntax. The syntax means “there is some b to which a is not equal.” Using <> *SOME* instead helps ensure that everyone understands the true meaning of the query.

You can use *TABLE* in a scalar *IN*, *ANY*, or *SOME* subquery provided the table contains only a single column. If *t2* has only one column, the statements shown previously in this section can be written as shown here, in each case substituting *TABLE t2* for *SELECT s1 FROM t2*:

```sql
SELECT s1 FROM t1 WHERE s1 > ANY (TABLE t2);
SELECT s1 FROM t1 WHERE s1 = ANY (TABLE t2);
SELECT s1 FROM t1 WHERE s1 IN (TABLE t2);
SELECT s1 FROM t1 WHERE s1 <> ANY (TABLE t2);
SELECT s1 FROM t1 WHERE s1 <> SOME (TABLE t2);
```

### 15.2.15.4 Subqueries with ALL

**Syntax:**

```sql
operand comparison_operator ALL (subquery)
```

The word *ALL*, which must follow a comparison operator, means “return TRUE if the comparison is TRUE for ALL of the values in the column that the subquery returns.” For example:

```sql
SELECT s1 FROM t1 WHERE s1 > ALL (SELECT s1 FROM t2);
```

Suppose that there is a row in table *t1* containing (10). The expression is TRUE if table *t2* contains (-5,0,+5) because 10 is greater than all three values in *t2*. The expression is FALSE if table *t2* contains (-5,0,+5) because 10 is greater than all three values in *t2*.
contains \((12, 6, \text{NULL}, -100)\) because there is a single value 12 in table \(t2\) that is greater than 10. The expression is *unknown* (that is, \(\text{NULL}\)) if table \(t2\) contains \((0, \text{NULL}, 1)\).

Finally, the expression is *TRUE* if table \(t2\) is empty. So, the following expression is *TRUE* when table \(t2\) is empty:

```sql
SELECT * FROM t1 WHERE 1 > ALL (SELECT s1 FROM t2);
```

But this expression is *NULL* when table \(t2\) is empty:

```sql
SELECT * FROM t1 WHERE 1 > (SELECT s1 FROM t2);
```

In addition, the following expression is *NULL* when table \(t2\) is empty:

```sql
SELECT * FROM t1 WHERE 1 > ALL (SELECT MAX(s1) FROM t2);
```

In general, *tables containing NULL values* and *empty tables* are “edge cases.” When writing subqueries, always consider whether you have taken those two possibilities into account.

**NOT IN** is an alias for *<> ALL*. Thus, these two statements are the same:

```sql
SELECT s1 FROM t1 WHERE s1 <> ALL (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 NOT IN (SELECT s1 FROM t2);
```

As with **IN**, **ANY**, and **SOME**, you can use **TABLE** with **ALL** and **NOT IN** provided that the following two conditions are met:

- The table in the subquery contains only one column
- The subquery does not depend on a column expression

For example, assuming that table \(t2\) consists of a single column, the last two statements shown previously can be written using **TABLE** \(t2\) like this:

```sql
SELECT s1 FROM t1 WHERE s1 <> ALL (TABLE t2);
SELECT s1 FROM t1 WHERE s1 NOT IN (TABLE t2);
```

A query such as

```sql
SELECT * FROM t1 WHERE 1 > ALL (SELECT MAX(s1) FROM t2);
```

cannot be written using **TABLE** \(t2\) because the subquery depends on a column expression.

### 15.2.15.5 Row Subqueries

Scalar or column subqueries return a single value or a column of values. A row subquery is a subquery variant that returns a single row and can thus return more than one column value. Legal operators for row subquery comparisons are:

- \(=\)
- \(<\)
- \(\leq\)
- \(\geq\)
- \(!=\)
- \(<>\)
- \(!<>\)

Here are two examples:

```sql
SELECT * FROM t1
WHERE (col1, col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);
SELECT * FROM t1
WHERE ROW(col1, col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);
```

For both queries, if the table \(t2\) contains a single row with \(id = 10\), the subquery returns a single row. If this row has \(col3\) and \(col4\) values equal to the \(col1\) and \(col2\) values of any rows in \(t1\), the \(WHERE\) expression is *TRUE* and each query returns those \(t1\) rows. If the \(t2\) row \(col3\) and \(col4\) values are not equal the \(col1\) and \(col2\) values of any \(t1\) row, the expression is *FALSE* and the query returns an empty result set. The expression is *unknown* (that is, \(\text{NULL}\)) if the subquery produces no rows. An error occurs if the subquery produces multiple rows because a row subquery can return at most one row.
For information about how each operator works for row comparisons, see Section 14.4.2, “Comparison Functions and Operators”.

The expressions (1,2) and \texttt{ROW(1,2)} are sometimes called row constructors. The two are equivalent. The row constructor and the row returned by the subquery must contain the same number of values.

A row constructor is used for comparisons with subqueries that return two or more columns. When a subquery returns a single column, this is regarded as a scalar value and not as a row, so a row constructor cannot be used with a subquery that does not return at least two columns. Thus, the following query fails with a syntax error:

\begin{verbatim}
SELECT * FROM t1 WHERE ROW(1) = (SELECT column1 FROM t2)
\end{verbatim}

Row constructors are legal in other contexts. For example, the following two statements are semantically equivalent (and are handled in the same way by the optimizer):

\begin{verbatim}
SELECT * FROM t1 WHERE (column1,column2) = (1,1);
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;
\end{verbatim}

The following query answers the request, “find all rows in table \texttt{t1} that also exist in table \texttt{t2}”:

\begin{verbatim}
SELECT column1,column2,column3 FROM t1 WHERE (column1,column2,column3) IN (SELECT column1,column2,column3 FROM t2);
\end{verbatim}

For more information about the optimizer and row constructors, see Section 10.2.1.22, “Row Constructor Expression Optimization”

### 15.2.15.6 Subqueries with EXISTS or NOT EXISTS

If a subquery returns any rows at all, EXISTS subquery is TRUE, and NOT EXISTS subquery is FALSE. For example:

\begin{verbatim}
SELECT column1 FROM t1 WHERE EXISTS (SELECT * FROM t2);
\end{verbatim}

Traditionally, an EXISTS subquery starts with SELECT *, but it could begin with SELECT 5 or SELECT column1 or anything at all. MySQL ignores the SELECT list in such a subquery, so it makes no difference.

For the preceding example, if \texttt{t2} contains any rows, even rows with nothing but NULL values, the EXISTS condition is TRUE. This is actually an unlikely example because a \texttt{[NOT] EXISTS} subquery almost always contains correlations. Here are some more realistic examples:

- What kind of store is present in one or more cities?

\begin{verbatim}
SELECT DISTINCT store_type FROM stores WHERE EXISTS (SELECT * FROM cities_stores WHERE cities_stores.store_type = stores.store_type);
\end{verbatim}

- What kind of store is present in no cities?

\begin{verbatim}
SELECT DISTINCT store_type FROM stores WHERE NOT EXISTS (SELECT * FROM cities WHERE NOT EXISTS (SELECT * FROM cities_stores WHERE cities_stores.city = cities.city AND cities_stores.store_type = stores.store_type));
\end{verbatim}

- What kind of store is present in all cities?

\begin{verbatim}
SELECT DISTINCT store_type FROM stores WHERE NOT EXISTS (
  SELECT * FROM cities WHERE NOT EXISTS (
    SELECT * FROM cities_stores
    WHERE cities_stores.city = cities.city
    AND cities_stores.store_type = stores.store_type));
\end{verbatim}
The last example is a double-nested `NOT EXISTS` query. That is, it has a `NOT EXISTS` clause within a `NOT EXISTS` clause. Formally, it answers the question “does a city exist with a store that is not in `Stores`”? But it is easier to say that a nested `NOT EXISTS` answers the question “is \( x \) TRUE for all \( y \)?”

You can also use `NOT EXISTS` or `NOT EXISTS` with `TABLE` in the subquery, like this:

```sql
SELECT column1 FROM t1 WHERE EXISTS (TABLE t2);
```

The results are the same as when using `SELECT *` with no `WHERE` clause in the subquery.

### 15.2.15.7 Correlated Subqueries

A **correlated subquery** is a subquery that contains a reference to a table that also appears in the outer query. For example:

```sql
SELECT * FROM t1
  WHERE column1 = ANY (SELECT column1 FROM t2
                        WHERE t2.column2 = t1.column2);
```

Notice that the subquery contains a reference to a column of `t1`, even though the subquery's `FROM` clause does not mention a table `t1`. So, MySQL looks outside the subquery, and finds `t1` in the outer query.

Suppose that table `t1` contains a row where `column1 = 5` and `column2 = 6`; meanwhile, table `t2` contains a row where `column1 = 5` and `column2 = 7`. The simple expression `WHERE column1 = ANY (SELECT column1 FROM t2)` would be TRUE, but in this example, the `WHERE` clause within the subquery is FALSE (because \((5,6)\) is not equal to \((5,7)\)), so the expression as a whole is FALSE.

**Scoping rule**: MySQL evaluates from inside to outside. For example:

```sql
SELECT column1 FROM t1 AS x
  WHERE x.column1 = (SELECT column1 FROM t2 AS x
                     WHERE x.column1 = (SELECT column1 FROM t3
                           WHERE x.column2 = t3.column1));
```

In this statement, `x.column2` must be a column in table `t2` because `SELECT column1 FROM t2 AS x ...` renames `t2`. It is not a column in table `t1` because `SELECT column1 FROM t1 ...` is an outer query that is farther out.

The optimizer can transform a correlated scalar subquery to a derived table when the `subquery_to_derived` flag of the `optimizer_switch` variable is enabled. Consider the query shown here:

```sql
SELECT * FROM t1
  WHERE (SELECT a FROM t2
          WHERE t2.a = t1.a) > 0;
```

To avoid materializing several times for a given derived table, we can instead materialize—once—a derived table which adds a grouping on the join column from the table referenced in the inner query (`t2.a`) and then an outer join on the lifted predicate (`t1.a = derived.a`) in order to select the correct group to match up with the outer row. (If the subquery already has an explicit grouping, the extra grouping is added to the end of the grouping list.) The query previously shown can thus be rewritten like this:

```sql
SELECT t1.* FROM t1
  LEFT OUTER JOIN
    (SELECT a, COUNT(*) AS ct FROM t2 GROUP BY a) AS derived
  ON  t1.a = derived.a
  AND
  REJECT_IF(
    (ct > 1),
    "ERROR 1242 (21000): Subquery returns more than 1 row"
  )
  WHERE derived.a > 0;
```
In the rewritten query, `REJECT_IF()` represents an internal function which tests a given condition (here, the comparison `ct > 1`) and raises a given error (in this case, `ER_SUBQUERY_NO_1_ROW`) if the condition is true. This reflects the cardinality check that the optimizer performs as part of evaluating the `JOIN` or `WHERE` clause, prior to evaluating any lifted predicate, which is done only if the subquery does not return more than one row.

This type of transformation can be performed, provided the following conditions are met:

- The subquery can be part of a `SELECT` list, `WHERE` condition, or `HAVING` condition, but cannot be part of a `JOIN` condition, and cannot contain a `LIMIT` or `OFFSET` clause. In addition, the subquery cannot contain any set operations such as `UNION`.

- The `WHERE` clause may contain one or more predicates, combined with `AND`. If the `WHERE` clause contains an `OR` clause, it cannot be transformed. At least one of the `WHERE` clause predicates must be eligible for transformation, and none of them may reject transformation.

- To be eligible for transformation, a `WHERE` clause predicate must be an equality predicate in which each operand should be a simple column reference. No other predicates—including other comparison predicates—are eligible for transformation. The predicate must employ the equality operator `=` for making the comparison; the null-safe `<>` operator is not supported in this context.

- A `WHERE` clause predicate that contains only inner references is not eligible for transformation, since it can be evaluated before the grouping. A `WHERE` clause predicate that contains only outer references is eligible for transformation, even though it can be lifted up to the outer query block. This is made possible by adding a cardinality check without grouping in the derived table.

- To be eligible, a `WHERE` clause predicate must have one operand that contains only inner references and one operand that contains only outer references. If the predicate is not eligible due to this rule, transformation of the query is rejected.

- A correlated column can be present only in the subquery's `WHERE` clause (and not in the `SELECT` list, a `JOIN` or `ORDER BY` clause, a `GROUP BY` list, or a `HAVING` clause). Nor can there be any correlated column inside a derived table in the subquery's `FROM` list.

- A correlated column can not be contained in an aggregate function's list of arguments.

- A correlated column must be resolved in the query block directly containing the subquery being considered for transformation.

- A correlated column cannot be present in a nested scalar subquery in the `WHERE` clause.

- The subquery cannot contain any window functions, and must not contain any aggregate function which aggregates in a query block outer to the subquery. A `COUNT()` aggregate function, if contained in the `SELECT` list element of the subquery, must be at the topmost level, and cannot be part of an expression.

See also Section 15.2.15.8, “Derived Tables”.

### 15.2.15.8 Derived Tables

This section discusses general characteristics of derived tables. For information about lateral derived tables preceded by the `LATERAL` keyword, see Section 15.2.15.9, “Lateral Derived Tables”.

A derived table is an expression that generates a table within the scope of a query `FROM` clause. For example, a subquery in a `SELECT` statement `FROM` clause is a derived table:

```
SELECT ... FROM (subquery) [AS] tbl_name ...
```

The `JSON_TABLE()` function generates a table and provides another way to create a derived table:

```
SELECT * FROM JSON_TABLE(arg_list) [AS] tbl_name ...
```
The `AS tbl_name` clause is mandatory because every table in a `FROM` clause must have a name. Any columns in the derived table must have unique names. Alternatively, `tbl_name` may be followed by a parenthesized list of names for the derived table columns:

```
SELECT ... FROM (subquery) [AS] tbl_name (col_list) ...
```

The number of column names must be the same as the number of table columns.

For the sake of illustration, assume that you have this table:

```sql
CREATE TABLE t1 (s1 INT, s2 CHAR(5), s3 FLOAT);
```

Here is how to use a subquery in the `FROM` clause, using the example table:

```sql
INSERT INTO t1 VALUES (1,'1',1.0);
INSERT INTO t1 VALUES (2,'2',2.0);
SELECT s1 AS sb1, s2 AS sb2, s3*2 AS sb3 FROM t1 AS sb
WHERE sb1 > 1;
```

Result:

```
+------|---|------+
| sb1  | sb2| sb3  |
+------|---|------+
|    2 | 2  |    4 |
+------|---|------+
```

Here is another example: Suppose that you want to know the average of a set of sums for a grouped table. This does not work:

```
SELECT AVG(SUM(column1)) FROM t1 GROUP BY column1;
```

However, this query provides the desired information:

```
SELECT AVG(sum_column1)
FROM (SELECT SUM(column1) AS sum_column1
     FROM t1 GROUP BY column1) AS t1;
```

Notice that the column name used within the subquery (`sum_column1`) is recognized in the outer query.

The column names for a derived table come from its select list:

```
mysql> SELECT * FROM (SELECT 1, 2, 3, 4) AS dt;
+---+---+---+---+
<table>
<thead>
<tr>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
</tr>
</thead>
</table>
```

To provide column names explicitly, follow the derived table name with a parenthesized list of column names:

```
mysql> SELECT * FROM (SELECT 1, 2, 3, 4) AS dt (a, b, c, d);
+-----+-----+-----+-----+
| a   | b   | c   | d   |
+-----+-----+-----+-----|
| 1   | 2   | 3   | 4   |
+-----+-----+-----+-----+
```

A derived table can return a scalar, column, row, or table.

Derived tables are subject to these restrictions:

- A derived table cannot contain references to other tables of the same `SELECT` (use a `LATERAL` derived table for that; see Section 15.2.15.9, "Lateral Derived Tables").
Subqueries

The optimizer determines information about derived tables in such a way that `EXPLAIN` does not need to materialize them. See Section 10.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”.

It is possible under certain circumstances that using `EXPLAIN SELECT` modifies table data. This can occur if the outer query accesses any tables and an inner query invokes a stored function that changes one or more rows of a table. Suppose that there are two tables `t1` and `t2` in database `d1`, and a stored function `f1` that modifies `t2`, created as shown here:

```sql
CREATE DATABASE d1;
USE d1;
CREATE TABLE t1 (c1 INT);
CREATE TABLE t2 (c1 INT);
CREATE FUNCTION f1(p1 INT) RETURNS INT
BEGIN
  INSERT INTO t2 VALUES (p1);
  RETURN p1;
END;
```

Referencing the function directly in an `EXPLAIN SELECT` has no effect on `t2`, as shown here:

```sql
mysql> SELECT * FROM t2;
Empty set (0.02 sec)

mysql> EXPLAIN SELECT f1(5)\G
*************************** 1. row ***************************
  id: 1
  select_type: SIMPLE
  table: NULL
  partitions: NULL
  type: NULL
  possible_keys: NULL
  key: NULL
  key_len: NULL
  ref: NULL
  rows: NULL
  filtered: NULL
  Extra: No tables used
1 row in set (0.01 sec)

mysql> SELECT * FROM t2;
Empty set (0.01 sec)
```

This is because the `SELECT` statement did not reference any tables, as can be seen in the `table` and `Extra` columns of the output. This is also true of the following nested `SELECT`:

```sql
mysql> EXPLAIN SELECT NOW() AS a1, (SELECT f1(5)) AS a2\G
*************************** 1. row ***************************
  id: 1
  select_type: PRIMARY
  table: NULL
  type: NULL
  possible_keys: NULL
  key: NULL
  key_len: NULL
  ref: NULL
  rows: NULL
  filtered: NULL
  Extra: No tables used
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-------+------+------------------------------------------+
<table>
<thead>
<tr>
<th>Level</th>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Note</td>
<td>1249</td>
<td>Select 2 was reduced during optimization</td>
</tr>
</tbody>
</table>
+-------+------+------------------------------------------+
1 row in set (0.00 sec)
```

```sql
mysql> SELECT * FROM t2;
```
However, if the outer SELECT references any tables, the optimizer executes the statement in the subquery as well, with the result that \( t_2 \) is modified:

```
mysql> EXPLAIN SELECT * FROM t1 AS a1, (SELECT f1(5)) AS a2;
+--------------------+---------+---------+---------+---------+---------+
| id | select_type | table | partitions | type | possible_keys |
+----+------------+-------+------------+------+---------------
| 1  | PRIMARY    | <derived2> | NULL       | system | NULL          |
| 2  | PRIMARY    | a1    | NULL       | ALL   | NULL          |
| 3  | DERIVED    | NULL  | NULL       | NULL  | NULL          |
+----+------------+-------+------------+------+---------------
|    |            |       |            |       |               |
|    |            |       |            |       |               |
|    |            |       |            |       |               |
+----+------------+-------+------------+------+---------------
```

```
mysql> SELECT * FROM t2;
+----+
| c1 |
+----+
| 5  |
+----+
1 row in set (0.00 sec)
```

The derived table optimization can also be employed with many correlated (scalar) subqueries. For more information and examples, see Section 15.2.15.7, “Correlated Subqueries”.

### 15.2.15.9 Lateral Derived Tables

A derived table cannot normally refer to (depend on) columns of preceding tables in the same `FROM` clause. A derived table may be defined as a lateral derived table to specify that such references are permitted.

Nonlateral derived tables are specified using the syntax discussed in Section 15.2.15.8, “Derived Tables”: The syntax for a lateral derived table is the same as for a nonlateral derived table except that the keyword `LATERAL` is specified before the derived table specification. The `LATERAL` keyword must precede each table to be used as a lateral derived table.

Lateral derived tables are subject to these restrictions:
Subqueries

- A lateral derived table can occur only in a FROM clause, either in a list of tables separated with commas or in a join specification (JOIN, INNER JOIN, CROSS JOIN, LEFT [OUTER] JOIN, or RIGHT [OUTER] JOIN).

- If a lateral derived table is in the right operand of a join clause and contains a reference to the left operand, the join operation must be an INNER JOIN, CROSS JOIN, or LEFT [OUTER] JOIN.

  If the table is in the left operand and contains a reference to the right operand, the join operation must be an INNER JOIN, CROSS JOIN, or RIGHT [OUTER] JOIN.

- If a lateral derived table references an aggregate function, the function's aggregation query cannot be the one that owns the FROM clause in which the lateral derived table occurs.

- In accordance with the SQL standard, MySQL always treats a join with a table function such as JSON_TABLE() as though LATERAL had been used. Since the LATERAL keyword is implicit, it is not allowed before JSON_TABLE(); this is also according to the SQL standard.

The following discussion shows how lateral derived tables make possible certain SQL operations that cannot be done with nonlateral derived tables or that require less-efficient workarounds.

Suppose that we want to solve this problem: Given a table of people in a sales force (where each row describes a member of the sales force), and a table of all sales (where each row describes a sale: salesperson, customer, amount, date), determine the size and customer of the largest sale for each salesperson. This problem can be approached two ways.

First approach to solving the problem: For each salesperson, calculate the maximum sale size, and also find the customer who provided this maximum. In MySQL, that can be done like this:

```sql
SELECT
  salesperson.name,
  -- find maximum sale size for this salesperson
  (SELECT MAX(amount) AS amount
   FROM all_sales
   WHERE all_sales.salesperson_id = salesperson.id)
  AS amount,
  -- find customer for this maximum size
  (SELECT customer_name
   FROM all_sales
   WHERE all_sales.salesperson_id = salesperson.id
   AND all_sales.amount =
   -- find maximum size, again
   (SELECT MAX(amount) AS amount
    FROM all_sales
    WHERE all_sales.salesperson_id = salesperson.id))
  AS customer_name
FROM
  salesperson;
```

That query is inefficient because it calculates the maximum size twice per salesperson (once in the first subquery and once in the second).

We can try to achieve an efficiency gain by calculating the maximum once per salesperson and “caching” it in a derived table, as shown by this modified query:

```sql
SELECT
  salesperson.name,
  max_sale.amount,
  max_sale_customer.customer_name
FROM
  salesperson,
  -- calculate maximum size, cache it in transient derived table max_sale
  (SELECT MAX(amount) AS amount
   FROM all_sales
   WHERE all_sales.salesperson_id = salesperson.id)
  AS max_sale,
  -- find customer, reusing cached maximum size
  (SELECT customer_name
   FROM all_sales
   WHERE all_sales.salesperson_id = salesperson.id) AS customer_name
```
FROM all_sales
WHERE all_sales.salesperson_id = salesperson.id
AND all_sales.amount =
  -- the cached maximum size
  max_sale.amount)
AS max_sale_customer;

However, the query is illegal in SQL-92 because derived tables cannot depend on other tables in the same FROM clause. Derived tables must be constant over the query’s duration, not contain references to columns of other FROM clause tables. As written, the query produces this error:

ERROR 1054 (42S22): Unknown column 'salesperson.id' in 'where clause'

In SQL:1999, the query becomes legal if the derived tables are preceded by the LATERAL keyword (which means “this derived table depends on previous tables on its left side”):

```
SELECT salesperson.name,
       max_sale.amount,
       max_sale_customer.customer_name
FROM salesperson,
     -- calculate maximum size, cache it in transient derived table max_sale
     LATERAL (SELECT MAX(amount) AS amount
              FROM all_sales
              WHERE all_sales.salesperson_id = salesperson.id)
       AS max_sale,
     -- find customer, reusing cached maximum size
     LATERAL (SELECT customer_name
              FROM all_sales
              WHERE all_sales.salesperson_id = salesperson.id
              AND all_sales.amount =
              -- the cached maximum size
              max_sale.amount)
       AS max_sale_customer;
```

A lateral derived table need not be constant and is brought up to date each time a new row from a preceding table on which it depends is processed by the top query.

Second approach to solving the problem: A different solution could be used if a subquery in the SELECT list could return multiple columns:

```
SELECT salesperson.name,
       -- find maximum size and customer at same time
       (SELECT amount, customer_name
        FROM all_sales
        WHERE all_sales.salesperson_id = salesperson.id
        ORDER BY amount DESC LIMIT 1)
FROM salesperson;
```

That is efficient but illegal. It does not work because such subqueries can return only a single column:

ERROR 1241 (21000): Operand should contain 1 column(s)

One attempt at rewriting the query is to select multiple columns from a derived table:

```
SELECT salesperson.name,
       max_sale.amount,
       max_sale.customer_name
FROM salesperson,
     -- find maximum size and customer at same time
     (SELECT amount, customer_name
      FROM all_sales
      WHERE all_sales.salesperson_id = salesperson.id)
```
ORDER BY amount DESC LIMIT 1) AS max_sale;

However, that also does not work. The derived table is dependent on the `salesperson` table and thus fails without `LATERAL`:

```
ERROR 1054 (42S22): Unknown column 'salesperson.id' in 'where clause'
```

Adding the `LATERAL` keyword makes the query legal:

```
SELECT
  salesperson.name,
  max_sale.amount,
  max_sale.customer_name
FROM
  salesperson,
  -- find maximum size and customer at same time
  LATERAL
  (SELECT amount, customer_name
   FROM all_sales
   WHERE all_sales.salesperson_id = salesperson.id
   ORDER BY amount DESC LIMIT 1)
  AS max_sale;
```

In short, `LATERAL` is the efficient solution to all drawbacks in the two approaches just discussed.

15.2.15.10 Subquery Errors

There are some errors that apply only to subqueries. This section describes them.

* Unsupported subquery syntax:

```
ERROR 1235 (ER_NOT_SUPPORTED_YET)
SQLSTATE = 42000
Message = "This version of MySQL doesn't yet support 'LIMIT & IN/ALL/ANY/SOME subquery'"
```

This means that MySQL does not support statements like the following:

```
SELECT * FROM t1 WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1)
```

* Incorrect number of columns from subquery:

```
ERROR 1241 (ER_OPERAND_COL)
SQLSTATE = 21000
Message = "Operand should contain 1 column(s)"
```

This error occurs in cases like this:

```
SELECT (SELECT column1, column2 FROM t2) FROM t1;
```

You may use a subquery that returns multiple columns, if the purpose is row comparison. In other contexts, the subquery must be a scalar operand. See Section 15.2.15.5, “Row Subqueries”.

* Incorrect number of rows from subquery:

```
ERROR 1242 (ER_SUBSELECT_NO_1_ROW)
SQLSTATE = 21000
Message = "Subquery returns more than 1 row"
```

This error occurs for statements where the subquery must return at most one row but returns multiple rows. Consider the following example:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

If `SELECT column1 FROM t2` returns just one row, the previous query works. If the subquery returns more than one row, error 1242 occurs. In that case, the query should be rewritten as:
Subqueries

SELECT * FROM t1 WHERE column1 = ANY (SELECT column1 FROM t2);

• Incorrectly used table in subquery:

Error 1093 (ER_UPDATE_TABLE_USED)
SQLSTATE = HY000
Message = "You can't specify target table 'x' for update in FROM clause"

This error occurs in cases such as the following, which attempts to modify a table and select from the same table in the subquery:

UPDATE t1 SET column2 = (SELECT MAX(column1) FROM t1);

You can use a common table expression or derived table to work around this. See Section 15.2.15.12, “Restrictions on Subqueries”.

All of the errors described in this section also apply when using TABLE in subqueries.

For transactional storage engines, the failure of a subquery causes the entire statement to fail. For nontransactional storage engines, data modifications made before the error was encountered are preserved.

15.2.15.11 Optimizing Subqueries

Development is ongoing, so no optimization tip is reliable for the long term. The following list provides some interesting tricks that you might want to play with. See also Section 10.2.2, “Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions”.

• Move clauses from outside to inside the subquery. For example, use this query:

SELECT * FROM t1
WHERE s1 IN (SELECT s1 FROM t1 UNION ALL SELECT s1 FROM t2);

Instead of this query:

SELECT * FROM t1
WHERE s1 IN (SELECT s1 FROM t1) OR s1 IN (SELECT s1 FROM t2);

For another example, use this query:

SELECT (SELECT column1 + 5 FROM t1) FROM t2;

Instead of this query:

SELECT (SELECT column1 FROM t1) + 5 FROM t2;

15.2.15.12 Restrictions on Subqueries

• In general, you cannot modify a table and select from the same table in a subquery. For example, this limitation applies to statements of the following forms:

DELETE FROM t WHERE ... (SELECT ... FROM t ...);
UPDATE t ... WHERE col = (SELECT ... FROM t ...);
{INSERT|REPLACE} INTO t (SELECT ... FROM t ...);

Exception: The preceding prohibition does not apply if for the modified table you are using a derived table and that derived table is materialized rather than merged into the outer query. (See Section 10.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”.) Example:

UPDATE t ... WHERE col = (SELECT * FROM (SELECT ... FROM t...) AS dt ...);

Here the result from the derived table is materialized as a temporary table, so the relevant rows in t have already been selected by the time the update to t takes place.
In general, you may be able to influence the optimizer to materialize a derived table by adding a NO_MERGE optimizer hint. See Section 10.9.3, “Optimizer Hints”.

• Row comparison operations are only partially supported:
  
  • For expr [NOT] IN subquery, expr can be an \(n\)-tuple (specified using row constructor syntax) and the subquery can return rows of \(n\)-tuples. The permitted syntax is therefore more specifically expressed as row_constructor [NOT] IN table_subquery
  
  • For expr op {ALL|ANY|SOME} subquery, expr must be a scalar value and the subquery must be a column subquery; it cannot return multiple-column rows.

In other words, for a subquery that returns rows of \(n\)-tuples, this is supported:

\[
(expr_1, ..., expr_n) [NOT] IN table_subquery
\]

But this is not supported:

\[
(expr_1, ..., expr_n) op \{ALL|ANY|SOME\} subquery
\]

The reason for supporting row comparisons for IN but not for the others is that IN is implemented by rewriting it as a sequence of = comparisons and AND operations. This approach cannot be used for ALL, ANY, or SOME.

• MySQL does not support LIMIT in subqueries for certain subquery operators:

```sql
mysql> SELECT * FROM t1 WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1);
ERROR 1235 (42000): This version of MySQL doesn't yet support 'LIMIT & IN/ALL/ANY/SOME subquery'
```

See Section 15.2.15.10, “Subquery Errors”.

• MySQL permits a subquery to refer to a stored function that has data-modifying side effects such as inserting rows into a table. For example, if \(f()\) inserts rows, the following query can modify data:

```sql
SELECT ... WHERE x IN (SELECT f() ...);
```

This behavior is an extension to the SQL standard. In MySQL, it can produce nondeterministic results because \(f()\) might be executed a different number of times for different executions of a given query depending on how the optimizer chooses to handle it.

For statement-based or mixed-format replication, one implication of this indeterminism is that such a query can produce different results on the source and its replicas.

### 15.2.16 TABLE Statement

**TABLE** is a DML statement which returns rows and columns of the named table.

```sql
TABLE table_name [ORDER BY column_name] [LIMIT number [OFFSET number]]
```

The **TABLE** statement in some ways acts like SELECT. Given the existence of a table named \(t\), the following two statements produce identical output:

```sql
TABLE t;
SELECT * FROM t;
```

You can order and limit the number of rows produced by **TABLE** using ORDER BY and LIMIT clauses, respectively. These function identically to the same clauses when used with **SELECT** (including an optional OFFSET clause with LIMIT), as you can see here:

```sql
mysql> TABLE t;
+----+
|    |
+----+
```
TABLE differs from SELECT in two key respects:

- **TABLE** always displays all columns of the table.

  *Exception: The output of **TABLE** does not include invisible columns. See Section 15.1.20.10, “Invisible Columns”.*

- **TABLE** does not allow for any arbitrary filtering of rows; that is, **TABLE** does not support any **WHERE** clause.

For limiting which table columns are returned, filtering rows beyond what can be accomplished using **ORDER BY** and **LIMIT**, or both, use **SELECT**.

**TABLE** can be used with temporary tables.
**TABLE Statement**

**TABLE** can also be used in place of **SELECT** in a number of other constructs, including those listed here:

- With set operators such as **UNION**, as shown here:

  ```
  mysql> TABLE t1;
  +---+----+
  | a | b  |
  +---+----+
  | 2 | 10 |
  | 5 |  3 |
  | 7 |  8 |
  +---+----+
  3 rows in set (0.00 sec)
  
  mysql> TABLE t2;
  +---+---+
  | a | b |
  +---+---+
  | 1 | 2 |
  | 3 | 4 |
  | 6 | 7 |
  +---+---+
  3 rows in set (0.00 sec)
  
  mysql> TABLE t1 UNION TABLE t2;
  +---+----+
  | a | b  |
  +---+----+
  | 2 | 10 |
  | 5 |  3 |
  | 7 |  8 |
  | 1 |  2 |
  | 3 |  4 |
  | 6 |  7 |
  +---+----+
  6 rows in set (0.00 sec)
  
  The **UNION** just shown is equivalent to the following statement:

  ```
  mysql> SELECT * FROM t1 UNION SELECT * FROM t2;
  +---+----+
  | a | b  |
  +---+----+
  | 2 | 10 |
  | 5 |  3 |
  | 7 |  8 |
  | 1 |  2 |
  | 3 |  4 |
  | 6 |  7 |
  +---+----+
  6 rows in set (0.00 sec)
  ```

**TABLE** can also be used together in set operations with **SELECT** statements, **VALUES** statements, or both. See Section 15.2.18, “**UNION Clause**”, Section 15.2.4, “**EXCEPT Clause**”, and Section 15.2.8, “**INTERSECT Clause**”, for more information and examples. See also Section 15.2.14, “Set Operations with UNIOn, INTERSECT, and EXCEPT”.

- With **INTO** to populate user variables, and with **INTO OUTFILE** or **INTO DUMPFILE** to write table data to a file. See Section 15.2.13.1, “**SELECT ... INTO Statement**”, for more specific information and examples.

- In many cases where you can employ subqueries. Given any table **t1** with a column named **a**, and a second table **t2** having a single column, statements such as the following are possible:

  ```
  SELECT * FROM t1 WHERE a IN (TABLE t2);
  ```

  Assuming that the single column of table **t1** is named **x**, the preceding is equivalent to each of the statements shown here (and produces exactly the same result in either case):
UPDATE Statement

**UPDATE Statement**

**UPDATE** is a DML statement that modifies rows in a table.

An **UPDATE** statement can start with a **WITH** clause to define common table expressions accessible within the **UPDATE**. See Section 15.2.20, “WITH (Common Table Expressions)”.

**Single-table syntax:**

```
UPDATE [LOW_PRIORITY] [IGNORE] table_reference
    SET assignment_list
    [WHERE where_condition]
    [ORDER BY ...]
    [LIMIT row_count]

value:
    {expr | DEFAULT}

assignment:
    col_name = value

assignment_list:
    assignment [, assignment] ...
```

**Multiple-table syntax:**

```
UPDATE [LOW_PRIORITY] [IGNORE] table_references
    SET assignment_list
    [WHERE where_condition]
```

For the single-table syntax, the **UPDATE** statement updates columns of existing rows in the named table with new values. The **SET** clause indicates which columns to modify and the values they should be given. Each value can be given as an expression, or the keyword **DEFAULT** to set a column explicitly to its default value. The **WHERE** clause, if given, specifies the conditions that identify which rows to update. With no **WHERE** clause, all rows are updated. If the **ORDER BY** clause is specified, the rows are updated in the order that is specified. The **LIMIT** clause places a limit on the number of rows that can be updated.

For the multiple-table syntax, **UPDATE** updates rows in each table named in **table_references** that satisfy the conditions. Each matching row is updated once, even if it matches the conditions multiple times. For multiple-table syntax, **ORDER BY** and **LIMIT** cannot be used.

For partitioned tables, both the single-single and multiple-table forms of this statement support the use of a **PARTITION** clause as part of a table reference. This option takes a list of one or more partitions or subpartitions (or both). Only the partitions (or subpartitions) listed are checked for matches, and a row that is not in any of these partitions or subpartitions is not updated, whether it satisfies the **where_condition** or not.

**Note**

Unlike the case when using **PARTITION** with an **INSERT** or **REPLACE** statement, an otherwise valid **UPDATE ... PARTITION** statement is
UPDATE Statement

considered successful even if no rows in the listed partitions (or subpartitions) match the \textit{where condition}.

For more information and examples, see Section 26.5, “Partition Selection”.

\textit{where condition} is an expression that evaluates to true for each row to be updated. For expression syntax, see Section 11.5, “Expressions”.

table\_references and \textit{where condition} are specified as described in Section 15.2.13, “SELECT Statement”.

You need the \texttt{UPDATE} privilege only for columns referenced in an \texttt{UPDATE} that are actually updated. You need only the \texttt{SELECT} privilege for any columns that are read but not modified.

The \texttt{UPDATE} statement supports the following modifiers:

• With the \texttt{LOW\_PRIORITY} modifier, execution of the \texttt{UPDATE} is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as \texttt{MyISAM}, \texttt{MEMORY}, and \texttt{MERGE}).

• With the \texttt{IGNORE} modifier, the update statement does not abort even if errors occur during the update. Rows for which duplicate-key conflicts occur on a unique key value are not updated. Rows updated to values that would cause data conversion errors are updated to the closest valid values instead. For more information, see The Effect of IGNORE on Statement Execution.

\texttt{UPDATE} \texttt{IGNORE} statements, including those having an \texttt{ORDER BY} clause, are flagged as unsafe for statement-based replication. (This is because the order in which the rows are updated determines which rows are ignored.) Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using \texttt{MIXED} mode. (Bug #11758262, Bug #50439) See Section 19.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”, for more information.

If you access a column from the table to be updated in an expression, \texttt{UPDATE} uses the current value of the column. For example, the following statement sets \texttt{col1} to one more than its current value:

\begin{verbatim}
UPDATE t1 SET col1 = col1 + 1;
\end{verbatim}

The second assignment in the following statement sets \texttt{col2} to the current (updated) \texttt{col1} value, not the original \texttt{col1} value. The result is that \texttt{col1} and \texttt{col2} have the same value. This behavior differs from standard SQL.

\begin{verbatim}
UPDATE t1 SET col1 = col1 + 1, col2 = col1;
\end{verbatim}

Single-table \texttt{UPDATE} assignments are generally evaluated from left to right. For multiple-table updates, there is no guarantee that assignments are carried out in any particular order.

If you set a column to the value it currently has, MySQL notices this and does not update it.

If you update a column that has been declared \texttt{NOT NULL} by setting to \texttt{NULL}, an error occurs if strict SQL mode is enabled; otherwise, the column is set to the implicit default value for the column data type and the warning count is incremented. The implicit default value is 0 for numeric types, the empty string (""") for string types, and the “zero” value for date and time types. See Section 13.6, “Data Type Default Values”.

If a generated column is updated explicitly, the only permitted value is \texttt{DEFAULT}. For information about generated columns, see Section 15.1.20.8, “CREATE TABLE and Generated Columns”.

\texttt{UPDATE} returns the number of rows that were actually changed. The \texttt{mysql\_info()} C API function returns the number of rows that were matched and updated and the number of warnings that occurred during the \texttt{UPDATE}.
You can use `LIMIT row_count` to restrict the scope of the `UPDATE`. A `LIMIT` clause is a rows-matched restriction. The statement stops as soon as it has found `row_count` rows that satisfy the `WHERE` clause, whether or not they actually were changed.

If an `UPDATE` statement includes an `ORDER BY` clause, the rows are updated in the order specified by the clause. This can be useful in certain situations that might otherwise result in an error. Suppose that a table `t` contains a column `id` that has a unique index. The following statement could fail with a duplicate-key error, depending on the order in which rows are updated:

```sql
UPDATE t SET id = id + 1;
```

For example, if the table contains 1 and 2 in the `id` column and 1 is updated to 2 before 2 is updated to 3, an error occurs. To avoid this problem, add an `ORDER BY` clause to cause the rows with larger `id` values to be updated before those with smaller values:

```sql
UPDATE t SET id = id + 1 ORDER BY id DESC;
```

You can also perform `UPDATE` operations covering multiple tables. However, you cannot use `ORDER BY` or `LIMIT` with a multiple-table `UPDATE`. The `table_references` clause lists the tables involved in the join. Its syntax is described in Section 15.2.13.2, "JOIN Clause". Here is an example:

```sql
UPDATE items,month SET items.price=month.price
WHERE items.id=month.id;
```

The preceding example shows an inner join that uses the comma operator, but multiple-table `UPDATE` statements can use any type of join permitted in `SELECT` statements, such as `LEFT JOIN`.

If you use a multiple-table `UPDATE` statement involving InnoDB tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, update a single table and rely on the `ON UPDATE` capabilities that InnoDB provides to cause the other tables to be modified accordingly. See Section 15.1.20.5, "FOREIGN KEY Constraints".

You cannot update a table and select directly from the same table in a subquery. You can work around this by using a multi-table update in which one of the tables is derived from the table that you actually wish to update, and referring to the derived table using an alias. Suppose you wish to update a table named `items` which is defined using the statement shown here:

```sql
CREATE TABLE items (
    id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    wholesale DECIMAL(6,2) NOT NULL DEFAULT 0.00,
    retail DECIMAL(6,2) NOT NULL DEFAULT 0.00,
    quantity BIGINT NOT NULL DEFAULT 0
);
```

To reduce the retail price of any items for which the markup is 30% or greater and of which you have fewer than one hundred in stock, you might try to use an `UPDATE` statement such as the one following, which uses a subquery in the `WHERE` clause. As shown here, this statement does not work:

```sql
mysql> UPDATE items
    -> SET retail = retail * 0.9
    -> WHERE id IN
    -> (SELECT id FROM items
    -> WHERE retail / wholesale >= 1.3 AND quantity > 100);
ERROR 1093 (HY000): You can't specify target table 'items' for update in FROM clause
```

Instead, you can employ a multi-table update in which the subquery is moved into the list of tables to be updated, using an alias to reference it in the outermost `WHERE` clause, like this:

```sql
UPDATE items,
    (SELECT id FROM items
    WHERE id IN
    (SELECT id FROM items
    WHERE retail / wholesale >= 1.3 AND quantity > 100)))
```

You cannot update a table and select directly from the same table in a subquery. You can work around this by using a multi-table update in which one of the tables is derived from the table that you actually wish to update, and referring to the derived table using an alias. Suppose you wish to update a table named `items` which is defined using the statement shown here:
WHERE retail / wholesale >= 1.3 AND quantity < 100))
AS discounted
SET items.retail = items.retail * 0.9
WHERE items.id = discounted.id;

Because the optimizer tries by default to merge the derived table discounted into the outermost query block, this works only if you force materialization of the derived table. You can do this by setting the derived_merge flag of the optimizer_switch system variable to off before running the update, or by using the NO_MERGE optimizer hint, as shown here:

UPDATE /*+ NO_MERGE(discounted) */ items,
(SELECT id FROM items
  WHERE retail / wholesale >= 1.3 AND quantity < 100)
AS discounted
SET items.retail = items.retail * 0.9
WHERE items.id = discounted.id;

The advantage of using the optimizer hint in such a case is that it applies only within the query block where it is used, so that it is not necessary to change the value of optimizer_switch again after executing the UPDATE.

Another possibility is to rewrite the subquery so that it does not use IN or EXISTS, like this:

UPDATE items,
(SELECT id, retail / wholesale AS markup, quantity FROM items)
AS discounted
SET items.retail = items.retail * 0.9
WHERE discounted.markup >= 1.3
  AND discounted.quantity < 100
  AND items.id = discounted.id;

In this case, the subquery is materialized by default rather than merged, so it is not necessary to disable merging of the derived table.

15.2.18 UNION Clause

```
query_expression_body UNION [ALL | DISTINCT] query_block
  UNION [ALL | DISTINCT] query_expression_body
[...
```

UNION combines the result from multiple query blocks into a single result set. This example uses SELECT statements:

```
mysql> SELECT 1, 2;
+---+---+
| 1 | 2 |
|---+---|
+---+---+
mysql> SELECT 'a', 'b';
+---+---+
| a | b |
|---+---|
+---+---+
mysql> SELECT 1, 2 UNION SELECT 'a', 'b';
+---+---+
| 1 | 2 |
|---+---|
+---+---+
```

15.2.19 VALUES Statement
VALUES is a DML statement which returns a set of one or more rows as a table. In other words, it is a table value constructor which also functions as a standalone SQL statement.

VALUES row_constructor_list [ORDER BY column_designator] [LIMIT number]

row_constructor_list:
   ROW(value_list), ROW(value_list)][, ...]
value_list:
   value[, value][, ...]
column_designator:
   column_index

The VALUES statement consists of the VALUES keyword followed by a list of one or more row constructors, separated by commas. A row constructor consists of the ROW() row constructor clause with a value list of one or more scalar values enclosed in the parentheses. A value can be a literal of any MySQL data type or an expression that resolves to a scalar value.

ROW() cannot be empty (but each of the supplied scalar values can be NULL). Each ROW() in the same VALUES statement must have the same number of values in its value list.

The DEFAULT keyword is not supported by VALUES and causes a syntax error, except when it is used to supply values in an INSERT statement.

The output of VALUES is a table:

```
mysql> VALUES ROW(1,-2,3), ROW(5,7,9), ROW(4,6,8);
+----------+----------+----------+
| column_0 | column_1 | column_2 |
+----------+----------+----------+
|        1 |       -2 |        3 |
|        5 |        7 |        9 |
|        4 |        6 |        8 |
+----------+----------+----------+
3 rows in set (0.00 sec)
```

The columns of the table output from VALUES have the implicitly named columns column_0, column_1, column_2, and so on, always beginning with 0. This fact can be used to order the rows by column using an optional ORDER BY clause in the same way that this clause works with a SELECT statement, as shown here:

```
mysql> VALUES ROW(1,-2,3), ROW(5,7,9), ROW(4,6,8) ORDER BY column_1;
+----------+----------+----------+
| column_0 | column_1 | column_2 |
+----------+----------+----------+
|        1 |       -2 |        3 |
|        4 |        6 |        8 |
|        5 |        7 |        9 |
+----------+----------+----------+
3 rows in set (0.00 sec)
```

VALUES statement also supports a LIMIT clause for limiting the number of rows in the output.

The VALUES statement is permissive regarding data types of column values; you can mix types within the same column, as shown here:

```
mysql> VALUES ROW("q", 42, '2019-12-18'),
   ->   ROW(23, "abc", 98.6),
   ->   ROW(27.0002, "Mary Smith", '{"a": 10, "b": 25}');
+----------+------------+--------------------+
| column_0 | column_1   | column_2           |
+----------+------------+--------------------+
|    q     |          42 | 2019-12-18         |
|        23 |        abc |         98.6       |
+----------+------------+--------------------+
```
VALUES Statement

Important

VALUES with one or more instances of ROW() acts as a table value constructor; although it can be used to supply values in an INSERT or REPLACE statement, do not confuse it with the VALUES keyword that is also used for this purpose. You should also not confuse it with the VALUES() function that refers to column values in INSERT ... ON DUPLICATE KEY UPDATE.

You should also bear in mind that ROW() is a row value constructor (see Section 15.2.15.5, “Row Subqueries”), whereas VALUES ROW() is a table value constructor; the two cannot be used interchangeably.

VALUES can be used in many cases where you could employ SELECT, including those listed here:

• With UNION, as shown here:

```
mysql> SELECT 1,2 UNION SELECT 10,15;
+----+----+
| 1  | 2  |
| 10 | 15 |
+----+----+
2 rows in set (0.00 sec)
```

```
mysql> VALUES ROW(1,2) UNION VALUES ROW(10,15);
+----------+----------+
| column_0 | column_1 |
|        1 |        2 |
|        10|       15 |
+----------+----------+
2 rows in set (0.00 sec)
```

You can union together constructed tables having more than one row, like this:

```
mysql> VALUES ROW(1,2), ROW(3,4), ROW(5,6) > UNION VALUES ROW(10,15),ROW(20,25);
+----------+----------+
| column_0 | column_1 |
|        1 |        2 |
|        3 |        4 |
|        5 |        6 |
|        10|       15 |
|       20 |       25 |
+----------+----------+
5 rows in set (0.00 sec)
```

You can also (and it is usually preferable to) omit UNION altogether in such cases and use a single VALUES statement, like this:

```
mysql> VALUES ROW(1,2), ROW(3,4), ROW(5,6), ROW(10,15), ROW(20,25);
+----------+----------+
| column_0 | column_1 |
|        1 |        2 |
|        3 |        4 |
|        5 |        6 |
|        10|       15 |
|       20 |       25 |
+----------+----------+
```

VALUES can also be used in unions with SELECT statements, TABLE statements, or both.

2642
The constructed tables in the \textit{UNION} must contain the same number of columns, just as if you were using \textit{SELECT}. See Section 15.2.18, “\textit{UNION} Clause”, for further examples.

You can use \textit{EXCEPT} and \textit{INTERSECT} with \textit{VALUES} in much the same way as \textit{UNION}, as shown here:

\begin{verbatim}
mysql> VALUES ROW(1,2), ROW(3,4), ROW(5,6)
  -> INTERSECT
  -> VALUES ROW(10,15), ROW(20,25), ROW(3,4);
+----------+----------+
<table>
<thead>
<tr>
<th>column_0</th>
<th>column_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>4</td>
</tr>
</tbody>
</table>
+----------+----------+
1 row in set (0.00 sec)

mysql> VALUES ROW(1,2), ROW(3,4), ROW(5,6)
  -> EXCEPT
  -> VALUES ROW(10,15), ROW(20,25), ROW(3,4);
+----------+----------+
<table>
<thead>
<tr>
<th>column_0</th>
<th>column_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>5</td>
<td>6</td>
</tr>
</tbody>
</table>
+----------+----------+
2 rows in set (0.00 sec)
\end{verbatim}

See Section 15.2.4, “\textit{EXCEPT} Clause”, and Section 15.2.8, “\textit{INTERSECT} Clause”, for more information.

\begin{itemize}
  \item In joins. See Section 15.2.13.2, “\textit{JOIN} Clause”, for more information and examples.
  \item In place of \textit{VALUES()} in an \textit{INSERT} or \textit{REPLACE} statement, in which case its semantics differ slightly from what is described here. See Section 15.2.7, “\textit{INSERT} Statement”, for details.
  \item In place of the source table in \textit{CREATE TABLE ... SELECT} and \textit{CREATE VIEW ... SELECT}. See the descriptions of these statements for more information and examples.
\end{itemize}

15.2.20 \textit{WITH} (Common Table Expressions)

A common table expression (CTE) is a named temporary result set that exists within the scope of a single statement and that can be referred to later within that statement, possibly multiple times. The following discussion describes how to write statements that use CTEs.

\begin{itemize}
  \item Common Table Expressions
  \item Recursive Common Table Expressions
  \item Limiting Common Table Expression Recursion
  \item Recursive Common Table Expression Examples
  \item Common Table Expressions Compared to Similar Constructs
\end{itemize}

For information about CTE optimization, see Section 10.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”.

\textbf{Common Table Expressions}

To specify common table expressions, use a \textit{WITH} clause that has one or more comma-separated subclauses. Each subclause provides a subquery that produces a result set, and associates a name with the subquery. The following example defines CTEs named cte1 and cte2 in the \textit{WITH} clause, and refers to them in the top-level \textit{SELECT} that follows the \textit{WITH} clause:
WITH (Common Table Expressions)

WITH
  cte1 AS (SELECT a, b FROM table1),
  cte2 AS (SELECT c, d FROM table2)
SELECT b, d FROM cte1 JOIN cte2
WHERE cte1.a = cte2.c;

In the statement containing the WITH clause, each CTE name can be referenced to access the corresponding CTE result set.

A CTE name can be referenced in other CTEs, enabling CTEs to be defined based on other CTEs.

A CTE can refer to itself to define a recursive CTE. Common applications of recursive CTEs include series generation and traversal of hierarchical or tree-structured data.

Common table expressions are an optional part of the syntax for DML statements. They are defined using a WITH clause:

```
with_clause:
  WITH [RECURSIVE]
    cte_name [(col_name [, col_name] ...)] AS (subquery)
      [, cte_name [(col_name [, col_name] ...)] AS (subquery)] ...
```

cte_name names a single common table expression and can be used as a table reference in the statement containing the WITH clause.

The subquery part of AS (subquery) is called the “subquery of the CTE” and is what produces the CTE result set. The parentheses following AS are required.

A common table expression is recursive if its subquery refers to its own name. The RECURSIVE keyword must be included if any CTE in the WITH clause is recursive. For more information, see Recursive Common Table Expressions.

Determination of column names for a given CTE occurs as follows:

• If a parenthesized list of names follows the CTE name, those names are the column names:

```
WITH cte (col1, col2) AS
  (SELECT 1, 2
    UNION ALL
    SELECT 3, 4)
SELECT col1, col2 FROM cte;
```

The number of names in the list must be the same as the number of columns in the result set.

• Otherwise, the column names come from the select list of the first SELECT within the AS (subquery) part:

```
WITH cte AS
  (SELECT 1 AS col1, 2 AS col2
    UNION ALL
    SELECT 3, 4)
SELECT col1, col2 FROM cte;
```

A WITH clause is permitted in these contexts:

• At the beginning of SELECT, UPDATE, and DELETE statements.

```
WITH ... SELECT ...
WITH ... UPDATE ...
WITH ... DELETE ...
```

• At the beginning of subqueries (including derived table subqueries):
WITH (Common Table Expressions)

SELECT ... WHERE id IN (WITH ... SELECT ...) ...
SELECT * FROM (WITH ... SELECT ...) AS dt ...

• Immediately preceding SELECT for statements that include a SELECT statement:

INSERT ... WITH ... SELECT ...
REPLACE ... WITH ... SELECT ...
CREATE TABLE ... WITH ... SELECT ...
CREATE VIEW ... WITH ... SELECT ...
DECLARE CURSOR ... WITH ... SELECT ...
EXPLAIN ... WITH ... SELECT ...

Only one WITH clause is permitted at the same level. WITH followed by WITH at the same level is not permitted, so this is illegal:

WITH cte1 AS (...) WITH cte2 AS (...) SELECT ...

To make the statement legal, use a single WITH clause that separates the subclauses by a comma:

WITH cte1 AS (...), cte2 AS (...) SELECT ...

However, a statement can contain multiple WITH clauses if they occur at different levels:

WITH cte1 AS (SELECT 1)
SELECT * FROM (WITH cte2 AS (SELECT 2) SELECT * FROM cte2 JOIN cte1) AS dt;

A WITH clause can define one or more common table expressions, but each CTE name must be unique to the clause. This is illegal:

WITH cte1 AS (...), cte1 AS (...) SELECT ...

To make the statement legal, define the CTEs with unique names:

WITH cte1 AS (...), cte2 AS (...) SELECT ...

A CTE can refer to itself or to other CTEs:

• A self-referencing CTE is recursive.

• A CTE can refer to CTEs defined earlier in the same WITH clause, but not those defined later.

This constraint rules out mutually-recursive CTEs, where cte1 references cte2 and cte2 references cte1. One of those references must be to a CTE defined later, which is not permitted.

• A CTE in a given query block can refer to CTEs defined in query blocks at a more outer level, but not CTEs defined in query blocks at a more inner level.

For resolving references to objects with the same names, derived tables hide CTEs; and CTEs hide base tables, TEMPORARY tables, and views. Name resolution occurs by searching for objects in the same query block, then proceeding to outer blocks in turn while no object with the name is found.

For additional syntax considerations specific to recursive CTEs, see Recursive Common Table Expressions.

Recursive Common Table Expressions

A recursive common table expression is one having a subquery that refers to its own name. For example:

WITH RECURSIVE cte (n) AS
  (SELECT 1
   UNION ALL
WITH (Common Table Expressions)

```
SELECT n + 1 FROM cte WHERE n < 5
)
SELECT * FROM cte;
```

When executed, the statement produces this result, a single column containing a simple linear sequence:

```
+----+
| n  |
+----+
| 1  |
| 2  |
| 3  |
| 4  |
| 5  |
+----+
```

A recursive CTE has this structure:

- The `WITH` clause must begin with `WITH RECURSIVE` if any CTE in the `WITH` clause refers to itself. (If no CTE refers to itself, `RECURSIVE` is permitted but not required.)

  If you forget `RECURSIVE` for a recursive CTE, this error is a likely result:

  ```
  ERROR 1146 (42S02): Table 'cte_name' doesn't exist
  ```

- The recursive CTE subquery has two parts, separated by `UNION ALL` or `UNION [DISTINCT]`:

  ```
  SELECT ...  -- return initial row set
  UNION ALL
  SELECT ...  -- return additional row sets
  ```

  The first `SELECT` produces the initial row or rows for the CTE and does not refer to the CTE name. The second `SELECT` produces additional rows and recurses by referring to the CTE name in its `FROM` clause. Recursion ends when this part produces no new rows. Thus, a recursive CTE consists of a nonrecursive `SELECT` part followed by a recursive `SELECT` part.

  Each `SELECT` part can itself be a union of multiple `SELECT` statements.

  - The types of the CTE result columns are inferred from the column types of the nonrecursive `SELECT` part only, and the columns are all nullable. For type determination, the recursive `SELECT` part is ignored.

  - If the nonrecursive and recursive parts are separated by `UNION DISTINCT`, duplicate rows are eliminated. This is useful for queries that perform transitive closures, to avoid infinite loops.

  - Each iteration of the recursive part operates only on the rows produced by the previous iteration. If the recursive part has multiple query blocks, iterations of each query block are scheduled in unspecified order, and each query block operates on rows that have been produced either by its previous iteration or by other query blocks since that previous iteration's end.

  The recursive CTE subquery shown earlier has this nonrecursive part that retrieves a single row to produce the initial row set:

  ```
  SELECT 1
  ```

  The CTE subquery also has this recursive part:

  ```
  SELECT n + 1 FROM cte WHERE n < 5
  ```

  At each iteration, that `SELECT` produces a row with a new value one greater than the value of `n` from the previous row set. The first iteration operates on the initial row set (1) and produces 1+1=2; the second iteration operates on the first iteration's row set (2) and produces 2+1=3; and so forth. This continues until recursion ends, which occurs when `n` is no longer less than 5.
If the recursive part of a CTE produces wider values for a column than the nonrecursive part, it may be necessary to widen the column in the nonrecursive part to avoid data truncation. Consider this statement:

```sql
WITH RECURSIVE cte AS
  (
    SELECT 1 AS n, 'abc' AS str
    UNION ALL
    SELECT n + 1, CONCAT(str, str) FROM cte WHERE n < 3
  )
SELECT * FROM cte;
```

In nonstrict SQL mode, the statement produces this output:

```
+------+------+
| n    | str  |
+------+------+
|    1 | abc  |
|    2 | abc  |
|    3 | abc  |
+------+------+
```

The `str` column values are all `'abc'` because the nonrecursive `SELECT` determines the column widths. Consequently, the wider `str` values produced by the recursive `SELECT` are truncated.

In strict SQL mode, the statement produces an error:

```
ERROR 1406 (22001): Data too long for column 'str' at row 1
```

To address this issue, so that the statement does not produce truncation or errors, use `CAST()` in the nonrecursive `SELECT` to make the `str` column wider:

```sql
WITH RECURSIVE cte AS
  (
    SELECT 1 AS n, CAST('abc' AS CHAR(20)) AS str
    UNION ALL
    SELECT n + 1, CONCAT(str, str) FROM cte WHERE n < 3
  )
SELECT * FROM cte;
```

Now the statement produces this result, without truncation:

```
+-----+--------------+
| n   | str          |
+-----+--------------+
|    1| abc          |
|    2| abcabc       |
|    3| abcabcabcabc |
+-----+--------------+
```

Columns are accessed by name, not position, which means that columns in the recursive part can access columns in the nonrecursive part that have a different position, as this CTE illustrates:

```sql
WITH RECURSIVE cte AS
  (
    SELECT 1 AS n, 1 AS p, -1 AS q
    UNION ALL
    SELECT n + 1, q * 2, p * 2 FROM cte WHERE n < 5
  )
SELECT * FROM cte;
```

Because `p` in one row is derived from `q` in the previous row, and vice versa, the positive and negative values swap positions in each successive row of the output:

```
+------+------+------+
| n   | p    | q    |
+------+------+------+
|    1| 1    | -1   |
|    2| -2   |  2   |
+------+------+------+
```
WITH (Common Table Expressions)

Some syntax constraints apply within recursive CTE subqueries:

- The recursive SELECT part must not contain these constructs:
  - Aggregate functions such as `SUM()`
  - Window functions
  - `GROUP BY`
  - `ORDER BY`
  - `DISTINCT`

The recursive SELECT part of a recursive CTE can also use a `LIMIT` clause, along with an optional `OFFSET` clause. The effect on the result set is the same as when using `LIMIT` in the outermost SELECT, but is also more efficient, since using it with the recursive SELECT stops the generation of rows as soon as the requested number of them has been produced.

The prohibition on `DISTINCT` applies only to `UNION` members; `UNION DISTINCT` is permitted.

- The recursive SELECT part must reference the CTE only once and only in its `FROM` clause, not in any subquery. It can reference tables other than the CTE and join them with the CTE. If used in a join like this, the CTE must not be on the right side of a `LEFT JOIN`.

These constraints come from the SQL standard, other than the MySQL-specific exclusions mentioned previously.

For recursive CTEs, `EXPLAIN` output rows for recursive SELECT parts display `Recursive` in the Extra column.

Cost estimates displayed by `EXPLAIN` represent cost per iteration, which might differ considerably from total cost. The optimizer cannot predict the number of iterations because it cannot predict at what point the `WHERE` clause becomes false.

CTE actual cost may also be affected by result set size. A CTE that produces many rows may require an internal temporary table large enough to be converted from in-memory to on-disk format and may suffer a performance penalty. If so, increasing the permitted in-memory temporary table size may improve performance; see Section 10.4.4, “Internal Temporary Table Use in MySQL”.

### Limiting Common Table Expression Recursion

It is important for recursive CTEs that the recursive SELECT part include a condition to terminate recursion. As a development technique to guard against a runaway recursive CTE, you can force termination by placing a limit on execution time:

- The `cte_max_recursion_depth` system variable enforces a limit on the number of recursion levels for CTEs. The server terminates execution of any CTE that recurses more levels than the value of this variable.

- The `max_execution_time` system variable enforces an execution timeout for SELECT statements executed within the current session.

- The `MAX_EXECUTION_TIME` optimizer hint enforces a per-query execution timeout for the SELECT statement in which it appears.

Suppose that a recursive CTE is mistakenly written with no recursion execution termination condition:
WITH RECURSIVE cte (n) AS
{
    SELECT 1
    UNION ALL
    SELECT n + 1 FROM cte
}
SELECT * FROM cte;

By default, `cte_max_recursion_depth` has a value of 1000, causing the CTE to terminate when it recurses past 1000 levels. Applications can change the session value to adjust for their requirements:

```sql
SET SESSION cte_max_recursion_depth = 10; -- permit only shallow recursion
SET SESSION cte_max_recursion_depth = 1000000; -- permit deeper recursion
```

You can also set the global `cte_max_recursion_depth` value to affect all sessions that begin subsequently.

For queries that execute and thus recurse slowly or in contexts for which there is reason to set the `cte_max_recursion_depth` value very high, another way to guard against deep recursion is to set a per-session timeout. To do so, execute a statement like this prior to executing the CTE statement:

```sql
SET max_execution_time = 1000; -- impose one second timeout
```

Alternatively, include an optimizer hint within the CTE statement itself:

```sql
WITH RECURSIVE cte (n) AS
{
    SELECT 1
    UNION ALL
    SELECT n + 1 FROM cte
} /*+ SET_VAR(cte_max_recursion_depth = 1M) */
SELECT * FROM cte;
```

You can also use `LIMIT` within the recursive query to impose a maximum number of rows to be returned to the outermost `SELECT`, for example:

```sql
WITH RECURSIVE cte (n) AS
{
    SELECT 1
    UNION ALL
    SELECT n + 1 FROM cte LIMIT 10000
}
SELECT * FROM cte;
```

You can do this in addition to or instead of setting a time limit. Thus, the following CTE terminates after returning ten thousand rows or running for one second (1000 milliseconds), whichever occurs first:

```sql
WITH RECURSIVE cte (n) AS
{
    SELECT 1
    UNION ALL
    SELECT n + 1 FROM cte LIMIT 10000
} /*+ MAX_EXECUTION_TIME(1000) */
SELECT * FROM cte;
```

If a recursive query without an execution time limit enters an infinite loop, you can terminate it from another session using `KILL QUERY`. Within the session itself, the client program used to run the query might provide a way to kill the query. For example, in `mysql`, typing `Control+C` interrupts the current statement.
Recursive Common Table Expression Examples

As mentioned previously, recursive common table expressions (CTEs) are frequently used for series generation and traversing hierarchical or tree-structured data. This section shows some simple examples of these techniques.

- Fibonacci Series Generation
- Date Series Generation
- Hierarchical Data Traversal

Fibonacci Series Generation

A Fibonacci series begins with the two numbers 0 and 1 (or 1 and 1) and each number after that is the sum of the previous two numbers. A recursive common table expression can generate a Fibonacci series if each row produced by the recursive SELECT has access to the two previous numbers from the series. The following CTE generates a 10-number series using 0 and 1 as the first two numbers:

```sql
WITH RECURSIVE fibonacci (n, fib_n, next_fib_n) AS
(
  SELECT 1, 0, 1
  UNION ALL
  SELECT n + 1, next_fib_n, fib_n + next_fib_n
  FROM fibonacci WHERE n < 10
)
SELECT * FROM fibonacci;
```

The CTE produces this result:

```
<table>
<thead>
<tr>
<th>n</th>
<th>fib_n</th>
<th>next_fib_n</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>5</td>
<td>3</td>
<td>5</td>
</tr>
<tr>
<td>6</td>
<td>5</td>
<td>8</td>
</tr>
<tr>
<td>7</td>
<td>8</td>
<td>13</td>
</tr>
<tr>
<td>8</td>
<td>13</td>
<td>21</td>
</tr>
<tr>
<td>9</td>
<td>21</td>
<td>34</td>
</tr>
<tr>
<td>10</td>
<td>34</td>
<td>55</td>
</tr>
</tbody>
</table>
```

How the CTE works:

- `n` is a display column to indicate that the row contains the `n`-th Fibonacci number. For example, the 8th Fibonacci number is 13.
- The `fib_n` column displays Fibonacci number `n`.
- The `next_fib_n` column displays the next Fibonacci number after number `n`. This column provides the next series value to the next row, so that row can produce the sum of the two previous series values in its `fib_n` column.
- Recursion ends when `n` reaches 10. This is an arbitrary choice, to limit the output to a small set of rows.

The preceding output shows the entire CTE result. To select just part of it, add an appropriate `WHERE` clause to the top-level `SELECT`. For example, to select the 8th Fibonacci number, do this:

```sql
mysql> WITH RECURSIVE fibonacci ... 
... 
  SELECT fib_n FROM fibonacci WHERE n = 8;
+-------+
<table>
<thead>
<tr>
<th>fib_n</th>
</tr>
</thead>
<tbody>
<tr>
<td>13</td>
</tr>
</tbody>
</table>
+-------+
```
Date Series Generation

A common table expression can generate a series of successive dates, which is useful for generating summaries that include a row for all dates in the series, including dates not represented in the summarized data.

Suppose that a table of sales numbers contains these rows:

```sql
mysql> SELECT * FROM sales ORDER BY date, price;
+------------+--------+
<table>
<thead>
<tr>
<th>date</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>2017-01-03</td>
<td>100.00</td>
</tr>
<tr>
<td>2017-01-03</td>
<td>200.00</td>
</tr>
<tr>
<td>2017-01-06</td>
<td>50.00</td>
</tr>
<tr>
<td>2017-01-08</td>
<td>10.00</td>
</tr>
<tr>
<td>2017-01-08</td>
<td>20.00</td>
</tr>
<tr>
<td>2017-01-08</td>
<td>150.00</td>
</tr>
<tr>
<td>2017-01-10</td>
<td>5.00</td>
</tr>
</tbody>
</table>
+------------+--------+
```

This query summarizes the sales per day:

```sql
mysql> SELECT date, SUM(price) AS sum_price
FROM sales
GROUP BY date
ORDER BY date;
+------------+-----------+
<table>
<thead>
<tr>
<th>date</th>
<th>sum_price</th>
</tr>
</thead>
<tbody>
<tr>
<td>2017-01-03</td>
<td>300.00</td>
</tr>
<tr>
<td>2017-01-06</td>
<td>50.00</td>
</tr>
<tr>
<td>2017-01-08</td>
<td>180.00</td>
</tr>
<tr>
<td>2017-01-10</td>
<td>5.00</td>
</tr>
</tbody>
</table>
+------------+-----------+
```

However, that result contains “holes” for dates not represented in the range of dates spanned by the table. A result that represents all dates in the range can be produced using a recursive CTE to generate that set of dates, joined with a LEFT JOIN to the sales data.

Here is the CTE to generate the date range series:

```sql
WITH RECURSIVE dates (date) AS
(  SELECT MIN(date) FROM sales
  UNION ALL
  SELECT date + INTERVAL 1 DAY FROM dates
  WHERE date + INTERVAL 1 DAY <= (SELECT MAX(date) FROM sales)
)
SELECT * FROM dates;
```

The CTE produces this result:

```sql
+------------+
<table>
<thead>
<tr>
<th>date</th>
</tr>
</thead>
<tbody>
<tr>
<td>2017-01-03</td>
</tr>
<tr>
<td>2017-01-04</td>
</tr>
<tr>
<td>2017-01-05</td>
</tr>
<tr>
<td>2017-01-06</td>
</tr>
<tr>
<td>2017-01-07</td>
</tr>
<tr>
<td>2017-01-08</td>
</tr>
<tr>
<td>2017-01-09</td>
</tr>
<tr>
<td>2017-01-10</td>
</tr>
</tbody>
</table>
+------------+
```
WITH (Common Table Expressions)

How the CTE works:

- The nonrecursive `SELECT` produces the lowest date in the date range spanned by the `sales` table.
- Each row produced by the recursive `SELECT` adds one day to the date produced by the previous row.
- Recursion ends after the dates reach the highest date in the date range spanned by the `sales` table.

Joining the CTE with a `LEFT JOIN` against the `sales` table produces the sales summary with a row for each date in the range:

```
WITH RECURSIVE dates (date) AS
  (
    SELECT MIN(date) FROM sales
    UNION ALL
    SELECT date + INTERVAL 1 DAY FROM dates
    WHERE date + INTERVAL 1 DAY <= (SELECT MAX(date) FROM sales)
  )
SELECT dates.date, COALESCE(SUM(price), 0) AS sum_price
FROM dates LEFT JOIN sales ON dates.date = sales.date
GROUP BY dates.date
ORDER BY dates.date;
```

The output looks like this:

<table>
<thead>
<tr>
<th>date</th>
<th>sum_price</th>
</tr>
</thead>
<tbody>
<tr>
<td>2017-01-03</td>
<td>300.00</td>
</tr>
<tr>
<td>2017-01-04</td>
<td>0.00</td>
</tr>
<tr>
<td>2017-01-05</td>
<td>0.00</td>
</tr>
<tr>
<td>2017-01-06</td>
<td>50.00</td>
</tr>
<tr>
<td>2017-01-07</td>
<td>0.00</td>
</tr>
<tr>
<td>2017-01-08</td>
<td>180.00</td>
</tr>
<tr>
<td>2017-01-09</td>
<td>0.00</td>
</tr>
<tr>
<td>2017-01-10</td>
<td>5.00</td>
</tr>
</tbody>
</table>

Some points to note:

- Are the queries inefficient, particularly the one with the `MAX()` subquery executed for each row in the recursive `SELECT`? `EXPLAIN` shows that the subquery containing `MAX()` is evaluated only once and the result is cached.
- The use of `COALESCE()` avoids displaying `NULL` in the `sum_price` column on days for which no sales data occur in the `sales` table.

**Hierarchical Data Traversal**

Recursive common table expressions are useful for traversing data that forms a hierarchy. Consider these statements that create a small data set that shows, for each employee in a company, the employee name and ID number, and the ID of the employee's manager. The top-level employee (the CEO), has a manager ID of `NULL` (no manager).

```
CREATE TABLE employees (id INT PRIMARY KEY NOT NULL,
    name VARCHAR(100) NOT NULL,
    manager_id INT NULL,
    INDEX (manager_id),
FOREIGN KEY (manager_id) REFERENCES employees (id) );
INSERT INTO employees VALUES
(333, "Yasmina", NULL),  # Yasmina is the CEO (manager_id is NULL)
(198, "John", 333),      # John has ID 198 and reports to 333 (Yasmina)
(692, "Tarek", 333),
(29, "Pedro", 198),
(4610, "Sarah", 29),
(72, "Pierre", 29),
```

2652
The resulting data set looks like this:

```
mysql> SELECT * FROM employees ORDER BY id;
+------+---------+------------+
<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>manager_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>29</td>
<td>Pedro</td>
<td>198</td>
</tr>
<tr>
<td>72</td>
<td>Pierre</td>
<td>29</td>
</tr>
<tr>
<td>123</td>
<td>Adil</td>
<td>692</td>
</tr>
<tr>
<td>198</td>
<td>John</td>
<td>333</td>
</tr>
<tr>
<td>333</td>
<td>Yasmina</td>
<td>NULL</td>
</tr>
<tr>
<td>692</td>
<td>Tarek</td>
<td>333</td>
</tr>
<tr>
<td>4610</td>
<td>Sarah</td>
<td>29</td>
</tr>
</tbody>
</table>
+------+---------+------------+
```

To produce the organizational chart with the management chain for each employee (that is, the path from CEO to employee), use a recursive CTE:

```sql
WITH RECURSIVE employee_paths (id, name, path) AS
(
  SELECT id, name, CAST(id AS CHAR(200))
  FROM employees
  WHERE manager_id IS NULL
  UNION ALL
  SELECT e.id, e.name, CONCAT(ep.path, ',', e.id)
  FROM employee_paths AS ep JOIN employees AS e
  ON ep.id = e.manager_id
)
SELECT * FROM employee_paths ORDER BY path;
```

The CTE produces this output:

```
+------+---------+-----------------+
<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>path</th>
</tr>
</thead>
<tbody>
<tr>
<td>333</td>
<td>Yasmina</td>
<td>333</td>
</tr>
<tr>
<td>198</td>
<td>John</td>
<td>333,198</td>
</tr>
<tr>
<td>29</td>
<td>Pedro</td>
<td>333,198,29</td>
</tr>
<tr>
<td>4610</td>
<td>Sarah</td>
<td>333,198,29,4610</td>
</tr>
<tr>
<td>72</td>
<td>Pierre</td>
<td>333,198,29,72</td>
</tr>
<tr>
<td>692</td>
<td>Tarek</td>
<td>333,692</td>
</tr>
<tr>
<td>123</td>
<td>Adil</td>
<td>333,692,123</td>
</tr>
</tbody>
</table>
+------+---------+-----------------+
```

How the CTE works:

- The nonrecursive `SELECT` produces the row for the CEO (the row with a `NULL` manager ID).
  - The `path` column is widened to `CHAR(200)` to ensure that there is room for the longer `path` values produced by the recursive `SELECT`.
- Each row produced by the recursive `SELECT` finds all employees who report directly to an employee produced by a previous row. For each such employee, the row includes the employee ID and name, and the employee management chain. The chain is the manager's chain, with the employee ID added to the end.
- Recursion ends when employees have no others who report to them.

To find the path for a specific employee or employees, add a `WHERE` clause to the top-level `SELECT`. For example, to display the results for Tarek and Sarah, modify that `SELECT` like this:

```
mysql> WITH RECURSIVE ... 
... 
  SELECT * FROM employees_extended 
  WHERE id IN (692, 4610) 
  ORDER BY path;
```

Common Table Expressions Compared to Similar Constructs

Common table expressions (CTEs) are similar to derived tables in some ways:

- Both constructs are named.
- Both constructs exist for the scope of a single statement.

Because of these similarities, CTEs and derived tables often can be used interchangeably. As a trivial example, these statements are equivalent:

```
WITH cte AS (SELECT 1) SELECT * FROM cte;
SELECT * FROM (SELECT 1) AS dt;
```

However, CTEs have some advantages over derived tables:

- A derived table can be referenced only a single time within a query. A CTE can be referenced multiple times. To use multiple instances of a derived table result, you must derive the result multiple times.
- A CTE can be self-referencing (recursive).
- One CTE can refer to another.
- A CTE may be easier to read when its definition appears at the beginning of the statement rather than embedded within it.

CTEs are similar to tables created with `CREATE [TEMPORARY] TABLE` but need not be defined or dropped explicitly. For a CTE, you need no privileges to create tables.

### 15.3 Transactional and Locking Statements

MySQL supports local transactions (within a given client session) through statements such as `SET autocommit`, `START TRANSACTION`, `COMMIT`, and `ROLLBACK`. See Section 15.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Statements”. XA transaction support enables MySQL to participate in distributed transactions as well. See Section 15.3.8, “XA Transactions”.

#### 15.3.1 START TRANSACTION, COMMIT, and ROLLBACK Statements

START TRANSACTION

```
[transaction_characteristic [, transaction_characteristic] ...]
```

`transaction_characteristic`: |
  WITH CONSISTENT SNAPSHOT
  | READ WRITE
  | READ ONLY

BEGIN [WORK]

COMMIT [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
ROLLBACK [WORK] [AND [NO] CHAIN] [[NO] RELEASE]

SET autocommit = {0 | 1}

These statements provide control over use of transactions:

- **START TRANSACTION** or **BEGIN** start a new transaction.
- **COMMIT** commits the current transaction, making its changes permanent.
- **ROLLBACK** rolls back the current transaction, canceling its changes.
• **SET autocommit** disables or enables the default autocommit mode for the current session.

By default, MySQL runs with autocommit mode enabled. This means that, when not otherwise inside a transaction, each statement is atomic, as if it were surrounded by `START TRANSACTION` and `COMMIT`. You cannot use `ROLLBACK` to undo the effect; however, if an error occurs during statement execution, the statement is rolled back.

To disable autocommit mode implicitly for a single series of statements, use the `START TRANSACTION` statement:

```
START TRANSACTION;
SELECT @A:=SUM(salary) FROM table1 WHERE type=1;
UPDATE table2 SET summary=@A WHERE type=1;
COMMIT;
```

With `START TRANSACTION`, autocommit remains disabled until you end the transaction with `COMMIT` or `ROLLBACK`. The autocommit mode then reverts to its previous state.

`START TRANSACTION` permits several modifiers that control transaction characteristics. To specify multiple modifiers, separate them by commas.

• The **WITH CONSISTENT SNAPSHOT** modifier starts a consistent read for storage engines that are capable of it. This applies only to InnoDB. The effect is the same as issuing a `START TRANSACTION` followed by a `SELECT` from any InnoDB table. See Section 17.7.2.3, “Consistent Nonlocking Reads”. The **WITH CONSISTENT SNAPSHOT** modifier does not change the current transaction isolation level, so it provides a consistent snapshot only if the current isolation level is one that permits a consistent read. The only isolation level that permits a consistent read is REPEATABLE READ. For all other isolation levels, the **WITH CONSISTENT SNAPSHOT** clause is ignored. A warning is generated when the **WITH CONSISTENT SNAPSHOT** clause is ignored.

• The **READ WRITE** and **READ ONLY** modifiers set the transaction access mode. They permit or prohibit changes to tables used in the transaction. The **READ ONLY** restriction prevents the transaction from modifying or locking both transactional and nontransactional tables that are visible to other transactions; the transaction can still modify or lock temporary tables.

MySQL enables extra optimizations for queries on InnoDB tables when the transaction is known to be read-only. Specifying **READ ONLY** ensures these optimizations are applied in cases where the read-only status cannot be determined automatically. See Section 10.5.3, “Optimizing InnoDB Read-Only Transactions” for more information.

If no access mode is specified, the default mode applies. Unless the default has been changed, it is read/write. It is not permitted to specify both **READ WRITE** and **READ ONLY** in the same statement.

In read-only mode, it remains possible to change tables created with the **TEMPORARY** keyword using DML statements. Changes made with DDL statements are not permitted, just as with permanent tables.

For additional information about transaction access mode, including ways to change the default mode, see Section 15.3.7, “SET TRANSACTION Statement”.

If the **read_only** system variable is enabled, explicitly starting a transaction with `START TRANSACTION READ WRITE` requires the **CONNECTION_ADMIN** privilege (or the deprecated **SUPER** privilege).

---

**Important**

Many APIs used for writing MySQL client applications (such as JDBC) provide their own methods for starting transactions that can (and sometimes should) be used instead of sending a `START TRANSACTION` statement from the client. See Chapter 31, *Connectors and APIs*, or the documentation for your API, for more information.
To disable autocommit mode explicitly, use the following statement:

```
SET autocommit=0;
```

After disabling autocommit mode by setting the `autocommit` variable to zero, changes to transaction-safe tables (such as those for InnoDB or NDB) are not made permanent immediately. You must use `COMMIT` to store your changes to disk or `ROLLBACK` to ignore the changes.

`autocommit` is a session variable and must be set for each session. To disable autocommit mode for each new connection, see the description of the `autocommit` system variable at Section 7.1.8, “Server System Variables”.

`BEGIN` and `BEGIN WORK` are supported as aliases of `START TRANSACTION` for initiating a transaction. `START TRANSACTION` is standard SQL syntax, is the recommended way to start an ad-hoc transaction, and permits modifiers that `BEGIN` does not.

The `BEGIN` statement differs from the use of the `BEGIN` keyword that starts a `BEGIN ... END` compound statement. The latter does not begin a transaction. See Section 15.6.1, “BEGIN ... END Compound Statement”.

**Note**

Within all stored programs (stored procedures and functions, triggers, and events), the parser treats `BEGIN [WORK]` as the beginning of a `BEGIN ... END` block. Begin a transaction in this context with `START TRANSACTION` instead.

The optional `WORK` keyword is supported for `COMMIT` and `ROLLBACK`, as are the `CHAIN` and `RELEASE` clauses. `CHAIN` and `RELEASE` can be used for additional control over transaction completion. The value of the `completion_type` system variable determines the default completion behavior. See Section 7.1.8, “Server System Variables”.

The `AND CHAIN` clause causes a new transaction to begin as soon as the current one ends, and the new transaction has the same isolation level as the just-terminated transaction. The new transaction also uses the same access mode (READ WRITE or READ ONLY) as the just-terminated transaction. The `RELEASE` clause causes the server to disconnect the current client session after terminating the current transaction. Including the `NO` keyword suppresses `CHAIN` or `RELEASE` completion, which can be useful if the `completion_type` system variable is set to cause chaining or release completion by default.

Beginning a transaction causes any pending transaction to be committed. See Section 15.3.3, “Statements That Cause an Implicit Commit”, for more information.

Beginning a transaction also causes table locks acquired with `LOCK TABLES` to be released, as though you had executed `UNLOCK TABLES`. Beginning a transaction does not release a global read lock acquired with `FLUSH TABLES WITH READ LOCK`.

For best results, transactions should be performed using only tables managed by a single transaction-safe storage engine. Otherwise, the following problems can occur:

- If you use tables from more than one transaction-safe storage engine (such as InnoDB), and the transaction isolation level is not `SERIALIZABLE`, it is possible that when one transaction commits, another ongoing transaction that uses the same tables sees only some of the changes made by the first transaction. That is, the atomicity of transactions is not guaranteed with mixed engines and inconsistencies can result. (If mixed-engine transactions are infrequent, you can use `SET TRANSACTION ISOLATION LEVEL` to set the isolation level to `SERIALIZABLE` on a per-transaction basis as necessary.)
- If you use tables that are not transaction-safe within a transaction, changes to those tables are stored at once, regardless of the status of autocommit mode.
Statements That Cannot Be Rolled Back

- If you issue a ROLLBACK statement after updating a nontransactional table within a transaction, an ER_WARNING_NOT_COMPLETE_ROLLBACK warning occurs. Changes to transaction-safe tables are rolled back, but not changes to nontransactional-safe tables.

Each transaction is stored in the binary log in one chunk, upon COMMIT. Transactions that are rolled back are not logged. (Exception: Modifications to nontransactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to nontransactional tables, the entire transaction is logged with a ROLLBACK statement at the end to ensure that modifications to the nontransactional tables are replicated.) See Section 7.4.4, “The Binary Log”.

You can change the isolation level or access mode for transactions with the SET TRANSACTION statement. See Section 15.3.7, “SET TRANSACTION Statement”.

Rolling back can be a slow operation that may occur implicitly without the user having explicitly asked for it (for example, when an error occurs). Because of this, SHOW PROCESSLIST displays Rolling back in the State column for the session, not only for explicit rollbacks performed with the ROLLBACK statement but also for implicit rollbacks.

Note
In MySQL 8.4, BEGIN, COMMIT, and ROLLBACK are not affected by --replicate-do-db or --replicate-ignore-db rules.

When InnoDB performs a complete rollback of a transaction, all locks set by the transaction are released. If a single SQL statement within a transaction rolls back as a result of an error, such as a duplicate key error, locks set by the statement are preserved while the transaction remains active. This happens because InnoDB stores row locks in a format such that it cannot know afterward which lock was set by which statement.

If a SELECT statement within a transaction calls a stored function, and a statement within the stored function fails, that statement rolls back. If ROLLBACK is executed for the transaction subsequently, the entire transaction rolls back.

15.3.2 Statements That Cannot Be Rolled Back

Some statements cannot be rolled back. In general, these include data definition language (DDL) statements, such as those that create or drop databases, those that create, drop, or alter tables or stored routines.

You should design your transactions not to include such statements. If you issue a statement early in a transaction that cannot be rolled back, and then another statement later fails, the full effect of the transaction cannot be rolled back in such cases by issuing a ROLLBACK statement.

15.3.3 Statements That Cause an Implicit Commit

The statements listed in this section (and any synonyms for them) implicitly end any transaction active in the current session, as if you had done a COMMIT before executing the statement.

Most of these statements also cause an implicit commit after executing. The intent is to handle each such statement in its own special transaction. Transaction-control and locking statements are exceptions: If an implicit commit occurs before execution, another does not occur after.

- Data definition language (DDL) statements that define or modify database objects. ALTER EVENT, ALTER FUNCTION, ALTER PROCEDURE, ALTER SERVER, ALTER TABLE, ALTER TABLESPACE, ALTER VIEW, CREATE DATABASE, CREATE EVENT, CREATE FUNCTION, CREATE INDEX, CREATE PROCEDURE, CREATE ROLE, CREATE SERVER, CREATE SPATIAL REFERENCE SYSTEM, CREATE TABLE, CREATE TABLESPACE, CREATE TRIGGER, CREATE VIEW, DROP DATABASE, DROP EVENT, DROP FUNCTION, DROP INDEX, DROP PROCEDURE, DROP ROLE, DROP SERVER, DROP SPATIAL REFERENCE SYSTEM, DROP TABLE, DROP TABLESPACE, DROP
SAVEPOINT, ROLLBACK TO SAVEPOINT, and RELEASE SAVEPOINT Statements

CREATE TABLE and DROP TABLE statements do not commit a transaction if the TEMPORARY keyword is used. (This does not apply to other operations on temporary tables such as ALTER TABLE and CREATE INDEX, which do cause a commit.) However, although no implicit commit occurs, neither can the statement be rolled back, which means that the use of such statements causes transactional atomicity to be violated. For example, if you use CREATE TEMPORARY TABLE and then roll back the transaction, the table remains in existence.

The CREATE TABLE statement in InnoDB is processed as a single transaction. This means that a ROLLBACK from the user does not undo CREATE TABLE statements the user made during that transaction.

CREATE TABLE ... SELECT causes an implicit commit before and after the statement is executed when you are creating nontemporary tables. (No commit occurs for CREATE TEMPORARY TABLE ... SELECT.)

- Statements that implicitly use or modify tables in the mysql database. ALTER USER, CREATE USER, DROP USER, GRANT, RENAME USER, REVOKE, SET PASSWORD.
- Transaction-control and locking statements. BEGIN, LOCK TABLES, SET autocommit = 1 (if the value is not already 1), START TRANSACTION, UNLOCK TABLES.

UNLOCK TABLES commits a transaction only if any tables currently have been locked with LOCK TABLES to acquire nontransactional table locks. A commit does not occur for UNLOCK TABLES following FLUSH TABLES WITH READ LOCK because the latter statement does not acquire table-level locks.

Transactions cannot be nested. This is a consequence of the implicit commit performed for any current transaction when you issue a START TRANSACTION statement or one of its synonyms.

Statements that cause an implicit commit cannot be used in an XA transaction while the transaction is in an ACTIVE state.

The BEGIN statement differs from the use of the BEGIN keyword that starts a BEGIN ... END compound statement. The latter does not cause an implicit commit. See Section 15.6.1, “BEGIN ... END Compound Statement”.

- Data loading statements. LOAD DATA. LOAD DATA causes an implicit commit only for tables using the NDB storage engine.
- Administrative statements. ANALYZE TABLE, CACHE INDEX, CHECK TABLE, FLUSH, LOAD INDEX INTO CACHE, OPTIMIZE TABLE, REPAIR TABLE, RESET (but not RESET PERSIST).
- Replication control statements. START REPLICA, STOP REPLICA, RESET REPLICA, CHANGE REPLICA SOURCE TO.

15.3.4 SAVEPOINT, ROLLBACK TO SAVEPOINT, and RELEASE SAVEPOINT Statements

SAVEPOINT identifier
ROLLBACK [WORK] TO [SAVEPOINT] identifier
RELEASE SAVEPOINT identifier

InnoDB supports the SQL statements SAVEPOINT, ROLLBACK TO SAVEPOINT, RELEASE SAVEPOINT and the optional WORK keyword for ROLLBACK.

The SAVEPOINT statement sets a named transaction savepoint with a name of identifier. If the current transaction has a savepoint with the same name, the old savepoint is deleted and a new one is set.
The `ROLLBACK TO SAVEPOINT` statement rolls back a transaction to the named savepoint without terminating the transaction. Modifications that the current transaction made to rows after the savepoint was set are undone in the rollback, but InnoDB does not release the row locks that were stored in memory after the savepoint. (For a new inserted row, the lock information is carried by the transaction ID stored in the row; the lock is not separately stored in memory. In this case, the row lock is released in the undo.) Savepoints that were set at a later time than the named savepoint are deleted.

If the `ROLLBACK TO SAVEPOINT` statement returns the following error, it means that no savepoint with the specified name exists:

```
ERROR 1305 (42000): SAVEPOINT identifier does not exist
```

The `RELEASE SAVEPOINT` statement removes the named savepoint from the set of savepoints of the current transaction. No commit or rollback occurs. It is an error if the savepoint does not exist.

All savepoints of the current transaction are deleted if you execute a `COMMIT`, or a `ROLLBACK` that does not name a savepoint.

A new savepoint level is created when a stored function is invoked or a trigger is activated. The savepoints on previous levels become unavailable and thus do not conflict with savepoints on the new level. When the function or trigger terminates, any savepoints it created are released and the previous savepoint level is restored.

### 15.3.5 LOCK INSTANCE FOR BACKUP and UNLOCK INSTANCE Statements

**LOCK INSTANCE FOR BACKUP** acquires an instance-level backup lock that permits DML during an online backup while preventing operations that could result in an inconsistent snapshot.

Executing the `LOCK INSTANCE FOR BACKUP` statement requires the `BACKUP_ADMIN` privilege. The `BACKUP_ADMIN` privilege is automatically granted to users with the `RELOAD` privilege when performing an in-place upgrade to MySQL 8.4 from an earlier version.

Multiple sessions can hold a backup lock simultaneously.

**UNLOCK INSTANCE** releases a backup lock held by the current session. A backup lock held by a session is also released if the session is terminated.

**LOCK INSTANCE FOR BACKUP** prevents files from being created, renamed, or removed. `REPAIR TABLE`, `TRUNCATE TABLE`, `OPTIMIZE TABLE`, and account management statements are blocked. See Section 15.7.1, “Account Management Statements”. Operations that modify InnoDB files that are not recorded in the InnoDB redo log are also blocked.

**LOCK INSTANCE FOR BACKUP** permits DDL operations that only affect user-created temporary tables. In effect, files that belong to user-created temporary tables can be created, renamed, or removed while a backup lock is held. Creation of binary log files is also permitted.

**PURGE BINARY LOGS** cannot be issued while a `LOCK INSTANCE FOR BACKUP` statement is in effect for the instance, because it contravenes the rules of the backup lock by removing files from the server.

A backup lock acquired by `LOCK INSTANCE FOR BACKUP` is independent of transactional locks and locks taken by `FLUSH TABLES tbl_name [, tbl_name] ... WITH READ LOCK`, and the following sequences of statements are permitted:

```
LOCK INSTANCE FOR BACKUP;
FLUSH TABLES tbl_name [, tbl_name] ... WITH READ LOCK;
UNLOCK TABLES;
UNLOCK INSTANCE;
```
The `lock_wait_timeout` setting defines the amount of time that a `LOCK INSTANCE FOR BACKUP` statement waits to acquire a lock before giving up.

15.3.6 LOCK TABLES and UNLOCK TABLES Statements

MySQL enables client sessions to acquire table locks explicitly for the purpose of cooperating with other sessions for access to tables, or to prevent other sessions from modifying tables during periods when a session requires exclusive access to them. A session can acquire or release locks only for itself. One session cannot acquire locks for another session or release locks held by another session.

Locks may be used to emulate transactions or to get more speed when updating tables. This is explained in more detail in Table-Locking Restrictions and Conditions.

`LOCK TABLES` explicitly acquires table locks for the current client session. Table locks can be acquired for base tables or views. You must have the `LOCK TABLES` privilege, and the `SELECT` privilege for each object to be locked.

For view locking, `LOCK TABLES` adds all base tables used in the view to the set of tables to be locked and locks them automatically. For tables underlying any view being locked, `LOCK TABLES` checks that the view definer (for `SQL SECURITY DEFINER` views) or invoker (for all views) has the proper privileges on the tables.

If you lock a table explicitly with `LOCK TABLES`, any tables used in triggers are also locked implicitly, as described in LOCK TABLES and Triggers.

If you lock a table explicitly with `LOCK TABLES`, any tables related by a foreign key constraint are opened and locked implicitly. For foreign key checks, a shared read-only lock (`LOCK TABLES READ`) is taken on related tables. For cascading updates, a shared-nothing write lock (`LOCK TABLES WRITE`) is taken on related tables that are involved in the operation.

`UNLOCK TABLES` explicitly releases any table locks held by the current session. `LOCK TABLES` implicitly releases any table locks held by the current session before acquiring new locks.

Another use for `UNLOCK TABLES` is to release the global read lock acquired with the `FLUSH TABLES WITH READ LOCK` statement, which enables you to lock all tables in all databases. See Section 15.7.8.3, “FLUSH Statement”. (This is a very convenient way to get backups if you have a file system such as Veritas that can take snapshots in time.)

`LOCK TABLE` is a synonym for `LOCK TABLES`; `UNLOCK TABLE` is a synonym for `UNLOCK TABLES`.

A table lock protects only against inappropriate reads or writes by other sessions. A session holding a `WRITE` lock can perform table-level operations such as `DROP TABLE` or `TRUNCATE TABLE`. For sessions holding a `READ` lock, `DROP TABLE` and `TRUNCATE TABLE` operations are not permitted.

The following discussion applies only to non-`TEMPORARY` tables. `LOCK TABLES` is permitted (but ignored) for a `TEMPORARY` table. The table can be accessed freely by the session within which it was
created, regardless of what other locking may be in effect. No lock is necessary because no other session can see the table.

- **Table Lock Acquisition**
- **Table Lock Release**
- **Interaction of Table Locking and Transactions**
- **LOCK TABLES and Triggers**
- **Table-Locking Restrictions and Conditions**

### Table Lock Acquisition

To acquire table locks within the current session, use the `LOCK TABLES` statement, which acquires metadata locks (see Section 10.11.4, “Metadata Locking”).

The following lock types are available:

- **READ [LOCAL] lock:**
  - The session that holds the lock can read the table (but not write it).
  - Multiple sessions can acquire a `READ` lock for the table at the same time.
  - Other sessions can read the table without explicitly acquiring a `READ` lock.
  - The `LOCAL` modifier enables nonconflicting `INSERT` statements (concurrent inserts) by other sessions to execute while the lock is held. (See Section 10.11.3, “Concurrent Inserts”.) However, `READ LOCAL` cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock. For InnoDB tables, `READ LOCAL` is the same as `READ`.

- **WRITE lock:**
  - The session that holds the lock can read and write the table.
  - Only the session that holds the lock can access the table. No other session can access it until the lock is released.
  - Lock requests for the table by other sessions block while the `WRITE` lock is held.

`WRITE` locks normally have higher priority than `READ` locks to ensure that updates are processed as soon as possible. This means that if one session obtains a `READ` lock and then another session requests a `WRITE` lock, subsequent `READ` lock requests wait until the session that requested the `WRITE` lock has obtained the lock and released it. (An exception to this policy can occur for small values of the `max_write_lock_count` system variable; see Section 10.11.4, “Metadata Locking”.)

If the `LOCK TABLES` statement must wait due to locks held by other sessions on any of the tables, it blocks until all locks can be acquired.

A session that requires locks must acquire all the locks that it needs in a single `LOCK TABLES` statement. While the locks thus obtained are held, the session can access only the locked tables. For example, in the following sequence of statements, an error occurs for the attempt to access `t2` because it was not locked in the `LOCK TABLES` statement:

```sql
mysql> LOCK TABLES t1 READ,
mysql> SELECT COUNT(*) FROM t1;
+----------+
| COUNT(*) |
+----------+
|        3 |
+----------+
```
Tables in the `INFORMATION_SCHEMA` database are an exception. They can be accessed without being locked explicitly even while a session holds table locks obtained with `LOCK TABLES`.

You cannot refer to a locked table multiple times in a single query using the same name. Use aliases instead, and obtain a separate lock for the table and each alias:

```
mysql> LOCK TABLE t WRITE, t AS t1 READ;
mysql> INSERT INTO t SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> INSERT INTO t SELECT * FROM t AS t1;
```

The error occurs for the first `INSERT` because there are two references to the same name for a locked table. The second `INSERT` succeeds because the references to the table use different names.

If your statements refer to a table by means of an alias, you must lock the table using that same alias. It does not work to lock the table without specifying the alias:

```
mysql> LOCK TABLE t READ;
mysql> SELECT * FROM t AS myalias;
ERROR 1100: Table 'myalias' was not locked with LOCK TABLES
```

Conversely, if you lock a table using an alias, you must refer to it in your statements using that alias:

```
mysql> LOCK TABLE t AS myalias READ;
mysql> SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> SELECT * FROM t AS myalias;
```

**Table Lock Release**

When the table locks held by a session are released, they are all released at the same time. A session can release its locks explicitly, or locks may be released implicitly under certain conditions.

- A session can release its locks explicitly with `UNLOCK TABLES`.
- If a session issues a `LOCK TABLES` statement to acquire a lock while already holding locks, its existing locks are released implicitly before the new locks are granted.
- If a session begins a transaction (for example, with `START TRANSACTION`), an implicit `UNLOCK TABLES` is performed, which causes existing locks to be released. (For additional information about the interaction between table locking and transactions, see Interaction of Table Locking and Transactions.)

If the connection for a client session terminates, whether normally or abnormally, the server implicitly releases all table locks held by the session (transactional and nontransactional). If the client reconnects, the locks are no longer in effect. In addition, if the client had an active transaction, the server rolls back the transaction upon disconnect, and if reconnect occurs, the new session begins with autocommit enabled. For this reason, clients may wish to disable auto-reconnect. With auto-reconnect in effect, the client is not notified if reconnect occurs but any table locks or current transaction are lost. With auto-reconnect disabled, if the connection drops, an error occurs for the next statement issued. The client can detect the error and take appropriate action such as reacquiring the locks or redoing the transaction. See Automatic Reconnection Control.

**Note**

If you use `ALTER TABLE` on a locked table, it may become unlocked. For example, if you attempt a second `ALTER TABLE` operation, the result may be an error `Table 'tbl_name' was not locked with LOCK TABLES`. To handle this, lock the table again prior to the second alteration. See also Section B.3.6.1, “Problems with ALTER TABLE”.
Interaction of Table Locking and Transactions

LOCK TABLES and UNLOCK TABLES interact with the use of transactions as follows:

- **LOCK TABLES** is not transaction-safe and implicitly commits any active transaction before attempting to lock the tables.

- **UNLOCK TABLES** implicitly commits any active transaction, but only if **LOCK TABLES** has been used to acquire table locks. For example, in the following set of statements, UNLOCK TABLES releases the global read lock but does not commit the transaction because no table locks are in effect:

  ```sql
  FLUSH TABLES WITH READ LOCK;
  START TRANSACTION;
  SELECT ... ;
  UNLOCK TABLES;
  ```

- Beginning a transaction (for example, with **START TRANSACTION**) implicitly commits any current transaction and releases existing table locks.

- **FLUSH TABLES WITH READ LOCK** acquires a global read lock and not table locks, so it is not subject to the same behavior as **LOCK TABLES** and **UNLOCK TABLES** with respect to table locking and implicit commits. For example, **START TRANSACTION** does not release the global read lock. See Section 15.7.8.3, “FLUSH Statement”.

- Other statements that implicitly cause transactions to be committed do not release existing table locks. For a list of such statements, see Section 15.3.3, “Statements That Cause an Implicit Commit”.

- The correct way to use **LOCK TABLES** and **UNLOCK TABLES** with transactional tables, such as InnoDB tables, is to begin a transaction with **SET autocommit = 0** (not **START TRANSACTION**) followed by **LOCK TABLES**, and to not call **UNLOCK TABLES** until you commit the transaction explicitly. For example, if you need to write to table t1 and read from table t2, you can do this:

  ```sql
  SET autocommit=0;
  LOCK TABLES t1 WRITE, t2 READ, ...;
  ... do something with tables t1 and t2 here ... 
  COMMIT;
  UNLOCK TABLES;
  ```

  When you call **LOCK TABLES**, InnoDB internally takes its own table lock, and MySQL takes its own table lock. InnoDB releases its internal table lock at the next commit, but for MySQL to release its table lock, you have to call **UNLOCK TABLES**. You should not have **autocommit = 1**, because then InnoDB releases its internal table lock immediately after the call of **LOCK TABLES**, and deadlocks can very easily happen. InnoDB does not acquire the internal table lock at all if **autocommit = 1**, to help old applications avoid unnecessary deadlocks.

- **ROLLBACK** does not release table locks.

**LOCK TABLES** and Triggers

If you lock a table explicitly with **LOCK TABLES**, any tables used in triggers are also locked implicitly:

- The locks are taken as the same time as those acquired explicitly with the **LOCK TABLES** statement.

- The lock on a table used in a trigger depends on whether the table is used only for reading. If so, a read lock suffices. Otherwise, a write lock is used.

- If a table is locked explicitly for reading with **LOCK TABLES**, but needs to be locked for writing because it might be modified within a trigger, a write lock is taken rather than a read lock. (That is, an implicit write lock needed due to the table’s appearance within a trigger causes an explicit read lock request for the table to be converted to a write lock request.)

Suppose that you lock two tables, t1 and t2, using this statement:
LOCK TABLES t1 WRITE, t2 READ;

If t1 or t2 have any triggers, tables used within the triggers are also locked. Suppose that t1 has a trigger defined like this:

```
CREATE TRIGGER t1_a_ins AFTER INSERT ON t1 FOR EACH ROW
BEGIN
    UPDATE t4 SET count = count+1
    WHERE id = NEW.id AND EXISTS (SELECT a FROM t3);
    INSERT INTO t2 VALUES(1, 2);
END;
```

The result of the LOCK TABLES statement is that t1 and t2 are locked because they appear in the statement, and t3 and t4 are locked because they are used within the trigger:

- t1 is locked for writing per the WRITE lock request.
- t2 is locked for writing, even though the request is for a READ lock. This occurs because t2 is inserted into within the trigger, so the READ request is converted to a WRITE request.
- t3 is locked for reading because it is only read from within the trigger.
- t4 is locked for writing because it might be updated within the trigger.

### Table-Locking Restrictions and Conditions

You can safely use `KILL` to terminate a session that is waiting for a table lock. See Section 15.7.8.4, “KILL Statement”.

`LOCK TABLES` and `UNLOCK TABLES` cannot be used within stored programs.

Tables in the `performance_schema` database cannot be locked with `LOCK TABLES`, except the `setup_xxx` tables.

The scope of a lock generated by `LOCK TABLES` is a single MySQL server. It is not compatible with NDB Cluster, which has no way of enforcing an SQL-level lock across multiple instances of `mysqld`. You can enforce locking in an API application instead. See Section 25.2.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”, for more information.

The following statements are prohibited while a `LOCK TABLES` statement is in effect: `CREATE TABLE`, `CREATE TABLE ... LIKE`, `CREATE VIEW`, `DROP VIEW`, and DDL statements on stored functions and procedures and events.

For some operations, system tables in the `mysql` database must be accessed. For example, the `HELP` statement requires the contents of the server-side help tables, and `CONVERT_TZ()` might need to read the time zone tables. The server implicitly locks the system tables for reading as necessary so that you need not lock them explicitly. These tables are treated as just described:

```
mysql.help_category
mysql.help_keyword
mysql.help_relation
mysql.help_topic
mysql.time_zone
mysql.time_zone_leap_second
mysql.time_zone_name
mysql.time_zone_transition
mysql.time_zone_transition_type
```

If you want to explicitly place a WRITE lock on any of those tables with a `LOCK TABLES` statement, the table must be the only one locked; no other table can be locked with the same statement.

Normally, you do not need to lock tables, because all single `UPDATE` statements are atomic; no other session can interfere with any other currently executing SQL statement. However, there are a few cases when locking tables may provide an advantage:
SET TRANSACTION Statement

• If you are going to run many operations on a set of MyISAM tables, it is much faster to lock the tables you are going to use. Locking MyISAM tables speeds up inserting, updating, or deleting on them because MySQL does not flush the key cache for the locked tables until UNLOCK TABLES is called. Normally, the key cache is flushed after each SQL statement.

The downside to locking the tables is that no session can update a READ-locked table (including the one holding the lock) and no session can access a WRITE-locked table other than the one holding the lock.

• If you are using tables for a nontransactional storage engine, you must use LOCK TABLES if you want to ensure that no other session modifies the tables between a SELECT and an UPDATE. The example shown here requires LOCK TABLES to execute safely:

LOCK TABLES trans READ, customer WRITE;
SELECT SUM(value) FROM trans WHERE customer_id=some_id;
UPDATE customer
  SET total_value=sum_from_previous_statement
  WHERE customer_id=some_id;
UNLOCK TABLES;

Without LOCK TABLES, it is possible that another session might insert a new row in the trans table between execution of the SELECT and UPDATE statements.

You can avoid using LOCK TABLES in many cases by using relative updates (UPDATE customer SET value=value+new_value) or the LAST_INSERT_ID() function.

You can also avoid locking tables in some cases by using the user-level advisory lock functions GET_LOCK() and RELEASE_LOCK(). These locks are saved in a hash table in the server and implemented with pthread_mutex_lock() and pthread_mutex_unlock() for high speed. See Section 14.14, “Locking Functions”.

See Section 10.11.1, “Internal Locking Methods”, for more information on locking policy.

15.3.7 SET TRANSACTION Statement

This statement specifies transaction characteristics. It takes a list of one or more characteristic values separated by commas. Each characteristic value sets the transaction isolation level or access mode. The isolation level is used for operations on InnoDB tables. The access mode specifies whether transactions operate in read/write or read-only mode.

In addition, SET TRANSACTION can include an optional GLOBAL or SESSION keyword to indicate the scope of the statement.

• Transaction Isolation Levels
• Transaction Access Mode
SET TRANSACTION Statement

• **Transaction Characteristic Scope**

**Transaction Isolation Levels**

To set the transaction isolation level, use an `ISOLATION LEVEL` clause. It is not permitted to specify multiple `ISOLATION LEVEL` clauses in the same `SET TRANSACTION` statement.

The default isolation level is `REPEATABLE READ`. Other permitted values are `READ COMMITTED`, `READ UNCOMMITTED`, and `SERIALIZABLE`. For information about these isolation levels, see Section 17.7.2.1, “Transaction Isolation Levels”.

**Transaction Access Mode**

To set the transaction access mode, use a `READ WRITE` or `READ ONLY` clause. It is not permitted to specify multiple access-mode clauses in the same `SET TRANSACTION` statement.

By default, a transaction takes place in read/write mode, with both reads and writes permitted to tables used in the transaction. This mode may be specified explicitly using `SET TRANSACTION` with an access mode of `READ WRITE`.

If the transaction access mode is set to `READ ONLY`, changes to tables are prohibited. This may enable storage engines to make performance improvements that are possible when writes are not permitted.

In read-only mode, it remains possible to change tables created with the `TEMPORARY` keyword using DML statements. Changes made with DDL statements are not permitted, just as with permanent tables.

The `READ WRITE` and `READ ONLY` access modes also may be specified for an individual transaction using the `START TRANSACTION` statement.

**Transaction Characteristic Scope**

You can set transaction characteristics globally, for the current session, or for the next transaction only:

• **With the `GLOBAL` keyword:**
  
  • The statement applies globally for all subsequent sessions.
  
  • Existing sessions are unaffected.

• **With the `SESSION` keyword:**
  
  • The statement applies to all subsequent transactions performed within the current session.
  
  • The statement is permitted within transactions, but does not affect the current ongoing transaction.
  
  • If executed between transactions, the statement overrides any preceding statement that sets the next-transaction value of the named characteristics.

• **Without any `SESSION` or `GLOBAL` keyword:**
  
  • The statement applies only to the next single transaction performed within the session.
  
  • Subsequent transactions revert to using the session value of the named characteristics.
  
  • The statement is not permitted within transactions:

  ```
  mysql> START TRANSACTION;
  Query OK, 0 rows affected (0.02 sec)
  mysql> SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
  ERROR 1568 (25001): Transaction characteristics can’t be changed while a transaction is in progress
  ```
A change to global transaction characteristics requires the \texttt{CONNECTION\_ADMIN} privilege (or the deprecated \texttt{SUPER} privilege). Any session is free to change its session characteristics (even in the middle of a transaction), or the characteristics for its next transaction (prior to the start of that transaction).

To set the global isolation level at server startup, use the \texttt{--transaction-isolation=level} option on the command line or in an option file. Values of \texttt{level} for this option use dashes rather than spaces, so the permissible values are \texttt{READ-UNCOMMITTED}, \texttt{READ-COMMITTED}, \texttt{REPEATABLE-READ}, or \texttt{SERIALIZABLE}.

Similarly, to set the global transaction access mode at server startup, use the \texttt{--transaction-read-only} option. The default is \texttt{OFF} (read/write mode) but the value can be set to \texttt{ON} for a mode of read only.

For example, to set the isolation level to \texttt{REPEATABLE READ} and the access mode to \texttt{READ WRITE}, use these lines in the [mysqld] section of an option file:

```
[mysqld]
transaction-isolation = REPEATABLE-READ
transaction-read-only = OFF
```

At runtime, characteristics at the global, session, and next-transaction scope levels can be set indirectly using the \texttt{SET TRANSACTION} statement, as described previously. They can also be set directly using the \texttt{SET} statement to assign values to the \texttt{transaction_isolation} and \texttt{transaction_read_only} system variables:

- \texttt{SET TRANSACTION} permits optional \texttt{GLOBAL} and \texttt{SESSION} keywords for setting transaction characteristics at different scope levels.
- The \texttt{SET} statement for assigning values to the \texttt{transaction_isolation} and \texttt{transaction_read_only} system variables has syntaxes for setting these variables at different scope levels.

The following tables show the characteristic scope level set by each \texttt{SET TRANSACTION} and variable-assignment syntax.

### Table 15.9 SET TRANSACTION Syntax for Transaction Characteristics

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Affected Characteristic Scope</th>
</tr>

</table>
### 15.3.8 XA Transactions

Support for XA transactions is available for the InnoDB storage engine. The MySQL XA implementation is based on the X/Open CAE document *Distributed Transaction Processing: The XA Specification*. This document is published by The Open Group and available at [http://www.opengroup.org/public/pubs/catalog/c193.htm](http://www.opengroup.org/public/pubs/catalog/c193.htm). Limitations of the current XA implementation are described in Section 15.3.8.3, “Restrictions on XA Transactions”.

On the client side, there are no special requirements. The XA interface to a MySQL server consists of SQL statements that begin with the `XA` keyword. MySQL client programs must be able to send SQL statements and to understand the semantics of the XA statement interface. They do not need to be linked against a recent client library. Older client libraries also work.

Among the MySQL Connectors, MySQL Connector/J 5.0.0 and higher supports XA directly, by means of a class interface that handles the XA SQL statement interface for you.

XA supports distributed transactions, that is, the ability to permit multiple separate transactional resources to participate in a global transaction. Transactional resources often are RDBMSs but may be other kinds of resources.

A global transaction involves several actions that are transactional in themselves, but that all must either complete successfully as a group, or all be rolled back as a group. In essence, this extends ACID properties “up a level” so that multiple ACID transactions can be executed in concert as components of a global operation that also has ACID properties. (As with nondistributed transactions, `SERIALIZABLE` may be preferred if your applications are sensitive to read phenomena. `REPEATABLE READ` may not be sufficient for distributed transactions.)

Some examples of distributed transactions:

- An application may act as an integration tool that combines a messaging service with an RDBMS. The application makes sure that transactions dealing with message sending, retrieval, and processing that also involve a transactional database all happen in a global transaction. You can think of this as “transactional email.”

- An application performs actions that involve different database servers, such as a MySQL server and an Oracle server (or multiple MySQL servers), where actions that involve multiple servers must happen as part of a global transaction, rather than as separate transactions local to each server.

- A bank keeps account information in an RDBMS and distributes and receives money through automated teller machines (ATMs). It is necessary to ensure that ATM actions are correctly reflected in the accounts, but this cannot be done with the RDBMS alone. A global transaction manager integrates the ATM and database resources to ensure overall consistency of financial transactions.

Applications that use global transactions involve one or more Resource Managers and a Transaction Manager:

- A Resource Manager (RM) provides access to transactional resources. A database server is one kind of resource manager. It must be possible to either commit or roll back transactions managed by the RM.
• A Transaction Manager (TM) coordinates the transactions that are part of a global transaction. It communicates with the RMs that handle each of these transactions. The individual transactions within a global transaction are “branches” of the global transaction. Global transactions and their branches are identified by a naming scheme described later.

The MySQL implementation of XA enables a MySQL server to act as a Resource Manager that handles XA transactions within a global transaction. A client program that connects to the MySQL server acts as the Transaction Manager.

To carry out a global transaction, it is necessary to know which components are involved, and bring each component to a point when it can be committed or rolled back. Depending on what each component reports about its ability to succeed, they must all commit or roll back as an atomic group. That is, either all components must commit, or all components must roll back. To manage a global transaction, it is necessary to take into account that any component or the connecting network might fail.

The process for executing a global transaction uses two-phase commit (2PC). This takes place after the actions performed by the branches of the global transaction have been executed.

1. In the first phase, all branches are prepared. That is, they are told by the TM to get ready to commit. Typically, this means each RM that manages a branch records the actions for the branch in stable storage. The branches indicate whether they are able to do this, and these results are used for the second phase.

2. In the second phase, the TM tells the RMs whether to commit or roll back. If all branches indicated when they were prepared that they were able to commit, all branches are told to commit. If any branch indicated when it was prepared that it was not able to commit, all branches are told to roll back.

In some cases, a global transaction might use one-phase commit (1PC). For example, when a Transaction Manager finds that a global transaction consists of only one transactional resource (that is, a single branch), that resource can be told to prepare and commit at the same time.

15.3.8.1 XA Transaction SQL Statements

To perform XA transactions in MySQL, use the following statements:

- `XA {START|BEGIN} xid [JOIN|RESUME]`
- `XA END xid [SUSPEND [FOR MIGRATE]]`
- `XA PREPARE xid`
- `XA COMMIT xid [ONE PHASE]`
- `XA ROLLBACK xid`
- `XA RECOVER [CONVERT XID]`

For `XA START`, the `JOIN` and `RESUME` clauses are recognized but have no effect.

For `XA END` the `SUSPEND [FOR MIGRATE]` clause is recognized but has no effect.

Each XA statement begins with the `XA` keyword, and most of them require an `xid` value. An `xid` is an XA transaction identifier. It indicates which transaction the statement applies to. `xid` values are supplied by the client, or generated by the MySQL server. An `xid` value has from one to three parts:

- `xid: gtrid [, bqual [, formatID ]]`

- `gtrid` is a global transaction identifier, `bqual` is a branch qualifier, and `formatID` is a number that identifies the format used by the `gtrid` and `bqual` values. As indicated by the syntax, `bqual` and `formatID` are optional. The default `bqual` value is '' if not given. The default `formatID` value is 1 if not given.
**gtrid** and **bqual** must be string literals, each up to 64 bytes (not characters) long. **gtrid** and **bqual** can be specified in several ways. You can use a quoted string ("ab"), hex string (X'6162', 0x6162), or bit value (b'nnnn').

**formatID** is an unsigned integer.

The **gtrid** and **bqual** values are interpreted in bytes by the MySQL server's underlying XA support routines. However, while an SQL statement containing an XA statement is being parsed, the server works with some specific character set. To be safe, write **gtrid** and **bqual** as hex strings.

**xid** values typically are generated by the Transaction Manager. Values generated by one TM must be different from values generated by other TMs. A given TM must be able to recognize its own **xid** values in a list of values returned by the **XA RECOVER** statement.

**XA START xid** starts an XA transaction with the given **xid** value. Each XA transaction must have a unique **xid** value, so the value must not currently be used by another XA transaction. Uniqueness is assessed using the **gtrid** and **bqual** values. All following XA statements for the XA transaction must be specified using the same **xid** value as that given in the **XA START** statement. If you use any of those statements but specify an **xid** value that does not correspond to some existing XA transaction, an error occurs.

**XA START, XA BEGIN, XA END, XA COMMIT, and XA ROLLBACK** statements are not filtered by the default database when the server is running with **--replicate-do-db or --replicate-ignore-db**.

One or more XA transactions can be part of the same global transaction. All XA transactions within a given global transaction must use the same **gtrid** value in the **xid** value. For this reason, **gtrid** values must be globally unique so that there is no ambiguity about which global transaction a given XA transaction is part of. The **bqual** part of the **xid** value must be different for each XA transaction within a global transaction. (The requirement that **bqual** values be different is a limitation of the current MySQL XA implementation. It is not part of the XA specification.)

The **XA RECOVER** statement returns information for those XA transactions on the MySQL server that are in the **PREPARED** state. (See Section 15.3.8.2, “XA Transaction States”.) The output includes a row for each such XA transaction on the server, regardless of which client started it.

**XA RECOVER** requires the **XA_RECOVER_ADMIN** privilege. This privilege requirement prevents users from discovering the XID values for outstanding prepared XA transactions other than their own. It does not affect normal commit or rollback of an XA transaction because the user who started it knows its XID.

**XA RECOVER** output rows look like this (for an example **xid** value consisting of the parts 'abc', 'def', and 7):

```
mysql> XA RECOVER;
+----------+-------------+-------------+--------+
| formatID | gtrid_length | bqual_length | data   |
+----------+-------------+-------------+--------+
|        7 |             3 |            3 | abcdef |
```

The output columns have the following meanings:

- **formatID** is the **formatID** part of the transaction **xid**
- **gtrid_length** is the length in bytes of the **gtrid** part of the **xid**
- **bqual_length** is the length in bytes of the **bqual** part of the **xid**
- **data** is the concatenation of the **gtrid** and **bqual** parts of the **xid**

XID values may contain nonprintable characters. **XA RECOVER** permits an optional **CONVERT XID** clause so that clients can request XID values in hexadecimal.
15.3.8.2 XA Transaction States

An XA transaction progresses through the following states:

1. Use XA START to start an XA transaction and put it in the ACTIVE state.

2. For an ACTIVE XA transaction, issue the SQL statements that make up the transaction, and then issue an XA END statement. XA END puts the transaction in the IDLE state.

3. For an IDLE XA transaction, you can issue either an XA PREPARE statement or an XA COMMIT ... ONE PHASE statement:
   - XA PREPARE puts the transaction in the PREPARED state. An XA RECOVER statement at this point includes the transaction's xid value in its output, because XA RECOVER lists all XA transactions that are in the PREPARED state.
   - XA COMMIT ... ONE PHASE prepares and commits the transaction. The xid value is not listed by XA RECOVER because the transaction terminates.

4. For a PREPARED XA transaction, you can issue an XA COMMIT statement to commit and terminate the transaction, or XA ROLLBACK to roll back and terminate the transaction.

Here is a simple XA transaction that inserts a row into a table as part of a global transaction:

```
mysql> XA START 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO mytable (i) VALUES(10);
Query OK, 1 row affected (0.04 sec)

mysql> XA END 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA PREPARE 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA COMMIT 'xatest';
Query OK, 0 rows affected (0.00 sec)
```

MySQL 8.4 supports detached XA transactions, enabled by the xa_detach_on_prepare system variable (ON by default). Detached transactions are disconnected from the current session following execution of XA PREPARE (and can be committed or rolled back by another connection). This means that the current session is free to start a new local transaction or XA transaction without having to wait for the prepared XA transaction to be committed or rolled back.

When XA transactions are detached, a connection has no special knowledge of any XA transaction that it has prepared. If the current session tries to commit or roll back a given XA transaction (even one which it prepared) after another connection has already done so, the attempt is rejected with an invalid XID error (ER_XAER_NOTA) since the requested xid no longer exists.

Note
Detached XA transactions cannot use temporary tables.

When detached XA transactions are disabled (xa_detach_on_prepare set to OFF), an XA transaction remains connected until it is committed or rolled back by the originating connection. Disabling detached XA transactions is not recommended for a MySQL server instance used in group replication; see Server Instance Configuration, for more information.

If an XA transaction is in the ACTIVE state, you cannot issue any statements that cause an implicit commit. That would violate the XA contract because you could not roll back the XA transaction. Trying to execute such a statement raises the following error:

```
ERROR 1399 (XAE07): XAER_RMFAIL: The command cannot be executed
```
when global transaction is in the ACTIVE state

Statements to which the preceding remark applies are listed at Section 15.3.3, “Statements That Cause an Implicit Commit”.

15.3.8.3 Restrictions on XA Transactions

XA transaction support is limited to the InnoDB storage engine.

For “external XA,” a MySQL server acts as a Resource Manager and client programs act as Transaction Managers. For “Internal XA”, storage engines within a MySQL server act as RMs, and the server itself acts as a TM. Internal XA support is limited by the capabilities of individual storage engines. Internal XA is required for handling XA transactions that involve more than one storage engine. The implementation of internal XA requires that a storage engine support two-phase commit at the table handler level, and currently this is true only for InnoDB.

For XA START, the JOIN and RESUME clauses are recognized but have no effect.

For XA END the SUSPEND [FOR MIGRATE] clause is recognized but has no effect.

The requirement that the bqual part of the xid value be different for each XA transaction within a global transaction is a limitation of the current MySQL XA implementation. It is not part of the XA specification.

An XA transaction is written to the binary log in two parts. When XA PREPARE is issued, the first part of the transaction up to XA PREPARE is written using an initial GTID. A XA_prepare_log_event is used to identify such transactions in the binary log. When XA COMMIT or XA ROLLBACK is issued, a second part of the transaction containing only the XA COMMIT or XA ROLLBACK statement is written using a second GTID. Note that the initial part of the transaction, identified by XA_prepare_log_event, is not necessarily followed by its XA COMMIT or XA ROLLBACK, which can cause interleaved binary logging of any two XA transactions. The two parts of the XA transaction can even appear in different binary log files. This means that an XA transaction in PREPARED state is now persistent until an explicit XA COMMIT or XA ROLLBACK statement is issued, ensuring that XA transactions are compatible with replication.

On a replica, immediately after the XA transaction is prepared, it is detached from the replication applier thread, and can be committed or rolled back by any thread on the replica. This means that the same XA transaction can appear in the events_transactions_current table with different states on different threads. The events_transactions_current table displays the current status of the most recent monitored transaction event on the thread, and does not update this status when the thread is idle. So the XA transaction can still be displayed in the PREPARED state for the original applier thread, after it has been processed by another thread. To positively identify XA transactions that are still in the PREPARED state and need to be recovered, use the XA RECOVER statement rather than the Performance Schema transaction tables.

The following restrictions exist for using XA transactions:

• The use of replication filters or binary log filters in combination with XA transactions is not supported. Filtering of tables could cause an XA transaction to be empty on a replica, and empty XA transactions are not supported. Also, with the replica's connection metadata repository and appliance metadata repository stored in InnoDB tables (the default), the internal state of the data engine transaction is changed following a filtered XA transaction, and can become inconsistent with the replication transaction context state.

The error ER_XA_REPLICATIONFILTERS is logged whenever an XA transaction is impacted by a replication filter, whether or not the transaction was empty as a result. If the transaction is not empty, the replica is able to continue running, but you should take steps to discontinue the use of replication filters with XA transactions in order to avoid potential issues. If the transaction is empty, the replica stops. In that event, the replica might be in an undetermined state in which the consistency of the replication process might be compromised. In particular, the gtid_executed set on a replica of the replica might be inconsistent with that on the source. To resolve this situation, isolate the source
and stop all replication, then check GTID consistency across the replication topology. Undo the XA transaction that generated the error message, then restart replication.

- XA transactions are considered unsafe for statement-based replication. If two XA transactions committed in parallel on the source are being prepared on the replica in the inverse order, locking dependencies can occur that cannot be safely resolved, and it is possible for replication to fail with deadlock on the replica. This situation can occur for a single-threaded or multithreaded replica. When `binlog_format=STATEMENT` is set, a warning is issued for DML statements inside XA transactions. When `binlog_format=MIXED` or `binlog_format=ROW` is set, DML statements inside XA transactions are logged using row-based replication, and the potential issue is not present.

- You should be aware that, when the same transaction XID is used to execute XA transactions sequentially and a break occurs during the processing of `XA COMMIT ... ONE PHASE`, it may no longer be possible to synchronize the state between the binary log and the storage engine. This can occur if the series of events just described takes place after this transaction has been prepared in the storage engine, while the `XA COMMIT` statement is still executing. This is a known issue.

### 15.4 Replication Statements

Replication can be controlled through the SQL interface using the statements described in this section. Statements are split into a group which controls source servers, a group which controls replica servers, and a group which can be applied to any replication servers.

#### 15.4.1 SQL Statements for Controlling Source Servers

This section discusses statements for managing replication source servers. Section 15.4.2, “SQL Statements for Controlling Replica Servers”, discusses statements for managing replica servers.

In addition to the statements described here, the following `SHOW` statements are used with source servers in replication. For information about these statements, see Section 15.7.7, “SHOW Statements”.

- `SHOW BINARY LOGS`
- `SHOW BINLOG EVENTS`
- `SHOW BINARY LOG STATUS`
- `SHOW REPLICAS`

#### 15.4.1.1 PURGE BINARY LOGS Statement

```
PURGE BINARY LOGS {
    TO 'log_name' 
    | BEFORE datetime_expr
}
```

The binary log is a set of files that contain information about data modifications made by the MySQL server. The log consists of a set of binary log files, plus an index file (see Section 7.4.4, “The Binary Log”).

The `PURGE BINARY LOGS` statement deletes all the binary log files listed in the log index file prior to the specified log file name or date. Deleted log files also are removed from the list recorded in the index file, so that the given log file becomes the first in the list.

`PURGE BINARY LOGS` requires the `BINLOG_ADMIN` privilege. This statement has no effect if the server was not started with the `--log-bin` option to enable binary logging.

Examples:

```
PURGE BINARY LOGS TO 'mysql-bin.010';
PURGE BINARY LOGS BEFORE '2019-04-02 22:46:26';
```
The **BEFORE** variant's `datetime_expr` argument should evaluate to a **DATETIME** value (a value in `'YYYY-MM-DD hh:mm:ss'` format).

**PURGE BINARY LOGS** is safe to run while replicas are replicating. You need not stop them. If you have an active replica that currently is reading one of the log files you are trying to delete, this statement does not delete the log file that is in use or any log files later than that one, but it deletes any earlier log files. A warning message is issued in this situation. However, if a replica is not connected and you happen to purge one of the log files it has yet to read, the replica cannot replicate after it reconnects.

**PURGE BINARY LOGS** cannot be issued while a **LOCK INSTANCE FOR BACKUP** statement is in effect for the instance, because it contravenes the rules of the backup lock by removing files from the server.

To safely purge binary log files, follow this procedure:

1. On each replica, use `SHOW REPLICA STATUS` to check which log file it is reading.
2. Obtain a listing of the binary log files on the source with `SHOW BINARY LOGS`.
3. Determine the earliest log file among all the replicas. This is the target file. If all the replicas are up to date, this is the last log file on the list.
4. Make a backup of all the log files you are about to delete. (This step is optional, but always advisable.)
5. Purge all log files up to but not including the target file.

**PURGE BINARY LOGS TO** and **PURGE BINARY LOGS BEFORE** both fail with an error when binary log files listed in the `.index` file had been removed from the system by some other means (such as using `rm` on Linux). (Bug #18199, Bug #18453) To handle such errors, edit the `.index` file (which is a simple text file) manually to ensure that it lists only the binary log files that are actually present, then run again the **PURGE BINARY LOGS** statement that failed.

Binary log files are automatically removed after the server's binary log expiration period. Removal of the files can take place at startup and when the binary log is flushed. The default binary log expiration period is 30 days. You can specify an alternative expiration period using the `binlog_expire_logs_seconds` system variable. If you are using replication, you should specify an expiration period that is no lower than the maximum amount of time your replicas might lag behind the source.

### 15.4.1.2 RESET BINARY LOGS AND GTIDS Statement

**RESET BINARY LOGS AND GTIDS**

**Warning**

Use this statement with caution to ensure you do not lose any wanted binary log file data and GTID execution history.

**RESET BINARY LOGS AND GTIDS** requires the **RELOAD** privilege.

For a server where binary logging is enabled (**log_bin** is **ON**), **RESET BINARY LOGS AND GTIDS** deletes all existing binary log files and resets the binary log index file, resetting the server to its state before binary logging was started. A new empty binary log file is created so that binary logging can be restarted.

For a server where GTIDs are in use (**gtid_mode** is **ON**), issuing **RESET BINARY LOGS AND GTIDS** resets the GTID execution history. The value of the `gtid_purged` system variable is set to an empty string (`''`), the global value (but not the session value) of the `gtid_executed` system variable is set to an empty string, and the `mysql.gtid_executed` table is cleared (see `mysql.gtid_executed` Table). If the GTID-enabled server has binary logging enabled, **RESET BINARY LOGS AND GTIDS** also resets the binary log as described above. Note that **RESET BINARY LOGS AND GTIDS** is the method...
to reset the GTID execution history even if the GTID-enabled server is a replica where binary logging is disabled; `RESET REPLICA` has no effect on the GTID execution history. For more information on resetting the GTID execution history, see `Resetting the GTID Execution History`.

Issuing `RESET BINARY LOGS AND GTIDS` without the optional `TO` clause deletes all binary log files listed in the index file, resets the binary log index file to be empty, and creates a new binary log file starting at 1. Use the optional `TO` clause to start the binary log file index from a number other than 1 after the reset.

Check that you are using a reasonable value for the index number. If you enter an incorrect value, you can correct this by issuing another `RESET BINARY LOGS AND GTIDS` statement with or without the `TO` clause. If you do not correct a value that is out of range, the server cannot be restarted.

The following example demonstrates `TO` clause usage:

```
RESET BINARY LOGS AND GTIDS TO 1234;
SHOW BINARY LOGS;
```

<table>
<thead>
<tr>
<th>Log_name</th>
<th>File_size</th>
<th>Encrypted</th>
</tr>
</thead>
<tbody>
<tr>
<td>source-bin.001234</td>
<td>154</td>
<td>No</td>
</tr>
</tbody>
</table>

**Important**

The effects of `RESET BINARY LOGS AND GTIDS` without the `TO` clause differ from those of `PURGE BINARY LOGS` in 2 key ways:

1. `RESET BINARY LOGS AND GTIDS` removes all binary log files that are listed in the index file, leaving only a single, empty binary log file with a numeric suffix of `.000001`, whereas the numbering is not reset by `PURGE BINARY LOGS`.

2. `RESET BINARY LOGS AND GTIDS` is not intended to be used while any replicas are running. The behavior of `RESET BINARY LOGS AND GTIDS` when used while replicas are running is undefined (and thus unsupported), whereas `PURGE BINARY LOGS` may be safely used while replicas are running.

See also Section 15.4.1.1, “PURGE BINARY LOGS Statement”.

`RESET BINARY LOGS AND GTIDS` without the `TO` clause can prove useful when you first set up a source and replica, so that you can verify the setup as follows:

1. Start the source and replica, and start replication (see Section 19.1.2, “Setting Up Binary Log File Position Based Replication”).

2. Execute a few test queries on the source.

3. Check that the queries were replicated to the replica.

4. When replication is running correctly, issue `STOP REPLICA` followed by `RESET REPLICA` (both on the replica), then verify that no unwanted data from the test queries exists on the replica. Following this, issue `RESET BINARY LOGS AND GTIDS` (also on the replica) to remove binary logs and and associated transaction IDs.

5. Remove the unwanted data from the source, then issue `RESET BINARY LOGS AND GTIDS` to purge any binary log entries and identifiers associated with it.

After verifying the setup, resetting the source and replica and ensuring that no unwanted data or binary log files generated by testing remain on the source or replica, you can start the replica and begin replicating.
15.4.1.3 SET sql_log_bin Statement

```
SET sql_log_bin = {OFF|ON}
```

The `sql_log_bin` variable controls whether logging to the binary log is enabled for the current session (assuming that the binary log itself is enabled). The default value is ON. To disable or enable binary logging for the current session, set the session `sql_log_bin` variable to OFF or ON.

Set this variable to OFF for a session to temporarily disable binary logging while making changes to the source that you do not want replicated to the replica.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 7.1.9.1, “System Variable Privileges”.

It is not possible to set the session value of `sql_log_bin` within a transaction or subquery.

Setting this variable to OFF prevents new GTIDs from being assigned to transactions in the binary log. If you are using GTIDs for replication, this means that even when binary logging is later enabled again, the GTIDs written into the log from this point do not account for any transactions that occurred in the meantime, so in effect those transactions are lost.

MySQL dump adds a `SET @@SESSION.sql_log_bin=0` statement to a dump file from a server where GTIDs are in use, which disables binary logging while the dump file is being reloaded. The statement prevents new GTIDs from being generated and assigned to the transactions in the dump file as they are executed, so that the original GTIDs for the transactions are used.

15.4.2 SQL Statements for Controlling Replica Servers

This section discusses statements for managing replica servers. Section 15.4.1, “SQL Statements for Controlling Source Servers”, discusses statements for managing source servers.

In addition to the statements described here, `SHOW REPLICA STATUS` and `SHOW RELAYLOG EVENTS` are also used with replicas. For information about these statements, see Section 15.7.7.34, “SHOW REPLICA STATUS Statement”, and Section 15.7.7.33, “SHOW RELAYLOG EVENTS Statement”.

15.4.2.1 CHANGE REPLICATION FILTER Statement

```
CHANGE REPLICATION FILTER filter[, filter] [, ...] FOR CHANNEL channel
filter: {
    REPLICATE_DO_DB = (db_list)
    REPLICATE_IGNORE_DB = (db_list)
    REPLICATE_DO_TABLE = (tbl_list)
    REPLICATE_IGNORE_TABLE = (tbl_list)
    REPLICATE_WILD_DO_TABLE = (wild_tbl_list)
    REPLICATE_WILD_IGNORE_TABLE = (wild_tbl_list)
    REPLICATE_REWRITE_DB = (db_pair_list)
}

db_list:    (db_name[, db_name][, ...])

tbl_list:    (db_name.table_name[, db_name.table_name][, ...])
wild_tbl_list:    ("db_pattern.table_pattern", "db_pattern.table_pattern")

db_pair_list:    (db_pair)[, (db_pair)][, ...]

db_pair:    (from_db, to_db)
```
CHANGE_REPLICATION_FILTER sets one or more replication filtering rules on the replica in the same way as starting the replica mysql with replication filtering options such as --replicate-do-db or --replicate-wild-ignore-table. Filters set using this statement differ from those set using the server options in two key respects:

1. The statement does not require restarting the server to take effect, only that the replication SQL thread be stopped using STOP_REPLICA_SQL_THREAD first (and restarted with START_REPLICA_SQL_THREAD afterwards).

2. The effects of the statement are not persistent; any filters set using CHANGE_REPLICATION_FILTER are lost following a restart of the replica mysql.

CHANGE_REPLICATION_FILTER requires the REPLICATION_SLAVE_ADMIN privilege (or the deprecated SUPER privilege).

Use the FOR_CHANNEL channel clause to make a replication filter specific to a replication channel, for example on a multi-source replica. Filters applied without a specific FOR_CHANNEL clause are considered global filters, meaning that they are applied to all replication channels.

Note

Global replication filters cannot be set on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be set on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replica to a source that is outside the group. They cannot be set on the group_replication_applier or group_replication_recovery channels.

The following list shows the CHANGE_REPLICATION_FILTER options and how they relate to --replicate-* server options:

- **REPLICATE_DO_DB**: Include updates based on database name. Equivalent to --replicate-do-db.
- **REPLICATE_IGNORE_DB**: Exclude updates based on database name. Equivalent to --replicate-ignore-db.
- **REPLICATE_DO_TABLE**: Include updates based on table name. Equivalent to --replicate-do-table.
- **REPLICATE_IGNORE_TABLE**: Exclude updates based on table name. Equivalent to --replicate-ignore-table.
- **REPLICATE_WILD_DO_TABLE**: Include updates based on wildcard pattern matching table name. Equivalent to --replicate-wild-do-table.
- **REPLICATE_WILD_IGNORE_TABLE**: Exclude updates based on wildcard pattern matching table name. Equivalent to --replicate-wild-ignore-table.
- **REPLICATE_REWRITE_DB**: Perform updates on replica after substituting new name on replica for specified database on source. Equivalent to --replicate-rewrite-db.

The precise effects of REPLICATE_DO_DB and REPLICATE_IGNORE_DB filters are dependent on whether statement-based or row-based replication is in effect. See Section 19.2.5, “How Servers Evaluate Replication Filtering Rules”, for more information.

Multiple replication filtering rules can be created in a single CHANGE_REPLICATION_FILTER statement by separating the rules with commas, as shown here:
Issuing the statement just shown is equivalent to starting the replica `mysqld` with the options `--replicate-do-db=d1 --replicate-ignore-db=d2`.

On a multi-source replica, which uses multiple replication channels to process transaction from different sources, use the `FOR CHANNEL channel` clause to set a replication filter on a replication channel:

```sql
CHANGE REPLICATION FILTER REPLICATE_DO_DB = (d1) FOR CHANNEL channel_1;
```

This enables you to create a channel specific replication filter to filter out selected data from a source. When a `FOR CHANNEL` clause is provided, the replication filter statement acts on that replication channel, removing any existing replication filter which has the same filter type as the specified replication filters, and replacing them with the specified filter. Filter types not explicitly listed in the statement are not modified. If issued against a replication channel which is not configured, the statement fails with an `ER_SLAVE_CONFIGURATION` error. If issued against Group Replication channels, the statement fails with an `ER_SLAVE_CHANNEL_OPERATION_NOT_ALLOWED` error.

On a replica with multiple replication channels configured, issuing `CHANGE REPLICATION FILTER` with no `FOR CHANNEL` clause configures the replication filter for every configured replication channel, and for the global replication filters. For every filter type, if the filter type is listed in the statement, then any existing filter rules of that type are replaced by the filter rules specified in the most recently issued statement, otherwise the old value of the filter type is retained. For more information see Section 19.2.5.4, “Replication Channel Based Filters”.

If the same filtering rule is specified multiple times, only the last such rule is actually used. For example, the two statements shown here have exactly the same effect, because the first `REPLICATE_DO_DB` rule in the first statement is ignored:

```sql
CHANGE REPLICATION FILTER
    REPLICATE_DO_DB = (db1, db2), REPLICATE_DO_DB = (db3, db4);

CHANGE REPLICATION FILTER
    REPLICATE_DO_DB = (db3, db4);
```

**Caution**

This behavior differs from that of the `--replicate-*` filter options where specifying the same option multiple times causes the creation of multiple filter rules.

Names of tables and databases not containing any special characters need not be quoted. Values used with `REPLICATION_WILD_TABLE` and `REPLICATION_WILD_IGNORE_TABLE` are string expressions, possibly containing (special) wildcard characters, and so must be quoted. This is shown in the following example statements:

```sql
CHANGE REPLICATION FILTER
    REPLICATE_WILD_DO_TABLE = ('db1.old%');

CHANGE REPLICATION FILTER
    REPLICATE_WILD_IGNORE_TABLE = ('db1.new%', 'db2.new%');
```

Values used with `REPLICATE_REWRITE_DB` represent pairs of database names; each such value must be enclosed in parentheses. The following statement rewrites statements occurring on database `db1` on the source to database `db2` on the replica:

```sql
CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB = ((db1, db2));
```

The statement just shown contains two sets of parentheses, one enclosing the pair of database names, and the other enclosing the entire list. This is perhaps more easily seen in the following example, which creates two `rewrite-db` rules, one rewriting database `dbA` to `dbB`, and one rewriting database `dbC` to `dbD`:

```sql
CHANGE REPLICATION FILTER
```
The `CHANGE REPLICATION FILTER` statement replaces replication filtering rules only for the filter types and replication channels affected by the statement, and leaves other rules and channels unchanged. If you want to unset all filters of a given type, set the filter's value to an explicitly empty list, as shown in this example, which removes all existing `REPLICATE_DO_DB` and `REPLICATE_IGNORE_DB` rules:

```
REPLICATE_DO_DB = (), REPLICATE_IGNORE_DB = ()
```

Setting a filter to empty in this way removes all existing rules, does not create any new ones, and does not restore any rules set at mysqld startup using `--replicate-*` options on the command line or in the configuration file.

The `RESET REPLICA ALL` statement removes channel specific replication filters that were set on channels deleted by the statement. When the deleted channel or channels are recreated, any global replication filters specified for the replica are copied to them, and no channel specific replication filters are applied.

For more information, see Section 19.2.5, “How Servers Evaluate Replication Filtering Rules”.

15.4.2.2 CHANGE REPLICATION SOURCE TO Statement

```
option:[
  SOURCE_BIND = 'interface_name'
  | SOURCE_HOST = 'host_name'
  | SOURCE_USER = 'user_name'
  | SOURCE_PASSWORD = 'password'
  | SOURCE_PORT = port_num
  PRIVILEGE_CHECKS_USER = [NULL | 'account']
  REQUIRE_ROW_FORMAT = {0|1}
  REQUIRE_TABLE_PRIMARY_KEY_CHECK = {STREAM | ON | OFF | GENERATE}
  ASSIGN_GIDS_TO_ANONYMOUS_TRANSACTIONS = {OFF | LOCAL | uuid}
  SOURCE_LOG_FILE = 'source_log_name'
  SOURCE_LOG_POS = source_log_pos
  SOURCE_AUTO_POSITION = {0|1}
  RELAY_LOG_FILE = 'relay_log_name'
  RELAY_LOG_POS = relay_log_pos
  SOURCE_HEARTBEAT_PERIOD = interval
  SOURCE_CONNECT_RETRY = interval
  SOURCE_RETRY_COUNT = count
  SOURCE_CONNECTION_AUTO_FAILOVER = {0|1}
  SOURCE_DELAY = interval
  SOURCE_COMPRESSION_ALGORITHMS = [algorithm[,algorithm][,algorithm]]
  SOURCE_SSL_CIPHERSUITES = [ciphersuite_list]
  SOURCE_PUBLIC_KEY_PATH = key_file_name
  SOURCE_SSL_VERIFY_SERVER_CERT = {0|1}
  SOURCE_TLS_VERSION = [protocol_list]
  SOURCE_TLS_CIPHERSUITES = [ciphersuite_list]
  NETWORK_NAMESPACE = namespace
  IGNORE_SERVER_IDS = (server_id_list),
  GTID_ONLY = {0|1}
]
```
server_id_list:
  [server_id [, server_id] ... ]

CHANGE REPLICATION SOURCE TO changes the parameters that the replica server uses for connecting to the source and reading data from the source. It also updates the contents of the replication metadata repositories (see Section 19.2.4, ”Relay Log and Replication Metadata Repositories”).

CHANGE REPLICATION SOURCE TO requires the REPLICATION_SLAVE_ADMIN privilege (or the deprecated SUPER privilege).

Options that you do not specify on a CHANGE REPLICATION SOURCE TO statement retain their value, except as indicated in the following discussion. In most cases, there is therefore no need to specify options that do not change.

Values used for SOURCE_HOST and other CHANGE REPLICATION SOURCE TO options are checked for linefeed (\n or 0x0A) characters. The presence of such characters in these values causes the statement to fail with an error.

The optional FOR CHANNEL channel clause lets you name which replication channel the statement applies to. Providing a FOR CHANNEL channel clause applies the CHANGE REPLICATION SOURCE TO statement to a specific replication channel, and is used to add a new channel or modify an existing channel. For example, to add a new channel called channel2:

```
CHANGE REPLICATION SOURCE TO SOURCE_HOST=host1, SOURCE_PORT=3002 FOR CHANNEL 'channel2';
```

If no clause is named and no extra channels exist, a CHANGE REPLICATION SOURCE TO statement applies to the default channel, whose name is the empty string (""). When you have set up multiple replication channels, every CHANGE REPLICATION SOURCE TO statement must name a channel using the FOR CHANNEL channel clause. See Section 19.2.2, ”Replication Channels” for more information.

For some of the options of the CHANGE REPLICATION SOURCE TO statement, you must issue a STOP REPLICA statement prior to issuing a CHANGE REPLICATION SOURCE TO statement (and a START REPLICA statement afterwards). Sometimes, you only need to stop the replication SQL (applier) thread or the replication I/O (receiver) thread, not both:

- When the applier thread is stopped, you can execute CHANGE REPLICATION SOURCE TO using any combination that is otherwise allowed of RELAY_LOG_FILE, RELAY_LOG_POS, and SOURCE_DELAY options, even if the replication receiver thread is running. No other options may be used with this statement when the receiver thread is running.

- When the receiver thread is stopped, you can execute CHANGE REPLICATION SOURCE TO using any of the options for this statement (in any allowed combination) except RELAY_LOG_FILE, RELAY_LOG_POS, SOURCE_DELAY, or SOURCE_AUTO_POSITION = 1 even when the applier thread is running.

- Both the receiver thread and the applier thread must be stopped before issuing a CHANGE REPLICATION SOURCE TO statement that employs SOURCE_AUTO_POSITION = 1, GTID_ONLY = 1, or ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS.

You can check the current state of the replication applier thread and replication receiver thread using SHOW REPLICA STATUS. Note that the Group Replication applier channel (group_replication_applier) has no receiver thread, only an applier thread.

CHANGE REPLICATION SOURCE TO statements have a number of side-effects and interactions that you should be aware of beforehand:

- CHANGE REPLICATION SOURCE TO causes an implicit commit of an ongoing transaction. See Section 15.3.3, ”Statements That Cause an Implicit Commit”.

---

2680
• **CHANGE REPLICATION SOURCE TO** causes the previous values for **SOURCE_HOST, SOURCE_PORT, SOURCE_LOG_FILE, and SOURCE_LOG_POS** to be written to the error log, along with other information about the replica’s state prior to execution.

• If you are using statement-based replication and temporary tables, it is possible for a **CHANGE REPLICATION SOURCE TO** statement following a **STOP REPLICA** statement to leave behind temporary tables on the replica. A warning (**ER_WARN_OPEN_TEMP_TABLES_MUST_BE_ZERO**) is issued whenever this occurs. You can avoid this in such cases by making sure that the value of the **Replica_open_temp_tables** system status variable is equal to 0 prior to executing such a **CHANGE REPLICATION SOURCE TO** statement.

• When using a multithreaded replica (**replica_parallel_workers > 0**), stopping the replica can cause gaps in the sequence of transactions that have been executed from the relay log, regardless of whether the replica was stopped intentionally or otherwise. In MySQL 8.4, these can be resolved using GTID auto-positioning.

The following options are available for **CHANGE REPLICATION SOURCE TO** statements:

• **ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS = {OFF | LOCAL | uuid}**

  Makes the replication channel assign a GTID to replicated transactions that do not have one, enabling replication from a source that does not use GTID-based replication, to a replica that does. For a multi-source replica, you can have a mix of channels that use **ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS**, and channels that do not. The default is **OFF**, meaning that the feature is not used.

  **LOCAL** assigns a GTID including the replica’s own UUID (the **server_uuid** setting). **uuid** assigns a GTID including the specified UUID, such as the **server_uuid** setting for the replication source server. Using a nonlocal UUID lets you differentiate between transactions that originated on the replica and transactions that originated on the source, and for a multi-source replica, between transactions that originated on different sources. The UUID you choose only has significance for the replica’s own use. If any of the transactions sent by the source do have a GTID already, that GTID is retained.

  Channels specific to Group Replication cannot use **ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS**, but an asynchronous replication channel for another source on a server instance that is a Group Replication group member can do so. In that case, do not specify the Group Replication group name as the UUID for creating the GTIDs.

  To set **ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS** to **LOCAL** or **uuid**, the replica must have **gtid_mode=ON** set, and this cannot be changed afterwards. This option is for use with a source that has binary log file position based replication, so **SOURCE_AUTO_POSITION=1** cannot be set for the channel. Both the replication SQL thread and the replication I/O (receiver) thread must be stopped before setting this option.

![Important](image.png)

A replica set up with **ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS** on any channel cannot be promoted to replace the replication source server in the event that a failover is required, and a backup taken from the replica cannot be used to restore the replication source server. The same restriction applies to replacing or restoring other replicas that use **ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS** on any channel.

For further restrictions and information, see Section 19.1.3.6, “Replication From a Source Without GTIDs to a Replica With GTIDs”.

• **GET_SOURCE_PUBLIC_KEY = {0 | 1}**

  Enables RSA key pair-based password exchange by requesting the public key from the source. The option is disabled by default.
This option applies to replicas that authenticate with the `caching_sha2_password` authentication plugin. For connections by accounts that authenticate using this plugin, the source does not send the public key unless requested, so it must be requested or specified in the client. If `SOURCE_PUBLIC_KEY_PATH` is given and specifies a valid public key file, it takes precedence over `GET_SOURCE_PUBLIC_KEY`. If you are using a replication user account that authenticates with the `caching_sha2_password` plugin (the default), and you are not using a secure connection, you must specify either this option or the `SOURCE_PUBLIC_KEY_PATH` option to provide the RSA public key to the replica.

- **GTID_ONLY = {0|1}**

  Stops the replication channel persisting file names and file positions in the replication metadata repositories. `GTID_ONLY` is disabled by default for asynchronous replication channels, but is enabled by default for Group Replication channels, for which it cannot be disabled.

  For replication channels with this setting, in-memory file positions are still tracked, and file positions can still be observed for debugging purposes in error messages and through interfaces such as `SHOW REPLICA STATUS` statements (where they are shown as being invalid if they are out of date). However, the writes and reads required to persist and check the file positions are avoided in situations where GTID-based replication does not actually require them, including the transaction queuing and application process.

  This option can be used only if both the replication SQL (applier) thread and replication I/O (receiver) thread are stopped. To set `GTID_ONLY = 1` for a replication channel, GTIDs must be in use on the server (`gtid_mode = ON`), and row-based binary logging must be in use on the source (statement-based replication is not supported). The options `REQUIRE_ROW_FORMAT = 1` and `SOURCE_AUTO_POSITION = 1` must be set for the replication channel.

  When `GTID_ONLY = 1` is set, the replica uses `replica_parallel_workers=1` if that system variable is set to zero for the server, so it is always technically a multi-threaded applier. This is because a multi-threaded applier uses saved positions rather than the replication metadata repositories to locate the start of a transaction that it needs to reapply.

  If you disable `GTID_ONLY` after setting it, the existing relay logs are deleted and the existing known binary log file positions are persisted, even if they are stale. The file positions for the binary log and relay log in the replication metadata repositories might be invalid, and a warning is returned if this is the case. Provided that `SOURCE_AUTO_POSITION` is still enabled, GTID auto-positioning is used to provide the correct positioning.

  If you also disable `SOURCE_AUTO_POSITION`, the file positions for the binary log and relay log in the replication metadata repositories are used for positioning if they are valid. If they are marked as invalid, you must provide a valid binary log file name and position (`SOURCE_LOG_FILE` and `SOURCE_LOG_POS`). If you also provide a relay log file name and position (`RELAY_LOG_FILE` and `RELAY_LOG_POS`), the relay logs are preserved and the applier position is set to the stated position. GTID auto-skip ensures that any transactions already applied are skipped even if the eventual applier position is not correct.

- **IGNORE_SERVER_IDS = (server_id_list)**

  Makes the replica ignore events originating from the specified servers. The option takes a comma-separated list of 0 or more server IDs. Log rotation and deletion events from the servers are not ignored, and are recorded in the relay log.

  In circular replication, the originating server normally acts as the terminator of its own events, so that they are not applied more than once. Thus, this option is useful in circular replication when one of the servers in the circle is removed. Suppose that you have a circular replication setup with 4 servers, having server IDs 1, 2, 3, and 4, and server 3 fails. When bridging the gap by starting replication from server 2 to server 4, you can include `IGNORE_SERVER_IDS = (3)` in the `CHANGE REPLICATION SOURCE TO` statement that you issue on server 4 to tell it to use server 2 as its source instead of
server 3. Doing so causes it to ignore and not to propagate any statements that originated with the server that is no longer in use.

If `IGNORE_SERVER_IDS` contains the server's own ID and the server was started with the `--replicate-same-server-id` option enabled, an error results.

The source metadata repository and the output of `SHOW REPLICA STATUS` provide the list of servers that are currently ignored. For more information, see Section 19.2.4.2, “Replication Metadata Repositories”, and Section 15.7.7.34, “SHOW REPLICA STATUS Statement”.

If a `CHANGE REPLICATION SOURCE TO` statement is issued without `IGNORE_SERVER_IDS`, any existing list is preserved. To clear the list of ignored servers, it is necessary to use the option with an empty list, like this:

```
CHANGE REPLICATION SOURCE TO IGNORE_SERVER_IDS = ();
```

`RESET REPLICA ALL` also clears `IGNORE_SERVER_IDS`.

When global transaction identifiers (GTIDs) are used for replication, transactions that have already been applied are automatically ignored. Because of this, `IGNORE_SERVER_IDS` is not compatible with `gtid_mode=ON`. If `gtid_mode` is `ON`, `CHANGE REPLICATION SOURCE TO` with a non-empty `IGNORE_SERVER_IDS` list is rejected with an error. Likewise, if any existing replication channel was created with a list of server IDs to be ignored, `SET gtid_mode=ON` is also rejected. Before starting GTID-based replication, check for and clear any ignored server ID lists on the servers involved; you can do this by checking the output from `SHOW REPLICA STATUS`. In such cases, you can clear the list by issuing `CHANGE REPLICATION SOURCE TO` with an empty list of server IDs as shown previously.

- **NETWORK_NAMESPACE = 'namespace'**

  The network namespace to use for TCP/IP connections to the replication source server or, if the MySQL communication stack is in use, for Group Replication’s group communication connections. The maximum length of the string value is 64 characters. If this option is omitted, connections from the replica use the default (global) namespace. On platforms that do not implement network namespace support, failure occurs when the replica attempts to connect to the source. For information about network namespaces, see Section 7.1.14, “Network Namespace Support”.

- **PRIVILEGE_CHECKS_USER = {NULL | 'account'}**

  Names a user account that supplies a security context for the specified channel. `NULL`, which is the default, means no security context is used.

  The user name and host name for the user account must follow the syntax described in Section 8.2.4, “Specifying Account Names”, and the user must not be an anonymous user (with a blank user name) or the `CURRENT_USER`. The account must have the `REPLICATION_APPLIER` privilege, plus the required privileges to execute the transactions replicated on the channel. For details of the privileges required by the account, see Section 19.3.3, “Replication Privilege Checks”. When you restart the replication channel, the privilege checks are applied from that point on. If you do not specify a channel and no other channels exist, the statement is applied to the default channel.

  The use of row-based binary logging is strongly recommended when `PRIVILEGE_CHECKS_USER` is set, and you can set `REQUIRE_ROW_FORMAT` to enforce this. For example, to start privilege checks on the channel `channel_1` on a running replica, issue the following statements:

  ```
  STOP REPLICA FOR CHANNEL 'channel_1';

  CHANGE REPLICATION SOURCE TO
    PRIVILEGE_CHECKS_USER = 'user'@'host',
    REQUIRE_ROW_FORMAT = 1,
    FOR CHANNEL 'channel_1';

  START REPLICA FOR CHANNEL 'channel_1';
  ```
• RELAY_LOG_FILE = 'relay_log_file', RELAY_LOG_POS = 'relay_log_pos'

The relay log file name, and the location in that file, at which the replication SQL thread begins reading from the replica's relay log the next time the thread starts. RELAY_LOG_FILE can use either an absolute or relative path, and uses the same base name as SOURCE_LOG_FILE. The maximum length of the string value is 511 characters.

A CHANGE_REPLICATION_SOURCE_TO statement using RELAY_LOG_FILE, RELAY_LOG_POS, or both options can be executed on a running replica when the replication SQL (applier) thread is stopped. Relay logs are preserved if at least one of the replication applier thread and the replication I/O (receiver) thread is running. If both threads are stopped, all relay log files are deleted unless at least one of RELAY_LOG_FILE or RELAY_LOG_POS is specified. For the Group Replication applier channel (group_replication_applier), which only has an applier thread and no receiver thread, this is the case if the applier thread is stopped, but with that channel you cannot use the RELAY_LOG_FILE and RELAY_LOG_POS options.

• REQUIRE_ROW_FORMAT = {0|1}

Permits only row-based replication events to be processed by the replication channel. This option prevents the replication applier from taking actions such as creating temporary tables and executing LOAD DATA INFILE requests, which increases the security of the channel. The REQUIRE_ROW_FORMAT option is disabled by default for asynchronous replication channels, but it is enabled by default for Group Replication channels, and it cannot be disabled for them. For more information, see Section 19.3.3, “Replication Privilege Checks”.

• REQUIRE_TABLE_PRIMARY_KEY_CHECK = {STREAM | ON | OFF | GENERATE}

This option lets a replica set its own policy for primary key checks, as follows:

• ON: The replica sets sql_require_primary_key = ON; any replicated CREATE TABLE or ALTER TABLE statement must result in a table that contains a primary key.

• OFF: The replica sets sql_require_primary_key = OFF; no replicated CREATE TABLE or ALTER TABLE statement is checked for the presence of a primary key.

• STREAM: The replica uses whatever value of sql_require_primary_key is replicated from the source for each transaction. This is the default value, and the default behavior.

• GENERATE: Causes the replica to generate an invisible primary key for any InnoDB table that, as replicated, lacks a primary key. See Section 15.1.20.11, “Generated Invisible Primary Keys”, for more information.

GENERATE is not compatible with Group Replication; you can use ON, OFF, or STREAM.

A divergence based on the presence of a generated invisible primary key solely on a source or replica table is supported by MySQL Replication as long as the source supports GIPKs and the replica uses MySQL version 8.0.32 or later. If you use GIPKs on a replica with the source using an earlier version of MySQL, such divergences in schema, other than the extra GIPK on the replica, are not supported and may result in replication errors.

For multisource replication, setting REQUIRE_TABLE_PRIMARY_KEY_CHECK to ON or OFF lets the replica normalize behavior across replication channels for different sources, and to keep a consistent setting for sql_require_primary_key. Using ON safeguards against the accidental loss of primary keys when multiple sources update the same set of tables. Using OFF lets sources that can manipulate primary keys to work alongside sources that cannot.

In the case of multiple replicas, when REQUIRE_TABLE_PRIMARY_KEY_CHECK is set to GENERATE, the generated invisible primary key added by a given replica is independent of any such key added on any other replica. This means that, if generated invisible primary keys are in use, the values in the
generated primary key columns on different replicas are not guaranteed to be the same. This may be an issue when failing over to such a replica.

When `PRIVILEGE_CHECKS_USER` is `NULL` (the default), the user account does not need administration level privileges to set restricted session variables. Setting this option to a value other than `NULL` means that, when `REQUIRE_TABLE_PRIMARY_KEY_CHECK` is `ON`, `OFF`, or `GENERATE`, the user account does not require session administration level privileges to set restricted session variables such as `sql_require_primary_key`, avoiding the need to grant the account such privileges. For more information, see Section 19.3.3, “Replication Privilege Checks”.

- `SOURCE_AUTO_POSITION = {0|1}`

Makes the replica attempt to connect to the source using the auto-positioning feature of GTID-based replication, rather than a binary log file based position. This option is used to start a replica using GTID-based replication. The default is 0, meaning that GTID auto-positioning and GTID-based replication are not used. This option can be used with `CHANGE REPLICATION SOURCE TO` only if both the replication SQL (applier) thread and replication I/O (receiver) thread are stopped.

Both the replica and the source must have GTIDs enabled (`GTID_MODE=ON`, `ON_PERMISSIVE`, or `OFF_PERMISSIVE` on the replica, and `GTID_MODE=ON` on the source). `SOURCE_LOG_FILE`, `SOURCE_LOG_POS`, `RELAY_LOG_FILE`, and `RELAY_LOG_POS` cannot be specified together with `SOURCE_AUTO_POSITION = 1`. If multi-source replication is enabled on the replica, you need to set the `SOURCE_AUTO_POSITION = 1` option for each applicable replication channel.

With `SOURCE_AUTO_POSITION = 1` set, in the initial connection handshake, the replica sends a GTID set containing the transactions that it has already received, committed, or both. The source responds by sending all transactions recorded in its binary log whose GTID is not included in the GTID set sent by the replica. This exchange ensures that the source only sends the transactions with a GTID that the replica has not already recorded or committed. If the replica receives transactions from more than one source, as in the case of a diamond topology, the auto-skip function ensures that the transactions are not applied twice. For details of how the GTID set sent by the replica is computed, see Section 19.1.3.3, “GTID Auto-Positioning”.

If any of the transactions that should be sent by the source have been purged from the source’s binary log, or added to the set of GTIDs in the `gtid_purged` system variable by another method, the source sends the error `ER_SOURCE_HAS_PURGED_REQUIRED_GTIDS` to the replica, and replication does not start. The GTIDs of the missing purged transactions are identified and listed in the source’s error log in the warning message `ER_FOUND_MISSING_GTIDS`. Also, if during the exchange of transactions it is found that the replica has recorded or committed transactions with the source’s UUID in the GTID, but the source itself has not committed them, the source sends the error `ER_REPLICA_HAS_MORE_GTIDS_THAN_SOURCE` to the replica and replication does not start. For information on how to handle these situations, see Section 19.1.3.3, “GTID Auto-Positioning”.

You can see whether replication is running with GTID auto-positioning enabled by checking the Performance Schema `replication_connection_status` table or the output of `SHOW REPLICA STATUS`. Disabling the `SOURCE_AUTO_POSITION` option again makes the replica revert to file-based replication.

- `SOURCE_BIND = 'interface_name'`

Determines which of the replica’s network interfaces is chosen for connecting to the source, for use on replicas that have multiple network interfaces. Specify the IP address of the network interface. The maximum length of the string value is 255 characters.

The IP address configured with this option, if any, can be seen in the `Source_Bind` column of the output from `SHOW REPLICA STATUS`. In the source metadata repository table `mysql.slave_master_info`, the value can be seen as the `Source_bind` column. The ability to bind a replica to a specific network interface is also supported by NDB Cluster.

- `SOURCE_COMPRESSION_ALGORITHMS = 'algorithm[,algorithm][,algorithm]'`
Specifies one, two, or three of the permitted compression algorithms for connections to the replication source server, separated by commas. The maximum length of the string value is 99 characters. The default value is uncompressed.

The available algorithms are zlib, zstd, and uncompressed, the same as for the protocol_compression_algorithms system variable. The algorithms can be specified in any order, but it is not an order of preference - the algorithm negotiation process attempts to use zlib, then zstd, then uncompressed, if they are specified.

The value of SOURCE_COMPRESSION_ALGORITHMS applies only if the replica_compressed_protocol system variable is disabled. If replica_compressed_protocol is enabled, it takes precedence over SOURCE_COMPRESSION_ALGORITHMS and connections to the source use zlib compression if both source and replica support that algorithm. For more information, see Section 6.2.8, “Connection Compression Control”.

Binary log transaction compression is activated by the binlog_transaction_compression system variable, and can also be used to save bandwidth. If you do this in combination with connection compression, connection compression has less opportunity to act on the data, but can still compress headers and those events and transaction payloads that are uncompressed. For more information on binary log transaction compression, see Section 7.4.4.5, “Binary Log Transaction Compression”.

• SOURCE_CONNECT_RETRY = interval

Specifies the interval in seconds between the reconnection attempts that the replica makes after the connection to the source times out. The default interval is 60.

The number of attempts is limited by the SOURCE_RETRY_COUNT option. If both the default settings are used, the replica waits 60 seconds between reconnection attempts (SOURCE_CONNECT_RETRY=60), and keeps attempting to reconnect at this rate for 10 minutes (SOURCE_RETRY_COUNT=10). These values are recorded in the source metadata repository and shown in the replication_connection_configuration Performance Schema table.

• SOURCE_CONNECTION_AUTO_FAILOVER = {0|1}

Activates the asynchronous connection failover mechanism for a replication channel if one or more alternative replication source servers are available (so when there are multiple MySQL servers or groups of servers that share the replicated data). The default is 0, meaning that the mechanism is not activated. For full information and instructions to set up this feature, see Section 19.4.9.2, “Asynchronous Connection Failover for Replicas”.

The asynchronous connection failover mechanism takes over after the reconnection attempts controlled by SOURCE_CONNECT_RETRY and SOURCE_RETRY_COUNT are exhausted. It reconnects the replica to an alternative source chosen from a specified source list, which you can manage using the functions asynchronous_connection_failover_add_source() and asynchronous_connection_failover_delete_source(). To add and remove managed groups of servers, use asynchronous_connection_failover_add_managed() and asynchronous_connection_failover_delete_managed() instead. For more information, see Section 19.4.9, “Switching Sources and Replicas with Asynchronous Connection Failover”.

Important

1. You can only set SOURCE_CONNECTION_AUTO_FAILOVER = 1 when GTID auto-positioning is in use (SOURCE_AUTO_POSITION = 1).
2. When you set SOURCE_CONNECTION_AUTO_FAILOVER = 1, set SOURCE_RETRY_COUNT and SOURCE_CONNECT_RETRY to minimal numbers that just allow a few retry attempts with the same source, in
case the connection failure is caused by a transient network outage. Otherwise the asynchronous connection failover mechanism cannot be activated promptly. Suitable values are `SOURCE_RETRY_COUNT=3` and `SOURCE_CONNECT_RETRY=10`, which make the replica retry the connection 3 times with 10-second intervals between.

3. When you set `SOURCE_CONNECTION_AUTO_FAILOVER = 1`, the replication metadata repositories must contain the credentials for a replication user account that can be used to connect to all the servers on the source list for the replication channel. The account must also have `SELECT` permissions on the Performance Schema tables. These credentials can be set using the `CHANGE REPLICA SOURCE TO` statement with the `SOURCE_USER` and `SOURCE_PASSWORD` options. For more information, see Section 19.4.9, “Switching Sources and Replicas with Asynchronous Connection Failover”.

4. When you set `SOURCE_CONNECTION_AUTO_FAILOVER = 1`, asynchronous connection failover for replicas is automatically activated if this replication channel is on a Group Replication primary in a group in single-primary mode. With this function active, if the primary that is replicating goes offline or into an error state, the new primary starts replication on the same channel when it is elected. If you want to use the function, this replication channel must also be set up on all the secondary servers in the replication group, and on any new joining members. (If the servers are provisioned using MySQL’s clone functionality, this all happens automatically.) If you do not want to use the function, disable it by using the `group_replication_disable_member_action()` function to disable the Group Replication member action `mysql_start_failover_channels_if_primary`, which is enabled by default. For more information, see Section 19.4.9.2, “Asynchronous Connection Failover for Replicas”.

- **SOURCE_DELAY = interval**

  Specifies how many seconds behind the source the replica must lag. An event received from the source is not executed until at least `interval` seconds later than its execution on the source. `interval` must be a nonnegative integer in the range from 0 to $2^{31} - 1$. The default is 0. For more information, see Section 19.4.11, “Delayed Replication”.

  A `CHANGE REPLICA SOURCE TO` statement using the `SOURCE_DELAY` option can be executed on a running replica when the replication SQL thread is stopped.

- **SOURCE_HEARTBEAT_PERIOD = interval**

  Controls the heartbeat interval, which stops the connection timeout occurring in the absence of data if the connection is still good. A heartbeat signal is sent to the replica after that number of seconds, and the waiting period is reset whenever the source’s binary log is updated with an event. Heartbeats are therefore sent by the source only if there are no unsent events in the binary log file for a period longer than this.

  The heartbeat interval `interval` is a decimal value having the range 0 to 4294967 seconds and a resolution in milliseconds: the smallest nonzero value is 0.001. Setting `interval` to 0 disables heartbeats altogether. The heartbeat interval defaults to half the value of the `replica_net_timeout` system variable. It is recorded in the source metadata repository and shown in the `replication_connection_configuration` Performance Schema table.

  The `replica_net_timeout` system variable specifies the number of seconds that the replica waits for either more data or a heartbeat signal from the source, before the replica considers the connection broken, aborts the read, and tries to reconnect. The default value is 60 seconds.
SQL Statements for Controlling Replica Servers

(one minute). Note that a change to the value or default setting of \texttt{replica_net_timeout} does not automatically change the heartbeat interval, whether that has been set explicitly or is using a previously calculated default. A warning is issued if you set the global value of \texttt{replica_net_timeout} to a value less than that of the current heartbeat interval. If \texttt{replica_net_timeout} is changed, you must also issue \texttt{CHANGE REPLICATION SOURCE TO} to adjust the heartbeat interval to an appropriate value so that the heartbeat signal occurs before the connection timeout. If you do not do this, the heartbeat signal has no effect, and if no data is received from the source, the replica can make repeated reconnection attempts, creating zombie dump threads.

- \texttt{SOURCE_HOST = 'host_name'}

The host name or IP address of the replication source server. The replica uses this to connect to the source. The maximum length of the string value is 255 characters.

If you specify \texttt{SOURCE_HOST} or \texttt{SOURCE_PORT}, the replica assumes that the source server is different from before (even if the option value is the same as its current value.) In this case, the old values for the source's binary log file name and position are considered no longer applicable, so if you do not specify \texttt{SOURCE_LOG_FILE} and \texttt{SOURCE_LOG_POS} in the statement, \texttt{SOURCE_LOG_FILE=''} and \texttt{SOURCE_LOG_POS=4} are silently appended to it.

Setting \texttt{SOURCE_HOST=''} (that is, setting its value explicitly to an empty string) is not the same as not setting \texttt{SOURCE_HOST} at all. Trying to set \texttt{SOURCE_HOST} to an empty string fails with an error.

- \texttt{SOURCE_LOG_FILE = 'source_log_name', SOURCE_LOG_POS = source_log_pos}

The binary log file name, and the location in that file, at which the replication I/O (receiver) thread begins reading from the source's binary log the next time the thread starts. Specify these options if you are using binary log file position based replication.

\texttt{SOURCE_LOG_FILE} must include the numeric suffix of a specific binary log file that is available on the source server, for example, \texttt{SOURCE_LOG_FILE='binlog.000145'}. The maximum length of the string value is 511 characters.

\texttt{SOURCE_LOG_POS} is the numeric position for the replica to start reading in that file. \texttt{SOURCE_LOG_POS=4} represents the start of the events in a binary log file.

If you specify either of \texttt{SOURCE_LOG_FILE} or \texttt{SOURCE_LOG_POS}, you cannot specify \texttt{SOURCE_AUTO_POSITION = 1}, which is for GTID-based replication.

If neither of \texttt{SOURCE_LOG_FILE} or \texttt{SOURCE_LOG_POS} is specified, the replica uses the last coordinates of the replication SQL thread before \texttt{CHANGE REPLICATION SOURCE TO} was issued. This ensures that there is no discontinuity in replication, even if the replication SQL (applier) thread was late compared to the replication I/O (receiver) thread.

- \texttt{SOURCE_PASSWORD = 'password'}

The password for the replication user account to use for connecting to the replication source server. The maximum length of the string value is 32 characters. If you specify \texttt{SOURCE_PASSWORD}, \texttt{SOURCE_USER} is also required.

The password used for a replication user account in a \texttt{CHANGE REPLICATION SOURCE TO} statement is limited to 32 characters in length. Trying to use a password of more than 32 characters causes \texttt{CHANGE REPLICATION SOURCE TO} to fail.

The password is masked in MySQL Server’s logs, Performance Schema tables, and \texttt{SHOW PROCESSLIST} statements.

- \texttt{SOURCE_PORT = port_num}

The TCP/IP port number that the replica uses to connect to the replication source server.
Replication cannot use Unix socket files. You must be able to connect to the replication source server using TCP/IP.

If you specify `SOURCE_HOST` or `SOURCE_PORT`, the replica assumes that the source server is different from before (even if the option value is the same as its current value.) In this case, the old values for the source's binary log file name and position are considered no longer applicable, so if you do not specify `SOURCE_LOG_FILE` and `SOURCE_LOG_POS` in the statement, `SOURCE_LOG_FILE=''` and `SOURCE_LOG_POS=4` are silently appended to it.

- **SOURCE_PUBLIC_KEY_PATH = 'key_file_name'**

  Enables RSA key pair-based password exchange by providing the path name to a file containing a replica-side copy of the public key required by the source. The file must be in PEM format. The maximum length of the string value is 511 characters.

  This option applies to replicas that authenticate with the `sha256_password` (deprecated) or `caching_sha2_password` authentication plugin. (For `sha256_password`, `SOURCE_PUBLIC_KEY_PATH` can be used only if MySQL was built using OpenSSL.) If you are using a replication user account that authenticates with the `caching_sha2_password` plugin (the default), and you are not using a secure connection, you must specify either this option or the `GET_SOURCE_PUBLIC_KEY=1` option to provide the RSA public key to the replica.

- **SOURCE_RETRY_COUNT = count**

  Sets the maximum number of reconnection attempts that the replica makes after the connection to the source times out, as determined by the `replica_net_timeout` system variable. If the replica does need to reconnect, the first retry occurs immediately after the timeout. The default is 10 attempts.

  The interval between the attempts is specified by the `SOURCE_CONNECT_RETRY` option. If both the default settings are used, the replica waits 60 seconds between reconnection attempts (`SOURCE_CONNECT_RETRY=60`), and keeps attempting to reconnect at this rate for 10 minutes (`SOURCE_RETRY_COUNT=10`). A setting of 0 for `SOURCE_RETRY_COUNT` means that there is no limit on the number of reconnection attempts, so the replica keeps trying to reconnect indefinitely.

  The values for `SOURCE_CONNECT_RETRY` and `SOURCE_RETRY_COUNT` are recorded in the source metadata repository and shown in the `replication_connection_configuration` Performance Schema table. `SOURCE_RETRY_COUNT` supersedes the `--master-retry-count` server startup option.

- **SOURCE_SSL = {0|1}**

  Specify whether the replica encrypts the replication connection. The default is 0, meaning that the replica does not encrypt the replication connection. If you set `SOURCE_SSL=1`, you can configure the encryption using the `SOURCE_SSL_xxx` and `SOURCE_TLS_xxx` options.

  Setting `SOURCE_SSL=1` for a replication connection and then setting no further `SOURCE_SSL_xxx` options corresponds to setting `--ssl-mode=REQUIRED` for the client, as described in Command Options for Encrypted Connections. With `SOURCE_SSL=1`, the connection attempt only succeeds if an encrypted connection can be established. A replication connection does not fall back to an unencrypted connection, so there is no setting corresponding to the `--ssl-mode=PREFERRED` setting for replication. If `SOURCE_SSL=0` is set, this corresponds to `--ssl-mode=DISABLED`.

Important

To help prevent sophisticated man-in-the-middle attacks, it is important for the replica to verify the server's identity. You can specify additional `SOURCE_SSL_xxx` options to correspond to the settings `--ssl-`
mode=VERIFY_CA and --ssl-mode=VERIFY_IDENTITY, which are a better choice than the default setting to help prevent this type of attack. With these settings, the replica checks that the server’s certificate is valid, and checks that the host name the replica is using matches the identity in the server’s certificate. To implement one of these levels of verification, you must first ensure that the CA certificate for the server is reliably available to the replica, otherwise availability issues will result. For this reason, they are not the default setting.

- **SOURCE_SSL_xxx, SOURCE_TLS_xxx**

Specify how the replica uses encryption and ciphers to secure the replication connection. These options can be changed even on replicas that are compiled without SSL support. They are saved to the source metadata repository, but are ignored if the replica does not have SSL support enabled. The maximum length of the value for the string-valued **SOURCE_SSL_xxx** and **SOURCE_TLS_xxx** options is 511 characters, with the exception of **SOURCE_TLS_CIPHERSUITES**, for which it is 4000 characters.

The **SOURCE_SSL_xxx** and **SOURCE_TLS_xxx** options perform the same functions as the --ssl-xxx and --tls-xxx client options described in Command Options for Encrypted Connections. The correspondence between the two sets of options, and the use of the **SOURCE_SSL_xxx** and **SOURCE_TLS_xxx** options to set up a secure connection, is explained in Section 19.3.1, “Setting Up Replication to Use Encrypted Connections”.

- **SOURCE_USER = 'user_name'**

The user name for the replication user account to use for connecting to the replication source server. The maximum length of the string value is 96 characters.

For Group Replication, this account must exist on every member of the replication group. It is used for distributed recovery if the XCom communication stack is in use for the group, and also used for group communication connections if the MySQL communication stack is in use for the group. With the MySQL communication stack, the account must have the GROUP_REPLICATION_STREAM permission.

It is possible to set an empty user name by specifying **SOURCE_USER='''**, but the replication channel cannot be started with an empty user name. It is valid to set an empty **SOURCE_USER** user name and use the channel afterwards if you always provide user credentials using the **START REPLICA** statement or **START GROUP_REPLICATION** statement that starts the replication channel. This approach means that the replication channel always needs operator intervention to restart, but the user credentials are not recorded in the replication metadata repositories.

**Important**

To connect to the source using a replication user account that authenticates with the caching_sha2_password plugin, you must either set up a secure connection as described in Section 19.3.1, “Setting Up Replication to Use Encrypted Connections”, or enable the unencrypted connection to support password exchange using an RSA key pair. The caching_sha2_password authentication plugin is the default for new users (see Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”). If the user account that you create or use for replication uses this authentication plugin, and you are not using a secure connection, you must enable RSA key pair-based password exchange for a successful connection. You can do this using either the **SOURCE_PUBLIC_KEY_PATH** option or the **GET_SOURCE_PUBLIC_KEY=1** option for this statement.
• **SOURCE_ZSTD_COMPRESSION_LEVEL = level**

The compression level to use for connections to the replication source server that use the `zstd` compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression. The default level is 3.

The compression level setting has no effect on connections that do not use `zstd` compression. For more information, see Section 6.2.8, "Connection Compression Control".

**Examples**

**CHANGE REPLICATION SOURCE TO** is useful for setting up a replica when you have the snapshot of the source and have recorded the source's binary log coordinates corresponding to the time of the snapshot. After loading the snapshot into the replica to synchronize it with the source, you can run **CHANGE REPLICATION SOURCE TO** `SOURCE_LOG_FILE='log_name', SOURCE_LOG_POS=log_pos` on the replica to specify the coordinates at which the replica should begin reading the source's binary log. The following example changes the source server the replica uses and establishes the source's binary log coordinates from which the replica begins reading:

```
CHANGE REPLICATION SOURCE TO
    SOURCE_HOST='source2.example.com',
    SOURCE_USER='replication',
    SOURCE_PASSWORD='password',
    SOURCE_PORT=3306,
    SOURCE_LOG_FILE='source2-bin.001',
    SOURCE_LOG_POS=4,
    SOURCE_CONNECT_RETRY=10;
```

For the procedure to switch an existing replica to a new source during failover, see Section 19.4.8, "Switching Sources During Failover".

When GTIDs are in use on the source and the replica, specify GTID auto-positioning instead of giving the binary log file position, as in the following example. For full instructions to configure and start GTID-based replication on new or stopped servers, online servers, or additional replicas, see Section 19.1.3, "Replication with Global Transaction Identifiers".

```
CHANGE REPLICATION SOURCE TO
    SOURCE_HOST='source3.example.com',
    SOURCE_USER='replication',
    SOURCE_PASSWORD='password',
    SOURCE_PORT=3306,
    SOURCE_AUTO_POSITION = 1,
    FOR CHANNEL "source_3";
```

In this example, multi-source replication is in use, and the **CHANGE REPLICATION SOURCE TO** statement is applied to the replication channel "source_3" that connects the replica to the specified host. For guidance on setting up multi-source replication, see Section 19.1.5, "MySQL Multi-Source Replication".

The next example shows how to make the replica apply transactions from relay log files that you want to repeat. To do this, the source need not be reachable. You can use **CHANGE REPLICATION SOURCE TO** to locate the relay log position where you want the replica to start reapplying transactions, and then start the SQL thread:

```
CHANGE REPLICATION SOURCE TO
    RELAY_LOG_FILE='replica-relay-bin.006',
    RELAY_LOG_POS=4025;
START REPLICA SQL_THREAD;
```

**CHANGE REPLICATION SOURCE TO** can also be used to skip over transactions in the binary log that are causing replication to stop. The appropriate method to do this depends on whether GTIDs are in use or not. For instructions to skip transactions using **CHANGE REPLICATION SOURCE TO** or another method, see Section 19.1.7.3, "Skipping Transactions".

15.4.2.3 **RESET REPLICA** Statement
RESET REPLICA [ALL] [channel_option]

channel_option:
  FOR CHANNEL channel

RESET REPLICA makes the replica forget its position in the source's binary log.

This statement is meant to be used for a clean start; it clears the replication metadata repositories, deletes all the relay log files, and starts a new relay log file. It also resets to 0 the replication delay specified with the SOURCE_DELAY option of the CHANGE REPLICATION SOURCE TO statement.

Note
All relay log files are deleted, even if they have not been completely executed by the replication SQL thread. (This is a condition likely to exist on a replica if you have issued a STOP REPLICA statement or if the replica is highly loaded.)

For a server where GTIDs are in use (gtid_mode is ON), issuing RESET REPLICA has no effect on the GTID execution history. The statement does not change the values of gtid_executed or gtid_purged, or the mysql.gtid_executed table. If you need to reset the GTID execution history, use RESET BINARY LOGS AND GTIDS, even if the GTID-enabled server is a replica where binary logging is disabled.

RESET REPLICA requires the RELOAD privilege.

To use RESET REPLICA, the replication SQL thread and replication I/O (receiver) thread must be stopped, so on a running replica use STOP REPLICA before issuing RESET REPLICA. To use RESET REPLICA on a Group Replication group member, the member status must be OFFLINE, meaning that the plugin is loaded but the member does not currently belong to any group. A group member can be taken offline by using a STOP GROUP REPLICATION statement.

The optional FOR CHANNEL channel clause enables you to name which replication channel the statement applies to. Providing a FOR CHANNEL channel clause applies the RESET REPLICA statement to a specific replication channel. Combining a FOR CHANNEL channel clause with the ALL option deletes the specified channel. If no channel is named and no extra channels exist, the statement applies to the default channel. Issuing a RESET REPLICA ALL statement without a FOR CHANNEL channel clause when multiple replication channels exist deletes all replication channels and recreates only the default channel. See Section 19.2.2, “Replication Channels” for more information.

RESET REPLICA does not change any replication connection parameters, which include the source's host name and port, the replication user account and its password, the PRIVILEGE_CHECKS_USER account, the REQUIRE_ROW_FORMAT option, the REQUIRE_TABLE_PRIMARY_KEY_CHECK option, and the ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS option. If you want to change any of the replication connection parameters, you can do this using a CHANGE REPLICATION SOURCE TO statement after the server starts. If you want to remove all of the replication connection parameters, use RESET REPLICA ALL. RESET REPLICA ALL also clears the IGNORE_SERVER_IDS list set by CHANGE REPLICATION SOURCE TO. When you have used RESET REPLICA ALL, if you want to use the instance as a replica again, you need to issue a CHANGE REPLICATION SOURCE TO statement after the server start to specify new connection parameters.

You can set the GTID_ONLY option on the CHANGE REPLICATION SOURCE TO statement to stop a replication channel from persisting file names and file positions in the replication metadata repositories. When you issue RESET REPLICA, the replication metadata repositories are synchronized. RESET REPLICA ALL deletes rather than updates the repositories, so they are synchronized implicitly.

In the event of an unexpected server exit or deliberate restart after issuing RESET REPLICA but before issuing START REPLICA, replication connection parameters are preserved in the crash-safe InnoDB tables mysql.slave_master_info and mysql.slave_relay_log_info as part of the RESET REPLICA operation. They are also retained in memory. In the event of an unexpected server exit or deliberate restart after issuing RESET REPLICA but before issuing START REPLICA, the replication connection parameters are retrieved from the tables and reapplied to the channel. This applies for both the connection and applier metadata repositories.
RESET REPLICA does not change any replication filter settings (such as 
"--replicate-ignore-table") for channels affected by the statement. However, RESET REPLICA ALL removes the replication filters that were set on the channels deleted by the statement. When the deleted channel or channels are recreated, any global replication filters specified for the replica are copied to them, and no channel specific replication filters are applied. For more information see Section 19.2.5.4, "Replication Channel Based Filters".

RESET REPLICA causes an implicit commit of an ongoing transaction. See Section 15.3.3, “Statements That Cause an Implicit Commit”.

If the replication SQL thread was in the middle of replicating temporary tables when it was stopped, and RESET REPLICA is issued, these replicated temporary tables are deleted on the replica.

Note

When used on an NDB Cluster replica SQL node, RESET REPLICA clears the mysql.ndb_apply_status table. You should keep in mind when using this statement that ndb_apply_status uses the NDB storage engine and so is shared by all SQL nodes attached to the cluster.

You can override this behavior by issuing SET GLOBAL @ndb_clear_apply_status=OFF prior to executing RESET REPLICA, which keeps the replica from purging the ndb_apply_status table in such cases.

15.4.2.4 START REPLICA Statement

```
START REPLICA [thread_types] [until_option] [connection_options] [channel_option]

thread_types:
  [thread_type [, thread_type] ... ]

thread_type:
  IO_THREAD | SQL_THREAD

until_option:
  UNTIL {   {SQL_BEFORE_GTIDS | SQL_AFTER_GTIDS} = gtid_set
          | SOURCE_LOG_FILE = 'log_name', SOURCE_LOG_POS = log_pos
          | RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos
          | SQL_AFTER_MTS_GAPS }

connection_options:
  [USER='user_name'] [PASSWORD='user_pass'] [DEFAULT_AUTH='plugin_name'] [PLUGIN_DIR='plugin_dir']

channel_option:
  FOR CHANNEL channel

gtid_set:
  uuid_set [, uuid_set] ...
  |''

uuid_set:
  uuid:interval[:interval]...

uuid:
  hhhhhhhhh-hhhh-hhhh-hhhh-hhhhhhhhhhhh
  h:
    [0-9,A-F]

interval:
  n[-n]
  (n >= 1)
```

START REPLICA starts the replication threads, either together or separately.
**START REPLICA** requires the `REPLICATION_SLAVE_ADMIN` privilege (or the deprecated `SUPER` privilege). **START REPLICA** causes an implicit commit of an ongoing transaction. See Section 15.3.3, "Statements That Cause an Implicit Commit".

For the thread type options, you can specify `IO_THREAD`, `SQL_THREAD`, both of these, or neither of them. Only the threads that are started are affected by the statement.

- **START REPLICA** with no thread type options starts all of the replication threads, and so does **START REPLICA** with both of the thread type options.
- **IO_THREAD** starts the replication receiver thread, which reads events from the source server and stores them in the relay log.
- **SQL_THREAD** starts the replication applier thread, which reads events from the relay log and executes them. A multithreaded replica (with `replica_parallel_workers > 0`) applies transactions using a coordinator thread and multiple applier threads, and **SQL_THREAD** starts all of these.

**Important**

**START REPLICA** sends an acknowledgment to the user after all the replication threads have started. However, the replication receiver thread might not yet have connected to the source successfully, or an applier thread might stop when applying an event right after starting. **START REPLICA** does not continue to monitor the threads after they are started, so it does not warn you if they subsequently stop or cannot connect. You must check the replica's error log for error messages generated by the replication threads, or check that they are running satisfactorily with **SHOW REPLICA STATUS**. A successful **START REPLICA** statement causes **SHOW REPLICA STATUS** to show `Replica_SQL_Running=Yes`, but it might or might not show `Replica_IO_Running=Yes`, because `Replica_IO_Running=Yes` is only shown if the receiver thread is both running and connected. For more information, see Section 19.1.7.1, "Checking Replication Status".

The optional `FOR CHANNEL channel` clause enables you to name which replication channel the statement applies to. Providing a `FOR CHANNEL channel` clause applies the **START REPLICA** statement to a specific replication channel. If no clause is named and no extra channels exist, the statement applies to the default channel. If a **START REPLICA** statement does not have a channel defined when using multiple channels, this statement starts the specified threads for all channels. See Section 19.2.2, "Replication Channels" for more information.

The replication channels for Group Replication (`group_replication_applier` and `group_replication_recovery`) are managed automatically by the server instance. **START REPLICA** cannot be used at all with the `group_replication_recovery` channel, and should only be used with the `group_replication_applier` channel when Group Replication is not running. The `group_replication_applier` channel only has an applier thread and has no receiver thread, so it can be started if required by using the `SQL_THREAD` option without the `IO_THREAD` option.

**START REPLICA** supports pluggable user-password authentication (see Section 8.2.17, "Pluggable Authentication") with the `USER`, `PASSWORD`, `DEFAULT_AUTH` and `PLUGIN_DIR` options, as described in the following list. When you use these options, you must start the receiver thread (`IO_THREAD` option) or all the replication threads; you cannot start the replication applier thread (`SQL_THREAD` option) alone.

- **USER** The user name for the account. You must set this if `PASSWORD` is used. The option cannot be set to an empty or null string.
- **PASSWORD** The password for the named user account.
- **DEFAULT_AUTH** The name of the authentication plugin. The default is MySQL native authentication.
**PLUGIN_DIR**

The location of the authentication plugin.

**Important**

The password that you set using `START REPLICA` is masked when it is written to MySQL Server's logs, Performance Schema tables, and `SHOW PROCESSLIST` statements. However, it is sent in plain text over the connection to the replica server instance. To protect the password in transit, use SSL/TLS encryption, an SSH tunnel, or another method of protecting the connection from unauthorized viewing, for the connection between the replica server instance and the client that you use to issue `START REPLICA`.

The `UNTIL` clause makes the replica start replication, then process transactions up to the point that you specify in the `UNTIL` clause, then stop again. The `UNTIL` clause can be used to make a replica proceed until just before the point where you want to skip a transaction that is unwanted, and then skip the transaction as described in Section 19.1.7.3, "Skipping Transactions". To identify a transaction, you can use `mysqlbinlog` with the source's binary log or the replica's relay log, or use a `SHOW BINLOG EVENTS` statement.

You can also use the `UNTIL` clause for debugging replication by processing transactions one at a time or in sections. If you are using the `UNTIL` clause to do this, start the replica with `--skip-replica-start` to prevent the SQL thread from running when the replica server starts. Remove the option or system variable setting after the procedure is complete, so that it is not forgotten in the event of an unexpected server restart.

The `SHOW REPLICA STATUS` statement includes output fields that display the current values of the `UNTIL` condition. The `UNTIL` condition lasts for as long as the affected threads are still running, and is removed when they stop.

The `UNTIL` clause operates on the replication applier thread (SQL_THREAD option). You can use the SQL_THREAD option or let the replica default to starting both threads. If you use the IO_THREAD option alone, the `UNTIL` clause is ignored because the applier thread is not started.

The point that you specify in the `UNTIL` clause can be any one (and only one) of the following options:

- **SOURCE_LOG_FILE** and **SOURCE_LOG_POS**
  
  These options make the replication applier process transactions up to a position in its relay log, identified by the file name and file position of the corresponding point in the binary log on the source server. The applier thread finds the nearest transaction boundary at or after the specified position, finishes applying the transaction, and stops there. For compressed transaction payloads, specify the end position of the compressed `Transaction_payload_event`.

  These options can still be used when the `GTID_ONLY` option was set on the `CHANGE REPLICATION SOURCE TO` statement to stop the replication channel from persisting file names and file positions in the replication metadata repositories. The file names and file positions are tracked in memory.

- **RELAY_LOG_FILE** and **RELAY_LOG_POS**
  
  These options make the replication applier process transactions up to a position in the replica's relay log, identified by the relay log file name and a position in that file. The applier thread finds the nearest transaction boundary at or after the specified position, finishes applying the transaction, and stops there. For compressed transaction payloads, specify the end position of the compressed `Transaction_payload_event`.

  These options can still be used when the `GTID_ONLY` option was set on the `CHANGE REPLICATION SOURCE TO` statement to stop the replication channel from persisting file names and file positions
in the replication metadata repositories. The file names and file positions are tracked in memory.

**SQL_BEFORE_GTIDS**

This option makes the replication applier start processing transactions and stop when it encounters any transaction that is in the specified GTID set. The encountered transaction from the GTID set is not applied, and nor are any of the other transactions in the GTID set. The option takes a GTID set containing one or more global transaction identifiers as an argument (see GTID Sets). Transactions in a GTID set do not necessarily appear in the replication stream in the order of their GTIDs, so the transaction before which the applier stops is not necessarily the earliest.

**SQL_AFTER_GTIDS**

This option makes the replication applier start processing transactions and stop when it has processed all of the transactions in a specified GTID set. The option takes a GTID set containing one or more global transaction identifiers as an argument (see GTID Sets).

With **SQL_AFTER_GTIDS**, the replication threads stop after they have processed all transactions in the GTID set. Transactions are processed in the order received, so it is possible that these include transactions which are not part of the GTID set, but which are received (and processed) before all transactions in the set have been committed. For example, executing `START REPLICA UNTIL SQL_AFTER_GTIDS = 3E11FA47-71CA-11E1-9E33-C80AA9429562:11-56` causes the replica to obtain (and process) all transactions from the source until all of the transactions having the sequence numbers 11 through 56 have been processed, and then to stop without processing any additional transactions after that point has been reached.

In older versions of MySQL, this option could not be used with `replica_parallel_workers > 1`. In MySQL 8.4, this is no longer an issue, and **SQL_AFTER_GTIDS** can be used without causing the replica to fall back into single-threaded mode.

**SQL_AFTER_MTS_GAPS**

For a multithreaded replica only (with `replica_parallel_workers > 0`), this option makes the replica process transactions up to the point where there are no more gaps in the sequence of transactions executed from the relay log. When using a multithreaded replica, there is a chance of gaps occurring in the following situations:

- The coordinator thread is stopped.
- An error occurs in the applier threads.
- `mysqld` shuts down unexpectedly.

When a replication channel has gaps, the replica’s database is in a state that might never have existed on the source. The replica tracks the gaps internally and disallows `CHANGE REPLICATION SOURCE TO` statements that would remove the gap information if they executed.

All replicas are multithreaded by default. When `replica_preserve_commit_order=ON` on the replica (the default), gaps should not occur except in the specific situations listed in the description for this variable. If
SQL Statements for Controlling Replica Servers

replica_preserve_commit_order is OFF, the commit order of transactions is not preserved, so the chance of gaps occurring is much larger.

If GTIDs are not in use and you need to change a failed multithreaded replica to single-threaded mode, you can issue the following series of statements, in the order shown:

START REPLICA UNTIL SQL_AFTER_MTS_GAPS;
SET @@GLOBAL.replica_parallel_workers = 0;
START REPLICA SQL_THREAD;

15.4.2.5 STOP REPLICA Statement

```
STOP REPLICA [thread_types] [channel_option]

thread_types:
  [thread_type [, thread_type] ... ]

thread_type: IO_THREAD | SQL_THREAD

channel_option:
  FOR CHANNEL channel
```

Stops the replication threads.

STOP REPLICA requires the REPLICATION_SLAVE_ADMIN privilege (or the deprecated SUPER privilege). Recommended best practice is to execute STOP REPLICA on the replica before stopping the replica server (see Section 7.1.19, "The Server Shutdown Process", for more information).

Like START REPLICA, this statement may be used with the IO_THREAD and SQL_THREAD options to name the replication thread or threads to be stopped. Note that the Group Replication applier channel (group_replication_applier) has no replication I/O (receiver) thread, only a replication SQL (applier) thread. Using the SQL_THREAD option therefore stops this channel completely.

STOP REPLICA causes an implicit commit of an ongoing transaction. See Section 15.3.3, "Statements That Cause an Implicit Commit".

gtid_next must be set to AUTOMATIC before issuing this statement.

You can control how long STOP REPLICA waits before timing out by setting the system variable rpl_stop_replica_timeout. This can be used to avoid deadlocks between STOP REPLICA and other SQL statements using different client connections to the replica. When the timeout value is reached, the issuing client returns an error message and stops waiting, but the STOP REPLICA instruction remains in effect. Once the replication threads are no longer busy, the STOP REPLICA statement is executed and the replica stops.

Some CHANGE REPLICATION SOURCE TO statements are allowed while the replica is running, depending on the states of the replication threads. However, using STOP REPLICA prior to executing a CHANGE REPLICATION SOURCE TO statement in such cases is still supported. See Section 15.4.2.2, "CHANGE REPLICATION SOURCE TO Statement", and Section 19.4.8, "Switching Sources During Failover", for more information.

The optional FOR CHANNEL channel clause enables you to name which replication channel the statement applies to. Providing a FOR CHANNEL channel clause applies the STOP REPLICA statement to a specific replication channel. If no channel is named and no extra channels exist, the statement applies to the default channel. If a STOP REPLICA statement does not name a channel when using multiple channels, this statement stops the specified threads for all channels. See Section 19.2.2, "Replication Channels" for more information.

The replication channels for Group Replication (group_replication_applier and group_replication_recovery) are managed automatically by the server instance. STOP REPLICA cannot be used at all with the group_replication_recovery channel, and should only
be used with the `group_replication_applier` channel when Group Replication is not running. The `group_replication_applier` channel only has an applier thread and has no receiver thread, so it can be stopped if required by using the `SQL_THREAD` option without the `IO_THREAD` option.

When the replica is multithreaded (`replica_parallel_workers` is a nonzero value), any gaps in the sequence of transactions executed from the relay log are closed as part of stopping the worker threads. If the replica is stopped unexpectedly (for example due to an error in a worker thread, or another thread issuing `KILL`) while a `STOP REPLICA` statement is executing, the sequence of executed transactions from the relay log may become inconsistent. See Section 19.5.1.34, “Replication and Transaction Inconsistencies”, for more information.

When the source is using the row-based binary logging format, you should execute `STOP REPLICA` or `STOP REPLICA SQL_THREAD` on the replica prior to shutting down the replica server if you are replicating any tables that use a nontransactional storage engine. If the current replication event group has modified one or more nontransactional tables, `STOP REPLICA` waits for up to 60 seconds for the event group to complete, unless you issue a `KILL QUERY` or `KILL CONNECTION` statement for the replication SQL thread. If the event group remains incomplete after the timeout, an error message is logged.

When the source is using the statement-based binary logging format, changing the source while it has open temporary tables is potentially unsafe. This is one of the reasons why statement-based replication of temporary tables is not recommended. You can find out whether there are any temporary tables on the replica by checking the value of `Replica_open_temp_tables`. When using statement-based replication, this value should be 0 before executing `CHANGE REPLICATION SOURCE TO`. If there are any temporary tables open on the replica, issuing a `CHANGE REPLICATION SOURCE TO` statement after issuing a `STOP REPLICA` causes an `ER_WARN_OPEN_TEMP_TABLES_MUST_BE_ZERO` warning.

15.4.3 SQL Statements for Controlling Group Replication

This section provides information about the statements used for controlling group replication.

15.4.3.1 START GROUP_REPLICATION Statement

```
START GROUP_REPLICATION
    [USER='user_name']
    [, PASSWORD='user_pass']
    [, DEFAULT_AUTH='plugin_name']
```

Starts group replication. This statement requires the `GROUP_REPLICATION_ADMIN` privilege (or the deprecated `SUPER` privilege). If `super_read_only=ON` is set and the member should join as a primary, `super_read_only` is set to `OFF` once Group Replication successfully starts.

A server that participates in a group in single-primary mode should use `skip_replica_start=ON`. Otherwise, the server is not allowed to join a group as a secondary.

You can specify user credentials for distributed recovery in the `START GROUP_REPLICATION` statement using the `USER`, `PASSWORD`, and `DEFAULT_AUTH` options, as follows:

- **USER**: The replication user for distributed recovery. For instructions to set up this account, see Section 20.2.1.3, “User Credentials For Distributed Recovery”. You cannot specify an empty or null string, or omit the `USER` option if `PASSWORD` is specified.
- **PASSWORD**: The password for the replication user account. The password cannot be encrypted, but it is masked in the query log.
- **DEFAULT_AUTH**: The name of the authentication plugin used for the replication user account. If you do not specify this option, MySQL native authentication (the `mysql_native_password` plugin) is assumed. This option acts as a hint to the server, and the donor for distributed recovery overrides it if a different plugin is associated with the user account on that server. The authentication plugin used by default when you create user accounts in MySQL 8 is the caching SHA-2 authentication plugin (`caching_sha2_password`). See Section 8.2.17, “Pluggable Authentication” for more information on authentication plugins.
SQL Statements for Controlling Group Replication

These credentials are used for distributed recovery on the `group_replication_recovery` channel. When you specify user credentials on `START GROUP_REPLICATION`, the credentials are saved in memory only, and are removed by a `STOP GROUP_REPLICATION` statement or server shutdown. You must issue a `START GROUP_REPLICATION` statement to provide the credentials again. This method is therefore not compatible with starting Group Replication automatically on server start, as specified by the `group_replication_start_on_boot` system variable.

User credentials specified on `START GROUP_REPLICATION` take precedence over any user credentials set for the `group_replication_recovery` channel using a `CHANGE REPLICATION SOURCE TO`. Note that user credentials set using these statements are stored in the replication metadata repositories, and are used when `START GROUP_REPLICATION` is specified without user credentials, including automatic starts if the `group_replication_start_on_boot` system variable is set to `ON`. To gain the security benefits of specifying user credentials on `START GROUP_REPLICATION`, ensure that `group_replication_start_on_boot` is set to `OFF` (the default is `ON`), and clear any user credentials previously set for the `group_replication_recovery` channel, following the instructions in Section 20.6.3, “Securing Distributed Recovery Connections”.

While a member is rejoining a replication group, its status can be displayed as `OFFLINE` or `ERROR` before the group completes the compatibility checks and accepts it as a member. When the member is catching up with the group's transactions, its status is `RECOVERING`.

**15.4.3.2 STOP GROUP_REPLICATION Statement**

`STOP GROUP_REPLICATION` stops Group Replication. This statement requires the `GROUP_REPLICATION_ADMIN` privilege (or the deprecated `SUPER` privilege). As soon as you issue `STOP GROUP_REPLICATION` the member is set to `super_read_only=ON`, which ensures that no writes can be made to the member while Group Replication stops. Any other asynchronous replication channels running on the member are also stopped. Any user credentials that you specified in the `START GROUP_REPLICATION` statement when starting Group Replication on this member are removed from memory, and must be supplied when you start Group Replication again.

**Warning**

Use this statement with extreme caution because it removes the server instance from the group, meaning it is no longer protected by Group Replication’s consistency guarantee mechanisms. To be completely safe, ensure that your applications can no longer connect to the instance before issuing this statement to avoid any chance of stale reads.

The `STOP GROUP_REPLICATION` statement stops asynchronous replication channels on the group member, but it does not implicitly commit transactions that are in progress on them like `STOP REPLICA` does. This is because on a Group Replication group member, an additional transaction committed during the shutdown operation would leave the member inconsistent with the group and cause an issue with rejoining. To avoid failed commits for transactions that are in progress while stopping Group Replication, the `STOP GROUP_REPLICATION` statement cannot be issued while a GTID is assigned as the value of the `gtid_next` system variable.

The `group_replication_components_stop_timeout` system variable specifies the time for which Group Replication waits for each of its modules to complete ongoing processes after this statement is issued. The timeout is used to resolve situations in which Group Replication components cannot be stopped normally, which can happen if the member is expelled from the group while it is in an error state, or while a process such as MySQL Enterprise Backup is holding a global lock on tables on the member. In such situations, the member cannot stop the applier thread or complete the distributed recovery process to rejoin. `STOP GROUP_REPLICATION` does not complete until either the situation is resolved (for example, by the lock being released), or the component timeout expires and the modules are shut down regardless of their status. The default value is 300 seconds; this means that Group Replication components are stopped after 5 minutes if the situation is not resolved before that time, allowing the member to be restarted and rejoin.
15.5 Prepared Statements

MySQL 8.4 provides support for server-side prepared statements. This support takes advantage of the efficient client/server binary protocol. Using prepared statements with placeholders for parameter values has the following benefits:

- Less overhead for parsing the statement each time it is executed. Typically, database applications process large volumes of almost-identical statements, with only changes to literal or variable values in clauses such as \texttt{WHERE} for queries and deletes, \texttt{SET} for updates, and \texttt{VALUES} for inserts.
- Protection against SQL injection attacks. The parameter values can contain unescaped SQL quote and delimiter characters.

The following sections provide an overview of the characteristics of prepared statements:

- Prepared Statements in Application Programs
- Prepared Statements in SQL Scripts
- \texttt{PREPARE}, \texttt{EXECUTE}, and \texttt{DEALLOCATE PREPARE} Statements
- SQL Syntax Permitted in Prepared Statements

Prepared Statements in Application Programs

You can use server-side prepared statements through client programming interfaces, including the MySQL C API client library for C programs, MySQL Connector/J for Java programs, and MySQL Connector/NET for programs using .NET technologies. For example, the C API provides a set of function calls that make up its prepared statement API. See C API Prepared Statement Interface. Other language interfaces can provide support for prepared statements that use the binary protocol by linking in the C client library, one example being the \texttt{mysqli} extension, available in PHP 5.0 and later.

Prepared Statements in SQL Scripts

An alternative SQL interface to prepared statements is available. This interface is not as efficient as using the binary protocol through a prepared statement API, but requires no programming because it is available directly at the SQL level:

- You can use it when no programming interface is available to you.
- You can use it from any program that can send SQL statements to the server to be executed, such as the \texttt{mysql} client program.
- You can use it even if the client is using an old version of the client library.

SQL syntax for prepared statements is intended to be used for situations such as these:

- To test how prepared statements work in your application before coding it.
- To use prepared statements when you do not have access to a programming API that supports them.
- To interactively troubleshoot application issues with prepared statements.
- To create a test case that reproduces a problem with prepared statements, so that you can file a bug report.

PREPARE, EXECUTE, and DEALLOCATE PREPARE Statements

SQL syntax for prepared statements is based on three SQL statements:

- \texttt{PREPARE} prepares a statement for execution (see Section 15.5.1, “PREPARE Statement”).
• **EXECUTE** executes a prepared statement (see Section 15.5.2, “EXECUTE Statement”).

• **DEALLOCATE PREPARE** releases a prepared statement (see Section 15.5.3, “DEALLOCATE PREPARE Statement”).

The following examples show two equivalent ways of preparing a statement that computes the hypotenuse of a triangle given the lengths of the two sides.

The first example shows how to create a prepared statement by using a string literal to supply the text of the statement:

```sql
mysql> PREPARE stmt1 FROM 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
```

```sql
mysql> SET @a = 3;
```

```sql
mysql> SET @b = 4;
```

```sql
mysql> EXECUTE stmt1 USING @a, @b;
```

+------------+
<table>
<thead>
<tr>
<th>hypotenuse</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
</tr>
</tbody>
</table>
+------------+

```sql
mysql> DEALLOCATE PREPARE stmt1;
```

The second example is similar, but supplies the text of the statement as a user variable:

```sql
mysql> SET @s = 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
```

```sql
mysql> PREPARE stmt2 FROM @s;
```

```sql
mysql> SET @a = 6;
```

```sql
mysql> SET @b = 8;
```

```sql
mysql> EXECUTE stmt2 USING @a, @b;
```

+------------+
<table>
<thead>
<tr>
<th>hypotenuse</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
</tr>
</tbody>
</table>
+------------+

mysql> DEALLOCATE PREPARE stmt2;
```

Here is an additional example that demonstrates how to choose the table on which to perform a query at runtime, by storing the name of the table as a user variable:

```sql
mysql> USE test;
```

```sql
mysql> CREATE TABLE t1 (a INT NOT NULL);
```

```sql
mysql> INSERT INTO t1 VALUES (4), (8), (11), (32), (80);
```

```sql
mysql> SET @table = 't1';
```

```sql
mysql> SET @s = CONCAT('SELECT * FROM ', @table);
```

```sql
mysql> PREPARE stmt3 FROM @s;
```

```sql
mysql> EXECUTE stmt3;
```

+----+
<table>
<thead>
<tr>
<th>a</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
</tr>
<tr>
<td>8</td>
</tr>
<tr>
<td>11</td>
</tr>
<tr>
<td>32</td>
</tr>
<tr>
<td>80</td>
</tr>
</tbody>
</table>
+----+

mysql> DEALLOCATE PREPARE stmt3;
```

A prepared statement is specific to the session in which it was created. If you terminate a session without deallocating a previously prepared statement, the server deallocates it automatically.

A prepared statement is also global to the session. If you create a prepared statement within a stored routine, it is not deallocated when the stored routine ends.

To guard against too many prepared statements being created simultaneously, set the `max_prepared_stmt_count` system variable. To prevent the use of prepared statements, set the value to 0.
SQL Syntax Permitted in Prepared Statements

The following SQL statements can be used as prepared statements:

```
ALTER TABLE
ALTER USER
ANALYZE TABLE
CACHE INDEX
CALL
CHANGE MASTER
CHECKSUM {TABLE | TABLES}
COMMIT
{CREATE | DROP} INDEX
{CREATE | RENAME | DROP} DATABASE
{CREATE | DROP} TABLE
{CREATE | RENAME | DROP} USER
{CREATE | DROP} VIEW
DELETE
DO
FLUSH {TABLE | TABLES | TABLES WITH READ LOCK | HOSTS | PRIVILEGES |
| LOGS | STATUS | MASTER | SLAVE | USER_RESOURCES}
GRANT
INSERT
INSTALL PLUGIN
KILL
LOAD INDEX INTO CACHE
OPTIMIZE TABLE
RENAME TABLE
REPAIR TABLE
REPLACE
RESET {MASTER | SLAVE}
REVOKE
SELECT
SET
SHOW BINLOG EVENTS
SHOW CREATE {PROCEDURE | FUNCTION | EVENT | TABLE | VIEW}
SHOW {MASTER | BINARY} LOGS
SHOW {MASTER | SLAVE} STATUS
SLAVE {START | STOP}
TRUNCATE TABLE
UNINSTALL PLUGIN
UPDATE
```

Other statements are not supported.

For compliance with the SQL standard, which states that diagnostics statements are not preparable, MySQL does not support the following as prepared statements:

- `SHOW WARNINGS, SHOW COUNT(*) WARNINGS`
- `SHOW ERRORS, SHOW COUNT(*) ERRORS`
- Statements containing any reference to the `warning_count` or `error_count` system variable.

Generally, statements not permitted in SQL prepared statements are also not permitted in stored programs. Exceptions are noted in Section 27.8, “Restrictions on Stored Programs”.

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic repreparation of the statement when it is next executed. For more information, see Section 10.10.3, “Caching of Prepared Statements and Stored Programs”.

Placeholders can be used for the arguments of the `LIMIT` clause when using prepared statements. See Section 15.2.13, “SELECT Statement”.

In prepared `CALL` statements used with `PREPARE` and `EXECUTE`, placeholder support for `OUT` and `INOUT` parameters is available beginning with MySQL 8.4. See Section 15.2.1, “CALL Statement”, for an example and a workaround for earlier versions. Placeholders can be used for `IN` parameters regardless of version.
SQL syntax for prepared statements cannot be used in nested fashion. That is, a statement passed to `PREPARE` cannot itself be a `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE` statement.

SQL syntax for prepared statements is distinct from using prepared statement API calls. For example, you cannot use the `mysql_stmt_prepare()` C API function to prepare a `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE` statement.

SQL syntax for prepared statements can be used within stored procedures, but not in stored functions or triggers. However, a cursor cannot be used for a dynamic statement that is prepared and executed with `PREPARE` and `EXECUTE`. The statement for a cursor is checked at cursor creation time, so the statement cannot be dynamic.

SQL syntax for prepared statements does not support multi-statements (that is, multiple statements within a single string separated by `;` characters).

To write C programs that use the `CALL` SQL statement to execute stored procedures that contain prepared statements, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`). For additional information, see Section 15.2.1, “CALL Statement”.

### 15.5.1 PREPARE Statement

```sql
PREPARE stmt_name FROM preparable_stmt
```

The `PREPARE` statement prepares a SQL statement and assigns it a name, `stmt_name`, by which to refer to the statement later. The prepared statement is executed with `EXECUTE` and released with `DEALLOCATE PREPARE`. For examples, see Section 15.5, “Prepared Statements”.

Statement names are not case-sensitive. `preparable_stmt` is either a string literal or a user variable that contains the text of the SQL statement. The text must represent a single statement, not multiple statements. Within the statement, `?` characters can be used as parameter markers to indicate where data values are to be bound to the query later when you execute it. The `?` characters should not be enclosed within quotation marks, even if you intend to bind them to string values. Parameter markers can be used only where data values should appear, not for SQL keywords, identifiers, and so forth.

If a prepared statement with the given name already exists, it is deallocated implicitly before the new statement is prepared. This means that if the new statement contains an error and cannot be prepared, an error is returned and no statement with the given name exists.

The scope of a prepared statement is the session within which it is created, which as several implications:

- A prepared statement created in one session is not available to other sessions.
- When a session ends, whether normally or abnormally, its prepared statements no longer exist. If auto-reconnect is enabled, the client is not notified that the connection was lost. For this reason, clients may wish to disable auto-reconnect. See Automatic Reconnection Control.
- A prepared statement created within a stored program continues to exist after the program finishes executing and can be executed outside the program later.
- A statement prepared in stored program context cannot refer to stored procedure or function parameters or local variables because they go out of scope when the program ends and would be unavailable were the statement to be executed later outside the program. As a workaround, refer
instead to user-defined variables, which also have session scope; see Section 11.4, “User-Defined Variables”.

The type of a parameter used in a prepared statement is determined when the statement is first prepared; it retains this type whenever EXECUTE is invoked for this prepared statement (unless the statement is reprepared, as explained later in this section). Rules for determining a parameter’s type are listed here:

- A parameter which is an operand of a binary arithmetic operator has the same data type as the other operand.
- If both operands of a binary arithmetic operator are parameters, the type of the parameters is decided by the context of the operator.
- If a parameter is the operand of a unary arithmetic operator, the parameter’s type is decided by the context of the operator.
- If an arithmetic operator has no type-determining context, the derived type for any parameters involved is DOUBLE PRECISION. This can happen, for example, when the parameter is a top-level node in a SELECT list, or when it is part of a comparison operator.
- A parameter which is an operand of a character string operator has the same derived type as the aggregated type of the other operands. If all operands of the operator are parameters, the derived type is VARCHAR; its collation is determined by the value of collation_connection.
- A parameter which is an operand of a temporal operator has type DATETIME if the operator returns a DATETIME, TIME if the operator returns a TIME, and DATE if the operator returns a DATE.
- A parameter which is an operand of a binary comparison operator has the same derived type as the other operand of the comparison.
- A parameter that is an operand of a ternary comparison operator such as BETWEEN has the same derived type as the aggregated type of the other operands.
- If all operands of a comparison operator are parameters, the derived type for each of them is VARCHAR, with collation determined by the value of collation_connection.
- A parameter that is an output operand of any of CASE, COALESCE, IF, IFNULL, or NULLIF has the same derived type as the aggregated type of the operator’s other output operands.
- If all output operands of any of CASE, COALESCE, IF, IFNULL, or NULLIF are parameters, or they are all NULL, the type of the parameter is decided by the context of the operator.
- If the parameter is an operand of any of CASE, COALESCE(), IF, or IFNULL, and has no type-determining context, the derived type for each of the parameters involved is VARCHAR, and its collation is determined by the value of collation_connection.
- A parameter which is the operand of a CAST() has the same type as specified by the CAST().
- If a parameter is an immediate member of a SELECT list that is not part of an INSERT statement, the derived type of the parameter is VARCHAR, and its collation is determined by the value of collation_connection.
- If a parameter is an immediate member of a SELECT list that is part of an INSERT statement, the derived type of the parameter is the type of the corresponding column into which the parameter is inserted.
- If a parameter is used as source for an assignment in a SET clause of an UPDATE statement or in the ON DUPLICATE KEY UPDATE clause of an INSERT statement, the derived type of the parameter is the type of the corresponding column which is updated by the SET or ON DUPLICATE KEY UPDATE clause.
- If a parameter is an argument of a function, the derived type depends on the function’s return type.
For some combinations of actual type and derived type, an automatic repreparation of the statement is triggered, to ensure closer compatibility with previous versions of MySQL. Repreparation does not occur if any of the following conditions are true:

- **NULL** is used as the actual parameter value.
- A parameter is an operand of a `CAST()`. (Instead, a cast to the derived type is attempted, and an exception raised if the cast fails.)
- A parameter is a string. (In this case, an implicit `CAST(? AS derived_type)` is performed.)
- The derived type and actual type of the parameter are both `INTEGER` and have the same sign.
- The parameter's derived type is `DECIMAL` and its actual type is either `DECIMAL` or `INTEGER`.
- The derived type is `DOUBLE` and the actual type is any numeric type.
- Both the derived type and the actual type are string types.
- If the derived type is temporal and the actual type is temporal. **Exceptions:** The derived type is `TIME` and the actual type is not `TIME`; the derived type is `DATE` and the actual type is not `DATE`.
- The derived type is temporal and the actual type is numeric.

For cases other than those just listed, the statement is reprepared and the actual parameter types are used instead of the derived parameter types.

These rules also apply to a user variable referenced in a prepared statement.

Using a different data type for a given parameter or user variable within a prepared statement for executions of the statement subsequent to the first execution causes the statement to be reprepared. This is less efficient; it may also lead to the parameter's (or variable's) actual type to vary, and thus for results to be inconsistent, with subsequent executions of the prepared statement. For these reasons, it is advisable to use the same data type for a given parameter when re-executing a prepared statement.

### 15.5.2 EXECUTE Statement

```sql
EXECUTE stmt_name
[USING @var_name [, @var_name] ...]
```

After preparing a statement with `PREPARE`, you execute it with an `EXECUTE` statement that refers to the prepared statement name. If the prepared statement contains any parameter markers, you must supply a `USING` clause that lists user variables containing the values to be bound to the parameters. Parameter values can be supplied only by user variables, and the `USING` clause must name exactly as many variables as the number of parameter markers in the statement.

You can execute a given prepared statement multiple times, passing different variables to it or setting the variables to different values before each execution.

For examples, see Section 15.5, “Prepared Statements”.

### 15.5.3 DEALLOCATE PREPARE Statement

```sql
{DEALLOCATE | DROP} PREPARE stmt_name
```

To deallocate a prepared statement produced with `PREPARE`, use a `DEALLOCATE PREPARE` statement that refers to the prepared statement name. Attempting to execute a prepared statement after deallocating it results in an error. If too many prepared statements are created and not deallocated by either the `DEALLOCATE PREPARE` statement or the end of the session, you might encounter the upper limit enforced by the `max_prepared_stmt_count` system variable.

For examples, see Section 15.5, “Prepared Statements”.

---

2705
15.6 Compound Statement Syntax

This section describes the syntax for the \texttt{BEGIN \ldots END} compound statement and other statements that can be used in the body of stored programs: Stored procedures and functions, triggers, and events. These objects are defined in terms of SQL code that is stored on the server for later invocation (see Chapter 27, \textit{Stored Objects}).

A compound statement is a block that can contain other blocks; declarations for variables, condition handlers, and cursors; and flow control constructs such as loops and conditional tests.

15.6.1 BEGIN ... END Compound Statement

\begin{verbatim}
[begin_label:] BEGIN
[statement_list]
END [end_label]
\end{verbatim}

\texttt{BEGIN \ldots END} syntax is used for writing compound statements, which can appear within stored programs (stored procedures and functions, triggers, and events). A compound statement can contain multiple statements, enclosed by the \texttt{BEGIN} and \texttt{END} keywords. \texttt{statement_list} represents a list of one or more statements, each terminated by a semicolon (\texttt{;}) statement delimiter. The \texttt{statement_list} itself is optional, so the empty compound statement (\texttt{BEGIN END}) is legal.

\texttt{BEGIN \ldots END} blocks can be nested.

Use of multiple statements requires that a client is able to send statement strings containing the \texttt{;} statement delimiter. In the \texttt{mysql} command-line client, this is handled with the \texttt{delimiter} command. Changing the \texttt{;} end-of-statement delimiter (for example, to //) permit \texttt{;} to be used in a program body. For an example, see Section 27.1, \textit{Defining Stored Programs}.

A \texttt{BEGIN \ldots END} block can be labeled. See Section 15.6.2, \textit{“Statement Labels”}.

The optional [NOT] ATOMIC clause is not supported. This means that no transactional savepoint is set at the start of the instruction block and the \texttt{BEGIN} clause used in this context has no effect on the current transaction.

\begin{note}
Within all stored programs, the parser treats \texttt{BEGIN [WORK]} as the beginning of a \texttt{BEGIN \ldots END} block. To begin a transaction in this context, use \texttt{START TRANSACTION} instead.
\end{note}

15.6.2 Statement Labels

\begin{verbatim}
[begin_label:] BEGIN
  [statement_list]
END [end_label]

[begin_label:] LOOP
  statement_list
END LOOP [end_label]

[begin_label:] REPEAT
  statement_list
UNTIL search_condition
END REPEAT [end_label]

[begin_label:] WHILE search_condition DO
  statement_list
END WHILE [end_label]
\end{verbatim}

Labels are permitted for \texttt{BEGIN \ldots END} blocks and for the \texttt{LOOP}, \texttt{REPEAT}, and \texttt{WHILE} statements. Label use for those statements follows these rules:

- \texttt{begin_label} must be followed by a colon.
• `begin_label` can be given without `end_label`. If `end_label` is present, it must be the same as `begin_label`.

• `end_label` cannot be given without `begin_label`.

• Labels at the same nesting level must be distinct.

• Labels can be up to 16 characters long.

To refer to a label within the labeled construct, use an `ITERATE` or `LEAVE` statement. The following example uses those statements to continue iterating or terminate the loop:

```sql
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
  label1: LOOP
    SET p1 = p1 + 1;
    IF p1 < 10 THEN ITERATE label1; END IF;
    LEAVE label1;
  END LOOP label1;
END;
```

The scope of a block label does not include the code for handlers declared within the block. For details, see Section 15.6.7.2, “DECLARE ... HANDLER Statement”.

### 15.6.3 DECLARE Statement

The `DECLARE` statement is used to define various items local to a program:

- Local variables. See Section 15.6.4, “Variables in Stored Programs”.

- Conditions and handlers. See Section 15.6.7, “Condition Handling”.

- Cursors. See Section 15.6.6, “Cursors”.

`DECLARE` is permitted only inside a `BEGIN ... END` compound statement and must be at its start, before any other statements.

Declarations must follow a certain order. Cursor declarations must appear before handler declarations. Variable and condition declarations must appear before cursor or handler declarations.

### 15.6.4 Variables in Stored Programs

System variables and user-defined variables can be used in stored programs, just as they can be used outside stored-program context. In addition, stored programs can use `DECLARE` to define local variables, and stored routines (procedures and functions) can be declared to take parameters that communicate values between the routine and its caller.

- To declare local variables, use the `DECLARE` statement, as described in Section 15.6.4.1, “Local Variable DECLARE Statement”.

- Variables can be set directly with the `SET` statement. See Section 15.7.6.1, “SET Syntax for Variable Assignment”.

- Results from queries can be retrieved into local variables using `SELECT ... INTO var_list` or by opening a cursor and using `FETCH ... INTO var_list`. See Section 15.2.13.1, “SELECT ... INTO Statement”, and Section 15.6.6, “Cursors”.

For information about the scope of local variables and how MySQL resolves ambiguous names, see Section 15.6.4.2, “Local Variable Scope and Resolution”.

It is not permitted to assign the value `DEFAULT` to stored procedure or function parameters or stored program local variables (for example with a `SET var_name = DEFAULT` statement). In MySQL 8.4, this results in a syntax error.
15.6.4.1 Local Variable DECLARE Statement

\[\text{DECLARE } \text{var\_name}[, \text{var\_name}] ... \text{type} [\text{DEFAULT } \text{value}]\]

This statement declares local variables within stored programs. To provide a default value for a variable, include a `DEFAULT` clause. The value can be specified as an expression; it need not be a constant. If the `DEFAULT` clause is missing, the initial value is `NULL`.

Local variables are treated like stored routine parameters with respect to data type and overflow checking. See Section 15.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”.

Variable declarations must appear before cursor or handler declarations.

Local variable names are not case-sensitive. Permissible characters and quoting rules are the same as for other identifiers, as described in Section 11.2, “Schema Object Names”.

The scope of a local variable is the `BEGIN ... END` block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

For examples of variable declarations, see Section 15.6.4.2, “Local Variable Scope and Resolution”.

15.6.4.2 Local Variable Scope and Resolution

The scope of a local variable is the `BEGIN ... END` block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

Because local variables are in scope only during stored program execution, references to them are not permitted in prepared statements created within a stored program. Prepared statement scope is the current session, not the stored program, so the statement could be executed after the program ends, at which point the variables would no longer be in scope. For example, `SELECT ... INTO` `local\_var` cannot be used as a prepared statement. This restriction also applies to stored procedure and function parameters. See Section 15.5.1, “PREPARE Statement”.

A local variable should not have the same name as a table column. If an SQL statement, such as a `SELECT ... INTO` statement, contains a reference to a column and a declared local variable with the same name, MySQL currently interprets the reference as the name of a variable. Consider the following procedure definition:

```sql
CREATE PROCEDURE sp1 (x VARCHAR(5))
BEGIN
    DECLARE xname VARCHAR(5) DEFAULT 'bob';
    DECLARE newname VARCHAR(5);
    DECLARE xid INT;
    SELECT xname, id INTO newname, xid
    FROM table1 WHERE xname = xname;
    SELECT newname;
END;
```

MySQL interprets `xname` in the `SELECT` statement as a reference to the `xname` variable rather than the `xname` column. Consequently, when the procedure `sp1()` is called, the `newname` variable returns the value ‘bob’ regardless of the value of the `table1.xname` column.

Similarly, the cursor definition in the following procedure contains a `SELECT` statement that refers to `xname`. MySQL interprets this as a reference to the variable of that name rather than a column reference.

```sql
CREATE PROCEDURE sp2 (x VARCHAR(5))
BEGIN
    DECLARE xname VARCHAR(5) DEFAULT 'bob';
    DECLARE newname VARCHAR(5);
    DECLARE xid INT;
```
DECLARE done TINYINT DEFAULT 0;
DECLARE cur1 CURSOR FOR SELECT xname, id FROM table1;
DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = 1;

OPEN cur1;
read_loop: LOOP
  FETCH FROM cur1 INTO newname, xid;
  IF done THEN LEAVE read_loop; END IF;
  SELECT newname;
END LOOP;
CLOSE cur1;
END;

See also Section 27.8, “Restrictions on Stored Programs”.

15.6.5 Flow Control Statements

MySQL supports the IF, CASE, ITERATE, LEAVE LOOP, WHILE, and REPEAT constructs for flow control within stored programs. It also supports RETURN within stored functions.

Many of these constructs contain other statements, as indicated by the grammar specifications in the following sections. Such constructs may be nested. For example, an IF statement might contain a WHILE loop, which itself contains a CASE statement.

MySQL does not support FOR loops.

15.6.5.1 CASE Statement

CASE case_value
  WHEN when_value THEN statement_list
  [WHEN when_value THEN statement_list] ...
  [ELSE statement_list]
END CASE

Or:

CASE
  WHEN search_condition THEN statement_list
  [WHEN search_condition THEN statement_list] ...
  [ELSE statement_list]
END CASE

The CASE statement for stored programs implements a complex conditional construct.

Note

There is also a CASE operator, which differs from the CASE statement described here. See Section 14.5, “Flow Control Functions”. The CASE statement cannot have an ELSE NULL clause, and it is terminated with END CASE instead of END.

For the first syntax, case_value is an expression. This value is compared to the when_value expression in each WHEN clause until one of them is equal. When an equal when_value is found, the corresponding THEN clause statement_list executes. If no when_value is equal, the ELSE clause statement_list executes, if there is one.

This syntax cannot be used to test for equality with NULL because NULL = NULL is false. See Section 5.3.4.6, “Working with NULL Values”.

For the second syntax, each WHEN clause search_condition expression is evaluated until one is true, at which point its corresponding THEN clause statement_list executes. If no search_condition is equal, the ELSE clause statement_list executes, if there is one.

If no when_value or search_condition matches the value tested and the CASE statement contains no ELSE clause, a Case not found for CASE statement error results.
Each *statement_list* consists of one or more SQL statements; an empty *statement_list* is not permitted.

To handle situations where no value is matched by any *WHEN* clause, use an *ELSE* containing an empty *BEGIN ... END* block, as shown in this example. (The indentation used here in the *ELSE* clause is for purposes of clarity only, and is not otherwise significant.)

```
DELIMITER |
|
CREATE PROCEDURE p()
BEGIN
  DECLARE v INT DEFAULT 1;
  CASE v
    WHEN 2 THEN SELECT v;
    WHEN 3 THEN SELECT 0;
    ELSE
      BEGIN
        END;
      END Case;
  END;
END;
|
```

### 15.6.5.2 IF Statement

```
IF search_condition THEN statement_list
  [ELSEIF search_condition THEN statement_list] ...
  [ELSE statement_list]
END IF
```

The **IF** statement for stored programs implements a basic conditional construct.

**Note**

There is also an **IF()** function, which differs from the **IF** statement described here. See [Section 14.5, “Flow Control Functions”](#). The **IF** statement can have **THEN**, **ELSE**, and **ELSEIF** clauses, and it is terminated with **END IF**.

If a given *search_condition* evaluates to true, the corresponding **THEN** or **ELSEIF** clause *statement_list* executes. If no *search_condition* matches, the **ELSE** clause *statement_list* executes.

Each *statement_list* consists of one or more SQL statements; an empty *statement_list* is not permitted.

An **IF ... END IF** block, like all other flow-control blocks used within stored programs, must be terminated with a semicolon, as shown in this example:

```
DELIMITER //
|
CREATE FUNCTION SimpleCompare(n INT, m INT)
RETURNS VARCHAR(20)
BEGIN
  DECLARE s VARCHAR(20);
  IF n > m THEN SET s = '>'; 
  ELSEIF n = m THEN SET s = '='; 
  ELSE SET s = '<'; 
  END IF; 
  SET s = CONCAT(n, ' ', s, ' ', m); 
  RETURN s; 
END //
|
```
Flow Control Statements

As with other flow-control constructs, IF ... END IF blocks may be nested within other flow-control constructs, including other IF statements. Each IF must be terminated by its own END IF followed by a semicolon. You can use indentation to make nested flow-control blocks more easily readable by humans (although this is not required by MySQL), as shown here:

```sql
DELIMITER //
CREATE FUNCTION VerboseCompare (n INT, m INT) RETURNS VARCHAR(50)
BEGIN
  DECLARE s VARCHAR(50);
  IF n = m THEN SET s = 'equals';
  ELSE
    IF n > m THEN SET s = 'greater';
    ELSE SET s = 'less';
    END IF;
  END IF;
  SET s = CONCAT('is ', s, ' than');
  END IF;
  SET s = CONCAT(n, ' ', s, ' ', m, '.');
  RETURN s;
END //
DELIMITER ;
```

In this example, the inner IF is evaluated only if n is not equal to m.

### 15.6.5.3 ITERATE Statement

```
ITERATE label
```

ITERATE can appear only within LOOP, REPEAT, and WHILE statements. ITERATE means "start the loop again."

For an example, see Section 15.6.5.5, "LOOP Statement".

### 15.6.5.4 LEAVE Statement

```
LEAVE label
```

This statement is used to exit the flow control construct that has the given label. If the label is for the outermost stored program block, LEAVE exits the program.

LEAVE can be used within BEGIN ... END or loop constructs (LOOP, REPEAT, WHILE).

For an example, see Section 15.6.5.5, "LOOP Statement".

### 15.6.5.5 LOOP Statement

```
[begin_label:] LOOP
  statement_list
END LOOP [end_label]
```

LOOP implements a simple loop construct, enabling repeated execution of the statement list, which consists of one or more statements, each terminated by a semicolon (;) statement delimiter. The statements within the loop are repeated until the loop is terminated. Usually, this is accomplished with a LEAVE statement. Within a stored function, RETURN can also be used, which exits the function entirely.

Neglecting to include a loop-termination statement results in an infinite loop.

A LOOP statement can be labeled. For the rules regarding label use, see Section 15.6.2, "Statement Labels".
Example:

```
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
    label1: LOOP
        SET p1 = p1 + 1;
        IF p1 < 10 THEN
            ITERATE label1;
        END IF;
        LEAVE label1;
    END LOOP label1;
    SET @x = p1;
END;
```

15.6.5.6 REPEAT Statement

```
[begin_label:] REPEAT
    statement_list
UNTIL search_condition
END REPEAT [end_label]
```

The statement list within a REPEAT statement is repeated until the search_condition expression is true. Thus, a REPEAT always enters the loop at least once. statement_list consists of one or more statements, each terminated by a semicolon (;) statement delimiter.

A REPEAT statement can be labeled. For the rules regarding label use, see Section 15.6.2, “Statement Labels”.

Example:

```
mysql> delimiter //
mysql> CREATE PROCEDURE dorepeat(p1 INT)
    -> BEGIN
    -> SET @x = 0;
    -> REPEAT
    ->    SET @x = @x + 1;
    ->    UNTIL @x > p1 END REPEAT;
    -> END
    -> //
Query OK, 0 rows affected (0.00 sec)
mysql> CALL dorepeat(1000) //
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @x //
+------+
| @x   |
+------+
| 1001  |
+------+
1 row in set (0.00 sec)
```

15.6.5.7 RETURN Statement

```
RETURN expr
```

The RETURN statement terminates execution of a stored function and returns the value expr to the function caller. There must be at least one RETURN statement in a stored function. There may be more than one if the function has multiple exit points.

This statement is not used in stored procedures, triggers, or events. The LEAVE statement can be used to exit a stored program of those types.

15.6.5.8 WHILE Statement

```
[begin_label:] WHILE search_condition DO
    statement_list
END WHILE [end_label]
```
The statement list within a `WHILE` statement is repeated as long as the `search_condition` expression is true. `statement_list` consists of one or more SQL statements, each terminated by a semicolon (`;`) statement delimiter.

A `WHILE` statement can be labeled. For the rules regarding label use, see Section 15.6.2, “Statement Labels”.

Example:

```sql
CREATE PROCEDURE dowhile()
BEGIN
  DECLARE v1 INT DEFAULT 5;
  WHILE v1 > 0 DO
    ...
    SET v1 = v1 - 1;
  END WHILE;
END;
```

15.6.6 Cursors

MySQL supports cursors inside stored programs. The syntax is as in embedded SQL. Cursors have these properties:

- **Asensitive**: The server may or may not make a copy of its result table
- **Read only**: Not updatable
- **Nonscrollable**: Can be traversed only in one direction and cannot skip rows

Cursor declarations must appear before handler declarations and after variable and condition declarations.

Example:

```sql
CREATE PROCEDURE curdemo()
BEGIN
  DECLARE done INT DEFAULT FALSE;
  DECLARE a CHAR(16);
  DECLARE b, c INT;
  DECLARE cur1 CURSOR FOR SELECT id,data FROM test.t1;
  DECLARE cur2 CURSOR FOR SELECT i FROM test.t2;
  DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = TRUE;

  OPEN cur1;
  OPEN cur2;

  read_loop: LOOP
    FETCH cur1 INTO a, b;
    FETCH cur2 INTO c;
    IF done THEN
      LEAVE read_loop;
    END IF;
    IF b < c THEN
      INSERT INTO test.t3 VALUES (a,b);
    ELSE
      INSERT INTO test.t3 VALUES (a,c);
    END IF;
  END LOOP;

  CLOSE cur1;
  CLOSE cur2;
END;
```

15.6.6.1 Cursor CLOSE Statement

```sql
CLOSE cursor_name
```
This statement closes a previously opened cursor. For an example, see Section 15.6.6, “Cursors”. An error occurs if the cursor is not open. If not closed explicitly, a cursor is closed at the end of the BEGIN ... END block in which it was declared.

### 15.6.6.2 Cursor DECLARE Statement

```
DECLARE cursor_name CURSOR FOR select_statement
```

This statement declares a cursor and associates it with a SELECT statement that retrieves the rows to be traversed by the cursor. To fetch the rows later, use a FETCH statement. The number of columns retrieved by the SELECT statement must match the number of output variables specified in the FETCH statement.

The SELECT statement cannot have an INTO clause.

Cursor declarations must appear before handler declarations and after variable and condition declarations.

A stored program may contain multiple cursor declarations, but each cursor declared in a given block must have a unique name. For an example, see Section 15.6.6, “Cursors”.

For information available through SHOW statements, it is possible in many cases to obtain equivalent information by using a cursor with an INFORMATION_SCHEMA table.

### 15.6.6.3 Cursor FETCH Statement

```
FETCH [[NEXT] FROM] cursor_name INTO var_name [, var_name] ...
```

This statement fetches the next row for the SELECT statement associated with the specified cursor (which must be open), and advances the cursor pointer. If a row exists, the fetched columns are stored in the named variables. The number of columns retrieved by the SELECT statement must match the number of output variables specified in the FETCH statement.

If no more rows are available, a No Data condition occurs with SQLSTATE value '02000'. To detect this condition, you can set up a handler for it (or for a NOT FOUND condition). For an example, see Section 15.6.6, “Cursors”.

Be aware that another operation, such as a SELECT or another FETCH, may also cause the handler to execute by raising the same condition. If it is necessary to distinguish which operation raised the condition, place the operation within its own BEGIN ... END block so that it can be associated with its own handler.

### 15.6.6.4 Cursor OPEN Statement

```
OPEN cursor_name
```

This statement opens a previously declared cursor. For an example, see Section 15.6.6, “Cursors”.

### 15.6.6.5 Restrictions on Server-Side Cursors

Server-side cursors are implemented in the C API using the `mysql_stmt_attr_set()` function. The same implementation is used for cursors in stored routines. A server-side cursor enables a result set to be generated on the server side, but not transferred to the client except for those rows that the client requests. For example, if a client executes a query but is only interested in the first row, the remaining rows are not transferred.

In MySQL, a server-side cursor is materialized into an internal temporary table. Initially, this is a MEMORY table, but is converted to a MyISAM table when its size exceeds the minimum value of the `max_heap_table_size` and `tmp_table_size` system variables. The same restrictions apply
to internal temporary tables created to hold the result set for a cursor as for other uses of internal temporary tables. See Section 10.4.4, “Internal Temporary Table Use in MySQL”. One limitation of the implementation is that for a large result set, retrieving its rows through a cursor might be slow.

Cursors are read only; you cannot use a cursor to update rows.

\texttt{UPDATE WHERE CURRENT OF} and \texttt{DELETE WHERE CURRENT OF} are not implemented, because updatable cursors are not supported.

Cursors are nonholdable (not held open after a commit).

Cursors are asensitive.

Cursors are nonscrollable.

Cursors are not named. The statement handler acts as the cursor ID.

You can have open only a single cursor per prepared statement. If you need several cursors, you must prepare several statements.

You cannot use a cursor for a statement that generates a result set if the statement is not supported in prepared mode. This includes statements such as \texttt{CHECK TABLE}, \texttt{HANDLER READ}, and \texttt{SHOW BINLOG EVENTS}.

### 15.6.7 Condition Handling

Conditions may arise during stored program execution that require special handling, such as exiting the current program block or continuing execution. Handlers can be defined for general conditions such as warnings or exceptions, or for specific conditions such as a particular error code. Specific conditions can be assigned names and referred to that way in handlers.

To name a condition, use the \texttt{DECLARE ... CONDITION} statement. To declare a handler, use the \texttt{DECLARE ... HANDLER} statement. See Section 15.6.7.1, “DECLARE ... CONDITION Statement”, and Section 15.6.7.2, “DECLARE ... HANDLER Statement”. For information about how the server chooses handlers when a condition occurs, see Section 15.6.7.6, “Scope Rules for Handlers”.

To raise a condition, use the \texttt{SIGNAL} statement. To modify condition information within a condition handler, use \texttt{RESIGNAL}. See Section 15.6.7.1, “DECLARE ... CONDITION Statement”, and Section 15.6.7.2, “DECLARE ... HANDLER Statement”.

To retrieve information from the diagnostics area, use the \texttt{GET DIAGNOSTICS} statement (see Section 15.6.7.3, “GET DIAGNOSTICS Statement”). For information about the diagnostics area, see Section 15.6.7.7, “The MySQL Diagnostics Area”.

#### 15.6.7.1 DECLARE ... CONDITION Statement

```
DECLARE condition_name CONDITION FOR condition_value
```

`condition_value`: 
- `mysql_error_code`: An integer literal indicating a MySQL error code.
- `SQLSTATE [VALUE] sqlstate_value`: SQLSTATE or SQLSTATE with value.

The \texttt{DECLARE ... CONDITION} statement declares a named error condition, associating a name with a condition that needs specific handling. The name can be referred to in a subsequent \texttt{DECLARE ... HANDLER} statement (see Section 15.6.7.2, “DECLARE ... HANDLER Statement”).

Condition declarations must appear before cursor or handler declarations.

The `condition_value` for \texttt{DECLARE ... CONDITION} indicates the specific condition or class of conditions to associate with the condition name. It can take the following forms:

- `mysql_error_code`: An integer literal indicating a MySQL error code.
Do not use MySQL error code 0 because that indicates success rather than an error condition. For a list of MySQL error codes, see Server Error Message Reference.

- **SQLSTATE [VALUE]** `sqlstate_value`: A 5-character string literal indicating an SQLSTATE value.

  Do not use SQLSTATE values that begin with '00' because those indicate success rather than an error condition. For a list of SQLSTATE values, see Server Error Message Reference.

Condition names referred to in `SIGNAL` or use `RESIGNAL` statements must be associated with SQLSTATE values, not MySQL error codes.

Using names for conditions can help make stored program code clearer. For example, this handler applies to attempts to drop a nonexistent table, but that is apparent only if you know that 1051 is the MySQL error code for "unknown table":

```sql
DECLARE CONTINUE HANDLER FOR 1051
BEGIN
  -- body of handler
END;
```

By declaring a name for the condition, the purpose of the handler is more readily seen:

```sql
DECLARE no_such_table CONDITION FOR 1051;
DECLARE CONTINUE HANDLER FOR no_such_table
BEGIN
  -- body of handler
END;
```

Here is a named condition for the same condition, but based on the corresponding SQLSTATE value rather than the MySQL error code:

```sql
DECLARE no_such_table CONDITION FOR SQLSTATE '42S02';
DECLARE CONTINUE HANDLER FOR no_such_table
BEGIN
  -- body of handler
END;
```

### 15.6.7.2 DECLARE ... HANDLER Statement

```sql
DECLAR handler_action HANDLER
  FOR condition_value [, condition_value] ...
  statement

handler_action: {
  CONTINUE
  | EXIT
  | UNDO
}

condition_value: {
  mysql_error_code
  | SQLSTATE [VALUE] sqlstate_value
  | condition_name
  | SQLWARNING
  | NOT FOUND
  | SQLEXCEPTION
}
```

The `DECLARE ... HANDLER` statement specifies a handler that deals with one or more conditions. If one of these conditions occurs, the specified `statement` executes. `statement` can be a simple statement such as `SET var_name = value`, or a compound statement written using `BEGIN` and `END` (see Section 15.6.1, “BEGIN ... END Compound Statement”).

Handler declarations must appear after variable or condition declarations.

The `handler_action` value indicates what action the handler takes after execution of the handler statement:
**Condition Handling**

- **CONTINUE**: Execution of the current program continues.
- **EXIT**: Execution terminates for the **BEGIN ... END** compound statement in which the handler is declared. This is true even if the condition occurs in an inner block.
- **UNDO**: Not supported.

The condition_value for **DECLARE ... HANDLER** indicates the specific condition or class of conditions that activates the handler. It can take the following forms:

- **mysql_error_code**: An integer literal indicating a MySQL error code, such as 1051 to specify “unknown table”:

```sql
DECLARE CONTINUE HANDLER FOR 1051
    BEGIN
        -- body of handler
    END;
```

Do not use MySQL error code 0 because that indicates success rather than an error condition. For a list of MySQL error codes, see [Server Error Message Reference](#).

- **SQLSTATE [VALUE] sqlstate_value**: A 5-character string literal indicating an SQLSTATE value, such as '42S01' to specify “unknown table”:

```sql
DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
    BEGIN
        -- body of handler
    END;
```

Do not use SQLSTATE values that begin with '00' because those indicate success rather than an error condition. For a list of SQLSTATE values, see [Server Error Message Reference](#).

- **condition_name**: A condition name previously specified with **DECLARE ... CONDITION**. A condition name can be associated with a MySQL error code or SQLSTATE value. See [Section 15.6.7.1, “DECLARE ... CONDITION Statement”](#).

- **SQLWARNING**: Shorthand for the class of SQLSTATE values that begin with '01'.

```sql
DECLARE CONTINUE HANDLER FOR SQLWARNING
    BEGIN
        -- body of handler
    END;
```

- **NOT FOUND**: Shorthand for the class of SQLSTATE values that begin with '02'. This is relevant within the context of cursors and is used to control what happens when a cursor reaches the end of a data set. If no more rows are available, a No Data condition occurs with SQLSTATE value '02000'. To detect this condition, you can set up a handler for it or for a **NOT FOUND** condition.

```sql
DECLARE CONTINUE HANDLER FOR NOT FOUND
    BEGIN
        -- body of handler
    END;
```

For another example, see [Section 15.6.6, “Cursors”](#). The **NOT FOUND** condition also occurs for **SELECT ... INTO var_list** statements that retrieve no rows.

- **SQLEXCEPTION**: Shorthand for the class of SQLSTATE values that do not begin with '00', '01', or '02'.

```sql
DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
    BEGIN
        -- body of handler
    END;
```

For information about how the server chooses handlers when a condition occurs, see [Section 15.6.7.6, “Scope Rules for Handlers”](#).
If a condition occurs for which no handler has been declared, the action taken depends on the condition class:

- For **SQLEXCEPTION** conditions, the stored program terminates at the statement that raised the condition, as if there were an **EXIT** handler. If the program was called by another stored program, the calling program handles the condition using the handler selection rules applied to its own handlers.

- For **SQLWARNING** conditions, the program continues executing, as if there were a **CONTINUE** handler.

- For **NOT FOUND** conditions, if the condition was raised normally, the action is **CONTINUE**. If it was raised by **SIGNAL** or **RESIGNAL**, the action is **EXIT**.

The following example uses a handler for **SQLSTATE '23000'**, which occurs for a duplicate-key error:

```sql
mysql> CREATE TABLE test.t (s1 INT, PRIMARY KEY (s1));
Query OK, 0 rows affected (0.00 sec)
mysql> delimiter //
mysql> CREATE PROCEDURE handlerdemo ()
BEGIN
    DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;
    SET @x = 1;
    INSERT INTO test.t VALUES (1);
    SET @x = 2;
    INSERT INTO test.t VALUES (1);
    SET @x = 3;
END;
//
Query OK, 0 rows affected (0.00 sec)
mysql> CALL handlerdemo()//
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @x//
+------+
<table>
<thead>
<tr>
<th>@x</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
</tr>
</tbody>
</table>
1 row in set (0.00 sec)
```

Notice that `@x` is `3` after the procedure executes, which shows that execution continued to the end of the procedure after the error occurred. If the **DECLARE ... HANDLER** statement had not been present, MySQL would have taken the default action (**EXIT**) after the second **INSERT** failed due to the **PRIMARY KEY** constraint, and **SELECT @x** would have returned `2`.

To ignore a condition, declare a **CONTINUE** handler for it and associate it with an empty block. For example:

```sql
DECLARE CONTINUE HANDLER FOR SQLWARNING BEGIN END;
```

The scope of a block label does not include the code for handlers declared within the block. Therefore, the statement associated with a handler cannot use **ITERATE** or **LEAVE** to refer to labels for blocks that enclose the handler declaration. Consider the following example, where the **REPEAT** block has a label of **retry**:

```sql
CREATE PROCEDURE p ()
BEGIN
    DECLARE i INT DEFAULT 3;
    retry:
    REPEAT
        BEGIN
            DECLARE CONTINUE HANDLER FOR SQLWARNING
            BEGIN
                ITERATE retry;  # illegal
```
The `retry` label is in scope for the `IF` statement within the block. It is not in scope for the `CONTINUE` handler, so the reference there is invalid and results in an error:

```
ERROR 1308 (42000): LEAVE with no matching label: retry
```

To avoid references to outer labels in handlers, use one of these strategies:

- To leave the block, use an `EXIT` handler. If no block cleanup is required, the `BEGIN ... END` handler body can be empty:

  ```
  DECLARE EXIT HANDLER FOR SQLWARNING BEGIN END;
  ```

  Otherwise, put the cleanup statements in the handler body:

  ```
  DECLARE EXIT HANDLER FOR SQLWARNING
  BEGIN
  block cleanup statements
  END;
  ```

- To continue execution, set a status variable in a `CONTINUE` handler that can be checked in the enclosing block to determine whether the handler was invoked. The following example uses the variable `done` for this purpose:

  ```
  CREATE PROCEDURE p ()
  BEGIN
  DECLARE i INT DEFAULT 3;
  DECLARE done INT DEFAULT FALSE;
  retry:
  REPEAT
  BEGIN
  DECLARE CONTINUE HANDLER FOR SQLWARNING 
  BEGIN
  SET done = TRUE;
  END;
  IF done OR i < 0 THEN
  LEAVE retry;
  END IF;
  SET i = i - 1;
  END;
  UNTIL FALSE END REPEAT;
  END;
  ```

### 15.6.7.3 GET DIAGNOSTICS Statement

```
GET [CURRENT | STACKED] DIAGNOSTICS { 
  statement_information_item 
  [, statement_information_item] ... 
  | CONDITION condition_number 
  condition_information_item 
  [, condition_information_item] ... 
}
```

- `statement_information_item`:
  ```
  target = statement_information_item_name
  ```

- `condition_information_item`:
  ```
  target = condition_information_item_name
  ```

- `statement_information_item_name`:
  ```
  NUMBER
  | ROW_COUNT
  ```
SQL statements produce diagnostic information that populates the diagnostics area. The `GET DIAGNOSTICS` statement enables applications to inspect this information. (You can also use `SHOW WARNINGS` or `SHOW ERRORS` to see conditions or errors.)

No special privileges are required to execute `GET DIAGNOSTICS`. The keyword `CURRENT` means to retrieve information from the current diagnostics area. The keyword `STACKED` means to retrieve information from the second diagnostics area, which is available only if the current context is a condition handler. If neither keyword is given, the default is to use the current diagnostics area.

The `GET DIAGNOSTICS` statement is typically used in a handler within a stored program. It is a MySQL extension that `GET [CURRENT] DIAGNOSTICS` is permitted outside handler context to check the execution of any SQL statement. For example, if you invoke the `mysql` client program, you can enter these statements at the prompt:

```sql
mysql> DROP TABLE test.no_such_table;
ERROR 1051 (42S02): Unknown table 'test.no_such_table'
mysql> GET DIAGNOSTICS CONDITION 1
@p1 = RETURNED_SQLSTATE, @p2 = MESSAGE_TEXT;
mysql> SELECT @p1, @p2;
+-------+------------------------------------+
<table>
<thead>
<tr>
<th>@p1</th>
<th>@p2</th>
</tr>
</thead>
<tbody>
<tr>
<td>42S02</td>
<td>Unknown table 'test.no_such_table'</td>
</tr>
</tbody>
</table>
```

This extension applies only to the current diagnostics area. It does not apply to the second diagnostics area because `GET STACKED DIAGNOSTICS` is permitted only if the current context is a condition handler. If that is not the case, a `GET STACKED DIAGNOSTICS when handler not active` error occurs.

For a description of the diagnostics area, see Section 15.6.7.7, “The MySQL Diagnostics Area”. Briefly, it contains two kinds of information:

- Statement information, such as the number of conditions that occurred or the affected-rows count.
- Condition information, such as the error code and message. If a statement raises multiple conditions, this part of the diagnostics area has a condition area for each one. If a statement raises no conditions, this part of the diagnostics area is empty.

For a statement that produces three conditions, the diagnostics area contains statement and condition information like this:

```
Statement information:
row count
```

```sql
```
... other statement information items ...

Condition area list:
Condition area 1:
  error code for condition 1
  error message for condition 1
  ... other condition information items ...
Condition area 2:
  error code for condition 2:
  error message for condition 2
  ... other condition information items ...
Condition area 3:
  error code for condition 3
  error message for condition 3
  ... other condition information items ...

GET DIAGNOSTICS can obtain either statement or condition information, but not both in the same statement:

- To obtain statement information, retrieve the desired statement items into target variables. This instance of `GET DIAGNOSTICS` assigns the number of available conditions and the rows-affected count to the user variables `@p1` and `@p2`:

  ```
  GET DIAGNOSTICS @p1 = NUMBER, @p2 = ROW_COUNT;
  ```

- To obtain condition information, specify the condition number and retrieve the desired condition items into target variables. This instance of `GET DIAGNOSTICS` assigns the SQLSTATE value and error message to the user variables `@p3` and `@p4`:

  ```
  GET DIAGNOSTICS CONDITION 1
  @p3 = RETURNED_SQLSTATE, @p4 = MESSAGE_TEXT;
  ```

The retrieval list specifies one or more `target = item_name` assignments, separated by commas. Each assignment names a target variable and either a `statement_information_item_name` or `condition_information_item_name` designator, depending on whether the statement retrieves statement or condition information.

Valid `target` designators for storing item information can be stored procedure or function parameters, stored program local variables declared with `DECLARE`, or user-defined variables.

Valid `condition_number` designators can be stored procedure or function parameters, stored program local variables declared with `DECLARE`, user-defined variables, system variables, or literals. A character literal may include a `_charset` introducer. A warning occurs if the condition number is not in the range from 1 to the number of condition areas that have information. In this case, the warning is added to the diagnostics area without clearing it.

When a condition occurs, MySQL does not populate all condition items recognized by `GET DIAGNOSTICS`. For example:

```
mysql> GET DIAGNOSTICS CONDITION 1
   @p5 = SCHEMA_NAME, @p6 = TABLE_NAME;

mysql> SELECT @p5, @p6;
```

<table>
<thead>
<tr>
<th>@p5</th>
<th>@p6</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In standard SQL, if there are multiple conditions, the first condition relates to the `SQLSTATE` value returned for the previous SQL statement. In MySQL, this is not guaranteed. To get the main error, you cannot do this:

```
GET DIAGNOSTICS CONDITION 1 @errno = MYSQL_ERRNO;
```

Instead, retrieve the condition count first, then use it to specify which condition number to inspect:

```
GET DIAGNOSTICS @cno = NUMBER;
GET DIAGNOSTICS CONDITION @cno @errno = MYSQL_ERRNO;
```
Condition Handling

For information about permissible statement and condition information items, and which ones are populated when a condition occurs, see Diagnostics Area Information Items.

Here is an example that uses GET DIAGNOSTICS and an exception handler in stored procedure context to assess the outcome of an insert operation. If the insert was successful, the procedure uses GET DIAGNOSTICS to get the rows-affected count. This shows that you can use GET DIAGNOSTICS multiple times to retrieve information about a statement as long as the current diagnostics area has not been cleared.

```sql
CREATE PROCEDURE do_insert(value INT)
BEGIN

-- Declare variables to hold diagnostics area information
DECLARE code CHAR(5) DEFAULT '00000';
DECLARE msg TEXT;
DECLARE nrows INT;
DECLARE result TEXT;

-- Declare exception handler for failed insert
DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
BEGIN

GET DIAGNOSTICS CONDITION 1
    code = RETURNED_SQLSTATE, msg = MESSAGE_TEXT;
END;

-- Perform the insert
INSERT INTO t1 (int_col) VALUES(value);

-- Check whether the insert was successful
IF code = '00000' THEN

GET DIAGNOSTICS nrows = ROW_COUNT;
SET result = CONCAT('insert succeeded, row count = ',nrows);
ELSE

SET result = CONCAT('insert failed, error = ',code,', message = ',msg);
END IF;

-- Say what happened
SELECT result;
END;

Suppose that t1.int_col is an integer column that is declared as NOT NULL. The procedure produces these results when invoked to insert non-NULL and NULL values, respectively:

mysql> CALL do_insert(1);
+--------------------------+
| result                   |
| insert succeeded, row count = 1 |
+--------------------------+

mysql> CALL do_insert(NULL);
+------------------------------------------------------------------------------------------+
| result                                                                                   |
| insert failed, error = 23000, message = Column 'int_col' cannot be null                  |
+------------------------------------------------------------------------------------------+

When a condition handler activates, a push to the diagnostics area stack occurs:

- The first (current) diagnostics area becomes the second (stacked) diagnostics area and a new current diagnostics area is created as a copy of it.
- `GET [CURRENT] DIAGNOSTICS` and `GET STACKED DIAGNOSTICS` can be used within the handler to access the contents of the current and stacked diagnostics areas.
- Initially, both diagnostics areas return the same result, so it is possible to get information from the current diagnostics area about the condition that activated the handler, as long as you execute no statements within the handler that change its current diagnostics area.
- However, statements executing within the handler can modify the current diagnostics area, clearing and setting its contents according to the normal rules (see How the Diagnostics Area is Cleared and Populated).
A more reliable way to obtain information about the handler-activating condition is to use the stacked diagnostics area, which cannot be modified by statements executing within the handler except \texttt{RESIGNAL}. For information about when the current diagnostics area is set and cleared, see Section 15.6.7.7, “The MySQL Diagnostics Area”.

The next example shows how \texttt{GET_STACKED_DIAGNOSTICS} can be used within a handler to obtain information about the handled exception, even after the current diagnostics area has been modified by handler statements.

Within a stored procedure \texttt{p()}, we attempt to insert two values into a table that contains a \texttt{TEXT NOT NULL} column. The first value is a non-\texttt{NULL} string and the second is \texttt{NULL}. The column prohibits \texttt{NULL} values, so the first insert succeeds but the second causes an exception. The procedure includes an exception handler that maps attempts to insert \texttt{NULL} into inserts of the empty string:

\begin{verbatim}
DROP TABLE IF EXISTS t1;
CREATE TABLE t1 (c1 TEXT NOT NULL);
DROP PROCEDURE IF EXISTS p;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  -- Declare variables to hold diagnostics area information
  DECLARE errcount INT;
  DECLARE errno INT;
  DECLARE msg TEXT;
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    -- Here the current DA is nonempty because no prior statements
    -- executing within the handler have cleared it
    GET CURRENT DIAGNOSTICS CONDITION 1
    errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
    SELECT 'current DA before mapped insert' AS op, errno, msg;
    GET STACKED DIAGNOSTICS CONDITION 1
    errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
    SELECT 'stacked DA before mapped insert' AS op, errno, msg;
    -- Map attempted NULL insert to empty string insert
    INSERT INTO t1 (c1) VALUES('');
    -- Here the current DA should be empty (if the INSERT succeeded),
    -- so check whether there are conditions before attempting to
    -- obtain condition information
    GET CURRENT DIAGNOSTICS errcount = NUMBER;
    IF errcount = 0
      THEN
        SELECT 'mapped insert succeeded, current DA is empty' AS op;
      ELSE
        GET CURRENT DIAGNOSTICS CONDITION 1
        errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
        SELECT 'current DA after mapped insert' AS op, errno, msg;
      END IF;
    GET STACKED DIAGNOSTICS CONDITION 1
    errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
    SELECT 'stacked DA after mapped insert' AS op, errno, msg;
  END;
END;
//
delimiter ;
CALL p();
SELECT * FROM t1;
\end{verbatim}

When the handler activates, a copy of the current diagnostics area is pushed to the diagnostics area stack. The handler first displays the contents of the current and stacked diagnostics areas, which are both the same initially:

\begin{verbatim}
+---------------------------------+-------+----------------------------+
| op                              | errno | msg                        |
|+---------------------------------+-------+----------------------------+|
| current DA before mapped insert |       |                            |
| stacked DA before mapped insert |       |                            |
| mapped insert succeeded, current DA is empty |       |                            |
| current DA after mapped insert |       |                            |
| stacked DA after mapped insert |       |                            |
\end{verbatim}
| current DA before mapped insert | 1048 | Column 'c1' cannot be null |
|-------------------------------+-------+----------------------------|

| op                              | errno | msg                        |
|---------------------------------+-------+----------------------------|
| stacked DA before mapped insert | 1048 | Column 'c1' cannot be null |

Statements executing after the `GET DIAGNOSTICS` statements may reset the current diagnostics area. Statements may reset the current diagnostics area. For example, the handler maps the `NULL` insert to an empty-string insert and displays the result. The new insert succeeds and clears the current diagnostics area, but the stacked diagnostics area remains unchanged and still contains information about the condition that activated the handler:

<table>
<thead>
<tr>
<th>op</th>
</tr>
</thead>
<tbody>
<tr>
<td>mapped insert succeeded, current DA is empty</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>op</th>
<th>errno</th>
<th>msg</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

When the condition handler ends, its current diagnostics area is popped from the stack and the stacked diagnostics area becomes the current diagnostics area in the stored procedure.

After the procedure returns, the table contains two rows. The empty row results from the attempt to insert `NULL` that was mapped to an empty-string insert:

<table>
<thead>
<tr>
<th>c1</th>
</tr>
</thead>
<tbody>
<tr>
<td>string 1</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

### 15.6.7.4 RESIGNAL Statement

**RESIGNAL**

```
RESIGNAL [condition_value]
[SET signal_information_item
[, signal_information_item] ...]
```

- **condition_value**: {
  - SQLSTATE [VALUE] sqlstate_value
  - condition_name
}

- **signal_information_item**:
  - condition_information_item_name = simple_value_specification

- **condition_information_item_name**:
  - CLASS_ORIGIN
  - SUBCLASS_ORIGIN
  - MESSAGE_TEXT
  - MYSQL_ERRNO
  - CONSTRAINT_CATALOG
  - CONSTRAINT_SCHEMA
  - CONSTRAINT_NAME
  - CATALOG_NAME
  - SCHEMA_NAME
  - TABLE_NAME
  - COLUMN_NAME
  - CURSOR_NAME
**RESIGNAL** passes on the error condition information that is available during execution of a condition handler within a compound statement inside a stored procedure or function, trigger, or event. **RESIGNAL** may change some or all information before passing it on. **RESIGNAL** is related to **SIGNAL**, but instead of originating a condition as **SIGNAL** does, **RESIGNAL** relays existing condition information, possibly after modifying it.

**RESIGNAL** makes it possible to both handle an error and return the error information. Otherwise, by executing an SQL statement within the handler, information that caused the handler's activation is destroyed. **RESIGNAL** also can make some procedures shorter if a given handler can handle part of a situation, then pass the condition “up the line” to another handler.

No privileges are required to execute the **RESIGNAL** statement.

All forms of **RESIGNAL** require that the current context be a condition handler. Otherwise, **RESIGNAL** is illegal and a **RESIGNAL when handler not active** error occurs.

To retrieve information from the diagnostics area, use the **GET DIAGNOSTICS** statement (see Section 15.6.7.3, “GET DIAGNOSTICS Statement”). For information about the diagnostics area, see Section 15.6.7.7, “The MySQL Diagnostics Area”.

- **RESIGNAL Overview**
- **RESIGNAL Alone**
- **RESIGNAL with New Signal Information**
- **RESIGNAL with a Condition Value and Optional New Signal Information**
- **RESIGNAL Requires Condition Handler Context**

**RESIGNAL Overview**

For **condition_value** and **signal_information_item**, the definitions and rules are the same for **RESIGNAL** as for **SIGNAL**. For example, the **condition_value** can be an **SQLSTATE** value, and the value can indicate errors, warnings, or “not found.” For additional information, see Section 15.6.7.5, “**SIGNAL** Statement”.

The **RESIGNAL** statement takes **condition_value** and **SET** clauses, both of which are optional. This leads to several possible uses:

- **RESIGNAL alone**:

  ```sql
  RESIGNAL;
  ```

- **RESIGNAL with new signal information**:

  ```sql
  RESIGNAL SET signal_information_item [, signal_information_item] ...;
  ```

- **RESIGNAL with a condition value and possibly new signal information**:

  ```sql
  RESIGNAL condition_value [SET signal_information_item [, signal_information_item] ...];
  ```

These use cases all cause changes to the diagnostics and condition areas:

- A diagnostics area contains one or more condition areas.
- A condition area contains condition information items, such as the **SQLSTATE** value, **MYSQL_ERRNO**, or **MESSAGE_TEXT**.

There is a stack of diagnostics areas. When a handler takes control, it pushes a diagnostics area to the top of the stack, so there are two diagnostics areas during handler execution:
The first (current) diagnostics area, which starts as a copy of the last diagnostics area, but is overwritten by the first statement in the handler that changes the current diagnostics area.

The last (stacked) diagnostics area, which has the condition areas that were set up before the handler took control.

The maximum number of condition areas in a diagnostics area is determined by the value of the `max_error_count` system variable. See Diagnostics Area-Related System Variables.

**RESIGNAL Alone**

A simple `RESIGNAL` alone means “pass on the error with no change.” It restores the last diagnostics area and makes it the current diagnostics area. That is, it “pops” the diagnostics area stack.

Within a condition handler that catches a condition, one use for `RESIGNAL` alone is to perform some other actions, and then pass on without change the original condition information (the information that existed before entry into the handler).

Example:

```sql
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SET @error_count = @error_count + 1;
    IF @a = 0 THEN RESIGNAL; END IF;
  END;
  DROP TABLE xx;
END;//
delimiter ;
SET @error_count = 0;
SET @a = 0;
CALL p();
```

Suppose that the `DROP TABLE xx` statement fails. The diagnostics area stack looks like this:

DA 1. ERROR 1051 (42S02): Unknown table 'xx'

Then execution enters the `EXIT` handler. It starts by pushing a diagnostics area to the top of the stack, which now looks like this:

DA 1. ERROR 1051 (42S02): Unknown table 'xx'
DA 2. ERROR 1051 (42S02): Unknown table 'xx'

At this point, the contents of the first (current) and second (stacked) diagnostics areas are the same. The first diagnostics area may be modified by statements executing subsequently within the handler.

Usually a procedure statement clears the first diagnostics area. `BEGIN` is an exception, it does not clear, it does nothing. `SET` is not an exception, it clears, performs the operation, and produces a result of “success.” The diagnostics area stack now looks like this:

DA 1. ERROR 0000 (00000): Successful operation
DA 2. ERROR 1051 (42S02): Unknown table 'xx'

At this point, if `@a = 0`, `RESIGNAL` pops the diagnostics area stack, which now looks like this:

DA 1. ERROR 1051 (42S02): Unknown table 'xx'

And that is what the caller sees.

If `@a` is not 0, the handler simply ends, which means that there is no more use for the current diagnostics area (it has been “handled”), so it can be thrown away, causing the stacked diagnostics area to become the current diagnostics area again. The diagnostics area stack looks like this:

DA 1. ERROR 0000 (00000): Successful operation
The details make it look complex, but the end result is quite useful: Handlers can execute without destroying information about the condition that caused activation of the handler.

**RESIGNAL with New Signal Information**

**RESIGNAL** with a **SET** clause provides new signal information, so the statement means “pass on the error with changes”:

```
RESIGNAL SET signal_information_item [, signal_information_item] ...;
```

As with **RESIGNAL** alone, the idea is to pop the diagnostics area stack so that the original information goes out. Unlike **RESIGNAL** alone, anything specified in the **SET** clause changes.

**Example:**

```
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
    DECLARE EXIT HANDLER FOR SQLEXCEPTION
    BEGIN
        SET @error_count = @error_count + 1;
        IF @a = 0 THEN RESIGNAL SET MYSQL_ERRNO = 5; END IF;
    END;
    DROP TABLE xx;
END;//
delimiter ;
SET @error_count = 0;
SET @a = 0;
CALL p();
```

Remember from the previous discussion that **RESIGNAL** alone results in a diagnostics area stack like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
```

The **RESIGNAL SET MYSQL_ERRNO = 5** statement results in this stack instead, which is what the caller sees:

```
DA 1. ERROR 5 (42S02): Unknown table 'xx'
```

In other words, it changes the error number, and nothing else.

The **RESIGNAL** statement can change any or all of the signal information items, making the first condition area of the diagnostics area look quite different.

**RESIGNAL with a Condition Value and Optional New Signal Information**

**RESIGNAL** with a condition value means “push a condition into the current diagnostics area.” If the **SET** clause is present, it also changes the error information.

```
RESIGNAL condition_value
    [SET signal_information_item [, signal_information_item] ...];
```

This form of **RESIGNAL** restores the last diagnostics area and makes it the current diagnostics area. That is, it “pops” the diagnostics area stack, which is the same as what a simple **RESIGNAL** alone would do. However, it also changes the diagnostics area depending on the condition value or signal information.

**Example:**

```
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
    DECLARE EXIT HANDLER FOR SQLEXCEPTION
    BEGIN
```

---

2727
SET @error_count = @error_count + 1;
IF @a = 0 THEN RESIGNAL SQLSTATE '45000' SET MYSQL_ERRNO=5; END IF;
END;
DROP TABLE xx;
END/
delimiter ;
SET @error_count = 0;
SET @a = 0;
SET @max_error_count = 2;
CALL p();
SHOW ERRORS;

This is similar to the previous example, and the effects are the same, except that if RESIGNAL happens, the current condition area looks different at the end. (The reason the condition adds to rather than replaces the existing condition is the use of a condition value.)

The RESIGNAL statement includes a condition value (SQLSTATE '45000'), so it adds a new condition area, resulting in a diagnostics area stack that looks like this:

DA 1. (condition 2) ERROR 1051 (42S02): Unknown table 'xx'
   (condition 1) ERROR 5 (45000) Unknown table 'xx'

The result of CALL p() and SHOW ERRORS for this example is:

mysql> CALL p();
ERROR 5 (45000): Unknown table 'xx'
mysql> SHOW ERRORS;
+-------+------+----------------------------------+
| Level | Code | Message                          |
+-------+------+----------------------------------+
| Error | 1051 | Unknown table 'xx'               |
| Error |    5 | Unknown table 'xx'               |
+-------+------+----------------------------------+

RESIGNAL Requires Condition Handler Context

All forms of RESIGNAL require that the current context be a condition handler. Otherwise, RESIGNAL is illegal and a RESIGNAL when handler not active error occurs. For example:

mysql> CREATE PROCEDURE p () RESIGNAL;
Query OK, 0 rows affected (0.00 sec)
mysql> CALL p();
ERROR 1645 (0K000): RESIGNAL when handler not active

Here is a more difficult example:

delimiter //
CREATE FUNCTION f () RETURNS INT
BEGIN
   RESIGNAL;
   RETURN 5;
END//
CREATE PROCEDURE p ()
BEGIN
   DECLARE EXIT HANDLER FOR SQLEXCEPTION SET @a=f();
   SIGNAL SQLSTATE '55555';
END//
delimiter ;
CALL p();

RESIGNAL occurs within the stored function f(). Although f() itself is invoked within the context of the EXIT handler, execution within f() has its own context, which is not handler context. Thus, RESIGNAL within f() results in a “handler not active” error.

15.6.7.5 SIGNAL Statement

SIGNAL condition_value
   |SET signal_information_item
SIGNAL is the way to “return” an error. SIGNAL provides error information to a handler, to an outer portion of the application, or to the client. Also, it provides control over the error’s characteristics (error number, SQLSTATE value, message). Without SIGNAL, it is necessary to resort to workarounds such as deliberately referring to a nonexistent table to cause a routine to return an error.

No privileges are required to execute the SIGNAL statement.

To retrieve information from the diagnostics area, use the GET DIAGNOSTICS statement (see Section 15.6.7.3, “GET DIAGNOSTICS Statement”). For information about the diagnostics area, see Section 15.6.7.7, “The MySQL Diagnostics Area”.

- SIGNAL Overview
- Signal Condition Information Items
- Effect of Signals on Handlers, Cursors, and Statements

**SIGNAL Overview**

The condition_value in a SIGNAL statement indicates the error value to be returned. It can be an SQLSTATE value (a 5-character string literal) or a condition_name that refers to a named condition previously defined with DECLARE ... CONDITION (see Section 15.6.7.1, “DECLARE ... CONDITION Statement”).

An SQLSTATE value can indicate errors, warnings, or “not found.” The first two characters of the value indicate its error class, as discussed in Signal Condition Information Items. Some signal values cause statement termination; see Effect of Signals on Handlers, Cursors, and Statements.

The SQLSTATE value for a SIGNAL statement should not start with '00' because such values indicate success and are not valid for signaling an error. This is true whether the SQLSTATE value is specified directly in the SIGNAL statement or in a named condition referred to in the statement. If the value is invalid, a Bad SQLSTATE error occurs.

To signal a generic SQLSTATE value, use '45000', which means “unhandled user-defined exception.”

The SIGNAL statement optionally includes a SET clause that contains multiple signal items, in a list of condition_information_item_name = simple_value_specification assignments, separated by commas.
Each condition_information_item_name may be specified only once in the SET clause. Otherwise, a Duplicate condition information item error occurs.

Valid simple_value_specification designators can be specified using stored procedure or function parameters, stored program local variables declared with DECLARE, user-defined variables, system variables, or literals. A character literal may include a _charset introducer.

For information about permissible condition_information_item_name values, see Signal Condition Information Items.

The following procedure signals an error or warning depending on the value of pval, its input parameter:

```sql
CREATE PROCEDURE p (pval INT)
BEGIN
    DECLARE specialty CONDITION FOR SQLSTATE '45000';
    IF pval = 0 THEN
        SIGNAL SQLSTATE '01000';
    ELSEIF pval = 1 THEN
        SIGNAL SQLSTATE '45000'
        SET MESSAGE_TEXT = 'An error occurred';
    ELSEIF pval = 2 THEN
        SIGNAL specialty
        SET MESSAGE_TEXT = 'An error occurred';
    ELSE
        SIGNAL SQLSTATE '01000'
        SET MESSAGE_TEXT = 'An error occurred', MYSQL_ERRNO = 1000;
        SIGNAL SQLSTATE '45000'
        SET MESSAGE_TEXT = 'An error occurred', MYSQL_ERRNO = 1001;
    END IF;
END;
```

If pval is 0, p() signals a warning because SQLSTATE values that begin with '01' are signals in the warning class. The warning does not terminate the procedure, and can be seen with SHOW WARNINGS after the procedure returns.

If pval is 1, p() signals an error and sets the MESSAGE_TEXT condition information item. The error terminates the procedure, and the text is returned with the error information.

If pval is 2, the same error is signaled, although the SQLSTATE value is specified using a named condition in this case.

If pval is anything else, p() first signals a warning and sets the message text and error number condition information items. This warning does not terminate the procedure, so execution continues and p() then signals an error. The error does terminate the procedure. The message text and error number set by the warning are replaced by the values set by the error, which are returned with the error information.

**SIGNAL** is typically used within stored programs, but it is a MySQL extension that it is permitted outside handler context. For example, if you invoke the mysql client program, you can enter any of these statements at the prompt:

```sql
SIGNAL SQLSTATE '77777';
CREATE TRIGGER t_bi BEFORE INSERT ON t
    FOR EACH ROW SIGNAL SQLSTATE '77777';
CREATE EVENT e ON SCHEDULE EVERY 1 SECOND
    DO SIGNAL SQLSTATE '77777';
```

**SIGNAL** executes according to the following rules:

If the SIGNAL statement indicates a particular SQLSTATE value, that value is used to signal the condition specified. Example:

```sql
CREATE PROCEDURE p (divisor INT)
```
BEGIN
    IF divisor = 0 THEN
        SIGNAL SQLSTATE '22012';
    END IF;
END;

If the `SIGNAL` statement uses a named condition, the condition must be declared in some scope that applies to the `SIGNAL` statement, and must be defined using an `SQLSTATE` value, not a MySQL error number. Example:

CREATE PROCEDURE p (divisor INT)
BEGIN
    DECLARE divide_by_zero CONDITION FOR SQLSTATE '22012';
    IF divisor = 0 THEN
        SIGNAL divide_by_zero;
    END IF;
END;

If the named condition does not exist in the scope of the `SIGNAL` statement, an `Undefined CONDITION` error occurs.

If `SIGNAL` refers to a named condition that is defined with a MySQL error number rather than an `SQLSTATE` value, a `SIGNAL/RESIGNAL` can only use a `CONDITION` defined with `SQLSTATE` error occurs. The following statements cause that error because the named condition is associated with a MySQL error number:

DECLARE no_such_table CONDITION FOR 1051;
SIGNAL no_such_table;

If a condition with a given name is declared multiple times in different scopes, the declaration with the most local scope applies. Consider the following procedure:

CREATE PROCEDURE p (divisor INT)
BEGIN
    DECLARE my_error CONDITION FOR SQLSTATE '45000';
    IF divisor = 0 THEN
        BEGIN
            DECLARE my_error CONDITION FOR SQLSTATE '22012';
            SIGNAL my_error;
        END;
    END IF;
    SIGNAL my_error;
END;

If `divisor` is 0, the first `SIGNAL` statement executes. The innermost `my_error` condition declaration applies, raising `SQLSTATE '22012'`.

If `divisor` is not 0, the second `SIGNAL` statement executes. The outermost `my_error` condition declaration applies, raising `SQLSTATE '45000'`.

For information about how the server chooses handlers when a condition occurs, see Section 15.6.7.6, "Scope Rules for Handlers".

Signals can be raised within exception handlers:

CREATE PROCEDURE p ()
BEGIN
    DECLARE EXIT HANDLER FOR SQLEXCEPTION
    BEGIN
        SIGNAL SQLSTATE VALUE '99999'
        SET MESSAGE_TEXT = 'An error occurred';
    END;
    DROP TABLE no_such_table;
END;

CALL p() reaches the `DROP TABLE` statement. There is no table named `no_such_table`, so the error handler is activated. The error handler destroys the original error ("no such table") and makes a new error with `SQLSTATE '99999'` and message "An error occurred."
### Signal Condition Information Items

The following table lists the names of diagnostics area condition information items that can be set in a `SIGNAL` (or `RESIGNAL`) statement. All items are standard SQL except `MYSQL_ERRNO`, which is a MySQL extension. For more information about these items see Section 15.6.7.7, “The MySQL Diagnostics Area”.

<table>
<thead>
<tr>
<th>Item Name</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS_ORIGIN</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>SUBCLASS_ORIGIN</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CONSTRAINT_CATALOG</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CONSTRAINT_SCHEMA</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CONSTRAINT_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CATALOG_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CURSOR_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>MESSAGE_TEXT</td>
<td>VARCHAR(128)</td>
</tr>
<tr>
<td>MYSQL_ERRNO</td>
<td>SMALLINT UNSIGNED</td>
</tr>
</tbody>
</table>

The character set for character items is UTF-8.

It is illegal to assign `NULL` to a condition information item in a `SIGNAL` statement.

A `SIGNAL` statement always specifies an `SQLSTATE` value, either directly, or indirectly by referring to a named condition defined with an `SQLSTATE` value. The first two characters of an `SQLSTATE` value are its class, and the class determines the default value for the condition information items:

- **Class = '00'** (success)
  - Illegal. `SQLSTATE` values that begin with '00' indicate success and are not valid for `SIGNAL`.

- **Class = '01'** (warning)
  - `MESSAGE_TEXT` = 'Unhandled user-defined warning condition';
  - `MYSQL_ERRNO` = ER_SIGNAL_WARN

- **Class = '02'** (not found)
  - `MESSAGE_TEXT` = 'Unhandled user-defined not found condition';
  - `MYSQL_ERRNO` = ER_SIGNAL_NOT_FOUND

- **Class > '02'** (exception)
  - `MESSAGE_TEXT` = 'Unhandled user-defined exception condition';
  - `MYSQL_ERRNO` = ER_SIGNAL_EXCEPTION

For legal classes, the other condition information items are set as follows:

```
CLASS_ORIGIN = SUBCLASS_ORIGIN = '';
CONSTRAINT_CATALOG = CONSTRAINT_SCHEMA = CONSTRAINT_NAME = '';
CATALOG_NAME = SCHEMA_NAME = TABLE_NAME = COLUMN_NAME = '';
CURSOR_NAME = '';
```

The error values that are accessible after `SIGNAL` executes are the `SQLSTATE` value raised by the `SIGNAL` statement and the `MESSAGE_TEXT` and `MYSQL_ERRNO` items. These values are available from the C API:

- `mysql_sqlstate()` returns the `SQLSTATE` value.
- `mysql_errno()` returns the `MYSQL_ERRNO` value.
- `mysql_error()` returns the `MESSAGE_TEXT` value.

At the SQL level, the output from `SHOW WARNINGS` and `SHOW ERRORS` indicates the `MYSQL_ERRNO` and `MESSAGE_TEXT` values in the Code and Message columns.
To retrieve information from the diagnostics area, use the GET DIAGNOSTICS statement (see Section 15.6.7.3, “GET DIAGNOSTICS Statement”). For information about the diagnostics area, see Section 15.6.7.7, “The MySQL Diagnostics Area”.

### Effect of Signals on Handlers, Cursors, and Statements

Signals have different effects on statement execution depending on the signal class. The class determines how severe an error is. MySQL ignores the value of the sql_mode system variable; in particular, strict SQL mode does not matter. MySQL also ignores IGNORE: The intent of SIGNAL is to raise a user-generated error explicitly, so a signal is never ignored.

In the following descriptions, “unhandled” means that no handler for the signaled SQLSTATE value has been defined with DECLARE ... HANDLER.

- **Class = '00' (success)**
  - Illegal. SQLSTATE values that begin with '00' indicate success and are not valid for SIGNAL.

- **Class = '01' (warning)**
  - The value of the warning_count system variable goes up. SHOW WARNINGS shows the signal. SQLWARNING handlers catch the signal.
  - Warnings cannot be returned from stored functions because the RETURN statement that causes the function to return clears the diagnostic area. The statement thus clears any warnings that may have been present there (and resets warning_count to 0).

- **Class = '02' (not found)**
  - NOT FOUND handlers catch the signal. There is no effect on cursors. If the signal is unhandled in a stored function, statements end.

- **Class > '02' (exception)**
  - SQLEXCEPTION handlers catch the signal. If the signal is unhandled in a stored function, statements end.

- **Class = '40'**
  - Treated as an ordinary exception.

### 15.6.7.6 Scope Rules for Handlers

A stored program may include handlers to be invoked when certain conditions occur within the program. The applicability of each handler depends on its location within the program definition and on the condition or conditions that it handles:

- A handler declared in a BEGIN ... END block is in scope only for the SQL statements following the handler declarations in the block. If the handler itself raises a condition, it cannot handle that condition, nor can any other handlers declared in the block. In the following example, handlers H1 and H2 are in scope for conditions raised by statements stmt1 and stmt2. But neither H1 nor H2 are in scope for conditions raised in the body of H1 or H2.

```sql
BEGIN -- outer block
  DECLARE EXIT HANDLER FOR ...; -- handler H1
  DECLARE EXIT HANDLER FOR ...; -- handler H2
  stmt1;
  stmt2;
END;
```

- A handler is in scope only for the block in which it is declared, and cannot be activated for conditions occurring outside that block. In the following example, handler H1 is in scope for stmt1 in the inner block, but not for stmt2 in the outer block:

```sql
BEGIN -- outer block
  DECLARE EXIT HANDLER FOR ...; -- handler H1
  stmt1;
END;
```
BEGIN -- outer block
BEGIN -- inner block
    DECLARE EXIT HANDLER FOR ...; -- handler H1
    stmt1;
END;
stmt2;
END;

• A handler can be specific or general. A specific handler is for a MySQL error code, SQLSTATE value, or condition name. A general handler is for a condition in the SQLWARNING, SQLEXCEPTION, or NOT FOUND class. Condition specificity is related to condition precedence, as described later.

Multiple handlers can be declared in different scopes and with different specificities. For example, there might be a specific MySQL error code handler in an outer block, and a general SQLWARNING handler in an inner block. Or there might be handlers for a specific MySQL error code and the general SQLWARNING class in the same block.

Whether a handler is activated depends not only on its own scope and condition value, but on what other handlers are present. When a condition occurs in a stored program, the server searches for applicable handlers in the current scope (current BEGIN ... END block). If there are no applicable handlers, the search continues outward with the handlers in each successive containing scope (block). When the server finds one or more applicable handlers at a given scope, it chooses among them based on condition precedence:

• A MySQL error code handler takes precedence over an SQLSTATE value handler.

• An SQLSTATE value handler takes precedence over general SQLWARNING, SQLEXCEPTION, or NOT FOUND handlers.

• An SQLEXCEPTION handler takes precedence over an SQLWARNING handler.

• It is possible to have several applicable handlers with the same precedence. For example, a statement could generate multiple warnings with different error codes, for each of which an error-specific handler exists. In this case, the choice of which handler the server activates is nondeterministic, and may change depending on the circumstances under which the condition occurs.

One implication of the handler selection rules is that if multiple applicable handlers occur in different scopes, handlers with the most local scope take precedence over handlers in outer scopes, even over those for more specific conditions.

If there is no appropriate handler when a condition occurs, the action taken depends on the class of the condition:

• For SQLEXCEPTION conditions, the stored program terminates at the statement that raised the condition, as if there were an EXIT handler. If the program was called by another stored program, the calling program handles the condition using the handler selection rules applied to its own handlers.

• For SQLWARNING conditions, the program continues executing, as if there were a CONTINUE handler.

• For NOT FOUND conditions, if the condition was raised normally, the action is CONTINUE. If it was raised by SIGNAL or RESIGNAL, the action is EXIT.

The following examples demonstrate how MySQL applies the handler selection rules.

This procedure contains two handlers, one for the specific SQLSTATE value (‘42S02’) that occurs for attempts to drop a nonexistent table, and one for the general SQLEXCEPTION class:

CREATE PROCEDURE p1()
BEGIN
DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
  SELECT 'SQLSTATE handler was activated' AS msg;
DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
  SELECT 'SQLEXCEPTION handler was activated' AS msg;
DROP TABLE test.t;
END;

Both handlers are declared in the same block and have the same scope. However, SQLSTATE handlers take precedence over SQLEXCEPTION handlers, so if the table t is nonexistent, the DROP TABLE statement raises a condition that activates the SQLSTATE handler:

mysql> CALL p1();
+----------------------------------+
| msg                              |
|                                 |
| SQLSTATE handler was activated  |
+----------------------------------+

This procedure contains the same two handlers. But this time, the DROP TABLE statement and SQLEXCEPTION handler are in an inner block relative to the SQLSTATE handler:

CREATE PROCEDURE p2()
BEGIN -- outer block
  DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
  SELECT 'SQLSTATE handler was activated' AS msg;
BEGIN -- inner block
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
  SELECT 'SQLEXCEPTION handler was activated' AS msg;
  DROP TABLE test.t; -- occurs within inner block
END;
END;

In this case, the handler that is more local to where the condition occurs takes precedence. The SQLEXCEPTION handler activates, even though it is more general than the SQLSTATE handler:

mysql> CALL p2();
+------------------------------+
<table>
<thead>
<tr>
<th>msg</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLEXCEPTION handler...</td>
</tr>
</tbody>
</table>
+------------------------------+

In this procedure, one of the handlers is declared in a block inner to the scope of the DROP TABLE statement:

CREATE PROCEDURE p3()
BEGIN -- outer block
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
  SELECT 'SQLEXCEPTION handler was activated' AS msg;
BEGIN -- inner block
  DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
  SELECT 'SQLSTATE handler was activated' AS msg;
END;
DROP TABLE test.t; -- occurs within outer block
END;

Only the SQLEXCEPTION handler applies because the other one is not in scope for the condition raised by the DROP TABLE:

mysql> CALL p3();
+----------------------------+
<table>
<thead>
<tr>
<th>msg</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLEXCEPTION handler...</td>
</tr>
</tbody>
</table>
+----------------------------+
In this procedure, both handlers are declared in a block inner to the scope of the `DROP TABLE` statement:

```sql
CREATE PROCEDURE p4()
BEGIN -- outer block
    BEGIN -- inner block
        DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
            SELECT 'SQLEXCEPTION handler was activated' AS msg;
        DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
            SELECT 'SQLSTATE handler was activated' AS msg;
    END;

    DROP TABLE test.t; -- occurs within outer block
END;
```

Neither handler applies because they are not in scope for the `DROP TABLE`. The condition raised by the statement goes unhandled and terminates the procedure with an error:

```
mysql> CALL p4();
ERROR 1051 (42S02): Unknown table 'test.t'
```

### 15.6.7.7 The MySQL Diagnostics Area

SQL statements produce diagnostic information that populates the diagnostics area. Standard SQL has a diagnostics area stack, containing a diagnostics area for each nested execution context. Standard SQL also supports `GET STACKED DIAGNOSTICS` syntax for referring to the second diagnostics area during condition handler execution.

The following discussion describes the structure of the diagnostics area in MySQL, the information items recognized by MySQL, how statements clear and set the diagnostics area, and how diagnostics areas are pushed to and popped from the stack.

- **Diagnostics Area Structure**
- **Diagnostics Area Information Items**
- **How the Diagnostics Area is Cleared and Populated**
- **How the Diagnostics Area Stack Works**
- **Diagnostics Area-Related System Variables**

#### Diagnostics Area Structure

The diagnostics area contains two kinds of information:

- Statement information, such as the number of conditions that occurred or the affected-rows count.
- Condition information, such as the error code and message. If a statement raises multiple conditions, this part of the diagnostics area has a condition area for each one. If a statement raises no conditions, this part of the diagnostics area is empty.

For a statement that produces three conditions, the diagnostics area contains statement and condition information like this:

```
Statement information:
    row count
    ... other statement information items ...
Condition area list:
    Condition area 1:
        error code for condition 1
        error message for condition 1
        ... other condition information items ...
    Condition area 2:
        error code for condition 2:
        error message for condition 2
```

2736
Condition Handling

Diagnostics Area Information Items

The diagnostics area contains statement and condition information items. Numeric items are integers. The character set for character items is UTF-8. No item can be null. If a statement or condition item is not set by a statement that populates the diagnostics area, its value is 0 or the empty string, depending on the item data type.

The statement information part of the diagnostics area contains these items:

- **NUMBER**: An integer indicating the number of condition areas that have information.

- **ROW_COUNT**: An integer indicating the number of rows affected by the statement. **ROW_COUNT** has the same value as the **ROW_COUNT()** function (see Section 14.15, “Information Functions”).

The condition information part of the diagnostics area contains a condition area for each condition. Condition areas are numbered from 1 to the value of the **NUMBER** statement condition item. If **NUMBER** is 0, there are no condition areas.

Each condition area contains the items in the following list. All items are standard SQL except **MYSQL_ERRNO**, which is a MySQL extension. The definitions apply for conditions generated other than by a signal (that is, by a **SIGNAL** or **RESIGNAL** statement). For nonsignal conditions, MySQL populates only those condition items not described as always empty. The effects of signals on the condition area are described later.

- **CLASS_ORIGIN**: A string containing the class of the **RETURNED_SQLSTATE** value. If the **RETURNED_SQLSTATE** value begins with a class value defined in SQL standards document ISO 9075-2 (section 24.1, SQLSTATE), **CLASS_ORIGIN** is 'ISO 9075'. Otherwise, **CLASS_ORIGIN** is 'MySQL'.

- **SUBCLASS_ORIGIN**: A string containing the subclass of the **RETURNED_SQLSTATE** value. If **CLASS_ORIGIN** is 'ISO 9075' or **RETURNED_SQLSTATE** ends with '000', **SUBCLASS_ORIGIN** is 'ISO 9075'. Otherwise, **SUBCLASS_ORIGIN** is 'MySQL'.

- **RETURNED_SQLSTATE**: A string that indicates the SQLSTATE value for the condition.

- **MESSAGE_TEXT**: A string that indicates the error message for the condition.

- **MYSQL_ERRNO**: An integer that indicates the MySQL error code for the condition.

- **CONSTRAINT_CATALOG, CONSTRAINT_SCHEMA, CONSTRAINT_NAME**: Strings that indicate the catalog, schema, and name for a violated constraint. They are always empty.

- **CATALOG_NAME, SCHEMA_NAME, TABLE_NAME, COLUMN_NAME**: Strings that indicate the catalog, schema, table, and column related to the condition. They are always empty.

- **CURSOR_NAME**: A string that indicates the cursor name. This is always empty.

For the **RETURNED_SQLSTATE**, **MESSAGE_TEXT**, and **MYSQL_ERRNO** values for particular errors, see Server Error Message Reference.

If a **SIGNAL** (or **RESIGNAL**) statement populates the diagnostics area, its **SET** clause can assign to any condition information item except **RETURNED_SQLSTATE** any value that is legal for the item data type. **SIGNAL** also sets the **RETURNED_SQLSTATE** value, but not directly in its **SET** clause. That value comes from the **SIGNAL** statement **SQLSTATE** argument.

**SIGNAL** also sets statement information items. It sets **NUMBER** to 1. It sets **ROW_COUNT** to −1 for errors and 0 otherwise.
How the Diagnostics Area is Cleared and Populated

Nondiagnostic SQL statements populate the diagnostics area automatically, and its contents can be set explicitly with the `SIGNAL` and `RESIGNAL` statements. The diagnostics area can be examined with `GET DIAGNOSTICS` to extract specific items, or with `SHOW WARNINGS` or `SHOW ERRORS` to see conditions or errors.

SQL statements clear and set the diagnostics area as follows:

- When the server starts executing a statement after parsing it, it clears the diagnostics area for nondiagnostic statements. Diagnostic statements do not clear the diagnostics area. These statements are diagnostic:
  - `GET DIAGNOSTICS`
  - `SHOW ERRORS`
  - `SHOW WARNINGS`

- If a statement raises a condition, the diagnostics area is cleared of conditions that belong to earlier statements. The exception is that conditions raised by `GET DIAGNOSTICS` and `RESIGNAL` are added to the diagnostics area without clearing it.

Thus, even a statement that does not normally clear the diagnostics area when it begins executing clears it if the statement raises a condition.

The following example shows the effect of various statements on the diagnostics area, using `SHOW WARNINGS` to display information about conditions stored there.

This `DROP TABLE` statement clears the diagnostics area and populates it when the condition occurs:

```sql
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected, 1 warning (0.01 sec)
mysql> SHOW WARNINGS;
+-------+------+------------------------------------+
| Level | Code | Message                            |
+-------+------+------------------------------------+
| Note  | 1051 | Unknown table 'test.no_such_table' |
+-------+------+------------------------------------+
1 row in set (0.00 sec)
```

This `SET` statement generates an error, so it clears and populates the diagnostics area:

```sql
mysql> SET @x = @@x;
ERROR 1193 (HY000): Unknown system variable 'x'
mysql> SHOW WARNINGS;
+-------+------+-----------------------------+
| Level | Code | Message                     |
+-------+------+-----------------------------+
| Error | 1193 | Unknown system variable 'x' |
+-------+------+-----------------------------+
1 row in set (0.00 sec)
```

The previous `SET` statement produced a single condition, so 1 is the only valid condition number for `GET DIAGNOSTICS` at this point. The following statement uses a condition number of 2, which produces a warning that is added to the diagnostics area without clearing it:

```sql
mysql> GET DIAGNOSTICS CONDITION 2 @p = MESSAGE_TEXT;
Query OK, 0 rows affected, 1 warning (0.00 sec)
mysql> SHOW WARNINGS;
+-------+------+------------------------------+
| Level | Code | Message                      |
+-------+------+------------------------------+
| Error | 1193 | Unknown system variable 'xx' |
+-------+------+------------------------------+
```
Now there are two conditions in the diagnostics area, so the same `GET DIAGNOSTICS` statement succeeds:

```
mysql> GET DIAGNOSTICS CONDITION 2 @p = MESSAGE_TEXT;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @p;
+--------------------------+
<table>
<thead>
<tr>
<th>@p</th>
</tr>
</thead>
<tbody>
<tr>
<td>Invalid condition number</td>
</tr>
</tbody>
</table>
+--------------------------+
1 row in set (0.01 sec)
```

### How the Diagnostics Area Stack Works

When a push to the diagnostics area stack occurs, the first (current) diagnostics area becomes the second (stacked) diagnostics area and a new current diagnostics area is created as a copy of it. Diagnostics areas are pushed to and popped from the stack under the following circumstances:

- **Execution of a stored program**
  
  A push occurs before the program executes and a pop occurs afterward. If the stored program ends while handlers are executing, there can be more than one diagnostics area to pop; this occurs due to an exception for which there are no appropriate handlers or due to `RETURN` in the handler.

  Any warning or error conditions in the popped diagnostics areas then are added to the current diagnostics area, except that, for triggers, only errors are added. When the stored program ends, the caller sees these conditions in its current diagnostics area.

- **Execution of a condition handler within a stored program**
  
  When a push occurs as a result of condition handler activation, the stacked diagnostics area is the area that was current within the stored program prior to the push. The new now-current diagnostics area is the handler’s current diagnostics area. `GET [CURRENT] DIAGNOSTICS` and `GET STACKED DIAGNOSTICS` can be used within the handler to access the contents of the current (handler) and stacked (stored program) diagnostics areas. Initially, they return the same result, but statements executing within the handler modify the current diagnostics area, clearing and setting its contents according to the normal rules (see *How the Diagnostics Area is Cleared and Populated*). The stacked diagnostics area cannot be modified by statements executing within the handler except `RESIGNAL`.

  If the handler executes successfully, the current (handler) diagnostics area is popped and the stacked (stored program) diagnostics area again becomes the current diagnostics area. Conditions added to the handler diagnostics area during handler execution are added to the current diagnostics area.

- **Execution of `RESIGNAL`**
  
  The `RESIGNAL` statement passes on the error condition information that is available during execution of a condition handler within a compound statement inside a stored program. `RESIGNAL` may change some or all information before passing it on, modifying the diagnostics stack as described in Section 15.6.7.4, “`RESIGNAL` Statement”.

### Diagnostics Area-Related System Variables

Certain system variables control or are related to some aspects of the diagnostics area:

- **`max_error_count`** controls the number of condition areas in the diagnostics area. If more conditions than this occur, MySQL silently discards information for the excess conditions. (Conditions
Restrictions on Condition Handling

added by **RESIGNAL** are always added, with older conditions being discarded as necessary to make room.)

- **warning_count** indicates the number of conditions that occurred. This includes errors, warnings, and notes. Normally, **NUMBER** and **warning_count** are the same. However, as the number of conditions generated exceeds **max_error_count**, the value of **warning_count** continues to rise whereas **NUMBER** remains capped at **max_error_count** because no additional conditions are stored in the diagnostics area.

- **error_count** indicates the number of errors that occurred. This value includes “not found” and exception conditions, but excludes warnings and notes. Like **warning_count**, its value can exceed **max_error_count**.

- If the **sql_notes** system variable is set to 0, notes are not stored and do not increment **warning_count**.

Example: If **max_error_count** is 10, the diagnostics area can contain a maximum of 10 condition areas. Suppose that a statement raises 20 conditions, 12 of which are errors. In that case, the diagnostics area contains the first 10 conditions, **NUMBER** is 10, **warning_count** is 20, and **error_count** is 12.

Changes to the value of **max_error_count** have no effect until the next attempt to modify the diagnostics area. If the diagnostics area contains 10 condition areas and **max_error_count** is set to 5, that has no immediate effect on the size or content of the diagnostics area.

15.6.7.8 Condition Handling and OUT or INOUT Parameters

If a stored procedure exits with an unhandled exception, modified values of **OUT** and **INOUT** parameters are not propagated back to the caller.

If an exception is handled by a **CONTINUE** or **EXIT** handler that contains a **RESIGNAL** statement, execution of **RESIGNAL** pops the Diagnostics Area stack, thus signalling the exception (that is, the information that existed before entry into the handler). If the exception is an error, the values of **OUT** and **INOUT** parameters are not propagated back to the caller.

15.6.8 Restrictions on Condition Handling

**SIGNAL**, **RESIGNAL**, and **GET DIAGNOSTICS** are not permissible as prepared statements. For example, this statement is invalid:

```
PREPARE stmt1 FROM 'SIGNAL SQLSTATE "02000"';
```

**SQLSTATE** values in class '04' are not treated specially. They are handled the same as other exceptions.

In standard SQL, the first condition relates to the **SQLSTATE** value returned for the previous SQL statement. In MySQL, this is not guaranteed, so to get the main error, you cannot do this:

```
GET DIAGNOSTICS CONDITION 1 @errno = MYSQL_ERRNO;
```

Instead, do this:

```
GET DIAGNOSTICS @cno = NUMBER;
GET DIAGNOSTICS CONDITION @cno @errno = MYSQL_ERRNO;
```

15.7 Database Administration Statements

15.7.1 Account Management Statements

MySQL account information is stored in the tables of the **mysql** system schema. This database and the access control system are discussed extensively in *Chapter 7, MySQL Server Administration*, which you should consult for additional details.
Important

Some MySQL releases introduce changes to the grant tables to add new privileges or features. To make sure that you can take advantage of any new capabilities, update your grant tables to the current structure whenever you upgrade MySQL. See Chapter 3, Upgrading MySQL.

When the `read_only` system variable is enabled, account-management statements require the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege), in addition to any other required privileges. This is because they modify tables in the `mysql` system schema.

Account management statements are atomic and crash safe. For more information, see Section 15.1.1, “Atomic Data Definition Statement Support”.

15.7.1.1 ALTER USER Statement

```sql
ALTER USER [IF EXISTS]
  user [auth_option] [, user [auth_option]] ...
  [REQUIRE {NONE | tls_option [[AND] tls_option] ...}]
  [WITH resource_option [resource_option] ...]
  [password_option | lock_option] ...
  [COMMENT 'comment_string' | ATTRIBUTE 'json_object']
```

```sql
ALTER USER [IF EXISTS]
  USER() [user_func_auth_option]
```

```sql
ALTER USER [IF EXISTS]
  user [registration_option]
```

```sql
ALTER USER [IF EXISTS]
  USER() [registration_option]
```

```sql
ALTER USER [IF EXISTS]
  user DEFAULT ROLE
  {NONE | ALL | role [, role ] ...}
```

```sql
user:
  (see Section 8.2.4, “Specifying Account Names”)
```

```sql
auth_option: {
  IDENTIFIED BY 'auth_string'
  [REPLACE 'current_auth_string']
  [RETAIN CURRENT PASSWORD]
  | IDENTIFIED BY RANDOM PASSWORD
  [REPLACE 'current_auth_string']
  [RETAIN CURRENT PASSWORD]
  | IDENTIFIED WITH auth_plugin
  [REPLACE 'current_auth_string']
  [RETAIN CURRENT PASSWORD]
  | IDENTIFIED WITH auth_plugin BY 'auth_string'
  [REPLACE 'current_auth_string']
  [RETAIN CURRENT PASSWORD]
  | IDENTIFIED WITH auth_plugin BY RANDOM PASSWORD
  [REPLACE 'current_auth_string']
  [RETAIN CURRENT PASSWORD]
  | IDENTIFIED WITH auth_plugin AS 'auth_string'
  [REPLACE 'current_auth_string']
  [RETAIN CURRENT PASSWORD]
  | DISCARD OLD PASSWORD
  | ADD factor factor_auth_option [ADD factor factor_auth_option]
  | MODIFY factor factor_auth_option [MODIFY factor factor_auth_option]
  | DROP factor [DROP factor]
}
```

```sql
user_func_auth_option: {
  IDENTIFIED BY 'auth_string'
  [REPLACE 'current_auth_string']
  [RETAIN CURRENT PASSWORD]
  | DISCARD OLD PASSWORD
}
```

```sql
factor_auth_option: {
  IDENTIFIED BY 'auth_string'
}
```
The `ALTER USER` statement modifies MySQL accounts. It enables authentication, role, SSL/TLS, resource-limit, password-management, comment, and attribute properties to be modified for existing accounts. It can also be used to lock and unlock accounts.

In most cases, `ALTER USER` requires the global `CREATE USER` privilege, or the `UPDATE` privilege for the `mysql` system schema. The exceptions are:

- Any client who connects to the server using a nonanonymous account can change the password for that account. (In particular, you can change your own password.) To see which account the server authenticated you as, invoke the `CURRENT_USER()` function:

```sql
SELECT CURRENT_USER();
```

- For `DEFAULT ROLE` syntax, `ALTER USER` requires these privileges:
  - Setting the default roles for another user requires the global `CREATE USER` privilege, or the `UPDATE` privilege for the `mysql.default_roles` system table.
  - Setting the default roles for yourself requires no special privileges, as long as the roles you want as the default have been granted to you.

- Statements that modify secondary passwords require these privileges:
  - The `APPLICATION_PASSWORD_ADMIN` privilege is required to use the `RETAIN_CURRENT PASSWORD` or `DISCARD OLD PASSWORD` clause for `ALTER USER` statements that apply to your
own account. The privilege is required to manipulate your own secondary password because most
users require only one password.

- If an account is to be permitted to manipulate secondary passwords for all accounts, it requires the
  `CREATE_USER` privilege rather than `APPLICATION_PASSWORD_ADMIN`.

When the `read_only` system variable is enabled, `ALTER_USER` additionally requires the
`CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege).

These additional privilege considerations also apply:

- The `authentication_policy` system variable places certain constraints on how the
  authentication-related clauses of `ALTER_USER` statements may be used; for details,
  see the description of that variable. These constraints do not apply if you have the
  `AUTHENTICATION_POLICY_ADMIN` privilege.

- To modify an account that uses passwordless authentication, you must have the
  `PASSWORDLESS_USER_ADMIN` privilege.

By default, an error occurs if you try to modify a user that does not exist. If the `IF EXISTS` clause is
given, the statement produces a warning for each named user that does not exist, rather than an error.

---

### Important

Under some circumstances, `ALTER_USER` may be recorded in server logs or
on the client side in a history file such as `~/.mysql_history`, which means
that cleartext passwords may be read by anyone having read access to that
information. For information about the conditions under which this occurs for the
server logs and how to control it, see Section 8.1.2.3, “Passwords and Logging”.
For similar information about client-side logging, see Section 6.5.1.3, "mysql
Client Logging".

There are several aspects to the `ALTER_USER` statement, described under the following topics:

- ALTER USER Overview
- ALTER USER Authentication Options
- ALTER USER Multifactor Authentication Options
- ALTER USER Registration Options
- ALTER USER Role Options
- ALTER USER SSL/TLS Options
- ALTER USER Resource-Limit Options
- ALTER USER Password-Management Options
- ALTER USER Comment and Attribute Options
- ALTER USER Account-Locking Options
- ALTER USER Binary Logging

### ALTER USER Overview

For each affected account, `ALTER_USER` modifies the corresponding row in the `mysql.user` system
table to reflect the properties specified in the statement. Unspecified properties retain their current
values.
Each account name uses the format described in Section 8.2.4, “Specifying Account Names”. The host name part of the account name, if omitted, defaults to '%'. It is also possible to specify CURRENT_USER or CURRENT_USER() to refer to the account associated with the current session.

In one case only, the account may be specified with the USER() function:

```
ALTER USER USER() IDENTIFIED BY 'auth_string';
```

This syntax enables changing your own password without naming your account literally. (The syntax also supports the REPLACE, RETAIN CURRENT PASSWORD, and DISCARD OLD PASSWORD clauses described at ALTER USER Authentication Options.)

For ALTER USER syntax that permits an auth_option value to follow a user value, auth_option indicates how the account authenticates by specifying an account authentication plugin, credentials (for example, a password), or both. Each auth_option value applies only to the account named immediately preceding it.

Following the user specifications, the statement may include options for SSL/TLS, resource-limit, password-management, and locking properties. All such options are global to the statement and apply to all accounts named in the statement.

Example: Change an account's password and expire it. As a result, the user must connect with the named password and choose a new one at the next connection:

```
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED BY 'new_password' PASSWORD EXPIRE;
```

Example: Modify an account to use the caching_sha2_password authentication plugin and the given password. Require that a new password be chosen every 180 days, and enable failed-login tracking, such that three consecutive incorrect passwords cause temporary account locking for two days:

```
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED WITH caching_sha2_password BY 'new_password'
  PASSWORD EXPIRE INTERVAL 180 DAY
  FAILED_LOGIN_ATTEMPTS 3 PASSWORD_LOCK_TIME 2;
```

Example: Lock or unlock an account:

```
ALTER USER 'jeffrey'@'localhost' ACCOUNT LOCK;
ALTER USER 'jeffrey'@'localhost' ACCOUNT UNLOCK;
```

Example: Require an account to connect using SSL and establish a limit of 20 connections per hour:

```
ALTER USER 'jeffrey'@'localhost'
  REQUIRE SSL WITH MAX_CONNECTIONS_PER_HOUR 20;
```

Example: Alter multiple accounts, specifying some per-account properties and some global properties:

```
ALTER USER
  'jeffrey'@'localhost'
  IDENTIFIED BY 'jeffrey_new_password',
  'jeanne'@'localhost',
  'josh'@'localhost'
  IDENTIFIED BY 'josh_new_password'
  REPLACE 'josh_current_password'
  RETAIN CURRENT PASSWORD
  REQUIRE SSL WITH MAX_USER_CONNECTIONS 2
  PASSWORD HISTORY 5;
```

The IDENTIFIED BY value following jeffrey applies only to its immediately preceding account, so it changes the password to 'jeffrey_new_password' only for jeffrey. For jeanne, there is no per-account value (thus leaving the password unchanged). For josh, IDENTIFIED BY establishes
a new password ("josh\_new\_password"), REPLACE is specified to verify that the user issuing the ALTER USER statement knows the current password ("josh\_current\_password"), and that current password is also retained as the account secondary password. (As a result, josh can connect with either the primary or secondary password.)

The remaining properties apply globally to all accounts named in the statement, so for both accounts:

- Connections are required to use SSL.
- The account can be used for a maximum of two simultaneous connections.
- Password changes cannot reuse any of the five most recent passwords.

Example: Discard the secondary password for josh, leaving the account with only its primary password:

```
ALTER USER 'josh'@'localhost' DISCARD OLD PASSWORD;
```

In the absence of a particular type of option, the account remains unchanged in that respect. For example, with no locking option, the locking state of the account is not changed.

**ALTER USER Authentication Options**

An account name may be followed by an auth\_option authentication option that specifies the account authentication plugin, credentials, or both. It may also include a password-verification clause that specifies the account current password to be replaced, and clauses that manage whether an account has a secondary password.

### Note

Clauses for random password generation, password verification, and secondary passwords apply only to accounts that use an authentication plugin that stores credentials internally to MySQL. For accounts that use a plugin that performs authentication against a credentials system that is external to MySQL, password management must be handled externally against that system as well. For more information about internal credentials storage, see Section 8.2.15, “Password Management”.

- **auth\_plugin** names an authentication plugin. The plugin name can be a quoted string literal or an unquoted name. Plugin names are stored in the plugin column of the mysql.user system table.

  For auth\_option syntax that does not specify an authentication plugin, the server assigns the default plugin, determined as described in The Default Authentication Plugin. For descriptions of each plugin, see Section 8.4.1, “Authentication Plugins”.

- Credentials that are stored internally are stored in the mysql.user system table. An 'auth\_string' value or RANDOM PASSWORD specifies account credentials, either as a cleartext (unencrypted) string or hashed in the format expected by the authentication plugin associated with the account, respectively:

  - For syntax that uses BY 'auth\_string', the string is cleartext and is passed to the authentication plugin for possible hashing. The result returned by the plugin is stored in the mysql.user table. A plugin may use the value as specified, in which case no hashing occurs.

  - For syntax that uses BY RANDOM PASSWORD, MySQL generates a random password and as cleartext and passes it to the authentication plugin for possible hashing. The result returned by the plugin is stored in the mysql.user table. A plugin may use the value as specified, in which case no hashing occurs.

Randomly generated passwords have the characteristics described in Random Password Generation.
• For syntax that uses `AS 'auth_string'`, the string is assumed to be already in the format the authentication plugin requires, and is stored as is in the `mysql.user` table. If a plugin requires a hashed value, the value must be already hashed in a format appropriate for the plugin; otherwise, the value cannot be used by the plugin and correct authentication of client connections does not occur.

A hashed string can be either a string literal or a hexadecimal value. The latter corresponds to the type of value displayed by `SHOW CREATE USER` for password hashes containing unprintable characters when the `print_identified_with_as_hex` system variable is enabled.

• If an authentication plugin performs no hashing of the authentication string, the `BY 'auth_string'` and `AS 'auth_string'` clauses have the same effect: The authentication string is stored as is in the `mysql.user` system table.

The `REPLACE 'current_auth_string'` clause performs password verification. If given:

• `REPLACE` specifies the account current password to be replaced, as a cleartext (unencrypted) string.

• The clause must be given if password changes for the account are required to specify the current password, as verification that the user attempting to make the change actually knows the current password.

• The clause is optional if password changes for the account may but need not specify the current password.

• The statement fails if the clause is given but does not match the current password, even if the clause is optional.

• `REPLACE` can be specified only when changing the account password for the current user.

For more information about password verification by specifying the current password, see Section 8.2.15, “Password Management”.

• The `RETAIN CURRENT PASSWORD` and `DISCARD OLD PASSWORD` clauses implement dual-password capability. Both are optional, but if given, have the following effects:

• `RETAIN CURRENT PASSWORD` retains an account current password as its secondary password, replacing any existing secondary password. The new password becomes the primary password, but clients can use the account to connect to the server using either the primary or secondary password. (Exception: If the new password specified by the `ALTER USER` statement is empty, the secondary password becomes empty as well, even if `RETAIN CURRENT PASSWORD` is given.)

• If you specify `RETAIN CURRENT PASSWORD` for an account that has an empty primary password, the statement fails.

• If an account has a secondary password and you change its primary password without specifying `RETAIN CURRENT PASSWORD`, the secondary password remains unchanged.

• If you change the authentication plugin assigned to the account, the secondary password is discarded. If you change the authentication plugin and also specify `RETAIN CURRENT PASSWORD`, the statement fails.

• `DISCARD OLD PASSWORD` discards the secondary password, if one exists. The account retains only its primary password, and clients can use the account to connect to the server only with the primary password.

For more information about use of dual passwords, see Section 8.2.15, “Password Management”.

`ALTER USER` permits these `auth_option` syntaxes:
• IDENTIFIED BY 'auth_string' [REPLACE 'current_auth_string'] [RETAIN CURRENT PASSWORD]

Sets the account authentication plugin to the default plugin, passes the cleartext 'auth_string' value to the plugin for possible hashing, and stores the result in the account row in the `mysql.user` system table.

The **REPLACE** clause, if given, specifies the account current password, as described previously in this section.

The **RETAIN CURRENT PASSWORD** clause, if given, causes the account current password to be retained as its secondary password, as described previously in this section.

• IDENTIFIED BY RANDOM PASSWORD [REPLACE 'current_auth_string'] [RETAIN CURRENT PASSWORD]

Sets the account authentication plugin to the default plugin, generates a random password, passes the cleartext password value to the plugin for possible hashing, and stores the result in the account row in the `mysql.user` system table. The statement also returns the cleartext password in a result set to make it available to the user or application executing the statement. For details about the result set and characteristics of randomly generated passwords, see Random Password Generation.

The **REPLACE** clause, if given, specifies the account current password, as described previously in this section.

The **RETAIN CURRENT PASSWORD** clause, if given, causes the account current password to be retained as its secondary password, as described previously in this section.

• IDENTIFIED WITH auth_plugin

Sets the account authentication plugin to `auth_plugin`, clears the credentials to the empty string (the credentials are associated with the old authentication plugin, not the new one), and stores the result in the account row in the `mysql.user` system table.

In addition, the password is marked expired. The user must choose a new one when next connecting.

• IDENTIFIED WITH auth_plugin BY 'auth_string' [REPLACE 'current_auth_string'] [RETAIN CURRENT PASSWORD]

Sets the account authentication plugin to `auth_plugin`, passes the cleartext 'auth_string' value to the plugin for possible hashing, and stores the result in the account row in the `mysql.user` system table.

The **REPLACE** clause, if given, specifies the account current password, as described previously in this section.

The **RETAIN CURRENT PASSWORD** clause, if given, causes the account current password to be retained as its secondary password, as described previously in this section.

• IDENTIFIED WITH auth_plugin BY RANDOM PASSWORD [REPLACE 'current_auth_string'] [RETAIN CURRENT PASSWORD]

Sets the account authentication plugin to `auth_plugin`, generates a random password, passes the cleartext password value to the plugin for possible hashing, and stores the result in the account row in the `mysql.user` system table. The statement also returns the cleartext password in a result set to make it available to the user or application executing the statement. For details about the result set and characteristics of randomly generated passwords, see Random Password Generation.

The **REPLACE** clause, if given, specifies the account current password, as described previously in this section.
The **RETAIN CURRENT PASSWORD** clause, if given, causes the account current password to be retained as its secondary password, as described previously in this section.

- **IDENTIFIED WITH auth_plugin AS 'auth_string'**

  Sets the account authentication plugin to `auth_plugin` and stores the `'auth_string'` value as is in the `mysql.user` account row. If the plugin requires a hashed string, the string is assumed to be already hashed in the format the plugin requires.

- **DISCARD OLD PASSWORD**

  Discards the account secondary password, if there is one, as described previously in this section.

Example: Specify the password as cleartext; the default plugin is used:

```sql
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED BY 'password';
```

Example: Specify the authentication plugin, along with a cleartext password value:

```sql
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED WITH mysql_native_password
  BY 'password';
```

Example: Like the preceding example, but in addition, specify the current password as a cleartext value to satisfy any account requirement that the user making the change knows that password:

```sql
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED WITH mysql_native_password
  BY 'password'
  REPLACE 'current_password';
```

The preceding statement fails unless the current user is `jeffrey` because `REPLACE` is permitted only for changes to the current user's password.

Example: Establish a new primary password and retain the existing password as the secondary password:

```sql
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED BY 'new_password'
  RETAIN CURRENT PASSWORD;
```

Example: Discard the secondary password, leaving the account with only its primary password:

```sql
ALTER USER 'jeffrey'@'localhost' DISCARD OLD PASSWORD;
```

Example: Specify the authentication plugin, along with a hashed password value:

```sql
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED WITH mysql_native_password
  AS '6C8989366EAF75BB670AD8EA7FC1176A95CEF4';
```

For additional information about setting passwords and authentication plugins, see Section 8.2.14, “Assigning Account Passwords”, and Section 8.2.17, “Pluggable Authentication”.

**ALTER USER Multifactor Authentication Options**

`ALTER USER` has `ADD`, `MODIFY`, and `DROP` clauses that enable authentication factors to be added, modified, or dropped. In each case, the clause specifies an operation to perform on one authentication factor, and optionally an operation on another authentication factor. For each operation, the `factor` item specifies the `FACTOR` keyword preceded by the number 2 or 3 to indicate whether the operation applies to the second or third authentication factor. (1 is not permitted in this context. To act on the first authentication factor, use the syntax described in `ALTER USER Authentication Options`.)

`ALTER USER` multifactor authentication clause constraints are defined by the `authentication_policy` system variable. For example, the `authentication_policy` setting
controls the number of authentication factors that accounts may have, and for each factor, which
authentication methods are permitted. See Configuring the Multifactor Authentication Policy.

When `ALTER USER` adds, modifies, or drops second and third factors in a single statement, operations
are executed sequentially, but if any operation in the sequence fails the entire `ALTER USER` statement
fails.

For `ADD`, each named factor must not already exist or it cannot be added. For `MODIFY` and `DROP`, each
named factor must exist to be modified or dropped. If a second and third factor are defined, dropping
the second factor causes the third factor to take its place as the second factor.

This statement drops authentication factors 2 and 3, which has the effect of converting the account
from 3FA to 1FA:

```
ALTER USER 'user' DROP 2 FACTOR 3 FACTOR;
```

For additional `ADD`, `MODIFY`, and `DROP` examples, see Getting Started with Multifactor Authentication.

For information about factor-specific rules that determine the default authentication plugin for
authentication clauses that do not name a plugin, see The Default Authentication Plugin.

**ALTER USER Registration Options**

`ALTER USER` has clauses that enable FIDO/FIDO2 devices to be registered and unregistered. For
more information, see Using WebAuthn Authentication, Device Unregistration for WebAuthn, and the
`mysql` client `--register-factor` option description.

The `mysql` client `--register-factor` option, used for FIDO/FIDO2 device registration, causes
the `mysql` client to generate and execute `INITIATE_REGISTRATION` and `FINISH_REGISTRATION`
statements. These statements are not intended for manual execution.

**ALTER USER Role Options**

`ALTER USER` defines which roles become active when the user connects to
the server and authenticates, or when the user executes the `SET ROLE DEFAULT` statement during a
session.

`ALTER USER` is alternative syntax for `SET DEFAULT ROLE` (see
Section 15.7.1.9, "SET DEFAULT ROLE Statement"). However, `ALTER USER` can set the default for
only a single user, whereas `SET DEFAULT ROLE` can set the default for multiple users. On the other
hand, you can specify `CURRENT_USER` as the user name for the `ALTER USER` statement, whereas you
cannot for `SET DEFAULT ROLE`.

Each user account name uses the format described previously.

Each role name uses the format described in Section 8.2.5, “Specifying Role Names”. For example:

```
ALTER USER 'joe'@'10.0.0.1' DEFAULT ROLE administrator, developer;
```

The host name part of the role name, if omitted, defaults to '%'.

The clause following the `DEFAULT ROLE` keywords permits these values:

- **NONE**: Set the default to `NONE` (no roles).
- **ALL**: Set the default to all roles granted to the account.
- **role [, role ] ...**: Set the default to the named roles, which must exist and be granted to the
  account at the time `ALTER USER ... DEFAULT ROLE` is executed.

**ALTER USER SSL/TLS Options**

MySQL can check X.509 certificate attributes in addition to the usual authentication that is based on
the user name and credentials. For background information on the use of SSL/TLS with MySQL, see
Section 8.3, "Using Encrypted Connections".
To specify SSL/TLS-related options for a MySQL account, use a `REQUIRE` clause that specifies one or more `tls_option` values.

Order of `REQUIRE` options does not matter, but no option can be specified twice. The `AND` keyword is optional between `REQUIRE` options.

`ALTER USER` permits these `tls_option` values:

- **NONE**

  Indicates that all accounts named by the statement have no SSL or X.509 requirements. Unencrypted connections are permitted if the user name and password are valid. Encrypted connections can be used, at the client's option, if the client has the proper certificate and key files.

  ```sql
  ALTER USER 'jeffrey'@'localhost' REQUIRE NONE;
  ```

  Clients attempt to establish a secure connection by default. For clients that have `REQUIRE NONE`, the connection attempt falls back to an unencrypted connection if a secure connection cannot be established. To require an encrypted connection, a client need specify only the `--ssl-mode=REQUIRED` option; the connection attempt fails if a secure connection cannot be established.

- **SSL**

  Tells the server to permit only encrypted connections for all accounts named by the statement.

  ```sql
  ALTER USER 'jeffrey'@'localhost' REQUIRE SSL;
  ```

  Clients attempt to establish a secure connection by default. For accounts that have `REQUIRE SSL`, the connection attempt fails if a secure connection cannot be established.

- **X509**

  For all accounts named by the statement, requires that clients present a valid certificate, but the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates. Use of X.509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

  ```sql
  ALTER USER 'jeffrey'@'localhost' REQUIRE X509;
  ```

  For accounts with `REQUIRE X509`, clients must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.) This is true for `ISSUER` and `SUBJECT` as well because those `REQUIRE` options imply the requirements of `X509`.

- **ISSUER 'issuer'**

  For all accounts named by the statement, requires that clients present a valid X.509 certificate issued by CA 'issuer'. If a client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X.509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

  ```sql
  ALTER USER 'jeffrey'@'localhost'
  REQUIRE ISSUER '/C=SE/ST=Stockholm/L=Stockholm/O=MySQL/CN=CA/emailAddress=ca@example.com';
  ```

  Because `ISSUER` implies the requirements of `X509`, clients must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.)

- **SUBJECT 'subject'**

  For all accounts named by the statement, requires that clients present a valid X.509 certificate containing the subject `subject`. If a client presents a certificate that is valid but has a different
subject, the server rejects the connection. Use of X.509 certificates always implies encryption, so the SSL option is unnecessary in this case.

```sql
ALTER USER 'jeffrey'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL demo client certificate/
  CN=client/emailAddress=client@example.com';
```

MySQL does a simple string comparison of the 'subject' value to the value in the certificate, so lettercase and component ordering must be given exactly as present in the certificate.

Because SUBJECT implies the requirements of X509, clients must specify the --ssl-key and --ssl-cert options to connect. (It is recommended but not required that --ssl-ca also be specified so that the public certificate provided by the server can be verified.)

- **CIPHER 'cipher'**

For all accounts named by the statement, requires a specific cipher method for encrypting connections. This option is needed to ensure that ciphers and key lengths of sufficient strength are used. Encryption can be weak if old algorithms using short encryption keys are used.

```sql
ALTER USER 'jeffrey'@'localhost'
  REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The SUBJECT, ISSUER, and CIPHER options can be combined in the REQUIRE clause:

```sql
ALTER USER 'jeffrey'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL demo client certificate/
  CN=client/emailAddress=client@example.com'
  AND ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL/CN=CA/emailAddress=ca@example.com'
  AND CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

**ALTER USER Resource-Limit Options**

It is possible to place limits on use of server resources by an account, as discussed in Section 8.2.21, "Setting Account Resource Limits". To do so, use a WITH clause that specifies one or more resource_option values.

Order of WITH options does not matter, except that if a given resource limit is specified multiple times, the last instance takes precedence.

ALTER USER permits these resource_option values:

- **MAX_QUERIES_PER_HOUR count**, **MAX_UPDATES_PER_HOUR count**, **MAX_CONNECTIONS_PER_HOUR count**

  For all accounts named by the statement, these options restrict how many queries, updates, and connections to the server are permitted to each account during any given one-hour period. If count is 0 (the default), this means that there is no limitation for the account.

- **MAX_USER_CONNECTIONS count**

  For all accounts named by the statement, restricts the maximum number of simultaneous connections to the server by each account. A nonzero count specifies the limit for the account explicitly. If count is 0 (the default), the server determines the number of simultaneous connections for the account from the global value of the max_user_connections system variable. If max_user_connections is also zero, there is no limit for the account.

Example:

```sql
ALTER USER 'jeffrey'@'localhost'
  WITH MAX_QUERIES_PER_HOUR 500 MAX_UPDATES_PER_HOUR 100;
```
ALTER USER Password-Management Options

ALTER USER supports several password_option values for password management:

- Password expiration options: You can expire an account password manually and establish its password expiration policy. Policy options do not expire the password. Instead, they determine how the server applies automatic expiration to the account based on password age, which is assessed from the date and time of the most recent account password change.

- Password reuse options: You can restrict password reuse based on number of password changes, time elapsed, or both.

- Password verification-required options: You can indicate whether attempts to change an account password must specify the current password, as verification that the user attempting to make the change actually knows the current password.

- Incorrect-password failed-login tracking options: You can cause the server to track failed login attempts and temporarily lock accounts for which too many consecutive incorrect passwords are given. The required number of failures and the lock time are configurable.

This section describes the syntax for password-management options. For information about establishing policy for password management, see Section 8.2.15, “Password Management”.

If multiple password-management options of a given type are specified, the last one takes precedence. For example, PASSWORD EXPIRE DEFAULT PASSWORD EXPIRE NEVER is the same as PASSWORD EXPIRE NEVER.

Note

Except for the options that pertain to failed-login tracking, password-management options apply only to accounts that use an authentication plugin that stores credentials internally to MySQL. For accounts that use a plugin that performs authentication against a credentials system that is external to MySQL, password management must be handled externally against that system as well. For more information about internal credentials storage, see Section 8.2.15, “Password Management”.

A client has an expired password if the account password was expired manually or the password age is considered greater than its permitted lifetime per the automatic expiration policy. In this case, the server either disconnects the client or restricts the operations permitted to it (see Section 8.2.16, “Server Handling of Expired Passwords”). Operations performed by a restricted client result in an error until the user establishes a new account password.

Note

Although it is possible to “reset” an expired password by setting it to its current value, it is preferable, as a matter of good policy, to choose a different password. DBAs can enforce non-reuse by establishing an appropriate password-reuse policy. See Password Reuse Policy.

ALTER USER permits these password_option values for controlling password expiration:

- PASSWORD EXPIRE

Immediately marks the password expired for all accounts named by the statement.

ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE;

- PASSWORD EXPIRE DEFAULT

Sets all accounts named by the statement so that the global expiration policy applies, as specified by the default_password_lifetime system variable.
Account Management Statements

ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;

• PASSWORD EXPIRE NEVER

This expiration option overrides the global policy for all accounts named by the statement. For each, it disables password expiration so that the password never expires.

ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;

• PASSWORD EXPIRE INTERVAL N DAY

This expiration option overrides the global policy for all accounts named by the statement. For each, it sets the password lifetime to N days. The following statement requires the password to be changed every 180 days:

ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 180 DAY;

ALTER USER permits these password_option values for controlling reuse of previous passwords based on required minimum number of password changes:

• PASSWORD HISTORY DEFAULT

Sets all accounts named by the statement so that the global policy about password history length applies, to prohibit reuse of passwords before the number of changes specified by the password_history system variable.

ALTER USER 'jeffrey'@'localhost' PASSWORD HISTORY DEFAULT;

• PASSWORD HISTORY N

This history-length option overrides the global policy for all accounts named by the statement. For each, it sets the password history length to N passwords, to prohibit reusing any of the N most recently chosen passwords. The following statement prohibits reuse of any of the previous 6 passwords:

ALTER USER 'jeffrey'@'localhost' PASSWORD HISTORY 6;

ALTER USER permits these password_option values for controlling reuse of previous passwords based on time elapsed:

• PASSWORD REUSE INTERVAL DEFAULT

Sets all statements named by the account so that the global policy about time elapsed applies, to prohibit reuse of passwords newer than the number of days specified by the password_reuse_interval system variable.

ALTER USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL DEFAULT;

• PASSWORD REUSE INTERVAL N DAY

This time-elapsed option overrides the global policy for all accounts named by the statement. For each, it sets the password reuse interval to N days, to prohibit reuse of passwords newer than that many days. The following statement prohibits password reuse for 360 days:

ALTER USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL 360 DAY;

ALTER USER permits these password_option values for controlling whether attempts to change an account password must specify the current password, as verification that the user attempting to make the change actually knows the current password:

• PASSWORD REQUIRE CURRENT

This verification option overrides the global policy for all accounts named by the statement. For each, it requires that password changes specify the current password.
ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT;

- PASSWORD REQUIRE CURRENT OPTIONAL

This verification option overrides the global policy for all accounts named by the statement. For each, it does not require that password changes specify the current password. (The current password may but need not be given.)

ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT OPTIONAL;

- PASSWORD REQUIRE CURRENT DEFAULT

Sets all statements named by the account so that the global policy about password verification applies, as specified by the password_require_current system variable.

ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT DEFAULT;

ALTER USER permits these password_option values for controlling failed-login tracking:

- FAILED_LOGIN_ATTEMPTS N

Whether to track account login attempts that specify an incorrect password. N must be a number from 0 to 32767. A value of 0 disables failed-login tracking. Values greater than 0 indicate how many consecutive password failures cause temporary account locking (if PASSWORD_LOCK_TIME is also nonzero).

- PASSWORD_LOCK_TIME {N | UNBOUNDED}

How long to lock the account after too many consecutive login attempts provide an incorrect password. N must be a number from 0 to 32767, or UNBOUNDED. A value of 0 disables temporary account locking. Values greater than 0 indicate how long to lock the account in days. A value of UNBOUNDED causes the account locking duration to be unbounded; once locked, the account remains in a locked state until unlocked. For information about the conditions under which unlocking occurs, see Failed-Login Tracking and Temporary Account Locking.

For failed-login tracking and temporary locking to occur, an account's FAILED_LOGIN_ATTEMPTS and PASSWORD_LOCK_TIME options both must be nonzero. The following statement modifies an account such that it remains locked for two days after four consecutive password failures:

ALTER USER 'jeffrey'@'localhost' FAILED_LOGIN_ATTEMPTS 4 PASSWORD_LOCK_TIME 2;

ALTER USER Comment and Attribute Options

MySQL 8.4 supports user comments and user attributes, as described in Section 15.7.1.3, “CREATE USER Statement”. These can be modified employing ALTER USER by means of the COMMENT and ATTRIBUTE options, respectively. You cannot specify both options in the same ALTER USER statement; attempting to do so results in a syntax error.

The user comment and user attribute are stored in the Information Schema USER_ATTRIBUTES table as a JSON object; the user comment is stored as the value for a comment key in the ATTRIBUTE column of this table, as shown later in this discussion. The COMMENT text can be any arbitrary quoted text, and replaces any existing user comment. The ATTRIBUTE value must be the valid string representation of a JSON object. This is merged with any existing user attribute as if the JSON_MERGE_PATCH() function had been used on the existing user attribute and the new one; for any keys that are re-used, the new value overwrites the old one, as shown here:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
    -> WHERE USER='bill' AND HOST='localhost';
+---------+---------+----------------+
| USER    | HOST    | ATTRIBUTE       |
|---------+---------+----------------+
| bill    | localhost | {"foo": "bar"} |
|---------+---------+----------------+
```

2754
ALTER USER 'bill'@'localhost' ATTRIBUTE '{"baz": "faz", "foo": "moo"}';
Query OK, 0 rows affected (0.22 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
WHERE USER='bill' AND HOST='localhost';
+----------------+-------------------+------------------+
| USER           | HOST              | ATTRIBUTE         |
+----------------+-------------------+------------------+
| bill           | localhost         | {"baz": "faz",  |
|                |                   | "foo": "moo"}    |
+----------------+-------------------+------------------+
1 row in set (0.00 sec)

To remove a key and its value from the user attribute, set the key to JSON null (must be lowercase and unquoted), like this:

mysql> ALTER USER 'bill'@'localhost' ATTRIBUTE '{"foo": null}';
Query OK, 0 rows affected (0.08 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
WHERE USER='bill' AND HOST='localhost';
+----------------+-------------------+------------------+
| USER           | HOST              | ATTRIBUTE         |
+----------------+-------------------+------------------+
| bill           | localhost         | {"baz": "faz"}   |
+----------------+-------------------+------------------+
1 row in set (0.00 sec)

To set an existing user comment to an empty string, use ALTER USER ... COMMENT ''. This leaves an empty comment value in the USER_ATTRIBUTES table; to remove the user comment completely, use ALTER USER ... ATTRIBUTE ... with the value for the column key set to JSON null (unquoted, in lower case). This is illustrated by the following sequence of SQL statements:

mysql> ALTER USER 'bill'@'localhost' COMMENT 'Something about Bill';
Query OK, 0 rows affected (0.06 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
WHERE USER='bill' AND HOST='localhost';
+----------------+-------------------+------------------+
| USER           | HOST              | ATTRIBUTE         |
+----------------+-------------------+------------------+
| bill           | localhost         | {"baz": "faz", "comment": "Something about Bill"} |
+----------------+-------------------+------------------+
1 row in set (0.00 sec)

mysql> ALTER USER 'bill'@'localhost' COMMENT '';
Query OK, 0 rows affected (0.09 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
WHERE USER='bill' AND HOST='localhost';
+----------------+-------------------+------------------+
| USER           | HOST              | ATTRIBUTE         |
+----------------+-------------------+------------------+
| bill           | localhost         | {"baz": "faz", "comment": ""} |
+----------------+-------------------+------------------+
1 row in set (0.00 sec)

mysql> ALTER USER 'bill'@'localhost' ATTRIBUTE '{"comment": null}';
Query OK, 0 rows affected (0.07 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
WHERE USER='bill' AND HOST='localhost';
+----------------+-------------------+------------------+
| USER           | HOST              | ATTRIBUTE         |
+----------------+-------------------+------------------+
| bill           | localhost         | {"baz": "faz"}   |
+----------------+-------------------+------------------+
1 row in set (0.00 sec)

ALTER USER Account-Locking Options
MySQL supports account locking and unlocking using the `ACCOUNT LOCK` and `ACCOUNT UNLOCK` options, which specify the locking state for an account. For additional discussion, see Section 8.2.20, “Account Locking”.

If multiple account-locking options are specified, the last one takes precedence.

`ALTER USER ... ACCOUNT UNLOCK` unlocks any account named by the statement that is temporarily locked due to too many failed logins. See Section 8.2.15, “Password Management”.

### ALTER USER Binary Logging

`ALTER USER` is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named users. If the `IF EXISTS` clause is given, this includes even users that do not exist and were not altered.

If the original statement changes the credentials for a user, the statement written to the binary log specifies the applicable authentication plugin for that user, determined as follows:

- The plugin named in the original statement, if one was specified.
- Otherwise, the plugin associated with the user account if the user exists, or the default authentication plugin if the user does not exist. (If the statement written to the binary log must specify a particular authentication plugin for a user, include it in the original statement.)

If the server adds the default authentication plugin for any users in the statement written to the binary log, it writes a warning to the error log naming those users.

If the original statement specifies the `FAILED_LOGIN_ATTEMPTS` or `PASSWORD_LOCK_TIME` option, the statement written to the binary log includes the option.

`ALTER USER` statements with clauses that support multifactor authentication (MFA) are written to the binary log with the exception of `ALTER USER user factor INITIATE REGISTRATION` statements.

- `ALTER USER user factor FINISH REGISTRATION SET CHALLENGE_RESPONSE AS 'auth_string'` statements are written to the binary log as `ALTER USER user MODIFY factor IDENTIFIED WITH authentication_webauthn AS webauthn_hash_string`;

- In a replication context, the replication user requires `PASSWORDLESS_USER_ADMIN` privilege to execute `ALTER USER ... MODIFY` operations on accounts configured for passwordless authentication using the `authentication_webauthn` plugin.

### 15.7.1.2 CREATE ROLE Statement

`CREATE ROLE [IF NOT EXISTS] role [, role ] ...`

`CREATE ROLE` creates one or more roles, which are named collections of privileges. To use this statement, you must have the global `CREATE ROLE` or `CREATE USER` privilege. When the `read_only` system variable is enabled, `CREATE ROLE` additionally requires the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege).

A role when created is locked, has no password, and is assigned the default authentication plugin. (These role attributes can be changed later with the `ALTER USER` statement, by users who have the global `CREATE USER` privilege.)

`CREATE ROLE` either succeeds for all named roles or rolls back and has no effect if any error occurs. By default, an error occurs if you try to create a role that already exists. If the `IF NOT EXISTS` clause is given, the statement produces a warning for each named role that already exists, rather than an error.

The statement is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named roles. If the `IF NOT EXISTS` clause is given, this includes even roles that already exist and were not created.
Each role name uses the format described in Section 8.2.5, “Specifying Role Names”. For example:

```sql
CREATE ROLE 'admin', 'developer';
CREATE ROLE 'webapp'@'localhost';
```

The host name part of the role name, if omitted, defaults to ‘%’.

For role usage examples, see Section 8.2.10, “Using Roles”.

## 15.7.1.3 CREATE USER Statement

```sql
CREATE USER [IF NOT EXISTS]
  user [auth_option] [, user [auth_option]] ...
DEFAULT ROLE role [, role] ...
[REQUIRE {NONE | tls_option} [[AND] tls_option] ...]
[WITH resource_option [resource_option] ...]
[password_option | lock_option] ...
[COMMENT 'comment_string' | ATTRIBUTE 'json_object']

user: (see Section 8.2.4, "Specifying Account Names")

auth_option: {
  IDENTIFIED BY 'auth_string' [AND 2fa_auth_option]
  | IDENTIFIED BY RANDOM PASSWORD [AND 2fa_auth_option]
  | IDENTIFIED WITH auth_plugin [AND 2fa_auth_option]
  | IDENTIFIED WITH auth_plugin BY 'auth_string' [AND 2fa_auth_option]
  | IDENTIFIED WITH auth_plugin BY RANDOM PASSWORD [AND 2fa_auth_option]
  | IDENTIFIED WITH auth_plugin AS 'auth_string' [AND 2fa_auth_option]
  | IDENTIFIED WITH auth_plugin [initial_auth_option]

2fa_auth_option: {
  IDENTIFIED BY 'auth_string' [AND 3fa_auth_option]
  | IDENTIFIED BY RANDOM PASSWORD [AND 3fa_auth_option]
  | IDENTIFIED WITH auth_plugin [AND 3fa_auth_option]
  | IDENTIFIED WITH auth_plugin BY 'auth_string' [AND 3fa_auth_option]
  | IDENTIFIED WITH auth_plugin BY RANDOM PASSWORD [AND 3fa_auth_option]
  | IDENTIFIED WITH auth_plugin AS 'auth_string' [AND 3fa_auth_option]
}

3fa_auth_option: {
  IDENTIFIED BY 'auth_string'
  | IDENTIFIED BY RANDOM PASSWORD
  | IDENTIFIED WITH auth_plugin
  | IDENTIFIED WITH auth_plugin BY 'auth_string'
  | IDENTIFIED WITH auth_plugin BY RANDOM PASSWORD
  | IDENTIFIED WITH auth_plugin AS 'auth_string'
}

initial_auth_option: {
  INITIAL AUTHENTICATION IDENTIFIED BY {RANDOM PASSWORD | 'auth_string'}
  | INITIAL AUTHENTICATION IDENTIFIED WITH auth_plugin AS 'auth_string'
}

tls_option: {
  SSL
  | X509
  | CIPHER 'cipher'
  | ISSUER 'issuer'
  | SUBJECT 'subject'
}

resource_option: {
  MAX QUERIES PER HOUR count
  | MAX UPDATES PER HOUR count
  | MAX CONNECTIONS PER HOUR count
  | MAX USER CONNECTIONS count
}

password_option: {

```
The `CREATE USER` statement creates new MySQL accounts. It enables authentication, role, SSL/TLS, resource-limit, password-management, comment, and attribute properties to be established for new accounts. It also controls whether accounts are initially locked or unlocked.

To use `CREATE USER`, you must have the global `CREATE USER` privilege, or the `INSERT` privilege for the `mysql` system schema. When the `read_only` system variable is enabled, `CREATE USER` additionally requires the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege).

These additional privilege considerations also apply:

- The `authentication_policy` system variable places certain constraints on how the authentication-related clauses of `CREATE USER` statements may be used; for details, see the description of that variable. These constraints do not apply if you have the `AUTHENTICATION_POLICY_ADMIN` privilege.

- To create an account that uses passwordless authentication, you must have the `PASSWORDLESS_USER_ADMIN` privilege.

`CREATE USER` fails with an error if any account to be created is named as the `DEFINER` attribute for any stored object. (That is, the statement fails if creating an account would cause the account to adopt a currently orphaned stored object.) To perform the operation anyway, you must have the `SET_ANY_DEFINER` or `ALLOW_NONEXISTENT_DEFINER` privilege; in this case, the statement succeeds with a warning rather than failing with an error. To perform the user-creation operation without either of these, drop the orphan objects, create the account and grant its privileges, and then re-create the dropped objects. For additional information, including how to identify which objects name a given account as the `DEFINER` attribute, see Orphan Stored Objects.

`CREATE USER` either succeeds for all named users or rolls back and has no effect if any error occurs. By default, an error occurs if you try to create a user that already exists. If the `IF NOT EXISTS` clause is given, the statement produces a warning for each named user that already exists, rather than an error.

**Important**

Under some circumstances, `CREATE USER` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see Section 8.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 6.5.1.3, “mysql Client Logging”.

There are several aspects to the `CREATE USER` statement, described under the following topics:

- `CREATE USER` Overview
- `CREATE USER` Authentication Options
- `CREATE USER` Multifactor Authentication Options
- `CREATE USER` Role Options
**CREATE USER** Overview

For each account, **CREATE USER** creates a new row in the `mysql.user` system table. The account row reflects the properties specified in the statement. Unspecified properties are set to their default values:

- **Authentication**: The default authentication plugin (determined as described in The Default Authentication Plugin), and empty credentials
- **Default role**: NONE
- **SSL/TLS**: NONE
- **Resource limits**: Unlimited
- **Password management**: PASSWORD EXPIRE DEFAULT PASSWORD HISTORY DEFAULT PASSWORD REUSE INTERVAL DEFAULT PASSWORD REQUIRE CURRENT DEFAULT; failed-login tracking and temporary account locking are disabled
- **Account locking**: ACCOUNT UNLOCK

An account when first created has no privileges and the default role NONE. To assign privileges or roles to this account, use one or more **GRANT** statements.

Each account name uses the format described in Section 8.2.4, “Specifying Account Names”. For example:

```sql
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
```

The host name part of the account name, if omitted, defaults to '%'. You should be aware that, while MySQL 8.4 treats grants made to such a user as though they had been granted to 'user'@'localhost', this behavior is deprecated, and thus subject to removal in a future version of MySQL.

Each `user` value naming an account may be followed by an optional `auth_option` value that indicates how the account authenticates. These values enable account authentication plugins and credentials (for example, a password) to be specified. Each `auth_option` value applies only to the account named immediately preceding it.

Following the `user` specifications, the statement may include options for SSL/TLS, resource-limit, password-management, and locking properties. All such options are **global** to the statement and apply to **all** accounts named in the statement.

Example: Create an account that uses the default authentication plugin and the given password. Mark the password expired so that the user must choose a new one at the first connection to the server:

```sql
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'new_password' PASSWORD EXPIRE;
```

Example: Create an account that uses the **caching_sha2_password** authentication plugin and the given password. Require that a new password be chosen every 180 days, and enable failed-login tracking, such that three consecutive incorrect passwords cause temporary account locking for two days:
CREATE USER 'jeffrey'@'localhost' IDENTIFIED WITH caching_sha2_password BY 'new_password'
    PASSWORD EXPIRE INTERVAL 180 DAY
    FAILED_LOGIN_ATTEMPTS 3 PASSWORD_LOCK_TIME 2;

Example: Create multiple accounts, specifying some per-account properties and some global properties:

CREATE USER
    'jeffrey'@'localhost' IDENTIFIED WITH mysql_native_password BY 'new_password1',
    'jeanne'@'localhost' IDENTIFIED WITH caching_sha2_password BY 'new_password2'
    REQUIRE X509 WITH MAX_QUERIES_PER_HOUR 60
    PASSWORD HISTORY 5
    ACCOUNT LOCK;

Each auth_option value (IDENTIFIED WITH ... BY in this case) applies only to the account
named immediately preceding it, so each account uses the immediately following authentication plugin
and password.

The remaining properties apply globally to all accounts named in the statement, so for both accounts:

• Connections must be made using a valid X.509 certificate.
• Up to 60 queries per hour are permitted.
• Password changes cannot reuse any of the five most recent passwords.
• The account is locked initially, so effectively it is a placeholder and cannot be used until an
  administrator unlocks it.

CREATE USER Authentication Options

An account name may be followed by an auth_option authentication option that specifies the
account authentication plugin, credentials, or both.

Note
MySQL 8.4 supports multifactor authentication (MFA), such that accounts
can have up to three authentication methods. That is, accounts can use two-
factor authentication (2FA) or three-factor authentication (3FA). The syntax and
semantics of auth_option remain unchanged, but auth_option may be
followed by specifications for additional authentication methods. This section
describes auth_option. For details about the optional MFA-related following
clauses, see CREATE USER Multifactor Authentication Options.

Note
Clauses for random password generation apply only to accounts that use an
authentication plugin that stores credentials internally to MySQL. For accounts
that use a plugin that performs authentication against a credentials system
that is external to MySQL, password management must be handled externally
against that system as well. For more information about internal credentials
storage, see Section 8.2.15, “Password Management”.

• auth_plugin names an authentication plugin. The plugin name can be a quoted string literal or an
  unquoted name. Plugin names are stored in the plugin column of the mysql.user system table.

  For auth_option syntax that does not specify an authentication plugin, the server assigns the
default plugin, determined as described in The Default Authentication Plugin. For descriptions of
each plugin, see Section 8.4.1, “Authentication Plugins”.

• Credentials that are stored internally are stored in the mysql.user system table. An
auth_string value or RANDOM PASSWORD specifies account credentials, either as a cleartext
(unencrypted) string or hashed in the format expected by the authentication plugin associated with
the account, respectively:

- For syntax that uses BY 'auth_string', the string is cleartext and is passed to the
  authentication plugin for possible hashing. The result returned by the plugin is stored in the
  mysql.user table. A plugin may use the value as specified, in which case no hashing occurs.

- For syntax that uses BY RANDOM PASSWORD, MySQL generates a random password and as
  cleartext and passes it to the authentication plugin for possible hashing. The result returned by
  the plugin is stored in the mysql.user table. A plugin may use the value as specified, in which case
  no hashing occurs.

Randomly generated passwords have the characteristics described in Random Password
Generation.

- For syntax that uses AS 'auth_string', the string is assumed to be already in the format the
  authentication plugin requires, and is stored as is in the mysql.user table. If a plugin requires a
  hashed value, the value must be already hashed in a format appropriate for the plugin; otherwise,
  the value cannot be used by the plugin and correct authentication of client connections does not
  occur.

A hashed string can be either a string literal or a hexadecimal value. The latter corresponds to
the type of value displayed by SHOW CREATE USER for password hashes containing unprintable
characters when the print_identified_with_as_hex system variable is enabled.

Important
Although we show 'auth_string' with quotation marks, a hexadecimal
value used for this purpose must not be quoted.

- If an authentication plugin performs no hashing of the authentication string, the BY
  'auth_string' and AS 'auth_string' clauses have the same effect: The authentication
  string is stored as is in the mysql.user system table.

CREATE USER permits these auth_option syntaxes:

- IDENTIFIED BY 'auth_string'
  Sets the account authentication plugin to the default plugin, passes the cleartext 'auth_string'
  value to the plugin for possible hashing, and stores the result in the account row in the
  mysql.user system table.

- IDENTIFIED BY RANDOM PASSWORD
  Sets the account authentication plugin to the default plugin, generates a random password, passes
  the cleartext password value to the plugin for possible hashing, and stores the result in the account
  row in the mysql.user system table. The statement also returns the cleartext password in a result
  set to make it available to the user or application executing the statement. For details about the result
  set and characteristics of randomly generated passwords, see Random Password Generation.

- IDENTIFIED WITH auth_plugin
  Sets the account authentication plugin to auth_plugin, clears the credentials to the empty string,
  and stores the result in the account row in the mysql.user system table.

- IDENTIFIED WITH auth_plugin BY 'auth_string'
  Sets the account authentication plugin to auth_plugin, passes the cleartext 'auth_string'
  value to the plugin for possible hashing, and stores the result in the account row in the mysql.user
  system table.

- IDENTIFIED WITH auth_plugin BY RANDOM PASSWORD
Sets the account authentication plugin to `auth_plugin`, generates a random password, passes the cleartext password value to the plugin for possible hashing, and stores the result in the account row in the `mysql.user` system table. The statement also returns the cleartext password in a result set to make it available to the user or application executing the statement. For details about the result set and characteristics of randomly generated passwords, see Random Password Generation.

- **IDENTIFIED WITH `auth_plugin` AS `'auth_string'`**

  Sets the account authentication plugin to `auth_plugin` and stores the `'auth_string'` value as is in the `mysql.user` account row. If the plugin requires a hashed string, the string is assumed to be already hashed in the format the plugin requires.

Example: Specify the password as cleartext; the default plugin is used:

```
CREATE USER 'jeffrey'@'localhost'
   IDENTIFIED BY 'password';
```

Example: Specify the authentication plugin, along with a cleartext password value:

```
CREATE USER 'jeffrey'@'localhost'
   IDENTIFIED WITH mysql_native_password BY 'password';
```

In each case, the password value stored in the account row is the cleartext value `password` after it has been hashed by the authentication plugin associated with the account.

For additional information about setting passwords and authentication plugins, see Section 8.2.14, “Assigning Account Passwords”, and Section 8.2.17, “Pluggable Authentication”.

### CREATE USER Multifactor Authentication Options

The `auth_option` part of `CREATE USER` defines an authentication method for one-factor/single-factor authentication (1FA/SFA). `CREATE USER` also supports multifactor authentication (MFA), such that accounts can have up to three authentication methods. That is, accounts can use two-factor authentication (2FA) or three-factor authentication (3FA).

The `authentication_policy` system variable defines constraints for `CREATE USER` statements with multifactor authentication (MFA) clauses. For example, the `authentication_policy` setting controls the number of authentication factors that accounts may have, and for each factor, which authentication methods are permitted. See Configuring the Multifactor Authentication Policy.

For information about factor-specific rules that determine the default authentication plugin for authentication clauses that name no plugin, see The Default Authentication Plugin.

Following `auth_option`, there may appear different optional MFA clauses:

- **2fa_auth_option**: Specifies a factor 2 authentication method. The following example defines `caching_sha2_password` as the factor 1 authentication method, and `authentication_ldap_sasl` as the factor 2 authentication method.

  ```
  CREATE USER 'u1'@'localhost'
     IDENTIFIED WITH caching_sha2_password
     BY 'sha2_password'
     AND IDENTIFIED WITH authentication_ldap_sasl
     AS 'uid=u1_ldap,ou=People,dc=example,dc=com';
  ```

- **3fa_auth_option**: Following `2fa_auth_option`, there may appear a `3fa_auth_option` clause to specify a factor 3 authentication method. The following example defines `caching_sha2_password` as the factor 1 authentication method, `authentication_ldap_sasl` as the factor 2 authentication method, and `authentication_webauthn` as the factor 3 authentication method.

  ```
  CREATE USER 'u1'@'localhost'
     IDENTIFIED WITH caching_sha2_password
     BY 'sha2_password'
  ```
AND IDENTIFIED WITH authentication_ldap_sasl
AS 'uid=u1_ldap,ou=People,dc=example,dc=com'
AND IDENTIFIED WITH authentication_webauthn;

• **initial_auth_option**: Specifies an initial authentication method for configuring FIDO/FIDO2 passwordless authentication. As shown in the following, temporary authentication using either a generated random password or a user-specified *auth-string* is required to enable WebAuthn passwordless authentication.

    CREATE USER user
    IDENTIFIED WITH authentication_webauthn
    INITIAL AUTHENTICATION IDENTIFIED BY {RANDOM PASSWORD | *auth_string*};

For information about configuring passwordless authentication using WebAuthn pluggable authentication, See [WebAuthn Passwordless Authentication](#).

### CREATE USER Role Options

The **DEFAULT ROLE** clause defines which roles become active when the user connects to the server and authenticates, or when the user executes the `SET ROLE DEFAULT` statement during a session.

Each role name uses the format described in Section 8.2.5, “Specifying Role Names”. For example:

```
CREATE USER 'joe'@'10.0.0.1' DEFAULT ROLE administrator, developer;
```

The host name part of the role name, if omitted, defaults to '%'.

The **DEFAULT ROLE** clause permits a list of one or more comma-separated role names. These roles must exist at the time `CREATE USER` is executed; otherwise the statement raises an error (ER_USER_DOES_NOT_EXIST), and the user is not created.

### CREATE USER SSL/TLS Options

MySQL can check X.509 certificate attributes in addition to the usual authentication that is based on the user name and credentials. For background information on the use of SSL/TLS with MySQL, see Section 8.3, “Using Encrypted Connections”.

To specify SSL/TLS-related options for a MySQL account, use a `REQUIRE` clause that specifies one or more `tls_option` values.

Order of `REQUIRE` options does not matter, but no option can be specified twice. The `AND` keyword is optional between `REQUIRE` options.

`CREATE USER` permits these `tls_option` values:

- **NONE**
  Indicates that all accounts named by the statement have no SSL or X.509 requirements. Unencrypted connections are permitted if the user name and password are valid. Encrypted connections can be used, at the client’s option, if the client has the proper certificate and key files.

```
CREATE USER 'jeffrey'@'localhost' REQUIRE NONE;
```

Clients attempt to establish a secure connection by default. For clients that have `REQUIRE NONE`, the connection attempt falls back to an unencrypted connection if a secure connection cannot be established. To require an encrypted connection, a client need specify only the `--ssl-mode=REQUIRED` option; the connection attempt fails if a secure connection cannot be established.

**NONE** is the default if no SSL-related `REQUIRE` options are specified.

- **SSL**
  Tells the server to permit only encrypted connections for all accounts named by the statement.

```
CREATE USER 'jeffrey'@'localhost' REQUIRE SSL;
```
Clients attempt to establish a secure connection by default. For accounts that have `REQUIRE SSL`, the connection attempt fails if a secure connection cannot be established.

- **X509**

  For all accounts named by the statement, requires that clients present a valid certificate, but the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates. Use of X.509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

  ```sql
  CREATE USER 'jeffrey'@'localhost' REQUIRE X509;
  ```

  For accounts with `REQUIRE X509`, clients must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.) This is true for `ISSUER` and `SUBJECT` as well because those `REQUIRE` options imply the requirements of `X509`.

- **ISSUER 'issuer'**

  For all accounts named by the statement, requires that clients present a valid X.509 certificate issued by CA 'issuer'. If a client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X.509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

  ```sql
  CREATE USER 'jeffrey'@'localhost' REQUIRE ISSUER '/C=SE/ST=Stockholm/L=Stockholm/CN=CA/emailAddress=ca@example.com';
  ```

  Because `ISSUER` implies the requirements of `X509`, clients must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.)

- **SUBJECT 'subject'**

  For all accounts named by the statement, requires that clients present a valid X.509 certificate containing the subject `subject`. If a client presents a certificate that is valid but has a different subject, the server rejects the connection. Use of X.509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

  ```sql
  CREATE USER 'jeffrey'@'localhost' REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/CN=client/emailAddress=client@example.com';
  ```

  MySQL does a simple string comparison of the `subject` value to the value in the certificate, so lettercase and component ordering must be given exactly as present in the certificate.

  Because `SUBJECT` implies the requirements of `X509`, clients must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.)

- **CIPHER 'cipher'**

  For all accounts named by the statement, requires a specific cipher method for encrypting connections. This option is needed to ensure that ciphers and key lengths of sufficient strength are used. Encryption can be weak if old algorithms using short encryption keys are used.

  ```sql
  CREATE USER 'jeffrey'@'localhost' REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';
  ```

  The `SUBJECT`, `ISSUER`, and `CIPHER` options can be combined in the `REQUIRE` clause:

  ```sql
  CREATE USER 'jeffrey'@'localhost'
  ```
CREATE USER Resource-Limit Options

It is possible to place limits on use of server resources by an account, as discussed in Section 8.2.21, "Setting Account Resource Limits". To do so, use a WITH clause that specifies one or more `resource_option` values.

Order of WITH options does not matter, except that if a given resource limit is specified multiple times, the last instance takes precedence.

CREATE USER permits these `resource_option` values:

• `MAX_QUERIES_PER_HOUR count`, `MAX_UPDATES_PER_HOUR count`, `MAX_CONNECTIONS_PER_HOUR count`

For all accounts named by the statement, these options restrict how many queries, updates, and connections to the server are permitted to each account during any given one-hour period. If `count` is 0 (the default), this means that there is no limitation for the account.

• `MAX_USER_CONNECTIONS count`

For all accounts named by the statement, restricts the maximum number of simultaneous connections to the server by each account. A nonzero `count` specifies the limit for the account explicitly. If `count` is 0 (the default), the server determines the number of simultaneous connections for the account from the global value of the `max_user_connections` system variable. If `max_user_connections` is also zero, there is no limit for the account.

Example:

```sql
CREATE USER 'jeffrey'@'localhost'
  WITH MAX_QUERIES_PER_HOUR 500 MAX_UPDATES_PER_HOUR 100;
```

CREATE USER Password-Management Options

CREATE USER supports several `password_option` values for password management:

• Password expiration options: You can expire an account password manually and establish its password expiration policy. Policy options do not expire the password. Instead, they determine how the server applies automatic expiration to the account based on password age, which is assessed from the date and time of the most recent account password change.

• Password reuse options: You can restrict password reuse based on number of password changes, time elapsed, or both.

• Password verification-required options: You can indicate whether attempts to change an account password must specify the current password, as verification that the user attempting to make the change actually knows the current password.

• Incorrect-password failed-login tracking options: You can cause the server to track failed login attempts and temporarily lock accounts for which too many consecutive incorrect passwords are given. The required number of failures and the lock time are configurable.

This section describes the syntax for password-management options. For information about establishing policy for password management, see Section 8.2.15, "Password Management".

If multiple password-management options of a given type are specified, the last one takes precedence. For example, `PASSWORD EXPIRE DEFAULT PASSWORD EXPIRE NEVER` is the same as `PASSWORD EXPIRE NEVER`. 
Note

Except for the options that pertain to failed-login tracking, password-management options apply only to accounts that use an authentication plugin that stores credentials internally to MySQL. For accounts that use a plugin that performs authentication against a credentials system that is external to MySQL, password management must be handled externally against that system as well. For more information about internal credentials storage, see Section 8.2.15, “Password Management”.

A client has an expired password if the account password was expired manually or the password age is considered greater than its permitted lifetime per the automatic expiration policy. In this case, the server either disconnects the client or restricts the operations permitted to it (see Section 8.2.16, “Server Handling of Expired Passwords”). Operations performed by a restricted client result in an error until the user establishes a new account password.

CREATE USER permits these password_option values for controlling password expiration:

- **PASSWORD EXPIRE**
  
  Immediately marks the password expired for all accounts named by the statement.
  
  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE;
  ```

- **PASSWORD EXPIRE DEFAULT**
  
  Sets all accounts named by the statement so that the global expiration policy applies, as specified by the default_password_lifetime system variable.
  
  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
  ```

- **PASSWORD EXPIRE NEVER**
  
  This expiration option overrides the global policy for all accounts named by the statement. For each, it disables password expiration so that the password never expires.
  
  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
  ```

- **PASSWORD EXPIRE INTERVAL N DAY**
  
  This expiration option overrides the global policy for all accounts named by the statement. For each, it sets the password lifetime to \( N \) days. The following statement requires the password to be changed every 180 days:
  
  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 180 DAY;
  ```

CREATE USER permits these password_option values for controlling reuse of previous passwords based on required minimum number of password changes:

- **PASSWORD HISTORY DEFAULT**
  
  Sets all accounts named by the statement so that the global policy about password history length applies, to prohibit reuse of passwords before the number of changes specified by the password_history system variable.
  
  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD HISTORY DEFAULT;
  ```

- **PASSWORD HISTORY N**
  
  This history-length option overrides the global policy for all accounts named by the statement. For each, it sets the password history length to \( N \) passwords, to prohibit reusing any of the \( N \) most recently chosen passwords. The following statement prohibits reuse of any of the previous 6 passwords:
  
  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD HISTORY 6;
  ```
CREATE USER 'jeffrey'@'localhost' PASSWORD HISTORY 6;

CREATE USER permits these `password_option` values for controlling reuse of previous passwords based on time elapsed:

- **PASSWORD REUSE INTERVAL DEFAULT**

  Sets all statements named by the account so that the global policy about time elapsed applies, to prohibit reuse of passwords newer than the number of days specified by the `password_reuse_interval` system variable.

  CREATE USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL DEFAULT;

- **PASSWORD REUSE INTERVAL N DAY**

  This time-elapsed option overrides the global policy for all accounts named by the statement. For each, it sets the password reuse interval to `N` days, to prohibit reuse of passwords newer than that many days. The following statement prohibits password reuse for 360 days:

  CREATE USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL 360 DAY;

CREATE USER permits these `password_option` values for controlling whether attempts to change an account password must specify the current password, as verification that the user attempting to make the change actually knows the current password:

- **PASSWORD REQUIRE CURRENT**

  This verification option overrides the global policy for all accounts named by the statement. For each, it requires that password changes specify the current password.

  CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT;

- **PASSWORD REQUIRE CURRENT OPTIONAL**

  This verification option overrides the global policy for all accounts named by the statement. For each, it does not require that password changes specify the current password. (The current password may but need not be given.)

  CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT OPTIONAL;

- **PASSWORD REQUIRE CURRENT DEFAULT**

  Sets all statements named by the account so that the global policy about password verification applies, as specified by the `password_require_current` system variable.

  CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT DEFAULT;

CREATE USER permits these `password_option` values for controlling failed-login tracking:

- **FAILED_LOGIN_ATTEMPTS N**

  Whether to track account login attempts that specify an incorrect password. `N` must be a number from 0 to 32767. A value of 0 disables failed-login tracking. Values greater than 0 indicate how many consecutive password failures cause temporary account locking (if `PASSWORD_LOCK_TIME` is also nonzero).

- **PASSWORD_LOCK_TIME {N | UNBOUNDED}**

  How long to lock the account after too many consecutive login attempts provide an incorrect password. `N` must be a number from 0 to 32767, or `UNBOUNDED`. A value of 0 disables temporary account locking. Values greater than 0 indicate how long to lock the account in days. A value of `UNBOUNDED` causes the account locking duration to be unbounded; once locked, the account...
remains in a locked state until unlocked. For information about the conditions under which unlocking occurs, see Failed-Login Tracking and Temporary Account Locking.

For failed-login tracking and temporary locking to occur, an account’s `FAILED.LOGIN_ATTEMPTS` and `PASSWORD_LOCK_TIME` options both must be nonzero. The following statement creates an account that remains locked for two days after four consecutive password failures:

```sql
CREATE USER 'jeffrey'@'localhost'
FAILED_LOGIN_ATTEMPTS 4 PASSWORD_LOCK_TIME 2;
```

### CREATE USER Comment and Attribute Options

You can also include an optional comment or attribute when creating a user, as described here:

- **User comment**

To set a user comment, add `COMMENT 'user_comment'` to the `CREATE USER` statement, where `user_comment` is the text of the user comment.

Example (omitting any other options):

```sql
CREATE USER 'jon'@'localhost' COMMENT 'Some information about Jon';
```

- **User attribute**

A user attribute is a JSON object made up of one or more key-value pairs, and is set by including `ATTRIBUTE 'json_object'` as part of `CREATE USER`. `json_object` must be a valid JSON object.

Example (omitting any other options):

```sql
CREATE USER 'jim'@'localhost'
ATTRIBUTE '{"fname": "James", "lname": "Scott", "phone": "123-456-7890"}';
```

User comments and user attributes are stored together in the `ATTRIBUTE` column of the Information Schema `USER_ATTRIBUTES` table. This query displays the row in this table inserted by the statement just shown for creating the user `jim@localhost`:

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
WHERE USER = 'jim' AND HOST = 'localhost';
```

```plaintext
+------+-----------+-------------------------------------------+
<table>
<thead>
<tr>
<th>USER</th>
<th>HOST</th>
<th>ATTRIBUTE</th>
</tr>
</thead>
<tbody>
<tr>
<td>jim</td>
<td>localhost</td>
<td>{&quot;comment&quot;: &quot;Some information about Jon&quot;}</td>
</tr>
</tbody>
</table>
+------+-----------+-------------------------------------------+
1 row in set (0.00 sec)
```

The `COMMENT` option in actuality provides a shortcut for setting a user attribute whose only element has `comment` as its key and whose value is the argument supplied for the option. You can see this by executing the statement `CREATE USER 'jon'@'localhost' COMMENT 'Some information about Jon'`, and observing the row which it inserts into the `USER_ATTRIBUTES` table:

```sql
mysql> CREATE USER 'jon'@'localhost' COMMENT 'Some information about Jon';
Query OK, 0 rows affected (0.06 sec)
```

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.USER_ATTRIBUTES WHERE USER = 'jon' AND HOST = 'localhost';
```

```plaintext
<table>
<thead>
<tr>
<th>USER</th>
<th>HOST</th>
<th>ATTRIBUTE</th>
</tr>
</thead>
<tbody>
<tr>
<td>jon</td>
<td>localhost</td>
<td>{&quot;comment&quot;: &quot;Some information about Jon&quot;}</td>
</tr>
</tbody>
</table>
+------+-----------+-----------------------------------------------+
1 row in set (0.00 sec)
```

You cannot use `COMMENT` and `ATTRIBUTE` together in the same `CREATE USER` statement; attempting to do so causes a syntax error. To set a user comment concurrently with setting a user attribute, use `ATTRIBUTE` and include in its argument a value with a `comment` key, like this:
Since the content of the `ATTRIBUTE` row is a JSON object, you can employ any appropriate MySQL JSON functions or operators to manipulate it, as shown here:

```sql
mysql> SELECT
    >    USER AS User,
    >    HOST AS Host,
    >    CONCAT(ATTRIBUTE->>'$.fname', ' ', ATTRIBUTE->>'$.lname') AS 'Full Name',
    >    ATTRIBUTE->>'$.comment' AS Comment
    > FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
    > WHERE USER='bill' AND HOST='localhost';
```

<table>
<thead>
<tr>
<th>User</th>
<th>Host</th>
<th>Full Name</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>bill</td>
<td>localhost</td>
<td>William Schmidt</td>
<td>Website developer</td>
</tr>
</tbody>
</table>

To set or to make changes in the user comment or user attribute for an existing user, you can use a `COMMENT` or `ATTRIBUTE` option with an `ALTER USER` statement.

Because the user comment and user attribute are stored together internally in a single JSON column, this sets an upper limit on their maximum combined size; see JSON Storage Requirements, for more information.

See also the description of the Information Schema `USER_ATTRIBUTES` table for more information and examples.

### CREATE USER Account-Locking Options

MySQL supports account locking and unlocking using the `ACCOUNT_LOCK` and `ACCOUNT_UNLOCK` options, which specify the locking state for an account. For additional discussion, see Section 8.2.20, “Account Locking”.

If multiple account-locking options are specified, the last one takes precedence.

### CREATE USER Binary Logging

`CREATE USER` is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named users. If the `IF NOT EXISTS` clause is given, this includes even users that already exist and were not created.

The statement written to the binary log specifies an authentication plugin for each user, determined as follows:

- The plugin named in the original statement, if one was specified.
- Otherwise, the default authentication plugin. In particular, if a user `u1` already exists and uses a nondefault authentication plugin, the statement written to the binary log for `CREATE USER IF NOT EXISTS u1` names the default authentication plugin. (If the statement written to the binary log must specify a nondefault authentication plugin for a user, include it in the original statement.)

If the server adds the default authentication plugin for any nonexisting users in the statement written to the binary log, it writes a warning to the error log naming those users.

If the original statement specifies the `FAILED_LOGIN_ATTEMPTS` or `PASSWORD_LOCK_TIME` option, the statement written to the binary log includes the option.

`CREATE USER` statements with clauses that support multifactor authentication (MFA) are written to the binary log.
Account Management Statements

• CREATE USER ... IDENTIFIED WITH .. INITIAL AUTHENTICATION IDENTIFIED WITH ... statements are written to the binary log as CREATE USER .. IDENTIFIED WITH .. INITIAL AUTHENTICATION IDENTIFIED WITH AS 'password-hash', where the password-hash is the user-specified auth-string or the random password generated by server when the RANDOM PASSWORD clause is specified.

15.7.1.4 DROP ROLE Statement

DROP ROLE [IF EXISTS] role [, role ] ...

DROP ROLE removes one or more roles (named collections of privileges). To use this statement, you must have the global DROP ROLE or CREATE USER privilege. When the read_only system variable is enabled, DROP ROLE additionally requires the CONNECTION_ADMIN privilege (or the deprecated SUPER privilege).

Users who have the CREATE USER privilege can use this statement to drop accounts that are locked or unlocked. Users who have the DROP ROLE privilege can use this statement only to drop accounts that are locked (unlocked accounts are presumably user accounts used to log in to the server and not just as roles).

Roles named in the mandatory_roles system variable value cannot be dropped.

DROP ROLE either succeeds for all named roles or rolls back and has no effect if any error occurs. By default, an error occurs if you try to drop a role that does not exist. If the IF EXISTS clause is given, the statement produces a warning for each named role that does not exist, rather than an error.

The statement is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named roles. If the IF EXISTS clause is given, this includes even roles that do not exist and were not dropped.

Each role name uses the format described in Section 8.2.5, “Specifying Role Names”. For example:

DROP ROLE 'admin', 'developer';
DROP ROLE 'webapp'@'localhost';

The host name part of the role name, if omitted, defaults to '%'.

A dropped role is automatically revoked from any user account (or role) to which the role was granted. Within any current session for such an account, its adjusted privileges apply beginning with the next statement executed.

For role usage examples, see Section 8.2.10, “Using Roles”.

15.7.1.5 DROP USER Statement

DROP USER [IF EXISTS] user [, user ] ...

The DROP USER statement removes one or more MySQL accounts and their privileges. It removes privilege rows for the account from all grant tables.

Roles named in the mandatory_roles system variable value cannot be dropped.

To use DROP USER, you must have the global CREATE USER privilege, or the DELETE privilege for the mysql system schema. When the read_only system variable is enabled, DROP USER additionally requires the CONNECTION_ADMIN privilege (or the deprecated SUPER privilege).

DROP USER fails with an error if any account to be dropped is named as the DEFINER attribute for any stored object. (That is, the statement fails if dropping an account would cause a stored object to become orphaned.) To perform the operation anyway, you must have the SET_ANY_DEFINER or ALLOW_NONEXISTENT_DEFINER privilege; in this case, the statement succeeds with a warning rather than failing with an error. For additional information, including how to identify which objects name a given account as the DEFINER attribute, see Orphan Stored Objects.
**DROP USER** either succeeds for all named users or rolls back and has no effect if any error occurs. By default, an error occurs if you try to drop a user that does not exist. If the **IF EXISTS** clause is given, the statement produces a warning for each named user that does not exist, rather than an error.

The statement is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named users. If the **IF EXISTS** clause is given, this includes even users that do not exist and were not dropped.

Each account name uses the format described in Section 8.2.4, “Specifying Account Names”. For example:

```
DROP USER 'jeffrey'@'localhost';
```

The host name part of the account name, if omitted, defaults to `'%'`.

**Important**

**DROP USER** does not automatically close any open user sessions. Rather, in the event that a user with an open session is dropped, the statement does not take effect until that user's session is closed. Once the session is closed, the user is dropped, and that user's next attempt to log in fails. *This is by design.*

**DROP USER** does not automatically drop or invalidate databases or objects within them that the old user created. This includes stored programs or views for which the **DEFINER** attribute names the dropped user. Attempts to access such objects may produce an error if they execute in definer security context. (For information about security context, see Section 27.6, “Stored Object Access Control”.)

### 15.7.1.6 GRANT Statement

```
GRANT priv_type [(column_list)]
    [, priv_type [(column_list)]] ... ON [object_type] priv_level
    TO user_or_role [, user_or_role] ...
    [WITH GRANT OPTION]
    [AS user]
    [WITH ROLE
        DEFAULT
        | NONE
        | ALL
        ALL EXCEPT role [, role ] ... | role [, role ] ...
    ]
}
```

```
GRANT PROXY ON user_or_role
    TO user_or_role [, user_or_role] ...
    [WITH GRANT OPTION]
```

```
GRANT role [, role] ...
    TO user_or_role [, user_or_role] ...
    [WITH ADMIN OPTION]
```

```
object_type: {
    TABLE |
    FUNCTION |
    PROCEDURE
}
```

```
priv_level: {
    *, *
    | db_name.*
    | db_name.tbl_name
    | tbl_name
    | db_name.routine_name
}
```
The `GRANT` statement assigns privileges and roles to MySQL user accounts and roles. There are several aspects to the `GRANT` statement, described under the following topics:

- **GRANT General Overview**
- **Object Quoting Guidelines**
- **Account Names**
- **Privileges Supported by MySQL**
- **Global Privileges**
- **Database Privileges**
- **Table Privileges**
- **Column Privileges**
- **Stored Routine Privileges**
- **Proxy User Privileges**
- **Granting Roles**
- **The AS Clause and Privilege Restrictions**
- **Other Account Characteristics**
- **MySQL and Standard SQL Versions of GRANT**

### GRANT General Overview

The `GRANT` statement enables system administrators to grant privileges and roles, which can be granted to user accounts and roles. These syntax restrictions apply:

- `GRANT` cannot mix granting both privileges and roles in the same statement. A given `GRANT` statement must grant either privileges or roles.

- The `ON` clause distinguishes whether the statement grants privileges or roles:
  - With `ON`, the statement grants privileges.
  - Without `ON`, the statement grants roles.

- It is permitted to assign both privileges and roles to an account, but you must use separate `GRANT` statements, each with syntax appropriate to what is to be granted.

For more information about roles, see Section 8.2.10, “Using Roles”.

To grant a privilege with `GRANT`, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are granting. (Alternatively, if you have the `UPDATE` privilege for the grant tables in the `mysql` system schema, you can grant any account any privilege.) When the `read_only` system variable is enabled, `GRANT` additionally requires the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege).

`GRANT` either succeeds for all named users and roles or rolls back and has no effect if any error occurs. The statement is written to the binary log only if it succeeds for all named users and roles.

The `REVOKE` statement is related to `GRANT` and enables administrators to remove account privileges. See Section 15.7.1.8, “REVOKE Statement”.

---

**user_or_role:**

```user_or_role: {
  user (see Section 8.2.4, “Specifying Account Names”)
  | role (see Section 8.2.5, “Specifying Role Names”)
}
```
Each account name uses the format described in Section 8.2.4, “Specifying Account Names”. Each role name uses the format described in Section 8.2.5, “Specifying Role Names”. For example:

```
GRANT ALL ON db1.* TO 'jeffrey'@'localhost';
GRANT 'role1', 'role2' TO 'user1'@'localhost', 'user2'@'localhost';
GRANT SELECT ON world.* TO 'role3';
```

The host name part of the account or role name, if omitted, defaults to '%'.

Normally, a database administrator first uses `CREATE USER` to create an account and define its nonprivilege characteristics such as its password, whether it uses secure connections, and limits on access to server resources, then uses `GRANT` to define its privileges. `ALTER USER` may be used to change the nonprivilege characteristics of existing accounts. For example:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
GRANT ALL ON db1.* TO 'jeffrey'@'localhost';
GRANT SELECT ON db2.invoice TO 'jeffrey'@'localhost';
ALTER USER 'jeffrey'@'localhost' WITH MAX_QUERIES_PER_HOUR 90;
```

From the `mysql` program, `GRANT` responds with `Query OK, 0 rows affected` when executed successfully. To determine what privileges result from the operation, use `SHOW GRANTS`. See Section 15.7.7.22, “SHOW GRANTS Statement”.

---

**Important**

Under some circumstances, `GRANT` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see Section 8.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 6.5.1.3, “mysql Client Logging”.

`GRANT` supports host names up to 255 characters long. User names can be up to 32 characters. Database, table, column, and routine names can be up to 64 characters.

---

**Warning**

*Do not attempt to change the permissible length for user names by altering the `mysql.user` system table. Doing so results in unpredictable behavior which may even make it impossible for users to log in to the MySQL server. Never alter the structure of tables in the `mysql` system schema in any manner except by means of the procedure described in Chapter 3, *Upgrading MySQL*. *

---

**Object Quoting Guidelines**

Several objects within `GRANT` statements are subject to quoting, although quoting is optional in many cases: Account, role, database, table, column, and routine names. For example, if a `user_name` or `host_name` value in an account name is legal as an unquoted identifier, you need not quote it. However, quotation marks are necessary to specify a `user_name` string containing special characters (such as `-`), or a `host_name` string containing special characters or wildcard characters such as `%` (for example, `test-user'@'%.com`). Quote the user name and host name separately.

To specify quoted values:

- Quote database, table, column, and routine names as identifiers.
- Quote user names and host names as identifiers or as strings.
- Quote passwords as strings.

For string-quoting and identifier-quoting guidelines, see Section 11.1.1, “String Literals”, and Section 11.2, “Schema Object Names”.

---

2773
Important

The use of the wildcard characters % and _ as described in the next few paragraphs is deprecated, and thus subject to removal in a future version of MySQL.

The _ and % wildcards are permitted when specifying database names in GRANT statements that grant privileges at the database level (GRANT ... ON `db_name`. *). This means, for example, that to use a _ character as part of a database name, specify it using the \ escape character as \\_ in the GRANT statement, to prevent the user from being able to access additional databases matching the wildcard pattern (for example, GRANT ... ON `foo\_bar`. * TO ...).

Issuing multiple GRANT statements containing wildcards may not have the expected effect on DML statements; when resolving grants involving wildcards, MySQL takes only the first matching grant into consideration. In other words, if a user has two database-level grants using wildcards that match the same database, the grant which was created first is applied. Consider the database db and table t created using the statements shown here:

```
CREATE DATABASE db;
Query OK, 1 row affected (0.01 sec)

CREATE TABLE db.t (c INT);
Query OK, 0 rows affected (0.01 sec)

INSERT INTO db.t VALUES ROW(1);
Query OK, 1 row affected (0.00 sec)
```

Next (assuming that the current account is the MySQL root account or another account having the necessary privileges), we create a user u then issue two GRANT statements containing wildcards, like this:

```
CREATE USER u;
Query OK, 0 rows affected (0.01 sec)

GRANT SELECT ON `d_`. * TO u;
Query OK, 0 rows affected (0.01 sec)

GRANT INSERT ON `d%`. * TO u;
Query OK, 0 rows affected (0.00 sec)
```

Bye

If we end the session and then log in again with the mysql client, this time as u, we see that this account has only the privilege provided by the first matching grant, but not the second:

```
mysql> SHOW TABLES IN db;
+---------+
<p>| |</p>
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
</tr>
<tr>
<td>-------</td>
</tr>
<tr>
<td>l</td>
</tr>
</tbody>
</table>
+---------+
1 row in set (0.00 sec)
```

mysql> create database db;
Query OK, 1 row affected (0.01 sec)

mysql> create table db.t (c int);
Query OK, 0 rows affected (0.01 sec)

mysql> insert into db.t values row(1);
Query OK, 1 row affected (0.00 sec)

Next (assuming that the current account is the MySQL root account or another account having the necessary privileges), we create a user u then issue two GRANT statements containing wildcards, like this:

```
create user u;
Query OK, 0 rows affected (0.01 sec)

grant select on `d_`.* to u;
Query OK, 0 rows affected (0.01 sec)

grant insert on `d%`.* to u;
Query OK, 0 rows affected (0.00 sec)
```

Bye

If we end the session and then log in again with the mysql client, this time as u, we see that this account has only the privilege provided by the first matching grant, but not the second:

```
mysql> show tables in db;
+---------+
<p>| |</p>
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
</tr>
<tr>
<td>-------</td>
</tr>
<tr>
<td>l</td>
</tr>
</tbody>
</table>
+---------+
1 row in set (0.00 sec)
```
mysql> INSERT INTO db.t VALUES ROW(2);
ERROR 1142 (42000): INSERT command denied to user 'u'@'localhost' for table 't'

In privilege assignments, MySQL interprets occurrences of unescaped _ and % SQL wildcard characters in database names as literal characters under these circumstances:

- When a database name is not used to grant privileges at the database level, but as a qualifier for granting privileges to some other object such as a table or routine (for example, GRANT ... ON `db_name`.`tbl_name`).
- Enabling `partial_revokes` causes MySQL to interpret unescaped _ and % wildcard characters in database names as literal characters, just as if they had been escaped as \_ and \%. Because this changes how MySQL interprets privileges, it may be advisable to avoid unescaped wildcard characters in privilege assignments for installations where `partial_revokes` may be enabled. For more information, see Section 8.2.12, “Privilege Restriction Using Partial Revokes”.

**Account Names**

A user value in a GRANT statement indicates a MySQL account to which the statement applies. To accommodate granting rights to users from arbitrary hosts, MySQL supports specifying the user value in the form `'user_name'@'host_name'`.

You can specify wildcards in the host name. For example, `'user_name'@'%.example.com'` applies to `user_name` for any host in the example.com domain, and `'user_name'@'198.51.100.%%'` applies to `user_name` for any host in the 198.51.100 class C subnet.

The simple form `'user_name'` is a synonym for `'user_name'@'%'`.

**Note**

MySQL automatically assigns all privileges granted to `'username'@'%'` to the `'username'@'localhost'` account as well. This behavior is deprecated, and is subject to removal in a future version of MySQL.

MySQL does not support wildcards in user names. To refer to an anonymous user, specify an account with an empty user name with the GRANT statement:

```sql
GRANT ALL ON test.* TO ''@'localhost' ...;
```

In this case, any user who connects from the local host with the correct password for the anonymous user is permitted access, with the privileges associated with the anonymous-user account.

For additional information about user name and host name values in account names, see Section 8.2.4, “Specifying Account Names”.

**Warning**

If you permit local anonymous users to connect to the MySQL server, you should also grant privileges to all local users as `'user_name'@'localhost'`. Otherwise, the anonymous user account for localhost in the `mysql.user` system table is used when named users try to log in to the MySQL server from the local machine. For details, see Section 8.2.6, “Access Control, Stage 1: Connection Verification”.

To determine whether this issue applies to you, execute the following query, which lists any anonymous users:

```sql
SELECT Host, User FROM mysql.user WHERE User='';
```

To avoid the problem just described, delete the local anonymous user account using this statement:

```sql
DROP USER ''@'localhost';
```
Privileges Supported by MySQL

The following tables summarize the permissible static and dynamic `priv_type` privilege types that can be specified for the `GRANT` and `REVOKE` statements, and the levels at which each privilege can be granted. For additional information about each privilege, see Section 8.2.2, “Privileges Provided by MySQL”. For information about the differences between static and dynamic privileges, see Static Versus Dynamic Privileges.

Table 15.11 Permissible Static Privileges for GRANT and REVOKE

<table>
<thead>
<tr>
<th>Privilege</th>
<th>Meaning and Grantable Levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL [PRIVILEGES]</td>
<td>Grant all privileges at specified access level except <code>GRANT OPTION</code> and <code>PROXY</code>.</td>
</tr>
<tr>
<td>ALTER</td>
<td>Enable use of <code>ALTER TABLE</code>. Levels: Global, database, table.</td>
</tr>
<tr>
<td>ALTER ROUTINE</td>
<td>Enable stored routines to be altered or dropped. Levels: Global, database, routine.</td>
</tr>
<tr>
<td>CREATE</td>
<td>Enable database and table creation. Levels: Global, database, table.</td>
</tr>
<tr>
<td>CREATE ROLE</td>
<td>Enable role creation. Level: Global.</td>

</tr>
<tr>
<td>SYSTEM_USER</td>
<td>Designate account as system account. Level: Global.</td>
</tr>
<tr>
<td>SYSTEM_VARIABLES_ADMIN</td>
<td>Enable modifying or persisting global system variables. Level: Global.</td>
</tr>
<tr>
<td>TABLE_ENCRYPTION_ADMIN</td>
<td>Enable overriding default encryption settings. Level: Global.</td>
</tr>
</tbody>
</table>
Privilege | Meaning and Grantable Levels
--- | ---
TELEMETRY\_LOG\_ADMIN | Enable telemetry log configuration for HeatWave on AWS. Level: Global.
TP\_CONNECTION\_ADMIN | Enable thread pool connection administration. Level: Global.
VERSION\_TOKEN\_ADMIN | Enable use of Version Tokens functions. Level: Global.
XA\_RECOVER\_ADMIN | Enable XA RECOVER execution. Level: Global.

A trigger is associated with a table. To create or drop a trigger, you must have the TRIGGER privilege for the table, not the trigger.

In GRANT statements, the ALL \{PRIVILEGES\} or PROXY privilege must be named by itself and cannot be specified along with other privileges. ALL \{PRIVILEGES\} stands for all privileges available for the level at which privileges are to be granted except for the GRANT OPTION and PROXY privileges.

MySQL account information is stored in the tables of the mysql system schema. For additional details, consult Section 8.2, “Access Control and Account Management”, which discusses the mysql system schema and the access control system extensively.

If the grant tables hold privilege rows that contain mixed-case database or table names and the lower\_case\_table\_names system variable is set to a nonzero value, REVOKE cannot be used to revoke these privileges. It is necessary in such cases to manipulate the grant tables directly. (GRANT does not create such rows when lower\_case\_table\_names is set, but such rows might have been created prior to setting that variable. The lower\_case\_table\_names setting can only be configured at server startup.)

Privileges can be granted at several levels, depending on the syntax used for the ON clause. For REVOKE, the same ON syntax specifies which privileges to remove.

For the global, database, table, and routine levels, GRANT ALL assigns only the privileges that exist at the level you are granting. For example, GRANT ALL ON db\_name.* is a database-level statement, so it does not grant any global-only privileges such as FILE. Granting ALL does not assign the GRANT OPTION or PROXY privilege.

The object\_type Clause, if present, should be specified as TABLE, FUNCTION, or PROCEDURE when the following object is a table, a stored function, or a stored procedure.

The privileges that a user holds for a database, table, column, or routine are formed additively as the logical OR of the account privileges at each of the privilege levels, including the global level. It is not possible to deny a privilege granted at a higher level by absence of that privilege at a lower level. For example, this statement grants the SELECT and INSERT privileges globally:

```sql
GRANT SELECT, INSERT ON *.* TO u1;
```

The globally granted privileges apply to all databases, tables, and columns, even though not granted at any of those lower levels.

It is possible to deny explicitly a privilege granted at the global level by revoking it for particular databases, if the partial\_revokes system variable is enabled:

```sql
GRANT SELECT, INSERT, UPDATE ON *.* TO u1;
REVOKE INSERT, UPDATE ON db1.* FROM u1;
```

The result of the preceding statements is that SELECT applies globally to all tables, whereas INSERT and UPDATE apply globally except to tables in db1. Account access to db1 is read only.

Details of the privilege-checking procedure are presented in Section 8.2.7, “Access Control, Stage 2: Request Verification”.

2779
If you are using table, column, or routine privileges for even one user, the server examines table, column, and routine privileges for all users and this slows down MySQL a bit. Similarly, if you limit the number of queries, updates, or connections for any users, the server must monitor these values.

MySQL enables you to grant privileges on databases or tables that do not exist. For tables, the privileges to be granted must include the **CREATE** privilege. *This behavior is by design*, and is intended to enable the database administrator to prepare user accounts and privileges for databases or tables that are to be created at a later time.

**Important**

MySQL does not automatically revoke any privileges when you drop a database or table. However, if you drop a routine, any routine-level privileges granted for that routine are revoked.

**Global Privileges**

Global privileges are administrative or apply to all databases on a given server. To assign global privileges, use **ON *.*** syntax:

```sql
GRANT ALL ON *.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON *.* TO 'someuser'@'somehost';
```

The **CREATE TABLESPACE**, **CREATE USER**, **FILE**, **PROCESS**, **RELOAD**, **REPLICATION CLIENT**, **REPLICATION SLAVE**, **SHOW DATABASES**, **SHUTDOWN**, and **SUPER** static privileges are administrative and can only be granted globally.

Dynamic privileges are all global and can only be granted globally.

Other privileges can be granted globally or at more specific levels.

The effect of **GRANT OPTION** granted at the global level differs for static and dynamic privileges:

- **GRANT OPTION** granted for any static global privilege applies to all static global privileges.
- **GRANT OPTION** granted for any dynamic privilege applies only to that dynamic privilege.

**GRANT ALL** at the global level grants all static global privileges and all currently registered dynamic privileges. A dynamic privilege registered subsequent to execution of the **GRANT** statement is not granted retroactively to any account.

MySQL stores global privileges in the **mysql.user** system table.

**Database Privileges**

Database privileges apply to all objects in a given database. To assign database-level privileges, use **ON db_name.*** syntax:

```sql
GRANT ALL ON mydb.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.* TO 'someuser'@'somehost';
```

If you use **ON * syntax** (rather than **ON *.*)), privileges are assigned at the database level for the default database. An error occurs if there is no default database.

The **CREATE**, **DROP**, **EVENT**, **GRANT OPTION**, **LOCK TABLES**, and **REFERENCES** privileges can be specified at the database level. Table or routine privileges also can be specified at the database level, in which case they apply to all tables or routines in the database.

MySQL stores database privileges in the **mysql.db** system table.

**Table Privileges**

Table privileges apply to all columns in a given table. To assign table-level privileges, use **ON db_name.tbl_name** syntax:
 Account Management Statements

GRANT ALL ON mydb.mytbl TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.mytbl TO 'someuser'@'somehost';

If you specify `tbl_name` rather than `db_name.tbl_name`, the statement applies to `tbl_name` in the default database. An error occurs if there is no default database.

The permissible `priv_type` values at the table level are `ALTER`, `CREATE VIEW`, `CREATE`, `DELETE`, `DROP`, `GRANT OPTION`, `INDEX`, `INSERT`, `REFERENCES`, `SELECT`, `SHOW VIEW`, `TRIGGER`, and `UPDATE`.

Table-level privileges apply to base tables and views. They do not apply to tables created with `CREATE TEMPORARY TABLE`, even if the table names match. For information about `TEMPORARY` table privileges, see Section 15.1.20.2, “CREATE TEMPORARY TABLE Statement”.

MySQL stores table privileges in the `mysql.tables_priv` system table.

Column Privileges

Column privileges apply to single columns in a given table. Each privilege to be granted at the column level must be followed by the column or columns, enclosed within parentheses.

GRANT SELECT (col1), INSERT (col1, col2) ON mydb.mytbl TO 'someuser'@'somehost';

The permissible `priv_type` values for a column (that is, when you use a `column_list` clause) are `INSERT`, `REFERENCES`, `SELECT`, and `UPDATE`.

MySQL stores column privileges in the `mysql.columns_priv` system table.

Stored Routine Privileges

The `ALTER ROUTINE`, `CREATE ROUTINE`, `EXECUTE`, and `GRANT OPTION` privileges apply to stored routines (procedures and functions). They can be granted at the global and database levels. Except for `CREATE ROUTINE`, these privileges can be granted at the routine level for individual routines.

GRANT CREATE ROUTINE ON mydb.* TO 'someuser'@'somehost';
GRANT EXECUTE ON PROCEDURE mydb.myproc TO 'someuser'@'somehost';

The permissible `priv_type` values at the routine level are `ALTER ROUTINE`, `EXECUTE`, and `GRANT OPTION`. `CREATE ROUTINE` is not a routine-level privilege because you must have the privilege at the global or database level to create a routine in the first place.

MySQL stores routine-level privileges in the `mysql.procs_priv` system table.

Proxy User Privileges

The `PROXY` privilege enables one user to be a proxy for another. The proxy user impersonates or takes the identity of the proxied user; that is, it assumes the privileges of the proxied user.

GRANT PROXY ON 'localuser'@'localhost' TO 'externaluser'@'somehost';

When `PROXY` is granted, it must be the only privilege named in the `GRANT` statement, and the only permitted `WITH` option is `WITH GRANT OPTION`.

Proxying requires that the proxy user authenticate through a plugin that returns the name of the proxied user to the server when the proxy user connects, and that the proxy user have the `PROXY` privilege for the proxied user. For details and examples, see Section 8.2.19, “Proxy Users”.

MySQL stores proxy privileges in the `mysql.proxies_priv` system table.

Granting Roles

`GRANT` syntax without an `ON` clause grants roles rather than individual privileges. A role is a named collection of privileges; see Section 8.2.10, “Using Roles”. For example:
GRANT 'role1', 'role2' TO 'user1'@'localhost', 'user2'@'localhost';

Each role to be granted must exist, as well as each user account or role to which it is to be granted. Roles cannot be granted to anonymous users.

Granting a role does not automatically cause the role to be active. For information about role activation and inactivation, see Activating Roles.

These privileges are required to grant roles:

- If you have the ROLE_ADMIN privilege (or the deprecated SUPER privilege), you can grant or revoke any role to users or roles.

- If you were granted a role with a GRANT statement that includes the WITH ADMIN OPTION clause, you become able to grant that role to other users or roles, or revoke it from other users or roles, as long as the role is active at such time as you subsequently grant or revoke it. This includes the ability to use WITH ADMIN OPTION itself.

- To grant a role that has the SYSTEM_USER privilege, you must have the SYSTEM_USER privilege.

It is possible to create circular references with GRANT. For example:

CREATE USER 'u1', 'u2';
CREATE ROLE 'r1', 'r2';
GRANT 'u1' TO 'u1';  -- simple loop: u1 => u1
GRANT 'r1' TO 'r1';  -- simple loop: r1 => r1
GRANT 'r2' TO 'u2';
GRANT 'u2' TO 'r2';  -- mixed user/role loop: u2 => r2 => u2

Circular grant references are permitted but add no new privileges or roles to the grantee because a user or role already has its privileges and roles.

The AS Clause and Privilege Restrictions

GRANT can specify additional information about the privilege context to use for statement execution by using an AS user [WITH ROLE] clause. This syntax is visible at the SQL level, although its primary purpose is to enable uniform replication across all nodes of grantor privilege restrictions imposed by partial revokes, by causing those restrictions to appear in the binary log. For information about partial revokes, see Section 8.2.12, “Privilege Restriction Using Partial Revokes”.

When the AS user clause is specified, statement execution takes into account any privilege restrictions associated with the named user, including all roles specified by WITH ROLE, if present. The result is that the privileges actually granted by the statement may be reduced relative to those specified.

These conditions apply to the AS user clause:

- **AS** has an effect only when the named user has privilege restrictions (which implies that the partial_revokes system variable is enabled).

- If WITH ROLE is given, all roles named must be granted to the named user.

- The named user should be a MySQL account specified as 'user_name'@'host_name', CURRENT_USER, or CURRENT_USER(). The current user may be named together with WITH ROLE for the case that the executing user wants GRANT to execute with a set of roles applied that may differ from the roles active within the current session.

- **AS** cannot be used to gain privileges not possessed by the user who executes the GRANT statement. The executing user must have at least the privileges to be granted, but the **AS** clause can only restrict the privileges granted, not escalate them.
Account Management Statements

- With respect to the privileges to be granted, `AS` cannot specify a user/role combination that has more privileges (fewer restrictions) than the user who executes the `GRANT` statement. The `AS` user/role combination is permitted to have more privileges than the executing user, but only if the statement does not grant those additional privileges.

- `AS` is supported only for granting global privileges (`ON *.*`).

- `AS` is not supported for `PROXY` grants.

The following example illustrates the effect of the `AS` clause. Create a user `u1` that has some global privileges, as well as restrictions on those privileges:

```sql
CREATE USER u1;
GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO u1;
REVOKE INSERT, UPDATE ON schema1.* FROM u1;
REVOKE SELECT ON schema2.* FROM u1;
```

Also create a role `r1` that lifts some of the privilege restrictions and grant the role to `u1`:

```sql
CREATE ROLE r1;
GRANT INSERT ON schema1.* TO r1;
GRANT SELECT ON schema2.* TO r1;
GRANT r1 TO u1;
```

Now, using an account that has no privilege restrictions of its own, grant to multiple users the same set of global privileges, but each with different restrictions imposed by the `AS` clause, and check which privileges are actually granted.

- The `GRANT` statement here has no `AS` clause, so the privileges granted are exactly those specified:

```sql
mysql> CREATE USER u2;
mysql> GRANT SELECT, INSERT, UPDATE ON *.* TO u2;
mysql> SHOW GRANTS FOR u2;
+-------------------------------------------------+
| Grants for u2@%                                 |
| GRANT SELECT, INSERT, UPDATE ON *.* TO `u2`@`%` |
+-------------------------------------------------+
```

- The `GRANT` statement here has an `AS` clause, so the privileges granted are those specified but with the restrictions from `u1` applied:

```sql
mysql> CREATE USER u3;
mysql> GRANT SELECT, INSERT, UPDATE ON *.* TO u3 AS u1;
mysql> SHOW GRANTS FOR u3;
+----------------------------------------------------+
| Grants for u3@%                                    |
| GRANT SELECT, INSERT, UPDATE ON *.* TO `u3`@`%`    |
| REVOKE INSERT, UPDATE ON `schema1`.* FROM `u3`@`%` |
| REVOKE SELECT ON `schema2`.* FROM `u3`@`%`         |
+----------------------------------------------------+
```

As mentioned previously, the `AS` clause can only add privilege restrictions; it cannot escalate privileges. Thus, although `u1` has the `DELETE` privilege, that is not included in the privileges granted because the statement does not specify granting `DELETE`.

- The `AS` clause for the `GRANT` statement here makes the role `r1` active for `u1`. That role lifts some of the restrictions on `u1`. Consequently, the privileges granted have some restrictions, but not so many as for the previous `GRANT` statement:

```sql
mysql> CREATE USER u4;
mysql> GRANT SELECT, INSERT, UPDATE ON *.* TO u4 AS u1 WITH ROLE r1;
mysql> SHOW GRANTS FOR u4;
+-------------------------------------------------+
| Grants for u4@%                                 |
+-------------------------------------------------+
```
If a `GRANT` statement includes an `AS` user clause, privilege restrictions on the user who executes the statement are ignored (rather than applied as they would be in the absence of an `AS` clause).

Other Account Characteristics

The optional `WITH` clause is used to enable a user to grant privileges to other users. The `WITH GRANT OPTION` clause gives the user the ability to give to other users any privileges the user has at the specified privilege level.

To grant the `GRANT OPTION` privilege to an account without otherwise changing its privileges, do this:

```
GRANT USAGE ON *.* TO 'someuser'@'somehost' WITH GRANT OPTION;
```

Be careful to whom you give the `GRANT OPTION` privilege because two users with different privileges may be able to combine privileges!

You cannot grant another user a privilege which you yourself do not have; the `GRANT OPTION` privilege enables you to assign only those privileges which you yourself possess.

Be aware that when you grant a user the `GRANT OPTION` privilege at a particular privilege level, any privileges the user possesses (or may be given in the future) at that level can also be granted by that user to other users. Suppose that you grant a user the `INSERT` privilege on a database. If you then grant the `SELECT` privilege on the database and specify `WITH GRANT OPTION`, that user can give to other users not only the `SELECT` privilege, but also `INSERT`. If you then grant the `UPDATE` privilege to the user on the database, the user can grant `INSERT`, `SELECT`, and `UPDATE`.

For a nonadministrative user, you should not grant the `ALTER` privilege globally or for the `mysql` system schema. If you do that, the user can try to subvert the privilege system by renaming tables!

For additional information about security risks associated with particular privileges, see Section 8.2.2, “Privileges Provided by MySQL”.

MySQL and Standard SQL Versions of GRANT

The biggest differences between the MySQL and standard SQL versions of `GRANT` are:

- MySQL associates privileges with the combination of a host name and user name and not with only a user name.
- Standard SQL does not have global or database-level privileges, nor does it support all the privilege types that MySQL supports.
- MySQL does not support the standard SQL `UNDER` privilege.
- Standard SQL privileges are structured in a hierarchical manner. If you remove a user, all privileges the user has been granted are revoked. This is also true in MySQL if you use `DROP USER`. See Section 15.7.1.5, “DROP USER Statement”.
- In standard SQL, when you drop a table, all privileges for the table are revoked. In standard SQL, when you revoke a privilege, all privileges that were granted based on that privilege are also revoked. In MySQL, privileges can be dropped with `DROP USER` or `REVOKE` statements.
- In MySQL, it is possible to have the `INSERT` privilege for only some of the columns in a table. In this case, you can still execute `INSERT` statements on the table, provided that you insert values only for those columns for which you have the `INSERT` privilege. The omitted columns are set to their implicit default values if strict SQL mode is not enabled. In strict mode, the statement is rejected if any of the omitted columns have no default value. (Standard SQL requires you to have the `INSERT` privilege on
all columns.) For information about strict SQL mode and implicit default values, see Section 7.1.11, “Server SQL Modes”, and Section 13.6, “Data Type Default Values”.

15.7.1.7 RENAME USER Statement

```
RENAME USER old_user TO new_user
 [, old_user TO new_user] ...
```

The `RENAME USER` statement renames existing MySQL accounts. An error occurs for old accounts that do not exist or new accounts that already exist.

To use `RENAME USER`, you must have the global `CREATE USER` privilege, or the `UPDATE` privilege for the `mysql` system schema. When the `read_only` system variable is enabled, `RENAME USER` additionally requires the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege).

`RENAME USER` fails with an error if any account to be renamed is named as the `DEFINER` attribute for any stored object. (That is, the statement fails if renaming an account would cause a stored object to become orphaned.) To perform the operation anyway, you must have the `SET_ANY_DEFINER` or `ALLOW_NONEXISTENT_DEFINER` privilege; in this case, the statement succeeds with a warning rather than failing with an error. For additional information, including how to identify which objects name a given account as the `DEFINER` attribute, see Orphan Stored Objects.

Each account name uses the format described in Section 8.2.4, “Specifying Account Names”. For example:

```
RENAME USER 'jeffrey'@'localhost' TO 'jeff'@'127.0.0.1';
```

The host name part of the account name, if omitted, defaults to ‘%’.

`RENAME USER` causes the privileges held by the old user to be those held by the new user. However, `RENAME USER` does not automatically drop or invalidate databases or objects within them that the old user created. This includes stored programs or views for which the `DEFINER` attribute names the old user. Attempts to access such objects may produce an error if they execute in definer security context. (For information about security context, see Section 27.6, “Stored Object Access Control”.)

The privilege changes take effect as indicated in Section 8.2.13, “When Privilege Changes Take Effect”.

15.7.1.8 REVOKE Statement

```
REVOKE [IF EXISTS]
 priv_type [(column_list)]
 [, priv_type [(column_list)]] ...
ON [object_type] priv_level
FROM user_or_role [, user_or_role] ...
[IGNORE UNKNOWN USER]

REVOKE [IF EXISTS] ALL [PRIVILEGES], GRANT OPTION
FROM user_or_role [, user_or_role] ...
[IGNORE UNKNOWN USER]

REVOKE [IF EXISTS] PROXY ON user_or_role
FROM user_or_role [, user_or_role] ...
[IGNORE UNKNOWN USER]

REVOKE [IF EXISTS] role [, role ] ...
FROM user_or_role [, user_or_role ] ...
[IGNORE UNKNOWN USER]
```

The `REVOKE` statement enables system administrators to revoke privileges and roles, which can be revoked from user accounts and roles.
Account Management Statements

For details on the levels at which privileges exist, the permissible `priv_type`, `priv_level`, and `object_type` values, and the syntax for specifying users and passwords, see Section 15.7.1.6, “GRANT Statement”.

For information about roles, see Section 8.2.10, “Using Roles”.

When the `read_only` system variable is enabled, `REVOKE` requires the `CONNECTION_ADMIN` or `privilege` (or the deprecated `SUPER` privilege), in addition to any other required privileges described in the following discussion.

All the forms shown for `REVOKE` support an `IF EXISTS` option as well as an `IGNORE UNKNOWN USER` option. With neither of these modifications, `REVOKE` either succeeds for all named users and roles, or rolls back and has no effect if any error occurs; the statement is written to the binary log only if it succeeds for all named users and roles. The precise effects of `IF EXISTS` and `IGNORE UNKNOWN USER` are discussed later in this section.

Each account name uses the format described in Section 8.2.4, “Specifying Account Names”. Each role name uses the format described in Section 8.2.5, “Specifying Role Names”. For example:

```
REVOKE INSERT ON *.* FROM 'jeffrey'@'localhost';
REVOKE 'role1', 'role2' FROM 'user1'@'localhost', 'user2'@'localhost';
REVOKE SELECT ON world.* FROM 'role3';
```

The host name part of the account or role name, if omitted, defaults to `'%'`.

To use the first `REVOKE` syntax, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are revoking.

To revoke all privileges, use the second syntax, which drops all global, database, table, column, and routine privileges for the named users or roles:

```
REVOKE ALL PRIVILEGES, GRANT OPTION
    FROM user_or_role [, user_or_role] ...  
```

`REVOKE ALL PRIVILEGES, GRANT OPTION` does not revoke any roles.

To use this `REVOKE` syntax, you must have the global `CREATE USER` privilege, or the `UPDATE` privilege for the `mysql` system schema.

The syntax for which the `REVOKE` keyword is followed by one or more role names takes a `FROM` clause indicating one or more users or roles from which to revoke the roles.

The `IF EXISTS` and `IGNORE UNKNOWN USER` options have the effects listed here:

- `IF EXISTS` means that, if the target user or role exists but no such privilege or role is found assigned to the target for any reason, a warning is raised, instead of an error; if no privilege or role named by the statement is assigned to the target, the statement has no (other) effect. Otherwise, `REVOKE` executes normally; if the user does not exist, the statement raises an error.

**Example:** Given table `t1` in database `test`, we execute the following statements, with the results shown.

```
mysql> CREATE USER jerry@localhost;
Query OK, 0 rows affected (0.01 sec)

mysql> REVOKE SELECT ON test.t1 FROM jerry@localhost;
ERROR 1147 (42000): There is no such grant defined for user 'jerry' on host 'localhost' on table 't1'

mysql> REVOKE IF EXISTS SELECT ON test.t1 FROM jerry@localhost;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Warning
Code: 1147

mysql>
```
Account Management Statements

Message: There is no such grant defined for user 'jerry' on host 'localhost' on table 't1'
1 row in set (0.00 sec)

**IF EXISTS** causes an error to be demoted to a warning even if the privilege or role named does not exist, or the statement attempts to assign it at the wrong level.

- If the **REVOKE** statement includes **IGNORE UNKNOWN USER**, the statement raises a warning for any target user or role named in the statement but not found; if no target named by the statement exists, **REVOKE** succeeds but has no actual effect. Otherwise, the statement executes as usual, and attempting to revoke a privilege not assigned to the target for whatever reason raises an error, as expected.

**Example** (continuing from the previous example):

```sql
mysql> DROP USER IF EXISTS jerry@localhost;
Query OK, 0 rows affected (0.01 sec)
mysql> REVOKE SELECT ON test.t1 FROM jerry@localhost;
ERROR 1147 (42000): There is no such grant defined for user 'jerry' on host 'localhost' on table 't1'
mysql> REVOKE SELECT ON test.t1 FROM jerry@localhost IGNORE UNKNOWN USER;
Query OK, 0 rows affected, 1 warning (0.01 sec)
mysql> SHOW WARNINGS
*************************** 1. row ***************************
<table>
<thead>
<tr>
<th>Level</th>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Warning</td>
<td>3162</td>
<td>Authorization ID jerry does not exist.</td>
</tr>
</tbody>
</table>
1 row in set (0.00 sec)
```

- The combination of **IF EXISTS** and **IGNORE UNKNOWN USER** means that **REVOKE** never raises an error for an unknown target user or role or for an unassigned or unavailable privilege, and the statement as whole in such cases succeeds; roles or privileges are removed from existing target users or roles whenever possible, and any revocation which is not possible raises a warning and executes as a **NOOP**.

**Example** (again continuing from example in the previous item):

```sql
# No such user, no such role
mysql> DROP ROLE IF EXISTS Bogus;
Query OK, 0 rows affected, 1 warning (0.02 sec)
mysql> SHOW WARNINGS;
+-------+------+----------------------------------------------+
<table>
<thead>
<tr>
<th>Level</th>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Note</td>
<td>3162</td>
<td>Authorization ID 'Bogus'@'%' does not exist.</td>
</tr>
</tbody>
</table>
+-------+------+----------------------------------------------+
1 row in set (0.00 sec)
```

# This statement attempts to revoke a nonexistent role from a nonexistent user
```sql
mysql> REVOKE Bogus ON test FROM jerry@localhost;
ERROR 3619 (HY000): Illegal privilege level specified for test
```

# The same, with IF EXISTS
```sql
mysql> REVOKE IF EXISTS Bogus ON test FROM jerry@localhost;
ERROR 1147 (42000): There is no such grant defined for user 'jerry' on host 'localhost' on table 'test'
```

# The same, with IGNORE UNKNOWN USER
```sql
mysql> REVOKE Bogus ON test FROM jerry@localhost IGNORE UNKNOWN USER;
ERROR 3619 (HY000): Illegal privilege level specified for test
```

# The same, with both options
```sql
mysql> REVOKE IF EXISTS Bogus ON test FROM jerry@localhost IGNORE UNKNOWN USER;
Query OK, 0 rows affected, 2 warnings (0.01 sec)
```
Roles named in the `mandatory_roles` system variable value cannot be revoked. When `IF EXISTS` and `IGNORE UNKNOWN USER` are used together in a statement that tries to remove a mandatory privilege, the error normally raised by attempting to do this is demoted to a warning; the statement executes successfully, but does not make any changes.

A revoked role immediately affects any user account from which it was revoked, such that within any current session for the account, its privileges are adjusted for the next statement executed.

Revoking a role revokes the role itself, not the privileges that it represents. Suppose that an account is granted a role that includes a given privilege, and is also granted the privilege explicitly or another role that includes the privilege. In this case, the account still possesses that privilege if the first role is revoked. For example, if an account is granted two roles that each include `SELECT`, the account still can select after either role is revoked.

`REVOKE ALL ON *.*` (at the global level) revokes all granted static global privileges and all granted dynamic privileges.

A revoked privilege that is granted but not known to the server is revoked with a warning. This situation can occur for dynamic privileges. For example, a dynamic privilege can be granted while the component that registers it is installed, but if that component is subsequently uninstalled, the privilege becomes unregistered, although accounts that possess the privilege still possess it and it can be revoked from them.

`REVOKE` removes privileges, but does not remove rows from the `mysql.user` system table. To remove a user account entirely, use `DROP USER`. See Section 15.7.1.5, “DROP USER Statement”.

If the grant tables hold privilege rows that contain mixed-case database or table names and the `lower_case_table_names` system variable is set to a nonzero value, `REVOKE` cannot be used to revoke these privileges. It is necessary in such cases to manipulate the grant tables directly. (GRANT does not create such rows when `lower_case_table_names` is set; but such rows might have been created prior to setting the variable. The `lower_case_table_names` setting can only be configured when initializing the server.)

When successfully executed from the `mysql` program, `REVOKE` responds with `Query OK, 0 rows affected`. To determine what privileges remain after the operation, use `SHOW GRANTS`. See Section 15.7.7.22, “SHOW GRANTS Statement”.

### 15.7.1.9 SET DEFAULT ROLE Statement

```sql
SET DEFAULT ROLE
    [NONE | ALL | role [, role ] ...]
TO user [, user ] ...
```

For each `user` named immediately after the `TO` keyword, this statement defines which roles become active when the user connects to the server and authenticates, or when the user executes the `SET ROLE DEFAULT` statement during a session.

`SET DEFAULT ROLE` is alternative syntax for `ALTER USER ... DEFAULT ROLE` (see Section 15.7.1.1, “ALTER USER Statement”). However, `ALTER USER` can set the default for only a single user, whereas `SET DEFAULT ROLE` can set the default for multiple users. On the other hand, you can specify `CURRENT_USER` as the user name for the `ALTER USER` statement, whereas you cannot for `SET DEFAULT ROLE`.

`SET DEFAULT ROLE` requires these privileges:
• Setting the default roles for another user requires the global CREATE USER privilege, or the UPDATE privilege for the mysql.default_roles system table.

• Setting the default roles for yourself requires no special privileges, as long as the roles you want as the default have been granted to you.

Each role name uses the format described in Section 8.2.5, “Specifying Role Names”. For example:

```
SET DEFAULT ROLE 'admin', 'developer' TO 'joe'@'10.0.0.1';
```

The host name part of the role name, if omitted, defaults to '%'.

The clause following the DEFAULT ROLE keywords permits these values:

- **NONE**: Set the default to NONE (no roles).
- **ALL**: Set the default to all roles granted to the account.
- **role [, role ] ...**: Set the default to the named roles, which must exist and be granted to the account at the time SET DEFAULT ROLE is executed.

**Note**

`SET DEFAULT ROLE` and `SET ROLE DEFAULT` are different statements:

- **SET DEFAULT ROLE** defines which account roles to activate by default within account sessions.
- **SET ROLE DEFAULT** sets the active roles within the current session to the current account default roles.

For role usage examples, see Section 8.2.10, “Using Roles”.

### 15.7.1.10 SET PASSWORD Statement

```
SET PASSWORD [FOR user] auth_option
[REPLACE 'current_auth_string']
[RETAIN CURRENT PASSWORD]
```

`auth_option`: {
  = 'auth_string'
  | TO RANDOM
}

The SET PASSWORD statement assigns a password to a MySQL user account. The password may be either explicitly specified in the statement or randomly generated by MySQL. The statement may also include a password-verification clause that specifies the account current password to be replaced, and a clause that manages whether an account has a secondary password. 'auth_string' and 'current_auth_string' each represent a cleartext (unencrypted) password.

**Note**

Rather than using SET PASSWORD to assign passwords, ALTER USER is the preferred statement for account alterations, including assigning passwords. For example:

```
ALTER USER user IDENTIFIED BY 'auth_string';
```

**Note**

Clauses for random password generation, password verification, and secondary passwords apply only to accounts that use an authentication plugin that stores credentials internally to MySQL. For accounts that use a plugin that performs
authentication against a credentials system that is external to MySQL, password management must be handled externally against that system as well. For more information about internal credentials storage, see Section 8.2.15, “Password Management”.

The `REPLACE 'current_auth_string'` clause performs password verification. If given:

- `REPLACE` specifies the account current password to be replaced, as a cleartext (unencrypted) string.
- The clause must be given if password changes for the account are required to specify the current password, as verification that the user attempting to make the change actually knows the current password.
- The clause is optional if password changes for the account may but need not specify the current password.
- The statement fails if the clause is given but does not match the current password, even if the clause is optional.
- `REPLACE` can be specified only when changing the account password for the current user.

For more information about password verification by specifying the current password, see Section 8.2.15, “Password Management”.

The `RETAIN CURRENT PASSWORD` clause implements dual-password capability. If given:

- `RETAIN CURRENT PASSWORD` retains an account current password as its secondary password, replacing any existing secondary password. The new password becomes the primary password, but clients can use the account to connect to the server using either the primary or secondary password. (Exception: If the new password specified by the `SET PASSWORD` statement is empty, the secondary password becomes empty as well, even if `RETAIN CURRENT PASSWORD` is given.)
- If you specify `RETAIN CURRENT PASSWORD` for an account that has an empty primary password, the statement fails.
- If an account has a secondary password and you change its primary password without specifying `RETAIN CURRENT PASSWORD`, the secondary password remains unchanged.

For more information about use of dual passwords, see Section 8.2.15, “Password Management”.

`SET PASSWORD` permits these `auth_option` syntaxes:

- `= 'auth_string'`
  
  Assigns the account the given literal password.

- `TO RANDOM`
  
  Assigns the account a password randomly generated by MySQL. The statement also returns the cleartext password in a result set to make it available to the user or application executing the statement.

  For details about the result set and characteristics of randomly generated passwords, see Random Password Generation.

**Important**

Under some circumstances, `SET PASSWORD` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see Section 8.1.2.3, “Passwords and Logging”.
For similar information about client-side logging, see Section 6.5.1.3, "mysql Client Logging".

**SET PASSWORD** can be used with or without a **FOR** clause that explicitly names a user account:

- **With a **FOR user** clause**, the statement sets the password for the named account, which must exist:

  ```sql
  SET PASSWORD FOR 'jeffrey'@'localhost' = 'auth_string';
  ```

- **With no **FOR user** clause**, the statement sets the password for the current user:

  ```sql
  SET PASSWORD = 'auth_string';
  ```

Any client who connects to the server using a nonanonymous account can change the password for that account. (In particular, you can change your own password.) To see which account the server authenticated you as, invoke the **CURRENT_USER()** function:

```sql
SELECT CURRENT_USER();
```

If a **FOR user** clause is given, the account name uses the format described in Section 8.2.4, “Specifying Account Names”. For example:

```sql
SET PASSWORD FOR 'bob'@'%.example.org' = 'auth_string';
```

The host name part of the account name, if omitted, defaults to ' %'.

**SET PASSWORD** interprets the string as a cleartext string, passes it to the authentication plugin associated with the account, and stores the result returned by the plugin in the account row in the mysql.user system table. (The plugin is given the opportunity to hash the value into the encryption format it expects. The plugin may use the value as specified, in which case no hashing occurs.)

Setting the password for a named account (with a **FOR** clause) requires the **UPDATE** privilege for the mysql system schema. Setting the password for yourself (for a nonanonymous account with no **FOR** clause) requires no special privileges.

Statements that modify secondary passwords require these privileges:

- The **APPLICATION_PASSWORD_ADMIN** privilege is required to use the **RETAIN CURRENT PASSWORD** clause for **SET PASSWORD** statements that apply to your own account. The privilege is required to manipulate your own secondary password because most users require only one password.

- If an account is to be permitted to manipulate secondary passwords for all accounts, it should be granted the **CREATE USER** privilege rather than **APPLICATION_PASSWORD_ADMIN**.

When the **read_only** system variable is enabled, **SET PASSWORD** requires the **CONNECTION_ADMIN** privilege (or the deprecated **SUPER** privilege), in addition to any other required privileges.

For additional information about setting passwords and authentication plugins, see Section 8.2.14, “Assigning Account Passwords”, and Section 8.2.17, “Pluggable Authentication”.

### 15.7.1.11 SET ROLE Statement

**SET ROLE** modifies the current user’s effective privileges within the current session by specifying which of its granted roles are active. Granted roles include those granted explicitly to the user and those named in the **mandatory_roles** system variable value.

```sql
SET ROLE {
  DEFAULT
  | NONE
  | ALL
  | ALL EXCEPT role [, role ] ...
  | role [, role ] ...
}
```
Examples:

```
SET ROLE DEFAULT;
SET ROLE 'role1', 'role2';
SET ROLE ALL;
SET ROLE ALL EXCEPT 'role1', 'role2';
```

Each role name uses the format described in Section 8.2.5, “Specifying Role Names”. The host name part of the role name, if omitted, defaults to '%'.

Privileges that the user has been granted directly (rather than through roles) remain unaffected by changes to the active roles.

The statement permits these role specifiers:

- **DEFAULT**: Activate the account default roles. Default roles are those specified with `SET DEFAULT ROLE`.
  
  When a user connects to the server and authenticates successfully, the server determines which roles to activate as the default roles. If the `activate_all_roles_on_login` system variable is enabled, the server activates all granted roles. Otherwise, the server executes `SET ROLE DEFAULT` implicitly. The server activates only default roles that can be activated. The server writes warnings to its error log for default roles that cannot be activated, but the client receives no warnings.

  If a user executes `SET ROLE DEFAULT` during a session, an error occurs if any default role cannot be activated (for example, if it does not exist or is not granted to the user). In this case, the current active roles are not changed.

- **NONE**: Set the active roles to `NONE` (no active roles).

- **ALL**: Activate all roles granted to the account.

- **ALL EXCEPT role [, role ] ...**: Activate all roles granted to the account except those named. The named roles need not exist or be granted to the account.

- **role [, role ] ...**: Activate the named roles, which must be granted to the account.

**Note**

`SET DEFAULT ROLE` and `SET ROLE DEFAULT` are different statements:

- `SET DEFAULT ROLE` defines which account roles to activate by default within account sessions.

- `SET ROLE DEFAULT` sets the active roles within the current session to the current account default roles.

For role usage examples, see Section 8.2.10, “Using Roles”.

### 15.7.2 Resource Group Management Statements

MySQL supports creation and management of resource groups, and permits assigning threads running within the server to particular groups so that threads execute according to the resources available to the group. This section describes the SQL statements available for resource group management. For general discussion of the resource group capability, see Section 7.1.16, “Resource Groups”.

#### 15.7.2.1 ALTER RESOURCE GROUP Statement

```
ALTER RESOURCE GROUP group_name
  [VCPU [=] vcpu_spec [, vcpu_spec] ...]
  [THREAD_PRIORITY [=] N]
  [ENABLE|DISABLE [FORCE]]
```
Resource Group Management Statements

ALTER RESOURCE GROUP is used for resource group management (see Section 7.1.16, “Resource Groups”). This statement alters modifiable attributes of an existing resource group. It requires the RESOURCE_GROUP_ADMIN privilege.

group_name identifies which resource group to alter. If the group does not exist, an error occurs.

The attributes for CPU affinity, priority, and whether the group is enabled can be modified with ALTER RESOURCE GROUP. These attributes are specified the same way as described for CREATE RESOURCE GROUP (see Section 15.7.2.2, “CREATE RESOURCE GROUP Statement”). Only the attributes specified are altered. Unspecified attributes retain their current values.

The FORCE modifier is used with DISABLE. It determines statement behavior if the resource group has any threads assigned to it:

- If FORCE is not given, existing threads in the group continue to run until they terminate, but new threads cannot be assigned to the group.
- If FORCE is given, existing threads in the group are moved to their respective default group (system threads to SYS_default, user threads to USR_default).

The name and type attributes are set at group creation time and cannot be modified thereafter with ALTER RESOURCE GROUP.

Examples:

- Alter a group CPU affinity:
  
  ```sql
  ALTER RESOURCE GROUP rg1 VCPU = 0-63;
  ```

- Alter a group thread priority:
  
  ```sql
  ALTER RESOURCE GROUP rg2 THREAD_PRIORITY = 5;
  ```

- Disable a group, moving any threads assigned to it to the default groups:
  
  ```sql
  ALTER RESOURCE GROUP rg3 DISABLE FORCE;
  ```

Resource group management is local to the server on which it occurs. ALTER RESOURCE GROUP statements are not written to the binary log and are not replicated.

15.7.2.2 CREATE RESOURCE GROUP Statement

CREATE RESOURCE GROUP group_name
  TYPE = {SYSTEM|USER}
  [VCPU = [N | M - N]]
  [THREAD_PRIORITY = N]
  [ENABLE|DISABLE]

CREATE RESOURCE GROUP is used for resource group management (see Section 7.1.16, “Resource Groups”). This statement creates a new resource group and assigns its initial attribute values. It requires the RESOURCE_GROUP_ADMIN privilege.

group_name identifies which resource group to create. If the group already exists, an error occurs.

The TYPE attribute is required. It should be SYSTEM for a system resource group, USER for a user resource group. The group type affects permitted THREAD_PRIORITY values, as described later.

The VCPU attribute indicates the CPU affinity; that is, the set of virtual CPUs the group can use:
• If `VCPU` is not given, the resource group has no CPU affinity and can use all available CPUs.

• If `VCPU` is given, the attribute value is a list of comma-separated CPU numbers or ranges:
  
  • Each number must be an integer in the range from 0 to the number of CPUs – 1. For example, on a system with 64 CPUs, the number can range from 0 to 63.

  • A range is given in the form `M – N`, where `M` is less than or equal to `N` and both numbers are in the CPU range.

  • If a CPU number is an integer outside the permitted range or is not an integer, an error occurs.

Example `VCPU` specifiers (these are all equivalent):

<table>
<thead>
<tr>
<th>VCPU</th>
</tr>
</thead>
<tbody>
<tr>
<td>0,1,2,3,9,10</td>
</tr>
<tr>
<td>0-3,9-10</td>
</tr>
<tr>
<td>9,10,0-3</td>
</tr>
<tr>
<td>0,10,1,9,3,2</td>
</tr>
</tbody>
</table>

The `THREAD_PRIORITY` attribute indicates the priority for threads assigned to the group:

• If `THREAD_PRIORITY` is not given, the default priority is 0.

• If `THREAD_PRIORITY` is given, the attribute value must be in the range from -20 (highest priority) to 19 (lowest priority). The priority for system resource groups must be in the range from -20 to 0. The priority for user resource groups must be in the range from 0 to 19. Use of different ranges for system and user groups ensures that user threads never have a higher priority than system threads.

`ENABLE` and `DISABLE` specify that the resource group is initially enabled or disabled. If neither is specified, the group is enabled by default. A disabled group cannot have threads assigned to it.

Examples:

• Create an enabled user group that has a single CPU and the lowest priority:

  ```sql
  CREATE RESOURCE GROUP rg1
  TYPE = USER
  VCPU = 0
  THREAD_PRIORITY = 19;
  ```

• Create a disabled system group that has no CPU affinity (can use all CPUs) and the highest priority:

  ```sql
  CREATE RESOURCE GROUP rg2
  TYPE = SYSTEM
  THREAD_PRIORITY = -20
  DISABLE;
  ```

Resource group management is local to the server on which it occurs. `CREATE RESOURCE GROUP` statements are not written to the binary log and are not replicated.

### 15.7.2.3 DROP RESOURCE GROUP Statement

`DROP RESOURCE GROUP group_name [FORCE]`

`DROP RESOURCE GROUP` is used for resource group management (see Section 7.1.16, "Resource Groups"). This statement drops a resource group. It requires the `RESOURCE_GROUP_ADMIN` privilege.

`group_name` identifies which resource group to drop. If the group does not exist, an error occurs.

The `FORCE` modifier determines statement behavior if the resource group has any threads assigned to it:

• If `FORCE` is not given and any threads are assigned to the group, an error occurs.
• If `FORCE` is given, existing threads in the group are moved to their respective default group (system threads to `SYS_default`, user threads to `USR_default`).

Examples:

• Drop a group, failing if the group contains any threads:

  ```
  DROP RESOURCE GROUP rg1;
  ```

• Drop a group and move existing threads to the default groups:

  ```
  DROP RESOURCE GROUP rg2 FORCE;
  ```

Resource group management is local to the server on which it occurs. `DROP RESOURCE GROUP` statements are not written to the binary log and are not replicated.

### 15.7.2.4 SET RESOURCE GROUP Statement

```
SET RESOURCE GROUP group_name
  [FOR thread_id [, thread_id] ...]
```

`SET RESOURCE GROUP` is used for resource group management (see Section 7.1.16, “Resource Groups”). This statement assigns threads to a resource group. It requires the `RESOURCE_GROUP_ADMIN` or `RESOURCE_GROUP_USER` privilege.

`group_name` identifies which resource group to be assigned. Any `thread_id` values indicate threads to assign to the group. Thread IDs can be determined from the Performance Schema `threads` table. If the resource group or any named thread ID does not exist, an error occurs.

With no `FOR` clause, the statement assigns the current thread for the session to the resource group.

With a `FOR` clause that names thread IDs, the statement assigns those threads to the resource group.

For attempts to assign a system thread to a user resource group or a user thread to a system resource group, a warning occurs.

Examples:

• Assign the current session thread to a group:

  ```
  SET RESOURCE GROUP rg1;
  ```

• Assign the named threads to a group:

  ```
  SET RESOURCE GROUP rg2 FOR 14, 78, 4;
  ```

Resource group management is local to the server on which it occurs. `SET RESOURCE GROUP` statements are not written to the binary log and are not replicated.

An alternative to `SET RESOURCE GROUP` is the `RESOURCE_GROUP` optimizer hint, which assigns individual statements to a resource group. See Section 10.9.3, “Optimizer Hints”.

### 15.7.3 Table Maintenance Statements

#### 15.7.3.1 ANALYZE TABLE Statement

```
ANALYZE [NO_WRITE_TO_BINLOG | LOCAL] 
  TABLE tbl_name [, tbl_name] ...
```

```
ANALYZE [NO_WRITE_TO_BINLOG | LOCAL] 
  TABLE tbl_name
    UPDATE HISTOGRAM ON col_name [, col_name] ...
```
Table Maintenance Statements

[WITH N BUCKETS]
[MANUAL | AUTO] UPDATE

ANALYZE [NO_WRITE_TO_BINLOG | LOCAL]
  TABLE tbl_name
  UPDATE HISTOGRAM ON col_name [USING DATA 'json_data']

ANALYZE [NO_WRITE_TO_BINLOG | LOCAL]
  TABLE tbl_name
  DROP HISTOGRAM ON col_name [, col_name] ...

**ANALYZE TABLE** generates table statistics:

- **ANALYZE TABLE** without any **HISTOGRAM** clause performs a key distribution analysis and stores the distribution for the named table or tables. For **MyISAM** tables, **ANALYZE TABLE** for key distribution analysis is equivalent to using `myisamchk --analyze`.

- **ANALYZE TABLE** with the **UPDATE HISTOGRAM** clause generates histogram statistics for the named table columns and stores them in the data dictionary. Only one table name is permitted with this syntax. MySQL also supports setting the histogram of a single column to a user-defined JSON value.

- **ANALYZE TABLE** with the **DROP HISTOGRAM** clause removes histogram statistics for the named table columns from the data dictionary. Only one table name is permitted for this syntax.

This statement requires **SELECT** and **INSERT** privileges for the table.

**ANALYZE TABLE** works with **InnoDB**, **NDB**, and **MyISAM** tables. It does not work with views.

If the `innodb_read_only` system variable is enabled, **ANALYZE TABLE** may fail because it cannot update statistics tables in the data dictionary, which use **InnoDB**. For **ANALYZE TABLE** operations that update the key distribution, failure may occur even if the operation updates the table itself (for example, if it is a **MyISAM** table). To obtain the updated distribution statistics, set `information_schema_stats_expiry=0`.

**ANALYZE TABLE** is supported for partitioned tables, and you can use **ALTER TABLE ... ANALYZE PARTITION** to analyze one or more partitions; for more information, see Section 15.1.9, “ALTER TABLE Statement”, and Section 26.3.4, “Maintenance of Partitions”.

During the analysis, the table is locked with a read lock for **InnoDB** and **MyISAM**.

By default, the server writes **ANALYZE TABLE** statements to the binary log so that they replicate to replicas. To suppress logging, specify the optional **NO_WRITE_TO_BINLOG** keyword or its alias **LOCAL**.

- **ANALYZE TABLE Output**
- **Key Distribution Analysis**
- **Histogram Statistics Analysis**
- **Other Considerations**

**ANALYZE TABLE Output**

**ANALYZE TABLE** returns a result set with the columns shown in the following table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td><strong>analyze</strong> or <strong>histogram</strong></td>
</tr>
<tr>
<td>Msg_type</td>
<td><strong>status</strong>, <strong>error</strong>, <strong>info</strong>, <strong>note</strong>, or <strong>warning</strong></td>
</tr>
<tr>
<td>Msg_text</td>
<td>An informational message</td>
</tr>
</tbody>
</table>
**Key Distribution Analysis**

`ANALYZE TABLE` without either `HISTOGRAM` clause performs a key distribution analysis and stores the distribution for the table or tables. Any existing histogram statistics remain unaffected.

If the table has not changed since the last key distribution analysis, the table is not analyzed again.

MySQL uses the stored key distribution to decide the order in which tables should be joined for joins on something other than a constant. In addition, key distributions can be used when deciding which indexes to use for a specific table within a query.

To check the stored key distribution cardinality, use the `SHOW INDEX` statement or the `INFORMATION_SCHEMA STATISTICS` table. See Section 15.7.7.23, “SHOW INDEX Statement”, and Section 28.3.34, “The INFORMATION_SCHEMA STATISTICS Table”.

For InnoDB tables, `ANALYZE TABLE` determines index cardinality by performing random dives on each of the index trees and updating index cardinality estimates accordingly. Because these are only estimates, repeated runs of `ANALYZE TABLE` could produce different numbers. This makes `ANALYZE TABLE` fast on InnoDB tables but not 100% accurate because it does not take all rows into account.

You can make the statistics collected by `ANALYZE TABLE` more precise and more stable by enabling `innodb_stats_persistent`, as explained in Section 17.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”. When `innodb_stats_persistent` is enabled, it is important to run `ANALYZE TABLE` after major changes to index column data, as statistics are not recalculated periodically (such as after a server restart).

If `innodb_stats_persistent` is enabled, you can change the number of random dives by modifying the `innodb_stats_persistent_sample_pages` system variable. If `innodb_stats_persistent` is disabled, modify `innodb_stats_transient_sample_pages` instead.

For more information about key distribution analysis in InnoDB, see Section 17.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”, and Section 17.8.10.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”.

MySQL uses index cardinality estimates in join optimization. If a join is not optimized in the right way, try running `ANALYZE TABLE`. In the few cases that `ANALYZE TABLE` does not produce values good enough for your particular tables, you can use `FORCE INDEX` with your queries to force the use of a particular index, or set the `max_seeks_for_key` system variable to ensure that MySQL prefers index lookups over table scans. See Section B.3.5, “Optimizer-Related Issues”.

**Histogram Statistics Analysis**

`ANALYZE TABLE` with the `HISTOGRAM` clause enables management of histogram statistics for table column values. For information about histogram statistics, see Section 10.9.6, “Optimizer Statistics”.

These histogram operations are available:

- `ANALYZE TABLE` with an `UPDATE HISTOGRAM` clause generates histogram statistics for the named table columns and stores them in the data dictionary. Only one table name is permitted for this syntax.

  The optional `WITH N BUCKETS` clause specifies the number of buckets for the histogram. The value of `N` must be an integer in the range from 1 to 1024. If this clause is omitted, the number of buckets is 100.

  The optional `AUTO UPDATE` clause enables automatic updates of histograms on the table. When enabled, an `ANALYZE TABLE` statement on this table automatically updates the histogram, using the same number of buckets as last specified by `WITH ... BUCKETS` if this was previously set for this table. In addition, when recalculating persistent statistics for the table (see Section 17.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”), the InnoDB background statistics thread...
Table Maintenance Statements

also updates the histogram. MANUAL UPDATE disables automatic updates, and is the default setting
if not specified.
• ANALYZE TABLE with a DROP HISTOGRAM clause removes histogram statistics for the named table
columns from the data dictionary. Only one table name is permitted for this syntax.
Stored histogram management statements affect only the named columns. Consider these statements:
ANALYZE TABLE t UPDATE HISTOGRAM ON c1, c2, c3 WITH 10 BUCKETS;
ANALYZE TABLE t UPDATE HISTOGRAM ON c1, c3 WITH 10 BUCKETS;
ANALYZE TABLE t DROP HISTOGRAM ON c2;

The first statement updates the histograms for columns c1, c2, and c3, replacing any existing
histograms for those columns. The second statement updates the histograms for c1 and c3, leaving
the c2 histogram unaffected. The third statement removes the histogram for c2, leaving those for c1
and c3 unaffected.
When sampling user data as part of building a histogram, not all values are read; this may lead to
missing some values considered important. In such cases, it might be useful to modify the histogram,
or to set your own histogram explicitly based on your own criteria, such as the complete data set.
ANALYZE TABLE tbl_name UPDATE HISTOGRAM ON col_name USING DATA 'json_data'
updates a column of the histogram table with data supplied in the same JSON format used to display
HISTOGRAM column values from the Information Schema COLUMN_STATISTICS table. Only one
column can be modified when updating the histogram with JSON data.
We can illustrate the use of USING DATA by first generating a histogram on column c1 of table t, like
this:
mysql> ANALYZE TABLE t UPDATE HISTOGRAM ON c1;
+-------+-----------+----------+-----------------------------------------------+
| Table | Op
| Msg_type | Msg_text
|
+-------+-----------+----------+-----------------------------------------------+
| h.t
| histogram | status
| Histogram statistics created for column 'c1'. |
+-------+-----------+----------+-----------------------------------------------+
1 row in set (0.00 sec)

We can see the histogram generated in the COLUMN_STATISTICS table:
mysql> TABLE information_schema.column_statistics\G
*************************** 1. row ***************************
SCHEMA_NAME: h
TABLE_NAME: t
COLUMN_NAME: c1
HISTOGRAM: {"buckets": [], "data-type": "int", "auto-update": false,
"null-values": 0.0, "collation-id": 8, "last-updated": "2024-03-26
16:54:43.674995", "sampling-rate": 1.0, "histogram-type": "singleton",
"number-of-buckets-specified": 100}
1 row in set (0.00 sec)

Now we drop the histogram, and when we check COLUMN_STATISTICS, it is empty:
mysql> ANALYZE TABLE t DROP HISTOGRAM ON c1;
+-------+-----------+----------+-----------------------------------------------+
| Table | Op
| Msg_type | Msg_text
|
+-------+-----------+----------+-----------------------------------------------+
| h.t
| histogram | status
| Histogram statistics removed for column 'c1'. |
+-------+-----------+----------+-----------------------------------------------+
1 row in set (0.01 sec)
mysql> TABLE information_schema.column_statistics\G
Empty set (0.00 sec)

We can restore the dropped histogram by inserting its JSON representation obtained previously from
the HISTOGRAM column of the COLUMN_STATISTICS table, and when we query that table again, we
can see that the histogram has been restored to its previous state:
mysql> ANALYZE TABLE t UPDATE HISTOGRAM ON c1
->
USING DATA '{"buckets": [], "data-type": "int", "auto-update": false,

2798


Histogram generation is not supported for encrypted tables (to avoid exposing data in the statistics) or **TEMPORARY** tables.

Histogram generation applies to columns of all data types except geometry types (spatial data) and JSON.

Histograms can be generated for stored and virtual generated columns.

Histograms cannot be generated for columns that are covered by single-column unique indexes.

Histogram management statements attempt to perform as much of the requested operation as possible, and report diagnostic messages for the remainder. For example, if an UPDATE HISTOGRAM statement names multiple columns, but some of them do not exist or have an unsupported data type, histograms are generated for the other columns, and messages are produced for the invalid columns.

Histograms are affected by these DDL statements:

- **DROP TABLE** removes histograms for columns in the dropped table.
- **DROP DATABASE** removes histograms for any table in the dropped database because the statement drops all tables in the database.
- **RENAME TABLE** does not remove histograms. Instead, it renames histograms for the renamed table to be associated with the new table name.
- **ALTER TABLE** statements that remove or modify a column remove histograms for that column.
- **ALTER TABLE ... CONVERT TO CHARACTER SET** removes histograms for character columns because they are affected by the change of character set. Histograms for noncharacter columns remain unaffected.

The `histogram_generation_max_mem_size` system variable controls the maximum amount of memory available for histogram generation. The global and session values may be set at runtime.

Changing the global `histogram_generation_max_mem_size` value requires privileges sufficient to set global system variables. Changing the session `histogram_generation_max_mem_size` value requires privileges sufficient to set restricted session system variables. See Section 7.1.9.1, “System Variable Privileges”.

If the estimated amount of data to be read into memory for histogram generation exceeds the limit defined by `histogram_generation_max_mem_size`, MySQL samples the data rather than reading all of it into memory. Sampling is evenly distributed over the entire table. MySQL uses **SYSTEM** sampling, which is a page-level sampling method.

The `sampling-rate` value in the HISTOGRAM column of the Information Schema `COLUMN_STATISTICS` table can be queried to determine the fraction of data that was sampled to
create the histogram. The **sampling-rate** is a number between 0.0 and 1.0. A value of 1 means that all of the data was read (no sampling).

The following example demonstrates sampling. To ensure that the amount of data exceeds the **histogram_generation_max_mem_size** limit for the purpose of the example, the limit is set to a low value (2000000 bytes) prior to generating histogram statistics for the `birth_date` column of the `employees` table.

```sql
mysql> SET histogram_generation_max_mem_size = 2000000;

mysql> USE employees;

mysql> ANALYZE TABLE employees UPDATE HISTOGRAM ON birth_date WITH 16 BUCKETS;  
```

A **sampling-rate** value of 0.0491431208869665 means that approximately 4.9% of the data from the `birth_date` column was read into memory for generating histogram statistics.

The InnoDB storage engine provides its own sampling implementation for data stored in InnoDB tables. The default sampling implementation used by MySQL when storage engines do not provide their own requires a full table scan, which is costly for large tables. The InnoDB sampling implementation improves sampling performance by avoiding full table scans.

The **sampled_pages_read** and **sampled_pages_skipped** INNODB_METRICS counters can be used to monitor sampling of InnoDB data pages. (For general INNODB_METRICS counter usage information, see Section 28.4.21, “The INFORMATION_SCHEMA INNODB_METRICS Table”.)

The following example demonstrates sampling counter usage, which requires enabling the counters prior to generating histogram statistics.

```sql
mysql> SET GLOBAL innodb_monitor_enable = 'sampled%';

mysql> USE employees;

mysql> ANALYZE TABLE employees UPDATE HISTOGRAM ON birth_date WITH 16 BUCKETS;  
```

```sql
mysql> USE INFORMATION_SCHEMA;

mysql> SELECT NAME, COUNT FROM INNODB_METRICS WHERE NAME LIKE 'sampled%';  
```

This formula approximates a sampling rate based on the sampling counter data:

```
sampling rate = sampled_page_read/(sampled_pages_read + sampled_pages_skipped)
```
A sampling rate based on sampling counter data is roughly the same as the `sampling-rate` value in the `HISTOGRAM` column of the Information Schema `COLUMN_STATISTICS` table.

For information about memory allocations performed for histogram generation, monitor the Performance Schema `memory/sql/histograms` instrument. See Section 29.12.20.10, “Memory Summary Tables”.

**Other Considerations**

`ANALYZE TABLE` clears table statistics from the Information Schema `INNODB_TABLESTATS` table and sets the `STATS_INITIALIZED` column to `Uninitialized`. Statistics are collected again the next time the table is accessed.

### 15.7.3.2 CHECK TABLE Statement

```
CHECK TABLE tbl_name[, tbl_name] ... [option] ...
```

`CHECK TABLE` checks a table or tables for errors. `CHECK TABLE` can also check views for problems, such as tables that are referenced in the view definition that no longer exist.

To check a table, you must have some privilege for it.

`CHECK TABLE` works for InnoDB, MyISAM, Archive, and CSV tables.

Before running `CHECK TABLE` on InnoDB tables, see CHECK TABLE Usage Notes for InnoDB Tables.

`CHECK TABLE` is supported for partitioned tables, and you can use `ALTER TABLE ... CHECK PARTITION` to check one or more partitions; for more information, see Section 15.1.9, “ALTER TABLE Statement”, and Section 26.3.4, “Maintenance of Partitions”.

`CHECK TABLE` ignores virtual generated columns that are not indexed.

- **CHECK TABLE Output**
- Checking Version Compatibility
- Checking Data Consistency
- **CHECK TABLE Usage Notes for InnoDB Tables**
- **CHECK TABLE Usage Notes for MyISAM Tables**

**CHECK TABLE Output**

`CHECK TABLE` returns a result set with the columns shown in the following table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td>Always check</td>
</tr>
<tr>
<td>Msg_type</td>
<td><code>status, error, info, note, or warning</code></td>
</tr>
<tr>
<td>Msg_text</td>
<td>An informational message</td>
</tr>
</tbody>
</table>
Table Maintenance Statements

The statement might produce many rows of information for each checked table. The last row has a `Msg_type` value of `status` and the `Msg_text` normally should be `OK`. `Table is already up to date` means that the storage engine for the table indicated that there was no need to check the table.

Checking Version Compatibility

The `FOR UPGRADE` option checks whether the named tables are compatible with the current version of MySQL. With `FOR UPGRADE`, the server checks each table to determine whether there have been any incompatible changes in any of the table's data types or indexes since the table was created. If not, the check succeeds. Otherwise, if there is a possible incompatibility, the server runs a full check on the table (which might take some time).

Incompatibilities might occur because the storage format for a data type has changed or because its sort order has changed. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases.

`FOR UPGRADE` discovers these incompatibilities:

- The indexing order for end-space in `TEXT` columns for `InnoDB` and `MyISAM` tables changed between MySQL 4.1 and 5.0.
- The storage method of the new `DECIMAL` data type changed between MySQL 5.0.3 and 5.0.5.
- Changes are sometimes made to character sets or collations that require table indexes to be rebuilt. For details about such changes, see Section 3.5, “Changes in MySQL 8.4”. For information about rebuilding tables, see Section 3.14, “Rebuilding or Repairing Tables or Indexes”.
- MySQL 8.4 does not support the 2-digit `YEAR(2)` data type permitted in older versions of MySQL. For tables containing `YEAR(2)` columns, `CHECK TABLE` recommends `REPAIR TABLE`, which converts 2-digit `YEAR(2)` columns to 4-digit `YEAR` columns.
- Trigger creation time is maintained.
- A table is reported as needing a rebuild if it contains old temporal columns in pre-5.6.4 format (`TIME`, `DATETIME`, and `TIMESTAMP` columns without support for fractional seconds precision). This helps the MySQL upgrade procedure detect and upgrade tables containing old temporal columns.
- Warnings are issued for tables that use nonnative partitioning because nonnative partitioning is removed in MySQL 8.4. See Chapter 26, Partitioning.

Checking Data Consistency

The following table shows the other check options that can be given. These options are passed to the storage engine, which may use or ignore them.

<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUICK</td>
<td>Do not scan the rows to check for incorrect links. Applies to <code>InnoDB</code> and <code>MyISAM</code> tables and views.</td>
</tr>
<tr>
<td>FAST</td>
<td>Check only tables that have not been closed properly. Ignored for <code>InnoDB</code>; applies only to <code>MyISAM</code> tables and views.</td>
</tr>
<tr>
<td>CHANGED</td>
<td>Check only tables that have been changed since the last check or that have not been closed properly. Ignored for <code>InnoDB</code>; applies only to <code>MyISAM</code> tables and views.</td>
</tr>
<tr>
<td>MEDIUM</td>
<td>Scan rows to verify that deleted links are valid. This also calculates a key checksum for the rows and verifies this with a calculated checksum for</td>
</tr>
</tbody>
</table>
Table Maintenance Statements

<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>the keys. Ignored for InnoDB; applies only to MyISAM tables and views.</td>
</tr>
<tr>
<td>EXTENDED</td>
<td>Do a full key lookup for all keys for each row. This ensures that the table is 100% consistent, but takes a long time. Ignored for InnoDB; applies only to MyISAM tables and views.</td>
</tr>
</tbody>
</table>

You can combine check options, as in the following example that does a quick check on the table to determine whether it was closed properly:

```
CHECK TABLE test_table FAST QUICK;
```

**Note**

If `CHECK TABLE` finds no problems with a table that is marked as "corrupted" or "not closed properly", `CHECK TABLE` may remove the mark.

If a table is corrupted, the problem is most likely in the indexes and not in the data part. All of the preceding check types check the indexes thoroughly and should thus find most errors.

To check a table that you assume is okay, use no check options or the `QUICK` option. The latter should be used when you are in a hurry and can take the very small risk that `QUICK` does not find an error in the data file. (In most cases, under normal usage, MySQL should find any error in the data file. If this happens, the table is marked as "corrupted" and cannot be used until it is repaired.)

`FAST` and `CHANGED` are mostly intended to be used from a script (for example, to be executed from `cron`) to check tables periodically. In most cases, `FAST` is to be preferred over `CHANGED`. (The only case when it is not preferred is when you suspect that you have found a bug in the MyISAM code.)

`EXTENDED` is to be used only after you have run a normal check but still get errors from a table when MySQL tries to update a row or find a row by key. This is very unlikely if a normal check has succeeded.

Use of `CHECK TABLE ... EXTENDED` might influence execution plans generated by the query optimizer.

Some problems reported by `CHECK TABLE` cannot be corrected automatically:

- **Found row where the auto_increment column has the value 0.**

  This means that you have a row in the table where the `AUTO_INCREMENT` index column contains the value 0. (It is possible to create a row where the `AUTO_INCREMENT` column is 0 by explicitly setting the column to 0 with an `UPDATE` statement.)

  This is not an error in itself, but could cause trouble if you decide to dump the table and restore it or do an `ALTER TABLE` on the table. In this case, the `AUTO_INCREMENT` column changes value according to the rules of `AUTO_INCREMENT` columns, which could cause problems such as a duplicate-key error.

  To get rid of the warning, execute an `UPDATE` statement to set the column to some value other than 0.

**CHECK TABLE Usage Notes for InnoDB Tables**

The following notes apply to InnoDB tables:

- **If `CHECK TABLE` encounters a corrupt page, the server exits to prevent error propagation (Bug #10132). If the corruption occurs in a secondary index but table data is readable, running `CHECK TABLE` can still cause a server exit.**
Table Maintenance Statements

- If CHECK_TABLE encounters a corrupted DB_TRX_ID or DB_ROLL_PTR field in a clustered index, CHECK_TABLE can cause InnoDB to access an invalid undo log record, resulting in an MVCC-related server exit.

- If CHECK_TABLE encounters errors in InnoDB tables or indexes, it reports an error, and usually marks the index and sometimes marks the table as corrupted, preventing further use of the index or table. Such errors include an incorrect number of entries in a secondary index or incorrect links.

- If CHECK_TABLE finds an incorrect number of entries in a secondary index, it reports an error but does not cause a server exit or prevent access to the file.

- CHECK_TABLE surveys the index page structure, then surveys each key entry. It does not validate the key pointer to a clustered record or follow the path for BLOB pointers.

- When an InnoDB table is stored in its own .ibd file, the first 3 pages of the .ibd file contain header information rather than table or index data. The CHECK_TABLE statement does not detect inconsistencies that affect only the header data. To verify the entire contents of an InnoDB .ibd file, use the innochecksum command.

- When running CHECK_TABLE on large InnoDB tables, other threads may be blocked during CHECK_TABLE execution. To avoid timeouts, the semaphore wait threshold (600 seconds) is extended by 2 hours (7200 seconds) for CHECK_TABLE operations. If InnoDB detects semaphore waits of 240 seconds or more, it starts printing InnoDB monitor output to the error log. If a lock request extends beyond the semaphore wait threshold, InnoDB aborts the process. To avoid the possibility of a semaphore wait timeout entirely, run CHECK_TABLE QUICK instead of CHECK_TABLE.

- CHECK_TABLE functionality for InnoDB SPATIAL indexes includes an R-tree validity check and a check to ensure that the R-tree row count matches the clustered index.

- CHECK_TABLE supports secondary indexes on virtual generated columns, which are supported by InnoDB.

- InnoDB supports parallel clustered index reads, which can improve CHECK_TABLE performance. InnoDB reads the clustered index twice during a CHECK_TABLE operation. The second read can be performed in parallel. The innodb_parallel_read_threads session variable must be set to a value greater than 1 for parallel clustered index reads to occur. The actual number of threads used to perform a parallel clustered index read is determined by the innodb_parallel_read_threads setting or the number of index subtrees to scan, whichever is smaller.

CHECK TABLE Usage Notes for MyISAM Tables

The following notes apply to MyISAM tables:

- CHECK_TABLE updates key statistics for MyISAM tables.

- If CHECK_TABLE output does not return OK or Table is already up to date, you should normally run a repair of the table. See Section 9.6, "MyISAM Table Maintenance and Crash Recovery".

- If none of the CHECK_TABLE options QUICK, MEDIUM, or EXTENDED are specified, the default check type for dynamic-format MyISAM tables is MEDIUM. This has the same result as running myisamchk --medium-check tbl_name on the table. The default check type also is MEDIUM for static-format MyISAM tables, unless CHANGED or FAST is specified. In that case, the default is QUICK. The row scan is skipped for CHANGED and FAST because the rows are very seldom corrupted.

15.7.3.3 CHECKSUM TABLE Statement

CHECKSUM TABLE tbl_name [,...] [QUICK | EXTENDED]

CHECKSUM_TABLE reports a checksum for the contents of a table. You can use this statement to verify that the contents are the same before and after a backup, rollback, or other operation that is intended to put the data back to a known state.
Table Maintenance Statements

This statement requires the `SELECT` privilege for the table.

This statement is not supported for views. If you run `CHECKSUM TABLE` against a view, the checksum value is always `NULL`, and a warning is returned.

For a nonexistent table, `CHECKSUM TABLE` returns `NULL` and generates a warning.

During the checksum operation, the table is locked with a read lock for InnoDB and MyISAM.

**Performance Considerations**

By default, the entire table is read row by row and the checksum is calculated. For large tables, this could take a long time, thus you would only perform this operation occasionally. This row-by-row calculation is what you get with the `EXTENDED` clause, with InnoDB and all other storage engines other than MyISAM, and with MyISAM tables not created with the `CHECKSUM=1` clause.

For MyISAM tables created with the `CHECKSUM=1` clause, `CHECKSUM TABLE` or `CHECKSUM TABLE ... QUICK` returns the “live” table checksum that can be returned very fast. If the table does not meet all these conditions, the `QUICK` method returns `NULL`. The `QUICK` method is not supported with InnoDB tables. See Section 15.1.20, “CREATE TABLE Statement” for the syntax of the `CHECKSUM` clause.

The checksum value depends on the table row format. If the row format changes, the checksum also changes. For example, the storage format for temporal types such as `TIME`, `DATETIME`, and `TIMESTAMP` changed in MySQL 5.6 prior to MySQL 5.6.5, so if a 5.5 table is upgraded to MySQL 5.6, the checksum value may change.

---

**Important**

If the checksums for two tables are different, then it is almost certain that the tables are different in some way. However, because the hashing function used by `CHECKSUM TABLE` is not guaranteed to be collision-free, there is a slight chance that two tables which are not identical can produce the same checksum.

---

### 15.7.3.4 OPTIMIZE TABLE Statement

```
OPTIMIZE [NO_WRITE_TO_BINLOG | LOCAL]
TABLE tbl_name [, tbl_name] ...
```

**OPTIMIZE TABLE** reorganizes the physical storage of table data and associated index data, to reduce storage space and improve I/O efficiency when accessing the table. The exact changes made to each table depend on the storage engine used by that table.

Use **OPTIMIZE TABLE** in these cases, depending on the type of table:

- After doing substantial insert, update, or delete operations on an InnoDB table that has its own .ibd file because it was created with the `innodb_file_per_table` option enabled. The table and indexes are reorganized, and disk space can be reclaimed for use by the operating system.

- After doing substantial insert, update, or delete operations on columns that are part of a FULLTEXT index in an InnoDB table. Set the configuration option `innodb_optimize_fulltext_only=1` first. To keep the index maintenance period to a reasonable time, set the `innodb_ft_num_word_optimize` option to specify how many words to update in the search index, and run a sequence of **OPTIMIZE TABLE** statements until the search index is fully updated.

- After deleting a large part of a MyISAM or ARCHIVE table, or making many changes to a MyISAM or ARCHIVE table with variable-length rows (tables that have VARCHAR, VARBINARY, BLOB, or TEXT columns). Deleted rows are maintained in a linked list and subsequent INSERT operations reuse old row positions. You can use **OPTIMIZE TABLE** to reclaim the unused space and to defragment...
the data file. After extensive changes to a table, this statement may also improve performance of statements that use the table, sometimes significantly.

This statement requires SELECT and INSERT privileges for the table.

OPTIMIZE TABLE works for InnoDB, MyISAM, and ARCHIVE tables. OPTIMIZE TABLE is also supported for dynamic columns of in-memory NDB tables. It does not work for fixed-width columns of in-memory tables, nor does it work for Disk Data tables. The performance of OPTIMIZE on NDB Cluster tables can be tuned using --ndb-optimization-delay, which controls the length of time to wait between processing batches of rows by OPTIMIZE TABLE. For more information, see Section 25.2.7.11, “Previous NDB Cluster Issues Resolved in NDB Cluster 8.4”.

For NDB Cluster tables, OPTIMIZE TABLE can be interrupted by (for example) killing the SQL thread performing the OPTIMIZE operation.

By default, OPTIMIZE TABLE does not work for tables created using any other storage engine and returns a result indicating this lack of support. You can make OPTIMIZE TABLE work for other storage engines by starting mysqld with the --skip-new option. In this case, OPTIMIZE TABLE is just mapped to ALTER TABLE.

This statement does not work with views.

OPTIMIZE TABLE is supported for partitioned tables. For information about using this statement with partitioned tables and table partitions, see Section 26.3.4, “Maintenance of Partitions”.

By default, the server writes OPTIMIZE TABLE statements to the binary log so that they replicate to replicas. To suppress logging, specify the optional NO_WRITE_TO_BINLOG keyword or its alias LOCAL. You must have the OPTIMIZE_LOCAL_TABLE privilege to use this option.

• OPTIMIZE TABLE Output
• InnoDB Details
• MyISAM Details
• Other Considerations

OPTIMIZE TABLE Output

OPTIMIZE TABLE returns a result set with the columns shown in the following table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td>Always optimize</td>
</tr>
<tr>
<td>Msg_type</td>
<td>status, error, info, note, or warning</td>
</tr>
<tr>
<td>Msg_text</td>
<td>An informational message</td>
</tr>
</tbody>
</table>

OPTIMIZE TABLE table catches and throws any errors that occur while copying table statistics from the old file to the newly created file. For example, if the user ID of the owner of the .MYD or .MYI file is different from the user ID of the mysqld process, OPTIMIZE TABLE generates a “cannot change ownership of the file” error unless mysqld is started by the root user.

InnoDB Details

For InnoDB tables, OPTIMIZE TABLE is mapped to ALTER TABLE ... FORCE, which rebuilds the table to update index statistics and free unused space in the clustered index. This is displayed in the output of OPTIMIZE TABLE when you run it on an InnoDB table, as shown here:

```sql
mysql> OPTIMIZE TABLE foo;
```
OPTIMIZE_TABLE uses online DDL for regular and partitioned InnoDB tables, which reduces downtime for concurrent DML operations. The table rebuild triggered by OPTIMIZE_TABLE is completed in place. An exclusive table lock is only taken briefly during the prepare phase and the commit phase of the operation. During the prepare phase, metadata is updated and an intermediate table is created. During the commit phase, table metadata changes are committed.

OPTIMIZE TABLE rebuilds the table using the table copy method under the following conditions:

- When the `old_alter_table` system variable is enabled.
- When the server is started with the `--skip-new` option.

OPTIMIZE_TABLE using online DDL is not supported for InnoDB tables that contain FULLTEXT indexes. The table copy method is used instead.

InnoDB stores data using a page-allocation method and does not suffer from fragmentation in the same way that legacy storage engines (such as MyISAM) do. When considering whether or not to run optimize, consider the workload of transactions that your server is expected to process:

- Some level of fragmentation is expected. InnoDB only fills pages 93% full, to leave room for updates without having to split pages.
- Delete operations might leave gaps that leave pages less filled than desired, which could make it worthwhile to optimize the table.
- Updates to rows usually rewrite the data within the same page, depending on the data type and row format, when sufficient space is available. See Section 17.9.1.5, “How Compression Works for InnoDB Tables” and Section 17.10, “InnoDB Row Formats”.
- High-concurrency workloads might leave gaps in indexes over time, as InnoDB retains multiple versions of the same data due through its MVCC mechanism. See Section 17.3, “InnoDB Multi-Versioning”.

MyISAM Details

For MyISAM tables, OPTIMIZE_TABLE works as follows:
1. If the table has deleted or split rows, repair the table.
2. If the index pages are not sorted, sort them.
3. If the table's statistics are not up to date (and the repair could not be accomplished by sorting the index), update them.

Other Considerations

OPTIMIZE TABLE is performed online for regular and partitioned InnoDB tables. Otherwise, MySQL locks the table during the time OPTIMIZE_TABLE is running.

OPTIMIZE_TABLE does not sort R-tree indexes, such as spatial indexes on POINT columns. (Bug #23578)

15.7.3.5 REPAIR TABLE Statement

REPAIR [NO_WRITE_TO_BINLOG | LOCAL] TABLE tbl_name [, tbl_name] ...
REPAIR TABLE repairs a possibly corrupted table, for certain storage engines only.

This statement requires SELECT and INSERT privileges for the table.

Although normally you should never have to run REPAIR TABLE, if disaster strikes, this statement is very likely to get back all your data from a MyISAM table. If your tables become corrupted often, try to find the reason for it, to eliminate the need to use REPAIR TABLE. See Section B.3.3.3, “What to Do If MySQL Keeps Crashing”, and Section 18.2.4, “MyISAM Table Problems”.

REPAIR TABLE checks the table to see whether an upgrade is required. If so, it performs the upgrade, following the same rules as CHECK TABLE ... FOR UPGRADE. See Section 15.7.3.2, “CHECK TABLE Statement”, for more information.

Important

- Make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors. See Chapter 9, Backup and Recovery.

- If the server exits during a REPAIR TABLE operation, it is essential after restarting it that you immediately execute another REPAIR TABLE statement for the table before performing any other operations on it. In the worst case, you might have a new clean index file without information about the data file, and then the next operation you perform could overwrite the data file. This is an unlikely but possible scenario that underscores the value of making a backup first.

- In the event that a table on the source becomes corrupted and you run REPAIR TABLE on it, any resulting changes to the original table are not propagated to replicas.

- REPAIR TABLE Storage Engine and Partitioning Support
- REPAIR TABLE Options
- REPAIR TABLE Output
- Table Repair Considerations

REPAIR TABLE Storage Engine and Partitioning Support

REPAIR TABLE works for MyISAM, ARCHIVE, and CSV tables. For MyISAM tables, it has the same effect as myisamchk --recover tbl_name by default. This statement does not work with views.

REPAIR TABLE is supported for partitioned tables. However, the USE_FRM option cannot be used with this statement on a partitioned table.

You can use ALTER TABLE ... REPAIR PARTITION to repair one or more partitions; for more information, see Section 15.1.9, “ALTER TABLE Statement”, and Section 26.3.4, “Maintenance of Partitions”.

REPAIR TABLE Options

- NO_WRITE_TO_BINLOG or LOCAL

By default, the server writes REPAIR TABLE statements to the binary log so that they replicate to replicas. To suppress logging, specify the optional NO_WRITE_TO_BINLOG keyword or its alias LOCAL.
Table Maintenance Statements

- **QUICK**

  If you use the **QUICK** option, **REPAIR TABLE** tries to repair only the index file, and not the data file. This type of repair is like that done by `myisamchk --recover --quick`.

- **EXTENDED**

  If you use the **EXTENDED** option, MySQL creates the index row by row instead of creating one index at a time with sorting. This type of repair is like that done by `myisamchk --safe-recover`.

- **USE_FRM**

  The **USE_FRM** option is available for use if the .MYI index file is missing or if its header is corrupted. This option tells MySQL not to trust the information in the .MYI file header and to re-create it using information from the data dictionary. This kind of repair cannot be done with `myisamchk`.

  **Caution**

  Use the **USE_FRM** option *only* if you cannot use regular **REPAIR** modes. Telling the server to ignore the .MYI file makes important table metadata stored in the .MYI unavailable to the repair process, which can have deleterious consequences:

  - The current **AUTO_INCREMENT** value is lost.
  - The link to deleted records in the table is lost, which means that free space for deleted records remains unoccupied thereafter.
  - The .MYI header indicates whether the table is compressed. If the server ignores this information, it cannot tell that a table is compressed and repair can cause change or loss of table contents. This means that **USE_FRM** should not be used with compressed tables. That should not be necessary, anyway: Compressed tables are read only, so they should not become corrupt.

  If you use **USE_FRM** for a table that was created by a different version of the MySQL server than the one you are currently running, **REPAIR TABLE** does not attempt to repair the table. In this case, the result set returned by **REPAIR TABLE** contains a line with a **Msg_type** value of **error** and a **Msg_text** value of **Failed repairing incompatible .FRM file**.

  If **USE_FRM** is used, **REPAIR TABLE** does not check the table to see whether an upgrade is required.

**REPAIR TABLE Output**

**REPAIR TABLE** returns a result set with the columns shown in the following table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Table</strong></td>
<td>The table name</td>
</tr>
<tr>
<td><strong>Op</strong></td>
<td><strong>Always repair</strong></td>
</tr>
<tr>
<td><strong>Msg_type</strong></td>
<td><strong>status, error, info, note, or warning</strong></td>
</tr>
<tr>
<td><strong>Msg_text</strong></td>
<td>An informational message</td>
</tr>
</tbody>
</table>

The **REPAIR TABLE** statement might produce many rows of information for each repaired table. The last row has a **Msg_type** value of **status** and **Msg_text** normally should be **OK**. For a **MyISAM** table, if you do not get **OK**, you should try repairing it with `myisamchk --safe-recover`. (**REPAIR TABLE** does not implement all the options of `myisamchk`. With `myisamchk --safe-recover`, you can also use options that **REPAIR TABLE** does not support, such as `--max-record-length`).

2809
REPAIR TABLE table catches and throws any errors that occur while copying table statistics from the old corrupted file to the newly created file. For example, if the user ID of the owner of the .MYD or .MYI file is different from the user ID of the mysqld process, REPAIR TABLE generates a "cannot change ownership of the file" error unless mysqld is started by the root user.

Table Repair Considerations

You may be able to increase REPAIR TABLE performance by setting certain system variables. See Section 10.6.3, “Optimizing REPAIR TABLE Statements”.

REPAIR TABLE upgrades a table if it contains old temporal columns in pre-5.6.4 format; namely, the TIME, DATETIME, and TIMESTAMP columns that lacked support for fractional seconds precision.

15.7.4 Component, Plugin, and Loadable Function Statements

15.7.4.1 CREATE FUNCTION Statement for Loadable Functions

CREATE [AGGREGATE] FUNCTION [IF NOT EXISTS] function_name
RETURNS {STRING|INTEGER|REAL|DECIMAL} SONAME shared_library_name

This statement loads the loadable function named function_name. (CREATE FUNCTION is also used to created stored functions; see Section 15.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”.)

A loadable function is a way to extend MySQL with a new function that works like a native (built-in) MySQL function such as ABS() or CONCAT(). See Adding a Loadable Function.

function_name is the name that should be used in SQL statements to invoke the function. The RETURNS clause indicates the type of the function's return value. DECIMAL is a legal value after RETURNS, but currently DECIMAL functions return string values and should be written like STRING functions.

IF NOT EXISTS prevents an error from occurring if there already exists a loadable function with the same name. It does not prevent an error from occurring if there already exists a built-in function having the same name. IF NOT EXISTS is also supported for CREATE FUNCTION statements. See Function Name Resolution.

The AGGREGATE keyword, if given, signifies that the function is an aggregate (group) function. An aggregate function works exactly like a native MySQL aggregate function such as SUM() or COUNT().

shared_library_name is the base name of the shared library file containing the code that implements the function. The file must be located in the plugin directory. This directory is given by the value of the plugin_dir system variable. For more information, see Section 7.7.1, “Installing and Uninstalling Loadable Functions”.

CREATE FUNCTION requires the INSERT privilege for the mysql system schema because it adds a row to the mysql.func system table to register the function.

CREATE FUNCTION also adds the function to the Performance Schema user_defined_functions table that provides runtime information about installed loadable functions. See Section 29.12.22.10, “The user_defined_functions Table”.

Note

Like the mysql.func system table, the Performance Schema user_defined_functions table lists loadable functions installed using CREATE FUNCTION. Unlike the mysql.func table, the user_defined_functions table also lists loadable functions installed automatically by server components or plugins. This difference makes
Component, Plugin, and Loadable Function Statements

user_defined_functions preferable to mysql.func for checking which loadable functions are installed.

During the normal startup sequence, the server loads functions registered in the mysql.func table. If the server is started with the --skip-grant-tables option, functions registered in the table are not loaded and are unavailable.

Note
To upgrade the shared library associated with a loadable function, issue a DROP FUNCTION statement, upgrade the shared library, and then issue a CREATE FUNCTION statement. If you upgrade the shared library first and then use DROP FUNCTION, the server may unexpectedly shut down.

15.7.4.2 DROP FUNCTION Statement for Loadable Functions

DROP FUNCTION [IF EXISTS] function_name

This statement drops the loadable function named function_name. (DROP FUNCTION is also used to drop stored functions; see Section 15.1.29, “DROP PROCEDURE and DROP FUNCTION Statements”.)

DROP FUNCTION is the complement of CREATE FUNCTION. It requires the DELETE privilege for the mysql system schema because it removes the row from the mysql.func system table that registers the function.

DROP FUNCTION also removes the function from the Performance Schema user_defined_functions table that provides runtime information about installed loadable functions. See Section 29.12.22.10, “The user_defined_functions Table”.

During the normal startup sequence, the server loads functions registered in the mysql.func table. Because DROP FUNCTION removes the mysql.func row for the dropped function, the server does not load the function during subsequent restarts.

DROP FUNCTION cannot be used to drop a loadable function that is installed automatically by components or plugins rather than by using CREATE FUNCTION. Such a function is also dropped automatically, when the component or plugin that installed it is uninstalled.

Note
To upgrade the shared library associated with a loadable function, issue a DROP FUNCTION statement, upgrade the shared library, and then issue a CREATE FUNCTION statement. If you upgrade the shared library first and then use DROP FUNCTION, the server may unexpectedly shut down.

15.7.4.3 INSTALL COMPONENT Statement

INSTALL COMPONENT component_name [, component_name ... ]
[SET variable = expr [, variable = expr] ...]

variable: {
  {GLOBAL | @@GLOBAL.} [component_prefix.]system_var_name
  | {PERSIST | @@PERSIST.} [component_prefix.]system_var_name
}

This statement installs one or more components, which become active immediately. A component provides services that are available to the server and other components; see Section 7.5, “MySQL Components”. INSTALL COMPONENT requires the INSERT privilege for the mysql.component system table because it adds a row to that table to register the component.

Example:
INSTALL COMPONENT 'file://component1', 'file://component2';
A component is named using a URN that begins with `file://` and indicates the base name of the library file that implements the component, located in the directory named by the `plugin_dir` system variable. Component names do not include any platform-dependent file name suffix such as `.so` or `.dll`. (These naming details are subject to change because component name interpretation is itself performed by a service and the component infrastructure makes it possible to replace the default service implementation with alternative implementations.)

**INSTALL COMPONENT** permits setting the values of component system variables when you install one or more components. The **SET** clause enables you to specify variable values precisely when they are needed, without the inconvenience or limitations associated with other forms of assignment. Specifically, you can also set component variables with these alternatives:

- At server startup using options on the command line or in an option file, but doing so involves a server restart. The values do not take effect until you install the component. You can specify an invalid variable name for a component on the command line without triggering an error.
- Dynamically while the server is running by means of the **SET** statement, which enables you to modify operation of the server without having to stop and restart it. Setting a read-only variable is not permitted.

The optional **SET** clause applies a value, or values, only to the component specified in the **INSTALL COMPONENT** statement, rather than to all subsequent installations of that component. **SET GLOBAL** or **PERSIST** works for all types of variables, including read-only variables, without having to restart the server. A component system variable that you set using **INSTALL COMPONENT** takes precedence over any conflicting value coming from the command line or an option file.

Example:

```
INSTALL COMPONENT 'file://component1', 'file://component2'
SET GLOBAL component1.var1 = 12 + 3, PERSIST component2.var2 = 'strings';
```

Omitting **PERSIST** or **GLOBAL** is equivalent to specifying **GLOBAL**.

Specifying **PERSIST** for any variable in **SET** silently executes **SET PERSIST_ONLY** immediately after **INSTALL COMPONENT** loads the components, but before updating the `mysql.component` table. If **SET PERSIST_ONLY** fails, then the server unloads all of the previously loaded new components without persisting anything to `mysql.component`.

The **SET** clause accepts only valid variable names of the component being installed and emits an error message for all invalid names. Subqueries, stored functions, and aggregate functions are not permitted as part of the value expression. If you install a single component, it is not necessary to prefix the variable name with the component name.

**Note**

While specifying a variable value using the **SET** clause is similar to that of the command line—it is available immediately at variable registration—there is a distinct difference in how the **SET** clause handles *invalid numerical* values for boolean variables. For example, if you set a boolean variable to 11 (component1.boolvar = 11), you see the following behavior:

- **SET** clause yields true
- Command line yields false (11 is neither ON nor 1)

If any error occurs, the statement fails and has no effect. For example, this happens if a component name is erroneous, a named component does not exist or is already installed, or component initialization fails.

A loader service handles component loading, which includes adding installed components to the `mysql.component` system table that serves as a registry. For subsequent server restarts, any
components listed in `mysql.component` are loaded by the loader service during the startup sequence. This occurs even if the server is started with the `--skip-grant-tables` option.

If a component depends on services not present in the registry and you attempt to install the component without also installing the component or components that provide the services on which it depends, an error occurs:

```
ERROR 3527 (HY000): Cannot satisfy dependency for service 'component_a'
required by component 'component_b'.
```

To avoid this problem, either install all components in the same statement, or install the dependent component after installing any components on which it depends.

**Note**

For keyring components, do not use `INSTALL COMPONENT`. Instead, configure keyring component loading using a manifest file. See Section 8.4.4.2, “Keyring Component Installation”.

### 15.7.4.4 INSTALL PLUGIN Statement

```
INSTALL PLUGIN plugin_name SONAME 'shared_library_name'
```

This statement installs a server plugin. It requires the `INSERT` privilege for the `mysql.plugin` system table because it adds a row to that table to register the plugin.

`plugin_name` is the name of the plugin as defined in the plugin descriptor structure contained in the library file (see Plugin Data Structures). Plugin names are not case-sensitive. For maximal compatibility, plugin names should be limited to ASCII letters, digits, and underscore because they are used in C source files, shell command lines, M4 and Bourne shell scripts, and SQL environments.

`shared_library_name` is the name of the shared library that contains the plugin code. The name includes the file name extension (for example, `libmyplugin.so`, `libmyplugin.dll`, or `libmyplugin.dylib`).

The shared library must be located in the plugin directory (the directory named by the `plugin_dir` system variable). The library must be in the plugin directory itself, not in a subdirectory. By default, `plugin_dir` is the plugin directory under the directory named by the `pkglibdir` configuration variable, but it can be changed by setting the value of `plugin_dir` at server startup. For example, set its value in a `my.cnf` file:

```
[mysqld]
plugin_dir=/path/to/plugin/directory
```

If the value of `plugin_dir` is a relative path name, it is taken to be relative to the MySQL base directory (the value of the `basedir` system variable).

`INSTALL PLUGIN` loads and initializes the plugin code to make the plugin available for use. A plugin is initialized by executing its initialization function, which handles any setup that the plugin must perform before it can be used. When the server shuts down, it executes the deinitialization function for each plugin that is loaded so that the plugin has a chance to perform any final cleanup.

`INSTALL PLUGIN` also registers the plugin by adding a line that indicates the plugin name and library file name to the `mysql.plugin` system table. During the normal startup sequence, the server loads and initializes plugins registered in `mysql.plugin`. This means that a plugin is installed with `INSTALL PLUGIN` only once, not every time the server starts. If the server is started with the `--skip-grant-tables` option, plugins registered in the `mysql.plugin` table are not loaded and are unavailable.

A plugin library can contain multiple plugins. For each of them to be installed, use a separate `INSTALL PLUGIN` statement. Each statement names a different plugin, but all of them specify the same library name.
INSTALL PLUGIN causes the server to read option (my.cnf) files just as during server startup. This enables the plugin to pick up any relevant options from those files. It is possible to add plugin options to an option file even before loading a plugin (if the loose prefix is used). It is also possible to uninstall a plugin, edit my.cnf, and install the plugin again. Restarting the plugin this way enables it to the new option values without a server restart.

For options that control individual plugin loading at server startup, see Section 7.6.1, “Installing and Uninstalling Plugins”. If you need to load plugins for a single server startup when the --skip-grant-tables option is given (which tells the server not to read system tables), use the --plugin-load option. See Section 7.1.7, “Server Command Options”.

To remove a plugin, use the UNINSTALL PLUGIN statement.

For additional information about plugin loading, see Section 7.6.1, “Installing and Uninstalling Plugins”.

To see what plugins are installed, use the SHOW PLUGINS statement or query the INFORMATION_SCHEMA the PLUGINS table.

If you recompile a plugin library and need to reinstall it, you can use either of the following methods:

- Use UNINSTALL PLUGIN to uninstall all plugins in the library, install the new plugin library file in the plugin directory, and then use INSTALL PLUGIN to install all plugins in the library. This procedure has the advantage that it can be used without stopping the server. However, if the plugin library contains many plugins, you must issue many INSTALL PLUGIN and UNINSTALL PLUGIN statements.

- Stop the server, install the new plugin library file in the plugin directory, and restart the server.

15.7.4.5 UNINSTALL COMPONENT Statement

UNINSTALL COMPONENT component_name [, component_name ] ...

This statement deactivates and uninstalls one or more components. A component provides services that are available to the server and other components; see Section 7.5, “MySQL Components”. UNINSTALL COMPONENT is the complement of INSTALL COMPONENT. It requires the DELETE privilege for the mysql.component system table because it removes the row from that table that registers the component. UNINSTALL COMPONENT does not undo persisted variables, including the variables persisted using INSTALL COMPONENT ... SET PERSIST.

Example:

UNINSTALL COMPONENT 'file://component1', 'file://component2';

For information about component naming, see Section 15.7.4.3, “INSTALL COMPONENT Statement”.

If any error occurs, the statement fails and has no effect. For example, this happens if a component name is erroneous, a named component is not installed, or cannot be uninstalled because other installed components depend on it.

A loader service handles component unloading, which includes removing uninstalled components from the mysql.component system table that serves as a registry. As a result, unloaded components are not loaded during the startup sequence for subsequent server restarts.

Note

This statement has no effect for keyring components, which are loaded using a manifest file and cannot be uninstalled. See Section 8.4.4.2, "Keyring Component Installation".

15.7.4.6 UNINSTALL PLUGIN Statement
UNINSTALL PLUGIN `plugin_name`

This statement removes an installed server plugin. `UNINSTALL PLUGIN` is the complement of `INSTALL PLUGIN`. It requires the `DELETE` privilege for the `mysql.plugin` system table because it removes the row from that table that registers the plugin.

`plugin_name` must be the name of some plugin that is listed in the `mysql.plugin` table. The server executes the plugin's deinitialization function and removes the row for the plugin from the `mysql.plugin` system table, so that subsequent server restarts do not load and initialize the plugin. `UNINSTALL PLUGIN` does not remove the plugin's shared library file.

You cannot uninstall a plugin if any table that uses it is open.

Plugin removal has implications for the use of associated tables. For example, if a full-text parser plugin is associated with a `FULLTEXT` index on the table, uninstalling the plugin makes the table unusable. Any attempt to access the table results in an error. The table cannot even be opened, so you cannot drop an index for which the plugin is used. This means that uninstalling a plugin is something to do with care unless you do not care about the table contents. If you are uninstalling a plugin with no intention of reinstalling it later and you care about the table contents, you should dump the table with `mysqldump` and remove the `WITH PARSER` clause from the dumped `CREATE TABLE` statement so that you can reload the table later. If you do not care about the table, `DROP TABLE` can be used even if any plugins associated with the table are missing.

For additional information about plugin loading, see Section 7.6.1, “Installing and Uninstalling Plugins”.

**15.7.5 CLONE Statement**

```sql
CLONE clone_action

clone_action: {
    LOCAL DATA DIRECTORY [=] 'clone_dir';
    INSTANCE FROM 'user'@'host':port
    IDENTIFIED BY 'password'
    [DATA DIRECTORY [=] 'clone_dir']
    [REQUIRE [NO] SSL]
}
```

The `CLONE` statement is used to clone data locally or from a remote MySQL server instance. To use `CLONE` syntax, the clone plugin must be installed. See Section 7.6.7, “The Clone Plugin”.

`CLONE LOCAL DATA DIRECTORY` syntax clones data from the local MySQL data directory to a directory on the same server or node where the MySQL server instance runs. The `clone_dir` directory is the full path of the local directory that data is cloned to. An absolute path is required. The specified directory must not exist, but the specified path must be an existent path. The MySQL server requires the necessary write access to create the specified directory. For more information, see Section 7.6.7.2, “Cloning Data Locally”.

`CLONE INSTANCE` syntax clones data from a remote MySQL server instance (the donor) and transfers it to the MySQL instance where the cloning operation was initiated (the recipient).

- `user` is the clone user on the donor MySQL server instance.
- `host` is the `hostname` address of the donor MySQL server instance. Internet Protocol version 6 (IPv6) address format is not supported. An alias to the IPv6 address can be used instead. An IPv4 address can be used as is.
- `port` is the `port` number of the donor MySQL server instance. (The X Protocol port specified by `mysqlx_port` is not supported. Connecting to the donor MySQL server instance through MySQL Router is also not supported.)
- `IDENTIFIED BY `password` specifies the password of the clone user on the donor MySQL server instance.
• **DATA DIRECTORY [=] 'clone_dir'** is an optional clause used to specify a directory on the recipient for the data you are cloning. Use this option if you do not want to remove existing data in the recipient data directory. An absolute path is required, and the directory must not exist. The MySQL server must have the necessary write access to create the directory.

When the optional **DATA DIRECTORY [=] 'clone_dir'** clause is not used, a cloning operation removes existing data in the recipient data directory, replaces it with the cloned data, and automatically restarts the server afterward.

• **[REQUIRE [NO] SSL]** explicitly specifies whether an encrypted connection is to be used or not when transferring cloned data over the network. An error is returned if the explicit specification cannot be satisfied. If an SSL clause is not specified, clone attempts to establish an encrypted connection by default, falling back to an insecure connection if the secure connection attempt fails. A secure connection is required when cloning encrypted data regardless of whether this clause is specified. For more information, see Configuring an Encrypted Connection for Cloning.

For additional information about cloning data from a remote MySQL server instance, see Section 7.6.7.3, “Cloning Remote Data”.

### 15.7.6 SET Statements

The **SET** statement has several forms. Descriptions for those forms that are not associated with a specific server capability appear in subsections of this section:

• **SET var_name = value** enables you to assign values to variables that affect the operation of the server or clients. See Section 15.7.6.1, “SET Syntax for Variable Assignment”.

• **SET CHARACTER SET** and **SET NAMES** assign values to character set and collation variables associated with the current connection to the server. See Section 15.7.6.2, “SET CHARACTER SET Statement”, and Section 15.7.6.3, “SET NAMES Statement”.

Descriptions for the other forms appear elsewhere, grouped with other statements related to the capability they help implement:

• **SET DEFAULT ROLE** and **SET ROLE** set the default role and current role for user accounts. See Section 15.7.1.9, “SET DEFAULT ROLE Statement”, and Section 15.7.1.11, “SET ROLE Statement”.

• **SET PASSWORD** assigns account passwords. See Section 15.7.1.10, “SET PASSWORD Statement”.

• **SET RESOURCE GROUP** assigns threads to a resource group. See Section 15.7.2.4, “SET RESOURCE GROUP Statement”.

• **SET TRANSACTION ISOLATION LEVEL** sets the isolation level for transaction processing. See Section 15.3.7, “SET TRANSACTION Statement”.

### 15.7.6.1 SET Syntax for Variable Assignment

```sql
SET variable = expr [, variable = expr] ...
```

**variable:**

- `user_var_name`
- `param_name`
- `local_var_name`
- `[GLOBAL | @@GLOBAL.] system_var_name`
- `[PERSIST | @@PERSIST.] system_var_name`
- `[PERSIST_ONLY | @@PERSIST_ONLY.] system_var_name`
- `[SESSION | @@SESSION.] system_var_name`

**SET** syntax for variable assignment enables you to assign values to different types of variables that affect the operation of the server or clients:

• User-defined variables. See Section 11.4, “User-Defined Variables”.

2816
- Stored procedure and function parameters, and stored program local variables. See Section 15.6.4, “Variables in Stored Programs”.

- System variables. See Section 7.1.8, “Server System Variables”. System variables also can be set at server startup, as described in Section 7.1.9, “Using System Variables”.

A `SET` statement that assigns variable values is not written to the binary log, so in replication scenarios it affects only the host on which you execute it. To affect all replication hosts, execute the statement on each host.

The following sections describe `SET` syntax for setting variables. They use the `=` assignment operator, but the `:=` assignment operator is also permitted for this purpose.

- User-Defined Variable Assignment
- Parameter and Local Variable Assignment
- System Variable Assignment
- SET Error Handling
- Multiple Variable Assignment
- System Variable References in Expressions

**User-Defined Variable Assignment**

User-defined variables are created locally within a session and exist only within the context of that session; see Section 11.4, “User-Defined Variables”.

A user-defined variable is written as `@var_name` and is assigned an expression value as follows:

```
SET @var_name = expr;
```

Examples:

```
SET @name = 43;
SET @total_tax = (SELECT SUM(tax) FROM taxable_transactions);
```

As demonstrated by those statements, `expr` can range from simple (a literal value) to more complex (the value returned by a scalar subquery).

The Performance Schema `user_variables_by_thread` table contains information about user-defined variables. See Section 29.12.10, “Performance Schema User-Defined Variable Tables”.

**Parameter and Local Variable Assignment**

`SET` applies to parameters and local variables in the context of the stored object within which they are defined. The following procedure uses the `increment` procedure parameter and `counter` local variable:

```
CREATE PROCEDURE p(increment INT)
BEGIN
  DECLARE counter INT DEFAULT 0;
  WHILE counter < 10 DO
    -- ... do work ...
    SET counter = counter + increment;
  END WHILE;
END;
```

**System Variable Assignment**

The MySQL server maintains system variables that configure its operation. A system variable can have a global value that affects server operation as a whole, a session value that affects the current...
session, or both. Many system variables are dynamic and can be changed at runtime using the `SET` statement to affect operation of the current server instance. `SET` can also be used to persist certain system variables to the `mysqld-auto.cnf` file in the data directory, to affect server operation for subsequent startups.

If a `SET` statement is issued for a sensitive system variable, the query is rewritten to replace the value with "<redacted>" before it is logged to the general log and audit log. This takes place even if secure storage through a keyring component is not available on the server instance.

If you change a session system variable, the value remains in effect within your session until you change the variable to a different value or the session ends. The change has no effect on other sessions.

If you change a global system variable, the value is remembered and used to initialize the session value for new sessions until you change the variable to a different value or the server exits. The change is visible to any client that accesses the global value. However, the change affects the corresponding session value only for clients that connect after the change. The global variable change does not affect the session value for any current client sessions (not even the session within which the global value change occurs).

To make a global system variable setting permanent so that it applies across server restarts, you can persist it to the `mysqld-auto.cnf` file in the data directory. It is also possible to make persistent configuration changes by manually modifying a `my.cnf` option file, but that is more cumbersome, and an error in a manually entered setting might not be discovered until much later. `SET` statements that persist system variables are more convenient and avoid the possibility of malformed settings because settings with syntax errors do not succeed and do not change server configuration. For more information about persisting system variables and the `mysqld-auto.cnf` file, see Section 7.1.9.3, “Persisted System Variables”.

**Note**

Setting or persisting a global system variable value always requires special privileges. Setting a session system variable value normally requires no special privileges and can be done by any user, although there are exceptions. For more information, see Section 7.1.9.1, “System Variable Privileges”.

The following discussion describes the syntax options for setting and persisting system variables:

- To assign a value to a global system variable, precede the variable name by the `GLOBAL` keyword or the `@@GLOBAL` qualifier:

  ```plaintext
  SET GLOBAL max_connections = 1000;
  SET @@GLOBAL.max_connections = 1000;
  ```

- To assign a value to a session system variable, precede the variable name by the `SESSION` or `LOCAL` keyword, by the `@@SESSION`, `@@LOCAL`, or `@@` qualifier, or by no keyword or no modifier at all:

  ```plaintext
  SET SESSION sql_mode = 'TRADITIONAL';
  SET LOCAL sql_mode = 'TRADITIONAL';
  SET @@SESSION.sql_mode = 'TRADITIONAL';
  SET @@LOCAL.sql_mode = 'TRADITIONAL';
  SET @sql_mode = 'TRADITIONAL';
  SET sql_mode = 'TRADITIONAL';
  ```

A client can change its own session variables, but not those of any other client.

- To persist a global system variable to the `mysqld-auto.cnf` option file in the data directory, precede the variable name by the `PERSIST` keyword or the `@@PERSIST` qualifier:

  ```plaintext
  SET PERSIST max_connections = 1000;
  SET @@PERSIST.max_connections = 1000;
  ```
This SET syntax enables you to make configuration changes at runtime that also persist across server restarts. Like SET GLOBAL, SET PERSIST sets the global variable runtime value, but also writes the variable setting to the mysql-auto.cnf file (replacing any existing variable setting if there is one).

- To persist a global system variable to the mysql-auto.cnf file without setting the global variable runtime value, precede the variable name by the PERSIST_ONLY keyword or the @@PERSIST_ONLY qualifier:

```sql
SET PERSIST_ONLY back_log = 100;
SET @@PERSIST_ONLY.back_log = 100;
```

Like PERSIST, PERSIST_ONLY writes the variable setting to mysql-auto.cnf. However, unlike PERSIST, PERSIST_ONLY does not modify the global variable runtime value. This makes PERSIST_ONLY suitable for configuring read-only system variables that can be set only at server startup.

To set a global system variable value to the compiled-in MySQL default value or a session system variable to the current corresponding global value, set the variable to the value DEFAULT. For example, the following two statements are identical in setting the session value of max_join_size to the current global value:

```sql
SET @@SESSION.max_join_size = DEFAULT;
SET @@SESSION.max_join_size = @@GLOBAL.max_join_size;
```

Using SET to persist a global system variable to a value of DEFAULT or to its literal default value assigns the variable its default value and adds a setting for the variable to mysql-auto.cnf. To remove the variable from the file, use RESET PERSIST.

Some system variables cannot be persisted or are persist-restricted. See Section 7.1.9.4, “Nonpersistible and Persist-Restricted System Variables”.

A system variable implemented by a plugin can be persisted if the plugin is installed when the SET statement is executed. Assignment of the persisted plugin variable takes effect for subsequent server restarts if the plugin is still installed. If the plugin is no longer installed, the plugin variable no longer exists when the server reads the mysql-auto.cnf file. In this case, the server writes a warning to the error log and continues:

```sql
currently unknown variable 'var_name'
was read from the persisted config file
```

To display system variable names and values:

- Use the SHOW VARIABLES statement; see Section 15.7.7.40, “SHOW VARIABLES Statement”.

- Several Performance Schema tables provide system variable information. See Section 29.12.14, “Performance Schema System Variable Tables”.

- The Performance Schema variables_info table contains information showing when and by which user each system variable was most recently set. See Section 29.12.14.2, “Performance Schema variables_info Table”.

- The Performance Schema persisted_variables table provides an SQL interface to the mysql-auto.cnf file, enabling its contents to be inspected at runtime using SELECT statements. See Section 29.12.14.1, “Performance Schema persisted_variables Table”.

**SET Error Handling**

If any variable assignment in a SET statement fails, the entire statement fails and no variables are changed, nor is the mysql-auto.cnf file changed.
SET produces an error under the circumstances described here. Most of the examples show SET statements that use keyword syntax (for example, GLOBAL or SESSION), but the principles are also true for statements that use the corresponding modifiers (for example, @@GLOBAL or @@SESSION.).

- Use of SET (any variant) to set a read-only variable:
  ```
  mysql> SET GLOBAL version = 'abc';
  ERROR 1238 (HY000): Variable 'version' is a read only variable
  ```

- Use of GLOBAL, PERSIST, or PERSIST_ONLY to set a variable that has only a session value:
  ```
  mysql> SET GLOBAL sql_log_bin = ON;
  ERROR 1228 (HY000): Variable 'sql_log_bin' is a SESSION variable and can't be used with SET GLOBAL
  ```

- Use of SESSION to set a variable that has only a global value:
  ```
  mysql> SET SESSION max_connections = 1000;
  ERROR 1229 (HY000): Variable 'max_connections' is a GLOBAL variable and should be set with SET GLOBAL
  ```

- Omission of GLOBAL, PERSIST, or PERSIST_ONLY to set a variable that has only a global value:
  ```
  mysql> SET max_connections = 1000;
  ERROR 1229 (HY000): Variable 'max_connections' is a GLOBAL variable and should be set with SET GLOBAL
  ```

- Use of PERSIST or PERSIST_ONLY to set a variable that cannot be persisted:
  ```
  mysql> SET PERSIST port = 3307;
  ERROR 1238 (HY000): Variable 'port' is a read only variable
  mysql> SET PERSIST_ONLY port = 3307;
  ERROR 1238 (HY000): Variable 'port' is a non persistent read only variable
  ```

- The @@GLOBAL., @@PERSIST., @@PERSIST_ONLY., @@SESSION., and @@ modifiers apply only to system variables. An error occurs for attempts to apply them to user-defined variables, stored procedure or function parameters, or stored program local variables.

- Not all system variables can be set to DEFAULT. In such cases, assigning DEFAULT results in an error.

- An error occurs for attempts to assign DEFAULT to user-defined variables, stored procedure or function parameters, or stored program local variables.

### Multiple Variable Assignment

A SET statement can contain multiple variable assignments, separated by commas. This statement assigns values to a user-defined variable and a system variable:

```
SET @x = 1, SESSION sql_mode = '';
```

If you set multiple system variables in a single statement, the most recent GLOBAL, PERSIST, PERSIST_ONLY, or SESSION keyword in the statement is used for following assignments that have no keyword specified.

Examples of multiple-variable assignment:

```
SET GLOBAL sort_buffer_size = 1000000, SESSION sort_buffer_size = 1000000;
SET @@GLOBAL.sort_buffer_size = 1000000, @@LOCAL.sort_buffer_size = 1000000;
SET GLOBAL max_connections = 1000, sort_buffer_size = 1000000;
```

The @@GLOBAL., @@PERSIST., @@PERSIST_ONLY., @@SESSION., and @@ modifiers apply only to the immediately following system variable, not any remaining system variables. This statement sets the sort_buffer_size global value to 50000 and the session value to 1000000:

```
SET @@GLOBAL.sort_buffer_size = 50000, sort_buffer_size = 1000000;
```
SHOW Statements

System Variable References in Expressions

To refer to the value of a system variable in expressions, use one of the @@-modifiers (except @@PERSIST and @@PERSIST_ONLY, which are not permitted in expressions). For example, you can retrieve system variable values in a SELECT statement like this:

SELECT @@GLOBAL.sql_mode, @@SESSION.sql_mode, @@sql_mode;

Note

A reference to a system variable in an expression as @@var_name (with @@ rather than @@GLOBAL. or @@SESSION.) returns the session value if it exists and the global value otherwise. This differs from SET @@var_name = expr, which always refers to the session value.

15.7.6.2 SET CHARACTER SET Statement

```
SET {CHARACTER SET | CHARSET}
   {'charset_name' | DEFAULT}
```

This statement maps all strings sent between the server and the current client with the given mapping. SET CHARACTER SET sets three session system variables: character_set_client and character_set_results are set to the given character set, and character_set_connection to the value of character_set_database. See Section 12.4, "Connection Character Sets and Collations".

```charsetName``` may be quoted or unquoted.

The default character set mapping can be restored by using the value DEFAULT. The default depends on the server configuration.

Some character sets cannot be used as the client character set. Attempting to use them with SET CHARACTER SET produces an error. See Impermissible Client Character Sets.

15.7.6.3 SET NAMES Statement

```
SET NAMES {'charsetName' ['COLLATE 'collation_name']} | DEFAULT]
```

This statement sets the three session system variables character_set_client, character_set_connection, and character_set_results to the given character set. Setting character_set_connection to charset_name also sets collation_connection to the default collation for charset_name. See Section 12.4, "Connection Character Sets and Collations".

The optional COLLATE clause may be used to specify a collation explicitly. If given, the collation must one of the permitted collations for charset_name.

```charsetName``` and ```collation_name``` may be quoted or unquoted.

The default mapping can be restored by using a value of DEFAULT. The default depends on the server configuration.

Some character sets cannot be used as the client character set. Attempting to use them with SET NAMES produces an error. See Impermissible Client Character Sets.

15.7.7 SHOW Statements

SHOW has many forms that provide information about databases, tables, columns, or status information about the server. This section describes those following:

SHOW BINARY LOG STATUS
SHOW Statements

SHOW BINARY LOGS
SHOW BINLOG EVENTS [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
SHOW {CHARACTER SET | CHARSET} [like_or_where]
SHOW COLLATION [like_or_where]
SHOW [FULL] COLUMNS FROM tbl_name [FROM db_name] [like_or_where]
SHOW CREATE DATABASE db_name
SHOW CREATE EVENT event_name
SHOW CREATE FUNCTION func_name
SHOW CREATE PROCEDURE proc_name
SHOW CREATE TABLE tbl_name
SHOW CREATE TRIGGER trigger_name
SHOW CREATE VIEW view_name
SHOW DATABASES [like_or_where]
SHOW ENGINE engine_name {STATUS | MUTEX}
SHOW [STORAGE] ENGINES
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW EVENTS
SHOW FUNCTION CODE func_name
SHOW FUNCTION STATUS [like_or_where]
SHOW GRANTS FOR user
SHOW INDEX FROM tbl_name [FROM db_name]
SHOW OPEN TABLES [FROM db_name] [like_or_where]
SHOW PLUGINS
SHOW PROCEDURE CODE proc_name
SHOW PROCEDURE STATUS [like_or_where]
SHOW PRIVILEGES
SHOW [FULL] PROCESSLIST
SHOW PROFILE [types] [FOR QUERY n] [OFFSET n] [LIMIT n]
SHOW PROFILES
SHOW RELAYLOG EVENTS [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
SHOW REPLICA STATUS [FOR CHANNEL channel]
SHOW REPLICAS
SHOW [GLOBAL | SESSION] STATUS [like_or_where]
SHOW TABLE STATUS [FROM db_name] [like_or_where]
SHOW [FULL] TABLES [FROM db_name] [like_or_where]
SHOW TRIGGERS [FROM db_name] [like_or_where]
SHOW [GLOBAL | SESSION] VARIABLES [like_or_where]
SHOW WARNINGS [LIMIT [offset,] row_count]

like_or_where: { LIKE 'pattern'
  | WHERE expr
}

If the syntax for a given SHOW statement includes a LIKE 'pattern' part, 'pattern' is a string that can contain the SQL % and _ wildcard characters. The pattern is useful for restricting statement output to matching values.

Several SHOW statements also accept a WHERE clause that provides more flexibility in specifying which rows to display. See Section 28.8, “Extensions to SHOW Statements”.

In SHOW statement results, user names and host names are quoted using backticks (`).

Many MySQL APIs (such as PHP) enable you to treat the result returned from a SHOW statement as you would a result set from a SELECT; see Chapter 31, Connectors and APIs, or your API documentation for more information. In addition, you can work in SQL with results from queries on tables in the INFORMATION_SCHEMA database, which you cannot easily do with results from SHOW statements. See Chapter 28, INFORMATION_SCHEMA Tables.

15.7.7.1 SHOW BINARY LOG STATUS Statement

SHOW BINARY LOG STATUS

This statement provides status information about binary log files on the source server, and requires the REPLICATION_CLIENT privilege (or the deprecated SUPER privilege).

Example:
SHOW Statements

mysql> SHOW BINARY LOG STATUS\G
*************************** 1. row ***************************
File: source-bin.000002
Position: 1307
Binlog_Do_DB: test
Binlog_Ignore_DB: manual, mysql
Executed_Gtid_Set: 3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5
1 row in set (0.00 sec)

When global transaction IDs are in use, Executed_Gtid_Set shows the set of GTIDs for transactions that have been executed on the source. This is the same as the value for the gtid_executed system variable on this server, as well as the value for Executed_Gtid_Set in the output of SHOW REPLICATION STATUS on this server.

15.7.7.2 SHOW BINARY LOGS Statement

SHOW BINARY LOGS

Lists the binary log files on the server. This statement is used as part of the procedure described in Section 15.4.1.1, “PURGE BINARY LOGS Statement”, that shows how to determine which logs can be purged. SHOW BINARY LOGS requires the REPLICATION CLIENT privilege (or the deprecated SUPER privilege).

Encrypted binary log files have a 512-byte file header that stores information required for encryption and decryption of the file. This is included in the file size displayed by SHOW BINARY LOGS. The Encrypted column shows whether or not the binary log file is encrypted. Binary log encryption is active if binlog_encryption=ON is set for the server. Existing binary log files are not encrypted or decrypted if binary log encryption is activated or deactivated while the server is running.

mysql> SHOW BINARY LOGS;
+---------------+-----------+-----------+
| Log_name      | File_size | Encrypted |
+---------------+-----------+-----------+
| binlog.000015 |    724935 |       Yes |
| binlog.000016 |    733481 |       Yes |
+---------------+-----------+-----------+

15.7.7.3 SHOW BINLOG EVENTS Statement

SHOW BINLOG EVENTS
[IN 'log_name']
[FROM pos]
[LIMIT [offset], row_count]

Shows the events in the binary log. If you do not specify 'log_name', the first binary log is displayed. SHOW BINLOG EVENTS requires the REPLICATION SLAVE privilege.

The LIMIT clause has the same syntax as for the SELECT statement. See Section 15.2.13, “SELECT Statement”.

Note

Issuing a SHOW BINLOG EVENTS with no LIMIT clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the binary log (which includes all statements executed by the server that modify data). As an alternative to SHOW BINLOG EVENTS, use the mysqlbinlog utility to save the binary log to a text file for later examination and analysis. See Section 6.6.9, “mysqlbinlog — Utility for Processing Binary Log Files”.

SHOW BINLOG EVENTS displays the following fields for each event in the binary log:

- Log_name
SHOW Statements

The name of the file that is being listed.

- **Pos**
The position at which the event occurs.

- **Event_type**
An identifier that describes the event type.

- **Server_id**
The server ID of the server on which the event originated.

- **End_log_pos**
The position at which the next event begins, which is equal to Pos plus the size of the event.

- **Info**
More detailed information about the event type. The format of this information depends on the event type.

For compressed transaction payloads, the Transaction_payload_event is first printed as a single unit, then it is unpacked and each event inside it is printed.

Some events relating to the setting of user and system variables are not included in the output from SHOW BINLOG EVENTS. To get complete coverage of events within a binary log, use mysqlbinlog.

SHOW BINLOG EVENTS does not work with relay log files. You can use SHOW RELAYLOG EVENTS for this purpose.

### 15.7.7.4 SHOW CHARACTER SET Statement

```
SHOW {CHARACTER SET | CHARSET} [LIKE 'pattern'| WHERE expr]
```

The SHOW CHARACTER SET statement shows all available character sets. The LIKE clause, if present, indicates which character set names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 28.8, “Extensions to SHOW Statements”. For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin%';
+---------+-----------------------------+-------------------+--------+
| Charset | Description                 | Default collation | Maxlen |
|---------+-----------------------------+-------------------+--------|
| latin1  | cp1252 West European        | latin1_swedish_ci |      1 |
| latin2  | ISO 8859-2 Central European | latin2_general_ci |      1 |
| latin5  | ISO 8859-9 Turkish          | latin5_turkish_ci |      1 |
| latin7  | ISO 8859-13 Baltic          | latin7_general_ci |      1 |
+---------+-----------------------------+-------------------+--------+
```

SHOW CHARACTER SET output has these columns:

- **Charset**
The character set name.

- **Description**
A description of the character set.

- **Default collation**
SHOW Statements

The default collation for the character set.

- **Maxlen**

  The maximum number of bytes required to store one character.

The `filename` character set is for internal use only; consequently, `SHOW CHARACTER SET` does not display it.

Character set information is also available from the `INFORMATION_SCHEMA CHARACTER_SETS` table.

### 15.7.7.5 SHOW COLLATION Statement

```
SHOW COLLATION [LIKE 'pattern' | WHERE expr]
```

This statement lists collations supported by the server. By default, the output from `SHOW COLLATION` includes all available collations. The `LIKE` clause, if present, indicates which collation names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 28.8, “Extensions to SHOW Statements”. For example:

```
mysql> SHOW COLLATION WHERE Charset = 'latin1';
```

<table>
<thead>
<tr>
<th>Collation</th>
<th>Charset</th>
<th>Id</th>
<th>Default</th>
<th>Compiled</th>
<th>Sortlen</th>
</tr>
</thead>
<tbody>
<tr>
<td>latin1_german1_ci</td>
<td>latin1</td>
<td>5</td>
<td></td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_swedish_ci</td>
<td>latin1</td>
<td>8</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_danish_ci</td>
<td>latin1</td>
<td>15</td>
<td></td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_german2_ci</td>
<td>latin1</td>
<td>31</td>
<td></td>
<td>Yes</td>
<td>2</td>
</tr>
<tr>
<td>latin1_bin</td>
<td>latin1</td>
<td>47</td>
<td>Yes</td>
<td></td>
<td>1</td>
</tr>
<tr>
<td>latin1_general_ci</td>
<td>latin1</td>
<td>48</td>
<td>Yes</td>
<td></td>
<td>1</td>
</tr>
<tr>
<td>latin1_general_cs</td>
<td>latin1</td>
<td>49</td>
<td>Yes</td>
<td></td>
<td>1</td>
</tr>
<tr>
<td>latin1_spanish_ci</td>
<td>latin1</td>
<td>94</td>
<td>Yes</td>
<td></td>
<td>1</td>
</tr>
</tbody>
</table>

`SHOW COLLATION` output has these columns:

- **Collation**

  The collation name.

- **Charset**

  The name of the character set with which the collation is associated.

- **Id**

  The collation ID.

- **Default**

  Whether the collation is the default for its character set.

- **Compiled**

  Whether the character set is compiled into the server.

- **Sortlen**

  This is related to the amount of memory required to sort strings expressed in the character set.

To see the default collation for each character set, use the following statement. `Default` is a reserved word, so to use it as an identifier, it must be quoted as such:
SHOW Statements

mysql> SHOW COLLATION WHERE `Default` = 'Yes';
+---------------------+----------+----+---------+----------+---------+
| Collation           | Charset  | Id | Default | Compiled | Sortlen |
+---------------------+----------+----+---------+----------+---------+
| big5_chinese_ci     | big5     |  1 | Yes     | Yes      |       1 |
| dec8_swedish_ci     | dec8     |  3 | Yes     | Yes      |       1 |
| cp850_general_ci    | cp850    |  4 | Yes     | Yes      |       1 |
| hp8_english_ci      | hp8      |  6 | Yes     | Yes      |       1 |
| koi8r_general_ci    | koi8r    |  7 | Yes     | Yes      |       1 |
| latin1_swedish_ci   | latin1   |  8 | Yes     | Yes      |       1 |
+---------------------+----------+----+---------+----------+---------+

Collation information is also available from the INFORMATION_SCHEMA COLLATIONS table. See Section 28.3.6, “The INFORMATION_SCHEMA COLLATIONS Table”.

15.7.7.6 SHOW COLUMNS Statement

SHOW [EXTENDED] [FULL] {COLUMNS | FIELDS}
    [FROM | IN] tbl_name
    [{FROM | IN} db_name]
    [LIKE 'pattern'] [WHERE expr]

SHOW COLUMNS displays information about the columns in a given table. It also works for views. SHOW COLUMNS displays information only for those columns for which you have some privilege.

mysql> SHOW COLUMNS FROM City;
+-------------+----------+------+-----+---------+----------------+
| Field       | Type     | Null | Key | Default | Extra          |
+-------------+----------+------+-----+---------+----------------+
| ID          | int(11)  | NO   | PRI | NULL    | auto_increment |
| Name        | char(35) | NO   |     |         |                |
| CountryCode | char(3)  | NO   | MUL |         |                |
| District    | char(20) | NO   |     |         |                |
| Population  | int(11)  | NO   | 0   |         |                |
+-------------+----------+------+-----+---------+----------------+

An alternative to tbl_name FROM db_name syntax is db_name.tbl_name. These two statements are equivalent:

SHOW COLUMNS FROM mytable FROM mydb;
SHOW COLUMNS FROM mydb.mytable;

The optional EXTENDED keyword causes the output to include information about hidden columns that MySQL uses internally and are not accessible by users.

The optional FULL keyword causes the output to include the column collation and comments, as well as the privileges you have for each column.

The LIKE clause, if present, indicates which column names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 28.8, “Extensions to SHOW Statements”.

The data types may differ from what you expect them to be based on a CREATE TABLE statement because MySQL sometimes changes data types when you create or alter a table. The conditions under which this occurs are described in Section 15.1.20.7, “Silent Column Specification Changes”.

SHOW COLUMNS displays the following values for each table column:

- **Field**
  The name of the column.

- **Type**
  The column data type.
SHOW Statements

- **Collation**
  
The collation for nonbinary string columns, or **NULL** for other columns. This value is displayed only if you use the **FULL** keyword.

- **Null**
  
The column nullability. The value is **YES** if **NULL** values can be stored in the column, **NO** if not.

- **Key**
  
  Whether the column is indexed:
  
  - If **Key** is empty, the column either is not indexed or is indexed only as a secondary column in a multiple-column, nonunique index.
  
  - If **Key** is **PRI**, the column is a **PRIMARY KEY** or is one of the columns in a multiple-column **PRIMARY KEY**.
  
  - If **Key** is **UNI**, the column is the first column of a **UNIQUE** index. (A **UNIQUE** index permits multiple **NULL** values, but you can tell whether the column permits **NULL** by checking the **Null** field.)
  
  - If **Key** is **MUL**, the column is the first column of a nonunique index in which multiple occurrences of a given value are permitted within the column.
  
  If more than one of the **Key** values applies to a given column of a table, **Key** displays the one with the highest priority, in the order **PRI**, **UNI**, **MUL**.

  A **UNIQUE** index may be displayed as **PRI** if it cannot contain **NULL** values and there is no **PRIMARY KEY** in the table. A **UNIQUE** index may display as **MUL** if several columns form a composite **UNIQUE** index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value.

- **Default**
  
The default value for the column. This is **NULL** if the column has an explicit default of **NULL**, or if the column definition includes no **DEFAULT** clause.

- **Extra**
  
  Any additional information that is available about a given column. The value is nonempty in these cases:
  
  - **auto_increment** for columns that have the **AUTO_INCREMENT** attribute.
  
  - **on update CURRENT_TIMESTAMP** for **TIMESTAMP** or **DATETIME** columns that have the **ON UPDATE CURRENT_TIMESTAMP** attribute.
  
  - **VIRTUAL GENERATED** or **STORED GENERATED** for generated columns.
  
  - **DEFAULT_GENERATED** for columns that have an expression default value.

- **Privileges**
  
  The privileges you have for the column. This value is displayed only if you use the **FULL** keyword.

- **Comment**
  
  Any comment included in the column definition. This value is displayed only if you use the **FULL** keyword.

Table column information is also available from the **INFORMATION_SCHEMA.COLUMNS** table. See Section 28.3.8, “The INFORMATION_SCHEMA.COLUMNS Table”. The extended information about
hidden columns is available only using `SHOW EXTENDED COLUMNS`; it cannot be obtained from the `COLUMNS` table.

You can list a table's columns with the `mysqlshow db_name tbl_name` command.

The `DESCRIBE` statement provides information similar to `SHOW COLUMNS`. See Section 15.8.1, “DESCRIBE Statement”.

The `SHOW CREATE TABLE`, `SHOW TABLE STATUS`, and `SHOW INDEX` statements also provide information about tables. See Section 15.7.7, “SHOW Statements”.

`SHOW COLUMNS` includes the table’s generated invisible primary key, if it has one, by default. You can cause this information to be suppressed in the statement's output by setting `show_gipk_in_create_table_and_information_schema = OFF`. For more information, see Section 15.1.20.11, “Generated Invisible Primary Keys”.

### 15.7.7.7 SHOW CREATE DATABASE Statement

```
SHOW CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
```

Shows the `CREATE DATABASE` statement that creates the named database. If the `SHOW` statement includes an `IF NOT EXISTS` clause, the output too includes such a clause. `SHOW CREATE SCHEMA` is a synonym for `SHOW CREATE DATABASE`.

```
mysql> SHOW CREATE DATABASE test\G
*************************** 1. row ***************************
  Database: test
  Create Database: CREATE DATABASE `test` /*!40100 DEFAULT CHARACTER SET utf8mb4 COLLATE utf8mb4_0900_ai_ci */ /*!80014 DEFAULT ENCRYPTION='N' */

mysql> SHOW CREATE SCHEMA test\G
*************************** 1. row ***************************
  Database: test
  Create Database: CREATE DATABASE `test` /*!40100 DEFAULT CHARACTER SET utf8mb4 COLLATE utf8mb4_0900_ai_ci */ /*!80014 DEFAULT ENCRYPTION='N' */
```

`SHOW CREATE DATABASE` quotes table and column names according to the value of the `sql_quote_show_create` option. See Section 7.1.8, “Server System Variables”.

### 15.7.7.8 SHOW CREATE EVENT Statement

```
SHOW CREATE EVENT event_name
```

This statement displays the `CREATE EVENT` statement needed to re-create a given event. It requires the `EVENT` privilege for the database from which the event is to be shown. For example (using the same event `e_daily` defined and then altered in Section 15.7.7.19, “SHOW EVENTS Statement”):

```
mysql> SHOW CREATE EVENT myschema.e_daily\G
*************************** 1. row ***************************
  Event: e_daily
  sql_mode: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,
            NO_ZERO_IN_DATE,NO_ZERO_DATE,
            ERROR_FOR_DIVISION_BY_ZERO,
            NO_ENGINE_SUBSTITUTION
time_zone: SYSTEM
  Create Event: CREATE DEFINER=`jon`@`ghidora` EVENT `e_daily`
               ON SCHEDULE EVERY 1 DAY
               STARTS CURRENT_TIMESTAMP + INTERVAL 6 HOUR
               ON COMPLETION NOT PRESERVE ENABLE
               COMMENT 'Saves total number of sessions then
                       clears the table each day'
               DO BEGIN
                   INSERT INTO site_activity.totals (time, total)
                   SELECT CURRENT_TIMESTAMP, COUNT(*)
               END END
```
SHOW Statements

SHOW Statements

FROM site_activity.sessions;
DELETE FROM site_activity.sessions;
END

character_set_client is the session value of the character_set_client system variable when the event was created. collation_connection is the session value of the collation_connection system variable when the event was created. Database Collation is the collation of the database with which the event is associated.

The output reflects the current status of the event (ENABLE) rather than the status with which it was created.

15.7.7.9 SHOW CREATE FUNCTION Statement

SHOW CREATE FUNCTION func_name

This statement is similar to SHOW CREATE PROCEDURE but for stored functions. See Section 15.7.7.10, “SHOW CREATE PROCEDURE Statement”.

15.7.7.10 SHOW CREATE PROCEDURE Statement

SHOW CREATE PROCEDURE proc_name

This statement is a MySQL extension. It returns the exact string that can be used to re-create the named stored procedure. A similar statement, SHOW CREATE FUNCTION, displays information about stored functions (see Section 15.7.7.9, “SHOW CREATE FUNCTION Statement”).

To use either statement, you must be the user named as the routine DEFINER, have the SHOW_ROUTINE privilege, have the SELECT privilege at the global level, or have the CREATE ROUTINE, ALTER ROUTINE, or EXECUTE privilege granted at a scope that includes the routine. The value displayed for the Create Procedure or Create Function field is NULL if you have only CREATE ROUTINE, ALTER ROUTINE, or EXECUTE.

mysql> SHOW CREATE PROCEDURE test.citycount\G
*************************** 1. row ***************************
Procedure: citycount
sql_mode: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,
NO_ZERO_IN_DATE,NO_ZERO_DATE,
ERROR_FOR_DIVISION_BY_ZERO,
NO_ENGINE_SUBSTITUTION
Create Procedure: CREATE DEFINER=`me`@`localhost`
PROCEDURE `citycount`(IN country VARCHAR(3), OUT cities INT)
BEGIN
SELECT COUNT(*) INTO cities FROM world.city
WHERE CountryCode = country;
END
character_set_client: utf8mb4
collation_connection: utf8mb4_0900_ai_ci
Database Collation: utf8mb4_0900_ai_ci
mysql>

mysql> SHOW CREATE FUNCTION test.hello\G
*************************** 1. row ***************************
Function: hello
sql_mode: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,
NO_ZERO_IN_DATE,NO_ZERO_DATE,
ERROR_FOR_DIVISION_BY_ZERO,
NO_ENGINE_SUBSTITUTION
Create Function: CREATE DEFINER=`me`@`localhost`
FUNCTION `hello`(s CHAR(20))
RETURNS char(50) CHARSET utf8mb4
DETERMINISTIC
RETURN CONCAT('Hello, ',s,'!')
character_set_client: utf8mb4
collation_connection: utf8mb4_0900_ai_ci
SHOW Statements

Database Collation: utf8mb4_0900_ai_ci

.character_set_client. is the session value of the character_set_client system variable when the routine was created. collation_connection is the session value of the collation_connection system variable when the routine was created. Database Collation is the collation of the database with which the routine is associated.

15.7.7.11 SHOW CREATE TABLE Statement

SHOW CREATE TABLE tbl_name

Shows the CREATE TABLE statement that creates the named table. To use this statement, you must have some privilege for the table. This statement also works with views.

SHOW CREATE TABLE,tbl_name

SHOW CREATE TABLE displays all CHECK constraints as table constraints. That is, a CHECK constraint originally specified as part of a column definition displays as a separate clause not part of the column definition. Example:

mysql> CREATE TABLE t1 (    
    
| i1 | INT CHECK (i1 <> 0), -- column constraint    
| i2 | INT,    
| CHECK (i2 > i1), -- table constraint    
| CHECK (i2 <> 0) NOT ENFORCED -- table constraint, not enforced    
|    
    
);

SHOW CREATE TABLE,t1

SHOW CREATE TABLE,tbl_name

SHOW CREATE TABLE quotes table and column names according to the value of the sql_quote_show_create option. See Section 7.1.8, "Server System Variables".

When altering the storage engine of a table, table options that are not applicable to the new storage engine are retained in the table definition to enable reverting the table with its previously defined options to the original storage engine, if necessary. For example, when changing the storage engine from InnoDB to MyISAM, options specific to InnoDB, such as ROW_FORMAT=COMPACT, are retained, as shown here:

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) ROW_FORMAT=COMPACT ENGINE=InnoDB;  
mysql> ALTER TABLE t1 ENGINE=MyISAM;  
mysql> SHOW CREATE TABLE t1

When creating a table with strict mode disabled, the storage engine's default row format is used if the specified row format is not supported. The actual row format of the table is reported in the

2830
SHOW Statements

**Row_format** column in response to `SHOW TABLE STATUS`. `SHOW CREATE TABLE` shows the row format that was specified in the `CREATE TABLE` statement.

`SHOW CREATE TABLE` also includes the definition of the table's generated invisible primary key, if it has such a key, by default. You can cause this information to be suppressed in the statement's output by setting `show_gipk_in_create_table_and_information_schema = OFF`. For more information, see Section 15.1.20.11, "Generated Invisible Primary Keys".

### 15.7.7.12 SHOW CREATE TRIGGER Statement

`SHOW CREATE TRIGGER trigger_name`

This statement shows the `CREATE TRIGGER` statement that creates the named trigger. This statement requires the `TRIGGER` privilege for the table associated with the trigger.

```sql
mysql> SHOW CREATE TRIGGER ins_sum;
```

```
*************************** 1. row ***************************
Trigger: ins_sum
sql_mode: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,
         NO_ZERO_IN_DATE,NO_ZERO_DATE,
         ERROR_FOR_DIVISION_BY_ZERO,
         NO_ENGINE_SUBSTITUTION
SQL Original Statement: CREATE DEFINER=`me`@`localhost` TRIGGER `ins_sum`
BEFORE INSERT ON `account`
FOR EACH ROW SET @sum = @sum + NEW.amount
character_set_client: utf8mb4
collation_connection: utf8mb4_0900_ai_ci
Database Collation: utf8mb4_0900_ai_ci
Created: 2018-08-08 10:10:12.61
```

`SHOW CREATE TRIGGER` output has these columns:

- **Trigger**: The trigger name.
- **sql_mode**: The SQL mode in effect when the trigger executes.
- **SQL Original Statement**: The `CREATE TRIGGER` statement that defines the trigger.
- **character_set_client**: The session value of the `character_set_client` system variable when the trigger was created.
- **collation_connection**: The session value of the `collation_connection` system variable when the trigger was created.
- **Database Collation**: The collation of the database with which the trigger is associated.
- **Created**: The date and time when the trigger was created. This is a `TIMESTAMP(2)` value (with a fractional part in hundredths of seconds) for triggers.

Trigger information is also available from the `INFORMATION_SCHEMA TRIGGERS` table. See Section 28.3.44, "The INFORMATION_SCHEMA TRIGGERS Table".

### 15.7.7.13 SHOW CREATE USER Statement

`SHOW CREATE USER user`

This statement shows the `CREATE USER` statement that creates the named user. An error occurs if the user does not exist. The statement requires the `SELECT` privilege for the `mysql` system schema, except to see information for the current user. For the current user, the `SELECT` privilege for the `mysql.user` system table is required for display of the password hash in the `IDENTIFIED AS` clause; otherwise, the hash displays as `<secret>`.

To name the account, use the format described in Section 8.2.4, "Specifying Account Names". The host name part of the account name, if omitted, defaults to ‘%’. It is also possible to specify `CURRENT_USER` or `CURRENT_USER()` to refer to the account associated with the current session.
Password hash values displayed in the IDENTIFIED WITH clause of output from SHOW CREATE USER may contain unprintable characters that have adverse effects on terminal displays and in other environments. Enabling the print_identified_with_as_hex system variable causes SHOW CREATE USER to display such hash values as hexadecimal strings rather than as regular string literals. Hash values that do not contain unprintable characters still display as regular string literals, even with this variable enabled.

```sql
mysql> CREATE USER 'u1'@'localhost' IDENTIFIED BY 'secret';
mysql> SET print_identified_with_as_hex = ON;
mysql> SHOW CREATE USER 'u1'@'localhost'
```

```
*************************** 1. row ***************************
CREATE USER for u1@localhost: CREATE USER `u1`@`localhost` IDENTIFIED WITH 'caching_sha2_password'
AS 0x244124303035240C7745603626313D613C4C10633E0A104B1E14135A544A7871567245614F4F872344643546336546F624F6C78
REQUIRE NONE PASSWORD EXPIRE DEFAULT ACCOUNT UNLOCK PASSWORD HISTORY DEFAULT PASSWORD REUSE INTERVAL DEFAULT
PASSWORD REQUIRE CURRENT DEFAULT
```

To display the privileges granted to an account, use the SHOW GRANTS statement. See Section 15.7.7.22, “SHOW GRANTS Statement”.

15.7.7.14 SHOW CREATE VIEW Statement

```sql
SHOW CREATE VIEW view_name
```

This statement shows the CREATE VIEW statement that creates the named view.

```sql
mysql> SHOW CREATE VIEW v
```

```
*************************** 1. row ***************************
View: v
  Create View: CREATE ALGORITHM=UNDEFINED
              DEFINER=`bob`@`localhost`
              SQL SECURITY DEFINER VIEW
              `v` AS select 1 AS `a`, 2 AS `b`
character_set_client: utf8mb4
collation_connection: utf8mb4_0900_ai_ci
```

`character_set_client` is the session value of the `character_set_client` system variable when the view was created. `collation_connection` is the session value of the `collation_connection` system variable when the view was created.

Use of `SHOW CREATE VIEW` requires the `SHOW VIEW` privilege, and the `SELECT` privilege for the view in question.

View information is also available from the INFORMATION_SCHEMA VIEWS table. See Section 28.3.47, “The INFORMATION_SCHEMA VIEWS Table”.

MySQL lets you use different `sql_mode` settings to tell the server the type of SQL syntax to support. For example, you might use the ANSI SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (||), in your queries. If you then create a view that concatenates items, you might worry that changing the `sql_mode` setting to a value different from ANSI could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a CONCAT() function:

```sql
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as coll;
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW CREATE VIEW test.v
```

```
*************************** 1. row ***************************
View: v
  Create View: CREATE VIEW "v" AS select concat('a','b') AS "coll"
... 1 row in set (0.00 sec)
```
The advantage of storing a view definition in canonical form is that changes made later to the value of `sql_mode` do not affect the results from the view. However an additional consequence is that comments prior to `SELECT` are stripped from the definition by the server.

### 15.7.7.15 SHOW DATABASES Statement

```sql
SHOW {DATABASES | SCHEMAS}
[LIKE 'pattern' | WHERE expr]
```

*SHOW DATABASES* lists the databases on the MySQL server host. *SHOW SCHEMAS* is a synonym for *SHOW DATABASES*. The `LIKE` clause, if present, indicates which database names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 28.8, “Extensions to SHOW Statements”.

You see only those databases for which you have some kind of privilege, unless you have the global *SHOW DATABASES* privilege. You can also get this list using the `mysqlshow` command.

If the server was started with the `--skip-show-database` option, you cannot use this statement at all unless you have the *SHOW DATABASES* privilege.

MySQL implements databases as directories in the data directory, so this statement simply lists directories in that location. However, the output may include names of directories that do not correspond to actual databases.

Database information is also available from the `INFORMATION_SCHEMA SCHEMATA` table. See Section 28.3.31, “The INFORMATION_SCHEMA SCHEMATA Table”.

**Caution**
Because any static global privilege is considered a privilege for all databases, any static global privilege enables a user to see all database names with *SHOW DATABASES* or by examining the `SCHEMATA` table of `INFORMATION_SCHEMA`, except databases that have been restricted at the database level by partial revokes.

### 15.7.7.16 SHOW ENGINE Statement

```sql
SHOW ENGINE engine_name {STATUS | MUTEX}
```

*SHOW ENGINE* displays operational information about a storage engine. It requires the `PROCESS` privilege. The statement has these variants:

*SHOW ENGINE INNODB STATUS*
*SHOW ENGINE INNODB MUTEX*
*SHOW ENGINE PERFORMANCE_SCHEMA STATUS*

*SHOW ENGINE INNODB STATUS* displays extensive information from the standard InnoDB Monitor about the state of the InnoDB storage engine. For information about the standard monitor and other InnoDB Monitors that provide information about InnoDB processing, see Section 17.17, “InnoDB Monitors”.

*SHOW ENGINE INNODB MUTEX* displays InnoDB `mutex` and `rw-lock` statistics.

**Note**

InnoDB mutexes and rwlocks can also be monitored using Performance Schema tables. See Section 17.16.2, “Monitoring InnoDB Mutex Waits Using Performance Schema”.

Mutex statistics collection is configured dynamically using the following options:

- To enable the collection of mutex statistics, run:
SHOW Statements

```sql
SET GLOBAL innodb_monitor_enable='latch';

- To reset mutex statistics, run:
  ```sql
  SET GLOBAL innodb_monitor_reset='latch';
  ```

- To disable the collection of mutex statistics, run:
  ```sql
  SET GLOBAL innodb_monitor_disable='latch';
  ```

Collection of mutex statistics for `SHOW ENGINE INNODB_MUTEX` can also be enabled by setting `innodb_monitor_enable='all'`, or disabled by setting `innodb_monitor_disable='all'`.

`SHOW ENGINE INNODB_MUTEX` output has these columns:

- **Type**
  - Always InnoDB.

- **Name**
  For mutexes, the `Name` field reports only the mutex name. For rwlocks, the `Name` field reports the source file where the rwlock is implemented, and the line number in the file where the rwlock is created. The line number is specific to your version of MySQL.

- **Status**
  The mutex status. This field reports the number of spins, waits, and calls. Statistics for low-level operating system mutexes, which are implemented outside of InnoDB, are not reported.
  - **spins** indicates the number of spins.
  - **waits** indicates the number of mutex waits.
  - **calls** indicates how many times the mutex was requested.

`SHOW ENGINE INNODB_MUTEX` does not list mutexes and rw-locks for each buffer pool block, as the amount of output would be overwhelming on systems with a large buffer pool. `SHOW ENGINE INNODB_MUTEX` does, however, print aggregate `BUF_BLOCK_MUTEX` spin, wait, and call values for buffer pool block mutexes and rw-locks. `SHOW ENGINE INNODB_MUTEX` also does not list any mutexes or rw-locks that have never been waited on (`os_waits=0`). Thus, `SHOW ENGINE INNODB_MUTEX` only displays information about mutexes and rw-locks outside of the buffer pool that have caused at least one OS-level wait.

Use `SHOW ENGINE PERFORMANCE_SCHEMA STATUS` to inspect the internal operation of the Performance Schema code:

```sql
mysql> SHOW ENGINE PERFORMANCE_SCHEMA STATUS\G
...  
*************************** 3. row ***************************
| Type: performance_schema | Name: events_waits_history.size | Status: 76 |
*************************** 4. row ***************************
| Type: performance_schema | Name: events_waits_history.count | Status: 10000 |
*************************** 5. row ***************************
| Type: performance_schema | Name: events_waits_history.memory | Status: 760000 |
...  
*************************** 57. row ***************************
| Type: performance_schema | Name: performance_schema.memory | 2834 |
```
This statement is intended to help the DBA understand the effects that different Performance Schema options have on memory requirements.

**Name** values consist of two parts, which name an internal buffer and a buffer attribute, respectively. Interpret buffer names as follows:

- An internal buffer that is not exposed as a table is named within parentheses. Examples: 
  
  `(pfs_cond_class).size, (pfs_mutex_class).memory`

- An internal buffer that is exposed as a table in the `performance_schema` database is named after the table, without parentheses. Examples: 
  
  `events_waits_history.size, mutex_instances.count`

- A value that applies to the Performance Schema as a whole begins with `performance_schema`. Example: `performance_schema.memory`

Buffer attributes have these meanings:

- **size** is the size of the internal record used by the implementation, such as the size of a row in a table. **size** values cannot be changed.

- **count** is the number of internal records, such as the number of rows in a table. **count** values can be changed using Performance Schema configuration options.

- For a table, `tbl_name.memory` is the product of **size** and **count**. For the Performance Schema as a whole, `performance_schema.memory` is the sum of all the memory used (the sum of all other **memory** values).

In some cases, there is a direct relationship between a Performance Schema configuration parameter and a **SHOW ENGINE** value. For example, `events_waits_history_long.count` corresponds to `performance_schema_events_waits_history_long_size`. In other cases, the relationship is more complex. For example, `events_waits_history.count` corresponds to `performance_schema_events_waits_history_size` (the number of rows per thread) multiplied by `performance_schema_max_thread_instances` (the number of threads).

**SHOW ENGINE NDB STATUS.** If the server has the NDB storage engine enabled, **SHOW ENGINE NDB STATUS** displays cluster status information such as the number of connected data nodes, the cluster connectstring, and cluster binary log epochs, as well as counts of various Cluster API objects created by the MySQL Server when connected to the cluster. Sample output from this statement is shown here:

```sql
mysql> SHOW ENGINE NDB STATUS;
+------------+-----------------------+--------------------------------------------------+
| Type       | Name                  | Status                                           |
+------------+-----------------------+--------------------------------------------------+
| ndbcluster | connection            | cluster_node_id=7, connected_host=198.51.100.103, connected_port=1186, number_of_data_nodes=4, number_of_ready_data_nodes=3, connect_count=0 |
| ndbcluster | NdbTransaction        | created=6, free=0, sizeof=212                    |
| ndbcluster | NdbOperation          | created=8, free=8, sizeof=660                    |
| ndbcluster | NdbIndexScanOperation | created=1, free=1, sizeof=744                    |
| ndbcluster | NdbIndexOperation     | created=0, free=0, sizeof=664                    |
| ndbcluster | NdbRecAttr            | created=1285, free=1285, sizeof=60               |
| ndbcluster | NdbApiSignal          | created=16, free=16, sizeof=136                  |
| ndbcluster | NdbLabel              | created=0, free=0, sizeof=196                    |
| ndbcluster | NdbBranch             | created=0, free=0, sizeof=24                     |
| ndbcluster | NdbSubroutine         | created=0, free=0, sizeof=68                     |
| ndbcluster | NdbCall               | created=0, free=0, sizeof=16                     |
| ndbcluster | NdbBlob               | created=1, free=1, sizeof=264                    |
| ndbcluster | NdbReceiver           | created=4, free=0, sizeof=68                     |
| ndbcluster | binlog                | latest_epoch=155467, latest_trans_epoch=148126, latest_received_binlog_epoch=0, latest_handled_binlog_epoch=0, latest_applied_binlog_epoch=0 |
+------------+-----------------------+--------------------------------------------------+
```
The Status column in each of these rows provides information about the MySQL server's connection to the cluster and about the cluster binary log's status, respectively. The Status information is in the form of comma-delimited set of name-value pairs.

The connection row's Status column contains the name-value pairs described in the following table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>cluster_node_id</td>
<td>The node ID of the MySQL server in the cluster</td>
</tr>
<tr>
<td>connected_host</td>
<td>The host name or IP address of the cluster management server to which the MySQL server is connected</td>
</tr>
<tr>
<td>connected_port</td>
<td>The port used by the MySQL server to connect to the management server (connected_host)</td>
</tr>
<tr>
<td>number_of_data_nodes</td>
<td>The number of data nodes configured for the cluster (that is, the number of [ndbd] sections in the cluster config.ini file)</td>
</tr>
<tr>
<td>number_of_ready_data_nodes</td>
<td>The number of data nodes in the cluster that are actually running</td>
</tr>
<tr>
<td>connect_count</td>
<td>The number of times this mysqld has connected or reconnected to cluster data nodes</td>
</tr>
</tbody>
</table>

The binlog row's Status column contains information relating to NDB Cluster Replication. The name-value pairs it contains are described in the following table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>latest_epoch</td>
<td>The most recent epoch most recently run on this MySQL server (that is, the sequence number of the most recent transaction run on the server)</td>
</tr>
<tr>
<td>latest_trans_epoch</td>
<td>The most recent epoch processed by the cluster's data nodes</td>
</tr>
<tr>
<td>latest_received_binlog_epoch</td>
<td>The most recent epoch received by the binary log thread</td>
</tr>
<tr>
<td>latest_handled_binlog_epoch</td>
<td>The most recent epoch processed by the binary log thread (for writing to the binary log)</td>
</tr>
<tr>
<td>latest_applied_binlog_epoch</td>
<td>The most recent epoch actually written to the binary log</td>
</tr>
</tbody>
</table>

See Section 25.7, “NDB Cluster Replication”, for more information.

The remaining rows from the output of SHOW ENGINE NDB STATUS which are most likely to prove useful in monitoring the cluster are listed here by Name:

- **NdbTransaction**: The number and size of NdbTransaction objects that have been created. An NdbTransaction is created each time a table schema operation (such as CREATE TABLE or ALTER TABLE) is performed on an NDB table.

- **NdbOperation**: The number and size of NdbOperation objects that have been created.

- **NdbIndexScanOperation**: The number and size of NdbIndexScanOperation objects that have been created.

- **NdbIndexOperation**: The number and size of NdbIndexOperation objects that have been created.
SHOW Statements

- **NdbRecAttr**: The number and size of `NdbRecAttr` objects that have been created. In general, one of these is created each time a data manipulation statement is performed by an SQL node.

- **NdbBlob**: The number and size of `NdbBlob` objects that have been created. An `NdbBlob` is created for each new operation involving a BLOB column in an NDB table.

- **NdbReceiver**: The number and size of any `NdbReceiver` object that have been created. The number in the `created` column is the same as the number of data nodes in the cluster to which the MySQL server has connected.

**Note**

`SHOW ENGINE NDB STATUS` returns an empty result if no operations involving NDB tables have been performed during the current session by the MySQL client accessing the SQL node on which this statement is run.

15.7.17 SHOW ENGINES Statement

```
SHOW [STORAGE] ENGINES

SHOW ENGINES displays status information about the server’s storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is.

For information about MySQL storage engines, see Chapter 17, The InnoDB Storage Engine, and Chapter 18, Alternative Storage Engines.
```

```sql
mysql> SHOW ENGINES\G
*************************** 1. row ***************************
   Engine: MEMORY
   Support: YES
   Comment: Hash based, stored in memory, useful for temporary tables
Transactions: NO
 XA: NO
Savepoints: NO
*************************** 2. row ***************************
   Engine: InnoDB
   Support: DEFAULT
   Comment: Supports transactions, row-level locking, and foreign keys
Transactions: YES
 XA: YES
Savepoints: YES
*************************** 3. row ***************************
   Engine: PERFORMANCE_SCHEMA
   Support: YES
   Comment: Performance Schema
Transactions: NO
 XA: NO
Savepoints: NO
*************************** 4. row ***************************
   Engine: MyISAM
   Support: YES
   Comment: MyISAM storage engine
Transactions: NO
 XA: NO
Savepoints: NO
*************************** 5. row ***************************
   Engine: MRG_MYISAM
   Support: YES
   Comment: Collection of identical MyISAM tables
Transactions: NO
 XA: NO
Savepoints: NO
*************************** 6. row ***************************
   Engine: BLACKHOLE
   Support: YES
   Comment: /dev/null storage engine (anything you write to it disappears)
Transactions: NO
 XA: NO
```
SHOW Statements

The output from `SHOW ENGINES` may vary according to the MySQL version used and other factors.

`SHOW ENGINES` output has these columns:

- **Engine**
  The name of the storage engine.

- **Support**
  The server's level of support for the storage engine, as shown in the following table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>YES</td>
<td>The engine is supported and is active</td>
</tr>
<tr>
<td>DEFAULT</td>
<td>Like YES, plus this is the default engine</td>
</tr>
<tr>
<td>NO</td>
<td>The engine is not supported</td>
</tr>
<tr>
<td>DISABLED</td>
<td>The engine is supported but has been disabled</td>
</tr>
</tbody>
</table>

A value of **NO** means that the server was compiled without support for the engine, so it cannot be enabled at runtime.

A value of **DISABLED** occurs either because the server was started with an option that disables the engine, or because not all options required to enable it were given. In the latter case, the error log should contain a reason indicating why the option is disabled. See Section 7.4.2, “The Error Log”.

You might also see **DISABLED** for a storage engine if the server was compiled to support it, but was started with a `--skip-engine_name` option. For the NDB storage engine, **DISABLED** means the server was compiled with support for NDB Cluster, but was not started with the `--ndbcluster` option.

All MySQL servers support **MyISAM** tables. It is not possible to disable **MyISAM**.

- **Comment**
  A brief description of the storage engine.

- **Transactions**
  Whether the storage engine supports transactions.

- **XA**
  Whether the storage engine supports XA transactions.

- **Savepoints**
  Whether the storage engine supports savepoints.
Storage engine information is also available from the `INFORMATION_SCHEMA ENGINES` table. See Section 28.3.13, “The INFORMATION_SCHEMA ENGINES Table”.

### 15.7.7.18 SHOW ERRORS Statement

```
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW COUNT(*) ERRORS
```

`SHOW ERRORS` is a diagnostic statement that is similar to `SHOW WARNINGS`, except that it displays information only for errors, rather than for errors, warnings, and notes.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See Section 15.2.13, “SELECT Statement”.

The `SHOW COUNT(*) ERRORS` statement displays the number of errors. You can also retrieve this number from the `error_count` variable:

```
SHOW COUNT(*) ERRORS;
SELECT @@error_count;
```

`SHOW ERRORS` and `error_count` apply only to errors, not warnings or notes. In other respects, they are similar to `SHOW WARNINGS` and `warning_count`. In particular, `SHOW ERRORS` cannot display information for more than `max_error_count` messages, and `error_count` can exceed the value of `max_error_count` if the number of errors exceeds `max_error_count`.

For more information, see Section 15.7.7.41, “SHOW WARNINGS Statement”.

### 15.7.7.19 SHOW EVENTS Statement

```
SHOW EVENTS [[FROM | IN] schema_name]
[LIKE 'pattern' | WHERE expr]
```

This statement displays information about Event Manager events, which are discussed in Section 27.4, “Using the Event Scheduler”. It requires the `EVENT` privilege for the database from which the events are to be shown.

In its simplest form, `SHOW EVENTS` lists all of the events in the current schema:

```
mysql> SELECT CURRENT_USER(), SCHEMA();
+----------------+----------+
| CURRENT_USER() | SCHEMA() |
+----------------+----------+
| jon@ghidora    | myschema |
+----------------+----------+
1 row in set (0.00 sec)
```

```
mysql> SHOW EVENTS\G
*************************** 1. row ***************************
Db: myschema
Name: e_daily
Definer: jon@ghidora
Time zone: SYSTEM
Type: RECURRING
Execute at: NULL
Interval value: 1
Interval field: DAY
Starts: 2018-08-08 11:06:34
Ends: NULL
Status: ENABLED
Originator: 1
character_set_client: utf8mb4
collation_connection: utf8mb4_0900_ai_ci
Database Collation: utf8mb4_0900_ai_ci
```

To see events for a specific schema, use the `FROM` clause. For example, to see events for the `test` schema, use the following statement:
**SHOW EVENTS FROM** test;

The **LIKE** clause, if present, indicates which event names to match. The **WHERE** clause can be given to select rows using more general conditions, as discussed in **Section 28.8, “Extensions to SHOW Statements”**.

**SHOW EVENTS** output has these columns:

- **Db**
  The name of the schema (database) to which the event belongs.

- **Name**
  The name of the event.

- **Definer**
  The account of the user who created the event, in ‘*user_name*@’*host_name*’ format.

- **Time zone**
  The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is **SYSTEM**.

- **Type**
  The event repetition type, either **ONE_TIME** (transient) or **RECURRING** (repeating).

- **Execute At**
  For a one-time event, this is the **DATETIME** value specified in the **AT** clause of the **CREATE EVENT** statement used to create the event, or of the last **ALTER EVENT** statement that modified the event. The value shown in this column reflects the addition or subtraction of any **INTERVAL** value included in the event's **AT** clause. For example, if an event is created using **ON_SCHEDULE AT CURRENT_TIMESTAMP + '1:6' DAY_HOUR**, and the event was created at 2018-02-09 14:05:30, the value shown in this column would be '2018-02-10 20:05:30'. If the event's timing is determined by an **EVERY** clause instead of an **AT** clause (that is, if the event is recurring), the value of this column is **NULL**.

- **Interval Value**
  For a recurring event, the number of intervals to wait between event executions. For a transient event, the value of this column is always **NULL**.

- **Interval Field**
  The time units used for the interval which a recurring event waits before repeating. For a transient event, the value of this column is always **NULL**.

- **Starts**
  The start date and time for a recurring event. This is displayed as a **DATETIME** value, and is **NULL** if no start date and time are defined for the event. For a transient event, this column is always **NULL**. For a recurring event whose definition includes a **STARTS** clause, this column contains the corresponding **DATETIME** value. As with the **Execute At** column, this value resolves any expressions used. If there is no **STARTS** clause affecting the timing of the event, this column is **NULL**.

- **Ends**
  For a recurring event whose definition includes a **ENDS** clause, this column contains the corresponding **DATETIME** value. As with the **Execute At** column, this value resolves any expressions used. If there is no **ENDS** clause affecting the timing of the event, this column is **NULL**.
• **Status**

The event status. One of **ENABLED**, **DISABLED**, or **REPLICA_SIDE_DISABLED**.

**REPLICA_SIDE_DISABLED** indicates that the creation of the event occurred on another MySQL server acting as a replication source and replicated to the current MySQL server which is acting as a replica, but the event is not presently being executed on the replica. For more information, see Section 19.5.1.16, “Replication of Invoked Features”. information.

**REPLICA_SIDE_DISABLED** replaces **SLAVESIDE_DISABLED**, which is now deprecated and subject to removal in a future version of MySQL.

• **Originator**

The server ID of the MySQL server on which the event was created; used in replication. This value may be updated by `ALTER EVENT` to the server ID of the server on which that statement occurs, if executed on a source server. The default value is 0.

• **character_set_client**

The session value of the `character_set_client` system variable when the event was created.

• **collation_connection**

The session value of the `collation_connection` system variable when the event was created.

• **Database Collation**

The collation of the database with which the event is associated.

For more information about **REPLICA_SIDE_DISABLED** and the **Originator** column, see Section 19.5.1.16, “Replication of Invoked Features”.

Times displayed by `SHOW EVENTS` are given in the event time zone, as discussed in Section 27.4.4, “Event Metadata”.

Event information is also available from the `INFORMATION_SCHEMA EVENTS` table. See Section 28.3.14, “The INFORMATION_SCHEMA EVENTS Table”.

The event action statement is not shown in the output of `SHOW EVENTS`. Use `SHOW CREATE EVENT` or the `INFORMATION_SCHEMA EVENTS` table.

**15.7.7.20 SHOW FUNCTION CODE Statement**

```
SHOW FUNCTION CODE  func_name
```

This statement is similar to `SHOW PROCEDURE CODE` but for stored functions. See Section 15.7.7.28, “SHOW PROCEDURE CODE Statement”.

**15.7.7.21 SHOW FUNCTION STATUS Statement**

```
SHOW FUNCTION STATUS
    [LIKE 'pattern' | WHERE expr]
```

This statement is similar to `SHOW PROCEDURE STATUS` but for stored functions. See Section 15.7.7.29, “SHOW PROCEDURE STATUS Statement”.

**15.7.7.22 SHOW GRANTS Statement**

```
SHOW GRANTS
    [FOR user_or_role
      [USING role [, role] ...]]
```
SHOW Statements

This statement displays the privileges and roles that are assigned to a MySQL user account or role, in the form of `GRANT` statements that must be executed to duplicate the privilege and role assignments.

**Note**

To display nonprivilege information for MySQL accounts, use the `SHOW CREATE USER` statement. See Section 15.7.7.13, “SHOW CREATE USER Statement”.

`SHOW GRANTS` requires the `SELECT` privilege for the `mysql` system schema, except to display privileges and roles for the current user.

To name the account or role for `SHOW GRANTS`, use the same format as for the `GRANT` statement (for example, `'jeffrey'@'localhost'`):

```sql
mysql> SHOW GRANTS FOR 'jeffrey'@'localhost';
+------------------------------------------------------------------+
| Grants for jeffrey@localhost                                     |
+------------------------------------------------------------------+
| GRANT USAGE ON *.* TO `jeffrey`@`localhost`                      |
| GRANT SELECT, INSERT, UPDATE ON `db1`.* TO `jeffrey`@`localhost` |
+------------------------------------------------------------------+
```

The host part, if omitted, defaults to `'%'`. For additional information about specifying account and role names, see Section 8.2.4, “Specifying Account Names”, and Section 8.2.5, “Specifying Role Names”.

To display the privileges granted to the current user (the account you are using to connect to the server), you can use any of the following statements:

- `SHOW GRANTS;`
- `SHOW GRANTS FOR CURRENT_USER;`
- `SHOW GRANTS FOR CURRENT_USER();`

If `SHOW GRANTS FOR CURRENT_USER` (or any equivalent syntax) is used in definer context, such as within a stored procedure that executes with definer rather than invoker privileges, the grants displayed are those of the definer and not the invoker.

In MySQL 8.4 compared to previous series, `SHOW GRANTS` no longer displays `ALL PRIVILEGES` in its global-privileges output because the meaning of `ALL PRIVILEGES` at the global level varies depending on which dynamic privileges are defined. Instead, `SHOW GRANTS` explicitly lists each granted global privilege:

```sql
mysql> SHOW GRANTS FOR 'root'@'localhost';
+---------------------------------------------------------------------+
| Grants for root@localhost                                           |
+---------------------------------------------------------------------+
| GRANT SELECT, INSERT, UPDATE, DELETE, CREATE, DROP, RELOAD,         |
| SHUTDOWN, PROCESS, FILE, REFERENCES, INDEX, ALTER, SHOW DATABASES, |
| SUPER, CREATE TEMPORARY TABLES, LOCK TABLES, EXECUTE, REPLICATION   |
| SLAVE, REPLICATION CLIENT, CREATE VIEW, SHOW VIEW, CREATE ROUTINE,  |
| ALTER ROUTINE, CREATE USER, EVENT, TRIGGER, CREATE TABLESPACE,     |
| CREATE ROLE, DROP ROLE ON *.* TO `root'@'localhost' WITH GRANT      |
| OPTION |
| GRANT PROXY ON ''@'' TO `root'@'localhost' WITH GRANT OPTION        |
+---------------------------------------------------------------------+
```

Applications that process `SHOW GRANTS` output should be adjusted accordingly.

At the global level, `GRANT OPTION` applies to all granted static global privileges if granted for any of them, but applies individually to granted dynamic privileges. `SHOW GRANTS` displays global privileges this way:
SHOW Statements

- One line listing all granted static privileges, if there are any, including `WITH GRANT OPTION` if appropriate.
- One line listing all granted dynamic privileges for which `GRANT OPTION` is granted, if there are any, including `WITH GRANT OPTION`.
- One line listing all granted dynamic privileges for which `GRANT OPTION` is not granted, if there are any, without `WITH GRANT OPTION`.

With the optional `USING` clause, `SHOW GRANTS` enables you to examine the privileges associated with roles for the user. Each role named in the `USING` clause must be granted to the user.

Suppose that user `u1` is assigned roles `r1` and `r2`, as follows:

```sql
CREATE ROLE 'r1', 'r2';
GRANT SELECT ON db1.* TO 'r1';
GRANT INSERT, UPDATE, DELETE ON db1.* TO 'r2';
CREATE USER 'u1'@'localhost' IDENTIFIED BY 'u1pass';
GRANT 'r1', 'r2' TO 'u1'@'localhost';
```

`SHOW GRANTS` without `USING` shows the granted roles:

```sql
mysql> SHOW GRANTS FOR 'u1'@'localhost';
+---------------------------------------------+
| Grants for u1@localhost                     |
+---------------------------------------------+
| GRANT USAGE ON *.* TO `u1`@`localhost`      |
| GRANT `r1`@`%`,`r2`@`%` TO `u1`@`localhost` |
+---------------------------------------------+
```

Adding a `USING` clause causes the statement to also display the privileges associated with each role named in the clause:

```sql
mysql> SHOW GRANTS FOR 'u1'@'localhost' USING 'r1';
+---------------------------------------------+
| Grants for u1@localhost                   |
| GRANT USAGE ON *.* TO `u1`@`localhost`     |
| GRANT SELECT ON `db1`.* TO `u1`@`localhost`|
| GRANT `r1`@`%`,`r2`@`%` TO `u1`@`localhost`|
+---------------------------------------------+

mysql> SHOW GRANTS FOR 'u1'@'localhost' USING 'r2';
+---------------------------------------------+
| Grants for u1@localhost                   |
| GRANT USAGE ON *.* TO `u1`@`localhost`     |
| GRANT INSERT, UPDATE, DELETE ON `db1`.* TO `u1`@`localhost`|
| GRANT `r1`@`%`,`r2`@`%` TO `u1`@`localhost`|
+---------------------------------------------+
```

```sql
mysql> SHOW GRANTS FOR 'u1'@'localhost' USING 'r1', 'r2';
+---------------------------------------------+
| Grants for u1@localhost                   |
| GRANT USAGE ON *.* TO `u1`@`localhost`     |
| GRANT SELECT, INSERT, UPDATE, DELETE ON `db1`.* TO `u1`@`localhost`|
| GRANT `r1`@`%`,`r2`@`%` TO `u1`@`localhost`|
+---------------------------------------------+
```

**Note**

A privilege granted to an account is always in effect, but a role is not. The active roles for an account can differ across and within sessions, depending on the value of the `activate_all_roles_on_login` system variable, the account default roles, and whether `SET ROLE` has been executed within a session.

MySQL supports partial revocation of global privileges, such that a global privilege can be restricted from applying to particular schemas (see Section 8.2.12, "Privilege Restriction Using Partial Revokes").
To indicate which global schema privileges have been revoked for particular schemas, `SHOW GRANTS` output includes `REVOKE` statements:

```sql
mysql> SET PERSIST partial_revokes = ON;
mysql> CREATE USER u1;
mysql> GRANT SELECT, INSERT, DELETE ON *.* TO u1;
mysql> REVOKE SELECT, INSERT ON mysql.* FROM u1;
mysql> REVOKE DELETE ON world.* FROM u1;
mysql> SHOW GRANTS FOR u1;
```

---

`SHOW GRANTS` does not display privileges that are available to the named account but are granted to a different account. For example, if an anonymous account exists, the named account might be able to use its privileges, but `SHOW GRANTS` does not display them.

`SHOW GRANTS` displays mandatory roles named in the `mandatory_roles` system variable value as follows:

- `SHOW GRANTS` without a `FOR` clause displays privileges for the current user, and includes mandatory roles.

- `SHOW GRANTS FOR` `user` displays privileges for the named user, and does not include mandatory roles.

This behavior is for the benefit of applications that use the output of `SHOW GRANTS FOR` `user` to determine which privileges are granted explicitly to the named user. Were that output to include mandatory roles, it would be difficult to distinguish roles granted explicitly to the user from mandatory roles.

For the current user, applications can determine privileges with or without mandatory roles by using `SHOW GRANTS` or `SHOW GRANTS FOR CURRENT_USER`, respectively.

### 15.7.7.23 SHOW INDEX Statement

`SHOW [EXTENDED] [INDEX | INDEXES | KEYS]

FROM | IN

tbl_name

| FROM | IN
db_name

| WHERE expr|

`SHOW INDEX` returns table index information. The format resembles that of the `SQLStatistics` call in ODBC. This statement requires some privilege for any column in the table.

```sql
mysql> SHOW INDEX FROM City\G
```

---

**1. row**

- Table: city
- Non_unique: 0
- Key_name: PRIMARY
- Seq_in_index: 1
- Column_name: ID
- Collation: A
- Cardinality: 4188
- Sub_part: NULL
- Packed: NULL
- Null:
- Index_type: BTREE
- Comment:
- Index_comment:
- Visible: YES
- Expression: NULL

---

**2. row**

- Table: city
- Non_unique: 1
An alternative to `tbl_name FROM db_name` syntax is `db_name.tbl_name`. These two statements are equivalent:

```sql
SHOW INDEX FROM mytable FROM mydb;
SHOW INDEX FROM mydb.mytable;
```

The optional `EXTENDED` keyword causes the output to include information about hidden indexes that MySQL uses internally and are not accessible by users.

The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 28.8, “Extensions to SHOW Statements”.

`SHOW INDEX` returns the following fields:

- **Table**
  The name of the table.

- **Non_unique**
  0 if the index cannot contain duplicates, 1 if it can.

- **Key_name**
  The name of the index. If the index is the primary key, the name is always `PRIMARY`.

- **Seq_in_index**
  The column sequence number in the index, starting with 1.

- **Column_name**
  The column name. See also the description for the `Expression` column.

- **Collation**
  How the column is sorted in the index. This can have values `A` (ascending), `D` (descending), or `NULL` (not sorted).

- **Cardinality**
  An estimate of the number of unique values in the index. To update this number, run `ANALYZE TABLE` or (for MyISAM tables) `myisamchk -a`.

  `Cardinality` is counted based on statistics stored as integers, so the value is not necessarily exact even for small tables. The higher the cardinality, the greater the chance that MySQL uses the index when doing joins.

- **Sub_part**
  The index prefix. That is, the number of indexed characters if the column is only partly indexed, `NULL` if the entire column is indexed.
Prefix *limits* are measured in bytes. However, prefix *lengths* for index specifications in CREATE TABLE, ALTER TABLE, and CREATE INDEX statements are interpreted as number of characters for nonbinary string types (CHAR, VARCHAR, TEXT) and number of bytes for binary string types (BINARY, VARBINARY, BLOB). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

For additional information about index prefixes, see Section 10.3.5, “Column Indexes”, and Section 15.1.15, “CREATE INDEX Statement”.

- **Packed**
  Indicates how the key is packed. NULL if it is not.

- **Null**
  Contains YES if the column may contain NULL values and '' if not.

- **Index_type**
  The index method used (BTREE, FULLTEXT, HASH, RTREE).

- **Comment**
  Information about the index not described in its own column, such as disabled if the index is disabled.

- **Index_comment**
  Any comment provided for the index with a COMMENT attribute when the index was created.

- **Visible**
  Whether the index is visible to the optimizer. See Section 10.3.12, “Invisible Indexes”.

- **Expression**
  MySQL supports functional key parts (see Functional Key Parts); this affects both the Column_name and Expression columns:
  
  - For a nonfunctional key part, Column_name indicates the column indexed by the key part and Expression is NULL.
  
  - For a functional key part, Column_name column is NULL and Expression indicates the expression for the key part.

Information about table indexes is also available from the INFORMATION_SCHEMA STATISTICS table. See Section 28.3.34, “The INFORMATION_SCHEMA STATISTICS Table”. The extended information about hidden indexes is available only using SHOW EXTENDED INDEX; it cannot be obtained from the STATISTICS table.

You can list a table’s indexes with the **mysqlshow -k db_name tbl_name** command.

**SHOW INDEX** includes the table’s generated invisible key, if it has one, by default. You can cause this information to be suppressed in the statement’s output by setting `show_gipk_in_create_table_and_information_schema = OFF`. For more information, see Section 15.1.20.11, “Generated Invisible Primary Keys”.

**15.7.7.24 SHOW OPEN TABLES Statement**
SHOW OPEN TABLES lists the non-TEMPORARY tables that are currently open in the table cache. See Section 10.4.3.1, “How MySQL Opens and Closes Tables”. The FROM clause, if present, restricts the tables shown to those present in the db_name database. The LIKE clause, if present, indicates which table names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 28.8, “Extensions to SHOW Statements”.

SHOW OPEN TABLES output has these columns:

- **Database**
  The database containing the table.

- **Table**
  The table name.

- **In_use**
  The number of table locks or lock requests there are for the table. For example, if one client acquires a lock for a table using `LOCK TABLE t1 WRITE`, `In_use` is 1. If another client issues `LOCK TABLE t1 WRITE` while the table remains locked, the client blocks, waiting for the lock, but the lock request causes `In_use` to be 2. If the count is zero, the table is open but not currently being used. `In_use` is also increased by the `HANDLER ... OPEN` statement and decreased by `HANDLER ... CLOSE`.

- **Name_locked**
  Whether the table name is locked. Name locking is used for operations such as dropping or renaming tables.

If you have no privileges for a table, it does not show up in the output from SHOW OPEN TABLES.

### 15.7.7.25 SHOW PARSE_TREE Statement

SHOW PARSE_TREE displays a representation of the parse tree for the input SELECT statement, in JSON format.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>This statement is available only in debug builds, or if the MySQL server was built using <code>-DWITH_SHOW_PARSE_TREE</code>. It is intended for use in testing and development only, and not in production.</td>
</tr>
</tbody>
</table>

Example:

```sql
mysql> SHOW PARSE_TREE SELECT * FROM t3 WHERE o_id > 2
G
*************************** 1. row ***************************
Show_parse_tree: {
  "text": "SELECT * FROM t3 WHERE o_id > 2",
  "type": "PT_select_stmt",
  "components": [
    {
      "text": "SELECT * FROM t3 WHERE o_id > 2",
      "type": "PT_query_expression",
      "components": [
        {
          "text": "SELECT * FROM t3 WHERE o_id > 2",
          "type": "PT_query_specification",
          "components": [
            {
              "text": "SELECT * FROM t3 WHERE o_id > 2",
              "type": "PT_query_expression",
              "components": [
                {
                  "text": "SELECT * FROM t3 WHERE o_id > 2",
                  "type": "PT_query_specification",
                  "components": [
                    {
                      "text": "SELECT * FROM t3 WHERE o_id > 2",
                      "type": "PT_query_expression",
                      "components": [
                        {
                          "text": "SELECT * FROM t3 WHERE o_id > 2",
                          "type": "PT_query_specification",
                          "components": [
                            {
                              "text": "SELECT * FROM t3 WHERE o_id > 2",
                              "type": "PT_query_expression",
                              "components": [
                                {
                                  "text": "SELECT * FROM t3 WHERE o_id > 2",
                                  "type": "PT_query_specification",
                                  "components": [
                                    {
                                      "text": "SELECT * FROM t3 WHERE o_id > 2",
                                      "type": "PT_query_expression",
                                      "components": [
                                        {
                                          "text": "SELECT * FROM t3 WHERE o_id > 2",
                                          "type": "PT_query_specification",
                                          "components": [
                                            {
                                              "text": "SELECT * FROM t3 WHERE o_id > 2",
                                              "type": "PT_query_expression",
                                              "components": [
                                                {
                                                  "text": "SELECT * FROM t3 WHERE o_id > 2",
                                                  "type": "PT_query_specification",
                                                  "components": [
                                                    {
                                                      "text": "SELECT * FROM t3 WHERE o_id > 2",
                                                      "type": "PT_query_expression",
                                                      "components": [
                                                        {
                                                          "text": "SELECT * FROM t3 WHERE o_id > 2",
                                                          "type": "PT_query_specification",
                                                          "components": [
                                                            {
                                                              "text": "SELECT * FROM t3 WHERE o_id > 2",
                                                              "type": "PT_query_expression",
                                                              "components": [
                                                                {
                                                                  "text": "SELECT * FROM t3 WHERE o_id > 2",
                                                                  "type": "PT_query_specification",
                                                                  "components": [
                                                                    {
                                                                      "text": "SELECT * FROM t3 WHERE o_id > 2",
                                                                      "type": "PT_query_expression",
                                                                      "components": [
                                                                        {
                                                                          "text": "SELECT * FROM t3 WHERE o_id > 2",
                                                                          "type": "PT_query_specification",
                                                                          "components": [
                                                                            {
                                                                              "text": "SELECT * FROM t3 WHERE o_id > 2",
                                                                              "type": "PT_query_expression",
                                                                              "components": [
                                                                                {
                                                                                  "text": "SELECT * FROM t3 WHERE o_id > 2",
                                                                                  "type": "PT_query_specification",
                                                                                  "components": [
                                                                                    {
                                                                                      "text": "SELECT * FROM t3 WHERE o_id > 2",
                                                                                      "type": "PT_query_expression",
                                                                                      "components": [
                                                                                      ]
                    ]
                ]
            ]
        ]
      ]
  ]
}]
```

2847
15.7.7.26 SHOW PLUGINS Statement

**SHOW PLUGINS** displays information about server plugins.

Example of `SHOW PLUGINS` output:

```
mysql> SHOW PLUGINS\G
*************************** 1. row ***************************
Name: binlog
   Status: ACTIVE
   Type: STORAGE ENGINE
   Library: NULL
   License: GPL
*************************** 2. row ***************************
Name: CSV
   Status: ACTIVE
   Type: STORAGE ENGINE
   Library: NULL
   License: GPL
*************************** 3. row ***************************
Name: MEMORY
   Status: ACTIVE
   Type: STORAGE ENGINE
   Library: NULL
   License: GPL
*************************** 4. row ***************************
Name: MyISAM
```
SHOW Statements

SHOW PLUGINS output has these columns:

- **Name**
  The name used to refer to the plugin in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`.

- **Status**
  The plugin status, one of `ACTIVE`, `INACTIVE`, `DISABLED`, `DELETING`, or `DELETED`.

- **Type**
  The type of plugin, such as `STORAGE ENGINE`, `INFORMATION_SCHEMA`, or `AUTHENTICATION`.

- **Library**
  The name of the plugin shared library file. This is the name used to refer to the plugin file in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`. This file is located in the directory named by the `plugin_dir` system variable. If the library name is `NULL`, the plugin is compiled in and cannot be uninstalled with `UNINSTALL PLUGIN`.

- **License**
  How the plugin is licensed (for example, GPL).

For plugins installed with `INSTALL PLUGIN`, the Name and Library values are also registered in the `mysql.plugin` system table.

For information about plugin data structures that form the basis of the information displayed by SHOW PLUGINS, see The MySQL Plugin API.

Plugin information is also available from the `INFORMATION_SCHEMA.PLUGINS` table. See Section 28.3.22, “The INFORMATION_SCHEMA PLUGINS Table”.

15.7.7.27 SHOW PRIVILEGES Statement

`SHOW PRIVILEGES` shows the list of system privileges that the MySQL server supports. The privileges displayed include all static privileges, and all currently registered dynamic privileges.

```
mysql> SHOW PRIVILEGES
+----------------+------------------------------------------+----------------+------------------------------------------+----------------+------------------------------------------+----------------+------------------------------------------+----------------+------------------------------------------+----------------+------------------------------------------+----------------+------------------------------------------+----------------+------------------------------------------+----------------+------------------------------------------+----------------+------------------------------------------+----------------+------------------------------------------+----------------+------------------------------------------+----------------+------------------------------------------+

<td>To create new databases and tables</td>
</tr>
</tbody>
</table>
+----------------+------------------------------+---------------|----------------|------------------------------|---------------|----------------|------------------------------|---------------|
```

2849
SHOW Statements

Privileges belonging to a specific user are displayed by the `SHOW GRANTS` statement. See Section 15.7.7.22, "SHOW GRANTS Statement", for more information.

### 15.7.7.28 SHOW PROCEDURE CODE Statement

```
SHOW PROCEDURE CODE proc_name
```

This statement is a MySQL extension that is available only for servers that have been built with debugging support. It displays a representation of the internal implementation of the named stored procedure. A similar statement, `SHOW FUNCTION CODE`, displays information about stored functions (see Section 15.7.7.20, "SHOW FUNCTION CODE Statement").

To use either statement, you must be the user named as the routine `DEFINER`, have the `SHOW_ROUTINE` privilege, or have the `SELECT` privilege at the global level.

If the named routine is available, each statement produces a result set. Each row in the result set corresponds to one "instruction" in the routine. The first column is `Pos`, which is an ordinal number beginning with 0. The second column is `Instruction`, which contains an SQL statement (usually changed from the original source), or a directive which has meaning only to the stored-routine handler.

```sql
mysql> DELIMITER //
mysql> CREATE PROCEDURE p1 ()
    BEGIN
        DECLARE fanta INT DEFAULT 55;
        DROP TABLE t2;
        LOOP
            INSERT INTO t3 VALUES (fanta);
        END LOOP;
    END/
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW PROCEDURE CODE p1;  //
+-----+----------------------------------------+
| Pos | Instruction                            |
+-----+----------------------------------------+
|   0 | set fanta@0 55                         |
|   1 | stmt 9 "DROP TABLE t2"                 |
|   2 | stmt 5 "INSERT INTO t3 VALUES (fanta)" |
|   3 | jump 2                                 |
+-----+----------------------------------------+
4 rows in set (0.00 sec)

mysql> CREATE FUNCTION test.hello (s CHAR(20))
    RETURNS CHAR(50) DETERMINISTIC
    RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW FUNCTION CODE test.hello;
+-----+---------------------------------------+
| Pos | Instruction                           |
+-----+---------------------------------------+
|   0 | freturn 254 concat('Hello, ',s@0,'!') |
+-----+---------------------------------------+
1 row in set (0.00 sec)
```

In this example, the nonexecutable `BEGIN` and `END` statements have disappeared, and for the `DECLARE variable_name` statement, only the executable part appears (the part where the default is assigned). For each statement that is taken from source, there is a code word `stmt` followed by a type (9 means `DROP`, 5 means `INSERT`, and so on). The final row contains an instruction `jump 2`, meaning `GOTO` instruction #2.

### 15.7.7.29 SHOW PROCEDURE STATUS Statement

```
SHOW PROCEDURE STATUS
```

2850
SHOW Statements

This statement is a MySQL extension. It returns characteristics of a stored procedure, such as the
database, name, type, creator, creation and modification dates, and character set information. A
similar statement, `SHOW FUNCTION STATUS`, displays information about stored functions (see
Section 15.7.7.21, “SHOW FUNCTION STATUS Statement”).

To use either statement, you must be the user named as the routine DEFINER, have the
SHOW_ROUTINE privilege, have the SELECT privilege at the global level, or have the CREATE
ROUTINE, ALTER ROUTINE, or EXECUTE privilege granted at a scope that includes the routine.

The LIKE clause, if present, indicates which procedure or function names to match. The WHERE clause
can be given to select rows using more general conditions, as discussed in Section 28.8, “Extensions to SHOW Statements”.

```sql
mysql> SHOW PROCEDURE STATUS LIKE 'sp1'
```

```
Db: test
Name: sp1
Type: PROCEDURE
Definer: testuser@localhost
Modified: 2018-08-08 13:54:11
Created: 2018-08-08 13:54:11
Security_type: DEFINER
Comment: 
character_set_client: utf8mb4
collation_connection: utf8mb4_0900_ai_ci
Database Collation: utf8mb4_0900_ai_ci
```

```sql
mysql> SHOW FUNCTION STATUS LIKE 'hello'
```

```
Db: test
Name: hello
Type: FUNCTION
Definer: testuser@localhost
Modified: 2020-03-10 11:10:03
Created: 2020-03-10 11:10:03
Security_type: DEFINER
Comment: 
character_set_client: utf8mb4
collation_connection: utf8mb4_0900_ai_ci
Database Collation: utf8mb4_0900_ai_ci
```

character_set_client is the session value of the character_set_client system variable when the routine was created. collation_connection is the session value of the
collation_connection system variable when the routine was created. Database Collation is the
collation of the database with which the routine is associated.

Stored routine information is also available from the INFORMATION_SCHEMA PARAMETERS and
ROUTINES tables. See Section 28.3.20, “The INFORMATION_SCHEMA PARAMETERS Table”, and
Section 28.3.30, “The INFORMATION_SCHEMA ROUTINES Table”.

15.7.7.30 SHOW PROCESSLIST Statement

```
SHOW [FULL] PROCESSLIST
```

**Important**

The INFORMATION SCHEMA implementation of `SHOW PROCESSLIST`
is deprecated and subject to removal in a future MySQL release. It is
recommended to use the Performance Schema implementation of `SHOW PROCESSLIST` instead.

The MySQL process list indicates the operations currently being performed by the set of threads
executing within the server. The `SHOW PROCESSLIST` statement is one source of process information.
For a comparison of this statement with other sources, see Sources of Process Information.
SHOW Statements

Note

An alternative implementation for `SHOW PROCESSLIST` is available based on the Performance Schema `processlist` table, which, unlike the default `SHOW PROCESSLIST` implementation, does not require a mutex and has better performance characteristics. For details, see Section 29.12.22.7, “The processlist Table”.

If you have the `PROCESS` privilege, you can see all threads, even those belonging to other users. Otherwise (without the `PROCESS` privilege), nonanonymous users have access to information about their own threads but not threads for other users, and anonymous users have no access to thread information.

Without the `FULL` keyword, `SHOW PROCESSLIST` displays only the first 100 characters of each statement in the `Info` field.

The `SHOW PROCESSLIST` statement is very useful if you get the “too many connections” error message and want to find out what is going on. MySQL reserves one extra connection to be used by accounts that have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege), to ensure that administrators should always be able to connect and check the system (assuming that you are not giving this privilege to all your users).

Threads can be killed with the `KILL` statement. See Section 15.7.8.4, “KILL Statement”.

Example of `SHOW PROCESSLIST` output:

```
mysql> SHOW FULL PROCESSLIST\G
*************************** 1. row ***************************
   Id: 1
   User: system user
   Host: 
   db: NULL
   Command: Connect
   Time: 1030455
   State: Waiting for source to send event
   Info: NULL
*************************** 2. row ***************************
   Id: 2
   User: system user
   Host: 
   db: NULL
   Command: Connect
   Time: 1004
   State: Has read all relay log; waiting for the replica I/O thread to update it
   Info: NULL
*************************** 3. row ***************************
   Id: 3112
   User: replikator
   Host: artemis:2204
   db: NULL
   Command: Binlog Dump
   Time: 2144
   State: Has sent all binlog to replica; waiting for binlog to be updated
   Info: NULL
*************************** 4. row ***************************
   Id: 3113
   User: replikator
   Host: iconnect2:45781
   db: NULL
   Command: Binlog Dump
   Time: 2086
   State: Has sent all binlog to replica; waiting for binlog to be updated
   Info: NULL
*************************** 5. row ***************************
   Id: 3123
   User: stefan
   Host: localhost
```
SHOW Statements

SHOW PROCESSLIST output has these columns:

• **Id**
  
The connection identifier. This is the same value displayed in the **ID** column of the `INFORMATION_SCHEMA.PROCESSLIST` table, displayed in the `PROCESSLIST_ID` column of the Performance Schema `threads` table, and returned by the `CONNECTION_ID()` function within the thread.

• **User**
  
The MySQL user who issued the statement. A value of **system user** refers to a non-client thread spawned by the server to handle tasks internally, for example, a delayed-row handler thread or an I/O (receiver) or SQL (applier) thread used on replica hosts. For **system user**, there is no host specified in the **Host** column. **unauthenticated user** refers to a thread that has become associated with a client connection but for which authentication of the client user has not yet occurred. **event_scheduler** refers to the thread that monitors scheduled events (see Section 27.4, “Using the Event Scheduler”).

  **Note**

  A **User** value of **system user** is distinct from the **SYSTEM_USER** privilege. The former designates internal threads. The latter distinguishes the system user and regular user account categories (see Section 8.2.11, “Account Categories”).

• **Host**
  
The host name of the client issuing the statement (except for **system user**, for which there is no host). The host name for TCP/IP connections is reported in `host_name:client_port` format to make it easier to determine which client is doing what.

• **db**
  
The default database for the thread, or **NULL** if none has been selected.

• **Command**
  
The type of command the thread is executing on behalf of the client, or **Sleep** if the session is idle. For descriptions of thread commands, see Section 10.14, “Examining Server Thread (Process) Information”. The value of this column corresponds to the `COM_XXX` commands of the client/server protocol and `Com_XXX` status variables. See Section 7.1.10, “Server Status Variables”.

• **Time**
  
The time in seconds that the thread has been in its current state. For a replica SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the replica host. See Section 19.2.3, “Replication Threads”.

• **State**
  
  An action, event, or state that indicates what the thread is doing. For descriptions of **State** values, see Section 10.14, “Examining Server Thread (Process) Information”.

  Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.
SHOW Statements

- **Info**

  The statement the thread is executing, or **NULL** if it is executing no statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For example, if a **CALL** statement executes a stored procedure that is executing a **SELECT** statement, the *Info* value shows the **SELECT** statement.

15.7.7.31 SHOW PROFILE Statement

```sql
SHOW PROFILE [type [, type] ... ]
  [FOR QUERY n]
  [LIMIT row_count [OFFSET offset]]
```

**type**: 
  - ALL
  - BLOCK IO
  - CONTEXT SWITCHES
  - CPU
  - IPC
  - MEMORY
  - PAGE FAULTS
  - SOURCE
  - SWAPS

The **SHOW PROFILE** and **SHOW PROFILES** statements display profiling information that indicates resource usage for statements executed during the course of the current session.

![Note]

The **SHOW PROFILE** and **SHOW PROFILES** statements are deprecated; expect them to be removed in a future MySQL release. Use the **Performance Schema** instead; see Section 29.19.1, “Query Profiling Using Performance Schema”.

To control profiling, use the **profiling** session variable, which has a default value of 0 (**OFF**). Enable profiling by setting **profiling** to 1 or **ON**:

```
mysql> SET profiling = 1;
```

**SHOW PROFILES** displays a list of the most recent statements sent to the server. The size of the list is controlled by the **profiling_history_size** session variable, which has a default value of 15. The maximum value is 100. Setting the value to 0 has the practical effect of disabling profiling.

All statements are profiled except **SHOW PROFILE** and **SHOW PROFILES**, so neither of those statements appears in the profile list. Malformed statements are profiled. For example, **SHOW PROFILING** is an illegal statement, and a syntax error occurs if you try to execute it, but it shows up in the profiling list.

**SHOW PROFILE** displays detailed information about a single statement. Without the **FOR QUERY n** clause, the output pertains to the most recently executed statement. If **FOR QUERY n** is included, **SHOW PROFILE** displays information for statement **n**. The values of **n** correspond to the **Query_ID** values displayed by **SHOW PROFILES**.

The **LIMIT row_count** clause may be given to limit the output to **row_count** rows. If **LIMIT** is given, **OFFSET offset** may be added to begin the output **offset** rows into the full set of rows.

By default, **SHOW PROFILE** displays **Status** and **Duration** columns. The **Status** values are like the **State** values displayed by **SHOW PROCESSLIST**, although there might be some minor differences in interpretation for the two statements for some status values (see Section 10.14, “Examining Server Thread (Process) Information”).

Optional **type** values may be specified to display specific additional types of information:
SHOW Statements

- **ALL** displays all information
- **BLOCK IO** displays counts for block input and output operations
- **CONTEXT SWITCHES** displays counts for voluntary and involuntary context switches
- **CPU** displays user and system CPU usage times
- **IPC** displays counts for messages sent and received
- **MEMORY** is not currently implemented
- **PAGE FAULTS** displays counts for major and minor page faults
- **SOURCE** displays the names of functions from the source code, together with the name and line number of the file in which the function occurs
- **SWAPS** displays swap counts

Profiling is enabled per session. When a session ends, its profiling information is lost.

```sql
mysql> SELECT @@profiling;
+-------------+
| @@profiling |
+-------------+
| 0           |
+-------------+
1 row in set (0.00 sec)

mysql> SET profiling = 1;
Query OK, 0 rows affected (0.00 sec)

mysql> DROP TABLE IF EXISTS t1;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> CREATE TABLE T1 (id INT);
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW PROFILES;
+----------+----------+--------------------------+
| Query_ID | Duration | Query                    |
+----------+----------+--------------------------+
|        0 | 0.000088 | SET PROFILING = 1        |
|        1 | 0.000136 | DROP TABLE IF EXISTS t1  |
|        2 | 0.011947 | CREATE TABLE t1 (id INT) |
+----------+----------+--------------------------+
3 rows in set (0.00 sec)

mysql> SHOW PROFILE;
+----------------------+----------+
| Status               | Duration |
+----------------------+----------+
| checking permissions | 0.000040 |
| creating table       | 0.000056 |
| After create         | 0.011363 |
| query end            | 0.000375 |
| freeing items        | 0.000089 |
| logging slow query   | 0.000019 |
| cleaning up          | 0.000005 |
+----------------------+----------+
7 rows in set (0.00 sec)

mysql> SHOW PROFILE FOR QUERY 1;
+----------------------+----------+
| Status               | Duration |
+----------------------+----------+
| query end            | 0.000107 |
| freeing items        | 0.000008 |
| logging slow query   | 0.000015 |
| cleaning up          | 0.000006 |
+----------------------+----------+
```
SHOW Statements

MySQL> SHOW PROFILE CPU FOR QUERY 2;
+----------------------+----------+----------+------------+
| Status               | Duration | CPU_user | CPU_system |
|-----------------------|----------|----------+------------|
| checking permissions  | 0.000040 | 0.000038 | 0.000002   |
| creating table       | 0.000056 | 0.000028 | 0.000028   |
| After create         | 0.011363 | 0.000217 | 0.001571   |
| query end            | 0.000375 | 0.000013 | 0.000028   |
| freeing items        | 0.000089 | 0.000010 | 0.000014   |
| logging slow query   | 0.000019 | 0.000009 | 0.000010   |
| cleaning up          | 0.000005 | 0.000003 | 0.000002   |
+-----------------------+----------+----------+------------+

Note
Profiling is only partially functional on some architectures. For values that depend on the `getrusage()` system call, `NULL` is returned on systems such as Windows that do not support the call. In addition, profiling is per process and not per thread. This means that activity on threads within the server other than your own may affect the timing information that you see.

Profiling information is also available from the `INFORMATION_SCHEMA.PROFILING` table. See Section 28.3.24, “The INFORMATION_SCHEMA PROFILING Table”. For example, the following queries are equivalent:

```
SHOW PROFILE FOR QUERY 2;
```

```
SELECT STATE, FORMAT(DURATION, 6) AS DURATION
FROM INFORMATION_SCHEMA.PROFILING
WHERE QUERY_ID = 2 ORDER BY SEQ;
```

15.7.7.32 SHOW PROFILES Statement

SHOW PROFILES

The `SHOW PROFILES` statement, together with `SHOW PROFILE`, displays profiling information that indicates resource usage for statements executed during the course of the current session. For more information, see Section 15.7.7.31, “SHOW PROFILE Statement”.

Note
The `SHOW PROFILE` and `SHOW PROFILES` statements are deprecated; expect it to be removed in a future MySQL release. Use the `Performance Schema` instead; see Section 29.19.1, “Query Profiling Using Performance Schema”.

15.7.7.33 SHOW RELAYLOG EVENTS Statement

SHOW RELAYLOG EVENTS
    [IN 'log_name']
    [FROM pos]
    [LIMIT [offset,,] row_count]
    [channel_option]

channel_option: FOR CHANNEL channel

Shows the events in the relay log of a replica. If you do not specify `log_name`, the first relay log is displayed. This statement has no effect on the source. `SHOW RELAYLOG EVENTS` requires the `REPLICATION SLAVE` privilege.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See Section 15.2.13, “SELECT Statement”.

2856
SHOW Statements

Note
Issuing a **SHOW RELAYLOG EVENTS** with no **LIMIT** clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the relay log (including all statements modifying data that have been received by the replica).

The optional **FOR CHANNEL channel** clause enables you to name which replication channel the statement applies to. Providing a **FOR CHANNEL channel** clause applies the statement to a specific replication channel. If no channel is named and no extra channels exist, the statement applies to the default channel.

When using multiple replication channels, if a **SHOW RELAYLOG EVENTS** statement does not have a channel defined using a **FOR CHANNEL channel** clause an error is generated. See Section 19.2.2, “Replication Channels” for more information.

**SHOW RELAYLOG EVENTS** displays the following fields for each event in the relay log:

- **Log_name**
  The name of the file that is being listed.
- **Pos**
  The position at which the event occurs.
- **Event_type**
  An identifier that describes the event type.
- **Server_id**
  The server ID of the server on which the event originated.
- **End_log_pos**
  The value of **End_log_pos** for this event in the source's binary log.
- **Info**
  More detailed information about the event type. The format of this information depends on the event type.

For compressed transaction payloads, the **Transaction_payload_event** is first printed as a single unit, then it is unpacked and each event inside it is printed.

Some events relating to the setting of user and system variables are not included in the output from **SHOW RELAYLOG EVENTS**. To get complete coverage of events within a relay log, use **mysqlbinlog**.

15.7.7.34 SHOW REPLICA STATUS Statement

**SHOW REPLICA STATUS [FOR CHANNEL channel]**

This statement provides status information on essential parameters of the replica threads. The statement requires the **REPLICATION CLIENT** privilege (or the deprecated **SUPER** privilege).

**SHOW REPLICA STATUS** is nonblocking. When run concurrently with **STOP REPLICA**, **SHOW REPLICA STATUS** returns without waiting for **STOP REPLICA** to finish shutting down the replication SQL (applier) thread or replication I/O (receiver) thread (or both). This permits use in monitoring and other applications where getting an immediate response from **SHOW REPLICA STATUS** is more important than ensuring that it returned the latest data.

If you issue this statement using the **mysql** client, you can use a **\G** statement terminator rather than a semicolon to obtain a more readable vertical layout:
The Performance Schema provides tables that expose replication information. This is similar to the information available from the `SHOW REPLICA STATUS` statement, but represented in table form. For details, see Section 29.12.11, “Performance Schema Replication Tables”.

You can set the `GTID_ONLY` option for the `CHANGE REPLICATION SOURCE TO` statement to stop a replication channel from persisting file names and file positions in the replication metadata repositories. With this setting, file positions for the source binary log file and the relay log file are tracked in memory. The `SHOW REPLICA STATUS` statement still displays file positions in normal use. However, because
the file positions are not being regularly updated in the connection metadata repository and the applier metadata repository except in a few situations, they are likely to be out of date if the server is restarted.

For a replication channel with the GTID_ONLY setting after a server start, the read and applied file positions for the source binary log file (Read_Source_Log_Pos and Exec_Source_Log_Pos) are set to zero, and the file names (Source_Log_File and Relay_Source_Log_File) are set to INVALID. The relay log file name (Relay_Log_File) is set according to the relay_log_recovery setting, either a new file that was created at server start or the first relay log file present. The file position (Relay_Log_Pos) is set to position 4, and GTID auto-skip is used to skip any transactions in the file that were already applied.

When the receiver thread contacts the source and gets valid position information, the read position (Read_Source_Log_Pos) and file name (Source_Log_File) are updated with the correct data and become valid. When the applier thread applies a transaction from the source, or skips an already executed transaction, the executed position (Exec_Source_Log_Pos) and file name (Relay_Source_Log_File) are updated with the correct data and become valid. The relay log file position (Relay_Log_Pos) is also updated at that time.

The following list describes the fields returned by SHOW REPLICA STATUS. For additional information about interpreting their meanings, see Section 19.1.7.1, “Checking Replication Status”.

• Replica_IO_State
  A copy of the State field of the SHOW PROCESSLIST output for the replica I/O (receiver) thread. This tells you what the thread is doing: trying to connect to the source, waiting for events from the source, reconnecting to the source, and so on. For a listing of possible states, see Section 10.14.5, “Replication I/O (Receiver) Thread States”.

• SourceHost
  The source host that the replica is connected to.

• SourceUser
  The user name of the account used to connect to the source.

• SourcePort
  The port used to connect to the source.

• ConnectRetry
  The number of seconds between connect retries (default 60). This can be set with a CHANGE REPLICATION SOURCE TO statement.

• SourceLogFile
  The name of the source binary log file from which the I/O (receiver) thread is currently reading. This is set to INVALID for a replication channel with the GTID_ONLY setting after a server start. It will be updated when the replica contacts the source.

• ReadSourceLogPos
  The position in the current source binary log file up to which the I/O (receiver) thread has read. This is set to zero for a replication channel with the GTID_ONLY setting after a server start. It will be updated when the replica contacts the source.

• RelayLogFile
  The name of the relay log file from which the SQL (applier) thread is currently reading and executing.

• RelayLogPos
SHOW Statements

The position in the current relay log file up to which the SQL (applier) thread has read and executed.

- **Relay_Source_Log_File**

  The name of the source binary log file containing the most recent event executed by the SQL (applier) thread. This is set to `INVALID` for a replication channel with the `GTID_ONLY` setting after a server start. It will be updated when a transaction is executed or skipped.

- **Replica_IO_Running**

  Whether the replication I/O (receiver) thread is started and has connected successfully to the source. Internally, the state of this thread is represented by one of the following three values:

  - **MYSQL_REPLICA_NOT_RUN.** The replication I/O (receiver) thread is not running. For this state, `Replica_IO_Running` is `No`.

  - **MYSQL_REPLICA_RUN_NOT_CONNECT.** The replication I/O (receiver) thread is running, but is not connected to a replication source. For this state, `Replica_IO_Running` is `Connecting`.

  - **MYSQL_REPLICA_RUN_CONNECT.** The replication I/O (receiver) thread is running, and is connected to a replication source. For this state, `Replica_IO_Running` is `Yes`.

- **Replica_SQL_Running**

  Whether the replication SQL (applier) thread is started.

- **Replicate_Do_DB, Replicate_Ignore_DB**

  The names of any databases that were specified with the `--replicate-do-db` and `--replicate-ignore-db` options, or the `CHANGE REPLICATION FILTER` statement. If the `FOR CHANNEL` clause was used, the channel specific replication filters are shown. Otherwise, the replication filters for every replication channel are shown.

- **Replicate_Do_Table, Replicate_Ignore_Table, Replicate_Wild_Do_Table, Replicate_Wild_Ignore_Table**

  The names of any tables that were specified with the `--replicate-do-table, --replicate-ignore-table, --replicate-wild-do-table, and --replicate-wild-ignore-table` options, or the `CHANGE REPLICATION FILTER` statement. If the `FOR CHANNEL` clause was used, the channel specific replication filters are shown. Otherwise, the replication filters for every replication channel are shown.

- **Last_Errno, Last_Error**

  These columns are aliases for `Last_SQL_Errno` and `Last_SQL_Error`.

  Issuing `RESET BINARY LOGS AND GTIDS` or `RESET REPLICA` resets the values shown in these columns.

  **Note**

  When the replication SQL thread receives an error, it reports the error first, then stops the SQL thread. This means that there is a small window of time during which `SHOW REPLICA STATUS` shows a nonzero value for `Last_SQL_Errno` even though `Replica_SQL_Running` still displays `Yes`.

- **Skip_Counter**

  The current value of the `sql_replica_skip_counter` system variable.

- **Exec_Source_Log_Pos**
SHOW Statements

The position in the current source binary log file to which the replication SQL thread has read and executed, marking the start of the next transaction or event to be processed. This is set to zero for a replication channel with the GTID_ONLY setting after a server start. It will be updated when a transaction is executed or skipped.

You can use this value with the CHANGE REPLICATION SOURCE TO statement's SOURCE_LOG_POS option when starting a new replica from an existing replica, so that the new replica reads from this point. The coordinates given by (Relay_Source_Log_File, Exec_Source_Log_Pos) in the source's binary log correspond to the coordinates given by (Relay_Log_File, Relay_Log_Pos) in the relay log.

Inconsistencies in the sequence of transactions from the relay log which have been executed can cause this value to be a “low-water mark”. In other words, transactions appearing before the position are guaranteed to have committed, but transactions after the position may have committed or not. If these gaps need to be corrected, use START REPLICA UNTIL SQL_AFTER_MTS_GAPS. See Section 19.5.1.34, “Replication and Transaction Inconsistencies” for more information.

- Relay_Log_Space
  
The total combined size of all existing relay log files.

- Until_Condition, Until_Log_File, Until_Log_Pos
  
The values specified in the UNTIL clause of the START REPLICA statement.

  Until_Condition has these values:
  
  - None if no UNTIL clause was specified.
  - Source if the replica is reading until a given position in the source's binary log.
  - Relay if the replica is reading until a given position in its relay log.
  - SQL_BEFORE_GTIDS if the replication SQL thread is processing transactions until it has reached the first transaction whose GTID is listed in the gtid_set.
  - SQL_AFTER_GTIDS if the replication threads are processing all transactions until the last transaction in the gtid_set has been processed by both threads.
  - SQL_AFTER_MTS_GAPS if a multithreaded replica's SQL threads are running until no more gaps are found in the relay log.

  Until_Log_File and Until_Log_Pos indicate the log file name and position that define the coordinates at which the replication SQL thread stops executing.

  For more information on UNTIL clauses, see Section 15.4.2.4, “START REPLICA Statement”.

- Source_SSL_Allowed, Source_SSL_CA_File, Source_SSL_CA_Path, Source_SSL_Cert, Source_SSL_Cipher, Source_SSL_CRL_File, Source_SSL_CRL_Path, Source_SSL_Key, Source_SSL_Verify_Server_Cert
  
  These fields show the SSL parameters used by the replica to connect to the source, if any.

  Source_SSL_Allowed has these values:
  
  - Yes if an SSL connection to the source is permitted.
  - No if an SSL connection to the source is not permitted.
  - Ignored if an SSL connection is permitted but the replica server does not have SSL support enabled.
SHOW Statements

The values of the other SSL-related fields correspond to the values of the `$SOURCE_SSL_*` options of the `CHANGE REPLICATION SOURCE TO` statement.

- **Seconds_Behind_Source**

  This field is an indication of how “late” the replica is:

  - When the replica is actively processing updates, this field shows the difference between the current timestamp on the replica and the original timestamp logged on the source for the event currently being processed on the replica.
  
  - When no event is currently being processed on the replica, this value is 0.

  In essence, this field measures the time difference in seconds between the replication SQL (applier) thread and the replication I/O (receiver) thread. If the network connection between source and replica is fast, the replication receiver thread is very close to the source, so this field is a good approximation of how late the replication applier thread is compared to the source. If the network is slow, this is not a good approximation; the replication applier thread may quite often be caught up with the slow-reading replication receiver thread, so `Seconds_Behind_Source` often shows a value of 0, even if the replication receiver thread is late compared to the source. In other words, this column is useful only for fast networks.

  This time difference computation works even if the source and replica do not have identical clock times, provided that the difference, computed when the replica receiver thread starts, remains constant from then on. Any changes, including NTP updates, can lead to clock skews that can make calculation of `Seconds_Behind_Source` less reliable.

  In MySQL 8.4, this field is NULL (undefined or unknown) if the replication applier thread is not running, or if the applier thread has consumed all of the relay log and the replication receiver thread is not running. (In older versions of MySQL, this field was NULL if the replication applier thread or the replication receiver thread was not running or was not connected to the source.) If the replication receiver thread is running but the relay log is exhausted, `Seconds_Behind_Source` is set to 0.

  The value of `Seconds_Behind_Source` is based on the timestamps stored in events, which are preserved through replication. This means that if a source M1 is itself a replica of M0, any event from M1’s binary log that originates from M0’s binary log has M0’s timestamp for that event. This enables MySQL to replicate `TIMESTAMP` successfully. However, the problem for `Seconds_Behind_Source` is that if M1 also receives direct updates from clients, the `Seconds_Behind_Source` value randomly fluctuates because sometimes the last event from M1 originates from M0 and sometimes is the result of a direct update on M1.

  When using a multithreaded replica, you should keep in mind that this value is based on `Exec_Source_Log_Pos`, and so may not reflect the position of the most recently committed transaction.

- **Last_IO_Errno, Last_IO_Error**

  The error number and error message of the most recent error that caused the replication I/O (receiver) thread to stop. An error number of 0 and message of the empty string mean “no error.” If the `Last_IO_Error` value is not empty, the error values also appear in the replica’s error log.

  I/O error information includes a timestamp showing when the most recent I/O (receiver) thread error occurred. This timestamp uses the format `YYMMDD hh:mm:ss`, and appears in the `Last_IO_Error_Timestamp` column.

  Issuing `RESET BINARY LOGS AND GTIDS` or `RESET REPLICA` resets the values shown in these columns.
SHOW Statements

• **Last_SQL_Errno, Last_SQL_Error**

The error number and error message of the most recent error that caused the replication SQL (applier) thread to stop. An error number of 0 and message of the empty string mean "no error." If the **Last_SQL_Error** value is not empty, the error values also appear in the replica's error log.

If the replica is multithreaded, the replication SQL thread is the coordinator for worker threads. In this case, the **Last_SQL_Error** field shows exactly what the **Last_Error_Message** column in the Performance Schema `replication_applier_status_by_coordinator` table shows. The field value is modified to suggest that there may be more failures in the other worker threads which can be seen in the `replication_applier_status_by_worker` table that shows each worker thread's status. If that table is not available, the replica error log can be used. The log or the `replication_applier_status_by_worker` table should also be used to learn more about the failure shown by **SHOW REPLICA STATUS** or the coordinator table.

SQL error information includes a timestamp showing when the most recent SQL (applier) thread error occurred. This timestamp uses the format **YYMMDD hh:mm:ss**, and appears in the **Last_SQL_Error_Timestamp** column.

Issuing **RESET BINARY LOGS AND GTIDS** or **RESET REPLICA** resets the values shown in these columns.

In MySQL 8.4, all error codes and messages displayed in the **Last_SQL_Errno** and **Last_SQL_Error** columns correspond to error values listed in **Server Error Message Reference**. This was not always true in previous versions. (Bug #11760365, Bug #52768)

• **Replicate_Ignore_Server_Ids**

Any server IDs that have been specified using the **IGNORE_SERVER_IDS** option of the **CHANGE REPLICATION SOURCE TO** statement, so that the replica ignores events from these servers. This option is used in a circular or other multi-source replication setup when one of the servers is removed. If any server IDs have been set in this way, a comma-delimited list of one or more numbers is shown. If no server IDs have been set, the field is blank.

**Note**

The **IGNORED_server_ids** value in the **slave_master_info** table also shows the server IDs to be ignored, but as a space-delimited list, preceded by the total number of server IDs to be ignored. For example, if a **CHANGE REPLICATION SOURCE TO** statement containing the **IGNORE_SERVER_IDS = (2,6,9)** option has been issued to tell a replica to ignore sources having the server ID 2, 6, or 9, that information appears as shown here:

<table>
<thead>
<tr>
<th>Replicate_Ignore_Server_Ids: 2, 6, 9</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ignored_server_ids: 3, 2, 6, 9</td>
</tr>
</tbody>
</table>

**Replicate_Ignore_Server_Ids** filtering is performed by the I/O (receiver) thread, rather than by the SQL (applier) thread, which means that events which are filtered out are not written to the relay log. This differs from the filtering actions taken by server options such **--replicate-do-table**, which apply to the applier thread.

If **SET gtid_mode=ON** is issued when any channel has existing server IDs set with **IGNORE_SERVER_IDS**, the statement is rejected with an error. Before starting GTID-based replication, use **SHOW REPLICA STATUS** to check for and clear all ignored server ID lists on the servers involved. You can clear a list by issuing a **CHANGE REPLICATION SOURCE TO** statement using **IGNORE_SERVER_IDS=()**—that is, with an empty list of server IDs.

• **Source_Server_Id**

The **server_id** value from the source.
SHOW Statements

- **Source_UUID**
  The `server_uuid` value from the source.

- **Source_Info_File**
  The location of the `master.info` file, the use of which is now deprecated. By default, a table is used instead for the replica's connection metadata repository.

- **SQL_Delay**
  The number of seconds that the replica must lag the source.

- **SQL_Remaining_Delay**
  When `Replica_SQL_Running_State` is `Waiting until SOURCE_DELAY seconds after source executed event`, this field contains the number of delay seconds remaining. At other times, this field is `NULL`.

- **Replica_SQL_Running_State**
  The state of the SQL thread (analogous to `Replica_IO_State`). The value is identical to the `State` value of the SQL thread as displayed by `SHOW PROCESSLIST`. Section 10.14.6, “Replication SQL Thread States”, provides a listing of possible states.

- **Source Retry Count**
  The number of times the replica can attempt to reconnect to the source in the event of a lost connection. This value can be set using the `SOURCE_RETRY_COUNT` option of the `CHANGE REPLICA SOURCE TO` statement.

- **Source_Bind**
  The network interface that the replica is bound to, if any. This is set using the `SOURCE_BIND` option for the `CHANGE REPLICA SOURCE TO` statement.

- **Last_IO_Error_Timestamp**
  A timestamp in `YYMMDD hh:mm:ss` format that shows when the most recent I/O error took place.

- **Last_SQL_Error_Timestamp**
  A timestamp in `YYMMDD hh:mm:ss` format that shows when the most recent SQL error occurred.

- **Retrieved_Gtid_Set**
  The set of global transaction IDs corresponding to all transactions received by this replica. Empty if GTIDs are not in use. See GTID Sets for more information.

  This is the set of all GTIDs that exist or have existed in the relay logs. Each GTID is added as soon as the `Gtid_log_event` is received. This can cause partially transmitted transactions to have their GTIDs included in the set.

  When all relay logs are lost due to executing `RESET REPLICA` or `CHANGE REPLICA SOURCE TO`, or due to the effects of the `--relay-log-recovery` option, the set is cleared. When `relay_log_purge = 1`, the newest relay log is always kept, and the set is not cleared.

- **Executed_Gtid_Set**
  The set of global transaction IDs written in the binary log. This is the same as the value for the global `gtid_executed` system variable on this server, as well as the value for `Executed_Gtid_Set` in the output of `SHOW BINARY LOG STATUS` on this server. Empty if GTIDs are not in use. See GTID Sets for more information.
SHOW Statements

• **Auto_Position**

  1 if GTID auto-positioning is in use for the channel, otherwise 0.

• **Replicate_Rewrite_DB**

  The `Replicate_Rewrite_DB` value displays any replication filtering rules that were specified. For example, if the following replication filter rule was set:

  ```sql
  CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB=((db1,db2), (db3,db4));
  ```

  the `Replicate_Rewrite_DB` value displays:

  ```plaintext
  Replicate_Rewrite_DB: (db1,db2), (db3,db4)
  ```

  For more information, see Section 15.4.2.1, “CHANGE REPLICATION FILTER Statement”.

• **Channel_name**

  The replication channel which is being displayed. There is always a default replication channel, and more replication channels can be added. See Section 19.2.2, “Replication Channels” for more information.

• **Master_TLS_Version**

  The TLS version used on the source. For TLS version information, see Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

• **Source_public_key_path**

  The path name to a file containing a replica-side copy of the public key required by the source for RSA key pair-based password exchange. The file must be in PEM format. This column applies to replicas that authenticate with the `sha256_password` (deprecated) or `caching_sha2_password` authentication plugin.

  If `Source_public_key_path` is given and specifies a valid public key file, it takes precedence over `Get_source_public_key`.

• **Get_source_public_key**

  Whether to request from the source the public key required for RSA key pair-based password exchange. This column applies to replicas that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the source does not send the public key unless requested.

  If `Source_public_key_path` is given and specifies a valid public key file, it takes precedence over `Get_source_public_key`.

• **Network_Namespace**

  The network namespace name; empty if the connection uses the default (global) namespace. For information about network namespaces, see Section 7.1.14, “Network Namespace Support”.

### 15.7.7.35 SHOW REPLICAS Statement

SHOW REPLICAS

Displays a list of replicas currently registered with the source. `SHOW REPLICAS` requires the `REPLICATION_SLAVE` privilege.

`SHOW REPLICAS` should be executed on a server that acts as a replication source. The statement displays information about servers that are or have been connected as replicas, with each row of the result corresponding to one replica server, as shown here:
SHOW Statements

mysql> SHOW REPLICAS;
+------------+-----------+------+-----------+--------------------------------------+
<table>
<thead>
<tr>
<th>Server_id</th>
<th>Host</th>
<th>Port</th>
<th>Source_id</th>
<th>Replica_UUID</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>iconnect2</td>
<td>3306</td>
<td>3</td>
<td>14cb6624-7f93-11e0-b2c0-c80aa9429562</td>
</tr>
<tr>
<td>21</td>
<td>athena</td>
<td>3306</td>
<td>3</td>
<td>07af4990-f41f-11df-a566-7ac56fda645</td>
</tr>
</tbody>
</table>
+------------+-----------+------|-----------|--------------------------------------+

- **Server_id**: The unique server ID of the replica server, as configured in the replica server's option file, or on the command line with `--server-id=value`.
- **Host**: The host name of the replica server, as specified on the replica with the `--report-host` option. This can differ from the machine name as configured in the operating system.
- **User**: The replica server user name, as specified on the replica with the `--report-user` option. Statement output includes this column only if the source server is started with the `--show-replica-auth-info` option.
- **Password**: The replica server password, as specified on the replica with the `--report-password` option. Statement output includes this column only if the source server is started with the `--show-replica-auth-info` option.
- **Port**: The port on the source to which the replica server is listening, as specified on the replica with the `--report-port` option. A zero in this column means that the replica port (`--report-port`) was not set.
- **Source_id**: The unique server ID of the source server that the replica server is replicating from. This is the server ID of the server on which `SHOW REPLICAS` is executed, so this same value is listed for each row in the result.
- **Replica_UUID**: The globally unique ID of this replica, as generated on the replica and found in the replica's `auto.cnf` file.

### 15.7.7.36 SHOW STATUS Statement

```
SHOW [GLOBAL | SESSION] STATUS
[LIKE 'pattern' | WHERE expr]
```

SHOW STATUS provides server status information (see Section 7.1.10, "Server Status Variables"). This statement does not require any privilege. It requires only the ability to connect to the server.

Status variable information is also available from these sources:

- Performance Schema tables. See Section 29.12.15, "Performance Schema Status Variable Tables".
- The `mysqladmin extended-status` command. See Section 6.5.2, "mysqladmin — A MySQL Server Administration Program".

For `SHOW STATUS`, a `LIKE` clause, if present, indicates which variable names to match. A `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 28.8, "Extensions to SHOW Statements".

SHOW STATUS accepts an optional `GLOBAL` or `SESSION` variable scope modifier:

- With a `GLOBAL` modifier, the statement displays the global status values. A global status variable may represent status for some aspect of the server itself (for example, `Aborted_connects`), or the aggregated status over all connections to MySQL (for example, `Bytes_received` and `Bytes_sent`). If a variable has no global value, the session value is displayed.
- With a `SESSION` modifier, the statement displays the status variable values for the current connection. If a variable has no session value, the global value is displayed. `LOCAL` is a synonym for `SESSION`. 
SHOW Statements

- If no modifier is present, the default is `SESSION`.

The scope for each status variable is listed at Section 7.1.10, “Server Status Variables”.

Each invocation of the `SHOW STATUS` statement uses an internal temporary table and increments the global `Created_tmp_tables` value.

Partial output is shown here. The list of names and values may differ for your server. The meaning of each variable is given in Section 7.1.10, “Server Status Variables”.

```
mysql> SHOW STATUS;
+--------------------------+------------+
| Variable_name            | Value      |
+--------------------------+------------+
| Aborted_clients          | 0          |
| Aborted_connects         | 0          |
| Bytes_received           | 155372598  |
| Bytes_sent               | 1176560426 |
| Connections              | 30023      |
| Created_tmp_disk_tables  | 0          |
| Created_tmp_tables       | 8340       |
| Created_tmp_files        | 60         |
| Open_tables              | 1          |
| Open_files               | 2          |
| Open_streams             | 0          |
| Opened_tables            | 44600      |
| Questions                | 2026873    |
| Table_locks_immediate    | 1920382    |
| Table_locks_waited       | 0          |
| Threads_cached           | 0          |
| Threads_created          | 30022      |
| Threads_connected        | 1          |
| Threads_running          | 1          |
| Uptime                   | 80380      |
+--------------------------+------------+
```

With a `LIKE` clause, the statement displays only rows for those variables with names that match the pattern:

```
mysql> SHOW STATUS LIKE 'Key%';
+--------------------+----------+
| Variable_name      | Value    |
+--------------------+----------+
| Key_blocks_used    | 14955    |
| Key_read_requests  | 96854827 |
| Key_reads          | 162040   |
| Key_write_requests | 7589728  |
| Key_writes         | 3813196  |
+--------------------+----------+
```

15.7.7.37 SHOW TABLE STATUS Statement

```
SHOW TABLE STATUS
[[FROM | IN] db_name]
[LIKE 'pattern' | WHERE expr]
```

`SHOW TABLE STATUS` works like `SHOW TABLES`, but provides a lot of information about each non-TEMPORARY table. You can also get this list using the `mysqlshow --status db_name` command. The `LIKE` clause, if present, indicates which table names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 28.8, “Extensions to SHOW Statements”.

This statement also displays information about views.

`SHOW TABLE STATUS` output has these columns:

- Name
SHOW Statements

The name of the table.

- **Engine**

  For partitioned tables, **Engine** shows the name of the storage engine used by all partitions.

- **Version**
  This column is unused. With the removal of `.frm` files in MySQL 8.0, this column now reports a hard-coded value of 10, which was the last `.frm` file version used in MySQL 5.7.

- **Row_format**
  The row-storage format (**Fixed**, **Dynamic**, **Compressed**, **Redundant**, **Compact**). For MyISAM tables, **Dynamic** corresponds to what `myisamchk -dvv` reports as **Packed**.

- **Rows**
  The number of rows. Some storage engines, such as MyISAM, store the exact count. For other storage engines, such as InnoDB, this value is an approximation, and may vary from the actual value by as much as 40% to 50%. In such cases, use `SELECT COUNT(*)` to obtain an accurate count.

  The **Rows** value is **NULL** for INFORMATION_SCHEMA tables.

  For InnoDB tables, the row count is only a rough estimate used in SQL optimization. (This is also true if the InnoDB table is partitioned.)

- **Avg_row_length**
  The average row length.

- **Data_length**
  For MyISAM, **Data_length** is the length of the data file, in bytes.

  For InnoDB, **Data_length** is the approximate amount of space allocated for the clustered index, in bytes. Specifically, it is the clustered index size, in pages, multiplied by the InnoDB page size.

  Refer to the notes at the end of this section for information regarding other storage engines.

- **Max_data_length**
  For MyISAM, **Max_data_length** is maximum length of the data file. This is the total number of bytes of data that can be stored in the table, given the data pointer size used.

  Unused for InnoDB.

  Refer to the notes at the end of this section for information regarding other storage engines.

- **Index_length**
  For MyISAM, **Index_length** is the length of the index file, in bytes.

  For InnoDB, **Index_length** is the approximate amount of space allocated for non-clustered indexes, in bytes. Specifically, it is the sum of non-clustered index sizes, in pages, multiplied by the InnoDB page size.

  Refer to the notes at the end of this section for information regarding other storage engines.
SHOW Statements

- **Data_free**

  The number of allocated but unused bytes.

  InnoDB tables report the free space of the tablespace to which the table belongs. For a table located in the shared tablespace, this is the free space of the shared tablespace. If you are using multiple tablespaces and the table has its own tablespace, the free space is for only that table. Free space means the number of bytes in completely free extents minus a safety margin. Even if free space displays as 0, it may be possible to insert rows as long as new extents need not be allocated.

  For NDB Cluster, **Data_free** shows the space allocated on disk for, but not used by, a Disk Data table or fragment on disk. (In-memory data resource usage is reported by the `Data_length` column.)

  For partitioned tables, this value is only an estimate and may not be absolutely correct. A more accurate method of obtaining this information in such cases is to query the `INFORMATION_SCHEMA PARTITIONS` table, as shown in this example:

  ```sql
  SELECT SUM(DATA_FREE)
  FROM INFORMATION_SCHEMA.PARTITIONS
  WHERE TABLE_SCHEMA = 'mydb'
  AND TABLE_NAME = 'mytable';
  ```

  For more information, see Section 28.3.21, "The INFORMATION_SCHEMA PARTITIONS Table".

- **Auto_increment**

  The next AUTO_INCREMENT value.

- **Create_time**

  When the table was created.

- **Update_time**

  When the data file was last updated. For some storage engines, this value is NULL. For example, InnoDB stores multiple tables in its system tablespace and the data file timestamp does not apply. Even with file-per-table mode with each InnoDB table in a separate .ibd file, change buffering can delay the write to the data file, so the file modification time is different from the time of the last insert, update, or delete. For MyISAM, the data file timestamp is used; however, on Windows the timestamp is not updated by updates, so the value is inaccurate.

  **Update_time** displays a timestamp value for the last UPDATE, INSERT, or DELETE performed on InnoDB tables that are not partitioned. For MVCC, the timestamp value reflects the COMMIT time, which is considered the last update time. Timestamps are not persisted when the server is restarted or when the table is evicted from the InnoDB data dictionary cache.

- **Check_time**

  When the table was last checked. Not all storage engines update this time, in which case, the value is always NULL.

  For partitioned InnoDB tables, **Check_time** is always NULL.

- **Collation**

  The table default collation. The output does not explicitly list the table default character set, but the collation name begins with the character set name.

- **Checksum**

  The live checksum value, if any.
SHOW Statements

• **Create_options**

  Extra options used with `CREATE TABLE`.

  `Create_options` shows partitioned for a partitioned table.

  `Create_options` shows the `ENCRYPTION` clause for file-per-table tablespaces if the table is encrypted or if the specified encryption differs from the schema encryption. The encryption clause is not shown for tables created in general tablespaces. To identify encrypted file-per-table and general tablespaces, query the `INNODB_TABLESPACES_ENCRYPTION` column.

  When creating a table with strict mode disabled, the storage engine's default row format is used if the specified row format is not supported. The actual row format of the table is reported in the `Row_format` column. `Create_options` shows the row format that was specified in the `CREATE TABLE` statement.

  When altering the storage engine of a table, table options that are not applicable to the new storage engine are retained in the table definition to enable reverting the table with its previously defined options to the original storage engine, if necessary. `Create_options` may show retained options.

• **Comment**

  The comment used when creating the table (or information as to why MySQL could not access the table information).

**Notes**

• For **InnoDB** tables, `SHOW TABLE STATUS` does not give accurate statistics except for the physical size reserved by the table. The row count is only a rough estimate used in SQL optimization.

• For **NDB** tables, the output of this statement shows appropriate values for the `Avg_row_length` and `Data_length` columns, with the exception that `BLOB` columns are not taken into account.

• For **NDB** tables, `Data_length` includes data stored in main memory only; the `Max_data_length` and `Data_free` columns apply to Disk Data.

• For NDB Cluster Disk Data tables, `Max_data_length` shows the space allocated for the disk part of a Disk Data table or fragment. (In-memory data resource usage is reported by the `Data_length` column.)

• For **MEMORY** tables, the `Data_length`, `Max_data_length`, and `Index_length` values approximate the actual amount of allocated memory. The allocation algorithm reserves memory in large amounts to reduce the number of allocation operations.

• For views, most columns displayed by `SHOW TABLE STATUS` are 0 or `NULL` except that `Name` indicates the view name, `Create_time` indicates the creation time, and `Comment` says `VIEW`.

Table information is also available from the `INFORMATION_SCHEMA TABLES` table. See Section 28.3.38, “The INFORMATION_SCHEMA TABLES Table”.

### 15.7.7.38 SHOW TABLES Statement

```sql
SHOW [EXTENDED] [FULL] TABLES
   [[FROM | IN] db_name]
   [LIKE 'pattern' | WHERE expr]
```

`SHOW TABLES` lists the non-TEMPORARY tables in a given database. You can also get this list using the `mysqlshow db_name` command. The `LIKE` clause, if present, indicates which table names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 28.8, “Extensions to SHOW Statements”.

Matching performed by the `LIKE` clause is dependent on the setting of the `lower_case_table_names` system variable.
SHOW Statements

The optional EXTENDED modifier causes SHOW TABLES to list hidden tables created by failed ALTER
TABLE statements. These temporary tables have names beginning with #sql and can be dropped using DROP TABLE.

This statement also lists any views in the database. The optional FULL modifier causes SHOW TABLES
to display a second output column with values of BASE TABLE for a table, VIEW for a view, or SYSTEM
VIEW for an INFORMATION_SCHEMA table.

If you have no privileges for a base table or view, it does not show up in the output from SHOW TABLES
or mysqlshow db_name.

Table information is also available from the INFORMATION_SCHEMA TABLES table. See
Section 28.3.38, “The INFORMATION_SCHEMA TABLES Table”.

15.7.7.39 SHOW TRIGGERS Statement

SHOW TRIGGERS
  [[FROM | IN] db_name]
  [LIKE 'pattern' | WHERE expr]

SHOW TRIGGERS lists the triggers currently defined for tables in a database (the default database
unless a FROM clause is given). This statement returns results only for databases and tables for which
you have the TRIGGER privilege. The LIKE clause, if present, indicates which table names (not trigger
names) to match and causes the statement to display triggers for those tables. The WHERE clause can
give to select rows using more general conditions, as discussed in Section 28.8, “Extensions to
SHOW Statements”.

For the ins_sum trigger defined in Section 27.3, “Using Triggers”, the output of SHOW TRIGGERS is as
shown here:

mysql> SHOW TRIGGERS LIKE 'acc%'\G

*************************** 1. row ***************************
Trigger: ins_sum
Event: INSERT
Table: account
Statement: SET @sum = @sum + NEW.amount
Timing: BEFORE
Created: 2018-08-08 10:10:12.61
sql_mode: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,
NO_ZERO_IN_DATE,NO_ZERO_DATE,
ERROR_FOR_DIVISION_BY_ZERO,
NO_ENGINE_SUBSTITUTION
Definer: me@localhost
character_set_client: utf8mb4
collation_connection: utf8mb4_0900_ai_ci
Database Collation: utf8mb4_0900_ai_ci

SHOW TRIGGERS output has these columns:

• Trigger

  The name of the trigger.

• Event

  The trigger event. This is the type of operation on the associated table for which the trigger activates.
  The value is INSERT (a row was inserted), DELETE (a row was deleted), or UPDATE (a row was
  modified).

• Table

  The table for which the trigger is defined.

• Statement

  The trigger body; that is, the statement executed when the trigger activates.
SHOW Statements

- **Timing**
  Whether the trigger activates before or after the triggering event. The value is **BEFORE** or **AFTER**.

- **Created**
  The date and time when the trigger was created. This is a **TIMESTAMP(2)** value (with a fractional part in hundredths of seconds) for triggers.

- **sql_mode**
  The SQL mode in effect when the trigger was created, and under which the trigger executes. For the permitted values, see Section 7.1.11, "Server SQL Modes".

- **Definer**
  The account of the user who created the trigger, in 'user_name'@'host_name' format.

- **character_set_client**
  The session value of the **character_set_client** system variable when the trigger was created.

- **collation_connection**
  The session value of the **collation_connection** system variable when the trigger was created.

- **Database Collation**
  The collation of the database with which the trigger is associated.

Trigger information is also available from the **INFORMATION_SCHEMA TRIGGERS** table. See Section 28.3.44, "The INFORMATION_SCHEMA TRIGGERS Table".

### 15.7.7.40 SHOW VARIABLES Statement

```
SHOW [GLOBAL | SESSION] VARIABLES
[LIKE 'pattern' | WHERE expr]
```

**SHOW VARIABLES** shows the values of MySQL system variables (see Section 7.1.8, "Server System Variables"). This statement does not require any privilege. It requires only the ability to connect to the server.

System variable information is also available from these sources:

- The **mysqladmin variables** command. See Section 6.5.2, "mysqladmin — A MySQL Server Administration Program".

For **SHOW VARIABLES**, a **LIKE** clause, if present, indicates which variable names to match. A **WHERE** clause can be given to select rows using more general conditions, as discussed in Section 28.8, "Extensions to SHOW Statements".

**SHOW VARIABLES** accepts an optional **GLOBAL** or **SESSION** variable scope modifier:

- With a **GLOBAL** modifier, the statement displays global system variable values. These are the values used to initialize the corresponding session variables for new connections to MySQL. If a variable has no global value, no value is displayed.

- With a **SESSION** modifier, the statement displays the system variable values that are in effect for the current connection. If a variable has no session value, the global value is displayed. **LOCAL** is a synonym for **SESSION**.
SHOW Statements

- If no modifier is present, the default is **SESSION**.

The scope for each system variable is listed at **Section 7.1.8, “Server System Variables”**.

**SHOW VARIABLES** is subject to a version-dependent display-width limit. For variables with very long values that are not completely displayed, use **SELECT** as a workaround. For example:

```
SELECT @@GLOBAL.innodb_data_file_path;
```

Most system variables can be set at server startup (read-only variables such as **version_comment** are exceptions). Many can be changed at runtime with the **SET** statement. See **Section 7.1.9, “Using System Variables”**, and **Section 15.7.6.1, “SET Syntax for Variable Assignment”**.

Partial output is shown here. The list of names and values may differ for your server. **Section 7.1.8, “Server System Variables”**, describes the meaning of each variable, and **Section 7.1.1, “Configuring the Server”**, provides information about tuning them.

```

<table>
<thead>
<tr>
<th>xa_detach_on_prepare</th>
<th>ON</th>
</tr>
</thead>
</table>

With a LIKE clause, the statement displays only rows for those variables with names that match the pattern. To obtain the row for a specific variable, use a LIKE clause as shown:

```sql
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the % wildcard character in a LIKE clause:

```sql
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because _ is a wildcard that matches any single character, you should escape it as \_ to match it literally. In practice, this is rarely necessary.

15.7.7.41 SHOW WARNINGS Statement

```sql
SHOW WARNINGS [LIMIT [offset,] row_count]
SHOW COUNT(*) WARNINGS
```

SHOW WARNINGS is a diagnostic statement that displays information about the conditions (errors, warnings, and notes) resulting from executing a statement in the current session. Warnings are generated for DML statements such as INSERT, UPDATE, and LOAD DATA as well as DDL statements such as CREATE TABLE and ALTER TABLE.

The LIMIT clause has the same syntax as for the SELECT statement. See Section 15.2.13, “SELECT Statement”.

SHOW WARNINGS is also used following EXPLAIN, to display the extended information generated by EXPLAIN. See Section 10.8.3, “Extended EXPLAIN Output Format”.

SHOW WARNINGS displays information about the conditions resulting from execution of the most recent nondiagnostic statement in the current session. If the most recent statement resulted in an error during parsing, SHOW WARNINGS shows the resulting conditions, regardless of statement type (diagnostic or nondiagnostic).

The SHOW COUNT(*) WARNINGS diagnostic statement displays the total number of errors, warnings, and notes. You can also retrieve this number from the warning_count system variable:

```sql
SHOW COUNT(*) WARNINGS;
SELECT @@warning_count;
```

2874
A difference in these statements is that the first is a diagnostic statement that does not clear the message list. The second, because it is a `SELECT` statement is considered nondiagnostic and does clear the message list.

A related diagnostic statement, `SHOW ERRORS`, shows only error conditions (it excludes warnings and notes), and `SHOW COUNT(*) ERRORS` statement displays the total number of errors. See Section 15.7.7.18, "SHOW ERRORS Statement". `GET DIAGNOSTICS` can be used to examine information for individual conditions. See Section 15.6.7.3, "GET DIAGNOSTICS Statement".

Here is a simple example that shows data-conversion warnings for `INSERT`. The example assumes that strict SQL mode is disabled. With strict mode enabled, the warnings would become errors and terminate the `INSERT`.

```sql
mysql> CREATE TABLE t1 (a TINYINT NOT NULL, b CHAR(4));
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t1 VALUES(10,'mysql'), (NULL,'test'), (300,'xyz');
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3 Duplicates: 0  Warnings: 3

mysql> SHOW WARNINGS
*************************** 1. row ***************************
    Level: Warning
    Code: 1265
  Message: Data truncated for column 'b' at row 1
*************************** 2. row ***************************
    Level: Warning
    Code: 1048
  Message: Column 'a' cannot be null
*************************** 3. row ***************************
    Level: Warning
    Code: 1264
  Message: Out of range value for column 'a' at row 3
3 rows in set (0.00 sec)
```

The `max_error_count` system variable controls the maximum number of error, warning, and note messages for which the server stores information, and thus the number of messages that `SHOW WARNINGS` displays. To change the number of messages the server can store, change the value of `max_error_count`.

`max_error_count` controls only how many messages are stored, not how many are counted. The value of `warning_count` is not limited by `max_error_count`, even if the number of messages generated exceeds `max_error_count`. The following example demonstrates this. The `ALTER TABLE` statement produces three warning messages (strict SQL mode is disabled for the example to prevent an error from occurring after a single conversion issue). Only one message is stored and displayed because `max_error_count` has been set to 1, but all three are counted (as shown by the value of `warning_count`):

```sql
mysql> SHOW VARIABLES LIKE 'max_error_count';
+-----------------+-------+
| Variable_name   | Value |
+-----------------+-------+
| max_error_count | 1024  |
+-----------------+-------+
1 row in set (0.00 sec)

mysql> SET max_error_count=1, sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> ALTER TABLE t1 MODIFY b CHAR;
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 3

mysql> SHOW WARNINGS;
+---------+------+----------------------------------------+
| Level   | Code | Message                                |
+---------+------+----------------------------------------+
2875
```
To disable message storage, set `max_error_count` to 0. In this case, `warning_count` still indicates how many warnings occurred, but messages are not stored and cannot be displayed.

The `sql_notes` system variable controls whether note messages increment `warning_count` and whether the server stores them. By default, `sql_notes` is 1, but if set to 0, notes do not increment `warning_count` and the server does not store them:

```
mysql> SET sql_notes = 1;
Query OK, 0 rows affected (0.00 sec)
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected, 1 warning (0.00 sec)
mysql> SHOW WARNINGS;
+-------+------+------------------------------------+
| Level | Code | Message                            |
+-------+------+------------------------------------+
| Note  | 1051 | Unknown table 'test.no_such_table' |
+-------+------+------------------------------------+
1 row in set (0.00 sec)
```

```
mysql> SET sql_notes = 0;
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected (0.00 sec)
mysql> SHOW WARNINGS;
Empty set (0.00 sec)
```

The MySQL server sends to each client a count indicating the total number of errors, warnings, and notes resulting from the most recent statement executed by that client. From the C API, this value can be obtained by calling `mysql_warning_count()`. See `mysql_warning_count()`.

In the `mysql` client, you can enable and disable automatic warnings display using the `warnings` and `nowarning` commands, respectively, or their shortcuts, `\W` and `\w` (see Section 6.5.1.2, “mysql Client Commands”). For example:

```
mysql> \W
Show warnings enabled.
mysql> SELECT 1/0;
+------+
| 1/0  |
+------+
1 row in set, 1 warning (0.03 sec)
Warning (Code 1365): Division by 0
mysql> \w
Show warnings disabled.
```

## Other Administrative Statements

### BINLOG Statement

**BINLOG** `str`

BINLOG is an internal-use statement. It is generated by the `mysqlbinlog` program as the printable representation of certain events in binary log files. (See Section 6.6.9, “mysqlbinlog — Utility for Processing Binary Log Files”.) The `str` value is a base 64-encoded string that the server decodes to determine the data change indicated by the corresponding event.
To execute `BINLOG` statements when applying `mysqlbinlog` output, a user account requires the `BINLOG_ADMIN` privilege (or the deprecated `SUPER` privilege), or the `REPLICATION_APPLIER` privilege plus the appropriate privileges to execute each log event.

This statement can execute only format description events and row events.

### 15.7.8.2 CACHE INDEX Statement

```sql
CACHE INDEX {
    tbl_index_list [, tbl_index_list] ...
    | tbl_name PARTITION (partition_list)
} IN key_cache_name

tbl_index_list:
    tbl_name [[INDEX|KEY] (index_name[, index_name] ...)]

partition_list: {
    partition_name[, partition_name] ...
    | ALL
}
```

The `CACHE INDEX` statement assigns table indexes to a specific key cache. It applies only to `MyISAM` tables, including partitioned `MyISAM` tables. After the indexes have been assigned, they can be preloaded into the cache if desired with `LOAD INDEX INTO CACHE`.

The following statement assigns indexes from the tables `t1`, `t2`, and `t3` to the key cache named `hot_cache`:

```sql
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
```

| Table   | Op                 | Msg_type | Msg_text |
|---------|--------------------+----------+----------|
| test.t1 | assign_to_keycache | status   | OK       |
| test.t2 | assign_to_keycache | status   | OK       |
| test.t3 | assign_to_keycache | status   | OK       |

The syntax of `CACHE INDEX` enables you to specify that only particular indexes from a table should be assigned to the cache. However, the implementation assigns all the table's indexes to the cache, so there is no reason to specify anything other than the table name.

The key cache referred to in a `CACHE INDEX` statement can be created by setting its size with a parameter setting statement or in the server parameter settings. For example:

```sql
SET GLOBAL keycache1.key_buffer_size=128*1024;
```

Key cache parameters are accessed as members of a structured system variable. See Section 7.1.9.5, "Structured System Variables".

A key cache must exist before you assign indexes to it, or an error occurs:

```sql
mysql> CACHE INDEX t1 IN non_existent_cache;
ERROR 1284 (HY000): Unknown key cache 'non_existent_cache'
```

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it are reassigned to the default key cache.

Index assignment affects the server globally: If one client assigns an index to a given cache, this cache is used for all queries involving the index, no matter which client issues the queries.

`CACHE INDEX` is supported for partitioned `MyISAM` tables. You can assign one or more indexes for one, several, or all partitions to a given key cache. For example, you can do the following:

```sql
CREATE TABLE pt (c1 INT, c2 VARCHAR(50), INDEX i(c1))
ENGINE=MyISAM
```
PARTITION BY HASH(c1)
PARTITIONS 4;

SET GLOBAL kc_fast.key_buffer_size = 128 * 1024;
SET GLOBAL kc_slow.key_buffer_size = 128 * 1024;

CACHE INDEX pt PARTITION (p0) IN kc_fast;
CACHE INDEX pt PARTITION (p1, p3) IN kc_slow;

The previous set of statements performs the following actions:

• Creates a partitioned table with 4 partitions; these partitions are automatically named p0, ..., p3; this table has an index named i on column c1.

• Creates 2 key caches named kc_fast and kc_slow

• Assigns the index for partition p0 to the kc_fast key cache and the index for partitions p1 and p3 to the kc_slow key cache; the index for the remaining partition (p2) uses the server's default key cache.

If you wish instead to assign the indexes for all partitions in table pt to a single key cache named kc_all, you can use either of the following two statements:

CACHE INDEX pt PARTITION (ALL) IN kc_all;
CACHE INDEX pt IN kc_all;

The two statements just shown are equivalent, and issuing either one has exactly the same effect. In other words, if you wish to assign indexes for all partitions of a partitioned table to the same key cache, the PARTITION (ALL) clause is optional.

When assigning indexes for multiple partitions to a key cache, the partitions need not be contiguous, and you need not list their names in any particular order. Indexes for any partitions not explicitly assigned to a key cache automatically use the server default key cache.

Index preloading is also supported for partitioned MyISAM tables. For more information, see Section 15.7.8.5, “LOAD INDEX INTO CACHE Statement”.

15.7.8.3 FLUSH Statement

FLUSH [NO_WRITE_TO_BINLOG | LOCAL] { 
  flush_option [, flush_option] ... 
  | tables_option 
}

flush_option: {
  BINARY LOGS 
  | ENGINE LOGS 
  | ERROR LOGS 
  | GENERAL LOGS 
  | LOGS 
  | PRIVILEGES 
  | OPTIMIZER_COSTS 
  | RELAY LOGS [FOR CHANNEL channel] 
  | SLOW LOGS 
  | STATUS 
  | USER_RESOURCES 
}

tables_option: {
  table_synonym 
  | table_synonym tbl_name [, tbl_name] ... 
  | table_synonym WITH READ LOCK 
  | table_synonym tbl_name [, tbl_name] ... WITH READ LOCK 
  | table_synonym tbl_name [, tbl_name] ... FOR EXPORT 
}

table_synonym: {
The `FLUSH` statement has several variant forms that clear or reload various internal caches, flush tables, or acquire locks. Each `FLUSH` operation requires the privileges indicated in its description.

Note

It is not possible to issue `FLUSH` statements within stored functions or triggers. However, you may use `FLUSH` in stored procedures, so long as these are not called from stored functions or triggers. See Section 27.8, “Restrictions on Stored Programs”.

By default, the server writes `FLUSH` statements to the binary log so that they replicate to replicas. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

Note

`FLUSH LOGS, FLUSH BINARY LOGS, FLUSH TABLES WITH READ LOCK` (with or without a table list), and `FLUSH TABLES tbl_name ... FOR EXPORT` are not written to the binary log in any case because they would cause problems if replicated to a replica.

The `FLUSH` statement causes an implicit commit. See Section 15.3.3, “Statements That Cause an Implicit Commit”.

The `mysqladmin` utility provides a command-line interface to some flush operations, using commands such as `flush-logs`, `flush-privileges`, `flush-status`, and `flush-tables`. See Section 6.5.2, “mysqladmin — A MySQL Server Administration Program”.

Sending a `SIGHUP` or `SIGUSR1` signal to the server causes several flush operations to occur that are similar to various forms of the `FLUSH` statement. Signals can be sent by the root system account or the system account that owns the server process. This enables the flush operations to be performed without having to connect to the server, which requires a MySQL account that has privileges sufficient for those operations. See Section 6.10, “Unix Signal Handling in MySQL”.

The `RESET` statement is similar to `FLUSH`. See Section 15.7.8.6, “RESET Statement”, for information about using `RESET` with replication.

The following list describes the permitted `FLUSH` statement `flush_option` values. For descriptions of the permitted `tables_option` values, see `FLUSH TABLES Syntax`.

- **FLUSH BINARY LOGS**

  Closes and reopens any binary log file to which the server is writing. If binary logging is enabled, the sequence number of the binary log file is incremented by one relative to the previous file.

  This operation requires the `RELOAD` privilege.

- **FLUSH ENGINE LOGS**

  Closes and reopens any flushable logs for installed storage engines. This causes InnoDB to flush its logs to disk.

  This operation requires the `RELOAD` privilege.

- **FLUSH ERROR LOGS**

  Closes and reopens any error log file to which the server is writing.

  This operation requires the `RELOAD` privilege.
• **FLUSH GENERAL LOGS**

Closes and reopens any general query log file to which the server is writing.

This operation requires the `RELOAD` privilege.

This operation has no effect on tables used for the general query log (see Section 7.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”).

• **FLUSH LOGS**

Closes and reopens any log file to which the server is writing.

This operation requires the `RELOAD` privilege.

The effect of this operation is equivalent to the combined effects of these operations:

```plaintext
FLUSH BINARY LOGS
FLUSH ENGINE LOGS
FLUSH ERROR LOGS
FLUSH GENERAL LOGS
FLUSH RELAY LOGS
FLUSH SLOW LOGS
```

• **FLUSH OPTIMIZER_COSTS**

Re-reads the cost model tables so that the optimizer starts using the current cost estimates stored in them.

This operation requires the `FLUSH_OPTIMIZER_COSTS` or `RELOAD` privilege.

The server writes a warning to the error log for any unrecognized cost model table entries. For information about these tables, see Section 10.9.5, “The Optimizer Cost Model”. This operation affects only sessions that begin subsequent to the flush. Existing sessions continue to use the cost estimates that were current when they began.

• **FLUSH PRIVILEGES**

Re-reads the privileges from the grant tables in the `mysql` system schema. As part of this operation, the server reads the `global_grants` table containing dynamic privilege assignments and registers any unregistered privileges found there.

Reloading the grant tables is necessary to enable updates to MySQL privileges and users only if you make such changes directly to the grant tables; it is not needed for account management statements such as `GRANT` or `REVOKE`, which take effect immediately. See Section 8.2.13, “When Privilege Changes Take Effect”, for more information.

This operation requires the `RELOAD` or `FLUSH_PRIVILEGES` privilege.

If the `--skip-grant-tables` option was specified at server startup to disable the MySQL privilege system, `FLUSH_PRIVILEGES` provides a way to enable the privilege system at runtime.

Resets failed-login tracking (or enables it if the server was started with `--skip-grant-tables`) and unlocks any temporarily locked accounts. See Section 8.2.15, “Password Management”.

Frees memory cached by the server as a result of `GRANT`, `CREATE USER`, `CREATE SERVER`, and `INSTALL PLUGIN` statements. This memory is not released by the corresponding `REVOKE`, `DROP USER`, `DROP SERVER`, and `UNINSTALL PLUGIN` statements, so for a server that executes many instances of the statements that cause caching, there is an increase in cached memory use unless it is freed with `FLUSH_PRIVILEGES`.

Clears the in-memory cache used by the `caching_sha2_password` authentication plugin. See Cache Operation for SHA-2 Pluggable Authentication.
Other Administrative Statements

- **FLUSH RELAY LOGS [FOR CHANNEL channel]**

  Closes and reopens any relay log file to which the server is writing. If relay logging is enabled, the sequence number of the relay log file is incremented by one relative to the previous file.

  This operation requires the **RELOAD** privilege.

  The **FOR CHANNEL channel** clause enables you to name which replication channel the operation applies to. Execute `FLUSH RELAY LOGS FOR CHANNEL channel` to flush the relay log for a specific replication channel. If no channel is named and no extra replication channels exist, the operation applies to the default channel. If no channel is named and multiple replication channels exist, the operation applies to all replication channels. For more information, see Section 19.2.2, “Replication Channels”.

- **FLUSH SLOW LOGS**

  Closes and reopens any slow query log file to which the server is writing.

  This operation requires the **RELOAD** privilege.

  This operation has no effect on tables used for the slow query log (see Section 7.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”).

- **FLUSH STATUS**

 Flushes status indicators.

  This operation adds the current thread's session status variable values to the global values and resets the session values to zero. Some global variables may be reset to zero as well. It also resets the counters for key caches (default and named) to zero and sets `Max_used_connections` to the current number of open connections. This information may be of use when debugging a query. See Section 1.6, “How to Report Bugs or Problems”.

  **FLUSH STATUS** is unaffected by `read_only` or `super_read_only`, and is always written to the binary log.

  This operation requires the **FLUSH_STATUS** or **RELOAD** privilege.

- **FLUSH USER_RESOURCES**

  Resets all per-hour user resource indicators to zero.

  This operation requires the **FLUSH_USER_RESOURCES** or **RELOAD** privilege.

  Resetting resource indicators enables clients that have reached their hourly connection, query, or update limits to resume activity immediately. **FLUSH USER_RESOURCES** does not apply to the limit on maximum simultaneous connections that is controlled by the `max_user_connections` system variable. See Section 8.2.21, “Setting Account Resource Limits”.

**FLUSH TABLES Syntax**

**FLUSH TABLES** flushes tables, and, depending on the variant used, acquires locks. Any **TABLES** variant used in a **FLUSH** statement must be the only option used. **FLUSH TABLE** is a synonym for **FLUSH TABLES**.

**Note**

The descriptions here that indicate tables are flushed by closing them apply differently for **InnoDB**, which flushes table contents to disk but leaves them open. This still permits table files to be copied while the tables are open, as long as other activity does not modify them.
• **FLUSH TABLES**

Closes all open tables, forces all tables in use to be closed, and flushes the prepared statement cache.

This operation requires the `FLUSH_TABLES` or `RELOAD` privilege.

For information about prepared statement caching, see Section 10.10.3, “Caching of Prepared Statements and Stored Programs”.

`FLUSH TABLES` is not permitted when there is an active `LOCK TABLES ... READ`. To flush and lock tables, use `FLUSH TABLES tbl_name ... WITH READ LOCK` instead.

• **FLUSH TABLES `tbl_name`, `tbl_name` ...**

With a list of one or more comma-separated table names, this operation is like `FLUSH TABLES` with no names except that the server flushes only the named tables. If a named table does not exist, no error occurs.

This operation requires the `FLUSH_TABLES` or `RELOAD` privilege.

• **FLUSH TABLES WITH READ LOCK**

Closes all open tables and locks all tables for all databases with a global read lock.

This operation requires the `FLUSH_TABLES` or `RELOAD` privilege.

This operation is a very convenient way to get backups if you have a file system such as Veritas or ZFS that can take snapshots in time. Use `UNLOCK TABLES` to release the lock.

`FLUSH TABLES WITH READ LOCK` acquires a global read lock rather than table locks, so it is not subject to the same behavior as `LOCK TABLES` and `UNLOCK TABLES` with respect to table locking and implicit commits:

• **UNLOCK TABLES** implicitly commits any active transaction only if any tables currently have been locked with `LOCK TABLES`. The commit does not occur for `UNLOCK TABLES` following `FLUSH TABLES WITH READ LOCK` because the latter statement does not acquire table locks.

• Beginning a transaction causes table locks acquired with `LOCK TABLES` to be released, as though you had executed `UNLOCK TABLES`. Beginning a transaction does not release a global read lock acquired with `FLUSH TABLES WITH READ LOCK`.

`FLUSH TABLES WITH READ LOCK` does not prevent the server from inserting rows into the log tables (see Section 7.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”).

• **FLUSH TABLES `tbl_name`, `tbl_name` ... WITH READ LOCK**

Flushes and acquires read locks for the named tables.

This operation requires the `FLUSH_TABLES` or `RELOAD` privilege. Because it acquires table locks, it also requires the `LOCK TABLES` privilege for each table.

The operation first acquires exclusive metadata locks for the tables, so it waits for transactions that have those tables open to complete. Then the operation flushes the tables from the table cache, reopens the tables, acquires table locks (like `LOCK TABLES ... READ`), and downgrades the
metadata locks from exclusive to shared. After the operation acquires locks and downgrades the metadata locks, other sessions can read but not modify the tables.

This operation applies only to existing base (non-TEMPORARY) tables. If a name refers to a base table, that table is used. If it refers to a TEMPORARY table, it is ignored. If a name applies to a view, an ER_WRONG_OBJECT error occurs. Otherwise, an ER_NO_SUCH_TABLE error occurs.

Use UNLOCK TABLES to release the locks, LOCK TABLES to release the locks and acquire other locks, or START TRANSACTION to release the locks and begin a new transaction.

This FLUSH TABLES variant enables tables to be flushed and locked in a single operation. It provides a workaround for the restriction that FLUSH TABLES is not permitted when there is an active LOCK TABLES ... READ.

This operation does not perform an implicit UNLOCK TABLES, so an error results if you perform the operation while there is any active LOCK TABLES or use it a second time without first releasing the locks acquired.

If a flushed table was opened with HANDLER, the handler is implicitly flushed and loses its position.

• FLUSH TABLES tbl_name [, tbl_name] ... FOR EXPORT

This FLUSH TABLES variant applies to InnoDB tables. It ensures that changes to the named tables have been flushed to disk so that binary table copies can be made while the server is running.

This operation requires the FLUSH_TABLES or RELOAD privilege. Because it acquires locks on tables in preparation for exporting them, it also requires the LOCK_TABLES and SELECT privileges for each table.

The operation works like this:

1. It acquires shared metadata locks for the named tables. The operation blocks as long as other sessions have active transactions that have modified those tables or hold table locks for them. When the locks have been acquired, the operation blocks transactions that attempt to update the tables, while permitting read-only operations to continue.

2. It checks whether all storage engines for the tables support FOR EXPORT. If any do not, an ER_ILLEGAL_HA error occurs and the operation fails.

3. The operation notifies the storage engine for each table to make the table ready for export. The storage engine must ensure that any pending changes are written to disk.

4. The operation puts the session in lock-tables mode so that the metadata locks acquired earlier are not released when the FOR EXPORT operation completes.

This operation applies only to existing base (non-TEMPORARY) tables. If a name refers to a base table, that table is used. If it refers to a TEMPORARY table, it is ignored. If a name applies to a view, an ER_WRONG_OBJECT error occurs. Otherwise, an ER_NO_SUCH_TABLE error occurs.

InnoDB supports FOR EXPORT for tables that have their own .ibd file file (that is, tables created with the innodb_file_per_table setting enabled). InnoDB ensures when notified by the FOR EXPORT operation that any changes have been flushed to disk. This permits a binary copy of table contents to be made while the FOR EXPORT operation is in effect because the .ibd file is transaction consistent and can be copied while the server is running. FOR EXPORT does not apply to InnoDB system tablespace files, or to InnoDB tables that have FULLTEXT indexes.

FLUSH TABLES ...FOR EXPORT is supported for partitioned InnoDB tables.

When notified by FOR EXPORT, InnoDB writes to disk certain kinds of data that is normally held in memory or in separate disk buffers outside the tablespace files. For each table, InnoDB also
produces a file named `table_name.cfg` in the same database directory as the table. The `cfg` file contains metadata needed to reimport the tablespace files later, into the same or different server.

When the `FOR EXPORT` operation completes, InnoDB has flushed all dirty pages to the table data files. Any change buffer entries are merged prior to flushing. At this point, the tables are locked and quiescent: The tables are in a transactionally consistent state on disk and you can copy the `.ibd` tablespace files along with the corresponding `.cfg` files to get a consistent snapshot of those tables.

For the procedure to reimport the copied table data into a MySQL instance, see Section 17.6.1.3, “Importing InnoDB Tables”.

After you are done with the tables, use `UNLOCK TABLES` to release the locks, `LOCK TABLES` to release the locks and acquire other locks, or `START TRANSACTION` to release the locks and begin a new transaction.

While any of these statements is in effect within the session, attempts to use `FLUSH TABLES ... FOR EXPORT` produce an error:

```
FLUSH TABLES ... WITH READ LOCK
FLUSH TABLES ... FOR EXPORT
LOCK TABLES ... READ
LOCK TABLES ... WRITE
```

While `FLUSH TABLES ... FOR EXPORT` is in effect within the session, attempts to use any of these statements produce an error:

```
FLUSH TABLES WITH READ LOCK
FLUSH TABLES ... WITH READ LOCK
FLUSH TABLES ... FOR EXPORT
```

### 15.7.8.4 KILL Statement

```
KILL [CONNECTION | QUERY] processlist_id
```

Each connection to `mysqld` runs in a separate thread. You can kill a thread with the `KILL processlist_id` statement.

Thread processlist identifiers can be determined from the `ID` column of the `INFORMATION_SCHEMA PROCESLIST` table, the `Id` column of `SHOW PROCESSLIST` output, and the `PROCESSLIST_ID` column of the Performance Schema `threads` table. The value for the current thread is returned by the `CONNECTION_ID()` function.

`KILL` permits an optional `CONNECTION` or `QUERY` modifier:

- **KILL CONNECTION** is the same as `KILL` with no modifier: It terminates the connection associated with the given `processlist_id`, after terminating any statement the connection is executing.

- **KILL QUERY** terminates the statement the connection is currently executing, but leaves the connection itself intact.

The ability to see which threads are available to be killed depends on the `PROCESS` privilege:

- Without `PROCESS`, you can see only your own threads.

- With `PROCESS`, you can see all threads.

The ability to kill threads and statements depends on the `CONNECTION_ADMIN` privilege and the deprecated `SUPER` privilege:

- Without `CONNECTION_ADMIN` or `SUPER`, you can kill only your own threads and statements.

- With `CONNECTION_ADMIN` or `SUPER`, you can kill all threads and statements, except that to affect a thread or statement that is executing with the `SYSTEM_USER` privilege, your own session must additionally have the `SYSTEM_USER` privilege.
You can also use the `mysqladmin processlist` and `mysqladmin kill` commands to examine and kill threads.

When you use `KILL`, a thread-specific kill flag is set for the thread. In most cases, it might take some time for the thread to die because the kill flag is checked only at specific intervals:

- During `SELECT` operations, for `ORDER BY` and `GROUP BY` loops, the flag is checked after reading a block of rows. If the kill flag is set, the statement is aborted.
- `ALTER TABLE` operations that make a table copy check the kill flag periodically for each few copied rows read from the original table. If the kill flag was set, the statement is aborted and the temporary table is deleted.

The `KILL` statement returns without waiting for confirmation, but the kill flag check aborts the operation within a reasonably small amount of time. Aborting the operation to perform any necessary cleanup also takes some time.

- During `UPDATE` or `DELETE` operations, the kill flag is checked after each block read and after each updated or deleted row. If the kill flag is set, the statement is aborted. If you are not using transactions, the changes are not rolled back.
- `GET_LOCK()` aborts and returns `NULL`.
- If the thread is in the table lock handler (state: Locked), the table lock is quickly aborted.
- If the thread is waiting for free disk space in a write call, the write is aborted with a “disk full” error message.
- `EXPLAIN ANALYZE` aborts and prints the first row of output.

### Warning

Killing a `REPAIR TABLE` or `OPTIMIZE TABLE` operation on a `MyISAM` table results in a table that is corrupted and unusable. Any reads or writes to such a table fail until you optimize or repair it again (without interruption).

#### 15.7.8.5 LOAD INDEX INTO CACHE Statement

```
LOAD INDEX INTO CACHE
  tbl_index_list [, tbl_index_list] ...

tbl_index_list:
  tbl_name
    [PARTITION (partition_list)]
    [[INDEX|KEY] (index_name[, index_name] ...)]
    [IGNORE LEAVES]

partition_list: {
  partition_name[, partition_name] ...
  | ALL
}
```

The `LOAD INDEX INTO CACHE` statement preloads a table index into the key cache to which it has been assigned by an explicit `CACHE INDEX` statement, or into the default key cache otherwise.

`LOAD INDEX INTO CACHE` applies only to `MyISAM` tables, including partitioned `MyISAM` tables. In addition, indexes on partitioned tables can be preloaded for one, several, or all partitions.

The `IGNORE LEAVES` modifier causes only blocks for the nonleaf nodes of the index to be preloaded.

`IGNORE LEAVES` is also supported for partitioned `MyISAM` tables.

The following statement preloads nodes (index blocks) of indexes for the tables `t1` and `t2`:

```
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
+---------+--------------+----------+----------+
2885
```
This statement preloads all index blocks from `t1`. It preloads only blocks for the nonleaf nodes from `t2`.

The syntax of `LOAD INDEX INTO CACHE` enables you to specify that only particular indexes from a table should be preloaded. However, the implementation preloads all the table's indexes into the cache, so there is no reason to specify anything other than the table name.

It is possible to preload indexes on specific partitions of partitioned `MyISAM` tables. For example, of the following 2 statements, the first preloads indexes for partition `p0` of a partitioned table `pt`, while the second preloads the indexes for partitions `p1` and `p3` of the same table:

```
LOAD INDEX INTO CACHE pt PARTITION (p0);
LOAD INDEX INTO CACHE pt PARTITION (p1, p3);
```

To preload the indexes for all partitions in table `pt`, you can use either of the following two statements:

```
LOAD INDEX INTO CACHE pt PARTITION (ALL);
LOAD INDEX INTO CACHE pt;
```

The two statements just shown are equivalent, and issuing either one has exactly the same effect. In other words, if you wish to preload indexes for all partitions of a partitioned table, the `PARTITION (ALL)` clause is optional.

When preloading indexes for multiple partitions, the partitions need not be contiguous, and you need not list their names in any particular order.

`LOAD INDEX INTO CACHE ... IGNORE LEAVES` fails unless all indexes in a table have the same block size. To determine index block sizes for a table, use `myisamchk -dv` and check the `Blocksize` column.

### 15.7.8.6 RESET Statement

```
RESET reset_option [, reset_option] ...
```

```
reset_option: {
    BINARY LOGS AND GTIDS
    | REPLICA
}
```

The `RESET` statement is used to clear the state of various server operations. You must have the `RELOAD` privilege to execute `RESET`.

For information about the `RESET PERSIST` statement that removes persisted global system variables, see Section 15.7.8.7, “RESET PERSIST Statement”.

`RESET` acts as a stronger version of the `FLUSH` statement. See Section 15.7.8.3, “FLUSH Statement”.

The `RESET` statement causes an implicit commit. See Section 15.3.3, “Statements That Cause an Implicit Commit”.

The following list describes the permitted `RESET` statement `reset_option` values:

- **RESET BINARY LOGS AND GTIDS**
  
  Deletes all binary logs listed in the index file, resets the binary log index file to be empty, and creates a new binary log file.

- **RESET REPLICA**

  Makes the replica forget its replication position in the source binary logs. Also resets the relay log by deleting any existing relay log files and beginning a new one.
15.7.8.7 RESET PERSIST Statement

\[
\text{RESET PERSIST }[[\text{IF EXISTS}] \ system\_var\_name]
\]

\text{RESET PERSIST} removes persisted global system variable settings from the \text{mysqld-auto.cnf} option file in the data directory. Removing a persisted system variable causes the variable no longer to be initialized from \text{mysqld-auto.cnf} at server startup. For more information about persisting system variables and the \text{mysqld-auto.cnf} file, see Section 7.1.9.3, “Persisted System Variables”.

The privileges required for \text{RESET PERSIST} depend on the type of system variable to be removed:

- For dynamic system variables, this statement requires the \text{SYSTEM_VARIABLES_ADMIN} privilege (or the deprecated \text{SUPER} privilege).
- For read-only system variables, this statement requires the \text{SYSTEM_VARIABLES_ADMIN} and \text{PERSIST_RO_VARIABLES_ADMIN} privileges.

See Section 7.1.9.1, “System Variable Privileges”.

Depending on whether the variable name and \text{IF EXISTS} clauses are present, the \text{RESET PERSIST} statement has these forms:

- To remove all persisted variables from \text{mysqld-auto.cnf}, use \text{RESET PERSIST} without naming any system variable:

  \[
  \text{RESET PERSIST;}
  \]

  You must have privileges for removing both dynamic and read-only system variables if \text{mysqld-auto.cnf} contains both kinds of variables.

- To remove a specific persisted variable from \text{mysqld-auto.cnf}, name it in the statement:

  \[
  \text{RESET PERSIST } system\_var\_name;
  \]

  This includes plugin system variables, even if the plugin is not currently installed. If the variable is not present in the file, an error occurs.

- To remove a specific persisted variable from \text{mysqld-auto.cnf}, but produce a warning rather than an error if the variable is not present in the file, add an \text{IF EXISTS} clause to the previous syntax:

  \[
  \text{RESET PERSIST IF EXISTS } system\_var\_name;
  \]

\text{RESET PERSIST} is not affected by the value of the \text{persisted_globals_load} system variable.

\text{RESET PERSIST} affects the contents of the Performance Schema \text{persisted_variables} table because the table contents correspond to the contents of the \text{mysqld-auto.cnf} file. On the other hand, because \text{RESET PERSIST} does not change variable values, it has no effect on the contents of the Performance Schema \text{variables_info} table until the server is restarted.

For information about \text{RESET} statement variants that clear the state of other server operations, see Section 15.7.8.6, “RESET Statement”.

15.7.8.8 RESTART Statement

\text{RESTART}

This statement stops and restarts the MySQL server. It requires the \text{SHUTDOWN} privilege.

One use for \text{RESTART} is when it is not possible or convenient to gain command-line access to the MySQL server on the server host to restart it. For example, \text{SET PERSIST_ONLY} can be used at runtime to make configuration changes to system variables that can be set only at server startup, but the server must still be restarted for those changes to take effect. The \text{RESTART} statement provides a way to do so from within client sessions, without requiring command-line access on the server host.
After executing a **RESTART** statement, the client can expect the current connection to be lost. If auto-reconnect is enabled, the connection is reestablished after the server restarts. Otherwise, the connection must be reestablished manually.

A successful **RESTART** operation requires **mysql** to be running in an environment that has a monitoring process available to detect a server shutdown performed for restart purposes:

- In the presence of a monitoring process, **RESTART** causes **mysql** to terminate such that the monitoring process can determine that it should start a new **mysql** instance.
- If no monitoring process is present, **RESTART** fails with an error.

These platforms provide the necessary monitoring support for the **RESTART** statement:

- Windows, when **mysql** is started as a Windows service or standalone. (**mysql** forks, and one process acts as a monitor to the other, which acts as the server.)
- Unix and Unix-like systems that use systemd or **mysqld_safe** to manage **mysql**.

To configure a monitoring environment such that **mysql** enables the **RESTART** statement:

1. Set the **MYSQLD_PARENT_PID** environment variable to the value of the process ID of the process that starts **mysql**, before starting **mysql**.
2. When **mysql** performs a shutdown due to use of the **RESTART** statement, it returns exit code 16.
3. When the monitoring process detects an exit code of 16, it starts **mysql** again. Otherwise, it exits.

Here is a minimal example as implemented in the **bash** shell:

```bash
#!/bin/bash
export MYSQLD_PARENT_PID=$$
export MYSQLD_RESTART_EXIT=16
while true ; do
    bin/mysqld mysqld options here
    if [ $? -ne $MYSQLD_RESTART_EXIT ]; then
        break
    fi
done
```

On Windows, the forking used to implement **RESTART** makes determining the server process to attach to for debugging more difficult. To alleviate this, starting the server with **--gdb** suppresses forking, in addition to its other actions done to set up a debugging environment. In non-debug settings, **--no-monitor** may be used for the sole purpose of suppressing forking the monitor process. For a server started with either **--gdb** or **--no-monitor**, executing **RESTART** causes the server to simply exit without restarting.

The **Com_restart** status variable tracks the number of **RESTART** statements. Because status variables are initialized for each server startup and do not persist across restarts, **Com_restart** normally has a value of zero, but can be nonzero if **RESTART** statements were executed but failed.

### 15.7.8.9 SHUTDOWN Statement

**SHUTDOWN**

This statement stops the MySQL server. It requires the **SHUTDOWN** privilege.

**SHUTDOWN** provides an SQL-level interface to the same functionality available using the **mysqladmin shutdown** command. A successful **SHUTDOWN** sequence consists of checking the privileges, validating the arguments, and sending an OK packet to the client. Then the server is shut down.
Utility Statements

The `Com_shutdown` status variable tracks the number of `SHUTDOWN` statements. Because status variables are initialized for each server startup and do not persist across restarts, `Com_shutdown` normally has a value of zero, but can be nonzero if `SHUTDOWN` statements were executed but failed.

Another way to stop the server is to send it a `SIGTERM` signal, which can be done by `root` or the account that owns the server process. `SIGTERM` enables server shutdown to be performed without having to connect to the server. See Section 6.10, “Unix Signal Handling in MySQL”.

### 15.8 Utility Statements

#### 15.8.1 DESCRIBE Statement

The `DESCRIBE` and `EXPLAIN` statements are synonyms, used either to obtain information about table structure or query execution plans. For more information, see Section 15.7.7.6, “SHOW COLUMNS Statement”, and Section 15.8.2, “EXPLAIN Statement”.

#### 15.8.2 EXPLAIN Statement

```
{EXPLAIN | DESCRIBE | DESC} [EXPLAIN | DESCRIBE | DESC] [EXPLAIN | DESCRIBE | DESC]
```

```
{[explain_type] [INTO variable] | | FOR CONNECTION connection_id]
{EXPLAIN | DESCRIBE | DESC} ANALYZE [FORMAT = TREE] [schema_spec] select_statement
```

```
explain_type: {
  FORMAT = format_name
}
```

```
format_name: {
  TRADITIONAL
  | JSON
  | TREE
}
```

```
explainable_stmt: {
  SELECT statement
  | TABLE statement
  | DELETE statement
  | INSERT statement
  | REPLACE statement
  | UPDATE statement
}
```

```
schema_spec:
  FOR {SCHEMA | DATABASE} schema_name
```

The `DESCRIBE` and `EXPLAIN` statements are synonyms. In practice, the `DESCRIBE` keyword is more often used to obtain information about table structure, whereas `EXPLAIN` is used to obtain a query execution plan (that is, an explanation of how MySQL would execute a query).

The following discussion uses the `DESCRIBE` and `EXPLAIN` keywords in accordance with those uses, but the MySQL parser treats them as completely synonymous.

- **Obtaining Table Structure Information**
- **Obtaining Execution Plan Information**
- **Obtaining Information with EXPLAIN ANALYZE**

### Obtaining Table Structure Information

`DESCRIBE` provides information about the columns in a table:

```
mysql> DESCRIBE City;
```
EXPLAIN Statement

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Null</th>
<th>Key</th>
<th>Default</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>Id</td>
<td>int(11)</td>
<td>NO</td>
<td>PRI</td>
<td>NULL</td>
<td>auto_increment</td>
</tr>
<tr>
<td>Name</td>
<td>char(35)</td>
<td>NO</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Country</td>
<td>char(3)</td>
<td>NO</td>
<td>UNI</td>
<td></td>
<td></td>
</tr>
<tr>
<td>District</td>
<td>char(20)</td>
<td>YES</td>
<td>MUL</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Population</td>
<td>int(11)</td>
<td>NO</td>
<td></td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

DESCRIBE is a shortcut for SHOW COLUMNS. These statements also display information for views. The description for SHOW COLUMNS provides more information about the output columns. See Section 15.7.7.6, “SHOW COLUMNS Statement”.

By default, DESCRIBE displays information about all columns in the table. col_name, if given, is the name of a column in the table. In this case, the statement displays information only for the named column. wild, if given, is a pattern string. It can contain the SQL % and _ wildcard characters. In this case, the statement displays output only for the columns with names matching the string. There is no need to enclose the string within quotation marks unless it contains spaces or other special characters.

The DESCRIBE statement is provided for compatibility with Oracle.

The SHOW CREATE TABLE, SHOW TABLE STATUS, and SHOW INDEX statements also provide information about tables. See Section 15.7.7, “SHOW Statements”.

The explain_format system variable has no effect on the output of EXPLAIN when used to obtain information about table columns.

Obtaining Execution Plan Information

The EXPLAIN statement provides information about how MySQL executes statements:

- EXPLAIN works with SELECT, DELETE, INSERT, REPLACE, UPDATE, and TABLE statements.

- When EXPLAIN is used with an explainable statement, MySQL displays information from the optimizer about the statement execution plan. That is, MySQL explains how it would process the statement, including information about how tables are joined and in which order. For information about using EXPLAIN to obtain execution plan information, see Section 10.8.2, “EXPLAIN Output Format”.

- When EXPLAIN is used with FOR CONNECTION connection_id rather than an explainable statement, it displays the execution plan for the statement executing in the named connection. See Section 10.8.4, “Obtaining Execution Plan Information for a Named Connection”.

- For explainable statements, EXPLAIN produces additional execution plan information that can be displayed using SHOW WARNINGS. See Section 10.8.3, “Extended EXPLAIN Output Format”.

- EXPLAIN is useful for examining queries involving partitioned tables. See Section 26.3.5, “Obtaining Information About Partitions”.

- The FORMAT option can be used to select the output format. TRADITIONAL presents the output in tabular format. This is the default if no FORMAT option is present. JSON format displays the information in JSON format. TREE provides tree-like output with more precise descriptions of query handling than the TRADITIONAL format; it is the only format which shows hash join usage (see Section 10.2.1.4, “Hash Join Optimization”) and is always used for EXPLAIN ANALYZE.

In MySQL 8.4, the default output format used by EXPLAIN (that is, when it has no FORMAT option) is determined by the value of the explain_format system variable. The precise effects of this variable are described later in this section.

MySQL 8.4 supports an additional INTO option with EXPLAIN FORMAT=JSON, which enables saving the JSON formatted output into a user variable, like this:

```
mysql> EXPLAIN FORMAT=JSON INTO @myselect
```
-> SELECT name FROM a WHERE id = 2;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @myselect

This works with any explainable statement (SELECT, TABLE, INSERT, UPDATE, REPLACE, or DELETE). Examples using UPDATE and DELETE statements are shown here:

mysql> EXPLAIN FORMAT=JSON INTO @myupdate
   --> UPDATE a SET name2 = "garcia" WHERE id = 3;
Query OK, 0 rows affected (0.00 sec)

mysql> EXPLAIN FORMAT=JSON INTO @mydelete
   --> DELETE FROM a WHERE name1 LIKE '%e%';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @myupdate, @mydelete

@myupdate: {
   "query_block": {
      "select_id": 1,
      "table": {
         "update": true,
         "table_name": "a",
         "access_type": "range",
         "possible_keys": [ "PRIMARY" ],
         "key": "PRIMARY",
         "used_key_parts": [ "id" ],
         "key_length": "4",
         "ref": [ "const" ],
         "query_cost": "1.00",
         "table_name": "a",
         "possible_keys": [ "PRIMARY" ],
         "key": "PRIMARY",
         "used_key_parts": [ "id" ],
         "key_length": "4",
         "ref": [ "const" ],
         "rows_examined_per_scan": 1,
         "rows_produced_per_join": 1,
         "filtered": "100.00",
         "cost_info": {
            "read_cost": "0.00",
            "eval_cost": "0.10",
            "prefix_cost": "0.00",
            "data_read_per_join": "408",
            "rows_examined_per_scan": 1,
            "rows_produced_per_join": 1,
            "filtered": "100.00",
            "cost_info": {
               "read_cost": "0.00",
               "eval_cost": "0.10",
               "prefix_cost": "0.00",
               "data_read_per_join": "408"
            },
            "used_columns": [ "id", "name" ]
         }
      }
   }
1 row in set (0.00 sec)
You can work with this value using MySQL JSON functions as you would with any other JSON value, as in these examples using `JSON_EXTRACT()`:

```sql
mysql> SELECT JSON_EXTRACT(@myselect, "$.query_block.table.key");
+----------------------------------------------------+
| JSON_EXTRACT(@myselect, "$.query_block.table.key") |
+----------------------------------------------------+
| "PRIMARY"                                          |
+----------------------------------------------------+
1 row in set (0.01 sec)

mysql> SELECT JSON_EXTRACT(@myupdate, "$.query_block.table.access_type") AS U_acc,
-> JSON_EXTRACT(@mydelete, "$.query_block.table.access_type") AS D_acc;
+---------+-------+
<table>
<thead>
<tr>
<th>U_acc</th>
<th>D_acc</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;range&quot;</td>
<td>&quot;ALL&quot;</td>
</tr>
</tbody>
</table>
+---------+-------+
1 row in set (0.00 sec)
```

See also Section 14.17, “JSON Functions”.

Trying to use an `INTO` clause without explicitly including `FORMAT=JSON` causes `EXPLAIN` to be rejected with `ER_EXPLAIN_INTO_IMPLICIT_FORMAT_NOT_SUPPORTED`. This is true regardless of the current value of the `explain_format` system variable.

The `INTO` clause is not supported with `EXPLAIN ANALYZE`; it is also not supported with `FOR CONNECTION`.

---

Important

If, for any reason, the statement to be analyzed is rejected, the user variable is not updated.

- MySQL 8.4 supports a `FOR_SCHEMA` clause, which causes `EXPLAIN` to behave as if the statement to be analyzed had been executed in the named database; `FOR_DATABASE` is supported as a synonym. A simple example of use is shown here:

```sql
mysql> USE b;
Database changed
mysql> CREATE SCHEMA s1;
Query OK, 1 row affected (0.01 sec)
mysql> CREATE SCHEMA s2;
Query OK, 1 row affected (0.01 sec)
```
EXPLAIN Statement

mysql> USE s1;
Database changed
mysql> CREATE TABLE t (c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY, c2 INT NOT NULL);
Query OK, 0 rows affected (0.04 sec)

mysql> USE s2;
Database changed
mysql> CREATE TABLE t (c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY, c2 INT NOT NULL, KEY i1 (c2));
Query OK, 0 rows affected (0.04 sec)

mysql> USE b;
Database changed
mysql> EXPLAIN FORMAT=TREE FOR SCHEMA s1 SELECT * FROM t WHERE c2 > 50\G
*************************** 1. row ***************************
EXPLAIN: -> Filter: (t.c2 > 50)  (cost=0.35 rows=1)
    -> Table scan on t  (cost=0.35 rows=1)
1 row in set (0.00 sec)

mysql> EXPLAIN FORMAT=TREE FOR SCHEMA s2 SELECT * FROM t WHERE c2 > 50\G
*************************** 1. row ***************************
EXPLAIN: -> Filter: (t.c2 > 50)  (cost=0.35 rows=1)
    -> Covering index scan on t using i1  (cost=0.35 rows=1)
1 row in set (0.00 sec)

If the database does not exist, the statement is rejected with **ER_BAD_DB_ERROR**. If the user does not have the necessary privileges to run the statement, it is rejected with **ER_DBACCESS_DENIED_ERROR**.

**FOR SCHEMA** is not compatible with **FOR CONNECTION**.

**EXPLAIN** requires the same privileges required to execute the explained statement. Additionally, **EXPLAIN** also requires the **SHOW VIEW** privilege for any explained view. **EXPLAIN ... FOR CONNECTION** also requires the **PROCESS** privilege if the specified connection belongs to a different user.

The **explain_format** system variable determines the format of the output from **EXPLAIN** when used to display a query execution plan. This variable can take any of the values used with the **FORMAT** option, with the addition of **DEFAULT** as a synonym for **TRADITIONAL**. The following example uses the **country** table from the **world** database which can be obtained from MySQL: Other Downloads:

mysql> USE world;  # Make world the current database
Database changed

Checking the value of **explain_format**, we see that it has the default value, and that **EXPLAIN** (with no **FORMAT** option) therefore uses the traditional tabular output:

```
mysql> SELECT @@explain_format;
+------------------+
| @@explain_format |
+------------------+
| TRADITIONAL      |
+------------------+
1 row in set (0.00 sec)
```

If we set the value of **explain_format** to **TREE**, then rerun the same **EXPLAIN** statement, the output uses the tree-like format:

```
mysql> SET @@explain_format=TREE;
Query OK, 0 rows affected (0.00 sec)
```
As stated previously, the `FORMAT` option overrides this setting. Executing the same `EXPLAIN` statement using `FORMAT=JSON` instead of `FORMAT=TREE` shows that this is the case:

```sql
mysql> EXPLAIN FORMAT=JSON SELECT Name FROM country WHERE Code LIKE 'A%';
+------------------------------------------------------------------------------+
| EXPLAIN                                                                      |
| {                                                                           |
|   "query_block": {                                                        |
|     "select_id": 1,                                                       |
|     "cost_info": {                                                        |
|       "query_cost": "3.67"                                                |
|     },                                                                      |
|     "table": {                                                            |
|       "table_name": "country",                                            |
|       "access_type": "range",                                            |
|       "possible_keys": [                                                 |
|         "PRIMARY"                                                        |
|       ],                                                                  |
|       "key": "PRIMARY",                                                  |
|       "used_key_parts": [                                                |
|         "Code"                                                           |
|       ],                                                                  |
|       "key_length": "12",                                                 |
|       "rows_examined_per_scan": 17,                                       |
|       "rows_produced_per_join": 17,                                       |
|       "filtered": "100.00",                                               |
|       "cost_info": {                                                      |
|         "read_cost": "1.97",                                             |
|         "eval_cost": "1.70",                                             |
|         "prefix_cost": "3.67",                                           |
|         "data_read_per_join": "16K"                                       |
|       },                                                                  |
|       "used_columns": [                                                  |
|         "Code",                                                          |
|         "Name"                                                           |
|       ],                                                                  |
|       "attached_condition": "("world`.`country`.`Code` like 'A%')"        |
|     }                                                                     |
| }                                                                           |
+------------------------------------------------------------------------------+
```

1 row in set, 1 warning (0.00 sec)

To return the default output of `EXPLAIN` to the tabular format, set `explain_format` to `TRADITIONAL`. Alternatively, you can set it to `DEFAULT`, which has the same effect, as shown here:

```sql
mysql> SET @@explain_format=DEFAULT;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@explain_format;
+------------------|
<table>
<thead>
<tr>
<th>@@explain_format</th>
</tr>
</thead>
</table>
+------------------|
```

2894
MySQL 8.4 supports two versions of the JSON output format. Version 1 is the linear format always used in MySQL 8.2 and earlier; this remains the default in MySQL 8.4, and is used in the examples already shown in this section. Version 2 of the JSON output format is based on access paths, and is intended to provide compatibility with future versions of the MySQL Optimizer. You can switch to the Version 2 format by setting the value of the explain_json_format_version server system variable to 2, as shown here for the same EXPLAIN statement used in the previous example:

```sql
mysql> SELECT @@explain_json_format_version;
+-------------------------------+
<table>
<thead>
<tr>
<th>@@explain_json_format_version</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
+-------------------------------+
1 row in set (0.00 sec)

mysql> SET @@explain_json_format_version = 2;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@explain_json_format_version;
+-------------------------------+
<table>
<thead>
<tr>
<th>@@explain_json_format_version</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
</tr>
</tbody>
</table>
+-------------------------------+
1 row in set (0.00 sec)

mysql> EXPLAIN FORMAT=JSON SELECT Name FROM country WHERE Code LIKE 'A%';
+------------------------------------------------------------------------------+
| EXPLAIN                                                                      |
| +------------------------------------------------------------------------------|
| {                                                                           |
|   "query": "/* select#1 */ select `world`.`country`.`Name` AS `Name` from `world`.`country` where (`world`.`country`.`Code` like 'A%')",
|   "inputs": [
|     {                                                                           |
|       "ranges": [                                                           |
|         "('A' <= Code <= 'A???????????')"
|       ],                                                                     |
|       "covering": false,                                                     |
